The task in this study was to elicit the relevant knowledge of expert procedural and OO software developers and cast it into appropriate structural representations. To accomplish this, expert procedural and OO software developers were identified, relevant knowledge was elicited, and the knowledge was cast into structural representations. The following sections describe this procedure.

Participants

Respondent organizations were selected based on their identification of available "expert software developers" in the procedural or OO software development approach and their willingness to participate. Over 15 organizations of various sizes (from 15 to 10,000 employees) and industries (e.g., telecommunications, manufacturing, and services) provided access to their software developers. The participants were expert procedural and OO software developers, as acknowledged by their peers using the snowball sampling technique (Shanteau, 1987, 1992).

In causal mapping research, the point of redundancy among the subjects represents the point at which further data collection would not lead to the identification of additional concepts (Axelrod, 1976). As the concepts emerge from the experts (rather than being imposed by the researchers), the point of redundancy serves to establish the adequacy of the sample. However, the point of redundancy is not calculated until after the interviews have been completed and the classification scheme has been developed. If redundancy is not reached, additional interviews are conducted. The point of redundancy was reached at 7 participants for procedural concepts and at 15 participants for the OO concepts. This indicates that the sample of 17 procedural experts and 24 OO experts was more than sufficient to capture all of the relevant concepts in the sample.

Elicitation

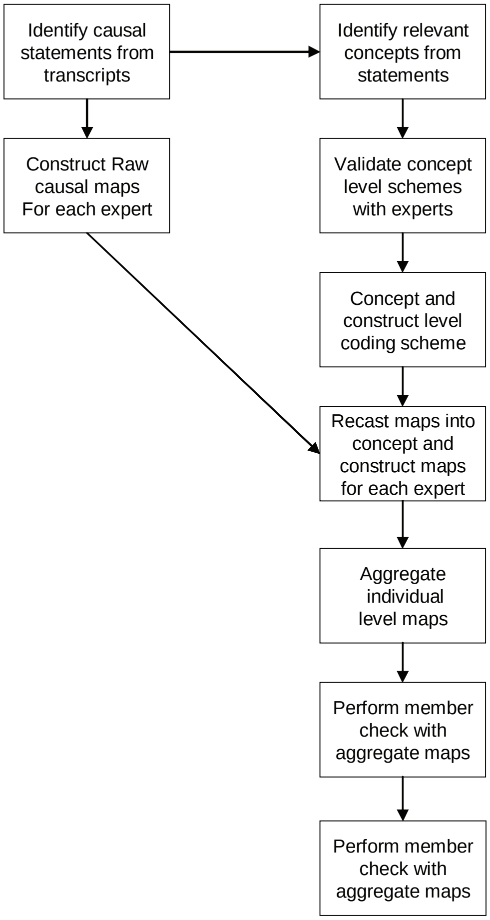
The interview process consisted of open-ended interviews with probes (Rossi, Wright, & Anderson, 1983) using an interview guide that was adapted from a previous study (Nelson, Armstrong, & Ghods, 2002). The guide was validated by two researchers, one with extensive revealed causal mapping experience and the other a software development expert. Each respondent was asked the same set of questions from the interview guide and included questions such as: "When a friend asks you what is object-oriented (procedural) development, what do you say?" Based on the respondent's answer to the question, follow up probes were asked to elicit further details regarding their software development thought process (e.g., "What did you think about next?"). Each interview lasted from 30 to 90 minutes. The range of interview lengths occurred because the interviewer did not constrain the responses to the questions. The interviews were transcribed into a document format ranging from 4 to 14 pages.

Deriving Revealed Causal Maps

Revealed causal mapping (RCM) (Narayanan & Fahey, 1990; Nelson et al., 2000) is a form of causal mapping, a collection of techniques used to explicate and assess the structure and content of knowledge structures (Axelrod, 1976; Fiol & Huff, 1992). Revealed causal maps provide a frame of reference for an expert's knowledge, how that knowledge is exhibited, and the reasoning behind the expert's actions. RCMs are consistent with exploratory research and have been successfully used in the software development context by Nelson, Nadkarni, Narayanan, and Ghods (2000). Figure 2 provides a flow chart of the revealed causal mapping process. Each phase in the process is described briefly.

Step 1: Identify causal statements. The first task is to identify the causal statements from the interview transcripts. Causal statements are

Figure 2. Revealed causal mapping process



statements that imply a cause-effect relationship. Some of the key words used in identifying causal statements are "if-then," "because," "so," and so forth. Consistent with Narayanan and Fahey (1990), all the statements in the form of concepts and relationships were captured in the language of the experts. To establish the reliability of the identification procedure, interview texts were coded by the primary researcher and one of the three raters who were not participants in any portion of the study. There were two rounds of coding that covered 12 interviews (six object-oriented and six procedural interview texts). Comparisons were made for agreement and disagreement between the researchers. Where disagreement occurred, the discrepancies were resolved through discussion. The reliability between the researchers was calculated by measuring the level of agreement on terms and linkages and averaged 0.80, suggesting an acceptable level of reliability.

Step 2: Construct raw causal maps. The causal statements identified in the first step were separated into causes and effects to construct the 'raw causal maps.' The Kruskal-Wallis significance test was performed to compare the causal statements elicited for the two groups of experts (procedural and object-oriented). The two groups were determined equivalent in terms of the causal statements they produced (b= .011, df =1, p= ns). Thus the two groups could be treated similarly for coding purposes.

Step 3: Develop coding scheme. The relevant concepts are identified from the statements (Narayanan & Fahey, 1990) by grouping frequently mentioned words in the statements. A word or word group was created that captured the essence of the statement. For example, the phrase, "You group the requirements document items based on functions" was labeled 'functions'. A second researcher who also is a software development expert reviewed the statements and independently placed them into conceptual categories. The level of agreement between the raters on the conceptual categories averaged 0.81. The level of agreement was slightly higher for the object-oriented concepts than the procedural but not significantly different. Three object-oriented and one procedural expert validated the concept level scheme. Validation was accomplished by an electronic card sort. The level of agreement between the raters averaged 0.77. There were a total of 28 concepts identified (17 object-oriented and 11 procedural). A construct level classification scheme was then developed from a composite classification scheme encompassing the favorable aspects of the most appropriate schemes. The scheme was validated by a total of six individuals, three object-oriented and three procedural software development experts. The reliability between the respondents was calculated by measuring the level of agreement on the card sort. The average level of agreement was 0.70.

Step 4: Recast the 'raw' maps into revealed causal maps. The causal statements for each respondent were placed into the appropriate concept and construct level categories. The result is a concept and construct level revealed causal map for each respondent. The individual maps were then aggregated (Axelrod, 1976; Bougon et al., 1977) at the concept level and the construct level. A member check was performed using the aggregated maps to ensure accurate and comprehensive representation (Lincoln & Guba, 1985). The member check was performed at the aggregate level because the emphasis of this research study was on the mindset level. No significant modifications were made to the aggregated maps based on the member check.

Step 5: Create measures for the maps. The analysis of the maps in this study was based on past research in causal mapping (Bougon et al., 1977; Ford & Hegarty, 1984; Huff, 1990; Narayanan & Fahey, 1990). The measures used were borrowed from the social network analysis field (Knoke & Kuklinski, 1982) and include the adjacency and reachability matrices, centrality, and density measures.

An *adjacency matrix* is a matrix representing the association of direct linkages between two constructs (Knoke & Kuklinski, 1982). For this study the interest is in the presence or absence of a causal relationship between concepts and thus the adjacency matrix contains only "0's" and "1's" (Carley & Palmquist, 1992). The *reachability matrix* indicates the cumulative direct and indirect effects of a variable on all other variables and allows for a more holistic picture of the causal relationships. The reachability of each linkage is reported on the linkage between the nodes on the revealed causal map. For a detailed explanation of adjacency and reachability matrices see Nelson et al. (2000). *Density* is a characteristic of the overall map and is a measure of how connected the concepts or constructs in the map are. It is a proportion that is calculated as the number of all linkages occurring in the matrix divided by the number of all possible linkages (Knoke & Kuklinski, 1982). *Centrality* is a measure used for the individual concepts or constructs within a map. In this study, it is a measure of how central or involved the construct is to the map. Centrality is a ratio of the aggregate of linkages involving the concept/construct divided by the total linkages in the matrix (Knoke & Kuklinski, 1982). Together these measures provide a systematic comparison of the RCMs in which all of the information contained in the map is utilized.

However, the structural measures of density, centrality, and reachability should be used with caution. While the validity of complexity and centrality have been demonstrated in an educational setting (Nadkarni & Narayanan, 2005), in causal mapping research efforts to establish the validity of the structural measures are still in the embryonic stages (Narayanan, 2005).

RESULTS

The OO and procedural software development concepts and constructs evoked in this study are shown in Table 1. The first two constructs for OO and procedural development are very much as expected. The structure construct contains foundation elements for each of the development techniques. OO development is structurally based on abstraction, encapsulation, and inheritance, generally implemented through objects, classes, attributes, and instantiation. Procedural development is structurally based on functional decomposition and interaction, implemented through functions and subroutines.

The second set of foundational constructs is behavior for OO and linear processing for procedural development. Where the structure construct captured the more static nature of the paradigms, these constructs capture their more dynamic natures. Object orientation is based on

Table 1. Construct level classification scheme

Object Oriented		**Procedural**	
Construct	**Concepts**	**Construct**	**Concepts**
Structure	Abstraction	Structure	Interaction
	Attribute		Functions
	Class		Functional Decomposition
	Encapsulation		Subroutine
	Inheritance		
	Instantiation		
	Object		
Behavior	Collaboration	Linear Processing	Linear Flow
	Message Passing		Linear Form
	Method		Linear Program
	Polymorphism		Linear Structure
	Relationship		Monolithic
OO Modeling	Identifying Objects	Functionality	Input-Process-Output
	Object Model		Data Modification
OO Development	OO Development		
	Layer		
	Patterns		

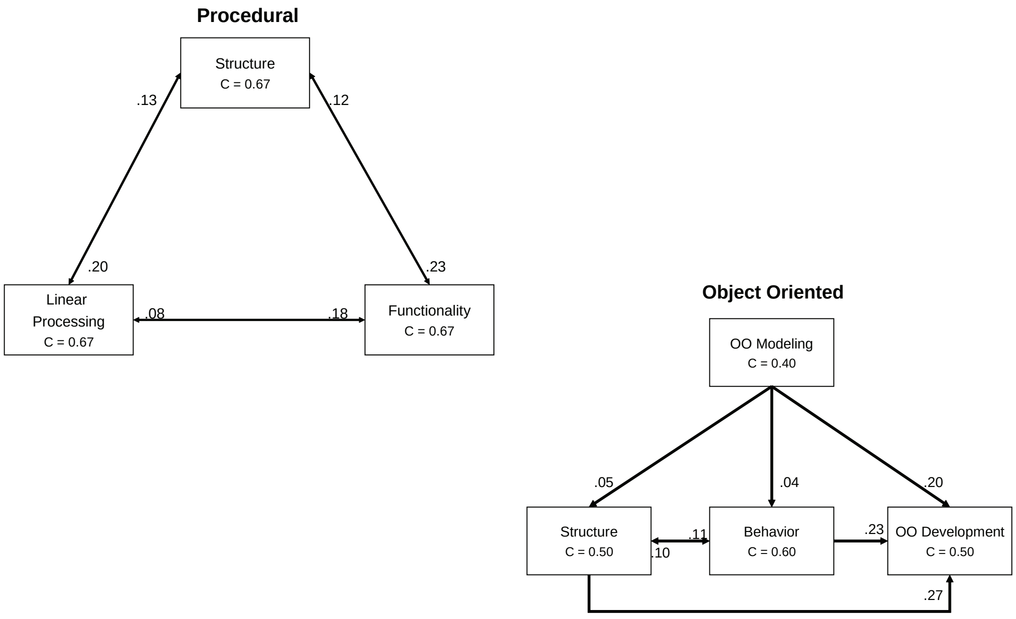
objects interacting with one another by methods passing messages. Relationships, collaboration, and polymorphism are related concepts. The procedural paradigm generally produces monolithic structures that have a linear form and a linear flow through linear structures and linear programs. These constructs capture the dynamic differences between OO and procedural. Procedural execution is very much top-down whereas OO is much more distributed and difficult to visualize.

The final two OO constructs capture its abstract nature. OO software development is more abstract with an emphasis on modeling: creating an object model by identifying objects. Development proceeds in layers, identifying and implementing patterns. Procedural development is much more concrete and focuses on functionality by modifying data through processes modeled as input—process—output structures.

Figure 3 shows the revealed causal maps for procedural and OO software development expertise. The centrality of each construct was equal (0.67) indicating that there was no central construct, and that all three constructs were all equally important to procedural software development. The aggregated RCM is fully connected has a density of 1.00, which indicates that experts saw strong connections between all of the constructs. The procedural constructs are intertwined with each other and are difficult to separate. There is no exclusive “cause” or “effect” construct, with all three being both causes and effects. The reachability ranged from 0.08 to 0.23 with a fairly equal reachability distribution.

The aggregated construct level RCM for OO constructs is very different from the procedural RCM. OO software development expertise was defined by four constructs: structure, behavior, OO modeling, and OO development. The majority of concepts in two constructs (structure and behavior) correspond to extant literature of OO software development, which suggests that the

Figure 3. Revealed causal maps



key concepts of OO include: abstraction, class, encapsulation, inheritance, message passing, method, object, and polymorphism. The structure construct focuses on the mechanisms that support the class/object structure and has a centrality of 0.50 and the behavior construct has a centrality of 0.60. Combined with the OO development construct with a centrality of 0.50, these three constructs occupy a central role in OO development. The OO modeling construct has a slightly smaller centrality of 0.40 suggesting a lesser role in OO software development. The importance of the OO development construct, its underlying concepts, and its connection to the foundational OO constructs (structure and behavior) has not been noted previously and is the focus of future research.

While the range of centrality measures was not large (0.40 – 0.60) the difference does underscore the differences in the roles that the constructs are assigned in OO development. This contributes to the complexity of learning OO development because developers not only need to learn the OO concepts but also where the different concepts fit into the OO development mindset. The density of the OO map was 0.83 indicating a high interconnectedness of constructs, which adds to the complexity of OO development.

In addition to complexity, the aggregated RCM reveals that experts saw OO modeling/analysis as a cause construct (all arrows originate from the construct) and OO development concepts as an effect construct (all arrows terminate into the construct). The structure and behavior constructs were mixed (both cause and effect constructs). The OO modeling/analysis (cause) construct was comprised of trigger concepts (e.g., identifying objects), that instigate the OO development process and trigger the use of other concepts. The OO development concepts (effect) construct was comprised of result concepts (e.g., OO development) that do not cause any further action. The structure and behavior constructs were mixed (both cause and effect) thus indicating the iterative nature of OO development in which both structure and behavior play key roles on an ongoing basis.

The OO map reachability values ranges from 0.04 to 0.27. The weakest connection was from OO modeling/analysis to behavior, and the strongest from structure to OO development concepts. There was a mutual connection between the structure and behavior constructs but the strongest reachability occurs for the linkages in which OO development concepts was the effect construct.

Object-Oriented versus Procedural

The OO approach was slower to reach redundancy than the procedural approach. This result could be attributed to the OO approach being less parsimonious than the procedural approach, or perhaps the more complex nature of OO (Shanteau, 1987). The content (similarity of concepts) was the next comparative measure. While there was some carryover of concepts from procedural to OO (e.g., abstraction), the procedural developers in this study did not address these as concepts associated with procedural development. There was negligible overlap in the concepts elicited for each approach. The cognitive distance between the two approaches appears to be significant, thus increasing the cognitive load on the developer making the transition to the OO approach (Morris, Speier, & Hoffer, 1999).

The OO map was more centralized with a hierarchical structure. In this study, it was found that the OO approach emphasized behavior (including concepts such as methods, message passing, and polymorphism) as a central theme (centrality 0.60). This is consistent with the definition of OO software development provided earlier. also It was also found that the OO development concepts and structure constructs had the next highest centrality (0.50). The centrality of the structure construct was consistent with the definition of OO and the concepts involved (e.g., object, class, encapsulation) were central to the approach. An interesting finding was that the centrality of the OO development concepts (e.g., layer) was higher than the centrality of the OO modeling/analysis construct (e.g., identifying objects). The OO modeling/analysis construct was expected to be more central because one "difference" between procedural and OO software development is how you think about the problem (Nelson et al., 2002). It appears that the different "approach" aspect was captured in the OO development concepts construct. As one developer stated,

> It took me a while to stop thinking linearly or procedurally and start looking at the things. Once I did that, started seeing the things, then I knew I was doing OO…. The biggest problem with the switch to OO is people that know procedural development are thinking in processes not objects.

In contrast to the OO map, the procedural constructs were all centrally placed (centrality 0.67). Thus, while the OO map was hierarchical with regard to the differences in centrality of the constructs, the procedural map was flat. This is not to say that the procedural concepts were of less importance, but that the program structure, program functionality, and linear processing nature of procedural development were so central to the essence of procedural development, it was difficult for the experts to cognitively separate them.

Looking at the connections between the constructs, the procedural map was perfectly dense (1.00) and the OO map was less dense (0.83), indicating the OO approach was more disconnected and compartmentalized. The procedural map was completely connected with all constructs, both causes and effects. With the OO map there was only one mutual arrow (arrow with two heads) between the structure and behavior constructs with the remaining connections having unilateral arrows (arrowhead with one head). The structure and behavior constructs were both causes and effects, which speaks to the interconnected nature of the OO approach. In contrast, the OO modeling/analysis construct was a cause construct only and OO development concepts was an effect construct only. Again, with OO modeling/analysis starting the development process it made sense that it would drive the remaining constructs. Similarly, the finding that the OO Development Concepts construct was a "result" of the OO development process is consistent with the emphasis of the construct on the system level aspects of development.

The last point of comparison was the elaboration of constructs. The higher elaboration of constructs for the OO approach (4.3 versus 3.7) indicated a slightly higher degree of chunking surrounding the constructs. Chunking occurs when a series of actions or grouping of concepts is abstracted into a conceptual chunk (e.g., Adelson, 1981). It appears that the OO developers abstracted more concepts into a chunk that the procedural developers.

DISCUSSION

The practice of software development is changing. The very early "spaghetti code" era gave way to the more disciplined structured/procedural development paradigm based on the process model: input—process—output. As the environment changed, this paradigm shifted to a more continuous, seamless development environment. This new paradigm emphasizes abstraction and modeling and deemphasizes the more linear processes of coding. This study examined the cognitive representations of expertise in both OO and procedural software development. When individuals think about developing software in these two paradigms, not only is the knowledge content different between procedural and OO development, but the structure and organization of that knowledge is also different.

The results of this study (the concepts, constructs, and their cognitive structure) provide a starting point for empirically representing the knowledge structure of expertise for each approach and for extrapolating the knowledge structures required as the next, strategic, revolution begins to take shape. The correspondence of the empirically evoked concepts to the theoretical constructs of procedural software development suggests that the RCM technique has empirical validity in the task of knowledge representation. On the other hand, the RCM technique not only uncovered concepts identified by extant OO literature such as encapsulation and object, but added important concepts to our understanding of OO expertise with the possible extension to patterns.

The representation of procedural and OO software development expertise contributes new constructs and concepts to the body of literature within the OO mindset. The concepts identified in this research not previously discussed as essential to OO development were patterns, layer, and OO development. Patterns are defined as collection of objects or classes that function in a certain way and can be reused with other projects (Johnson, 1997; Shull, Lanubile, & Basili, 2000). Layer is defined as the process of building a system in stages. The emphasis on "development" has not been previously captured as a focus of the OO mindset. The OO development concept evoked in this study acknowledges the importance of this cognitive focus. These concepts not previously identified as fundamental to the OO approach add to the understanding of OO development within the context of the larger system. While these contribute to the understanding of OO development, further research is needed to validate these new concepts and constructs before generalizations can be made.

In addition to theoretical contributions, several practical implications can be drawn from this study. Organizations switching to the OO approach need developers to put the new techniques into practice. One solution to this problem is to hire external OO developers, but while universities are turning out new employees who know OO programming, hiring these programmers is not an optimal solution because they do not possess the business domain knowledge that is necessary for successful OO development. A more workable solution is to retrain existing developers in the OO approach.

The results of this study show some of the difficulties and confusion that expert procedural programmers have when transitioning to OO development. For example, Table 1 shows the constructs and concepts discovered in interviews with expert OO and procedural developers. At the lowest, "programming in the small" level, the two mindsets are really quite similar and it is easy to transition from one to the other.

On the surface, the structure of the OO mindset is familiar to the procedural developer. Classes, objects, encapsulation, instantiation, and attributes are all familiar concepts and are all discovered through the process of functional decomposition and the identification of subroutines and the associated data that the subroutines operates upon. Data was not addressed as a procedural concept, primarily due to the clear data/process split in the procedural mindset. Data in the form of objects and classes is a fundamental part of the OO mindset so it is not surprising that it appears as a structural OO concept.

Moving on to the second part of programming in the small, the OO behavior and the procedural linear processing constructs are also similar on the surface. However, this is where the OO/procedural mindsets begin to differ. To those who see OO as an evolution of procedural development, message passing, methods, collaboration, and relationships are really no different than the linear programming, form, and flow of procedural functions and subroutines. However, the revealed causal map shows that the expert OO developers see OO structure and OO behavior as very different than expert procedural developers see procedural structure and procedural linear processing. OO structure and behavior are both effects of OO modeling with all three leading to OO development. Procedural causal maps have structure, linear processing, and functionality, all tightly related and connected.

The difference between the procedural and OO approaches is substantial. Clearly, not only the concepts used in these two approaches are different, but the cognitive organization of these concepts is also different. This is consistent with the arguments of some (Agarwal et al., 1996; Boehn-Davis & Ross, 1992; Fichman & Kemerer, 1992; Lee & Pennington, 1994) that at the conceptual phase of software development, the transition from procedural to OO represents a radical change. The transition to OO software development requires not merely a shift in tools and techniques, but also a fundamental shift in the way developers think about IS problems and solutions.

The combination of the revealed causal maps and the construct/concept table indicate that the OO mindset is truly a shift in thinking and not an extension of procedural development. The practical implications to this leads to the suggestion that the best method for transitioning programmers is a deep immersion into OO theory followed by a practical application of the OO language rather than trying to develop the OO theory by learning and then practicing the OO extensions to the language. For example, learning C then adding on the C++ extensions. While the transition works structurally in the small, this will interfere with learning the more abstract OO modeling and OO development constructs.

LIMITATIONS AND FUTURE RESEARCH

Although using practicing experts as respondents enhances the relevance of the results, external validity of the study is somewhat limited due to the sample size and snowball sampling technique utilized. The snowball sampling method is a non-probability method and consequently there is a potential for sample bias. Familiarity bias results from the person who is known to more people having a higher probability of being mentioned than the person known only to a few others (Sudman, 1976). This bias was minimized for this project because software development professionals were asked to identify others in their area with expertise (Abdolmohammadi & Shanteau, 1992). Thus selection was based on acknowledged expertise and not familiarity. Future research employing large samples is required to validate, refute, or modify the maps developed in this study. One potential limitation of the study was the use of retrospective recall in the data collection. During the interviews the developers were asked to think of their most recent software development experience as a reference for the questions. With any retrospective recall there is always a chance of inaccurate recall, but as acknowledged experts were used and the experts in the study completed an average of almost seven OO projects and 51 procedural projects, their recollections should provide an accurate reflection of expert conceptual knowledge.

The greater layering (complexity) of the OO approach map, one of the pieces of evidence unearthed by this study, suggests that the procedural and OO approach require very different mindsets. An alternate explanation is that the differences in complexity may be partly due to the differences in maturity of the software development approaches. While there are differences in the maturity of both mindsets, the OO approach has been in existence since the early 1960s. Perhaps the lack of maturity is a function of the complexity and not vice versa. Another possible explanation is that the findings were merely a function of the sample. As with any sample, there is a potential for bias. While the participants were experts as acknowledged by their peers, perhaps their expertise was insufficient to adequately capture the essential OO/procedural concepts. Although this is possible, it is not very likely because of the point of redundancy achieved for each sample was well below the number of experts interviewed. The list of concepts for each approach was exhausted well before the last participant was reached.

One of the first avenues for future research is replication with a large sample study. The cognitive structures of procedural and OO development expertise could be tested against the cognitive structures of a large sample of software developers. Another avenue for research would be to survey individuals who are expert OO software developers with no procedural experience. An analysis of their cognitive structures would not only be interesting but also would affirm or rebut the findings of this research. At this time, there are no expert OO software developers without any procedural experience, but perhaps in the future this avenue will be available. A third avenue for future research could include the retraining of expert procedural software developers. A laboratory experiment could be conducted in which retraining based on the constructs and linkages found in this study is tested against traditional retraining techniques.

This is the first part of a two part study. Future research will examine the cognitive structures of expert strategic, pattern-based software developers to determine how their mindsets differ from expert OO developers. It may be expected that the transition from abstract to strategic thinking will be just as difficult as the transition from procedural to abstract thinking.

Chapter 6.3

IT Infrastructure Capabilities and Business Process Improvements:

Association with IT Governance Characteristics

Chuck C. H. Law

ABSTRACT

It has been widely discussed in the management information systems (MIS) literature that the outcomes of information technologies (IT) and systems may be subject to the influence of the characteristics of the organization, including those of the IT and business leadership. This study was conducted to examine the relationships that may exist between IT infrastructure capabilities (ITC), business process improvements (BPI), and such IT governance-related constructs as the reporting relationship between the chief executive officer (CEO) and chief information officer (CIO), and senior management support of IT and BPI projects. Using a sample of 243 multinational and Hong Kong-listed firms operating in Greater China, this study yielded empirical support for the perceived achievement of capabilities in some dimensions of the IT infrastructure in the companies under study. It was found that the BPI construct was related to the reporting relationship between the CEO and CIO (CEO-CIO distance), and to the levels of senior management support. The dimensions of the ITC construct were also investigated and identified by an exploratory factor analysis (EFA). Associations were found between the selected organizational constructs and the ITC dimensions, except in two hypothesized relationships. Those between CEO-CIO distance and the ITC dimensions of data integration and training were not supported at the significance level of 0.05.

INTRODUCTION

The last decades have seen generous investment in information technologies (IT) by companies around the world (Mitra, 2005; Strassman, 2002), and expenditures for IT infrastructure are estimated to account for almost 60% of a company's IT budget (Byrd & Turner, 2000). As IT has increasingly been perceived as a critical business enabler, companies are eager to take advantage of IT to support their operational and strategic objectives. Despite the huge investments made in IT in recent decades, the effects of such investment are less than satisfactory in terms of organizational benefits (Dasgupta, Sarkis & Talluri, 1999; Hu & Plant, 2001). One of the reasons for this paradox is the mismanagement of IT projects, as shown in a number of notorious examples of IT failures (Grossman, 2003; Spitze, 2001). Against this background, a series of sensible questions can be asked. What are the factors that would favorably affect the outcomes of such investments in IT initiatives? What are the proper types and amounts of IT investment a company should make? The first one points to many aspects of IT planning, implementation and management while the second relates to the proper investment decisions that need to be made, perhaps jointly, by the senior IT and business leadership (Ein-Dor & Segev, 1978; Ross & Weill, 2002).

The IT literature has presented many organizational factors relevant to the successful adoption of IT, ranging from project management issues to user involvement, and senior management support (Caldeira & Ward, 2002; Chatterjee, Grewal & Sambamurthy, 2002). Ignoring or mismanaging these factors may subject the projects to the risk of failure (Sumner, 2000). Among the many organizational issues that are said to affect the investment, deployment and use of IT, are IT governance-related factors. As defined by Sambamurthy & Zmud (1999), "IT governance arrangements refers to the patterns of authority for key IT activities in business firms, including IT infrastructure, IT use, and project management" (p. 261). "The patterns of authority" could have many implications to the investment decisions, and running of the enterprise-wide IT initiatives. For instance, it may affect how much recognition and support an IT project could receive from the various levels of the organizations, and whether appropriate funding and resources would be allocated. In our article, the term "IT governance characteristics" focuses on the (a) reporting relationship between the chief executive and the IT leader, (b) the support and commitment of top management received by the IT projects, and (c) the support and commitment of top management on business process improvement. The former is used as a surrogate for the seniority of the IT leader as will be explained and discussed further in the next section. A review of the literature about enterprise IT and systems adoption indicates that many of the enterprise IT projects would not be successful unless the deployment of IT is accompanied by changes to business practices and processes (Davenport, 1998; Sumner, 2000; Wu, 2002). Thus, senior management's attitudes and commitment on business process changes would also be critical to the success of enterprise IT projects.

While many studies have discussed, and some empirically investigated the relationships among IT adoption, business process changes and such organizational factors as senior management support and the seniority of IT leadership, there is still a need for additional empirical evidence to support these concepts (Grover, Teng, Segars, & Fiedler, 1998). On the other hand, such studies mostly examined the relationships at a coarse level, and have not attempted to investigate what aspects of IT are affected by these IT governance factors and what aspects are not. It would be more interesting to investigate these associations with IT at finer granularities, that is, considering the various dimensions of IT. Therefore, the primary goals of this study are (a) to conduct a thorough literature review on the selected IT governance factors in relation to enterprise IT and business process initiatives, (b) to explore more deeply the concept of IT infrastructure capabilities and define its constituent dimensions, (c) to produce a conceptual model highlighting the relationships between the IT governance-related constructs and these two types of initiatives, and (d) to conduct an empirical study to substantiate or disconfirm the relationships.

The remainder of this article is organized as follows. A review of the literature and the conceptual model are presented, the methodologies and guidelines of the study are discussed, the analysis and the findings are presented, and concluding remarks are made following a discussion of the findings and their implications.

LITERATURE REVIEW

IT Infrastructure Capabilities

IT infrastructure is important to an organization as it embodies many of the components necessary to support the organization's overall information architecture (Allen & Boynton, 1991; Mudie & Schafer, 1985). It has also been argued in the MIS literature that the enterprise architecture of an organization is composed of the technical, data, and application architectures; which jointly enable the processing, sharing and management of data resources across divisional and organizational boundaries (Spewak & Hill, 1993).

This broader view of IT infrastructure has earned the acceptance of many authors in IT or MIS (Mitchell & Zmud, 1999; Weill & Broadbent, 1999). Generally speaking, IT infrastructure capabilities (ITC) would consist of a wide spectrum of components, including the IT platforms, standards, and policies, and different types of service arrangements that support the information-related activities of an organization. Included in this definition are corporate network infrastructure, hardware platforms, common business systems such as data management and project management systems, and IT management and support services. Among the latter is education and training (Weill & Broadbent, 1999). In fact, training has been considered an important issue by studies in IT investment and management (Brancheau, Janz & Wetherbe, 1996; Mahmood & Mann, 1993; Palvia & Wang, 1995; Sakaguchi & Dibrell, 1998). Many of these studies (Mahmood & Mann, 1993) put the focus on training IT staff, while some (Sakaguchi & Dibrell, 1998) considered IT training for users to be a key construct of the measurement model of the global use of information technology.

In summary, the construct of ITC is a multidimensional concept that may include many aspects of IT, ranging from the network infrastructure that enables communications within and across organizational boundaries, a portfolio of hardware and system software that supports transaction processing and information analysis, documentation that clearly defines the policies and procedures of IT management, expertise in managing the IT platforms and various stakeholders, and the training of IT staff and users.

In recognition of the contribution of IT to organizational performance, IT capabilities measures such as the monetary measures of IT investment and perceptual ratings have been used as surrogates in research on the business value of IT. Attempts have been made in such studies to explore the impact of IT capabilities on an organization. The studies of Bharadwaj (2000), and Santhanam and Hartono (2003) have confirmed the relationships between IT capability and the financial performance measures of profit- and cost-related ratios. In both studies, IT capability was defined using a dichotomous variable, by which a value of 1 denotes a firm that has been elected by InformationWeek as an "IT leader," and a value of 0 denotes a non-IT leader. In the study of Andersen and Segars (2001), the effects of IT on the decentralization of the decision structure and on the financial performance of firms in the apparel and textile industry were empirically investigated. The instrument for IT measured the extent to which electronic mail services, electronic data transmissions, the company-owned telecommunication network, and fiber distributed data interfaces are used in a company (Andersen & Segars, 2001). Other studies found that IT infrastructure such as electronic data interchange (EDI) and network infrastructure had a significant impact on improvements in business processes (Bhatt, 2000, 2001). In Bhatt (2000), two aspects of information system integration were measured: the degree of data integration, and the use of network communications. The use of EDI in Bhatt (2001) was measured using the following three items: (a) the extent to which the firm and its primary suppliers were linked by EDI, (b) the extent to which information on products and services could be distributed to suppliers by senior management using information systems, and (c) the extent to which information on products and services could be shared between the firm and its suppliers. Likewise, the relationships between IT diffusion and perceived productivity gain, and the mediating effects of the business process redesign construct for different types of information technologies such as electronic mail, relational database management systems, expert systems, imaging, and local area networks were examined and confirmed in the study of Grover et al. (1998).

The preceding literature review leads to two points that deserve further discussion. First, IT adoption or diffusion and business process changes are inter-related, according to the studies that have been discussed. Second, the instruments that were developed primarily measure the use of individual IT platforms, rather than multiple dimensions of the IT infrastructure. In fact, there is a paucity of studies on the development of standardized multi-dimensional instruments for measuring the ITC of firms. The development of such an instrument would be conducive to IT studies in that it would assist with the repetitive and systematic measurements of ITC (Santhanam & Hartono, 2003).

Business Process Improvements and IT Adoption

Business process redesign refers to the revolutionary approach of process changes, which often requires "rethinking," and a drastic transformation of current business practices and processes. This approach is also called business process reengineering (BPR) (Earl & Khan, 1994; Hammer, 1990). Academic studies have also found that many firms have successfully made use of a "milder" evolutionary approach, which is referred to as business process improvements (BPI) (Harkness, Kettinger, & Segars, 1996; Stoddard & Jarvenpaa, 1995). This latter approach calls for less drastic changes to existing practice and processes.

Regardless of the approach adopted, changes in business process aim at the betterment and simplification of current practices and processes, and are considered critical for the deployment of IT systems in many circumstances. The interrelationships between IT and BPR have been widely discussed in the academic studies on MIS and business process management (Wu, 2002). IT enables new practices that would have been impossible before the advent of the technologies or systems. A lack of, or poor, IT infrastructure will limit or jeopardize the success of business process changes. Conversely, deploying IT without proper changes to business processes could compromise the outcomes. Many have considered business process redesign to be an important organizational construct with the potential to affect the outcomes of IT adoption (Grover et al., 1998). While there is plenty of theoretical discussion of the relationship between IT and business process changes in the literature, many of the studies are qualitative in nature, each involving very few cases, and therefore lack of generalizability (Grover et al., 1998). On the other hand, some studies discussed the issues with very limited empirical support (Grover et al., 1998). This points to a need for further studies to gather empirical evidence across firms for the abovementioned relationship.

Organizational Factors for IT Adoption and Business Process Changes

The MIS literature is abundant in the discussion of organizational factors and how they may affect the outcomes of IT adoption and business process changes. These studies have explored a wide variety of organizational issues in different system contexts (Caldeira & Ward, 2002; Davenport, 1998; Chatterjee et al., 2002; Ein-Dor & Segev, 1978). To name a few as examples, organizational issues or factors discussed in these studies include the seniority of IT leaders (Ein-Dor & Segev, 1978), senior management support and attitudes (Caldeira & Ward, 2002; Counihan, Finnegan, & Sammon, 2002; Davenport, 1998; Wixom & Watson, 2001), IT governance and decisions (Ross & Weill, 2002), and many project management practices (Ahituv, Neumann, & Zviran, 2002; Kimberly & Evanisko, 1981; Wixom & Watson, 2001).

Support and Commitment of Top Management

Among the aforementioned organizational factors, those concerning the roles and behavior of top management may matter a great deal and probably be increasingly important since many IT initiatives nowadays are enterprise-wide projects, analogous to what is described as Type III IS Innovation in Swanson's (1994) taxonomy of IS innovations. This type of project would require a clear strategy and institutionalized efforts to mobilize the functions and its stakeholders across the organization to participate in the adoption process (Swanson, 1994). In many circumstances, the attitudes and actions of the company's leadership would help facilitate and shape the adoption process (Chatterjee et al., 2002; Swanson, 1994). Many IT initiatives such as ERP, are boundary-spanning efforts which often require a wide range of stakeholders to participate, and to accept changes to the business practices and processes. Unswerving support from the top management is necessary to resolve any conflict of interest among the various parties involved (Davenport, 1998; Grover, Jeong, Kettinger, & Teng, 1995; Ross & Weill, 2002). A lack of such support would likely pose a threat to the projects (Bingi, Sharman, & Godla, 1999; Sumner, 2000).

That said, the IT leadership may have an important role to play within an organization, for instance, in marketing an IT or business process initiative to the organization and to secure the support and resources for the initiative. The seniority of the IT leadership is one of the "IT governance characteristics" to be investigated in this study. The following subsections will explore into the concepts about the roles and the seniority of the IT leadership as found in the IT-related literature.

The Roles and Seniority of IT Leadership

The seniority of the IT leader within an organization is considered an important factor in the success of the abovementioned projects (Ein-Dor & Segev, 1978). The IT leader, called the IT manager, IT director, or CIO, is the most senior executive responsible for the IT function of an organization. In this study, we shall use the term CIO to refer to IT heads regardless of their formal job titles. A summary of relevant discussions about the ranks and roles of the IT leadership are provided in Table 1.

IT heads in some organizations are positioned under the finance function (Jones & Arnett, 1993). As reported by a survey conducted in 1990, 40% of the CIOs who participated in the survey reported to the COO, and a much smaller percentage reported to the CEO (Rothfeder, 1990). In other organizations, this leader is often a member of the senior management team, shares the responsibility of business planning, enjoys a senior status and, equally important, is perceived as a senior executive (Rockart, Bullen, & Ball, 1982). It was found

Table 1. Findings and discussions about the IT leadership

Findings and Discussions	References
Seniority–Hierarchical Position	
• Seniority of the IT executive is one of the factors affecting IT/IS adoption.	(Ein-Dor & Segev, 1978)
• The use of IT for competitive advantages must be supported by the rank and role of the IT leader.	(Karimi et al., 1996)
• "Proximity" between CEO and CIO would help to secure resources and support.	(Jain, 1997)
• Reporting relationship ("CEO-CIO distance") moderates outcomes of IT investment.	(Li & Ye, 1999)
• The position of IS affects IT/IS adoption.	(Marble, 2003)
• CIO's rank is conducive to business process reengineering	(Teng et al., 1998)
Seniority–Membership of TMT (Top Management Team)	
• CIO's participation in top management team enhances business knowledge.	(Armstrong & Sambamurthy, 1999)
• CIO's membership in TMT is more important than his reporting relationship.	(Earl & Feeney, 1994)
• CIO is a member of TMT and it is equally important to be perceived as senior executive.	(Rockart et al., 1982)
Responsibilities and Skill Requirements	
• CIO should possess competencies in four areas: business leadership, technology leadership, organizational leadership and functional leadership.	(Earl, 1989)
• CIO markets, and changes the perceptions about the IT function.	(Earl & Feeney, 1994; Lucas, 1999)
• CIO pro-actively communicates with and solicits support from the TMT.	(Lucas, 1999)
Problems Encountered	
• A junior IT leader finds it difficult to communicate with top management.	(Cash et al. 1992)
• Many IT leaders are not accepted by others in the TMT as senior executives.	(Rothfeder, 1990; Runyan, 1990; Strassmann, 1994)

in a survey conducted in 2002 that 51% of CIOs reported to the CEO (Field, 2002). This shows a trend that an increasing number of companies recognizes the strategic role of the IT leader and the IT organization, and places him or her higher in the corporate structure.

The CIO bears full responsibility for promoting the use of IT to improve or transform the current business practices of an organization, building relationships and soliciting support from the CEO and other executives (Lucas, 1999). In fact, one of the CIO's most challenging responsibilities is to manage the CEO's perceptions about IT—that is, to persuade the CEO to think that IT is an organizational asset, rather than a cost (Earl & Feeney, 1994; Lucas, 1999).

These responsibilities require quality bilateral communications with the chief executive and others in the top management team to achieve an appropriate degree of mutual understanding (or convergence) with each other (Johnson & Lederer, 2003). As the CIO does not possess authority over any of his or her peers in the senior management team, he or she must achieve these objectives through "influence behavior," rather than through authority. For instance, rational persuasion and personal appeal are the most effective forms of influence behavior in soliciting support from the senior management team (Enns, Huff, & Higgins, 2003).

However, many CIOs have reportedly failed to obtain the acceptance from their peers and are considered outsiders to the senior management team (Rothfeder, 1990; Runyan, 1990; Strassmann, 1994). This may create hurdles to their efforts in communicating with the senior executives, or participate effectively in strategic planning. One may find the communication problem more serious for a junior ranking CIO, or in firms with a culture of informal communications (Cash, McFarlan, Mckinney, & Applegate, 1992). Moreover, a low-ranking CIO may put his/her focus on handling daily operations, and managing his or her subordinates (Ives & Olson, 1981), likely at the expense of the more strategic responsibilities.

This problem has led to the view that a formal senior position in the organizational hierarchy would give the IT executive more authority and influence within the organization (Jain, 1997; Hambrick, 1981). Though some academics argue that a full membership in, and effective communication with the top management team are more important than a formal senior position, others believe that a formal place in the top management team would give the CIO many advantages in terms of closer bilateral communications, and enhanced understanding of business strategies (Feeny, Edwards & Simpson, 1992; Gupta, 1991; Raghunathan & Raghunathan, 1993; Watson, 1990). Some empirical studies seem to support the formal approach. Karimi, Gupta & Somers (1996) pointed out that successful competitive strategies must be supported by the rank and role of the CIO. Li and Ye (1999) also found that a closer reporting relationship between the CEO and CIO would be conducive to the productive use of IT. Accordingly, it is likely that a direct reporting relationship with the CEO may help a CIO execute his/her duties effectively.

Given these discussions, it would be interesting to determine how these IT governance characteristics would affect the achievement of IT infrastructure capabilities and business process improvements in the companies under study.

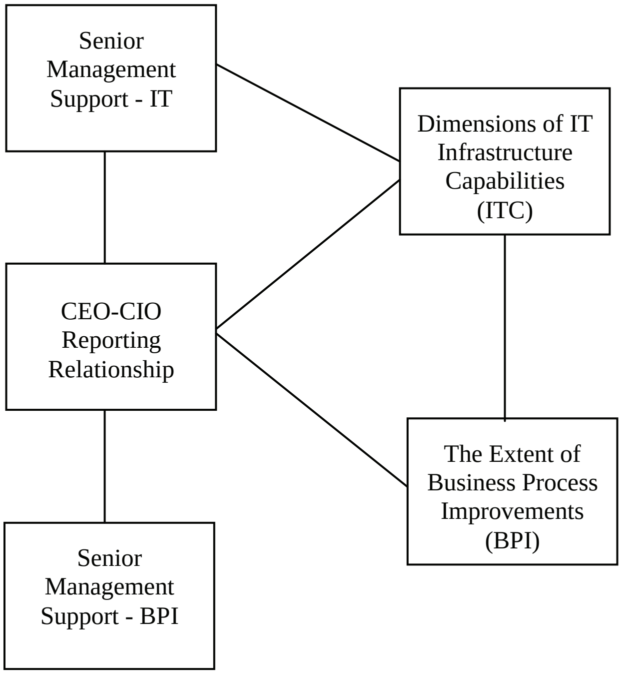
RESEARCH MODEL

To fulfill the objectives of this study, a research model is formulated to represent the key constructs and the conceptualized relationships, which will be discussed further in subsequent subsections. As depicted in Figure 1, the ITC dimensions and the extent of BPI are related, and these constructs are believed to be associated with the IT governance constructs of senior management support and CEO-CIO reporting relationship.

IT Infrastructure Capabilities

Following the broader definition presented in the last section (Weill & Broadbent, 1999), the construct of ITC is conceptualized to include items from five dimensions: network communications, data integration, hardware and system software, IT management and support, and training. The items of the first two dimensions, network communications and data integration, are based on a subset of items in the studies of Bhatt (2000, 2001); while training is derived from the study of Sakaguchi and Dibrell (1998) with modifications. The items of the dimensions of hardware and software, and IT management and support were developed after a thorough search through the literature on the subject (Allen & Boynton,

Figure 1. The conceptual model



1991; Sambamurthy & Zmud, 1999; Spewak & Hill, 1993; Weill & Broadbent, 1999).

It must be noted that this construct and its subordinate dimensions aim at measuring the perceived "realized" capabilities of IT infrastructure, rather than what is anticipated by the respondents.

The Extent of Business Process Improvements

The extent of BPI refers to the perceived degree to which changes in processes have been implemented to improve the efficiency and effectiveness of a company. The construct includes five items to measure process improvement in terms of error prevention, quality, ease of use, and intra- and inter-firm coordination. The first three items have been adopted from the study of Bhatt (2000), while the items concerning intra- and interfirm coordination have been added in recognition of the increasingly important concepts of cross-boundary coordination (Kogut, 1985; Stock, Greis, & Kasarda, 1998).

This study supports the assumption that a relationship may exist between IT deployment and process improvements. IT can be an enabler of changes to business processes, while the latter is necessary in many circumstances of IT deployment because automating inefficient processes would at best result in suboptimal outcomes (Hitt & Brynjolfsson, 1996; Stoddard & Jarvenpaa, 1995). Therefore, we put forward the following hypotheses:

$H_0$1: The perceived extent of a company's BPI and the perceived level of individual dimensions of ITC are positively related.

Senior Management Support and CEO-CIO Reporting Relationship

In this study, we have placed our focus on three IT governance-related constructs, namely senior management support of IT, senior management support of BPI, and the CEO-CIO reporting relationship. Senior management support is considered by many to be an important organizational factor for enterprise-wide IT and BPI projects (Ein-Dor & Segev, 1978; Grover et al., 1995; Sumner, 2000). The success of enterprise-wide projects requires the involvement of the user communities and the proper investment of resources (Nah, Zuckweiler, & Lau, 2003). The political roles played by senior executives in mitigating resistance to change and resolving conflicts between various interest groups must be accorded unequivocal importance (Davenport, 1998). Moreover, a supportive senior management team may influence the rest of the organization to take actions in favor of enterprise-wide initiatives. Senior management support in this study is a perceptual assessment, by the respondents, of the degree of support that top management gives to projects involving IT and BPI.

As a measure of the reporting relationship, the variable of CEO-CIO distance reflects how close or far apart the CIO is from the chief executive in the organizational structure. It can, therefore, be regarded as a surrogate of the seniority of the CIO. It is supposed that a CIO who reports directly to the chief executive will have a closer working relationship with him or her, and enjoy a higher status within the organization, than one who reports to other senior executives such as the COO or CFO.

We speculate that a high-ranking CIO would very likely have more opportunities to engage in high-quality two-way communications with the CEO and other senior executives, and a better understanding of business strategies than his or her low-ranking counterparts because of frequent participation in top management activities (Cash et al., 1992; Ives & Olson, 1981). This would be very important to the CIO in terms of the alignment of business and IT strategies, and his or her relationship with the senior management team. In addition to issues concerning communication and convergence between the senior IT and business leadership, having an IT governance structure in which the CIO is closer to the CEO and other senior executives may make it easier to implement the appropriate measures to secure from the rest of the organization the support and cooperation necessary for the success of an enterprise-wide initiative. For instance, a project bonus or award may be presented to the top performers of a project, or the contribution to the project may be considered as one of the important factors in annual staff performance appraisal.

We therefore posit that a CIO who enjoys a more senior position will be able to solicit stronger support for initiatives on IT and BPI, leading to more satisfactory outcomes for both types of projects. As the CIO is the head of the IT function, the status or importance of the IT function within the company is implied by his or her status. The following hypotheses are formulated:

H_0*2: CEO-CIO distance as a measure of the CEO-CIO reporting relationship is negatively associated with the perceived level of senior management support of IT projects.*

H_0*3: CEO-CIO distance as a measure of the CEO-CIO reporting relationship is negatively associated with the perceived level of senior management support of BPI projects.*

H_0*4: The perceived level of the individual IT infrastructure capabilities dimensions of a company is positively associated with senior management support for IT projects.*

H_0*5: The perceived level of the individual dimensions of the IT infrastructure capabilities of a company is negatively associated with the CEO-CIO distance used as a measure of the CEO-CIO reporting relationship.*

H_0*6: The perceived extent of the BPI of a company is positively associated with senior management support for BPI projects.*

$H_0$7: The perceived extent of the BPI of a company is negatively associated with the CEO-CIO distance used as a measure of the CEO-CIO reporting relationship.

RESEARCH METHODOLOGY

Data Sources

Perceptual data were collected by a postal survey. A survey package, containing a cover letter, a questionnaire booklet, and a return envelope with prepaid postage was sent to companies operating in different business sectors, including manufacturing, finance, logistics, wholesaling and retailing, and services. The 3,377 firms in the mailing list included 852 firms listed in the Stock Exchange of Hong Kong, and 2,525 multinationals operating in Hong Kong and China.

The cover letters, addressed to the chief executives or managing directors, solicited their support by explaining the objective of the research and the rules of confidentiality and anonymity, and asked them to forward the survey package, preferably to the IS executives, or to any officers nominated by them as appropriate to respond to the survey. A reminder postcard was sent to each nonresponding company at the end of the second week, and followed by telephone calls. These measures were taken to improve the response rate. In designing the study, serious consideration was given to the low response rates (around 10%) for social surveys conducted in Asian societies. This led to the decision to use a larger sampling frame for the survey.

Validity Guidelines and Research Procedures

Generally accepted guidelines in research (Churchill, 1979; Nunnally, 1978) were followed throughout the study, especially in the development of multi-item constructs. Items of individual constructs in this study were developed based on previously validated instruments and on a thorough review of the relevant literature. To ensure its face and content validity, the questionnaire was subject to a review and pretest, and then a pilot test.

An EFA was conducted for the sample, collected from the postal survey, on the ITC and the extent of BPI constructs to ascertain the convergent and divergent validity of the items under the dimensions (or subordinate constructs) in each construct. Items with factor loadings of 0.6 or above were retained for the constructs (Tracey, Vonderembse, & Lim, 1999), and those slightly below this cut-off point were reviewed for their importance and relevance to the objectives of the study following Dillon and Goldstein's (1984) guidelines. Internal consistencies were validated, and Cronbach's alpha coefficients equalling or exceeding 0.7 were considered acceptable (Kerlinger, 1973). In the purification process, items with corrected-item total correlations (CITC) of less than 0.5 were eliminated, or rephrased if they were important, following Churchill's (1979) recommendations.

This study followed a two-stage approach. An EFA was first performed to determine the dimensions of the high-level constructs, namely, the ITC and the extent of BPI constructs. Subsequent to the EFA, firm-level indices were calculated for individual ITC dimensions, and for the extent of BPI respectively. For example, the BPI index of a firm was derived by averaging the firm's perceptual inputs to the five BPI question items. The index for the training dimension of ITC was computed by taking the average of the firm's inputs to the three training items and so on. A data analysis was then conducted using a nonparametric correlation analysis (Spearman's rho) to test the relationships between the ITC dimensions, and the other constructs.

Instrument Development and Pilot Test

Instruments for soliciting perceptual ratings of ITC and the extent of BPI were developed based on a review of the literature, and on pretested instruments used in prior studies. The ITC instrument contains 16 items: four on network communications, three on data integration, three on hardware and system software, three on IT management and support, and three on training. The network communications and data integration items were based on the studies of Bhatt (2000, 2001) with adjustments to the wording. The training items included IT training for staff and users and were based on the study of Sakaguchi and Dibrell (1998). The items of hardware and software, and those of IT management and support measured the perceptual assessment of the capacities of the hardware and software facilities, administrative standards and procedures, and support services. These items were considered important to achieving a comprehensive ITC construct (Allen & Boynton, 1991; Mitchell & Zmud, 1999; Mudie & Schafer, 1985; Spewak & Hill, 1993; Weill & Broadbent, 1999).

The extent of BPI consisted of five items to capture assessments of realized process changes in terms of error prevention, process quality, ease of use, and inter- and intra-firm coordination. The first three items were derived from Bhatt (2000), with adjustments to the wording, and the items of coordination were added to improve the comprehensiveness of the instrument.

The instrument items are based on a 5-point Likert scale, with 1 being equal to *strongly disagree,* 2 to *disagree,* 3 to *neutral,* 4 to *agree,* and 5 to *strongly agree*. As discussed previously, these instruments were reviewed and pretested by six MIS executives and two academics, followed by the pilot test involving 60 evening MBA students. Their comments concerning the comprehensiveness and wording of the questionnaire items led to improvements of the instruments. Cronbach's alpha coefficients were computed using the 51 usable cases collected from the pilot test. The ITC instrument demonstrated acceptable internal consistency (Kerlinger, 1973). The alpha coefficient of the BPI items was below the cut-off value of 0.7; these items were therefore rephrased.

Measures of the IT Governance Constructs

As discussed, this study used the reporting relationship between the CEO and CIO as a surrogate for the status of the CIO (and the IT function). The questionnaire included a question with four options. The question reads "The head of IT in your company reports to (1) the CEO, (2) the CFO, (3) the COO, and (4) others, please specify". The responses to option 4 were to be analyzed to determine the levels of the IT head and his or her supervisor within the structure of the organization. This question was recoded to form the CEO-CIO distance variable, whose values were 1 for a CIO who directly reported to the CEO, 2 for a CIO who reported to a senior officer other than the CEO, 3 for a CIO who reported to a manager on the next level downward in the organizational hierarchy, and so forth, to reflect the reporting distance of the IT head from the CEO. This coding method was adopted and expanded from that used in Li and Ye (1999).

Two questions were included to solicit perceptual ratings on senior management support: one for IT and the other for BPI projects. Both were 5-point Likert scale questions, with 1 indicating *strongly disagree,* 3 *not certain*, and 5 *strongly agree.*

To operationalize the nonparametric tests for the relationships between the IT governance constructs, ITC dimensions, and the extent of BPI construct, the BPI index (labeled BPI_I) and indices for the individual ITC dimensions (labeled ITC_IFC, ITC_DI, ITC_FM and ITC_TR) were computed, after the EFA, for each firm based on its responses to the survey.

ANALYSIS AND FINDINGS

Profiles of the Respondents

Three hundred and six questionnaires were returned, giving a response rate of 9.1%. For the sake of data quality, returned questionnaires with missing data and those filled out by relatively junior staff such as programmers were dropped. Therefore, 243 usable cases were retained in the sample, yielding an effective rate of 7.1%. Among the 243 responding companies, 65 (26.7%) were listed in Hong Kong, 64 (26.3%) in Europe, 41 (16.97%) in North America, and 60 (24.7%) in other parts of Asia. The demographics of the respondents are presented in Table 2.

Exploratory Factor Analysis and Internal Consistency

Following the screening of returned questionnaires, an EFA was performed separately on the ITC and the extent of BPI items. Maximum likelihood was used as the extraction method and Varimax as the rotation method in this study. Items with factor loadings of less than the cut-off value of 0.6 were dropped from the construct (Tracey et al., 1999). The dimensions and their items (indicators) that satisfied the criterion are shown in Tables 3 and 4.

The EFA not only led to the elimination of some indicators from the ITC construct but also to the merger of two conceptualized dimensions. Two items concerning intra-firm communications under the "Network Communications" dimension ("NC3: Personnel can efficiently exchange information using e-mail systems," and "NC4: Company units can readily access data and applications on the network") were found to have insignificant factor loadings. One item, "HS3: Both hardware and system software are upgraded frequently," under the "Hardware and System Software" dimension was also dropped for low loading. The indicators initially conceptualized

Table 3. The four factors of the IT infrastructure capabilities construct

Item	Description	IFC	DI	FM	TR	Alpha
NC1	Networks link the firm and its main suppliers.	0.772				
NC2	Networks link the firm and its main customers.	0.795				0.8222
DI1	The same information in the database is shared across the firm.		0.761			
DI2	Duplication of data is eliminated.		0.769			0.8206
DI3	Definitions of data elements are standardized.		0.629			
HS1	Server platforms have sufficient capacity.			0.652		
HS2	Regular preventive maintenance minimizes down time.			0.684		
MS1	The firm has the expertise to manage IT facilities.			0.713		0.8848
MS2	Users are happy with the IT services.			0.663		
MS3	IT administration standards and procedures are well defined.			0.613		
TR1	The company has effective IT training programmes.				0.752	
TR2	Training for users is sufficient.				0.799	0.8841
TR3	Training for IT personnel is sufficient.				0.771	

Note. IFC = interfirm communications, DI = data integration, FM = IT facilities and management, TR = training, Alpha = Cronbach's alpha (α).

Table 4. The extent of business process improvement construct and factor loadings

Item	Description	BPI	Alpha
BP1	Process changes help prevent defects and errors.	0.663	
BP2	Process standards are raised periodically.	0.728	0.8395
BP3	New processes are easier to work with.	0.738	
BP4	Work processes are improved to facilitate coordination within the firm.	0.814	
BP5	Work processes are improved to facilitate coordination with external parties.	0.644	

Note. BPI = the extent of business process improvement, Alpha = Cronbach's alpha (α).

under the "Hardware and System Software" and "IT management and support" dimensions were identified as belonging to a single factor, renamed "IT Facilities and Management." Consequently, the ITC construct was found to be composed of four dimensions: "Interfirm Communications" (IFC), "Data Integration" (DI), "IT Facilities and Management" (FM), and "Training" (TR). An EFA found that the extent of BPI is unidimensional and that all five items loaded under a single factor.

The items under the extent of BPI, and those under individual dimensions of the ITC construct were analysed separately for internal consistency (refer to Tables 3 and 4). The Cronbach's alpha coefficients for the ITC dimensions exceeded the cut-off value of 0.7 (Kerlinger, 1973). The Cronbach's alpha coefficient of the BPI construct was 0.8395, thus satisfying the threshold value of 0.7 (Kerlinger, 1973). In addition, the CITC (i.e. corrected-item total correlations) value of each item under these two constructs exceeded 0.5, meeting Churchill's (1979) guidelines.

Hypothesis Testing

Subsequent to the purification of measures and the EFA, the firm-level indices, namely BPI_I (for the extent of BPI construct), and ITC_IFC, ITC_DI, ITC_FM and ITC_TR (for the individual ITC dimensions) were calculated for each responding firm. The responses concerning the reporting relationship of the IT leadership were analyzed before recoding. In this sample, 128 (52.7%) IT leaders reported directly to the CEO or managing director, 68 (28.0%) to the chief financial officer (CFO), and 44 (18.1%) to the chief operating officer (COO). Three respondents indicated that their IT leaders reported to supervisors other than the CEO, CFO, and COO. Based on the job titles entered by respondents, we determined that these supervisors were one level below that of the CEO/Managing Director. Responses to this question item were then recoded to form the CEO-CIO distance variable (CC_DIST), which reflected how far the IT leader was from the CEO/Managing Director in the organization chart. As a result, 128 IT leaders in the sample were assigned a value of "1," and the rest were assigned a value of "2" in the CEO-CIO distance variable (refer to Table 5).

In addition, the descriptive statistics of variables used in this study were computed and presented in Table 6, showing that the data does not conform to the assumption of normal distribution. This characteristic of data distribution and the fact that many variables are "ordered categories" justify the use of nonparametric statistical methods (Norusis, 2003).

Recall that the objectives of this study are to investigate whether the perceived level of ITC dimensions, and extent of BPI of a company are interrelated, and whether associations exist between the former constructs and the IT governance-related constructs of senior management support, and the status of the IT leader within that organization (using CEO-CIO distance as proxy). To fulfill these objectives, nonparametric tests were conducted. The findings are presented in Tables 7 and 8.

Using a nonparametric correlation analysis (Spearman's rho), the associations between the indices of individual dimensions of the ITC construct and the variables representing other constructs were tested. The indices computed for the individual ITC dimensions (namely, ITC_IFC, ITC_DI, ITC_FM, and ITC_TR) were first correlated to the BPI index (BPI_I), yielding statistical support for hypothesis 1 (refer to Tables 7 and 8 for the findings for $H_0$1a, $H_0$1b, $H_0$1c, $H_0$1d). The relationships between the individual indices of ITC dimensions and the variable of management support of IT projects (MS_IT) were tested, confirming hypothesis 4 (refer to Tables 7 and 8). Then,

Table 5. Reporting relationships of IT leadership

Title of Supervisor	Frequency	CEO-CIO Distance Encoded
CEO/Managing Director	128 (52.7%)	1
Chief Financial Officer (CFO)	68 (28.0%)	2
Chief Operating Officer (COO)	44 (18.1%)	2
Others[1]	3 (1.2%)	2
	243 (100.0%)	

Note. Three job titles entered by the respondents indicated positions that are one level below the CEO.

Table 6. Constructs, variables created, and descriptive statistics

Constructs	Variables Created	*N*	Mean	Std. Deviation
ITC Interfirm Communications	ITC_IFC	243	3.4486	0.91387
ITC Data Integration	ITC_DI	243	3.8299	0.75780

ITC Training	ITC_TR	243	3.1920	0.85960
The Extent of Business Process Improvement	BPI_I	243	3.4313	0.62272
Senior Management Support of IT Projects	MS_IT	242	3.8100	0.99200
Senior Management Support of BPI Projects	MS_BPI	242	3.8000	0.93500
CEO-CIO Reporting Relationship	CC_DIST	243	1.4733	0.50031

Note. ITC_IFC = Index of the ITC Interfirm Communication dimension, ITC_DI = Index of the ITC Data Integration dimension, ITC_FM = Index of the ITC IT Facilities and Management dimension, ITC_TR = Index of the ITC Training dimension, BPI_I = BPI Index, MS_IT = Management Support of IT, MS_BPI = Management Support of BPI, CC_DIST = CEO-CIO Distance.

Table 7. Correlation analysis (Spearman's rho)

Variables	ITC_IFC	ITC_DI	ITC_FM	ITC_TR	BPI_I	MS_IT	MS_BPI	CC_DIST
ITC_IFC	---	---	---	---				
ITC_DI	---	---	---	---				
ITC_FM	---	---	---	---				
ITC_TR	---	---	---	---				
BPI_I	0.333**	0.331**	0.548**	0.510**	---			
MS_IT	0.264**	0.298**	0.454**	0.355**	0.371**	---		
MS_BPI	0.279**	0.317**	0.424**	0.386**	0.445**	0.574**	---	
CC_DIST	-0.141*	-0.125	-0.187**	-0.114	-0.178**	-0.188**	-0.172**	---

Note. ITC_IFC = Index of the ITC Inter-firm Communication dimension, ITC_DI = Index of the ITC Data Integration dimension, ITC_FM = Index of the ITC IT Facilities and Management dimension, ITC_TR = Index of the ITC Training dimension, BPI_I = BPI Index, MS_IT = Management Support of IT, MS_BPI = Management Support of BPI, CC_DIST = CEO-CIO Distance.
** Correlation is significant at the 0.05 (2-tailed) level.*
*** Correlation is significant at the 0.01 (2-tailed) level.*

these indices for individual ITC dimensions were correlated to the variable of CEO-CIO distance (CC_DIST), and it was found that hypothesis 5 was only partially supported. While the negative associations between CC_DIST and ITC_IFC and ITC_FM were statistically supported, the ones between CC_DIST and ITC_DI and ITC_TR were not (Refer to $H_0$5a, $H_0$5b, $H_0$5c, and $H_0$5d in Tables 7 and 8).

Nonparametric correlation analyses were also performed respectively for the relationships between the variables of CEO-CIO distance (CC_Dist), and senior management support of IT projects (MS_IT); between the variables of CEO-CIO distance (CC_Dist), and senior management support of BPI projects (MS_BPI); between the variables of BPI index (BPI_I) and senior management support of BPI projects (MS_BPI);

Table 8. Summary of findings

	Hypothesis	Finding
$H_0$1a:	ITC_IFC and BPI_I positively related	S[a]
$H_0$1b:	ITC_DI and BPI_I positively related	S[a]
$H_0$1c:	ITC_FM and BPI_I positively related	S[a]
$H_0$1d:	ITC_TR and BPI_I positively related	S[a]
$H_0$2:	CC_Dist and MS_IT negatively related	S[a]
$H_0$3:	CC_Dist and MS_BPI negatively related	S[a]
$H_0$4a:	ITC_IFC and MS_IT positively related	S[a]
$H_0$4b:	ITC_DI and MS_IT positively related	S[a]
$H_0$4c:	ITC_FM and MS_IT positively related	S[a]
$H_0$4d:	ITC_TR and MS_IT positively related	S[a]
$H_0$5a:	ITC_IFC and CC_Dist negatively related	S[b]
$H_0$5b:	ITC_DI and CC_Dist negatively related	NS
$H_0$5c:	ITC_FM and CC_Dist negatively related	S[a]
$H_0$5d:	ITC_TR and CC_Dist negatively related	NS
$H_0$6:	BPI_I and MS_BPI positively related	S[a]
$H_0$7:	BPI_I and CC_Dist negatively related	S[a]

Note. ITC_IFC = Index of the ITC Interfirm Communication dimension, ITC_DI = Index of the ITC Data Integration dimension, ITC_FM = Index of the ITC IT Facilities and Management dimension, ITC_TR = Index of the ITC Training dimension, BPI_I = BPI Index; MS_IT = Management Support of IT, MS_BPI = Management Support of BPI, CC_DIST = CEO-CIO Distance, NS = Not Significant.

[a] *Significant at $p < 0.01$.* [b] *Significant at $p < 0.05$ (2-tailed).*

and between the variables of BPI index (BPI_I) and CEO-CIO distance (CC_Dist). The resulting correlation coefficients (Spearman's rho) were statistically significant, hence confirming hypotheses $H_0$2, $H_0$3, $H_0$6, and $H_0$7.

DISCUSSIONS AND IMPLICATIONS

Discussions of Findings

This study demonstrated the positive correlation between the capabilities of individual dimensions of IT infrastructure and the extent of BPI, reinforcing the symbiotic relationship widely discussed in the MIS literature. As an extrapolation from this finding, we would like to point out that the special relationship of these constructs needs to be given special attention. In IT deployment projects, business process issues need be properly managed, or vice versa. As is often discussed in the literature, IT deployment without process amelioration might be a waste of opportunities for efficiency gains and IT investment, as in the cases of implementing an ERP, or a document management/workflows system. On the other hand, IT would give business process redesign initiatives new possibilities in business practice and methods. For instance, the installation of networking and communications facilities (and the Internet) would give a firm the opportunities to reexamine how to organize its project teams and work processes. Therefore, we incline towards the viewpoint that the role of each of these interacting constructs varies in different situations and according to enterprise objectives. It would be difficult to ascertain the cause–effect relationships between them. Given the mutual influence between IT and business process changes, success factors for both constructs need to be considered thoroughly and managed properly if improvements are to be made to IT and process management practices. Ignoring such factors will render the management model incomplete, thus exposing the project to the risk of failure.

Higher levels of management support and a closer reporting relationship between the CEO and CIO were found to be associated with better performance in BPI, and some dimensions of ITC, as perceived by the respondents. In parallel to these findings, a closer CEO-CIO reporting relationship was also associated with higher levels of senior management support. The statistical results appear to suggest that, regardless of company background, management support and the status of the IT leader (and that of the IT function) are among the key factors to successful outcomes in achieving the objectives of ITC and BPI. The reporting relationship of the CIO is initially dictated by the organizational structure of a company. A closer direct reporting relationship, indicating a senior ranking, might possibly put the CIO in a better position to communicate with and influence senior business executives in comparison to an indirect reporting relationship (Cash et al., 1992; Hambrick, 1981; Jain, 1997). As an executive has said in a survey of CIOs (Field, 2002), whom the CIO reports to does matter a great deal. A CIO who reports directly to the chief executive is perceived as being more important than one who does not, and what he says would therefore carry more weight among the audience (Field, 2002). The findings of this study have shed light on the general belief that positioning the CIO and his or her team prominently in the organization structure may help the organization achieve better performance in IT and BPI projects. The findings of this study are in alignment with the propositions of Ein-Dor and Segev (1978).

The finding that who a CIO reports to is important is also consistent with what has been discussed in the ERP literature (Davenport, 1998; Willcocks & Sykes, 2000). These studies emphasized the importance of the support from senior executives in enterprise-wide projects, which often require changes to boundary-spanning processes. Business leaders should play a key role in mediating between different divisions to defuse difficult political situations concerning the interests of various stakeholders in these cases (Davenport, 1998). It would be of interest to IT practitioners and academic researchers to explore this issue further. However, we need to take note of the other school of thought that considers communication quality and membership in top management team as more important than a formal senior job title (Earl & Feeney, 1994). Earl and Feeney's opinion may not be in conflict with that of the other academics espousing a formal senior hierarchical position for the IT leader. A formal senior position may mean a greater chance to participate in the top management team. Moreover, it must be reminded that a closer reporting relationship in the organizational structure works only if the CIO is in possession of the right attributes to effectively perform his/her job (such as the personality, skills and commitment necessary for building a good and trustful working relationship with the business leaders). Violating this assumption may render the CIO unfit for the organization.

Noteworthy is the attempt in this study to understand and pinpoint the dimensions of the ITC and the extent of BPI constructs. An EFA showed that the latter is unidimensional and the former consists of four dimensions, namely inter-firm communications, data integration, IT facilities and management, and training.

Subsequent to the EFA, this study demonstrated the associations of each dimension of the ITC construct with the BPI construct and management support of IT projects. That is, the perceived levels in the extent of BPI, and senior management support are related to perceived levels of these individual aspects of IT. The CEO-CIO reporting relationship was found to relate significantly to the ITC dimensions of interfirm communications and IT facilities and management. These showed the associations between the organizational characteristics, particularly the chosen IT governance-related constructs, and enterprise IT capabilities. The reason for the insignificant relationships between the CEO-CIO reporting relationship and the ITC dimensions of data integration and training is unknown. Rather than contributing a speculative explanation, we would like to attribute these findings to data issues, and suggest that these relationships be retested using a different sample. As a consolation, the relationships were supported at the significance level of 0.10, indicating weak associations.

Academic and Professional Contributions

This study contributes to research by gathering empirical evidence on the associations between contextual constructs (such as senior management support and CEO-CIO reporting relationships), and the perceived levels of achievement in the various dimensions of ITC and BPI in Hong Kong-listed and multinational firms operating in Hong Kong and China. The influence of these constructs has been discussed in many studies, in some cases with limited empirical support, or in others with empirical findings that are weak in generalizability. The findings of this survey help fill the gaps that exist in the literature.

Executives and IT leaders are advised to learn to manage organizational constructs in conjunction with their enterprise-wide initiatives of IT adoption and BPI. Such organizational constructs as senior management support and CEO-CIO reporting relationship must be accorded paramount importance and managed cautiously. This also implies that firms that regard IT and business process management as important capabilities should place their CIOs and IT functions in prominent and influential positions (Karimi, Gupta, & Somers, 1996). Moreover, the CIO and CEO should work closely together to produce a synergistic effect on the strategic alignment of business and IT, and in securing support from other senior executives.

While this has important implications for business and IT executives, academic researchers in the disciplines of MIS and business management need to appreciate these findings and view them as pointers to more in-depth studies in the future.

Finally, in this study the concept of the ITC construct was empirically explored and those of its dimensions, comprising not only capabilities in communications and systems management but also those in data integration and training, were identified. An attempt was also made to investigate which of these ITC dimensions were associated with the organizational constructs under study.

Limitations

Although generally accepted guidelines and principles in research were followed in this study (Churchill, 1979; Nunnally, 1978), it has some potential limitations. First, this study relied on the perceptual inputs of the same respondents for the multiple variables in the research model; therefore, the likelihood of common method bias cannot be entirely ruled out. Second, this study is limited by its cross-sectional sample. The empirical findings, therefore, have substantiated correlational, but not necessarily causal relationships. For instance, while it is known that CEO-CIO distance and senior management support are negatively related, it cannot be determined whether higher levels of senior management support are the result of a closer CEO-CIO relationship, or vice versa.

Further Studies

Consequently, it must be added that a longitudinal study would help clarify and reinforce the relationships reported in this study. The findings of this study also point to many opportunities for further research. Practitioner reports have pointed to an upward trend over the last decade of placing the CIO directly under the chief executive (Field, 2002; Rothfeder, 1990). This practice may have hinted that more companies are treating IT as a strategic asset, rather than a cost to an organization. Studies should be conducted to examine whether there exists an association between the positioning of the CIO and the objective of using IT as an enabler of competitive capabilities in the business world as Karimi et al. (1996) suggested. Similarly, it would be of interest to ascertain whether the abovementioned trend in CIO positioning has actually contributed to the effective use of IT in supporting business strategies.

As a last note on the further advancement of MIS research, we would like to advise that academic researchers should continue to strengthen the theoretical explanations for the influence of the organizational constructs mentioned above. On the further development of the ITC construct, we would like to suggest that the ITC items and conceptualised dimensions be validated using another data sample as a further confirmation of its dimensionality. Additional efforts in this area would contribute to the development of a comprehensive standard instrument for measuring ITC that supports repetitive and systematic studies across contexts (Santhanam & Hartono, 2003).

Conclusion

This study has yielded empirical findings that demonstrate the associations between the perceived levels of achievement in some ITC dimensions and the organizational constructs, namely the BPI and IT governance constructs. Such associations may be regarded as hints that it is necessary for firms to properly manage these organizational factors, in the course of planning and executing any IT adoption and business process management initiatives. An in-depth understanding of the influence of various organizational factors may contribute to the further refinement of practice, and to better outcomes in IT adoption and business process management.

ACKNOWLEDGMENTS

The authors are grateful to three anonymous referees and Professor Janice Sipior, Associate Editor, for their constructive comments on the earlier version of the manuscript. This research was supported in part by The Hong Kong Polytechnic University.

Chapter 6.4

The Contingent Role of Innovation between IT Management Sophistication and Strategic Alignment

Leelien Ken Huang
Feng Chia University, Taichung, Taiwan

ABSTRACT

To provide deeper insight into IT managerial adaptive processes considered in strategic alignment mechanisms, we propose, using contingency theory, that the degree to which IT management sophistication contributes to a company's success is contingent upon its adaptive innovated behavior. Results suggested that Taiwanese companies could succeed when IT management sophistication is appropriate for a certain innovation. Our research model was generic for foreign companies' strategic behavior because, based on contingency theory, these companies make dynamic adaptations toward their particular environment for a competitive IT-based innovation. Implications of results are discussed. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

What certain sophisticated level of information technology (IT) management practices is more critical to the effectiveness of a particular innovation? Such a question has widespread practical, as well as theoretical, ramifications because a company's success may be realized only when appropriate IT is used to underlie a certain innovated business orientation (Kamal, 2006; Lacity, Willcocks, & Feeny, 1996).

IT management sophistication means evolution of a company's IT management practices such as information systems (IS) expenditure, IT use experience, IS function, and so forth (Gupta, Karimi, & Somers, 1997). It reflects the extent to which IS strategy can be formally pursued to support overall company goals, indicating that IS strategy should be progressively aligned with other strategies as the company grows over time toward maturity (Slaughter, Levine, Ramesh, Pries-Heje, et al., 2006). This implies that a company's success can be measured by a greater strategic alignment (Hirschheim & Sabherwal, 2001; Kearns & Lederer, 2004; Luftman, 2003; Luftman & Brier, 1999). Strategic alignment means achievement of cohesive goals across IT and other organizational functions (Luftman, 2000).

Various components of "strategic alignment" have been examined in different areas of IS research. For example, in IT governance, a control mechanism concerning decision-making, alignment, and communication is used to ensure the successful use of IT (Weill & Ross, 2004, 2005). In operations management, sustainability depends on internal consistency between companies' strategies and their manufacturing operations (Krajewski & Ritzman, 2005). In the role of senior executives in IS planning, top management support facilitates the effectiveness of IT assimilation (Liang, Saraf, Hu, & Xue, 2007). In the strategic IS planning process, analytical and administrative approaches are used to align strategic management to IT management through a set of capabilities (e.g., governance, technical, and personnel) (Henderson, Venkatraman, & Oldach, 1996; Venkatraman, Henderson, & Oldach, 1993). More recently, the impact of strategic alignment between IS function, IT infrastructure, organizational infrastructure, and business planning processes on company performance has been widely studied (Sabherwal & Chan, 2001; Sabherwal, Hirschheim, & Goles, 2003; Tallon, Kraemer, & Gurbaxani, 2000). In the effective use of IT, contextual factors (e.g., environmental uncertainty, information intensity, etc.) have significant impact on business dependence on IT (Kearns & Lederer, 2004). More recently, situational contingencies (e.g., employee training, technical complexity, task interdependence, etc.) influence successful IS implementation (Sharma & Yetton, 2007).

Since these and other studies have described various contexts of alignment between IS and business strategies, our focus is more macro; that is, we used contingency theory to conceptualize the research model (Figure 1). Contingency theory emphasizes the importance of situational influences on the management of organizations (Govindarajan, 1988; Zeithaml, Varadarajan, & Zeithmal, 1988). In our model, IT management sophistication and innovation play a critical role of contingency (i.e., antecedent and moderator) that influences the posterior: strategic alignment.

In strategic perspective, moreover, we consider variables in our model not only as content but also process-oriented factors because the environment is dynamic. Sabherwal and Chan (2001) noted that "strategy content" concerns aspects of business strategy aligned with aspects of IS strategy while "strategy process" is focused on how a company develops and implements its management practices.

Henderson and Venkatraman (1993) proposed a "logic strategic alignment framework for analyzing strategic choices in enough detail to ensure successful implementation of business, technology, and infrastructure direction" (p. 205). Although this model emphasizes the process of strategic alignment, Tallon (2003) regarded it as a range of managerial and administrative actions that transform the company by aligning the domain of choices contained within the content of strategic alignment. Hence, our model is both process and content oriented.

We treat "IT management sophistication" as process oriented, since it relates to the changing (adaptive) process of IT managerial activities that evolve toward formalization as the company grows over time (Gupta et al., 1997) and "strategic alignment" as content oriented, which refers to the aspect of IS plan to business plan and vice versa (Kearns, 1997).

By "innovation," we refer to a company's adaptation to the external environment, which can be considered as a typical business strategic typology

(Miles & Snow, 1978). With this contingent view, companies that seek innovation are more effective when their information processing requirements (e.g., business strategy) match their information processing capabilities (e.g., IT) (Teo, 1994). As such, innovation is a very social process by which there is awareness through certain channels (e.g., executive meeting, staff meeting, media, etc.) over time among members (e.g., manager, change agent, educated employee and client, etc.) of a social system (Rogers, 1983). Swanson and Ramiller (2004) also noted that "mindfulness plays a role in IT-based innovation by enhancing the recognition of organizational situations demanding inventive response" (p. 556), implying a strategic nature of innovation.

Our research objective is to clarify whether a certain sophisticated level of IT management practices is more important for a certain innovation pursued than for others to achieve a strategic alignment. Grounded on contingency theory, we proposed the strategic alignment framework of company adaptation. This framework addresses the issue: "how IT resources can be strategically used to be an innovative company."

Taiwan is an ideal location to examine the issue. Based on 2007 statistics by the Department of Investment Services, Ministry of Economic Affairs (twbusiness.nat.gov.tw/asp/invest.asp), Taiwan had one of the largest foreign direct investments (ranked third) in ASEAN (Association of Southeast Asian Nations). Moreover, the amount of its direct investment to China has had a substantial increase (21%) since 2006. Taiwanese companies have been facing increased foreign competition (e.g., China, ASEAN) after Taiwan's admission to the WTO in 2001, thereby making it increasingly necessary for them to focus on IT-based innovations in products and market development (Chen, 2003). For example, Singapore has implemented a series of national IT plans and programs to encourage diffusion of IT in both public and private sectors by providing various nationwide electronic networks (e.g., TradeNet, PortNet, MediNet) for business transactions (Thong, 1999). This has drawn the Taiwanese government's attention to retain its overall industry's global competitiveness by launching *e-Taiwan* project under 'Challenge 2008: The six-year national development plan".

However, difficulties such as high cost, technical complexity, and long time lag may contribute to "IT productivity paradox" (i.e., IT does not necessarily generate productivity) (Lucas, 1999). Although the use of IT has likewise evolved in substantial ways and indeed attracts senior management's interest by its importance to innovation, the over-hyped promise has left many senior executives uncertain about the outcome of IT (Lucas, 1999). For example, it was clear that the IT payoff has been identified as the key to the type of IT-based innovation determined in Taiwan (CIO, 2006), implying that using IT strategically (i.e., strategic alignment) becomes a key to Taiwanese executives when pursuing innovation. This local IS management argument is consistent with that in the Western business frameworks with increasing emphasis on the strategic alignment recently (Luftman & McLean, 2004; Maltz & DeBlois, 2005; Prewitt, 2004; Tallon & Kraemer, 2003).

This article extends the cumulative tradition of IS research to emphasize the importance of the contingent role of innovation that changes the relationship between IT management sophistication and strategic alignment directed towards a company's success. By showing how Taiwanese companies adjust the strategic sophisticated positions of IT in accordance with their pursuit of innovation, foreign companies are expected to refer to this adaptation in their IT management practices improvement.

First, we define the contingency theory for the basis of strategic alignment, IT management sophistication, and innovation. Next, we provide our research framework; followed by a description of the factors used to measure strategic alignment, IT management sophistication, and innovation; the method used to collect the data; and a discussion of the results obtained in our study. Finally, we conclude with implications for both researchers and practitioners.

THEORETICAL BACKGROUND

Contingency theory (CT) argues that "effectiveness" depends on appropriate fit of contextual factors with internal organizational designs (Pfeffer & Salancik, 2003). CT has contributed to the quality and productivity of IS function and to the larger company by providing feedback to manage and improve IS function to better fit the business needs (Benlian & Hess, 2007; Langdon, 2003). It argues that an IT-organizational relationship is not a simple linear causal one that can be identified by whether it is a technical or organizational imperative, but a dynamic evolution through organizational practices (e.g., managerial experiences) (Lee & Grover, 1999/2000) that match external characteristics (e.g., environment) (Pfeffer & Salancik, 2003)

In IS literature, several contingency antecedents (e.g., environmental [dynamism], technical [connectivity] or organizational [business knowledge of IS manager, business strategy, information intensity, size, structure, user satisfaction]) have been included in the analysis of a "fit" relationship (Benlian & Hess, 2007; Ducan, 1995; Earl, 1993; Jiang, 2003; Kearns, 2000; Kearns, 2005; Kearns & Lederer, 2004; Wang, 2001). Using these antecedents, IS research examined the problems, benefits, methodologies, and management issues of the IS planning process (Doherty, Marples, & Suhaimi, 1999; Lederer & Sethi, 1996; Ragu-Nathan, Apigian, Ragu-Nathan, & Tu, 2004; Tang & Tang, 1996; Teo & Ang, 2001).

Such an IS planning process generally relates to the sophisticated level of IT management practices emphasizing what contingencies should be included for IS planning approaches (e.g., techniques for identifying and deciding IT investment, and measuring IS success) and thus, affect a company's competitive position (Karimi, Somers, & Gupta, 2001; Saeed, Malhotra, & Grover, 2005; Wang & Tai, 2003).

To fulfill our research objective, using CT, we were able to examine a company's adaptive process for pursuing a competitive IT-based innovation, which is believed to be of interest to Taiwanese and global practitioners. The CT relevant theoretical concept of strategic alignment, IT management sophistication, and innovation are introduced in the followings.

Strategic Alignment

Based on CT, managers must consider (adapt) all kinds of situations to ensure cohesive goals across administrative and technological domains (Pfeffer & Salancik, 2003). Thus, "strategic alignment refers to applying IT in harmony with business strategies, goals, and needs" (Luftman, 2000, p. 3). Despite its criticism that "too fit" between IS and business strategies may reduce strategic flexibility (Jarvenpaa & Ives, 1994), researchers have argued that the inability to realize better business performance from IT, in part, is due to a mismatch between IS and business strategies (Benco & McFarlan, 2003; Croteau & Bergeron, 2001; Henderson & Venkatraman, 1999; Kearns & Lederer, 2003; Tallon, 2003).

While there is little agreement on conceptualizing strategic alignment and its research basis (Avison, Jones, Powell, & Wilson, 2004), Henderson and Venkatraman's (1991) strategic alignment model is believed to be the most influential research that conceptualized the strategic alignment between IT and business requirements. Their model contains four contingencies of business strategy, IS strategy, organizational infrastructure and processes, and IT infrastructure and processes by showing two fundamental "fit" relationships: strategic fit and functional integration. This implies that effective and efficient use of IT requires the alignment of IS and business strategies.

Henderson and Venkatraman (1993) argued that "strategic fit" recognizes the match between internal and external characteristics of the company when pursuing competitive IT-based market position. This "fit" generally leads to "functional integration" or "cross-domain alignment" that emphasizes how IS strategy affects business strategy (Burn & Szeto, 2000; Hu & Huang, 2006). Therefore, as business strategy changes, IS strategy and processes must keep pace (Burn & Szeto, 2000; Earl, 1993; Galliers & Newell, 2003). An effective IT-based market position becomes critical to the company's ability to adapt and successfully leverage technology (Pfeffer & Salancik, 2003). Functional integration provides the company with IT opportunities to gain competitive advantage (Reich & Benbasat, 1996).

After Henderson and Venkatraman's (1991) conceptual work, researchers have developed several alignment models to empirically demonstrate to practitioners the advantages of strategic alignment as shown in Table 1. While these studies focused on the process-oriented mechanics to realize strategic alignment, intellectual (i.e., content) factors are also emphasized. For example, Reich and Benbasat (2000) argued that although in the short term, communication between executives plays a significant role of strategic alignment, shared domain knowledge between IT and business managers may be potential to generate successful IS implementation in the long run. Chan (2002), Kim (2003), and Rathnam, Johnsen and Wen (2004) also noted that intellectual contingencies such as communications, trust, vision, and culture are important to strategic alignment as the company grows over time. More recently, Bassellier, Reich and Benbasat (2003) noted that a CEO's IT competence contributes to the effective use of IT. In support of that, Broadbent and Kitzis (2005) emphasized that collaboration between the CIO with the CEO is crucial to effective strategic alignment.

Table 1. Key empirical works of process-oriented strategic alignment

Contributors	Type of Alignment	Results
Byrd, Lewis & Bryan (2006)	IS-Business Alignment	Investigating moderating role of strategic alignment between IT investment and performance, indicting there is a synergistic coupling between strategic alignment and IT with company performance.
Hu & Huang (2006)	IS-Business Alignment	"Relationship management" has a significant impact on IS and business strategies alignment, using balanced score card.
Peak, Guynes & Kroon (2005)	IS-business Alignment	The planning process based on a case study is found to help align IT with business strategies and improve and facilitate the communication on IT project management.
Avison, et al. (2004)	IS-Business Alignment	Validating a strategic alignment framework that allows executives determine current alignment levels and monitor future alignment required.
Pollalis (2003)	Integration (Technological, Functional, Strategic)	Co-alignment improves overall organizational performance
Hartung, Reich & Benbasat (2000)	Business-IS Alignment	The lack of connection between business and IT planning due to the relatively immature business planning processes within the forces.
Kearns & Lederer (2000)	IS-Business Alignment Business-IS alignment	Both IS-business and business-IS predict the use of IT for competitive advantage.
Tallon, Kraemer & Gurbaxani (2000)	Business-IS Alignment	Strategic alignment and IT evaluation contribute to high-perceived value of IT business value.

Some researchers attempt to demonstrate to practitioners how to accomplish strategic alignment. For example, Luftman and Brier (1999) proposed a six-step approach to achieve greater strategic alignment by identifying contingencies (both enablers and inhibitors [also see Burn [1997]; Hsaio & Ormerod [1998]; Yetton [1997]]) in a survey of corporate executives of large U.S. companies. Luftman (2003) proposed five levels of IT-business alignment benchmark over six categories that cover business and IT issues to help executives assess the maturity of strategic alignment. Some researchers also argued that IT governance may help in aligning IS strategy to business strategy. For example, Weill and Ross (2004) proposed the executives' decision-making and accountability models to seeking appropriate IT investments. Brown and Grant (2005) further proposed a logistical IT governance framework to find an appropriate mechanism to govern corporate IT investments.

Realizing the strategic alignment is a difficult, complex, and long-term task (Hu & Huang, 2006). To facilitate this task, Weiss, Thorogood and Clark (2006) suggested that internal organization and external market factors should both take into account the alignment thinking in terms of technical resource, business enabler, and strategic weapon. In this sense, to respond to a dynamic environment, properly exploiting IT as a strategic resource has been viewed as important for sustaining competitive advantage (Chung, Rainer, & Lewis, 2003; Porter & Millar, 1985). To fulfill this expanded mission, the IS strategy must be in alignment with business strategy (Kohli & Devaraj, 2004).

IT Management Sophistication

IT management sophistication (ITMS) is defined as the progression toward increasingly formalized management of IS function (Karimi, Gupta, & Somers, 1996). Thus, ITMS is used to examine the extent of formalization (effectiveness) to which IT management practices can be pursued and linked to business strategy (Gupta et al., 1997).

Since its relevance to IS strategy, ITMS involves the changing process of how contextual factors can be appropriately matched to achieve effective IS planning and implementation (Kearns & Lederer, 2000). Kim (2003) argued that such a process can be viewed as being a strategic alignment process, seeking to the "fit" among contextual factors within an organization to demonstrate that a company's success is contingent upon those factors (Devaraj & Kohli, 2002).

The theoretical basis of ITMS has two forms. First, Nolan's (1979) studies on the stage hypothesis developed six growth stages construct—initiation, contagion, control, integration, data administration, and maturity—indicating that IS expenditure follows the path of an S curve over time from computer (less formal IT management [the first three stages]) to information management (more formal IT management [the last three stages]). Second, McFarlan and McKenney's (1982) technology assimilation model is an extension of the stage hypothesis model and attempts to provide a more detailed contextual view of the overall IT diffusion process and the evolution of IT management through four phases: investment, learning and adaptation, control, and widespread (Lu, Liu, Jing, & Huang, 2005).

Research on IS stage hypothesis and the technology assimilation model suggests using managerial practices (i.e., various stage-based adaptations in the face of environmental pressures) concerning IT-based activities as benchmark variables to measure the progression of a company's move towards a certain level of ITMS (Karimi, Bhattacherjee, Gupta, & Somers, 2000). Based on the two models, Karimi et al. (1996) classified ITMS benchmark variables into four contingencies: planning, control, organization, and integration to examine the extent of evolution of formalized management of IS functions that support a company's business need. Gupta et al. (1997) noted that the evolutionary role of IT and the extent to which IS strategy can be effectively pursued depend on the ITMS of a company.

As such, the ITMS contingency framework indicates significant variations between companies to the extent to which their IS strategy has been aligned with their business strategy (Karimi et al., 2000). These variations are reflected in three evolutionary roles (operational, strategic, and integrated) of the IT-based resources within a company (Gupta et al., 1997). Teng, Cheon, and Grover (1994) argued that a business strategy should be linked to this evolution. A greater ITMS represents a significant formalization of planning (Duh, Chow, & Chen, 2006;), control (Duh et al., 2006), organization (Palanisamy, 2005), and integration (Teo & Ang, 2001) of a company's IT-based activities, indicating that the IS function in a company evolves from computer data processing into a strategic IS orientation (Gupta et al., 1997), and then is more closely integrated into the company's business strategy (Lu et al., 2005).

Innovation

Innovation is defined as, "Implementing new ideas that create value" (Linder, Jarvennpa, & Davenport, 2003), and generally refers to the various types of innovation that can take place, such as product development, deployment of a new process technology, and/or innovative management practices (Zott, 2003). In the innovation literature, theoretical models such as Rogers' (1983) diffusion of theory (DOT) and Davis' (1989) technology acceptance model (TAM) have been widely used and are believed to be the most influential theories in explaining and predicting IT use and innovation (Chen & Tan, 2006).

DOT explains five stages (initiation [stage 1-2] and implementation [3-5]) of the decision process of adopting an innovation (Rogers, 1983), concerning contingencies such as relative advantage, compatibility, complexity, triability and observability that are associated with the adoption (Rogers, 2003). Based on these contingencies, the category of adopter is determined and helps predict the possibility and the rate of innovation adopted (Chen & Tan, 2006).

TAM is designed to explain the determinants of user acceptance of end-user computing technology, positing that perceived usefulness and perceived ease of use are the key to the adoption (Davis, Bagozzi, & Warshaw, 1989). This model hypothesizes that IT use is influenced by the user's behavior, which is in turn affected by the user's attitude to use and thus beliefs about new IT (Chen & Tan, 2006).

Based on both TAM and DOT, Chen, Gillenson and Sherrell (2002) found significant consumer behavior in a virtual store. Huang, Lu and Wong (2003) extended TAM and found that cultural factor "power distance" significantly moderates the relationship between subjective norms on perceived usefulness of e-mail. Hsu, Lu and Hsu (2007) further used DOT and found there was a significant difference between potential adopters and users by examining users' perceptions of adopting mobile Internet.

Besides the individual adoption, some researchers argued that innovation adoption can be made at the organizational level (Fichman & Kemerer, 1997). For example, Lucas, Ginsberg and Schultz's (1990) two-step model indicated that organization members' adoption of innovation depends on their higher authority (senior manager) decision after identifying objectives to change aspects of business and finding available innovation that fits company objectives (Gallivan, 2001).

Therefore, innovation is an organizational process of pursuing new IT to business (Gallivan, 2001). Swanson and Ramiller (2004) called this process an organizing vision that forms the notion of "mindfulness" of a company to determine the rate of innovation adoption. This organizing vision involves experiences, ideas, and beliefs of many diverse interests when adopting new IT (Swanson & Ramiller, 1997) and evolves innovation decision from material toward more company-oriented (Scott, 2000).

Since our research issue is strategic by nature, the term "innovation" would focus on the organizational process of management objectives and intentions for change and can be viewed as a business strategic process (Miles, Snow, Meyer, & Coleman, 1978). Based on CT, it drives a company to adapt to its environment through continuous strategic adjustments (e.g., business process, alliance, mergers and acquisitions) using innovation in technology and administrative processes (Patrakosol & Olson, 2007; Srivardhana & Pawlowski, 2007). Knott (2003) noted that innovation and business strategy are intertwined in the efforts to sustain competitive advantage. However, Shoham and Fieganbaum (2002) argued that the need exists for an additional integrated theory to link organizational (strategic) context with innovation.

Although there are many dimensions of strategic behavior (e.g., Porter's [1985] generic strategies), we used the Miles and Snow (1978) typology, since innovation is one of the principal drivers of prospectors. Having a strong theoretical and empirical foundation (Ghoshal, 2003), the Miles and Snow typology focuses on the dynamic process of adjusting to environmental changes and uncertainty (DeSarbo, Benedetto, Song, & Sinha, 2005). The key concept underlying Miles and Snow's typology is the rate at which a company changes its products/services or markets to sustain competitive advantage (Singh & Agarwal, 2002). In IS planning literature, it is often used as a surrogate for measuring the extent of a company's strategic orientation in conducting IT-based innovation (e.g., Kearns [2005]). The Miles and Snow typology is relevant to this study on strategic alignment, since IT is related to both strategic response and organizational systems (Hambrick, 2003).

Hence, "innovation" may be viewed as a company's adaptation that is a typical business strategy (Blumentritt & Danis, 2006). CT views this adaptability as "management flexibility" that emphasizes the influence of IT on organizational structure and its fit with the environment (Porter & Millar, 1985; Tallon, 2003). Various levels of executives perceived that environmental complexity and uncertainty give rise to different types of adaptation, and thus, different types of companies (Miles et al., 1978). Each type of company has an opportunity to succeed, as long as IT is effectively used to facilitate the characteristics of that type of company to match the complexity and uncertainty it perceives (Blumentritt & Danis, 2006).

Miles and Snow (1978) proposed alternative ways that companies define their product/market domains and construct mechanisms (i.e., structures and processes) to pursue those domains through the adaptive cycle. Using CT, the adaptive cycle focuses on the "fit" and conceptualizes three intricately adaptive problems—entrepreneurial, engineering, and administrative—that senior executives need to simultaneously and continually solve to maintain an effective alignment with its environment (O'Regan & Ghobadian, 2006; Shortell & Zajac, 1990). As shown in Table 2, the three adaptive problems are confronted within each of the four patterns in a company's adaptation (the strategic type)—defenders, prospectors, analyzers, and reactors—describing various levels of innovativeness pursued to respond to business dynamics (Miles & Snow, 1978).

Based on Table 2, a defender tends to provide relatively stable products/services, doing the best job in its area of expertise. It emphasizes tight control and continuously seeks to operate efficiently at lower costs. A prospector frequently adds and changes its products or services, being the first mover in the market. It tends to stress innovation and flexibility to quickly respond to market changes. An analyzer, which is a combination of the defender and prospector traits, emphasizes formal planning processes and balances cost containment and efficiency with risk taking and innovation. A reactor basically lacks any consistent strategy.

Both defenders and reactors are concerned with cost reduction and efficiency (Conant, Mokwa,

Table 2. The miles and snow typology

Strategic Type	Domain Concern (Solutions to Entrepreneurial Problem)	Technical Concern (Solutions to Engineering Problem)	Alignment / Innovation Concern (Solutions to Administrative Problem)
Defenders (Stable): Low Adaptive	✓ Follow a major shift in the market ✓ Create a stable set of products and customers	✓ Continuously improve a single core technology ✓ Protect that core technology by requiring technological problems to remain familiarity and predictability	✓ Maintain strict control for efficiency ✓ Achieve production and cost control efficiency with little or no new environment scanning
Prospectors (Flexible): High Adaptive	✓ Allocate and exploit new product and market opportunities ✓ Protect the company from a changing environment ✓ Deal with low profitability and overextension of resources while sustaining product and market innovation	✓ Avoid long-term commitment to a single technology and to manage a multiple technologies ✓ Maintain a good technology flexibility ✓ Maintain decentralized control	✓ Facilitate and coordinate numerous and diverse operations ✓ Maintain flexibility and effectiveness in decentralized units ✓ Manage risk associated with low profitability and overextension of resources
Analysers (Balanced): Hybrid	✓ Locate and exploit new product and market opportunities while maintaining a traditional products and customers base ✓ Minimize the risk while maximizing the profits by imitating successful products or market innovations ✓ Keep the balance between stability and flexibility	✓ Achieve and protect an equilibrium between conflicting demands for technological flexibility and for stability ✓ Deal with technological base that is not efficient or effective	✓ Differentiate the company's structure and process to accommodate both stable and dynamic operations ✓ Coordinate intensive planning between marketing, production, and engineering ✓ Maintain a moderately centralized systems with vertical and horizontal feedback loops
Reactors (Unstable): Non-Adaptive	✓ Articulate company's strategy ✓ Adjust to an environment that is both inconsistent and unstable	✓ Control cost	✓ Maintain the company's structure and processes despite overwhelming environmental changes

Note: Modified by the author based on Gupta et al. (1997), Hirschheim and Sabherwal (2001), Miles and Snow (1978), and Shortell and Zajac (1990).

& Varadarajan, 1990). However, a defender has a clear strategy to control costs, depending on its internal resources (Matsuno & Mentzer, 2000). An analyzer must also engage in environmental scanning, like a prospector (Kearns, 2005). Since both prospectors and analyzers engage heavily in environmental scanning (Kearns, 2005), IT may play a more strategic role (Gupta et al., 1997).

The most important differences among the strategic types were the change in product/market domain, environmental and organizational features of that domain (Miles & Snow, 1978), and the existence of a continuum of adaptation starting from the defender as a low adaptive company, prospector as a highly adaptive company, analyzer as a hybrid company, and reactor as a non-adaptive company (Shosham, Evangelista, & Albaum, 2002).

DEVELOPMENT OF RESEARCH FRAMEWORK

Research Concept and Model

Our integrated research concept derives that the company becomes success (i.e., towards strategic alignment) when there is a fit between the external market response (e.g., strategic types of innovation) and the internal resources and skills (e.g., IT management practices) possessed by the company (Porter, 1991). Since various strategic types cause different forms of IT use (Kettinger, Grover, Subanish, & Segar, 1994; Porter, 2001), we proposed that the degree to which IT management practices may contribute to a company's success (strategic alignment [SA]) is contingent upon its adaptive innovated behavior (business strategy [BS]), showing that ITMS increases the understanding between senior business and IS executives regarding the strategic value of IT-based resources, which can be used as a determinant of the effective use of IT to distinguish and support various levels of innovation pursued (Figure 1).

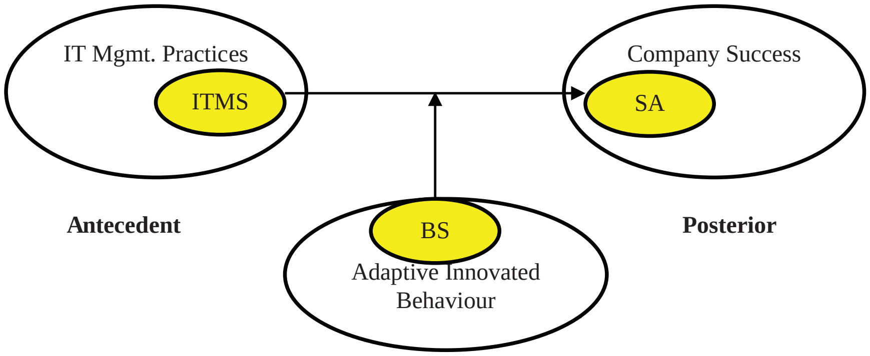
Research Hypothesis

To achieve competitive strategy, prospectors are usually aware of the changes and innovation of products or services and spend more time in scanning the uncertainty of customers and rivals' actions, toward opportunities for products, services, and market differentiations (Chong & Chong, 1997). They are likely to be first to the market place and seek to exploit this advantage; they also have a tolerance of risk and an acceptance of change, empowerment, and flexibility (O'Regan & Ghobadian, 2005). A prospector strategy requires organic features (e.g., coordination committee) to be effectively implemented (Karimi et al., 2000). This organic context will foster innovation relevant to prospecting and differentiation (Garcia-Dastugue & Lambert, 2003).

Prospectors require more sophisticated configuration of IT-based resources to handle divergent interests and heterogeneous points of the parties in the value chain (Kearns, 2005; O'Regan & Ghobadian, 2006). They emphasize the strategic alignment through business leadership and choose an IS strategy that allows them to both create and change the market (Hirschheim & Sabherwal, 2001). This IS strategy normally prefers "infusion" of IT into innovation (Segev, 1989). Specifically, the role of IT is proactive and opportunistic in innovating the business need (Hirschheim & Sabherwal, 2001).

Defenders spend less time in environmental scanning since the environment where they operate is more stable and predictable (Hambrick, 2003). Govindarajan and Fisher (1990) argued that a defender strategy could be more effective with mechanistic features such as less user in-

Figure 1. Contingency framework of IT management practices and company success



volvement and less motivation (less innovative). Under mechanistic features, a physical structure for the defender usually emphasizes rigid and cost-effective configuration appropriate for strict control and strong efficiency (Das, Zahra, & Warkentin, 1991; Matsuno & Mentzer, 2000). Miller (1987) found that strict control procedures, mechanistic administrative policies and output controls correlate with high performance for companies with more defensive and conservative orientation. Defenders favor IT developed internally and acquire transactional IT-based resources to manage their control and efficiency priorities effectively, reflecting less distributed and sophisticated types of IT-based resources utilized (Karimi et al., 1996; Kearns, 2005; Lu et al., 2005).

This is in contrast to prospectors who are externally postured and tend to acquire more computational, analytical, and decisional IT-based resources to scan the uncertain environment for managing complexity effectively (Crichton & Edgar, 1995). Teng et al. (1994) argued that defenders do not search outside their domain for new IT opportunities and sometimes overlook new IT development. They must rely on a few core technologies to offer high quality products or services at low prices and rarely adjust their organizational structure and technology (Sabherwal & Chan, 2001). Hence, defenders emphasize the strategic alignment through low cost delivery and choose an IS strategy that supports business through the most economical vehicle for the provision of current products or services and is based on a centralized IS function (Hirschheim & Sabherwal, 2001).

Combining a prospector's innovation and a defender's efficiency, analyzers use a comprehensive organizational structure and a dual technologies core, seeking effectiveness through both efficiency and new products or services and markets innovation (DeSarbo et al., 2005). Nevertheless, Gupta et al. (1997) argued that the company might fail to demonstrate one or both, since these conflicting demands are difficult to address simultaneously.

Despite that, analyzers usually can observe the market avidly and respond very quickly to the changes, since successful imitation is accomplished through high levels of internal and external analysis performed (Shortell & Zajac, 1990). They make strategic choices typical to prospectors in the newer and more dynamic endeavors (e.g., spending more time in IS planning activities) (Gupta et al., 1997) while adopting a strategy typical to defenders in the traditional and stable business lines (Teng et al., 1994). This requires a balance of locating new business opportunities and maintaining existing customer bases (Hambrick, 2003).

In the absence of clear strategic orientation, reactors make decisions in a reactive rather than a proactive way (Miles & Snow, 1978). Reactors seldom do environmental scanning for long-term forecasting because they believe that the environment will favorably support anything they do or not do (Zahra & Pearce, 1990). Reactors will not follow a specific strategy to secure IT-based resources (DeSarbo et al., 2005). Reactor IS executives are expected to spend more time in organization-related IT activities than to spend more time in impacting the company's competitive strategy (Matsuno & Mentzer, 2000).

Consequently, when a company emphasizes innovation, the company's IT management practices are likely to spend more time in adopting more complex decision-making tasks and have greater incentive for information processing in the form of scanning, planning, analysis, and consultation (Hambrick, 2003). On the contrary, when a company adopts a conservative strategy, the company's IT management practices are likely to spend more time in seeking to perform effective operational and managerial control (DeSarbo et al., 2005). For those companies in intermediate situations, they are likely to spend more time in promoting strategic control and synergy and providing the main benefits of the aforementioned both (Kearns, 2005). The following hypotheses are formulated.

H1: *Relationship between IT management sophistication and strategic alignment will be contingent on the strategic type of innovation pursued.*

H2: *To sustain competitiveness, the strategic type of innovation pursued will differ with respect to the degree of IT management sophistication.*

We assumed that the above relationship should be true in Taiwan's context since Wang and Tai (2003) have evidenced that Taiwanese organizations' strategic planning (i.e., how companies adapt to business environment [innovation]) mediates the relationship of internal organizational characteristics (e.g., formalization [planning], centralization [control], future role of IS [integration]) and IS planning effectiveness (organizational co-alignment). Based on CT, this hypothesized relationship also can be true in other countries since companies tend to seek to appropriate IT capabilities (e.g., IT management practices) for a better IS-business "fit" relationship while pursuing competitive innovation (e.g., Benedetto & Song's (2003) study in China).

METHODOLOGY

IS executives were selected as respondents because they were perceived as the most knowledgeable about the company with regard to strategic positioning and IT-based resources and activities (Gupta et al., 1997). For ease of discussion, we defined the term *CIO* (chief information officer) as the senior IS officials with various given titles. Respondents used a seven-point Likert scale ("7 = strongly agree" to "1 = strongly disagree") to record their responses on a questionnaire.

Measures

SA was measured by both alignment of IS strategy with business strategy (ISBUS) and alignment of business strategy with IS strategy (BUSIS) (Kearns & Lederer, 2004). Since it is content-oriented as noted, the former was measured by "IS plan reflects the business plan," "the recognition of external environment," and "the necessity of an IS plan because of resource constraints" (Kearns & Lederer, 2004; McFarlan & McKenney, 1982; Zviran, 1990). The latter was measured by "business plan reflects IS plan," "performance of IT," "use of IT to guide business strategy," "use of strategic capability of IT," and "reasonable expectations of IT" (Goldsmith, 1991; Premkumar & King, 1991, 1994).

Based on Karimi et al. (1996), we used 20-item containing four dimensions: planning IT (PLN), control IT (CTR), organization IT (OGN), and integration IT (ITR) to assess ITMS. "PLN" measures IS planning process characteristics by "types of IT," "strategic IT opportunities," "the current or potential use of IT," "the coverage and quality of IT," and "arrangement of IT project priorities" (Earl, 1993; Gupta et al., 1997; Premkumar & King, 1994). "CTR" measures manager's control over budgeting, priority setting, and resource planning for the IS function by "responsibility and authority," "development and operation," "proper appraisal of IT projects," "monitoring of IT performance," and "clear IS function" (Cash & Konsynski, 1985; Cash et al., 1992; Gupta et al., 1997). "OGN" measures the influence of IS department on the company by "special attention of user's ideas," "awareness of business and the organization," "coordination," and "good relationships between IT specialists and end users" (Cheney, Mann, & Amoroso, 1986; Gupta et al., 1997). "ITR" measures how IT integrates for various business functions through top-down planning process by "perceived strategic importance of future IT," "linkage between

IS planning and business needs," "IT resource available to business needs," and "adaptation and adoption of new technology" (Gupta et al., 1997; Johnston & Carrico, 1988).

To assess BS (i.e., innovation), the self-typing approach was used since the CIO is up-to-date on the company's direction and may identify intended innovation (Kearns & Lederer, 2000) and has been widely treated as an appropriate method to measure business strategy (Conant et al., 1990). We adopted paragraph descriptions of the four archetypes in Miles and Snow's (1978) typology: defenders, prospectors, analyzers, and reactors to assess company's strategic orientation. Accordingly, the respondents were asked to place their companies on a seven-point scale questionnaire that reflects a continuum of products or services innovation (Shortell & Zajac, 1990).

Sample and Pre-Tests

We examined companies grouped by Taiwan SIC (social industrial classification) (see general results in Table 6). Although this is a single country research, based on CT, the generalization of our research model to other countries is expected in terms of "fit" relationship that every country's business and IS executives should seek between business and IT-based resources.

The sample groups have been regarded as knowledge and information-intensive and use IT within all aspects of management and global implication, which is suitable for this kind of study (Sabherwal & Chan, 2001). *The Year 2006 Largest Corporations in Taiwan-Top 5000*, published by the China Credit Information Service, Ltd. (www.credit.com.tw), was used to search for companies. *The Year 2004 Top 1000 Firms in Taiwan*, published by "Commonwealth" magazine (www.cw.com.tw), provided the supplemental sources. After careful screening, 874 companies qualified for inclusion in the sample after satisfying five requirements (autonomy in selecting strategies, size over 250 employees, a structural position [IS manager], operation over three years, and implications of global business [overseas branches or affiliations]).

The development of questionnaire involves a series of refinement using IS doctoral students, IS professors, and IS practitioners. Changes in the wordings of certain items to improve clarity and minimize ambiguity were made. Forty-six face-to-face CIO interviews were completed over the one-month period of pre-test. A measure of internal consistency was calculated for each of four dimensions underlying ITMS construct and each of two dimensions underlying SA construct, respectively generating an acceptable Cronbach's Alpha value of 0.513~0.920 and 0.839~0.922 (Nunnally, 1978) and showing no significant difference from the comments received during the questionnaire refinement.

Survey Execution and Non-Respondent Bias Test

The survey was sent to CIOs in 874 sample companies via e-mail and post. During the survey, 209 useable questionnaires resulted, an overall response rate of 24% (209 of 874 surveys), regarded as a reasonable good rate that is corresponded with findings (20~28%) from previous Western IS planning research (Griffith & Finlay, 2004; Gupta, et al., 1997; Zahra & Covin, 1993). However, in contrast to 12~16% from local IS studies (Wang & Tai, 2003), our response rate is higher. This is perhaps because we are the first local study to examine the contingent effect of innovation on the strategic use of IT that draws Taiwanese companies' attention and our in-depth tracking and monitoring the completion of questionnaires reminded and encouraged non-responding CIOs to complete their surveys. Characteristics of respondents and non-respondents were compared for differences in terms of company type (chi-square = 5.33 [9 df, p = 0.804]), sales revenue (chi-square = 2.12 [6 df, p = 0.902]), and company size (chi-square = 7.03 [4 df, p = 0.134]). No significant differences were found at the .05 level of confidence ($p > 0.05$).

Reliability and Construct Validity of ITMS and SA Domains

Principal component analysis was used to retain the theoretical structure of factors ITMS and SA. Items with factor loadings below 0.5 on any factor or with factor loadings above 0.5 on more than one factor were dropped (Hair, Anserson, Tatham, & Black, 1998). When loading onto more than one factor, the varimax-rotated factors were used for subsequent analysis if they were statistically interpretable and theoretically meaningful. Items loadings in the rotated factor matrices were used to interpret and label the factors emergent. Eigenvalues for variation examined the number of factors largely responsible for variation in the data. The cut-off for the number of factors was one eigenvalue (Kaiser, 1974).

Based on this rule, the theoretical structure of factors "CTR" and "OGN" underlying ITMS and factors "ISBUS" and "BUSIS" underlying SA were confirmed (Table 3). Factor "PLN" extracted out two separated factors "AWR" (awareness) (F1, [PLN3 and PLN4]) that concerns the awareness of the outside changing the IT environment and "ISP" (IS plan) (F2, [PLN1, PLN2, PLN5~6]) that concerns the aspect of how the organization copes with the business environment through the IS plan. Emerging from factor "ITR," "TDW" (top-down) (F1, [ITR1 and ITR2]) concerns the aspect of IS top-down integrating process whereas "BUP"

Note 2: Only factor loadings greater than 0.5 are shown.

(bottom-up) (F2, [ITR3 and ITR4]) measures the aspect of IS bottom-up integrating process. Factor analysis was repeated to test the theoretical structure of each emergent factor. Correlation analysis was also conducted for two-item factors. Items for all respective individual emergent factors loaded onto a single factor, as expected, and item correlations for two-item factors were significant (0.01 level of confidence), thereby confirming the theoretical structure. Table 4 shows each (emergent) factor's loadings and acceptable Cronbach's coefficient alpha ranging 0.700~0.948 (Nunnally, 1978).

The representativeness of dimensions for ITMS and SA were tested by repeatedly dropping the factor with the smallest communality until the remaining factors loaded onto a single factor they represent (Chang, 2001), maximizing the percentage of variance (Bryman & Cramer, 1997). For each case, multiple items of a dimension were averaged into a single score that was used to compute factor loading. Consequently, a better ITMS factor structure including ISP, CTR, OGN, and TDW, which loaded onto a single factor (R^2 = 0.695, Table 5), was generated. ISBUS and BUSIS were used to reflect SA, which loaded onto a single factor (R^2 = 0.641, Table 5), indicating that they well captured the aspect of strategic alignment.

ANALYSIS AND DISCUSSION

Sample Characteristics

Table 6 contains several interesting general information about the companies. For example, sixty-five percentages of IT applications were implemented with cost reduction and efficiency as the primary purpose. Cost and efficiency remained the dominant objective for Taiwanese companies' strategic use of IT for innovation, although the Western IS literature has found effectiveness more often than efficiency as goals (Ward & Peppard, 2002). One plausible explanation is that Taiwanese companies are usually concerned with cost as they need to compete with companies in the region (e.g., China, Indonesia, Malaysia, Thailand, and Vietnam) where costs of doing business are generally less than that of Taiwan. Table 6 also shows 89% of CIOs wore the title managers or higher. This result suggested that responding executives were familiar with the strategic factors addressed in this survey. More than 60% of

participating CIOs had acquired considerable work experience in the company (mean = 10 years) and within an industry (mean = 16 years). Overall, these CIOs were knowledgeable about their companies and industries. Eighty percent of senior IS officials were reported as one-step junior to the CEO (chief executive officer), suggesting that the relationship between the majority of CIOs and CEOs was more familiar than distant. Thus, Taiwanese CIOs expected to have easy access to shared decision making and assist in selecting innovation strategies, which would not markedly bias the results of this study.

The self-typing approach yielded the following breakdown of innovation: 46 defenders, 94 prospectors, 57 analyzers, and 12 reactors, supporting our expectation that all four strategic types were pursued within Taiwan industry context. In other countries, based on CT, the mix of strategic types of innovation should be expected since executives may have different adaptations to the environment (Miles & Snow, 1978). The distribution of innovation supports the basic assumptions relating to the existence of significant linkage between innovation and company type (chi-square = 44.748 [27 df, $p<0.05$]) and between innovation and company size (chi-square = 44.497 [9 df, $p<0.05$]), implying that innovation pursued in different business sectors or different company sizes can be successful in a given environment when the company acts consistently in innovative business strategy (i.e., strategic alignment). Based on the "fit" concept of

CT, this also should be applicable in other countries. Our result is consistent with studies done in the United States, which found that innovation of financial institutions had a significant relationship with company size and type (e.g., Karimi et al. [1996]; Gupta et al. [1997]).

Contingent Effect Test

To explore contingent or moderating effect, Sharma, Durand and Gur-Arie's (1981) moderated regression analysis (MRA) typology shows the moderating effects of variable Z on variables X (predictor)-Y (criterion) relationship. Through MRA, if a significant interaction between Z and X is found, then determine whether Z is significantly related to Y or X. If it is significantly related, Z is a quasi moderator. Otherwise, Z is a pure moderator. If a non-significant interaction between Z and X is found, then determine whether Z is significantly related to Y or X. If it is significantly related, Z is not a moderator. Otherwise, split the total sample into subgroups based on the moderator and then do a test of significance for differences in predictive validity across sub-groups. If significant differences are found, Z is a moderator (homologizer). Otherwise, Z is not a moderator and the analysis is concluded. To carry out MRA, the regression models are formulated as the below:

$$Y = a + b1\ X + b2\ S + e$$
$$Y = a + b1\ X + b2\ S + b3\ Z + e$$
$$Y = a + b1\ X + b2\ S + b3\ Z + b4\ X*Z + e$$

Where Y is the criterion variable, b_i is the regression coefficient, X is the predictor variable, S is the company size, Z is the moderator, and X*Z is the interaction of X with Z. In IS literature, the company size is a very important variable that may influence IS-business relationship (Das et al., 1991) and was included in the model as a control variable.

Given the above procedures, the moderating effect of BS (Z) on ITMS (X) –SA (Y) relationship was tested. Since reactors have been ignored in the majority of previous studies (Hirschheim & Sabherwal, 2001; Sabherwal & Chan, 2001; Zahra & Pearce, 1990), this type was not included in the following analysis. Two dimensions: CTR and OGN underlying ITMS were significantly interacted with BS (interactive β=-1.196 and -1.808 respectively, $p<0.05$) while the other two dimensions: ISP and TDW were not (Table 7). Further tested by correlation analysis (Table 8), BS was found significantly correlated with either SA (0.148, $p<0.05$) or CTR (0.285, $p<0.01$), indicating that "innovation" is a quasi-moderator that impacts the form of the relationship between CTR and SA and between OGN and SA and simultaneously, has significant relationship with SA and CTR. As for those non-significant interactions between ISP and BS and between TDW and BS, BS has a significant correlation with either SA, ISP (0.195, $p<0.01$), or TDW (0.241, $p<0.01$), implying that "innovation" is not a moderator but a predictor that has a direct positive relationship with SA regardless of the degree of ISP or TDW.

Thus, H1 was partly supported, evidencing that although Taiwanese companies generally tend to be adaptive (i.e., innovative) in nature and perceive the importance of all four modes of IT management sophistication to their company success, two modes of "control IT" and "organization IT" substantially lower the degree of strategic alignment. For example, based on CT, IT management for prospectors is supposed to be more decentralized (low control IT) and more end user's involved (high organization IT) for the exploration of rapidly changing or prototypical technology to maintain technological flexibility. However, the evidence shows that some of their IT management practices have not yet evolved to an appropriately strategic maturity (i.e., "alignment" not well realized because IT is not decentralized enough for this proactive innovation). This was unexpected.

One plausible explanation is that because of cost disadvantage relative to ASEAN or China,

Taiwanese executives may tend to be conservative in approving expensive IT investment and thus prefer to centralize their IS function (more cost efficiency), while they have sensed the importance of aggressive innovation to keep global competitiveness. This should be true for other countries since Teo (2007) argued that companies, "who compete globally, regardless of their country of origin, are also concerned with cost as it is often linked to competitiveness of products/services offered" (p. 108). Consequently, conflicts may exist between intended innovations and realized IT management sophistication, leading to a poor strategic alignment.

ANOVA Test

A one-way ANOVA was carried out to provide a more micro view of our research hypothesis that how innovative strategic type differs with respect to the degree of ITMS. Several interesting and significant findings can be discerned from the results summarized in Table 9 and 10.

Defenders, analyzers, and prospectors are known to focus on different innovative behaviour of companies in products/services and market that may rely on IT (Kearns, 2005). So each of the companies should have its own appropriate inno-

Table 9. ANOVA of BS and ITMS

Table 10. Scheffe's test of mean differences in ITMS by BS

ITMS	Defenders vs. Analysers	Defenders vs. Prospectors	Analysers vs. Prospectors
ISP	0.095	-0.272	-0.367**
CTR	-0.017	-0.523**	-0.505**
OGN	0.122	-0.008	-0.210
TDW	0.252	-0.585**	-0.837**

*Note 1: ** significant at 0.01 level*
Note 2: In addition to similarity between defenders and analysers, it should be noted that the reason for there were no significant mean difference between defenders and analysers for any of IT management sophistication dimensions may be explained by competitive strategy.

vation pursued on ITMS. This argument is partly supported by the fact that there were significant mean differences (F statistics = 6.350, p<0.05; 10.132, p<0.01 and 13.384, p<0.01) across the strategic types in ISP, CTR, and TDW underlying ITMS, implying that Taiwanese companies generally differ in their emphasis on the sophisticated level of IT management in planning, control, and integration depending on innovation.

To further identify which pairs of mean score are significantly different, Scheffe's test shows that defenders and prospectors differed on CTR (MD [mean difference] = -0.523, p<0.01) and TDW (MD = -0.585, p<0.01) while analyzers and prospectors differed on ISP (MD = -0.367, p<0.01), CTR (MD = -0.505, p<0.01), and TDW (MD = -0.837, p<0.01).

It was expected that there was no significant difference in ISP between defenders and analyzers because the two types share some similar characteristics of cost efficiency. However, the emphasis on ISP did significantly vary between analyzers and prospectors (MD = -0.367, p<0.01), indicating that a higher level of IS planning is essential for prospectors. This finding was expected because one of key characteristics for prospectors is diversity of information needs, a higher level of planning of IT-based activities is required to facilitate and coordinate numerous and diverse business operations and decisions (Kearns, 2005; Sabherwal & Chan, 2001).

Similarly, there was no significant difference in CTR between defenders and analyzers. However, it was found that prospectors place more substantial emphasis on control IT than defenders and analyzers (MD = -0.523 and -0.505, p<0.01), which was unexpected because prospectors are supposed to have decentralized control because they rely on flexible and multiple technologies (low degree of routinization and mechanization) to respond to changing environment rapidly, defenders are supposed to have a centralized control (Matsuno & Mentzer, 2000) and vertical IS because they depend on a single-core IT and continuous improvements in IT (Hambrick, 2003), and analyzers are supposed to have mid-range control level somewhere in between because they attempt to minimize the risk associated with new technologies while maximizing the opportunity for profit (DeSarbo et al., 2005).

Mean difference in OGN was found non-significant (F statistics = 1.943, p>0.05) across all strategic types, implying that Taiwanese companies tend to place an equal emphasis on OGN regardless of innovation pursued. Nevertheless, this was unexpected. The reason for this is perhaps because some CIOs did not report this item questionnaire based on "realized" but "intended" perspective (Tallon, 2003). Perhaps when initially building IT infrastructure, there is a high involvement of non-IT members (i.e., decentralized) regardless of innovation pursued. However, concomitantly, the requirement or importance of OGN is changing from time to time during company's adaptation toward a certain dynamic environment. With this initially recognized importance of organization IT, some CIOs are likely to neglect the actual level of OGN that is required or realized under current innovation pursued and thus failed to appropriately report the requirement of a certain level of OGN in accordance with that evolved innovation.

Regarding TDW, it was expected that defenders have similar level of top-down integration IT as analyzers does. It was also expected that prospectors place substantially more emphasis on top-down integration IT than defenders and analyzers (MD = -0.585 and -0.837, p<0.01) because high innovative behavior of prospectors may emphasize external sources over internal sources in acquiring IT (O'Regan & Ghobadian, 2006). Hence, a higher integration IT is essential for prospectors to facilitate exploration of rapid changing technology to continue engagement in new business (Gupta et al., 1997).

Thus, H2 was partly supported, evidencing that Taiwanese companies generally differ in their emphasis on IT management sophistication depending on innovation pursued. This can be true for other countries since based on CT's "dependency" concept, foreign companies may repeatedly and continuously find the ultimate IS solutions- appropriate IT management practices evolved for a certain innovation. Such solutions will be varied during the adaptive process because of different contexts and can be successful when IT is strategically used (Lu et al., 2005). For example, MNCs may have different adaptations (i.e., IT-based innovation) under different global markets (Teo, 2007). Our result is consistent with studies done in the United States, which found that IT management sophistication would differ with innovation (e.g., Karimi, et al. [1996]).

LIMITATIONS

Although based on CT our proposed adaptation model can be generic to other foreign companies' contingent thinking, the generalizability of results still should be primarily limited to Taiwan context. Similar future research in other countries may consider using "case study" approach to increase "trustworthiness" of results. However to avoid research bias, we controlled the industry and size confounding effects on IT usage. Likewise, generalizability of results may be limited due to the low survey response although the response rate of 24% is acceptable in the literature.

To measure "innovation," a self-typing approach was used. However, CIOs may tend to report their companies' intended rather than realized strategies (Snow & Hambrick, 1980). If there is no intended strategy, the CIO may even create one for the benefit of the researcher (Kearns, 2005). This is a common problem faced in the field of social sciences (Nisbett & Wilson, 1977). Moreover, a lack of external validation of self-typing approach exists (Karimi et al., 1996).

Because of the size and the nature of the sample, external confirmation of the self-typing completed by the CIOs could not be obtained (Gupta et al., 1997). In a sense, a key assumption was that these individuals had accurate perception of the overall company's competitive position.

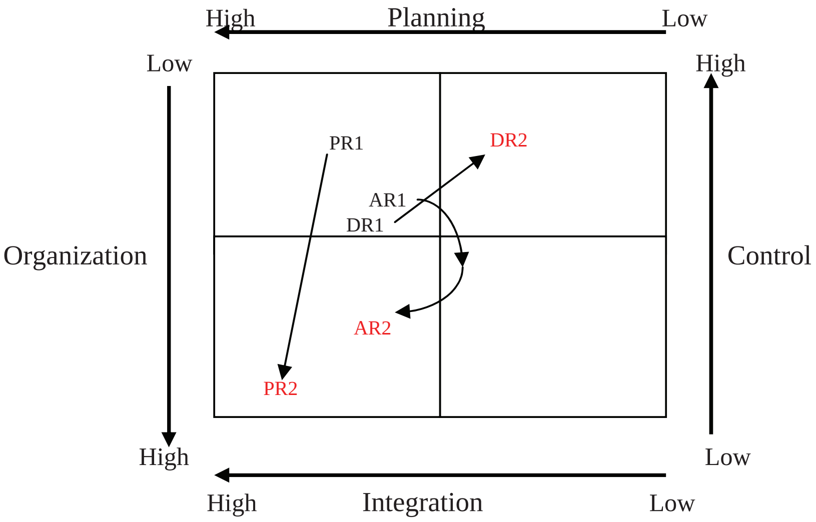
IMPLICATIONS

Theoretically, this study successfully incorporated the Miles and Snow typology to clarify the extent to which IT management sophistication is relatively important to a certain innovation. The results revealed that contextual factor "IT management sophistication" generally facilitates the strategic use of IT, and contextual factor "innovation" generally moderates that strategic alignment effect (Table 7). The results supported CT by showing that Taiwanese companies can succeed when IT management sophistication is appropriately evolved for a specific environmental adaptation (innovation).

Our research model was generic for other foreign companies, because, based on CT; they make dynamic adaptations toward their particular environments for a competitive IT-based innovation vis-à-vis global counterparts. Future research, which could contradict our findings, could examine innovation's role and its impact on the strategic use of IT in other countries. The results also revealed that innovation is a good predictor of a company's success (strategic alignment) (Table 7 and 8). Such results should reassure traditional IS researchers that aggressive companies tend to refer IS plans to business innovation missions and objectives and vice versa, through a more sophisticated planning and integration process. Future research could further examine the sustainability of this IS-business alignment.

A practical implication of the results is the matrix of company adaptation toward strategic alignment (Figure 2). This adaptive matrix provides guidelines to senior executives for allocating their time when making their IT more responsive (evolved) to their company's success. It is a new channel for effective communication between the CIO and senior executive, helping them to decide on the appropriate IT management sophistication consistent with innovation.

Figure 2. Company adaptation matrix for strategic alignment



Note 1: PR=prospectors, DR=defenders, AR= analysers
Note 2: The number "1" denoted as "current level" and the number "2" denoted as "ideal level".
Note 3: The current position of each strategic type is generally indicated based on our results.

Using the matrix, senior executives should generally realize the expected IT position by adjustments toward appropriate management maturity along the four dimensions, given a certain innovation. For example, we found that for prospectors, adjusting the position of IT management sophistication from current "PR_1" to ideal "PR_2" (high planning [more formal process], low control [more decentralization], high organization [more user involvement], and high integration [more reinforced frontline manager IT knowledge and responsibility]) is suggested, while for defenders, moving from "DR_1" to "DR_2" (high control and moderate-low organization) is suggested. Interestingly, we also found that the IT management sophistication of analyzers ("AR_1") was generally lower in "planning" and "integration" than that of defenders ("DR_1"). This, while unexpected, reflected the fact that these so-called "analyzer" participants are conservative in IT spending, although they aggressively explore more new IT-based opportunities for business operations. A plausible explanation is that in practice, analyzer strategy is very difficult to pursue because it shares characteristics with defenders and prospectors. Although "AR_2" (moderate-high in planning, organization, and integration) is preferred, the path from "AR_1" to "AR_2" would not be a simple linear direction and may be adaptive depending on executive's adjustment (i.e., defender-like or prospector-like).

This matrix shows that more than one strategy (no matter whether innovation is aggressive or conservative) can be successful in a given environment (regardless of context or country), provided that the company acts consistently in that strategy (Miles & Snow, 1978). Unfortunately, the move from a current IT position to an ideal one can be long or short, depending on whether communication is effective (Li & Yi, 1999). That is, the adjustment would be affected by IT expectation (e.g., returns) gap between the CIO and senior executive (Ranganathan & Kannabiran, 2004).

Senior executive's IT expectation is often needed to determine whether the company has obtained satisfactory outcomes after the use of IT, which impacts the strategic alignment (Hwang, Ku, Yen, & Cheng, 2004). Based on our participants' report, when pursuing aggressive innovation (e.g., prospector), the CIO expects to obtain more top management support and reported that the whole company has substantially benefited from IT. The senior executive is more concerned about realized IT payoffs when maintaining a good deal of technological flexibility because deploying IT and exploring future IT-based opportunities is a time-consuming, expensive task. Thus, senior executives are often more conservative (i.e., centralizing IS function [high control, mean = 5.914, Table 9]) and careful in evaluating IT for their exploration of new global markets, implying that they tend to be more unsatisfied with the outcomes of current IT.

This situation could be reversed when pursuing conservative innovation (e.g., defender) because senior executives may feel more confident of their IT investments and current positions on a single core technology. They are likely to be more satisfied with outcomes than a CIO, who is likely to receive less top management support, thus leading to lower IT integration. Future research may investigate perceptual differences between the CIO and senior executives concerning overall expected company performance after the use of IT. This would help to determine whether the evolution of IT management sophistication is moderated (or mediated) by those perceptions.

Since more companies have a prospector than a defender strategy (94 vs. 46, respectively), there is a substantial gap in achieving greater IT management sophistication. This provides us an opportunity to reassert that how senior executives perceive IT benefits in terms of efficiency, effectiveness, or strategic advantage is critical to reduce that gap (Silk, 1990). When the emphasis of evaluation of IT benefits shifts from efficient to strategic, there are resulting expectations that a more improved IS planning goal, with positive strategic impact on the profitability, either financial (ROI) or non-financial (synergy), is achievable (Bacon, 1992).

For example, under the e-logistics project (www.elogistics.org.tw/93/index.php), the government encouraged Taiwanese logistics companies to become more innovated in services. Recognizing the strategic potential of IT-enabled intangibles, senior executives of Taiwan Express Logistics Group (39% of participating logistics companies are prospectors) have sought alliances with their Hong Kong, Singapore, and Thailand counterparts to acquire technology know-how and generate synergy through consolidated resources to compete with global logistics counterparts (e.g., FedEx, UPS) (Geng, 2007).

However, as noted in the matrix, their overall current IT management sophistication may not be adequate to sustain the value of alliance strategy as a prospector until IT-based resources are more formally planned, more business oriented, and highly integrated. We suggest that as innovation becomes more aggressive, a more sophisticated evaluation process may be used to ensure that IT align with the companies' business goals, base policies, and procedures associated with control of IT activities.

For example, to evaluate IT projects with intangible benefits, non-financial management and development criteria could be used to balance both quantitative and qualitative forms of the IT investment decision (Silk, 1990). This would also prevent the loss of any associated cash flow due to difficulty of measurement (Chan, 2000), implying that as companies become more familiar with the control process of IT investment decision (i.e., from initiation to review and approval), senior executives are likely to view IT strategically, be committed to IS function, and gain more confidence in managing IT (Kearns, 2000).

Some defenders may also need this sophisticated evaluation process to improve both the alignment and the cost efficiency. For example, in Taiwan, computers/communication and financial services companies (in our sample, 26% were defenders and analyzers) that have been undergoing dramatic changes are now faced with competition from China or India and their relatively cheap labor markets. To defend their familiar products and services, it is also critical for defenders to have excellent external market sensing (mean = 5.608 in planning IT [Table 9]) and multiple electronic linking that helps them sense marketplace requirements from customers and competitors to compete effectively. Thus, a sophisticated evaluation of IT investment would be also needed to make senior executives support the progressive use of IT toward a higher sophistication.

CONCLUSION

Table 11 concludes our ideal IT management sophistication framework across innovation. For example, to increase IT payoff (strategic alignment), large companies must develop more sophisticated IT management practices when pursuing aggressive innovation (prospectors). That is, IS function should be structured more flexibly (responsively) to the company. Planning characteristics of existing and future IT applications should be more sophisticated (formal) and pay attention to the end user's ideas (i.e., high organization oriented). The direction, development, and operations should be co-located in business and IS units (i.e., high integration). As a result, the IS department will be much flatter, with specialized subunits organized around technologies and business needs; it will respond better to end user needs and will leverage IT more effectively. Future research should consider that for prospectors, complete integration might not be possible because of multiple technologies (Gupta et al., 1997) and innovativeness and creativity in the use of IT might be inhibited by too formal planning mechanism (Premkumar & King, 1994). Although the companies that pursue conservative innovation (defenders) tend to have

Table 11. Ideal IT management sophistication framework across innovation

	Level of Innovation		
	(Conservative) Defenders	Analysers	(Aggressive) Prospectors
Attribute of IS Function	Efficiency (Vertical IS)	Adaptiveness	Flexibility (Flat IS)
Level of IT Management Sophistication			
Planning (e.g., Formalization)	Moderate-Low	Moderate-High	High
Control (e.g., Centralization)	High	Moderate-Low	Low
Organization (e.g., Non-IT users involvement in IS)	Moderate-Low	Moderate-High	High
Integration (e.g., Co-location of IS / business resources; business driven IT initiatives)	Moderate-Low	Moderate-High	High

Note 1: Summarized based on "Company Adaptation Matrix" (Figure 2)
Note 2: As noted, "adaptiveness" indicates that the relationship of IS-innovation sometimes can be defender-like, sometimes can be prospector-like, depending on the environment that an analyser situates. This process continues until ideal level of IT management sophistication is reached.

less sophisticated IT management practices, they must improve the ability of the IS department to develop and direct IT (i.e., high control). They should convince the CIO that IT proposals are properly appraised and continuously monitor the IS function based on clear performance criteria, goals, and responsibilities.

Our study provided foreign companies insight into aspects where Taiwanese IT management practices are currently being or need to be developed to create and maintain effective global partnerships. Such insight may help them better focus on the appropriate level of IS functions needed to more strategically allocate IT-based resources when doing business with Taiwanese or even other country's partners. By checking the similarities and differences of innovation versus IT management sophistication position in the matrix, they also can discover the discrepancies in IT vision between two companies and determine whether a collaborative partner is receptive to a certain IT alliance strategy. The value of alliance strategy can be improved over time as two companies become more familiar with each other's IT management practices and manage that IT divide to ensure that the parties share a similar IT commitment and build trust, a long-term relationship, and commitment to shared objectives and risks.

Chapter 6.5

Inter-Organizational Information Systems and Strategic Alliances:

Symbiosis or Competition?

Sebastián Bruque-Cámara
University of Jaén, Spain

José Moyano-Fuentes
University of Jaén, Spain

ABSTRACT

In this chapter we analyze the relationships between the structures of inter-organizational information systems (IOS) and strategic alliances. The relationships between both structures tends to be framed within a collaborative dynamic in which the IOS serves the objectives of the alliance, thereby reinforcing the links that bind the alliance members together. However, in this chapter we also suggest that there may be a non-collaborative—that is, competitive—relationship between the IOS and the strategic alliance, especially when both structures compete for firms from the same sector and geographical area. To test our hypotheses we have analyzed a sample of 162 firms belonging to the agro-food sector in Spain.

INTRODUCTION

Information and communications technology (ICT) and information systems (IS) have had—and indeed continue to have—growing influence on the way firms are managed and organized. There can be no doubt that the lion's share of the modern organization's value chain has been changed in one way or the other by the introduction of computing, robotics, or telecommunications tools (Porter & Millar, 1986). ICT is likely to have a major impact on the components of the value chain that are most closely related to supplies, transport, or data processing. Moreover, in recent decades most of the primary or support activities of firms' value chains have gone through a process of intensification in terms of their need for information management, so ICT has been playing an increasingly important role within organizations.

However, one component of the ICT revolution that we have experienced (and that is still going on) has not taken place within the limits of the traditional organization, but has originated in the relationships that link organizations with each other. The sharing of resources and the collaboration (at the same time as competition) between organizations has meant that a large part of firms' managerial, financial, and productive resources have begun to acquire a virtual dimension. By means of this virtualization firms can make use of resources and capabilities that are geographically dispersed and, more importantly, that originally belonged to other institutions. The technological revolution therefore leads to a revolution in the relationships between firms and organizations, which put resources and capabilities into common use with the aim of improving individual competitive positions. The main advantage of inter-organizational cooperation comes not only from the possibility of accessing virtualized resources but of doing so much more cheaply than would be the case if these resources were acquired on the market for their individual use.

A direct consequence of this virtualization of resources and of the cooperation between institutions is the appearance of IOS (Kauffman, 1966; Konsynski, 1993) and of strategic alliances and networks (Gulati, Nohria, & Zaheer, 2000). Strategic alliances and IOS have traditionally been regarded as two sides of the same coin. Thus, many strategic alliances and stable cooperation agreements have as their main aim to create or strengthen an IOS (Medina Garrido & Bruque Cámara, 2004; Pigni, Ravarini, Sciuto, Zanaboni, & Burn, 2004). In this way, firms can either reduce the uncertainty inherent in today's complex environments or alternatively cut the transaction costs deriving from their relationships with other organizations (Ciborra, 1990; Gulati et al., 2000; Malone, Yates, & Benjamin, 1987).

However, the literature has shown little interest in situations in which the IOS and the strategic alliance interact competitively. In these cases the appearance of an IOS could actually destabilize the system of psychological or economic incentives that bind the members of a strategic alliance together. The disparity of structures and interests, or simply mutual ignorance, can lead to situations in which the IOS erodes the structure of the alliance. Thus, in this chapter we attempt to gain more knowledge about this question, illustrating the situation that occurs when IOS and alliance act competitively—that is, non-symbiotically—and suggesting some explanations for the problem. These explanations will provide us with the basis for offering a number of implications and recommendations, using data from the olive oil production sector in Spain.

This chapter is organized into five sections following on from this present introduction. In the second section we review the state of the question and propose our working hypotheses. In the third we describe the methods utilized to test the hypotheses. In the fourth we outline our findings. In the fifth section we outline our main conclusions, while in the final section we offer a series of recommendations for firms and public administrations, as well as directions for future research.

BACKGROUND AND HYPOTHESES

The relationship between the use of IOS and opting for the market (autonomy), hierarchy, or strategic alliance, has been widely studied in the literature (Brynjolfsson, Malone, Gurbaxani, & Kambil, 1994). In most previous analyses researchers have demonstrated that the IOS and strategic alliance come into being in a coordinated way with the aim of achieving similar objectives (Henderson & Venkatraman, 1993). The IOS serves to achieve the objectives set down by the alliance in terms of information management and the conversion of this information into knowledge. In parallel, the strategic alliance gives the IOS legitimacy in the eyes of the alliance members, as well as financial and human resources (Ciborra, 1993; Gurbaxani & Whang, 1991; Malone et al., 1987). However, less attention has been paid to the competitive relationship that may develop when a strategic alliance and an IOS interact in the same competitive sphere (or sector). Neither have we found any work comparing the use of the IOS by firms that are not members of strategic alliances and firms that are. These questions may have important implications for the management of these alliances as well as for the evolution of the IOS.

In a strategic alliance the functions of search, selection, analysis, and distribution of information are carried out by the structure of the alliance itself. Strategic alliances, when they take the form of a stable strategic network (Miles & Snow, 1986), tend to develop an ad hoc governance structure (Grandori & Soda, 1995). The governance structure takes responsibility for managing the activities within the remit of the alliance (joint commercialization, research and development, supply chain management, joint supplies, etc.). This ad hoc structure, which is a consequence of the alliance, tends to take the form of a new organization (joint venture, new capital firm, or horizontal cooperative arrangement) (Grandori & Soda, 1995; Gulati, 1998) charged with developing the elements (technological tools, personnel, and departments) required to carry out the activities for which the alliance is responsible.

On the other hand, IOS have been seen as useful tools in firms' management. There is substantial evidence of the various advantages firms can obtain from cooperating in an IOS. The IOS is a cooperation structure in itself; it aims to achieve goals such as reducing operational and management costs, sharing information that is strategic from the competitive perspective, reducing negotiation or information costs in economic transactions, strengthening the links that bind strategic alliance members, developing knowledge management systems that prove useful to all IOS participants, modifying the market structures in order to increase IOS participants' bargaining power, and so forth (Bakos, 1991; Eom, 2005; Kumar & Van Dissel, 1996).

When the information provided by an IOS lies within the decision scope of the alliance, the interface between the IOS and alliance members will be the alliance ad hoc governance structure. In this respect, according to Thorelli (1986), the alliance as a whole can be regarded as a single organization with defined strategic objectives. The ad hoc structure responsible for dealing with questions entrusted to the alliance should obtain, analyze, handle and if necessary, disseminate the information coming from the IOS. Thus, we can say that the information coming from the IOS will be distributed among the firms making up the alliance, respecting the decision and information flows previously established between the ad hoc governance structure and the alliance members. In other words, there should not be any direct use by the firms making up the alliance (individually regarded) of the resources provided by the IOS. In the case of non-alliance members, however, it is the firms themselves that must directly obtain the information and resources they need to carry out their activity. If the IOS proves to be an effective tool, firms outside the alliance will try to access and use the system in order to improve their competitive position in the sector or simply to survive in a complex and dynamic environment. In short, under the conditions discussed previously, firms not belonging to a strategic alliance are likely to use the IOS more than firms forming part of a strategic alliance. This idea is reflected in Hypothesis H1:

Hypothesis H1: Firms not forming part of a strategic alliance use IOS more than strategic alliance members.

The previous hypothesis allows us to infer that firms forming part of a strategic alliance—

individually considered—will have less need to access and use the IOS, since the ad hoc governance structure created by the alliance takes over the functions of obtaining and analyzing information. This ad hoc structure will be responsible for accessing and analyzing the information, and if necessary, distributing it to the alliance members respecting the traditional flows of decision and communication between the ad hoc structure and the member firms. In this case we can say that the IOS does not interfere either with the internal organization or with the decision-making structure operating within the alliance. In other words, there is a concordant relationship between the structure of the IOS and the structure of the alliance.

However, the internal situation of the strategic alliance will not always allow this concordant relationship to arise. The intensity with which firms become involved in their strategic alliances can vary depending on a number of explanatory factors (Medina Garrido, 2003; Thorelli, 1986). Firms in alliances are all formally members of the same structure, but some may behave opportunistically (Gulati et al., 2000), exploiting some of the advantages provided by the alliance on the one hand, and on the other, making key decisions independently and considering only their own individual interests. In these situations alliance members' degree of involvement with the alliance, measured by their delegation of decision making to the governance structure, will decline (Arino & de la Torre, 1998).

Opportunistic behavior appears to be associated with alliance members' reduced involvement with respect to the principles of cooperation and also with respect to the joint operation of the strategic alliance (Álvarez, Barney, & Bosse, 2004). When opportunistic behavior occurs, firms' individualistic orientation in the decision-making process means that they have a greater need to access key information. One of the ways of individually accessing key information for decision making is to make use of IOS (Porter & Millar, 1986). Thus, we would suggest that the reduced involvement that results from opportunistic behavior should lead to greater direct use of the IOS by firms behaving opportunistically. In these cases the flow of decisions and information established between the alliance governance structure and the alliance members will weaken since direct flows between the IOS and some alliance members will emerge; in other words, a discordant relationship develops between the structure of the IOS and the structure of the strategic alliance. In short, under the premise of opportunistic behavior we would expect members to become less involved in their alliance, making them more likely to make direct use of the IOS. In the context of reduced involvement and direct use of the IOS, discordant relationships would emerge between the IOS and strategic alliance structures. This idea is reflected in Hypothesis H2.

Hypothesis H2: Within a strategic alliance, the reduced involvement of member firms with their alliance is associated with an increased direct use of IOS.

METHODS

Data

To test the previous hypotheses we analyzed a sample of firms belonging to the olive oil production sector in the province of Jaén (Spain). This province produces 45% of the total Spanish production of olive oil. Spain, in turn, produces 40% of world production, according to the International Olive Oil Council (Consejo Oleícola Internacional, 2001; Moyano-Fuentes & Núñez-Nickel, 2004a). In 1998 the population of olive oil producing firms in the province of Jaén amounted to 323 organizations (Moyano-Fuentes & Núñez-Nickel, 2004b).

The data collection procedure was based on a questionnaire administered either by telephone or in a face-to-face interview. For this, the research team first contacted the firms selected in order to explain to them the objectives of the research. If the interlocutor was appropriate (chief executive or general manager) and if they agreed to participate in the study, we proceeded to carry out the survey by telephone. In some cases the managers requested that they be able to respond to the questionnaire in a face-to-face interview, so we then arranged for a subsequent interview in which the respondent could complete the questionnaire.

We used random sampling, stratified in proportion to the legal status of the firm (cooperative/non-cooperative)[1] and geographic area (district). We introduced the first stratification criterion in order to keep the same proportion of cooperative firms in the sample as in the global population. This precaution was necessary because cooperatives are more prone to participate in strategic alliances than non-cooperative firms (Torres-Ruiz, 1998). The stratification criterion by geographic areas, in turn, aimed to ensure that responses from urban areas were not over-represented to the detriment of rural areas. The final number of valid responses was 162, which represents 50.15% of the total population. Of the 162 firms participating, 94 habitually use IOS and 61 belong to stable strategic alliances in the form of horizontal cooperative arrangements.[2] These strategic alliances are made up of five organizations on average, and they started to appear in the sector from 1980 onward. The remaining technical specifications of the sample are reported in Appendix I.

As far as the IOS is concerned, we used as reference in this study, the Poolred System, set up by the Olive and Olive Oil Promotion and Development Foundation, which began to operate in January 1997. We chose this system because it is widely used among the firms in the sector and has ample experience in obtaining, analyzing, handling, and disseminating information generated by the markets for bulk olive oil in Spain. At present, the system is used by 541 institutions (producers, public administrations, and bottling firms) in Spain, and in 2003 it handled a volume of information relating to transactions valued at over 1.3 billion euro.

Questionnaire

The questionnaire for the current research contained a total of 39 questions, in which we included open questions, Likert-type closed questions and closed questions of the semantic differential-type. The Likert-type and semantic differential-type scales each consisted of five intervals. This chapter is part of a wider research project, so we have not used all the items included in the questionnaire here. Specifically, we only used the data pertaining to the use of IOS, membership of strategic alliances, and degree of involvement in the alliance.

Variables

In this section we describe the variables used in the research, as well as how they are measured.

Participation in strategic alliances. Dichotomous variable taking value 1 if the firm belongs to a stable strategic alliance (horizontal cooperative arrangement) and 0 if it does not belong to such an alliance.

Use of IOS. Dichotomous variable taking value 1 if the firm uses the Poolred System[3] and 0 otherwise.

Involvement in strategic alliance. These variables were measured using five five-point Likert-type scales. These scales measure the intensity with which the member firm uses the alliance mechanisms in its decision making, especially with decisions having important implications for the performance or survival of the organization. The items are as follows: (1) products are commercialized exclusively through the strategic alliance; (2) there are periodic contacts with the alliance's governance structures for consultation on economic and management aspects; (3) relationships with suppliers are channeled through the alliance's governance structure; (4) the remaining members in the alliance are consulted about economic and management aspects; and (5) relationships with the public administrations are channeled through the alliance's governance structure. In all cases 1 corresponds to never and 5 very frequently.

Analysis

Table 1 shows the means, standard deviations, and correlations between the variables used.

To test the proposed hypotheses we opted to carry out an analysis based on descriptive statistics and non-parametric statistical tests to observe the differences between members and non-members of strategic alliances. Specifically, we used contingency tables and the non-parametric Mann-Whitney U test, to test Hypothesis H1 (see Tables 2 and 3), and descriptive statistics and the Mann-Whitney U test, to test Hypothesis H2 (see Tables 4 and 5).

RESULTS

The results of the analyses carried out here allow us to draw a series of conclusions, which we now outline. With regards to Hypothesis H1, the descriptive statistics appearing in the contingency table (Table 2) support the relationship postulated in Hypothesis H1, although quite weakly. Observing the percentages in Table 2, the results show that 47% of the sample firms that do not participate in alliances use the IOS, while only 33% of alliance members directly use the system. However, the Mann-Whitney U test does not allow us to generalize this result and say that in the population as a whole firms not participating in alliances use IOS more than alliance members, since the differences observed between the two groups have a very weak statistical significance. In short, although the data collected in the sample are coherent with Hypothesis H1, it is only possible to assure that this situation occurs in the global population at the 90% level.

Hypothesis H2 is also only weakly supported by the statistical tests carried out here. At first sight (Table 4) the descriptive statistics appear to support the postulates of Hypothesis H2. The means corresponding to each involvement variable, ordered by groups (in function of whether they use the IOS or not) result in higher values when the firms do not use the IOS than when they do. Only once does this not occur—with the variable measuring relationships with suppliers

Table 1. Descriptive statistics and Spearman correlations

Variable	Mean (sd)	1	2	3	4	5	6
1. Participation in strategic alliances	0.38 (0.49)						
2. Use of IOS	0.42 (0.50)	-0.14

	YES	17	1.41	1.18

[a] Calculations only include firms forming part of strategic alliances.

through the alliance (variable 5). Considered overall, the data collected in Table 4 allows us to indicate that for the sample firms the inverse association relationship referred to in Hypothesis H2 is satisfied. That is, and again for the sample, firms belonging to alliances but not very involved in them use the IOS more than the firms that are more involved.

However, the results referred to in the previous paragraph cannot be generalized to the whole population, since the Mann-Whitney U tests do not result in statistically significant differences (this only occurs for the variable measuring involvement through relationships with the public administrations). In short, although the data from the sample is in line with Hypothesis H2, we cannot generalize them to the population as a whole.

SUMMARY

This work is one of the first attempts to link the degree of involvement of alliance members with the extent to which they use IOS. Although the results are not entirely satisfactory from the perspective of statistical significance or the possibility of generalization, they undoubtedly represent a starting point from which we can advance our understanding of the interrelations—sometimes interferences—that can develop between different cooperation structures that coexist in the organizational framework (the same sector). These structures (on the one hand strategic alliances, and on the other IOS) can be used symbiotically, ensuring that one structure reinforces the other. However, as we have been able to observe in this chapter, when the two cooperation structures (IOS or alliance) are set up at different times and backed by different institutions, a negative (or competitive) effect may be induced, which ends up weakening the bonds that exist within the strategic alliance.

The appearance of an IOS can weaken the structure of the alliance in two different but related ways. First, it can undermine some of the motivations encouraging firms to form strategic alliances in the first place. One of these motivations has to do with the access to more and better information, allowing firms to reduce uncertainty in dynamic and complex environments (Ciborra, 1993). If the firm can obtain this information in an IOS that remains outside the alliance it will be less likely to strengthen its links with the alliance. The second motivation concerns the opportunistic behavior of some alliance members, who will feel freer to act independently if they have access to key information autonomously. Taking this situation to the extreme, the disparity between the IOS and the strategic alliance may lead to the breakup of the latter, or even its disappearance. Whether the alliance fails, however, will depend on the degree of rivalry between the governance structures of the alliance and the IOS as well as on the strategic importance of the information managed by the IOS.

In short, this chapter attempts to provide new, useful explanations for the situations in which strategic alliances find themselves weakened by the appearance of cooperation structures (IOS) that erode part of their own responsibilities. Our findings may therefore prove interesting for the research stream analyzing the factors leading to the failure of cooperation between firms, as well as provide appropriate solutions (Harrigan, 1985; Kale, Dyer, & Singh, 2002; Mitchell &

Table 5. Test of hypothesis H2. Mann-Whitney U test

Singh, 1996). However, the work may also have implications for managers, particularly at the following three decision levels: the managers of the governance structure of the IOS, the managers of the strategic alliance's governance structure, and public administrations interested in promoting stable cooperation agreements. These management implications, together with possible lines of research for the future and the limitations of the work, are analyzed in the final section.

RECOMMENDATIONS AND FUTURE TRENDS

From the perspective of the management of strategic alliances, managers of these structures should not only be conscious of the opportunities but also the threats represented by the appearance of an IOS within the scope of activity of the alliance. This threat may be greater when the information provided by the IOS is closely linked to the activity controlled by the alliance. In these cases, alliance members can be motivated to behave opportunistically, or even simply to abandon the cooperation structure. The threat of the IOS is also greater when it is set up totally independent of the strategic alliance, that is, when it is backed by institutions outside the alliance, which may even be rivals.

We now offer a series of recommendations that can help to mitigate the situation that has been previously described. In all these limitations we have to take into account that for creating a strong and stable alliance it is necessary to provide value to the members of the alliance. There are several ways to create value such as improving logistics, decreasing production or transaction costs, improving the access to new markets, improving the organization's bargaining power, and so forth. For the case of interactions between IOS and strategic alliances we can provide some recommendations that may prove useful to increase the value transferred by the IOS to the strategic alliance. First, since the threat derives from the difference in the interests and structures between both systems, it is necessary to initiate a process of negotiation between the governance structures of the two systems (alliance and IOS). Thus, there is a need for a process of macro-cooperation between both structures, with the intention of aligning the interests of both systems. The optimal option for the alliance and the least harmful for the IOS would be for a single link between the alliance and the IOS to be formed by the alliance's governance structure itself. In exchange, the strategic alliance could help to strengthen the IOS, providing it with new resources or helping it to obtain, process, and disseminate information. In other words, this strategy of macro-cooperation would have the ultimate aim of establishing a symbiotic relationship between both structures and ensuring that neither interferes negatively with the other. We should point out that in this case the scope of the macro-cooperation could be limited to aspects relating to the strategic implications of the information handled by the IOS, so that both structures could maintain their autonomy in all the remaining areas.

The managers of the IOS governance structure could also benefit from the process of negotiation started with the strategic alliance. In this case, the IOS should weigh up the advantages of the aforementioned strategy of macro-cooperation: the strengthening of the structure itself; greater financial, technical, and human resources; and the broadening of the scope of the IOS itself.

Third, public administrations could play a fundamental role in the process of macro-cooperation initiated between both cooperation structures. In situations of rivalry or divergence of interests the public administrations could intervene to reestablish the balance of power, arbitrate compensation to one or another structure, or simply bring the managers of both cooperation structures into contact in order to facilitate negotiation. The function of the public administration is even more relevant when the sector in which the IOS and alliance operate can be regarded as strategic for the public interest, or when collaboration between the IOS and alliance could serve as a useful example for other key sectors.

With regards to advancing research, we might make some recommendations for the academic and research community. First, it is necessary to further the knowledge of the factors that might provoke the weakening or failure of inter-organizational cooperation structures (alliances or IOS). Greater understanding of the causes of success or failure may have positive implications, since it could inform public and private policies aimed at preventing situations of risk from arising. Second, there is a need to deepen understanding of the factors that encourage firms to become more involved in the various formulas of inter-organizational cooperation, thereby preempting opportunistic behaviors among the cooperating firms. Third, in the particular case of interference between the alliance and IOS, we would recommend that researchers attempt to generalize the results reported in this current chapter. It would be particularly interesting to see further research in other sectors, or in other countries in which differences of national culture may play an important role. Finally, it would be useful to obtain more information about the function that the structure of the sector (size and number of firms, technological development, transparency of market, etc.) may play in the relationships between strategic alliances and IOS.

As we have already mentioned, this work suffers from a number of limitations, which should be borne in mind when judging the significance of the results obtained here. In the first place, the statistical tests carried out are not entirely satisfactory, in the sense that they do not always allow us to confirm the association relationships postulated in the hypotheses. For this reason some conclusions are only applicable to the sample and not to the population as a whole. Second, in the proposed associations another series of moderating variables may play a role in clarifying the causes and effects that intervene in the problem. Thus, the greater propensity to use IOS of firms with little involvement in their alliances could be moderated by the initiation of corrective measures by the governance structure of the alliance. Other variables may also have intervened in this relationship, such as the culture of the organizations participating in the alliance; the existence of a collaborative relationship between the IOS structure and the governance structure of the alliance; or the degree of technological maturity of the institutions involved (governance structure, member firms, IOS management structure, etc.). Third, the design of the measuring instruments (dichotomous and Likert perceptual variables) may have proved inadequate for revealing complex relationships between the constructs under analysis. Fourth, we have analyzed the relationships between IOS structures and strategic alliances in a very specific sector (olive oil production sector in Spain), so we encourage other researchers to analyze this topic in other sectors. Finally, in this study we only analyze one type of strategic alliances (horizontal alliances) so further research is needed in the case of other types of alliances such as vertical alliances, diagonal alliances, or internal networks (Hinterhuber & Levin, 1994).

ENDNOTES

[1] The cooperative firm is constituted as a democratic organization and its management is based on the principle of one member, one vote. The other organizational forms (capitalist forms) have the characteristic that the number of votes is directly linked to the size of the shareholding (Barron, 1995, p. 138).

[2] A horizontal cooperative arrangement is an alliance made up of firms that are cooperative firms. The objective of a horizontal cooperative arrangement is to jointly manage some activities of the value chain (such as marketing, logistics, R&D, etc.).

[3] The Poolred System is an IOS run by the Foundation for Promotion and Development of Olive Oil. All the firms that are included in the system have to send, online, the data

APPENDIX I. TECHNICAL SPECIFICATIONS

Population	Olive oil producing firms in province of Jaén (Spain) (323 organizations).
Time	December 2003-March 2004.
Type of sampling	Probabilistic, stratified in proportion to legal form (cooperative/non-cooperative) and geographic location.
Sampling units	General manager or CEO.
Sample errors	±5.55% for p = q = 0.5 and confidence level 95.5%.
Sample size	162 valid responses.
Research technique	Telephone survey combined with face-to-face survey.

ABSTRACT

The creation and the use of knowledge have increasingly been regarded as important issues for management. A wide range of studies have investigated this topic during the past decade. Notwithstanding these contributions, very little systematic attention has been paid to the linkages between knowledge capabilities and strategy implementation. Drawing from knowledge capabilities theory and strategy implementation literature, two aspects of knowledge capabilities in an organization and their effect on strategy implementation effectiveness are investigated: knowledge process capabilities (KPC) and knowledge infrastructure capabilities (KIC). This study hypothesized that KPC affects strategy implementation effectiveness (SIE) and that KPC affects KIC. The third hypothesis proposed the effect of KIC on SIE by examining the mediating role played by KIC in linking KPC and SIE. 1,321 middle-managers were sent questionnaires via electronic mail and 162 were returned. The findings indicated the presence of a mediation effect of KIC on the relationship between KPC and SIE. This study provides guidelines for middle-managers to better understand how to develop activities of KPC and KIC for SIE. It is hoped that the results of this study will enhance our understanding of the strategic importance of knowledge in an organization, especially in the area of strategy implementation.

INTRODUCTION

Organizations improve their performances by enhancing current capabilities or developing new capabilities. This capability is complicated and believed to coincide closely with organizational knowledge that can be conceptualized in terms of digested information embedded within organizational routines and processes (Davenport & Prusak, 1998; Eisenhardt & Martin, 2000; Myers, 1996). In order to compete effectively, firms must leverage their existing knowledge and create new knowledge in their organizations (Grant, 1996). To achieve these effects, it is imperative for firms to develop and to utilize knowledge capability. Knowledge capability is important because it enables knowledge to flow across organizational routines, thus facilitating knowledge utilization and creation (Allard, 2003; Helfat & Raubitschek, 2003). Nevertheless, there are few empirical studies that investigate the relationship between organizational knowledge and strategy implementation.

A review of the relevant literature suggests a fertile and interesting area between the general strategy process and the knowledge-based view (KBV). Specifically, the area of strategy implementation is open to investigation. The implementation area mainly questions how to effectively manage and translate firm strategy into action. New models and constraints in the knowledge economy pose challenges to implementing strategies. For example, some organizations have to reengineer organizational processes and restructure organizational units by delayering the number of hierarchical levels or shortening the distance between top management and operational management (Keidal, 1994). Some organizations use information technology instead of humans to monitor and control activities directly (Leonard-Barton, 1995). The traditional strategy process has to adapt to the dynamic environment of the knowledge economy.

Since strategy implementation involves all activities in organizations (Beer, 1996; Gadiesh & Gilbert, 2001; Nobel, 1999) and knowledge capability is an important organizational capability, this study argues that these two areas are linked and support each other. Explicitly, from a review of the literature, little systemic attention has been given to the linkage between knowledge capabilities and the effectiveness of strategy implementation. This study examines that linkage. Middle managers were selected as respondents because they are key to the linkage (Floyd & Wooldridge, 2000; Huber & Power, 1985; Nonaka, 1991). At the front-line, middle managers are responsible for effective strategy implementation by mixing and matching organizational capabilities and resources. Furthermore, middle managers play important roles by integrating both vertical and horizontal knowledge flow (Nonaka, 1991). This integration relies on in depth experience and situation-specific knowledge. This study aims to benefit the strategy field by bringing about a better understanding of the relationship between knowledge capability and strategy implementation effectiveness.

In sum, this study addresses the important question: “How do knowledge capabilities affect strategy implementation?” It argues and demonstrates that knowledge capability influences the effectiveness of strategy implementation. Two kinds of knowledge capabilities are explored: knowledge process capabilities (KPC)—that is, the capability of a process to transform knowledge that is stored in the form of standard operating procedures and routines throughout the firm into valuable organizational knowledge, experience, and expertise, and knowledge infrastructure capabilities (KIC)—that is, the capability to manage infrastructures in the organization in order to support and facilitate organizational activities. These two knowledge constructs are believed to contribute to strategy implementation effectiveness (SIE), described as the successful performance of strategy implementation tasks (Ramanujam & Venkatraman, 1987).

This study argues that KPC are an antecedent of KIC. Also, KIC supports, assists, and facilitates SIE. To support the argument, this study employs a mediating model by positioning KIC as mediator between KPC and SIE. The study empirically demonstrates that KIC fully mediate the relationship between KPC and SIE. The demonstration involves two statistical steps. First, the study examines the positive influence of KPC over SIE when KIC is absented. Second, the study attempts to prove that when KIC is present, the positive influence does not hold. Furthermore, the positive influence from KPC to KIC and the positive influence from KIC to SIE are examined.

The contribution of the study is to expand the knowledge of the fields of strategic and knowledge management by providing empirical evidence of the effects of KPC and KIC on SIE. The findings of this study are expected to shed light on linkages between knowledge capabilities and strategy implementation effectiveness in the organization. Furthermore, contributions of this study could potentially go to other fields, such as human resources and management information systems. Not only in the academic field but also in the practical world, the results of this study potentially contribute to the effectiveness of middle managers in strategy implementation. Consequently, when good strategies are more successfully implemented, improvements in business' bottom line are more likely.

THEORETICAL FRAMEWORK AND HYPOTHESES

Organizational capability has its root in the resource-based theory of the firm, whose main argument is that a firm is a bundle of heterogeneous resources and capabilities which support competitive advantage. Organizational capabilities concern an organization's ability to combine different types of resources; especially, firm-specific knowledge enables employees of firms to create new resources. Kogut and Zander (1992) mention that organizational capabilities are a set of specific and identifiable processes that resemble a concept of routines consisting of specific strategic and organizational processes that are complicated and depend on existing knowledge. Nelson and Winter (1982) argue that a great deal of knowledge is stored in the form of standard operating procedure and routines throughout the firm that are embedded in employees. Grant (1996) also suggests that knowledge is integrated in organizational capabilities, embedded in employees. They point out that knowledge is shared across products and is linked to activities within the organization and also depend on social interaction among individuals who share and combine their knowledge to create new resources, bringing effectiveness to an organization.

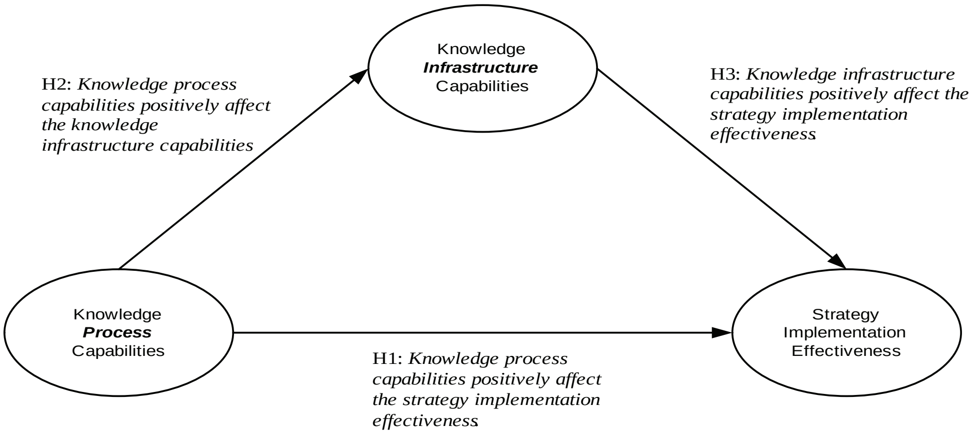
It was mentioned that strategy implementation is an antecedent of organizational effectiveness (Floyd & Wooldridge, 2000) involving all types of activities in the organization (Gadiesh & Gilbert, 2001). Many innovative strategies have failed because they could not be implemented. Leonard-Barton (1995) suggests that strategy implementation involves knowledge embodied in employees and related to communication patterns. The success of strategy implementation depends on leadership and implementation style as well as the communication and interaction process of employees (Argyris, 1991). According to Nobel (1999), strategy implementation is viewed as interpersonal process related to understanding among and commitment among coworkers. Digman (2006) mentions that top managements have to build organizational capability to carry out their strategies. In organizations, strategy usually emerges from top management and is implemented by organizational members. Top managements have to communicate their vision, strategy, and knowledge to organizational members. Also, they have to encourage employees to utilize existing knowledge and to create new knowledge to benefit SIE. Middle managers, who are at the center of the organizational capabilities development and strategy implementation, have to create social interactions by communicating, refining, executing, and interacting among organizational members in order to achieve SIE (Floyd & Wooldridge, 2000; Nonaka, Toyama & Byosiere, 2001).

In order to compete effectively, organizations must leverage their existing knowledge and explore new knowledge by developing knowledge management (KM) processes to create the ability to use knowledge and to develop SIE. The ability of employees to combine, transfer, and create knowledge (including ability to learn) is fundamental to KM and SIE in an organization. It can be implied that KM increases organizational effectiveness and enhances organizational capabilities. Jennex and Olfman (2006) mention that KM enhances decision making effectiveness by improving the ability of decision makers to find and retrieve appropriate knowledge. They propose a KM success model proposed by Delone and Mclean (2003). Three main parts of their KM success model consist of system quality, knowledge quality, and service quality. Jennex and Olfman view the knowledge management system (KMS) as a system that includes information technology (IT) components, users, and processes that use and generate knowledge. They also view knowledge quality in the process of linkage and richness of knowledge and service quality in a view of management support. Gold, Malholtra, and Segras (2001) studied the relationship of KM and organizational effectiveness. They studied the effect of KPC and KIC on organizational effectiveness. They believe that capabilities to manipulate and to manage knowledge that build on the organization's members enable a firm to expand organizational ability and strategy initiatives that benefit organizational effectiveness. Nonaka et al. (2004) state that knowledge creation succession depends on "Ba," or physical and environment factors supporting the process. Even though KM is defined in many different constructs, most of the KM constructs are proposed as KM processes and KM infrastructures. Furthermore, two capabilities of KM that knowledge scholars believe benefit organizational effectiveness capabilities in KM process and capabilities in dealing with infrastructures that support and facilitate the process (Gold et al., 2001; Jennex & Olfman, 2006). Therefore, in order to simplify the area of KM, this study proposes to break the analysis of KM into two main constructs: KPC and KIC.

Causal Model of the Study

Figure 1 shows the causal model of this study. Three hypotheses were proposed to support the

Figure 1. Causal model and hypotheses



research question. Based on the model, the study hypothesized that the impact of KPC on SIE may actually be a result of the mediation of KIC. This study believes that effective execution of KPC promotes organizational growth by allowing the organization to launch strategic initiatives effectively. KPC are believed to enable organizational members in acquiring, creating, sharing, and transferring knowledge in the organization. These KPC activities are believed to influence SIE. Thus, KPC are hypothesized to affect SIE. The study hypothesized that the impact of KPC on SIE may actually be a result of the mediation of KIC. From a review of literature, the mediation effect of KIC is presented by two arguments. First, there is evidence supporting the view that KPC requires and affects KIC. Changes in the capabilities to create knowledge are believed to result in changes in the capabilities to manage the organization's infrastructure. In other words, the KPC are antecedents of KIC. Second, this study argues that the KIC are a basic system in the organization that support and facilitate organizational activities. KIC are believed to inspire organizational members to work with greater effectiveness and efficiency in organizational activities. The capabilities to manage infrastructures in the organization are believed to influence SIE. Therefore, SIE is hypothesized to be effected by KIC.

The Effect of KPC on SIE

KPC are organizational capabilities to manipulate knowledge that are stored in the form of standard operating procedures and routines throughout the organization. KPC are believed to contribute positively to organizational effectiveness by enabling individuals to effectively exploit existing knowledge and explore new knowledge (Prahalad & Hamel, 1990). Effective execution of KPC can promote growth by allowing the organization to launch business initiatives, as well as gain cost and other advantages by improving operations (Trussler, 1998). KPC has been studied by many researchers. The first well-known KPC study is that of Nonaka (1991). He proposed four modes of "Spiral of Knowledge," or a "SECI" model, for the knowledge creation process that consists of knowledge socialization, externalization, combination, and internalization. Edvission (2000) suggests that KPC should consist of four steps: sharing tacit knowledge, creating concepts, justifying concepts, and cross-leveling knowledge. Gold et al (2001) offer another four-stage KPC model: acquisition, conversion, application, and protection, by grouping processes from other empirical studies. Van der Spek and Spijkervet (1997) propose still another four-stage KPC model: creation and sourcing, compilation and transformation, dissemination, and application and value realization. This process is believed to create new knowledge in organization. Alavi and Tiwana (2003) investigate KM process framework that consist of four stages of creation, storage/retrieval, transfer, and application. There is no empirical and systematical investigation to suggest which KPC is the preferred pattern. Holsapple and Joshi (2002) develop knowledge chain through the Delphi study with participant panelists who are knowledge management practitioners and academicians. They introduce five activities of the knowledge chain in order to realize KPC in an organization: knowledge acquisition, generation, selection, assimilation, and emission. Five activities under the knowledge chain are believed to be components of KPC, which is an important driver to transform knowledge in the organization (Holsapple & Singh [2001], whose work systematically studied the visible principle of KM ontology).

In sum, the result of efficiently managed KPC is believed to enhance SIE. Therefore, the components of KPC in organization are believed to assist in the task of translating strategy into action, bringing about the achievement of implementation (Spinello, 1998). This study proposes the first hypothesis below:

Hypothesis 1: Knowledge process capabilities positively affect strategy implementation effectiveness.

Knowledge Infrastructure Capabilities as a Mediator

From the KM success model of Jennex & Olfman (2005), infrastructure is mentioned in terms of system quality and the KMS. Jennex and Olfman determined the KMS as a common network structure focusing on systems hardware and software. They also suggest that the KMS enhances KM decision making skills by improving the ability of decision makers. In strategy field, infrastructure is always mentioned in conjunction with the information system, organizational infrastructure, and management system (Digman, 2006). Infrastructure is a basic system that must function properly. Many researchers suggest that infrastructure mediates organizational activities by supporting and facilitating. Madhok (1997) observes that when companies want to transfer know-how within or across organizational boundaries, managers must rearrange the infrastructures to support the transfer. Gomez-Mejia (1992) reveals that infrastructure is shaped to support organizational process and enhance organizational effectiveness in strategy formulation and implementation. Dyer and Nobeoka (2000) assert that infrastructure supports KPC among suppliers that create coordinating principles between networks. Worren, Moore, and Cardona (2002) mention that infrastructure facilitates knowledge sharing by using electronic networks and databases. In addition, King and Zeithaml (2001) point out that infrastructure is engineered in order to facilitate KPC among and between organizational levels.

Knowledge researchers have described infrastructure as capabilities that are required to support knowledge activities in organizations (Wiig, 1999). KIC are required to build and to maintain generic capabilities that are shared with organizational activities and functions. In this study, KIC includes information technology, management system, and organizational structure. A review of literature shows that KIC mediate organizational activities by supporting and facilitating organizational activities. However, once the organizational process or planning is changed, KIC is shaped and rearranged to match a new process and planning (Powell & Dent-Micallef, 1997).

KPC as an Antecedent of KIC

Infrastructures in the organization were believed by researchers to mediate organizational activities by supporting and facilitating organizational activities (Madhok, 1997; Dyer & Nobeoka, 2000; Worren et al., 2002). However, there are limited empirical investigations on the relationships among KPC, KIC, and organizational effectiveness. A recent study by Gold et al. (2001) shed light on the relationships among KPC, KIC, and organizational effectiveness. The results unveil the positive relationships between KPC and organizational effectiveness, and between KIC and organizational effectiveness. However, the study did not show the relationship between KPC and KIC.

While past studies have examined the role of infrastructure within the organization, it is still not clear how KIC affect KPC. However, there are interesting arguments that imply the effect and relationship of both KPC and KIC. Keidel (1994) suggests that in order to improve competitiveness, an organization redesigns, restructures, or reengineers its configuration to better serve its customer. Keidel mentioned the reengineering process starts with a “blank sheet of paper,” and then determines the pattern that requires the flow charting of the entire work process. The flow charting of the work process is needed before redesigning, reengineering, and restructuring the organization. Keidel also points out that infrastructure may be a mirror image of organizational learning that results from knowledge. It can be thus implied that KPC is an antecedent of KIC. In addition, Keidel suggests that redesigning the way of thinking or the process of knowledge management is needed before the capabilities of restructuring and reengineering infrastructures take place in organization. McDermott (1999) argues that redesigning is associated with a capability to create knowledge that is needed before changes to infrastructures in the organization. Wang and Majchrzak (1999) state when the organization wants to change or extent their organization infrastructures, such as work procedures or physical layout, management should encourage organizational members to share their expertise capabilities by brainstorming ideas and discussion problems. Another piece of literature from El Sawy and Josefek (2003) mentions that the newly created value results from the design of infrastructure capabilities supporting around the process.

These studies show evidence supporting the argument that KPC are an antecedent of KIC. This study argues that KIC support and facilitates organizational activities. However, it does not cause any augmentation of KPC. On the contrary, changes in KPC cause augmentations in the organizational infrastructure to support it. Thus, this study hypothesizes that:

Hypothesis 2: Knowledge process capabilities positively affect knowledge infrastructure capabilities.

The Effect of KIC on SIE

In this section, we describe how KIC evolved in response to strategy implementation needs. In the organization, principally, KIC are changed when they no longer provide the coordination, control, and direction when the organizational process or organizational structure is changed. As a basic system, infrastructure is a fundamental to organizational activities. Also, there were suggestions from strategy implementation scholars that infrastructure is needed as a supportive capability for the implementation activities.

Daft and Mcintosh (1984) studied the role of formal control system in the strategy implementation process. They found that a formal control system helps managers to manage business unit outputs and to control their functional activities. Broadbent, Weill, and St. Clair (1999) suggest that infrastructure capability is fundamental to the architecture of business process and the availability of appropriate infrastructure capability was a key factor preceding the successful implementation of redesigned business process. Shaw, Brown, and Bromiley (2001) comment that strategy implementation is inevitably involved with the decision of organizational infrastructures, such as technological, human resource, finance, or other systems. They mentioned that the congruence of those infrastructures effect relationship of strategy implementation effectiveness. Longman and Mullins (2004) suggest that a proper organization structure is an influence on the success of project implementation.

In organizations, synergies result from combining infrastructure capabilities and other organizational resources (Melville et al., 2004; Powell & Dent-Micallef, 1997). Infrastructure is required to build and maintain organizational capabilities and to share capabilities with other functions within and across organizations. KIC are essential capabilities to support organizational activities by coordinating and controlling strategies among divisions and business units. To increase SIE, the level of KIC is hypothesized to increase as well. The third hypothesis is proposed:

Hypothesis 3: Knowledge infrastructure capabilities positively affect the effectiveness of strategy implementation.

Measurement Model and Variables

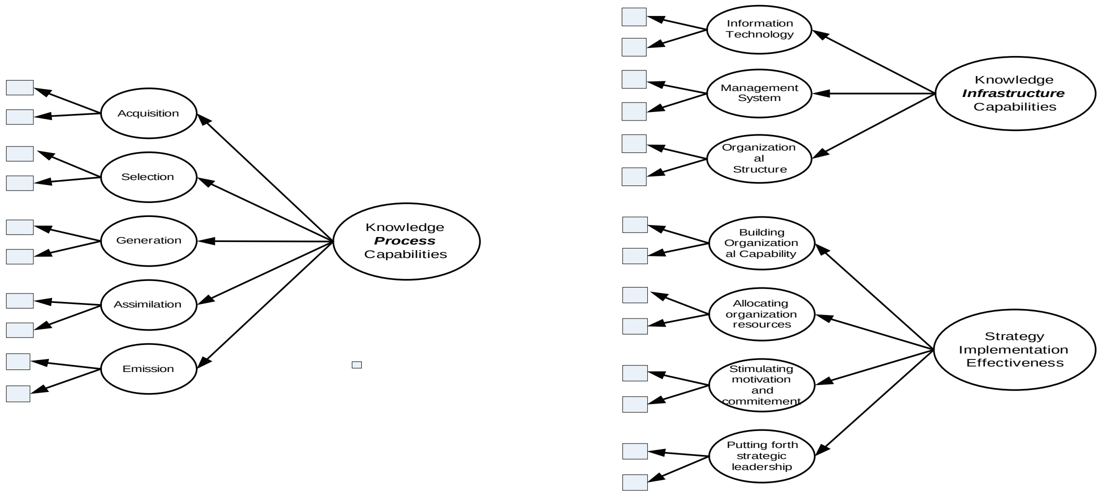
This measurement model consists of three main latent constructs: KPC, KIC, and SIE. In KPC, five subconstructs are knowledge acquisition, knowledge selection, knowledge generation, knowledge assimilation, and knowledge emission, tested as components of KPC. In KIC, three subconstructs are information technology, management system, and organizational structure, tested as components of KIC. In SIE, four subconstructs are building organizational capability, allocating organizational resources, stimulating motivation and commitment, and putting forth strategic leadership that will be tested as components of SIE. Figure 2 presents the measurement model of the study.

METHODS

This study focuses on middle managers as prime respondents. Huber and Power (1985) recognize that these managers are positioned toward the upper echelons of organizations and have important information about their organizations. Relevant to this study, middle managers are deeply and directly involved in strategy implementation (Floyd & Wooldrige, 2000). In addition, middle managers are crucial in developing organizational capabilities, facilitating adaptability, synthesizing information, and championing strategic alternatives (Gadiesh & Gilbert, 2001). They use their knowledge and social interaction to accomplish tasks and innovate and create new capabilities. In this study, middle managers are defined as those positioned below executive officers but above operational managers (such as the functional department managers, regional managers, and district managers) (Floyd & Wooldridge, 2000).

Standard and Poor's COMPUSTAT database was utilized to provide the sample, with sample firms randomly selected from this population. In order to control for industry bias, the study gathered a multi-industry sample to minimize the influence of systematic interindustry difference; the pool of industries from which sample was generated is random. Using the COMPUSTAT database as a sampling frame, the study population includes firms that have a formal organizational structure and clear organizational function because all functions in organizations have already been set and include activities that relate to knowledge activities. Important selection rules are applied to determine the scope of the study's population. In order to enhance the validity of the study, selection criteria are: 1) The firm must have been in business for at least five years, 2) The firm's capital registration must have been more than $50 million in 2003, and 3) The firm's

Figure 2. Measurement model



Note: A square represents observed variable . KPC has four observed variables for each latent variable . KIC has four observed variables for each latent variable . SIE has three observed variable for each latent variable .

profit must have been more than $300 million in 2003. We argue that those criteria are designed to narrow the study scope to firms that have potentially broader profiles of knowledge activities and broad ranges of strategy implementation. Finally, a total of 1,321 middle managers were found from the sampling population**.**

This study used a survey-questionnaire as the measurement instrument. Questionnaires were used to elicit responses related to attitude or preference of constructs (Bartholomew & Knott, 1999). Two main types of scaling techniques—the seven-point Likert scale and descriptive information—have been developed for deriving information. The questionnaire is divided into four main parts (Appendix A). The first part has one question. The objective of this part is to define "how well respondents understand the definition of 'strategy'" by providing the definition of strategy and asking respondents to identify their degree of familiarity with the definition, using the seven-point Likert scale. The scale in the first part is from "not familiar" at 1 to "very familiar" at 7.

The second part addresses knowledge capabilities and has 32 questions. As stated earlier, eight subconstructs (i.e., knowledge acquisition, knowledge selection, knowledge generation, knowledge assimilation, knowledge emission, information technology, organizational structure, and management system) are measured. In this part, seven-point Likert scales are applied to 32 questions. The scale in the second part is from "none" at 1 to "extremely high" at 7.

The third part addresses strategy implementation tasks and aims to answer "how much samplers agree with the key implementation tasks in organizations." There are five measurement constructs and fifteen questions in this part. In this part, seven-point Likert scales are applied to the fifteen questions. The scale is the same as the second part. The last part involves demographic information. In this part, the respondents were asked to provide descriptive information.

The initial draft of the questionnaire was reviewed by three faculty experts to ensure the face validity and readability of the scale items. Data was collected by sending questionnaires via e-mail. This substantially reduced the cost of reaching potential respondents (Schonlau, Fricker & Elliott, 2001).

There were two main stages of the data collection. The first stage included the two pilot projects; the last stage was the full survey. These two stages were implemented to ensure high reliability and validity of data collection.

The pilot study was conducted to determine the clarity and readability of the questionnaire, and to test the internal reliability of the measures. In the first pilot survey, a cover letter and questionnaires were sent via e-mail linked to the questionnaire Web site to 100 target respondents. Seven days following the initial mailing, a follow-up letter and the same Web link were presented to nonrespondents. Seven days after the follow-up mailing, a second follow-up letter and the same Web link were presented to the remaining nonrespondents.

Based on the experience of previous research, these three steps (the initial mailing and two follow-up mailings) could be expected to generate a high response rate. The response rate in the first pilot project was ten percent (10%). Although the returned questionnaires were not enough for a statistical test, "eye-ball" assessments could be made. The questionnaire was modified by adding one question to each construct in part two, and rewording ten questions in part two and one question in part three. These modifications were made to achieve both high internal consistency and high discriminant validity.

For the second pilot survey, modified questionnaires linked to the questionnaire Web-site were sent via e-mail to another 100 target respondents. The response rate in this pilot project was twenty nine percent (29%). The result from the second pilot survey was enough to have a statistical test. The result of the statistical test shows that questions in each construct have high reliability. In order to confirm the face validity and readability of the scale items, the questionnaire was reviewed by experts for the third time. No significant change was required. Therefore, the study used this questionnaire for the full survey.

For the full survey, questionnaires were sent by e-mail linked to the questionnaire Web-site to 1,321 target respondents. Questionnaires were sent to respondents three times, consisting of an initial letter and two follow-up letters. There was a waiting period of seven days before sending a follow-up questionnaire.

RESULTS

The first step in descriptive statistics was to analyze the response rate. The 1,321 questionnaires were sent to middle managers. Following the initial and two follow-up e-mails, the total number of returned questionnaires was 162 middle managers, or a 15.99% response rate. The respondents' positions are 101 division managers (62.3% of total returned questionnaires), and 61 regional managers (37.7% of total returned questionnaires). An average score for "How familiar are you with the concepts and practices of 'Strategy'?" in the first part of the questionnaire is 6.02, with 7.00 being the most familiar. This result shows that respondents feel they are familiar with the given meaning of strategy. In part four, respondents reported an average of 6.08 years in their current position, an average of 11.57 years in their current organization, an average of 17.44 years in knowledge management, and an average of 12.78 years in strategy implementation. The responses to the qualification questions indicated that the survey respondents were well qualified to respond to the questionnaire; the respondents are familiar with strategy implementation and knowledge management.

Structural Equation Modeling Analyses

A majority of the analyses were conducted by SEM framework utilizing MPlus 3 (Muthen & Muthen, 1998-2004) structural equation modeling (SEM) software. The two stage procedures recommended by Kline (2005) are: 1) measurement model analysis; and, 2) causal model analysis and the testing of three hypotheses. The data screening was needed because maximum likelihood estimation, which is the primary estimation method of SEM, relies on the normal distribution. The study's variables were assessed through multiple data screening methods. Distributions were inspected for completeness, normality, and outliers. The examination reveals that data fell within range with no outliers. Normality was assessed for all variables. All questionnaire items were confirmed to be normal. Data screening suggests no critical data-related problems in the study (Appendix B)

There are three goals in examining the measurement model. First is to remove nonrepresentative items. Second is to assess the reliability of constructs. Third is to assess the correlation relationships among constructs. Confirmatory factor analysis (CFA) was utilized in the examination of the measurement model of the constructs in this investigation. The initial CFA models of the three constructs indicate less fit between the theoretical model and empirical data; model respecification was needed. Item removal is recommended (Kline, 2005). Modification indices and factor loading were used to assist item removal. The indicators that failed to have substantial loading on the factors to which they are originally assigned and indicators loaded on a different factor were removed (Kline, 2005). Indicators with good psychometric characteristics and that have relatively high factor loadings were taken into account in the respecification stage (Match & Hau, 1999).

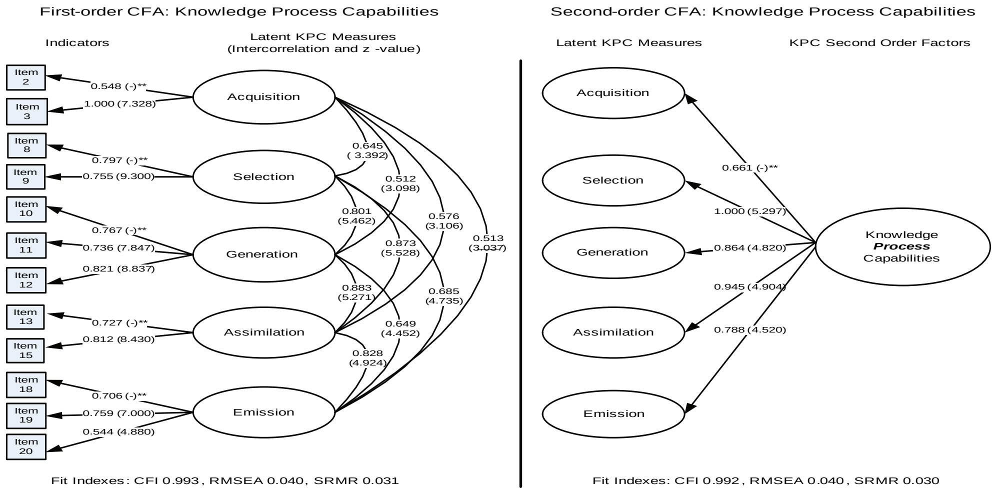
To assess the degree of compatibility between empirical data and study models, this study used three fit indices through our investigations: comparative fit index (CFI) index (Bentler, 1990; Carlson & Mulaik, 1993; Marsh & Hau, 1999); root mean square error of approximation (RMSEA) index (Hu & Bentler, 1999; Klien, 2005); and standardized root mean square residual (SRMR) index (Hu & Bentler, 1999; Kline, 2005). These fit indicators have been shown as the most stable in confirmatory factor analysis and structural equation modeling (Anderson & Gerbling, 1988; Hu & Bentler, 1999).

Hierarchical confirmatory factor analysis was used to examine whether the five activities of KPC, three KIC, and four SIE can be viewed as components of KPC, KIC, and SIE, respectively. We use the following procedures. According to Kline (2005), two analytical steps are part of the hierarchical CFA model. In the first order, we assess the bivariate correlations between the different measures to determine whether they are related. In the second order, in the presence of positive correlation, we estimate a CFA model that permits the identification of the relationship between the indicators, taking measurement error into account. After model respecification, all factor loadings provided acceptable loading on each construct. The results of fit indices of both first-order CFA and second-order CFA are within or better than the cut-off criteria. Especially, SRMR indices of every models show excellent fit. Figures 3, 4, and 5 present the result of the first-order and the second-order CFA. The results of the measurement model indicated that three first-order factor models under CFA showed that all factors are related and observed variables explained each factor well. In the other words, it can be concluded that the empirical data matches the theoretical model.

Evaluating Reliability and Validity

In order to evaluate the validity of the observed variables in a first-order level of measurement, examination of factor loadings of observed variables (items) on latent variables (factors) is recommended (Anderson & Gerbling, 1988; Bollen, 1989; Doll, Xia & Torkzadesh, 1994; Mueller, 1994). In this study, the results of first-order factor models show all items have large and significant loading on their corresponding factors. The result of the second-order factors model showed similar results. Based on the loading results, the measurements of the constructs have high validity.

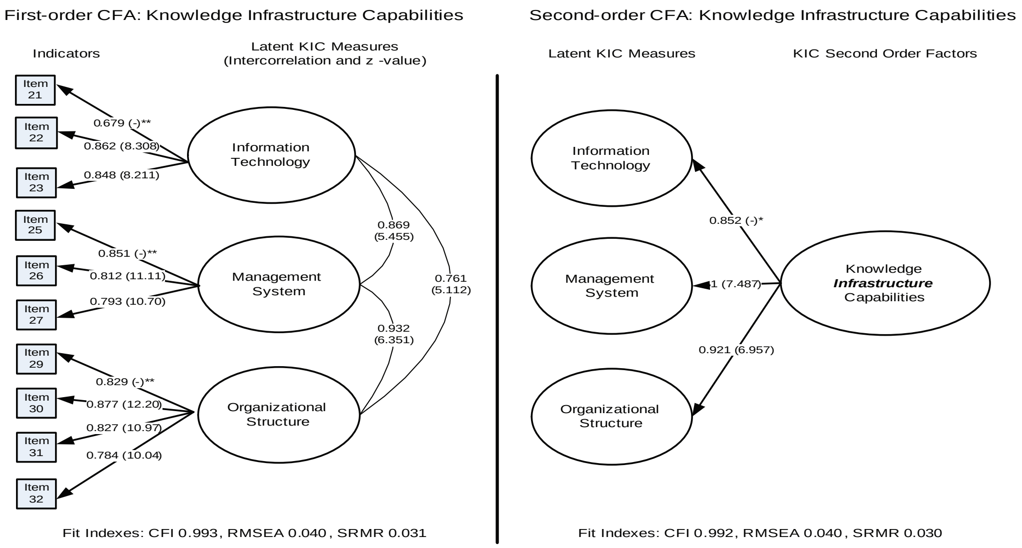
Figure 3. Summarized results CFA of KPC



* The value in the parentheses is z-statistics value. The result of z-statistic > +/-1.96 indicate p-value < 0.05

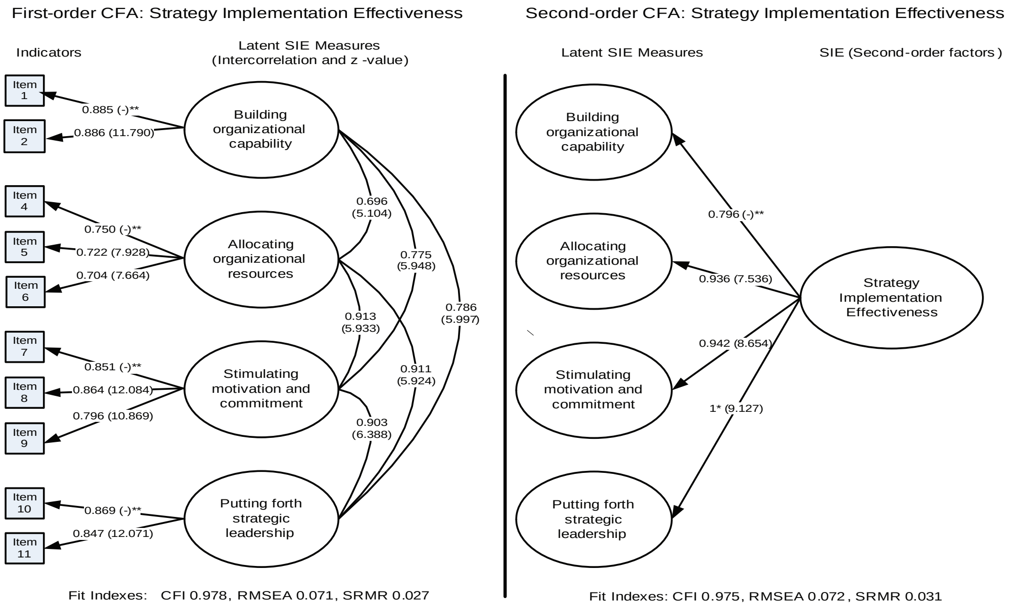
** Absence of a value indicates estimation is not applicable to the variable owing to limitations on simultaneous estimation .

Figure 4. Summarized results CFA of KIC



* The value in the parentheses is z -statistics value. The result of z-statistic > +/-1.96 indicate p-value < 0.05
** Absence of a value indicates estimation is not applicable to the variable owing to limitations on simultaneous estimation .

Figure 5. Summarized results CFA of SIE



* The value in the parentheses is z -statistics value. The result of z-statistic > +/-1.96 indicate p-value < 0.05
** Absence of a value indicates estimation is not applicable to the variable owing to limitations on simultaneous estimation .

Examining reliability, the majority of construct reliabilities exceed the suggested level of 0.70. The reliability in this study ranges from 0.540 to 0.969. Only two components in the KPC showed a result lower than 0.70: 0.540 for knowledge acquisition and 0.675 for knowledge emission. However, in many of the recent empirical investigations in the organizational knowledge area, the results of reliability tests are between 0.54 and 0.85 (e.g., Sabherwal & Becerra-Fernandez, 2003; Szulanski, 1996; Zander & Kogut, 1995). The lower-than-the-suggested level of the two components may suggest that knowledge is an abstraction that has moderate reliability by itself. Taking the observations into account, the reliability results suggest that the indicators are sufficiently reliable to measure latent constructs.

Causal Model

The overall model fit is examined through fit indices and is done to make sure that the empirical observed data actually correspond with the proposed model. For the first measure, the comparative fit index (CFI) index (Bentler, 1990), has a value of 0.923 that is above the commonly accepted rule of thumb at 0.90 to indicate a well-fitting model (Carlson & Mulaik, 1993; Marsh & Hau, 1999). We get the RMSEA of 0.060 for our proposed model. The result of RMSEA is in the range of recently researched results from 0.04-0.09 (Hoskission, Hitt, Johnson & Grossman 2002; Isobe, Makino & Montgomery, 2000). The result of RMSEA showed a good fit model. We get a SRMR of 0.056 for our model, well below the cutoff criteria for SRMR at 0.08 (Hu & Bentler, 1999). Compared with most recent research where the SRMR was used to measure model fit, and the results were in the range of 0.08-0.09 (Isobe et al., 2000; Hoskission et al., 2002). The SRMR index showed an excellent fit of the causal model.

Hypotheses Testing

A main objective of this article is to provide evidence supporting that KIC is a mediator of the causal model. From the literature review, we believe that KPC in organizations is an antecedent to KIC, and that KIC supports SIE. According to the methodology described by Baron and Kenny (1986), in order to demonstrate the mediation effect of KIC, two stages of hypotheses testing are required. The first stage is to demonstrate the positive effect from KPC to SIE, leaving KIC out of the model. This stage confirms Hypothesis 1. As shown in Table 2, the second stage is to integrate KIC and demonstrate a positive path from KPC to KIC and from KIC to SIE. Moreover, there must be no significant path from KPC to SIE. This stage is captured by confirming Hypothesis 2 and Hypothesis 3, and does not confirm Hypothesis 1. Perfect mediation holds if the independent vari-

Table 1. Measurement model: Construct reliability

Construct	Construct Reliability Estimates**
Knowledge process capabilities (KPC)	
Knowledge acquisition	0.540
Knowledge selection	1.000*
Knowledge generation	0.773
Knowledge assimilation	0.898
Knowledge emission	0.675
Knowledge infrastructure capabilities (KIC)	
Information technology	0.755
Organization structure	0.858
Management system	1.000*
Strategy Implementation Effectiveness (SIE)	
Building organizational capability	0.633
Allocating organizational resources	0.876
Stimulating motivation and commitment	0.888
Putting forth strategic leadership	1.000*

Note: * *Use as the reference or an anchor item.*
** *Construct Reliability formula =* $(\Sigma\lambda)^2 / (\Sigma\lambda)^2 + \Sigma\sigma^2$ *(*$\Sigma\lambda$ *represents summation of factor loading in each factor, and* $\Sigma\sigma^2$ *represents summation of measurement error of each factor.*

Table 2. Structural equation modeling results

Construct relationship	Parameter estimates	*z-statistic*	*Result*
The first stage			
H1: KPC → SIE	0.791	4.654	Supported
The second stage			
H1: KPC → SIE	0.260	0.952	Unsupported
H2: KPC → KIC	0.927	4.617	Supported
H3: KIC → SIE	0.571	2.221	Supported

able has no effect on the dependent variable or outcome variable when the mediator is presented in the model (Baron & Kenny, 1986). Therefore, the results of this study show the complete mediation effect of KIC over the path from KPC to SIE.

CONCLUSION

Results Discussion

The purpose of this study is to understand the effects of organizational knowledge capabilities on strategy implementation effectiveness. Two organizational knowledge capabilities (i.e., KPC and KIC) are hypothesized to positively influence SIE. The results demonstrate that the two knowledge capabilities have positive effects on the effectiveness of strategy implementation. However, one of them, KIC, exhibits a mediator property. The result confirms the beliefs of many and sheds deeper light on relationships between the two capabilities and strategy implementation effectiveness.

The discovery of the relationships involved two-step statistical testing, aimed to uncover a mediator. In the first step, the relationship between KPC and SIE was analyzed by disregarding KIC from the model. In this step, the result showed the positive effect of KPC on SIE. In support of prior suggestions (Prahalad & Hamel, 1994; Hertog & Huizenga, 2000; Liebeskind, 1996), the result indicates that the social interaction of KPC affects all functions and resources in the organization, including SIE. Furthermore, the company's capability to combine individual knowledge and skills across boundaries to create knowledge and to launch business initiatives enables firms to enhance SIE. The first-step result indicates that the capability of KPC directly benefits SIE in the organization.

In the second step, all three constructs were presented simultaneously in the model. The result clearly demonstrates the mediator effect of KIC. The positive relationship between KPC and SIE no longer exists. Instead, there are positive effects from KPC to KIC and from KIC to SIE. Our results provide strong support for our second hypothesis that suggests that KPC are an antecedent of KIC. This result supports the prior suggestion (Keidel, 1994; McDermott, 1999; El Sawy & Josefek, 2003) that infrastructures in the organization are changed after the pattern of work process is determined. In other words, the changes in process of knowledge determine any changes in organizational infrastructures (Wang & Majchrzak, 1999). The result supports our argument that KPC causes KIC. KIC do not influence the process as many have believed. Activities inside the five main knowledge-chain activities (such as brainstorming, sharing ideas, recruiting employees from outside, or participating in community practice) may benefit the capability to manage infrastructure in the organization.

Our result also provides strong support for our third hypothesis that KIC affect SIE. This finding suggests that KIC affect SIE as a whole. This result is consistent with position of Shaw et al. (2001) that strategy implementation is inevitably involved with the organizational infrastructure—such as information technology, human resources system, or organizational—and it is also consistent with Longman and Mullins (2004), who argue that a proper infrastructure influences the success of strategy implementation.

In the second step, the no-longer-existing Hypothesis 1 may suggest that the organization may gain advantages by using infrastructure to leverage intangible and complementary human and business resources (Melville et al., 2004). In addition, the results are thus consistent with the suggestions of Madhok (1997) and Dyer and Nobeoka (2000), who assert that KIC support and facilitate organizational members to transfer and to create knowledge within and across organizations. Furthermore, consistent with this explanation, Worren et al. (2002) and King and Zeithaml (2001) suggest that management restructures organizational infrastructures in order to facilitate KPC and to support organizational activities. In short, it may be concluded that the organization needs KIC in order to enhance organizational activities. It is influenced by KPC and it supports and facilitates strategy implementation tasks. In the knowledge economy, the fast-changing environment causes the organization to develop, mix, and match two kinds of knowledge capabilities in order to enhance SIE.

In addition to the contributions of the causal models, the results also demonstrate and confirm components of KPC and KIC. The measurement model of KPC clearly demonstrates that the five components are significantly correlated. Furthermore, all components load significantly under KPC. The statistical results could only suggest that knowledge acquisition, knowledge selection, knowledge generation, knowledge assimilation, and knowledge emission are the components of KPC. Bringing the components under a single construct shows the powerful nature of knowledge activities linked through the social fabric. A picture of social interactions among knowledge process activities can be drawn from the following: using information outside the company; training employees to know how to acquire new knowledge; training employees by using professionals inside organizations, using the company database; brainstorming; ongoing interaction; communicating new information; sharing information among organizational members; producing a market report; and encouraging interorganizational activities. All of these activities create seemingly positive effects on SIE until KIC is brought into the canvas.

In the second measurement model concerning KIC, the model shows and demonstrates information technology, the management system, and organizational structure as the three components of KIC. The interconnection of the three components takes an important place in the relationship between KPC and SIE. They support, assist, and facilitate organizational strategy implementation activities. They are also a function of KPC. In the light of these connections, it becomes important to reorient our understanding that good infrastructure may help strategy implementation. However, good infrastructure is a requirement for a good process. Both scholars and practitioners must balance the importance between KPC and KIC because the two are important in SIE.

In the third measurement model concerning SIE, the model shows and demonstrates four tasks of strategy implementation as the four components of SIE. The measurement model of strategy implementation clearly demonstrates that the four tasks are significantly correlated. Furthermore, all components load significantly under KPC. The statistical results could only suggest building organizational capability, allocating organizational resources, stimulating motivation and commitment, and putting forth strategic leadership as the components of effective strategy implementation. These four tasks of strategy implementation are tasks that top management and middle managers must concern themselves with. If an organization can achieve these four tasks, it can be concluded that the organization has succeeded in the implementation process.

Implications

Overall, this study expands the view of how knowledge capabilities affect the effectiveness of strategy implementation as well as the role of knowledge infrastructure capabilities as a mediator. Through analysis of theories and empirical testing, this research strongly supports the notion that organizations may possess powerful ingredients for successful strategy implementation through the development of key knowledge capabilities.

Implications for Management Practice

Beyond the theoretical contribution, there are some issues in which organizations should develop knowledge capability to ensure effectiveness of strategy implementation.

First, building on the knowledge capabilities, management should promote and develop knowledge process activities in the organization's members. Because knowledge is embedded into organizational routine and activities, promoting knowledge process activities will create social interactions among an organization's members and create knowledge sharing and culture transference. In addition, the top management team should recognize the importance of knowledge by creating a position specifically devoted to knowledge management (e.g., Chief Knowledge Officer [CKO]). This position will play an important role in overseeing knowledge activities and managing organizational knowledge. To enhance knowledge management efficiency, the CKO must establish programs to balance organizational knowledge and capabilities in order to leverage knowledge.

Second, another direct implication for managerial practice regarding key knowledge processes is that management should advocate the development of knowledge capabilities for effectiveness of strategy implementation. Management should pay and balance attention to both knowledge process activities and infrastructure. Davenport and Prusak (1998) caution management that optimizing one aspect of knowledge capabilities can cause detrimental effects in the development of organizational capabilities. Focusing only on process capabilities creates rich knowledge. However, the knowledge is not utilized because no infrastructure exists for it. Organizations must not forget that the observed benefits of knowledge are the result of a well-matched infrastructure. The knowledge process needs the infrastructure to store and to increase the efficiency of knowledge process activities. On the other hand, a study by Hansen, Nohria, and Tierney (1998) reveals that overemphasizing technology to capture and disseminate knowledge does not yield a satisfactory result. The organization does not have sources of knowledge to exploit for competitive advantage.

Third, the findings of this study point to the unique importance of knowledge infrastructure. Organizations should prepare the readiness of the three infrastructures (i.e., IT, management systems, and organizational structures). Ready-for-knowledge infrastructures help organizations to realize benefits of their knowledge in a timely manner when the knowledge becomes available from the knowledge process. If the infrastructure is not ready for knowledge, the knowledge from knowledge activities is less likely to be utilized effectively. The findings of this study also support the fact that strategy implementation tasks need infrastructure to support and to facilitate their activities. The state of technology, management, and organizational structure has to be assessed, as well as their readiness for supporting organizational activities.

Last, another important implementation of the knowledge process lies in the area of incremental innovation. The importance of sharing knowledge for better innovation has been investigated and discussed by many researchers, such as Hinloopen (2003), Carlile (2004), Smith, Collins, and Clark (2005). Therefore, improving KPC not only benefits SIE but also innovations that span within the knowledge process. It should be noted that innovations can happen almost anywhere in an organization (Damanpour, 1996). Furthermore, innovation involves more than product innovation. It includes process innovation, innovative adoption of technology, and innovative problem solving. In fact, innovation can be said to extend to strategy innovation (Hamel, 2002). Thus, organizations can expect the benefit of the KPC to include more than merely SIE.

Implications for Future Research

In the near future, the study model can be improvised to study the interplay among the components of the KPC and KIC. Furthermore, the interplay can be extended to each component of SIE. It is interesting to speculate that the whole is greater than the sum of the parts for each of the three main constructs. The result of the relationships among the three main constructs could be changed in light of the analyses of the interplay among their smaller components.

In the long run, the study presents many opportunities to expand beyond its basic findings. Many questions that require further analysis and investigation have been raised. Both knowledge capabilities, (examined in this study) and process and infrastructure can be explored further. There are several research areas with which this study can be integrated. New research is needed to understand specific strategies and organizational programs that facilitate knowledge capability and lead to an increase in the effectiveness of strategy implementation.

Concerning KPC, we could expand our understanding to explore obstacles in exercising knowledge process activities. Especially, the areas of political and social interaction at each component and across components of the process promise to yield insightful detail. Human resources management can also be linked to knowledge process capability. The area of recruiting and selecting knowledge workers can be linked to knowledge capabilities development.

Concerning the infrastructure capabilities, one direction of future research is to explore how to manage the readiness of infrastructures in organizations, what factors influence the change of infrastructures in organizations, as well as how to design infrastructures that benefit both the efficiency of a bureaucratic organization and the flexibility of knowledge process creation. Furthermore, in strategy implementation areas, we could study middle managers by linking them with strategy innovation and corporate entrepreneurship. Floyd and Wooldridge (2000) believe that middle managers occupy the position that creates organizational capability, knowledge capability, and strategy innovation.

The last interesting direction of future research is to explore how different project characteristics might change the result of this study. This study gathered only general information on strategy implementation effectiveness. However, the spectrum of strategy project characteristics can be explored in contingency with the study model. The spectrum of characteristics could range from evolutionary improvement to revolutionary improvement, from arm's length collaboration to close collaboration, or from intrafirm to interfirm. The end result is to observe how knowledge process and knowledge infrastructure respond to many characteristics of strategic initiatives.

Limitations of the Study

The main limitations of this study relate to the "snapshot nature" of the data; that is, the data represent a picture at only one point in time of organizational life. In reality, the relationships between knowledge capabilities and the effectiveness of strategy implementation are incrementally developed throughout the life of an organization. They could not be developed in a short period, especially the capability of knowledge process which is based on day-by-day social interactions among organization members. Although the snapshot enables us to conduct many analyses and to answer the research question, it limits our ability to analyze beyond current relationships. Therefore, in order to find out the in-depth relationship of knowledge capabilities and strategy implementation, longitudinal action research is recommended.

Conclusion

Knowledge and capabilities have to be built up slowly over time, shaped, and channeled in certain directions by hundreds of daily managerial decisions. The results of this study show that knowledge process capabilities positively affect the effectiveness of strategy implementation when knowledge infrastructure is ignored. However, KPC does not directly affect the effectiveness of strategy implementation when KIC is presented. The infrastructure plays the mediator role. Therefore, organizations should balance both types of knowledge capabilities. Effective execution of knowledge capabilities can promote growth by allowing an organization to launch business initiatives more effectively and successfully. Furthermore, contributions of this study could potentially go beyond the field of strategic management to other fields, such as human resources management and management information systems. The results of this study also benefit the practitioner's world by contributing to the effectiveness of middle managers in the area of knowledge capabilities. Successfully managing the capabilities to transform knowledge will add to the development of organizational members. Organizational members will learn additional knowledge as well as identify knowledge that can enhance the efficiency and effectiveness of strategy implementation. Furthermore, successfully managing the capabilities to manage infrastructures will also increase the ability to facilitate and support organizational activities. Therefore, managing both types of knowledge capabilities activities will contribute to the effective performance of middle managers in strategy implementation. Consequently, when strategies are more successfully implemented, the improvements in business' bottom line are more likely.

APPENDIX A.

Survey Questionnaire

Knowledge Management and Strategy Implementation

The objective of this questionnaire is to study the effect of knowledge processes and knowledge infrastructure capabilities on strategy implementation. Please respond to this questionnaire through the perspective of strategy implementation.

Part 1: This section focuses on your interpretation of the term "Strategy" Please use the following definition:

Strategy is the means that the organization utilizes or employs to achieve its goals, objectives, and vision as part of the company mission.

From the definition above, how familiar are you with the concepts and practices of "Strategy" Please answer by using the scale below.

(Not very familiar) 1 2 3 4 5 6 7 (Very familiar)

Part 2: This section focuses on the measurement of components of "knowledge capabilities" within your organization. Please use the following scale to rate the extent of your organization's use of the various components.

Rating definitions:
1=none, 2=slight, 3=below average, 4=average, 5=above average, 6=significant, and 7=extremely high

My organization…	*1*	*2*	*3*	*4*	*5*	*6*	*7*
Recruits and hires employees from other firms in order to access knowledge and expertise developed at these firms.	*1*	*2*	*3*	*4*	*5*	*6*	*7*
Uses information from outside the company, by such means as conducting external surveys or purchasing external data sets, in order to get more new information and generate new products and strategies.	*1*	*2*	*3*	*4*	*5*	*6*	*7*
Provides effective training for employees on how to identify and acquire information from external sources.	*1*	*2*	*3*	*4*	*5*	*6*	*7*
Utilize knowledge of customer needs to benefit new product development and organizational strategies.	*1*	*2*	*3*	*4*	*5*	*6*	*7*
Encourages employees to exchange or share their ideas, information, knowledge, and work experiences.	*1*	*2*	*3*	*4*	*5*	*6*	*7*

continued on following page

Rating definitions:

1=none, 2=slight, 3=below average, 4=average, 5=above average, 6=significant, and 7=extremely high

Uses appropriate procedure for forecasting	1	2	3	4	5	6	7
Routinely extracts and collects information and knowledge from available data bases.	1	2	3	4	5	6	7
Train employees by utilizing experienced colleagues or professionals within the organization	1	2	3	4	5	6	7
Uses company database (such as customer profile) in generating consistent, accurate, and faster decision about customers.	1	2	3	4	5	6	7
Promotes or supports brainstorming among employees to create new insights or to solve problems.	1	2	3	4	5	6	7
Promotes or supports various kinds of new inventions by employees.	1	2	3	4	5	6	7
Enables employees to create new knowledge through ongoing interactions and improvisations while they perform their jobs.	1	2	3	4	5	6	7
Encourages employees to share their information, ideas, or knowledge by using internal information systems (e.g., bulletin board, internal groupware, or internal publications.)	1	2	3	4	5	6	7
Provides on the job training to enable employees to better understand their responsibility/duty of their position.	1	2	3	4	5	6	7
Communicates new innovations, new policies, or new ideas to employees.	1	2	3	4	5	6	7
Promotes employee to participate in community service that related to their profession.	1	2	3	4	5	6	7
Provides information systems tools in order to enable its employees awareness utilize such information sources as the Internet	1	2	3	4	5	6	7
Gives lecture and presentations about product development and company situations to employees	1	2	3	4	5	6	7
Produce or publish market research reports and other status reports.	1	2	3	4	5	6	7
Participates in inter-organizational activities, such as trade groups, professional societies, and so forth.	1	2	3	4	5	6	7
Has effective information technology (IT) to provide information for business units planning (e.g., data mining for marketing forecasts)	1	2	3	4	5	6	7
Utilizes information technology (IT) to facilitate collaboration and communication among employees and business partners.	1	2	3	4	5	6	7
Encourages employees to find new information, innovations, ideas, knowledge, or skills using information technology (e.g., searching the Internet).	1	2	3	4	5	6	7
Identifies and tests new technologies for business purposes by developing applications specific to business-unit.	1	2	3	4	5	6	7
Enables employees to cooperate or to interact with the organization's planning system.	1	2	3	4	5	6	7
Encourages employees to develop work standards in day-to-day operations in order to stabilize organizational processes and quality.	1	2	3	4	5	6	7

continued on following page

Rating definitions:

1=none, 2=slight, 3=below average, 4=average, 5=above average, 6=significant, and 7=extremely high

Enhances development of employees' ideas, knowledge, or skills by job rotation, job redesign, or extensive training.	1	2	3	4	5	6	7
Encourage employees to build social relationships within the organization.	1	2	3	4	5	6	7
The organizational structure (divisions, departments, units) enhances effectiveness of interactions and sharing of knowledge.	1	2	3	4	5	6	7
Facilitates the transfer of new knowledge, ideas, skills, and innovations across the organizational hierarchy and functional boundaries.	1	2	3	4	5	6	7
Encourage employees to go where they need for knowledge regardless of the organizational structure.	1	2	3	4	5	6	7
Fosters an interdependent work community in which employees are able to exchange/transfer their information.	1	2	3	4	5	6	7

Part 4: Demographic information: Please provide the following descriptive information about your position with your organization. Your responses will remain anonymous and will not be associated with your name.

- What is your job title? …………………
- How many years have you been in this job? …………….years
- How many years have you been with this organization? …………….years
- How many years' experience do you have in knowledge management in this or other organizations? …………….years
- How many years' experience do you have in strategy implementation in this or other organizations? …………….years

Chapter 6.7

Empirical Investigation of Critical Success Factors for Implementing Business Intelligence Systems in Multiple Engineering Asset Management Organisations

William Yeoh
University of South Australia, Australia

Jing Gao
University of South Australia, Australia

Andy Koronios
University of South Australia, Australia

ABSTRACT

Engineering asset management organisations (EAMOs) are increasingly motivated to implement business intelligence (BI) systems in response to dispersed information environments and compliance requirements. However, the implementation of a business intelligence (BI) system is a complex undertaking requiring considerable resources. Yet, so far, there are few defined critical success factors (CSFs) to which management can refer. Drawing on the CSFs framework derived from a previous Delphi study, a multiple-case design was used to examine how these CSFs could be implemented by five EAMOs. The case studies substantiate the construct and applicability of the CSFs framework. These CSFs are: committed management support and sponsorship, a clear vision and well-established business case, business-centric championship and balanced

team composition, a business-driven and iterative development approach, user-oriented change management, a business-driven, scalable and flexible technical framework, and sustainable data quality and integrity. More significantly, the study further reveals that those organisations which address the CSFs from a business orientation approach will be more likely to achieve better results.

INTRODUCTION

Background

Engineering asset management organisations (EAMOs), such as utilities and transportation enterprises, store vast amounts of asset-orientated data (Lin, Gao, Koronios, & Chanana, 2007). However, the data and information environments in these organisations are typically fragmented and characterised by disparate operational, transactional, and legacy systems spread across multiple platforms, diverse structures, and different data formats (Haider, 2007; Haider & Koronios, 2003). The plethora of different systems makes it very difficult, even impossible, for a system in one functional unit to communicate with systems in other units. This lack of integration of information systems, together with the large volumes of transactional data which might be spread in different pools across the enterprise, can lead to increased difficulties in analysing, summarising, and extracting actionable information resulting in suboptimal management performance (Ponniah, 2001). Moreover, heightened competition resulting from market deregulation as well as increased regulatory compliance and governance requirements, such as the Sarbanes-Oxley ordinance in the U.S. and the CLERP 9 Acts in Australia, have demanded greater accountability for decision making within such organisations (Logan & Buytendijk, 2003; Mathew, 2003).

On the other hand, existing management information systems are no longer adequate for EAMO's modern business needs and not always meeting the expectations of decision makers at all hierarchical levels (Olszak & Ziemba, 2007). These systems were unable to handle the integration of different, dispersed, and heterogenic data within such enterprises. Nor could they effectively interpret such data in any broader contexts or discover new data interdependencies (Bui, 2000, cited in Olszak & Ziemba, 2007; Gray & Watson, 1998), due to improper techniques of data acquisition, analysis, discovery, and visualisation (Olszak & Ziemba, 2007). Therefore, in response to these pressing challenges of information dispersion and compliance requirements, EAMOs are compelled to improve their business execution and management decision support through the implementation of a contemporary BI system (Olszak & Ziemba, 2007).

According to Negash (2004), "BI systems combine data gathering, data storage, and knowledge management with analytical tools to present complex internal and competitive information to planners and decision makers." Whilst Moss and Atre (2003) state that "it is an architecture and a collection of integrated operational as well as decision-support applications and databases that provide the business community easy access to business data." Stated simply, the main tasks of a business intelligence (BI) system include "intelligent exploration, integration, aggregation and a multidimensional analysis of data originating from various information resources" (Olszak & Ziemba, 2007). Implicit in this definition, data is treated as a highly valuable corporate resource, and transformed from *quantity* to *quality* (Gangadharan & Swami, 2004). As a result, critical information from many different sources of an asset management enterprise can be integrated into a coherent body for strategic planning and effective allocation of assets and resources. Hence, meaningful information could be delivered at the right time, at the right location, and in the right form (Negash, 2004) to assist individuals, departments, divisions, or even larger units for improved decision-making (Jagielska, Darke, & Zagari, 2003).

From an architectural standpoint, a BI system is composed of a set of three complementary data management technologies, namely data warehousing, OLAP, and knowledge discovery (which is aided predominantly by data mining techniques). To be specific, Olszak and Ziemba (2007, p. 138) posit that a BI system is composed of the following components:

- Extraction-Transformation-Load (ETL) tools that are responsible for data transfer from operational or transaction systems to data warehouses;
- Data warehouses to provide some rooms for thematic storing of aggregated and analysed data;
- OLAP analytic tools to let users access, analyse and model business problems and share information that is stored in data warehouses;
- Data mining tools for determining patterns, generalisations, regularities, and rules in data resources;
- Reporting and ad hoc inquiry tools for creating and utilising different synthetic reports; and
- Presentation layers that include customised graphical and multimedia interfaces to provide users with information in a comfortable and accessible form.

In the past few years, the BI market has experienced extremely high growth as vendors continue to report substantial profits (Gartner, 2006a; IDC, 2007). Forrester's recent survey indicated that for most CIOs, BI was the most important application to be purchased (Brunelli, 2006). The results of the latest Merrill Lynch survey into CIO spending similarly found that the area with the top spending priority was BI (White, 2006). These findings are echoed by Gartner's CIOs priorities surveys in 2006 which revealed that BI ranked highest in technology priority (Gartner, 2006b). In the most recent survey of 1,400 CIOs, Gartner likewise found that BI leads the list of the top ten technology priorities (Gartner, 2007).

While the BI market appears vibrant and the importance of BI systems is becoming more widely recognised, particularly in EAMOs, nevertheless few studies have investigated the implementation of BI systems in general and critical success factors in particular. Although there have been a plethora of guidelines from the IT industry, most rely on anecdotal reports or quotations based on hearsay (Jagielska et al., 2003). This is because the study of BI systems is a relatively new area that has primarily been driven by the IT industry and vendors (Jagielska et al., 2003). Therefore, empirical research to shed more light on those critical factors influencing the implementation of BI systems is desirable because the understanding of critical success factors (CSFs) enables BI stakeholders to optimise their scarce resources and efforts on those significant factors that are most likely to have an impact on the system implementation, and thus increase the chances of implementation success.

Research Motivation

CSFs have been one of the earliest and most prominent topics in the area of IS research (Lu, Huang, & Heng, 2006). Rockart (1979) defines CSFs as "the limited number of areas in which results, if they are satisfactory, will ensure successful competitive performance for the organisation." Whilst Greene and Loughridge (1996) assert that the identification of CSFs can help to clarify the nature and amount of resources that must be gathered to permit the project team to concentrate their efforts on meeting priority issues rather than what the available technologies will allow. Thus, the emphasis here is on "few" and "must go right" (Khandelwal, 2000). For obvious reasons, CSFs are high-level management considerations as distinct from a detailed set of project deliverable specifications.

The IS literature contains many studies that investigate the factors that impact the implementation of an information system. As a result of such research efforts, a number of critical factors have been investigated and identified; for instance, top management commitment and adequate sponsorship (Lu et al., 2006). However, while these studies are helpful, the complexity involved in the implementation of BI systems is arguably different from traditional systems development efforts (Bischoff & Alexander, 1997; Fuchs, 2006; Han & Kamber, 2001; Ponniah, 2001; Power, 2002). The implementation of a BI system is not a conventional application-based IT project (such as an operational or transactional system), which has been the focus of many CSF studies (Wixom & Watson, 2001). Instead, it shares similar characteristics with other enterprise-wide infrastructure projects such as enterprise resource planning (ERP) systems implementation.

That is, a BI system implementation is regarded as a complicated infrastructure project and is defined as a set of shared, tangible IT resources that provide a foundation to enable present and future business applications (Duncan, 1995). It is not a simple activity to purchase a combination of software and hardware, but rather it is a complex undertaking requiring requisite infrastructure and resources; initially it involves various stakeholders several months to develop, and it may possibly take several years to become adopted fully across the enterprise (Moss & Atre, 2003; Moss & Hoberman, 2004; Olszak & Ziemba, 2007; Reinschmidt & Francoise, 2000; Watson & Haley, 1997). Typical expenditure on these systems includes all BI infrastructure, software programs, licenses, training, consulting, and implementation costs, and may demand seven-digit expenditure (Watson & Haley, 1997). Furthermore, BI stakeholders need to address issues foreign to the conventional systems, and these might include cross-functional data quality and integrity issues, technical complexities such as multidimensional data modelling, cross-organisational needs and socio-politics, and broader enterprise integration and consistency challenges (Shin, 2003).

Specifically, the key infrastructural component—a data warehouse—is a subject-oriented, integrated, time-variant, and nonvolatile collection of data that differ from conventional online transactional processing (OLTP) databases (Inmon, 1994). A complex data structure must be maintained in order to provide an integrated view of the organisation's data so users can query across departmental boundaries for dynamic retrieval of rich decision-support information. Furthermore, the BI system's architecture is highly complex owing to the back-end systems originating from multiple data sources and to the vast volume of data to be processed (Sen & Jacob, 1998). Moss and Atre (2003) reported that a surprisingly high rate of 60% of BI projects end in abandonment or failure due to an assortment of issues. The complexity of BI systems is further exemplified by Gartner's recent study which predicted that more than half of the systems that had been implemented would achieve only limited acceptance (Friedman, 2005). In brief, the implementation of a BI system is associated with many challenges as summarised below (Fuchs, 2006; Moss & Atre, 2003; Watson, Gerard, Gonzalez, Haywood, & Fenton, 1999):

- Lack of recognition of BI projects as cross-organisational business initiatives which differ from typical stand-alone solutions.
- Unengaged or weak business sponsors.
- Inadequate formal involvement from the business side of the enterprise.
- Inappropriate project team structure and dynamics.
- No software release concept (no iterative development method).
- No work breakdown structure (no methodology).
- Ineffective project management (only project administration).

- No business analysis and no standardisation activities (with too much reliance on disparate methods and tools)
- Underlying back-end systems and processes which originally were not adapted for BI applications because the normalised database structures in operational systems are suited to updating data, but not for exporting data to other systems.
- Poor data quality derived from source systems that can often go unnoticed until cross-systems analysis is conducted.
- Inadequate resources needed to keep the system alive and constantly adapted to the needs of users.
- The maintenance process for BI systems that tends to be vague and ill-defined because it is quite difficult to determine how the business users will work with the BI system if they are given such analytical and reporting freedom.

Despite the daunting complexities in implementing BI systems, there has been little empirical research about the CSFs impacting the implementation of BI systems. The gap in the literature is reflected in the low level of contributions to international conferences and journals (Yeoh, Gao, & Koronios, 2006). More importantly, the value of previous CSF studies will obviously decline with age (Little, 1998). As pointed out by Dickson, Leithesier, Wetherbe, and Nechis (1984), “New technologies, economic and legal conditions, and other developments will cause the relative importance of these issues to change and cause new ones to come into existence.” Thus the rapid advancement of technology innovation in general, and the pace at which new technologies are being adopted in particular, will apparently influence the state of criticality for such types of CSFs research (Little, 1998). Furthermore, CSFs applicable to other types of information systems may not necessarily apply to a contemporary BI system.

Therefore, the increased rate of adoption of BI systems, the complexities of implementing a contemporary BI system, the scarcity of academic research, and the far-reaching business implications justify a more focused examination of CSFs as well as the associated contextual issues required for implementing BI systems.

BI System vs. Operational System

As the focus of this study is on BI systems, it is critical to understand how they differ from other systems, and especially those for operational and transactional purposes. In general, there are two fundamental types of information systems within the IS literature, namely online transactional processing (OLTP) systems (also known as operational or transactional systems) and online analytical processing (OLAP) systems such as BI systems (Datta & Thomas, 1999; Ponniah, 2001; Power, 2002). There have been numerous successful cases associated with OLTP-based operational systems, but the knowledge required for building these systems is not adequate for successful implementation of OLAP-based BI systems (Fuchs, 2006; Power, 2002). In fact, BI systems differ in many ways from operational systems that process business transactions (Power, 2002), and there is a need for a more sophisticated technical and philosophical understanding of BI systems. A number of researchers have described the differences between BI systems and operational systems (see Datta & Thomas, 1999; Fuchs, 2006; Han & Kamber, 2001; Ponniah, 2001; Power, 2002) and these are summarised in Table 1 below, followed by detailed discussion.

The major difference between operational systems and BI systems is in the general purpose of each. Operational systems are online transactional processing (OLTP) systems designed to expedite and automate transaction processing, record keeping, and simple reporting of transactions (Datta & Thomas, 1999; Power, 2002). These so-called “bread-and-butter” systems,

Table 1. Comparison of BI system with operational system (Adapted from Fuchs, 2006; Han & Kamber, 2001; Ponniah, 2002; Power, 2002)

Attributes	Operational system	BI system
Business purpose	Support the operational business activities in an efficient manner.	Support strategic and tactical activities by giving the right information and new insights to the business.
Characteristic	Operational processing	Informational processing
Orientation	Transaction	Analysis
Function	Day-to-day operations	Long-term informational requirements, decision support
Business	The users often have no choice whether or not to use the system; he or she is not obligated to use the system in order to conduct business.	"Voluntarily," in the sense that users can perform analysis and reporting with other tools (such as spreadsheets), even though it may be less efficient.
Education	Easy to plan, because an operational system often consists of fixed business process that need to be taught.	Difficult to foresee, as most BI systems allow for many nonprocesses based ways to create reports and analyses.
User type	Frontline worker, operational staff	Knowledge worker, managerial staff
IT support	Relatively easy to plan, unless the system suffers from quality problems.	Demands flexibility
Focus	Data in	Information out
Unit of work	Short, simple transaction	Complex query
View	Detailed, flat relational	Summarised, multidimensional
Operations	Index/hash on primary key	Lots of scans
Data content	Current values	Archived, derived, summarised
Data structure	Optimised for transactions	Optimised for complex queries
Database design	Entity relational based, application oriented	Star/snowflake schema, subject oriented
Access frequency	High	Medium to low
Access type	Read/write, update, delete	Mostly read
Usage	Predictable, repetitive	Ad-Hoc, random, heuristic
Number of records accessed	Tens	millions
Priority	High performance, high availability	High flexibility, end-user autonomy
Metric	Transaction throughput	Query throughput, response time
Response time	Sub-seconds	Several seconds to minutes
Number of users	Large number	Relatively small number
Development	Most operational processes are known and taken into account when implementing the system	The BI system develops over time, because it is often difficult to foresee the usage of a new and mostly non-process based system
User reaction in case of system failure	Immediate when the system is not working, because the day-to-day business stops	The user "can wait" in the sense that the business will go on, even though the BI system stops

such as sales order processing, procurement, inventory control, claims processing, billing, and so on, are not designed to provide business intelligence. They are used to run the repetitive, day-to-day core business of an organisation and to support its daily business processing by capturing information about the economic activities of the company (Ponniah, 2001). For example, information processed for each transaction may include a single invoice, a single order, or a single purchase. Hence, an OLTP system records current information and maintains a database of transaction information which is a predictable usage (Corey, Abbey, Abramson, & Taub, 2001) whereas a BI system uses those transaction data for analysis (Power, 2002). In brief, the purpose of operational systems is to record data in the database of computers (Ponniah, 2001).

In contrast, specially designed BI systems are not intended to run the core business processes, but aim to retrieve information from existing computer's databases (Ponniah, 2001). It is an online analytical processing (OLAP) system that is used to support decision-making and thus facilitate better managerial work. In this information environment, summarised and aggregated data are much more critical than detailed records (Datta & Thomas, 1999). As a result, business users are able to scour data for information about the business to provide tactical or even operational decision support (Turban, Sharda, Aronson, & King, 2007). Therefore, a BI system is intended to provide competitive advantages that make an impact on the bottom line of the organisation (Kulkarni & King, 1997). The typical output information consists of summarised reports and consolidated statements that provide a picture of the overall performance of the enterprise, and in so doing they enable insights, new thinking, and new understanding of the business to knowledge workers. The database typically contains long periods of historical data comprising hundreds of gigabytes and terabytes (Chauduri & Dayal, 1997).

An analytical processing using OLAP system is performed through comparisons or by analysing patterns. For instance, sales trends are analysed along with specific marketing strategies to determine the relative success of those initiatives. However, such analysis is difficult to perform with OLTP systems because the data are sourced from different information systems across multiple departmental units (Poe, Klauer, Brobst, 1997). In other words, a BI system can be viewed as market-centric with a shrinking information time window as opposed to an operational system that is customer-centric and time specified (Han & Kamber, 2001).

The differing requirements of OLTP and OLAP systems demand different data models for each type of system (Datta & Thomas, 1999). The relational data model commonly used in OLTP systems is not meant for effective querying and so is unlike the dimensional data model used in OLAP systems (Datta & Thomas, 1999; Goede, 2001). However, the dimensional design of an OLAP system is not suitable for OLTP systems because of redundancy and the loss of referential integrity of the data (Datta & Thomas, 1999; Goede, 2001). Although these two qualities are crucial in every information system, an OLAP system primarily emphasises flexibility in the retrieval of decision-relevant information in conducting analysis (Power, 2002). Also, Eckerson (2003) asserts that the relational design (of an OLTP system) enforces a business process structure which should not be changed regularly, but dimensional design (of an OLAP system) needs to be changed dynamically to meet the ever-changing needs of the business. Thus, an OLAP-based BI system aims to enhance effectiveness of business decision-making rather than increasing efficiency in processing transactional data (Power, 2002).

Moreover, the maintenance process for BI systems differs significantly from operational systems (Fuchs, 2006). Typically, an operational system implementation has a standard project management plan. Usually, the system maintenance and support are not considered as part of the project, but a future process for which a system maintenance team will be held responsible. Unlike BI systems, the maintenance part can be relatively small once the system is put in place. In contrast to operational systems, the overall project management of a BI system implementation takes into account the maintenance process during the outset (Fuchs, 2006). The BI project evolves into a process that turns some of the usual IT project phases into a well-defined repetitive process. In order to optimise the investment, the existing BI application would be measured against certain predefined metrics and overall benefits. Based on this, together with the evolving business and user demands, the system is further modified and improved. This adaptive process model acknowledges that the user's needs change over time and that their way of working with BI applications is often difficult to predict at one single stage. Thus the maintenance process optimises the current BI solution in corresponding to the changing needs leading to a perception of positive benefits (Fuchs, 2006).

Therefore, given the above substantial differences, organisations are compelled to implement two separate types of information systems, one being an OLTP-based operational system and the other an OLAP-based BI system. Whilst there have been a number of studies on CSFs for operational systems, their applicability to contemporary BI systems cannot be taken for granted. The subtle differences warrant rigorous research to specifically address the CSFs affecting the implementation of BI systems.

Research Aim

Given the motivation for this research and drawing on the CSFs framework developed in a previous Delphi study, the authors used multiple case studies to:

- Examine the CSFs and their associated contextual issues that impact the implementation of BI systems in EAMOs

The remainder of this chapter has been structured as follows. The following section describes the research framework and discusses the definition of success criteria in this study before elaborating on the research methodology. The later section then presents the research findings. In the subsequent section the authors discuss the findings of the study and then state their conclusions.

RESEARCH FRAMEWORK

Implementation Success Criteria

A rigorous review of the literature has indicated that it is very difficult to quantify the benefits of a BI system implementation using standard economic evaluation methods. While the cost and timeframe of a BI system implementation can be estimated, assigning monetary value to the benefits is difficult since the benefits can be intangible and transient (Rockart & DeLong, 1988). Instead, the return on investment in a BI should be included in those of the business process as a whole (Liautaud & Hammond, 2001). Therefore, the benefits perceived by business stakeholders in this study should be considered to be qualitative, and dependent upon the particular features of each individual case. Nevertheless, Delone and McLean (1992, 2003) have suggested that the success of an information system could be evaluated against a number of criteria, and other researchers, such as Wixom and Watson (2001) and Ariyachandra and Watson (2006), have proposed additional criteria that can be used to determine the level of success of a data warehouse-based information system.

Based on their combined suggestions, especially Ariyachandra and Watson's proposition (2006), the implementation success criteria of this research takes into account two key dimensions: *infrastructure performance*, and *process performance*. The infrastructure performance has parallels with the three major IS success variables described by Delone and McLean (1992, 2003), namely system quality, information quality, and system use, whereas process performance can be assessed in terms of time-schedule and budgetary considerations. Specifically, system quality is concerned with the performance characteristics of the information processing system itself, in which the system should be flexible, scalable, and able to integrate data (Ariyachandra & Watson, 2006; Delone & McLean, 1992, 2003). Information quality refers to accuracy, completeness, timeliness, relevance, consistency, and usefulness of information generated by the system (Ariyachandra & Watson, 2006; Delone & McLean, 1992, 2003; Fisher, Lauria, Chengalur-Smith, & Wang, 2006). System use is defined as "recipient consumption of the output of an information system" (Delone & McLean, 1992, 2003). Given that many theoretical and empirical studies have used and tested DeLone and McLean's IS success criteria (albeit with a number of multiple dimensions), it is considered that the success criteria provide a solid foundation for measuring implementation success, and thus are suitable for this study into the related CSFs.

CSF Reviewed

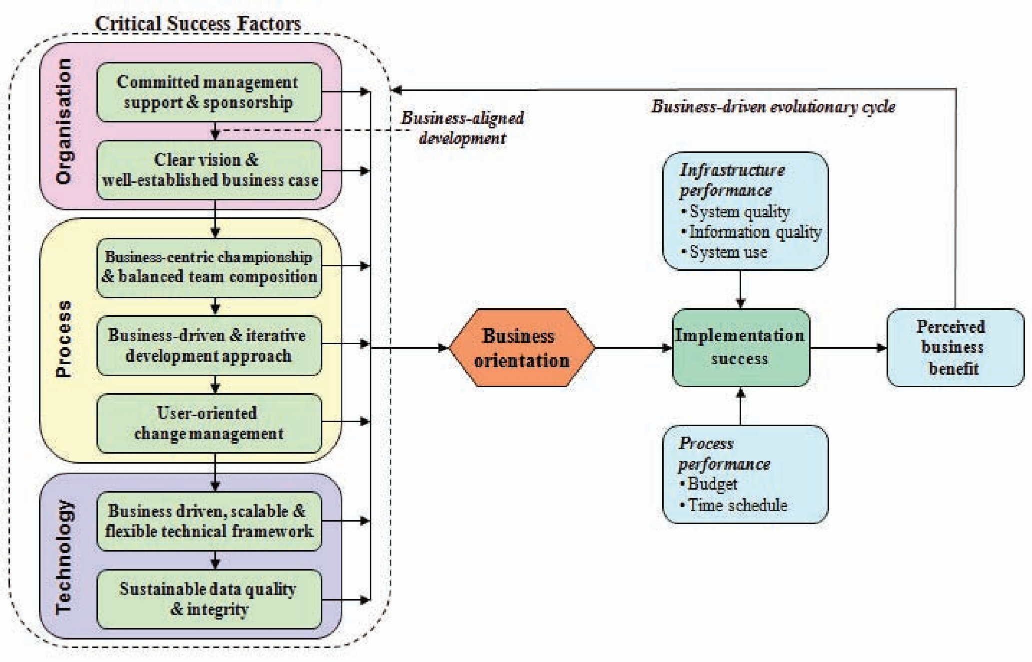
In the previous section, the measure for implementation success was introduced and defined. Those success criteria serve as the operationalisations of this study's dependent variables. The focus will now move on to the dependent variables, the so-called critical success factors.

There is relatively little academic literature on the subject of CSFs for successful BI system implementation. The field of BI systems is driven by industry, and it takes time for a tradition of academic scrutiny and evaluation to develop into a comprehensive literature. Nonetheless, there have been a number of studies which have sought to identify CSFs for the implementation of a data warehouse. Since a data warehouse is a core component of a BI system, their CSF studies are believed to be applicable to BI systems. Specifically, the synthesis of the literature (conducted in an earlier phase of this research, see Yeoh et al., 2006) provides a theoretical platform for this study about CSFs affecting the success of a BI system implementation. Following the literature review, a Delphi study was carried out with a panel of 15 BI system experts in order to identify the relevant CSFs (see Yeoh, Gao, & Koronios, 2007). Based on the Delphi findings, a CSF framework was developed to incorporate those CSFs which were endorsed by the panel.

This research framework outlines how a set of factors contribute to the success of a BI system implementation. It postulates that there is a set of CSFs which determine the quality of the BI system and its information output which, in turn, have a positive effect on the users' attitudes towards the use of the system. In other words, this framework treats the proposed factors as necessary factors for implementation success, whereas the absence of the CSFs would lead to failure of the system. Subsequently, individual users and their respective organisations would assess the benefits of the BI system implementation. This perception of the benefits would then become part of an interactive, business-driven evolutionary continuum to further support evolving business needs for improved BI systems (Arnott, 2004; Arnott & Pervan, 2005). This framework, and its related research issues, are the foci for the data collection and analysis of this research. The framework's components are illustrated in Figure 1. Within the framework, description of each CSFs identified by the Delphi study (Yeoh et al., 2007) is as follows.

Business orientation (BO) emphasises the business-aligned approach relating to the current and future needs of business intelligence in order to successfully address the CSFs influencing BI systems.

Figure 1. CSFs framework for implementation of BI systems



CSF#1: Committed management support and sponsorship*.* This refers to the commitment and sponsorship of top management to the BI initiative. This commitment is particularly required to overcome organisational challenges, including issues such as: flow of information, data ownership and technical framework development that is cross-functional, people issues, and consistent sponsorship of the initiative from the business side.

CSF#2: Clear vision and well-established business case. This refers to the existence of a strategic business vision with a clear outline of business objectives. In implementing BI systems, a detailed business case is required to describe the BI initiative in qualitative terms, and more importantly it must be aligned with the business vision. The case should clearly outline the business needs, processes and inadequacies of the existing information infrastructure to address the core decision-support problems of the business.

CSF#3: Business-centric championship and balanced team composition. This refers to a business-centric champion who views the BI system in strategic and organisational terms rather than in technical terms. Ideally the champion possesses strong business acumen, is technically knowledgeable, and committed to the leadership of the BI competency team. The team comprises cross-functional representatives from IT and business. They provide a central location to drive consistent BI deployments, and this ensures ease in coordinating and supporting BI and performance management initiatives that span multiple departments.

CSF#4: Business-driven and iterative development approach. The scope of the BI system implementation is clearly defined at the outset, and an incremental delivery (“iterative”) approach is adopted. The project commences in those areas which can readily be impacted in order to get buy-in and where programs can be scheduled to deliver quick wins.

CSF#5: User-oriented change management. Key users and relevant functional managers are involved throughout the entire implementation process, and during the business-driven, iterative maintenance process to develop further improvements. Training, education, and consistent support from the BI competency team are in place to induce individuals to embrace new practices, procedures, and technology throughout the period of the system implementation.

CSF#6: Business-driven, scalable, and flexible technical framework. This refers to the establishment of a strategic, scalable, and flexible technical framework covering both architecture design and data modelling in alignment with short and long-term business requirements, and including additional internal and external data sources. At the initial phase, a pilot prototype is used as proof-of-concept and stable source systems are in place.

CSF#7: Sustainable data quality and integrity. This refers to business-led establishment of common definitions, measures, and classifications that are used across the organisation, and the foundation of high-quality data at source systems, and a data governance framework is in place to monitor the data collection process.

RESEARCH METHODOLOGY

Methodology

This study applied a qualitative case study methodology with multiple-case design and content analysis techniques. The use of this approach is valid for the following reasons.

- As opposed to sampling logic, case study research is an empirical investigation following *replication* logic that leads to analytic generalisation (Eisenhardt, 1989; Yin, 2003); by
- Investigating a relatively new research area within a real-life context (Eisenhardt, 1989; Yin, 2003); to
- Provide in-depth and rich contextual information which describes an actual situation (Robson, 1993); from
- Rigorous observation and systematic examination using multiple sources (Miles & Huberman, 1994; Yin, 2003).

It should be noted that, unlike sampling logic, replication logic is a purposive selection—it does not aim to generalise the findings to an entire population (Firestone, 1993). Thus multiple case studies in this study should be regarded as multiple experiments and not multiple respondents in a survey (Yin, 2003). That is, relevance rather than representativeness is prioritised in case selection. Within each case, and guided by the research questions, the need for in-depth investigation and richer understanding of critical factors within the organisation's real-life context was the subject of this study. Given the research objectives, case study research with multiple-case design was the appropriate methodology.

Research Site

In order to maintain homogeneity and thus lessening the potential for confounding effects of different industries and IT environments, it was decided that all case organisations should come from the same industry. The engineering asset management organisations (EAMOs), such as electric, gas, water utilities, and railway companies, were selected for three reasons. First, the types of information systems in these asset-intensive organisations are identical. Typically, they are composed of asset operational systems, maintenance systems, condition monitoring, work management, and contract management. Secondly, due to fierce competition resulting from deregulation, increased regulatory compliance, and governance requirements, many EAMOs are on the verge of implementing large-scale BI systems, yet there is very limited literature to guide such organisations. For instance, a recent BI project introduced by an Australian water utility cost several millions dollars (LeMay, 2006). Third, the experiences of such EAMOs (that are traditionally characterised by its silo information environment) could provide better insights and richer contexts for comprehensive understanding.

Furthermore, fear of a shortage of cases was eliminated because this research was supported and sponsored by the Cooperative Research Centre for Integrated Engineering Asset Management (CIEAM). Hence, the BI system usage in this study focuses on the asset management business rather than the conventional market-centric applications. To assess the importance of the seven previously-identified CSFs, the authors studied five Australian EAMOs that had implemented BI systems. The backgrounds of these case companies are illustrated in Table 2.

Data Collection

Data collection for this study entailed semistructured interviews with key stakeholders of BI projects, and those interviewed included project managers, end users, key project stakeholders (who have been involved directly in either business or IT functions), and in two instances, external consultants/contractors. To facilitate data triangulation, data were also gathered from a number of sources including relevant documents (such as business cases), training documents, presentation slides, and publicly available reports (such as annual reports and financial statements).

In order to maintain consistency of questioning, the authors used the CSF research framework as a basis for the interviews, inviting participants to comment on the proposed CSF framework. After the interview, further clarifications (if any) were made by follow-up phone calls. The authors also observed the BI system in operation and gathered data about the CSFs for BI system implementation. However, the authors were cautious about being over-reliant on key informants, and attempted to seek contrary evidence when possible in order to corroborate findings and issues from other interviewees.

A cross case analysis approach was used in this study to gain better understandings and increase the generalisability of the findings (Miles & Huberman, 1994). In searching for patterns, the authors examined similarities and differences about relationships within the data (Eisenhardt, 1989). Hence, varying the order in which case data are arrayed enables patterns to become more obvious (Stuart et al., 2002). Moreover, this research did not produce quantitative data. In all cases, the authors were examining the pres-

Table 2. Background of case organisations

Case	Types of EAM Industry	Annual revenue *	No. of staff **	Total assets #
C1	Rail transport and network access	M	M	L
C2	Rail transport and network access	L	L	L
C3	Builder and maintainer of large engineering asset	M	M	S
C4	Electric and gas utilities	L	M	L
C5	Water, sewage, recycled water utilities	L	M	L

Note: Case descriptions have been disguised slightly to preserve the anonymity of participants.
**Small=<AUD $100 million, Medium=AUD $100 to $1000 million, Large= >AUD$1000 million*
*** Small = <1000 staff, Medium = 1000-5000 staff, Large = over 5000 staff*
#Small=<AUD $1000 million, Medium=AUD $1000 to $5000 million, Large= >AUD$5000 million

ence or absence of a particular CSF (e.g., were adequate resources provided?), while at the same time ascertaining whether that characteristic was fulfilled in a meaningful way.

RESULTS

Implementation Success

After analysis of the triangulated results for all five organisations, three instances of notable success emerged, together with one moderately successful case and one failure. The three successful cases of BI system implementation described their respective BI systems as stable, easy to use, fully functional, flexible, and responsive within anticipated times. Furthermore, the information generated was considered accurate, timely, complete, consistent, and relevant to most participants. In addition to the encouraging trend of system use among end-users, the project leaders of these organisations confirmed that their implementation projects were completed on time and within budget. However, the moderately successful case was experiencing uncontrollable external factors in its BI system implementation. The key application of its BI system was not identical to those of conventional commercial enterprises. Due to its unique form of business and the peculiar bonus system with its major client, it was more concerned with ensuring on-time delivery of assets and meeting quality and safety standards rather than reducing costs or staffing. The BI system thus enables them to analyse and investigate underlying business activities with ease. Also, auditable reporting can be generated from the system to assist the business meet its strict regulatory requirements.

On the other hand, the firm that experienced BI failure did so because it encountered business issues at the early phase of its implementation process. The business needs and requirements for BI system had not been clearly defined, yet there existed silo information systems with multiple versions of the truth. In that firm the BI initiative was driven mainly by the IT department alone and was viewed as a technological issue, and as a result the management had to suspend the BI initiative. This instance of failure served as a useful contrast case for comparative analysis in this research. Table 3 summarises the findings of implementation success for all cases.

Table 3. Implementation success measure for the five cases (source: developed from field data)

Success measures / Case code		**C1**	**C2**	**C3**	**C4**	**C5**
Infrastructure performance

2	Information quality	✓	✓	✓	✓	X
3	System use	✓	✓	*N*	✓	N/A
Process performance						
4	Budget	✓	*N*	✓	✓	X
5	Time schedule	✓	✓	✓	✓	X
	Overall	S	S	*N*	S	*U*

Note: ✓=Good; N =Acceptable; X=Poor; S=Successful; N =Partially successful; U =Unsuccessful

CSFs Observed

To demonstrate how the implementation success compared against the management of the CSFs of the five case organisations, an analysis of the CSFs 1 to 7 was conducted through a cross-case analysis. Table 4 summaries the relevant CSFs performance in matrices recommended by Miles and Huberman (1994), and these were used as an initial step in analysing patterns in the data. For each case, management of each CSF is rated through a summary rating of ✓ (for a CSF that was fully-addressed), *N* (for a CSF that was partially addressed), or X (for a CSF that was ignored). Moreover, the summary ratings are supported through factual data from field research with each organisation.

OVERALL ANALYSIS AND DISCUSSION

The CSFs identified from a previous Delphi study were examined empirically in five engineering asset management organisations. This section discusses the qualitative results of the case studies. Essentially, the evidence from these studies clearly substantiated the construct and applicability of the multidimensional CSFs framework proposed in the previous Delphi study. More importantly, the studies further reveal the significance of addressing those CSFs through the *business orientation* approach. That is, without a specific business purpose, the BI initiatives rarely produce a substantial impact on business. As a result, the implementation of a BI system has a much greater likelihood for success when business needs are identified at the outset and used as the driver behind the implementation effort. Thus, the entire system implementation must be business-driven and organisation-focussed. It should also have interactive business-side involvement, and be adapted to meet evolving business requirements throughout the lifecycle. Invariably, a "build it and they will come" approach which overlooks business-focused strategies in system implementation proves to be unsatisfactory and very expensive (Bates, 2000). In other words, this particular metafactor (i.e., a business orientation approach) dictates the commandment of the proposed CSFs, particularly within the following important aspects: business case formation, management commitment, championship, team composition, scoping and development methodology, organisational change management, technical framework development, data model, and data quality issues.

In essence, the three successful cases (C1, C2, and C4) seemed to emphasise the business-oriented approach when addressing the CSFs, while the partially successful case (C3) appeared to comprise a mixture of business and customer-centric approaches. The instance of failure (C5) was not totally business-driven but instead was technology oriented. The three successful cases shifted their focus from the technological view and instead adopted an approach that put their respective business needs first. On the basis of these case studies, it is apparent that the manner in which an organisation addresses those CSFs, whether through a business-oriented, technology-oriented, or customer-oriented approach, will have a substantial impact on the implementation outcome. Having a clearly-defined set of CSFs is important, but it is even more critical to address the CSFs from the right approach. In the case of BI systems implementation, the triangulated data of case studies clearly demonstrates that by placing business needs ahead of other issues an enterprise has a higher likelihood of achieving a useful business information system.

In order to meet the need for systems which provide management with dynamic analytics and business reporting, the findings of these case studies indicate that business stakeholders should involve interactively throughout the implementation process. One explanation is that a BI initiative "provides the users with access to information that

Table 4. Evaluation of critical success factors in multiple EAMOs

CSF	C1 (Rail company)	C2 (Rail company)	C3 (Large engineering asset builder and maintainer	C4 (Electric utility)	C5 (Water utility)
Background *Note:* *BIS = BI system*	*Due to new arrangement, the company has acquired a competitor company and is now overseeing a much wider area of rail network. *The BIS success story of the acquired company has inspired the executives to expand the BIS initiative to an enterprise-wide scale. *In order to facilitate "one-stop" planning, reporting and business analysis, the company adopted BIS with great enthusiasm.	*The company has been using BIS for more than a decade initially for its various silo functional needs, such as safety reporting, network access, maintenance and operation. *To better facilitate overall business performance, the organisation has recently been restructured accordingly, and the silos BIS are undergoing amalgamation.	*BIS was implemented as part of its ERP package. The key use of the system is for business reporting, analysis of asset lifecycle performance and supply chain management. *Due to its unique business nature, the BI tool was not meant to cut down the operating cost or for competitive advantage, but rather to meet the strict compliance requirements and bonus system.	*BIS was implemented for advanced analysis, planning and risk management of the vast electricity network. *Due to market deregulation, legislative compliance and auditing requirement, BIS was adopted and widely supported by all stakeholders. * For the BIS, conformance and compliance is more critical than cost saving.	*The BI initiative was mainly driven by its manager of business information system, who is a technology enthusiast. *He has been promoting the advantages of BIS, and organised a number of interactive sessions with BI vendors. *However, the BI effort was not supported by business stakeholder, as they clearly failed to identify their BI needs and requirement.
1. Committed management support and sponsorship	✓ *There was consistent support from the executives, and direct endorsement from the CEO. *Their endorsement of the BIS commanded respect and interest among others. *Budget described as generous.	✓ *The initial BIS development was strongly supported by functional managers. *Now the silos BIS have gained the attention of top executives. *As a result, it involved some degree of organisational restructuring (i.e., an amalgamated BIS is in progress for its major network access and maintenance divisions). *Budget described as adequate.	*N* *Initially the executives focused more on the benefits of ERP than the BIS. * However, the BIS was gaining momentum as in supporting auditable business reporting and complying with the needs of its key client and strict regulation. *Budget described as adequate.	✓ * Top management support was strong, MD is crucially aware. *Budget described as generous. * Top-down commitment was shown in defining process of business needs and report requirement.	X *Top management was not convinced about the usefulness of a BIS to their business. *The executives rather supported its ERP modules expansion projects.

continued on following page

Table 4. continued

2: Clear vision and well-established business case	✓ * There is clear business vision for the BI system adoption. * A link from the BI system to business objectives is defined. * The current BI initiative spans all functional boundaries of asset management. * The business case was highly endorsed by top management and supported by all relevant stakeholders.	✓ * Initially the business vision was more functionally oriented, but recently an enterprise-wide business vision has been in place. * The recent amalgamated BI initiative was a vision of top management. The actual business case is still in the preparation stage.	*N* * There was some degree of business vision in place, but the business case was mainly driven by its key customer who is still very influential. * The company was initially seen as a purpose-built contractor of the customer (who actually still maintains a large share of ownership with the company).	✓ * The current BI initiative spans all functional boundaries of asset management. * The business case was highly endorsed by top management and supported by all relevant stakeholders, and particularly welcomed by business analysts and general users.	X *There is no clear business vision from the senior management. *Business case was driven by technology and thus received little support from the business side.
3. Business-centric championship and balanced team composition	✓ *The team consists of IT manager (champion) and several IS staff in partnership with external consultants. *Particularly, the champion played a successful role as "coordinator" among executives, business stakeholders and key users. *However, the actual construction of the system was developed by external consultants and contractors with the assistance of some internal IS staff. *On-going incremental development was carried out by the internal team.	✓ *Owing to legacy, the two main silo BIS are championed respectively by two individual project managers. However, a "middleman" was recently appointed to coordinate silo BI systems integration issues from business perspective. *All systems were developed in-house and maintained by a large team and contractors. *The team comprises both BIS experts and business personnel. *Though the IT department alone comprises more than 50 competent IS employees, the challenges of silo BIS integration was due to the business issues.	*N* *Initially, the manager of business information system acted as the champion, but the actual implementation was contracted to external consultants and IT vendor. *After the system was in operation, a business analyst was assigned to the role of system owner to oversee the maintenance task. Nonetheless, his role is more like a coordinator between users and service provider.	✓ *The BI initiative was championed by a designated system manager, who was also a senior electrical engineer with strong business acumen. *The system was mainly developed by external contractors and assisted a team of internal IS staff. *For on-going development, a team of internal IS staff in partnership with external contractors acted upon the request of key users during regular review and, occasionally, upon ad-hoc request.	X *The BI initiative was championed by manager of business information system, a technology enthusiast. *The BI team comprises IT personnel only with minimal participation from business side.

Table 4. continued

4: Business-driven and iterative development approach	✓ *Project scope was clearly defined, covering almost the whole enterprise. *Top-down approach for setting report requirements. *Incremental delivery approach was adopted over a number of phases to deliver quick wins. *The project started on area most easily impacted. *The team learnt from the BIS experience of acquired company, and practiced it in parent company.	✓ *Project scope is clearly defined by functional area, but not meant to be enterprise-wide. *For second phase integrated BIS, incremental delivery approach was adopted with the initial focus on business integration issues. *Technical solutions will be introduced later according to the identified business problems.	*N* *Project scope was limited to those involved in asset management and integrated lifecycle support area. *Top-down approach was adopted as the company had little choice over the system vendor.	✓ *Project scope was clearly defined for engineering side of the business. *Incremental delivery approach was adopted to deliver quick wins. *Reporting requirement was set via top-down approach, but bottom-up implementation was widely practised.	X *Project scope is clearly defined. *The project started on several areas at once, "big-bang" approach. *The team faced communication issues with the business stakeholders.
5: User-oriented change management	✓ *The project manager consulted the CEO and top management individually before making final case. *Key business stakeholders and users were involved with project throughout the implementation process. *Consistent support was in place.	✓ *The users were familiar with and dependent on the BIS, and generally welcomed the integrated BIS effort. *Education was not an issue. *When any new requirement arose from respective functional units, unit manager called-in as local champion. *Consistent support is in place.	X *Users were not consulted but rather asked to use the system, especially in meeting the compliance requirement set by its key customer. *Consistent support is in place.	✓ *Key business analysts/users were involved from outset. *Regular workshops were conducted with user group. *Consistent support was in place.	X *Business stakeholders and key users were not involved in the early phase. *Business side were asked to suggest their BI needs rather than based on genuine, evolving business requirement.

*Note: * denotes emerging finding from multiple case studies*

Table 4. continued

6: Business-driven, scalable and flexible technical framework	✓ *The ERP implementation laid a solid infrastructure foundation for the BIS. *The data model was flexible, scalable and extensible cross all functional areas. *The technical framework was standardised centrally and driven by business needs. *The compatibility of various analytical, reporting and mining tools with the ERP was validated at outset.	*N* *The silo BIS and ERP implementation had provided adequate infrastructure foundation for the integrated BIS. *Though the data model of silo BIS was adequate and extensible, it was not meant for integrated BIS. *Integrating those silo BIS posed compatibility issues due to different IT vendors. *The team was working on the broader data model and technical framework in order to integrate the silo BIS.	✓ *The ERP implementation laid a good infrastructure foundation for the BIS. *Although the data model was flexible, scalable and extensible, it was limited to certain functional areas only. *There was a standardised technical framework, but with limited extensibility. *There was no compatibility issue for the various analytical and reporting tools as those tools are strategic partners of its ERP system.	✓ *The implementation of integrated asset management system provides a good infrastructure foundation for the BIS. * The data model is flexible, scalable and extensible across all asset management domains. *There was a standardised, scalable and extensible technical framework to accommodate both advanced analytics and mining requirements.	*N* *The ERP implementation and various silo systems provide somewhat stable foundation for BIS infrastructure. * The data model is flexible and extensible but meant for functional needs. *The technical framework is extensible to accommodate BI requirement. *There is compatibility issues with various IS application.
7: Sustainable data quality and integrity	✓ *Master data management approach was adopted. *A data dictionary framework was in place. It included a data governance committee, corporate coding policy, corporate glossary, and data dictionary. *A corporate data model has been developed, which includes candidate information entities and subject areas and baselines. *In doing so, workshops, interviews and questionnaires were done; corporate systems were reverse engineered. *Transaction systems were aligned to facilitate common hierarchy for management reporting and communication.	*N* *A functionally-based data dictionary framework was in place, and includes corporate glossary and data dictionary. *To address multiple versions of truth, the newly appointed Integrated BIS champion and the business decision support personnel were preparing a core asset information oriented framework. *These silo BIS are reverse-engineered, high-level steering committee and workshops were in place.	✓ *The quality of data was adequate as most of the glossary and measures had been fully supplied by its key customer. *The role of the data steward was well defined as being the functional steward. *Within the system, there was an automated data quality "watchdog" mechanism to track operational data quality issues. *Data provider will be alerted and asked to solve the issues.	✓ *A data dictionary framework was in place. *Data quality working group, corporate glossary and data dictionary were in place. *There were regular workshops with the key users. *Users were pro-active to report any data quality issues, and actions were taken promptly. *Data cleansing tool was applied.	*N* *A functional-based data dictionary framework is in place. * Visualisation tool and pictures of assets were incorporated as part of data quality and validation effort. *The data inconsistency was usually validated by long-time experienced personnel.
***Overall business orientation approach**	✓	✓	*N*	✓	X

*Note: * denotes emerging finding from multiple case studies* they did not already know that can actually be used to change their actions and decisions" (Hancock & Toren, 2006). In other words, it necessitates the participation of business stakeholders in the development of a process of business analysis and reporting that usually demands practical business experience (Hancock & Toren, 2006). Moreover, due to evolving business needs and ever-changing information requirements, it was found that the respective BI teams had to provide continual high-level maintenance and support not only on tools application, but also at broader data modelling and system scalability issues. The designing of data models and system architecture frameworks needs consistent input from those most familiar with the business needs of the enterprise.

In summary, the three successful cases clearly demonstrated that addressing the CSFs from a business perspective was the cornerstone on which they successfully based the implementation of their BI systems. Conversely, the unsuccessful case failed because it focused primarily on the technology and neglected the core requirements of its business. In order to better address the CSFs, it is essential for an organisation to emphasise the business orientation approach, and in so doing it will gain an advantage over competitors. Indeed, this view was supported by Gartner Research, which stated that, "best in class organisations focus on business objectives and use a business-driven approach to define and scope their people, process, application, technology and/or services strategy" (Burton, Geishecker, & Hostmann, 2006).

Also, it is relevant to note that in implementing a BI system neither data nor technical factors appeared to be as critical as other organisational and process factors. According to most research participants, technological difficulties can be solved by technical solutions. However, it was found that achieving management and organisational commitment for a BI initiative poses the greatest challenge because the BI teams considered them to be outside their direct control. The level of organisational support is reflected in the attitudes of the business stakeholders; that is, their attitudes to change, time, cost, technology, and project scope. Based on a large-scale survey result, Watson and Haley (1997) similarly pointed out that the most critical factors for successful data warehousing implementations (the antecedent of BI systems) were organisational in nature. Thus, committed management support and adequate resources were found to determine the implementation success because these factors worked to overcome sociopolitical resistance, address change-management issues, and increase organisational buy-in. This finding was also congruent with Gartner's recent observation that "overcoming complex organisational dynamics will become the most significant challenge to the success of BI initiatives" (Burton et al., 2006). Therefore, organisational and process-related factors must not be taken for granted in the implementation of BI systems.

CONCLUDING REMARK

Implementing a BI system is a costly, resourceful, and complex undertaking. This study examined the CSFs impacting BI systems implementation in EAMOs. Based on a previous Delphi study, it developed a multidimensional CSF framework for understanding those CSF issues. These CSFs are: committed management support and sponsorship, a clear vision and well-established business case, a business-centric championship and balanced team composition, a business-driven and iterative development approach, user-oriented change management, a business-driven, scalable and flexible technical framework, and sustainable data quality and integrity.

Subsequently, the proposed CSFs were then examined empirically in case studies of five engineering asset management organisations. The evidence from these studies clearly confirmed and substantiated the construct and applicability of the CSFs framework. Within the set of CSFs, an analysis of the findings indicated that non-technical factors, including organisational and process-related factors, were more influential and important than technological and data-related factors. More importantly, the research suggests that organisations are in a better position to successfully address those CSFs through the *business orientation* approach. Thus this business orientation meta-CSF should be regarded as the most critical factor in determining the implementation success of BI systems.

This research has made a contribution to our understanding of the CSFs that impact on BI systems implementation. The literature review reveals that there is a lack of research on CSFs for successful implementation of BI systems. This study, therefore, fills in the research gap. This research provides thought-provoking insights into multidimensional CSFs that influence the implementation of BI systems. The CSFs which have been identified allow a clear understanding of the pivotal factors that must be addressed. Hence, it focuses attention on those important areas that might otherwise be neglected or taken for granted but are significant for the implementation success. Moreover, the consolidated CSFs framework provides a significant contribution to theoretical understanding of how implementation of BI systems can be improved. More specifically, the findings suggest that in investigating the critical success factors researchers should not only consider the technical context but also focus on organisational and process dimensions to provide a more comprehensive research approach.

Not only does this research contribute to the academic literature on this topic but it also benefits organisations in several ways. The identification of CSFs enables BI stakeholders to gain a comprehensive understanding of those CSFs through a business orientation approach, especially in the planning and management of BI initiatives. Such outcomes will help them to determine those factors to which they should give priority. It also helps to ensure that those CSFs will receive deliberate and continuous management scrutiny. For senior management, this research finding can certainly assist them by optimising their scarce resources on those key areas that are most likely to have an impact on the implementation of the BI systems. Moreover, the management can concentrate their commitment to monitor, control and support those critical areas of implementation. In short, the CSFs findings represent the best practices of firms that have successfully implemented BI systems. The empirical evidence that was revealed provides insights for BI stakeholders and will significantly increase the chances of implementation success. Those that address the CSFs from a business orientation approach and translate the business needs into a well-managed BI system implementation will likely succeed.

IMPLICATION FOR FUTURE RESEARCH

The results of this study suggest several areas for future research. They include replication of current study, theory testing research, and longitudinal study. First, this research focused on engineering asset management industries that implement BI systems for better managing their asset-intensive business. Thus, further empirical research in other industries or in other countries may shed light on where and how the research findings can impact the success of a BI system implementation. Research on cross-industry or across-country comparisons of CSFs will enrich and complement this research with additional insights, and possibly new understanding of factors.

As it stands, this study was exploratory in nature and hence quantitative research can be conducted using a structured questionnaire with adequate samples. It could provide insight into the correlation between factors identified in the CSFs framework and determine the generalisablity of this study. In addition, a longitudinal study may be useful to further test the theory built in this research. It would be ideal if a researcher could observe a case organisation prior to commencing a BI system implementation project, and then follow the progress of implementation to completion. Nonetheless, a longitudinal research would require a long-term commitment by both the researcher and the participating organisation.

ACKNOWLEDGMENT

This research is conducted through the Cooperative Research Centre for Integrated Engineering Asset Management (CIEAM). The support of CIEAM partners is gratefully acknowledged.

Chapter 6.8

Exploring Relationship Between Information Systems Strategic Orientation and Small Business Performance

R. Rajendran
Sri Ramakrishna Institute of Technology, Coimbatore, India

K. Vivekanandan
Bharathiar University, India

ABSTRACT

Businesses invest in developing information systems resources to gain competitive advantages. Literature has demonstrated the requirement of strategic alignment in converting these competitive advantages into sustained superior business performance. The knowledge of information systems strategic orientation and its relationship with business performance will enable these businesses to fine tune their strategic information systems applications portfolio in achieving required strategic alignment. This study focuses on the information systems strategic orientation of small businesses and investigates its relationship with their perceived business performance. The organizational impact of adoption of the initial stages of electronic business development is also examined. The data were collected from small businesses on nine strategy areas, through mail survey. The result reveals three multifaceted dimensions of information systems strategic orientation. These dimensions of strategic orientation have significantly influenced their business performance. For the adopters of Web presence, all these three dimensions remain significant in explaining their business performance.

INTRODUCTION

Small businesses are an important and integral part of every nation's economy and their contributions are significant in the present business environment of globalisation and digitization. In response to changes in their environment, these small businesses are investing in information technologies at an increased rate to develop information systems to support their business strategy. The small businesses use the Internet and establish Web presence as a complement to traditional way of competing. Weill (1990) found that investment in strategic information systems, rather operational information systems, was risky but with a potential for high payoff in the long term. The Internet architecture has turned information systems into a far more powerful tool for strategy (Porter, 2001).

The translation of information systems investment into the attainment of competitive advantage and increased business performance are the focus of the attention of these small businesses. The knowledge about the extent to and manner in which information systems complement company strategy will help small firms to prioritize relative information systems investments. This enables small businesses to adjust portfolios of strategic information systems so that they could provide more business support that leads to superior business performance.

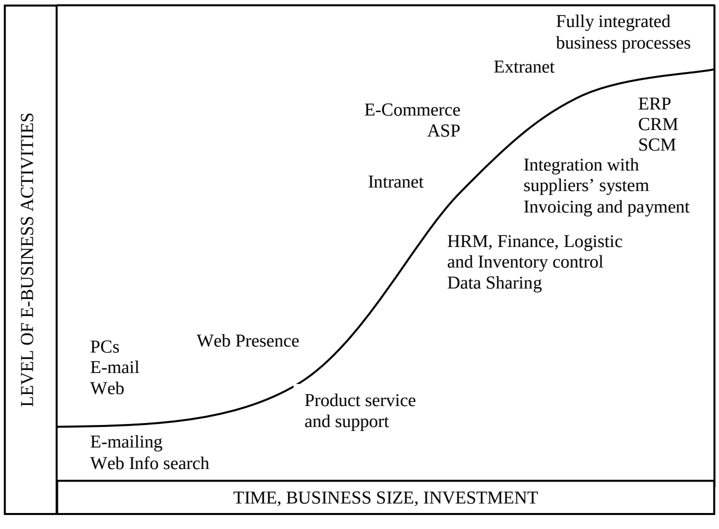
The present study examines the information systems strategic orientation in small businesses and explores its relationship with business performance. To study further the consequences of adoption of Web presence, one of the earlier stages of electronic business development (Figure 1), the impact of Web site ownership on the degree and the direction of this relationship is investigated.

The subsequent sections present the review of literature on strategic management of information systems in small businesses and describe the methodology used by the present study and it is followed by the presentation of results. Then the research findings and their implications are discussed. The article concludes with the summary of the study and its contributions.

Literature Review

Businesses allocate resources to develop information systems because it is believed that these investments provide them with competitive advantages and economic returns. While small businesses have been traditionally seen reluctant to develop information systems strategy (Hagmann & McCahon, 1993; Mehrtens, Cragg, & Mills,

Figure 1. E-business development (Source: E-Commerce and Development Report 2004, United Nations, Geneva, 2004, p 53)



2001), evidence over the past decade shows an increase in strategic use of information systems in small businesses (Naylor & Williams, 1994; Poon, 2000).

The information systems have evolved from its traditional orientation administrative support toward a more strategic role within an organization (Henderson & Venketraman, 1993). Blili and Raymond (1993) emphasize that small businesses must adopt some kind of framework for strategic planning information systems, if they wish to create information systems-based strategic advantage. Levy and Powell (2000) propose an approach (Figure 2) to information systems strategy development for small businesses.

For small businesses, the strategy execution perspective (Figure 3) proposed by Henderson and Venkatraman (1993) is more appropriate. This perspective is anchored on the notion that a business strategy is the driver of both organizational design choice and the design of information systems infrastructure. They argue that the

Figure 2. Information systems strategy approach for SMEs (Levy and Powell, 2000)

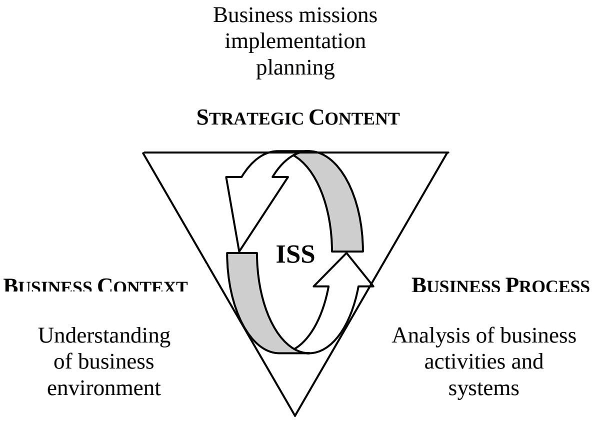


Figure 3. Strategy alignment model with strategy execution alignment perspective (Henderson and Venkatraman, 1993)

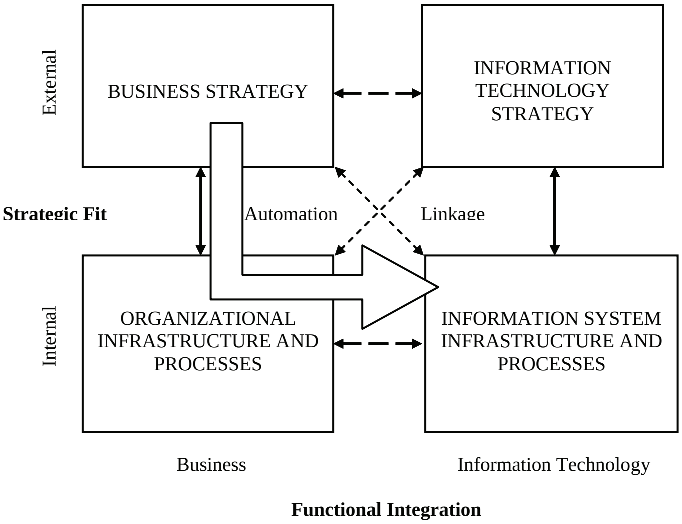

top management should play the role of strategy formulator to articulate the logic and choices pertaining to business strategy, whereas the role of the information systems manager should be that of a strategy implementer, who efficiently and effectively designs and implements the required information infrastructure and processes that support the chosen business strategy.

The resulted information systems strategy with implemented information systems infrastructure and processes, constitute the information systems resource for small business. The organizational performance impact of the information systems resource is commonly referred to as IT Business Value (Melville, Kraemer, & Gurbaxani, 2004). The process of IT business value generation is shown in Figure 4.

Wade and Hulland (2004) describe information systems resources using six resource attributes viz., value, rarity, appropriability, imitability, substitutability, and mobility based on the finding of prior information systems research. In resource-based view (Figure 5), these information systems resource attributes will enable a firm to achieve competitive advantages over others and lead to superior long-term performance.

However, resources rarely act alone in creating and sustaining competitive advantage. The information systems resources normally act in conjunction with other firm resources to provide strategic

Figure 4. IS business value model (Melville et al., 2004)

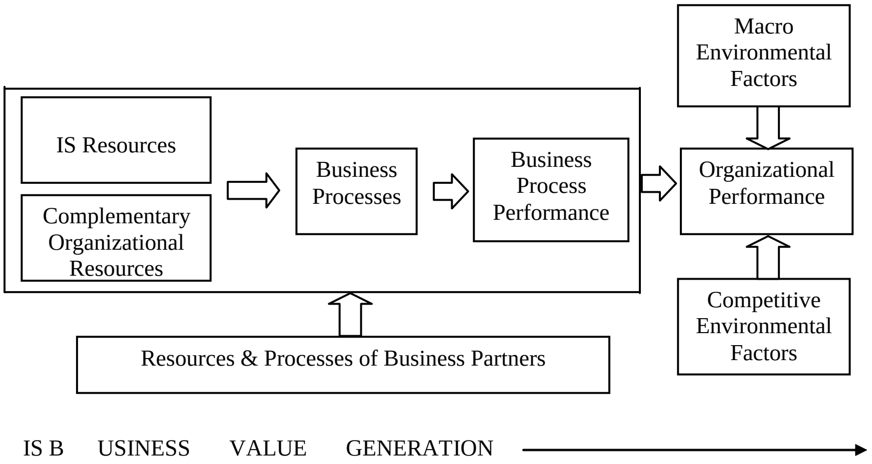

Figure 5. Resource-based view of IS (Wade and Hulland, 2004)

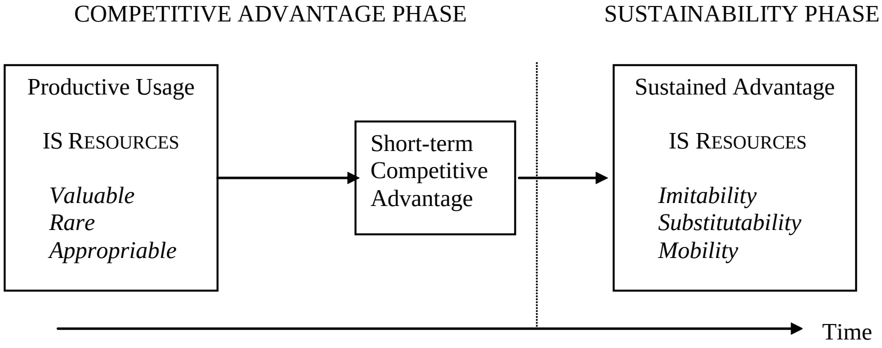
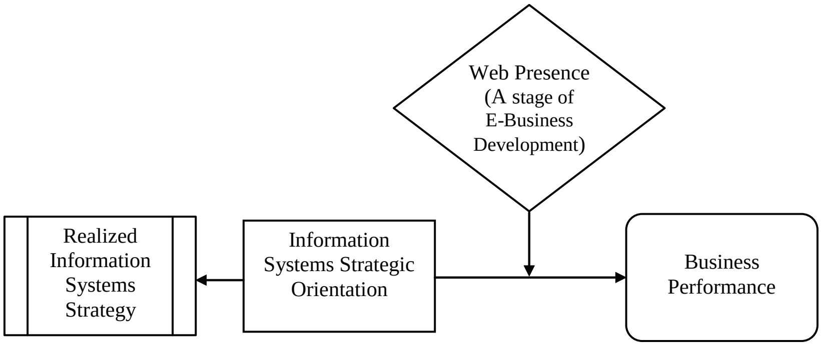


benefits (Ravichandran & Lertwongsatien, 2002). Benjamin and Levinson (1993) conclude that performance depends on how information systems resource is integrated with organizational, technical, and business resources. Chan, Huff, Barclay, and Copeland (1997) argue that the impact of information systems on performance may not be a direct one, but intermediated by other factors such as the alignment between information systems strategy and business strategy.

Luftman, Lewis, and Oldach (1993) recognize that for companies to succeed in an increasingly competitive, information intensive, dynamic environment, the alignment of business strategy and the information systems strategy is a necessity. Alignment expresses an idea that the objective of design, for example, an organizational structure or its information systems must match its context in order to be effective (Iivari, 1992). Strategic orientation expresses this context and its relationship with business performance, will set the direction to the measurement of strategic alignment. The moderation model of strategic alignment suggests that the strategic orientation of a business determines the relative importance of the alignment dimensions. Strategic orientation of information systems indicates the degree of information systems support for each strategic alignment dimension.

The strategic orientation of the existing portfolio of information systems applications, representing the general pattern of realized information systems strategy provides valuable predictive information regarding perceived business performance. Venkatraman (1989) identifies key traits of business strategic orientation based on the theoretical perspective and specifies the following six characteristics as dimensions a priori in developing valid measurement for strategic orientation of business enterprises (STROBE): Aggressiveness, Analysis, Defensiveness, Futurity, Proactiveness and Riskiness. Chan, Huff, Barclay, and Copeland (1997) use these dimensions to hypothesize the structure of information systems strategic orientation. But the empirical findings of their study suggest a parsimonious taxonomy of three generic realized information systems strategies. The three core dimensions of information systems strategic orientation that emerged are information systems support for anticipation, information systems support for analysis and information systems support for action. But the emergence of these dimensions is ignored in the further analyses of their study. However, they conclude that the concept of information systems strategic orientation is somewhat novel and is an area ripe for future information systems strategy research. Thus, a relevant question for small business information systems strategy research study could be to derive information systems strategic orientation and examine the efficacy of the dimensions of orientation to generate business value within the conditions set by the information systems resources (Figure 6). The approach

Figure 6. Research model



represented in the research model (Figure 6) is to empirically derive dimensions of information systems strategic orientation, a posteriori.

The recent streams of studies on net-enhanced large business organizations suggest that e-business initiatives tend to make information systems resources more valuable. Zhu and Kraemer (2002) emphasize that Web presence promotes the business value generation capability of information systems resources. To validate this finding in the small business context, the role of the Web presence in determining the relationship between information systems strategic orientation and their business performance could be investigated (Figure 6).

RESEARCH METHODOLOGY

Research Instrument

The studies of business strategy in small businesses provide evidence that small businesses have to adopt numerous strategies. Storey (1994) identifies strategy as one of the three main components that contribute toward growth among small businesses. Sougata (2004) argues that the environment played a significant role in shaping business strategy during reforms. These studies have drawn on typologies based on large firms viz. Ansoff (1965)'s matrix of strategies (Barkham, Gudgin, Hart, & Harvey, 1996; Hewitt-Dundas & Roper, 1999) and Porter (1980)'s generic strategies (Namiki, 1988; Reid, 1993; Kakati & Dhar, 2002). Julien, Joyal, Deshaies, and Ramangalahy (1997) have found out that exporters compete on price, technical superiority, product quality, and customer service. Gunasekaran, Okko, Martikainen, and Yli-Olli (1996) identify productivity and quality improvement strategies based on cost control, improving quality, new product, lower price, fast delivery, and increased market share, for small and medium enterprises in the manufacturing sector.

These studies have produced different typologies and have failed to provide a consensus model of strategy for small businesses (Southern & Tilley, 2000). As the approach to strategy formation in small business is informal, inexplicit, intuitive, and incremental (Mintzberg, 1988), the explicit identification of strategy is found to be more difficult (Lefebvre et al., 1992). Cragg, King, and Hussin (2002) extracted key factors that contributed toward small business competitiveness from these studies. Pretesting with practicing owner/managers of small businesses, they refined this list of business strategy items. For the present study, these nine strategies (Table 1) are considered as business strategies of small businesses.

As explained in the earlier paragraphs, the planning and development of strategy in small businesses are embryonic and informal. To capture the actual and realized deployment of information systems applications, the instrument for information systems strategies was designed around the same nine business strategies shown in Table 1 (Chan et al., 1997; Cragg et al., 2002). For each business strategy item (question), a parallel information systems strategy item was created to assess the extent to which the information systems support that particular aspect of business strategy. A five point Likert scale was used for measurement.

From a business perspective, performance is

Table 1. Business strategies of small businesses

7	Process Efficiency Strategy
8	Product Differentiation Strategy
9	Product Diversification Strategy

a complex and multifaceted concept (Venkatraman & Ramanujam, 1986). Strategic management research literature proposes a subjective approach to measure business performance and it is appropriate in a small business context where financial data are often unavailable or unreliable (Dess & Robinson, 1984; Sapienza, Smith, & Gannon, 1988). Khandwalla (1977) developed a four items (long term profitability, sales growth, availability of financial resources, and image and client loyalty) instrument to measure business performance based on the owner/manager's subjective assessment of the company's performance relative to its competitors. This business performance instrument was validated in the small business context (Raymond, Pane, & Bergeron, 1995; Cragg et al., 2002) and deemed appropriate for the present study. The suitability and face validity of the instrument along with business and information systems strategies were confirmed during the pretesting stage of the questionnaire development.

The status and the usage of information systems infrastructure of small manufacturing knitwear exporters with a Web site differ significantly from that of exporters not having a Web site (Vivekanandan & Rajendran, 2005). To examine the contingency effect of Web presence on the linkage between information systems strategic orientation and business performance, the necessary provisions were made in the questionnaire to collect details about their Web presence.

Research Method

A mail questionnaire survey was conducted among the small businesses of Tirupur, India. This cluster of small manufacturing businesses is well known for its excellent export performance and its participation in the global apparel supply chain as a quality supplier (Vivekanandan & Rajendran, 2006). The total number of knitwear apparel exporters identified was 1100. The manufacturing sector was selected as they could provide a range of levels of information systems sophistication (Cragg & King, 1993; Rajendran, 1999). Each questionnaire was sent with a prepaid business reply envelope and a letter explaining the purpose of the study. The questionnaire was pretested with two professionals associated with small businesses and then with the owner/managers of five leading exporting organizations and was suitably modified. Further, a pilot test was conducted among a randomly selected 150 exporters and it resulted in minor modifications in the questionnaire. Thus, the questionnaire was refined at three stages (Dillman, 1978).

The refined questionnaires were sent to other 950 exporters and in total 129 useable questionnaires were returned. To assess the nonresponse bias, the first 30 and last 30 responses were compared on the nine information systems strategy items (Armstrong & Overton, 1982). The Mann Whitney test revealed that the differences are not significant except for the new product strategy and so concluded that the nonresponse bias is not a significant factor that could affect the results of the data analysis.

Results

The results of preliminary analysis of the data are shown in Table 2.

The mean score and standard deviation of business performance and information systems strategies are shown in Table 3 and Table 4.

Factor analysis is a multivariate interdependency technique used for data reduction and structure simplification (Hair, Anderson, Tatham, & Black, 1998). To assess the appropriateness of factor analysis, the Bartlett test of sphericity was conducted and it was found satisfactory (Sig. 0.000). As the increasing the sample size causes the Bartlett test to become more sensitive, the measure of sampling adequacy (MSA) was used to reassess the appropriateness of factor analysis. The MSA index of 0.845 revealed the meritorious nature of the data for factor analysis. Under fac-

Quality Product	3.67	0.90
Intensive Marketing	3.47	0.80
Product Differentiation	3.29	0.84
New Product	3.22	0.93
Wide Product Range	3.19	0.85

Scale: 1- Strongly Disagree, 5 – Strongly Agree tor analysis procedure, the principal component analysis was used to extract minimum number of factors that explain maximum percentage of variation. The Varimax rotation with Kaiser normalization was used to simplify the revealed structure (Table 5).

The three factors extracted explained 76% of variation and were considered as the dimensions of information systems strategic orientation. These dimensions of information systems strategic orientation were labeled as 1. Cost-Quality Leadership, 2. Product Development and 3. Market Development. The rotated component matrix of the simplified structure (Table 5) reveals the convergent and discriminant validity of the above three constructs. The reliability coefficient, Cronbach's alpha being the most widely used measure (Peter, 1981) was used to assess the internal consistency of these constructs. The values of Cronbach's alpha were 0.83, 0.88 and 0.78 and these are well above the lower limit of 0.70 (Nunnally, 1978; Robinson, Shaver, & Wrightsman, 1991). The factor scores were computed based on the factor loadings of all variables on each factor, to replace the original scores of nine information systems strategies.

The Business performance was the dependent variable in this study. The factor analysis was conducted to convert the multiple measure of business performance into a single composite measure. However, the Principal Component Analysis resulted in a single factor that explained 56% variance with construct validity of 0.73 (Cronbach's alpha). The factor score was generated as a composite measure of business performance.

As the primary object of this study was to explore and explain the relationship between the dimensions of information systems strategic orientation and business performance, the multiple regression analysis was used. The multiple regression analysis is a multivariate dependency technique used to analyze the relationship between a single dependent (criterion) variable and several independent (predictor) variables.

The regression equation generated is a linear combination of the independent variables that best explains and predicts the dependent variable. It is the regression variate that is formed by a set of weighted independent variables. The weights (regression coefficient) represent the relative contribution of the independent variables to the overall prediction and facilitate interpretation on the influence of each variable in making the prediction. The correlations among the independent variables are also referred to as multicollinearity.

Table 5. Simplified structure of information systems strategic orientation (rotated component matrix)

Information Systems Strategy	Component		
	Factor 1	Factor 2	Factor 3
Process efficiency improvement	**.79**	.26	.22
Cost reduction	**.79**	.20	.02
Quality service	**.78**	.17	.34
Quality product	**.66**	.35	.18
Wider product range	.21	**.89**	.08
New products	.27	**.84**	.24
Product differentiation	.31	**.78**	.20
New market expansion	.14	.12	**.90**
Intensive marketing	.29	.27	**.80**

Extraction method: Principal component analysis.
Rotation method: Varimax with Kaiser Normalization.

Multicollinearity reduces the variables' predictive power and complicates the interpretation process (Hair et al., 1998).

The multiple regression analysis was conducted with the business performance as dependent variable and the dimensions of information systems strategic orientation as independent variables. To ensure the minimization of impact of multicollinearity, the factor scores generated in the factor analysis with Varimax as an orthogonal rotation method, were used in the regression procedure.

The coefficient of determination (R^2) for the regression model generated was 0.252 with adjusted R^2 equal to 0.234. The model was statistically significant (ANOVA – Sig. 0.000). All the three dimensions of information systems strategic orientation significantly influenced the business performance. The details of regression coefficient and their significance are shown in Table 6. To assess the influence of Web presence, the regression analyses were conducted independently for exporters having Web site and for others. The results are shown in Table 7.

DISCUSSION

The results of the preliminary analysis of the data show that 74% of the respondent businesses are more than 10 years old and 89% have reached the business growth stage of stabilization and beyond. As expected, the proprietorship and partnership are predominant (86%). All the exporters have Internet connectivity and two thirds of them have Web presence. Eighty three percent of the respondents have more than 3 years of experience in using Internet. This indicates their high receptivity to the adoption of initial stages of electronic business practices.

The quality service strategy receives the highest mean score and it is followed by process efficiency improvement and cost reduction strategies. The mean score of all the other strategies are also above 3.00 and the overall mean score is 3.57. The exporters perceive that the information systems in general support their business strategies. Thus, these small businesses are upgrading their ways of competing that can lead to successful national economic development (Porter, 2004). These small businesses assess their competitive positions in all four criteria of business performance as strong.

The factor analysis reveals the three dimensions of information systems strategic orientation. The strategies of process efficiency improvement, cost reduction, quality service, and quality product emerge as indicators of the information systems strategic orientation dimension, Cost-Quality Leadership. The other two dimensions of information systems strategic orientation are Product Development (wider product range, new product, and product differentiation strategies) and Market Development (new market expansion and intensive marketing strategies). These are in line with Ansoff's matrix of strategy and Porter's generic strategies.

The defensiveness (Venketraman, 1989) is the predominant characteristic of the Cost-Quality Leadership dimension. The Proactiveness (Venketraman, 1989) is the predominant characteristic of the Product Development dimension and Aggressiveness (Venketraman, 1989) is the predominant characteristic of Market Development dimension. The result presented in Table 5 was scrutinized to analyze the percentage of variance in each information systems strategy score, explained by these common factors and specific factors (Table 8). This analysis reveals that these three characteristics (common factors) mainly constitute the means (dimensions of strategic orientation) to achieve the formulated goals within the conditions set by the information systems resource in the external and internal domains. These characteristics are held together by unique factors that are specific to the concerned strategic goals. A few of these specific factors are jointly significant and may include the characteristics of Analysis, Futurity, Riskiness (Venketraman, 1989), and so forth. As they are not common to other strategies, these characteristics are not explicitly brought out by the factor analysis. All these characteristics collectively describe the information systems strategic orientation.

The extraction of a single factor from multiple measures of business performance indicates that the four different criteria reflect the overall business performance. The factor score is an indicator of their business performance and is used as dependent variable in the regression analyses. Multiple regression analysis provides insight into the relative importance of each dimension of information systems strategic orientation in the prediction of business performance. The order of importance is cost-quality leadership, product development and then market development. The strategic orientation, like strategic alignment, is a process and not an event. The information systems strategic orientation is strategy specific and industry oriented, whereas the strategy alignment is strategy independent and applicable to all industries. However, the strategic orientation analysis has set the direction to the measurement of alignment and its linkage with business performance.

The knowledge about the predictive value of the information systems strategic orientation is highly useful in understanding the business value generating process of information systems resource deployment in a given business setting. This facilitates the fine-tuning of the information systems investment and adjusting the portfolio of information systems applications by knowing the efficacy of a particular information systems strategy to attain certain ends within a particular setting. And strategic orientation as a process does not normally lead to competitive convergence (Porter, 2001).

Implication for Strategy Research

The major contribution of the present study is the revelation of three core multifaceted dimensions of information systems strategic orientation in small business context. This emphasizes that small businesses explicitly indulge in information systems strategic planning for business performance management (Frolick & Ariyachandra, 2006). Future research could focus on small business information systems strategic planning and investigate their strategy making process (Miller, 1987).

As the newer strategic management research paradigm explicitly separate goals from strategy, the information systems strategy could also be viewed as means to attain certain ends within a particular setting. Empirically deriving dimensions of strategic orientation a posteriori has certain limitations (Venkatraman, 1989). A valid operational measure could be developed specifying the identified dimensions a priori.

In net-enabled organizations (Straub, Hoffman, Weber, & Steinfield, 2002), strategy is fast becoming a dynamic process of recreating and executing innovative options to gain and sustain competitive advantages (Teece, Pisano, Shuen, 1997). The insight gained through the present study into the relationship among core dimensions of information systems strategic orientation in their prediction of business performance could be used in assessing and choosing emerging and enabling information technologies (ET). Selecting ET is the first stage in the Net-enabled Business Innovation Cycle (Wheeler, 2002) that asserts that choosing IT proceeds rather than aligns with business strategy in developing dynamic capabilities (Eisenhardt & Martin, 2000) to turn timely net-enabled business innovations into customer value (Chen, Chen, & Wu, 2005).

Future research studies could investigate whether the contingent effect of the Web presence on the relationship between information systems strategic orientation and business performance is a direct one or intermediated by any other factor. The capabilities of the Web site could also be examined in detail to ascertain its role (Whinston & Geng, 2004) in determining the degree and character of association between information systems strategic orientation and business performance.

Implications for E-Business Development

The Web presence strengthens the relationship between information systems strategic orientation and business performance as a “promoting” variable. This emphasizes the strategic benefits of adoption of Web presence, one of the initial stages of electronic business development. The market development dimension of information systems strategic orientation is equally significant for exporters who have not yet adopted Web presence (Table 7). Even though their regression model explains only 15% of the variation in their business performance, the model remains significant.

It seems that their participation in the global production networks, and the extent of trade liberalization forced these exporters to adopt the first stage of electronic business development viz. e-mailing and Web information search as a means of expanding their market. The near universal desire of business to gain advantages over their competitors, in addition to extend their markets, reach new markets, and protect existing markets, is perhaps the most significant force (Gibbs, Kraemer, & Dedrick, 2003), driving these exporters to move to the next stage of electronic business development viz. Web presence. It appears that Web presence creates information visibility (Straub et al., 2002) forcing the small businesses to improve their internal processes and strategic positioning that in turn lead to superior business performance.

As the strategic planning in small businesses is incremental in nature (Mintzberg, 1988), the demonstration of the beneficial results for adopters will enable the small businesses to move forward in the electronic business development. Rogers (1983) argues that change agents should recognize their responsibility for the consequences of the innovation they advocate. Thus, the results of the present study have practical implications to government and nongovernmental organizations that promote the diffusion of electronic business adoption in small businesses.

CONCLUSION

The small businesses are investing in information and communication technologies to develop information systems applications to support their business strategy and thereby establish a competitive advantage based on the distinctive capability created in their markets. However, these small businesses struggle to achieve business benefits from their information systems investments and in particular to obtain a sustained competitive advantage and superior business performance. To explore the relationship between the strategic orientation of these information systems and business performance, a study was designed. The mail survey was conducted among 950 small businesses manufacturing and exporting knitwear apparels.

The results reveal the three general patterns of their realized information systems strategies viz. cost-quality leadership, product development, and market development. These dimensions of information systems strategic orientation have strong positive relationship with their business performance. The consequences of their adoption of Web presence promote the degree of the linkage between information systems orientation and their business performance. The study demonstrates the business value of information systems investment and adoption of initial stages of electronic business development.

Chapter 6.9

Computational Intelligence in the Financial Functions of Industrial Firms

Petros Theodorou
Athens University of Economics and Business, Greece

Dimitrios Karyampas
University of York, UK

ABSTRACT

Information technology has been proved to be a strategic weapon in the business armory for the creation and sustention of competitive advantage, especially, when it is aligned with the needs of the internal and external environment. Solutions are provided from the operational level up to strategic planning and are capable to support every choice in the strategy portfolio, from cost to quality and flexibility. IT systems in the manufacturing and operational level were analyzed extensively in literature: ERP systems, computer aided design/computer aided manufacturing (CAD/CAM), and so forth. According to Wong, Bo, Bodnovich, and Selvi (1997), 53.5% of the reviewed literature in artificial intelligence refers to applications in production and operations management. Nevertheless, the second most important area for advanced IT applications is that of finance (25.4%). This research will be focused on the common set of the two previously mentioned areas: production management and the necessary financial tools. Production and operation management requires specific financial tools in order to accomplish the functions of production planning, costing, investment appraisal, and so forth. Computational intelligence in those financial functions is mostly needed for the production operation department and for the production operation strategy. Specifically, the weight will be put on information technology automation of financial functions adopted by production departments: forecasting production needs, production planning and control, profit volume analysis, cost analysis, investment appraisal analysis, and so forth. An attempt will be made to classify the various quantitative and qualitative techniques in relation to various

financial aspects. Specifically, advances of neural networks, expert systems, advanced statistical analysis and operational research methods, and various hybrid techniques will be presented in relation to financial models applied in production. Financial applications will be analyzed according to their modules and their outputs in a strategic alignment concept. Finally, a strategic alignment model will be derived for the adoption of financial applications in businesses.

INTRODUCTION

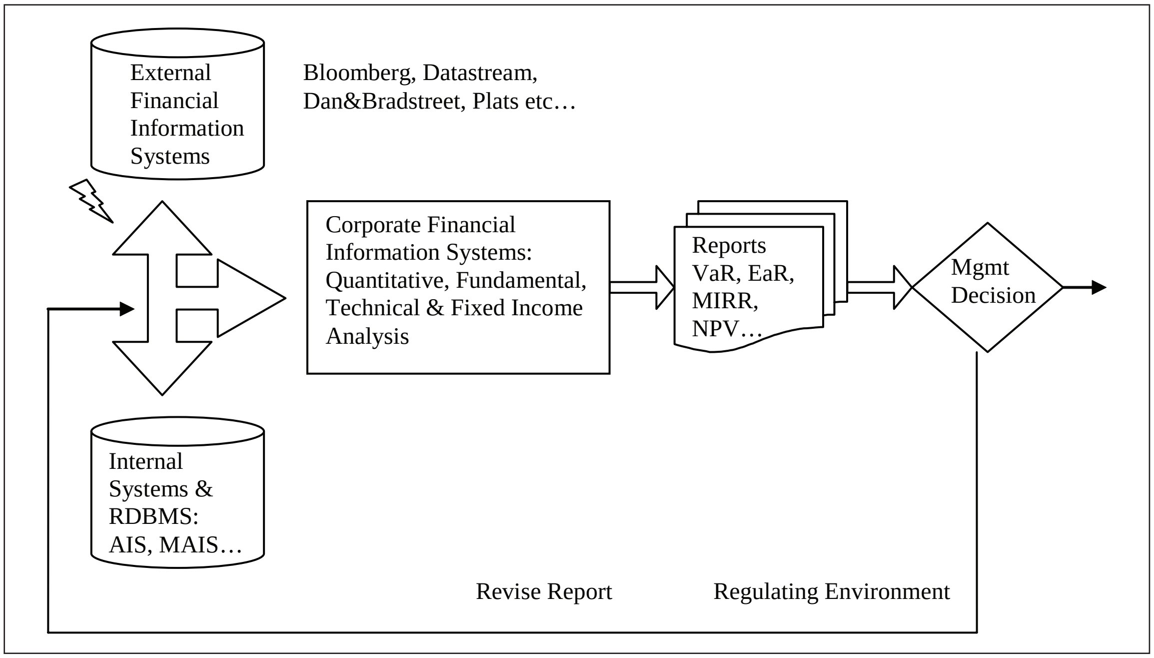
A tremendous progress in production methods happened in the last decade. The new production models customer and financially oriented incorporate new quantitative and qualitative techniques integrated with the known production and operations management models. The "black processing box" of this new financially oriented model incorporates advanced computational intelligence techniques. Production is not restricted on the shop floor management; instead a market oriented approach along with financial functions for the increase of financial performance is a prerequisite for the strategic survival. Computational intelligence employed in those financial models includes techniques of advanced statistics (mainly time series with exceptions, like discriminant analysis for the credit risk evaluation), simulation of stochastic processes, and artificial and neural network models. Logit-Probit models, multivariate discriminant analysis, simulation techniques (Monte-Carlo), weighted moving average (WMA), autoregressive conditional heteroskedasticity-generalized autoregressive conditional heteroskedasticity (ARCH-GARCH), and so forth are some of the techniques included in the statistics toolbox. Moreover, techniques of artificial intelligence and neural networks include case base reasoning, genetic algorithms, genetic programming, heuristic methods of linear programming and neural optimization, and so forth. Machine learning techniques are applied in portfolio optimization and derivatives pricing. Furthermore, those systems try to estimate risks in order to predict bankruptcy and rate credibility. The financial oriented production model targets to optimum allocation of funds among production activities, and to further hedge operational risks with financial impact. The diversification in demand and the variability in the external environment increased the need for rapid response with diversification in product and production. Therefore, computational intelligence must be incorporated in order to facilitate flexibility (Theodorou, 1996).

Manufacturing companies organize their systems in order to manage their operations on the spot and hedge the risks in the secondary markets. The operation in those markets requires extensive computational intelligence. The integration of financial information systems (FIS) with the production management systems is increased in order to gain competitive advantage. The performance of the advanced FIS should be measured in relation to the strategic factors of quality, flexibility, dependability, and valuate the benefits of scope economies and lead-time shortenings under the strategic alignment perspective. In the following paragraphs the generic FIS will be presented along with the literature review concerning its components. Specific attention will be given on the basic quantitative processing techniques which are based on statistics, artificial intelligence and neural networks. Finally, an attempt will be made to integrate the generic FIS within the strategic alignment model for future research.

LITERATURE REVIEW

Financial information systems (FIS) are usually found as a subtopic of the accounting information systems, but they must be separated due to differences in principles and practices. Especially, the quantitative character of finance demands a

Figure 1. Generic FIS



completely different approach than that of the accounting information systems, even though forecasting financial statements and budgeting analysis uses inputs from accounting information systems (AIS) and management accounting information systems (MAIS) (Covaleski & Dirsmith, 1986). AIS feed the systems with data and information for financial statements forecasting, and MAIS with information regarding the cost categories (Abernethy & Brownell, 1997; Abernethy & Stoelwinder, 1996; Bruggeman & Slagmulder, 1995; Chenhall & Langfield-Smith, 1998; Chenhall & Morris, 1986; Choe, 2004; Cooper, Hayes, & Wolf, 1981; Cooper & Kaplan, 1992, 1991; Cooper & Suver, 1994; Feltham & Xie, 1994; Flamholtz & Das, 1985; Foster & Swenson, 1997; Govindarajan, 1984; Ittner, Lanen, & Larcker, 2002; Johnson, 1992; Kaplan & Norton, 1992; Karmarkar, Lederer, & Zimmerman, 1990; Krumwiede, 1998; Lawrence, 1990; McNair, 1990; Miller, 1992; Preston, 1992; Shank & Govindarajan, 1993; Simons, 1987). Those systems must work close but each is separate from the other in scope and practice. The black box of FIS includes quantitative analysis, fundamental analysis, and technical and fixed income analysis. Stochastic processes and portfolio analysis make extensive use of artificial intelligence and neural networks where extensive literature can be found. Financial information systems use various quantitative techniques that are employed to model credit ratings and sovereign ratings, to evaluate credit risk, to forecast failure, bankruptcy and financial risk, to model stock selection, and so forth. All of these models are employing statistical and artificial intelligence techniques. Some of the statistical techniques employed are linear and nonlinear regression, probit regression, logit analysis, linear or quadratic multivariate discriminant analysis, multidimensional scaling, simulation techniques, logistic regression and linear programming, WMA, ARCH-GARCH, and various transformations (Altman, 1968; Baker & Wurgler, 2004; Belkaoi, 1980; Black, Jensen, & Scholes, 1972; Cambell & Shiller, 1988; Ederington, 1985; Fama & French, 1998, 2001; Hodrick, 1992; Horrigan, 1996; Jobson, 1982; Keim & Stambaugh, 1986; Kothari & Shanken, 1997; Kothari & Warner, 2001; Lewellen, 2004; Mar, Apellaniz, & Cinca, 1996; Mcinish & Wood, 1992; Taffler, 1983; Trevino & Thomas, 2000a, 200b). Artificial intelligence techniques consists of neural networks, case base reasoning, genetic algorithms, genetic programming ,and so forth (Ahn, Cho, & Kim, 2000; Bennell, Crabbe, Thomas, & Gwilym, 2006; Bennell & Sutcliffe, 2004; Bentz & Merunka, 2000; Brown, Coakley, & Phillips, 1995; Chen & Leung, 2005; De Freitas, Niranjan, Gee, & Doucet, 2000; Geigle & Aronson, 1999; Gemela, 2001; Healey, Dixon, Read, & Cai, 2002; Kelly, 1994; Kim, 2006; Mahfoud & Mani, 1996, 2002; Malliaris & Salchenberger, 1993a, 1993b; Odom & Sharda, 1990; Qi & Maddala, 1996; Tsakonas, Dounias, Doumpos, & Zopounidis, 2006). Risk management and financial forecasting make use of neural networks and expert systems advances as well as advanced statistics and operational research (Zhang, Patuwo, & Hu, 1998). In the coming sections a more detailed analysis will be presented. Fundamental analysis is basically based on financial statements and ratio analysis. From the basic outputs of accounting information systems, expost budgeting analysis forecast financial statements for the coming years (proforma). Technical analysis is trying to describe and forecast the movement of the prices on the markets using techniques such as trendlines, channels, candlesticks, point and figure, indicators and oscillators, various moving average methods (simple, linear, exponential), ARCH, GARCH, and so forth. Moreover, the state of efficiency according to efficient market hypotheses determines the type of analysis as well as the random walk hypotheses. A more detailed presentation will follow in the coming sections regarding the quantitative methods and its use in financial modeling. All these models should be examined in relation to the level of detail, frequency of reporting, and so forth under the alignment perspective (Figure 3). In the following paragraphs a generic FIS presentation will be made and its components will be discussed in detail along with relevant literature and their application field.

THE GENERIC MODEL

The generic model in an abstracting mode can be presented in the following diagram.

In this model a low level of detail is kept for the sake of discussion upon the generic topics. Further detail can be provided in future research for specific applications in specific industrial environment. This model should be adapted in the strategic alignment perspective (Figure 3) and should be discussed by taking in account relevant contingencies (Theodorou, 2003, 2004, 2005). The components of the generic FIS will be discussed in the following paragraphs.

The Internal RDBMS Systems

The internal relational database management system (RDBMS) include all available information and data generated and monitored within the firm by the firm's operations. Those systems comprise the internal pool of information separated conceptually (based on different economic principles) but interdependent and sometimes integrated from the software point of view. Those systems are the accounting information systems (AIS) and the costing or management accounting information systems (MAIS).

The accounting information systems generally include modules of accounts receivable-payable, generally ledger, payroll (sometimes separated module), order entry, billing, fixed assets accounting, and income tax preparation. The basic outputs of AIS used as inputs to the financial information systems are the income statements, the balance sheets, the cash flow statement, and the statement of changes in equity (based on the international financial reporting standards (IFRS)). Accounts receivable and payable record invoice and billing and helps schedule payments and issuing checks. Produce aging reports for cash collection that is also found in order entry applications. Payroll systems include pay rate, vacations hours tax, and other deductions and tax reports. Fixed asserts systems monitor and report the purchase of buildings, vehicles, and equipment for depreciation calculations and tax treatment, the gain or loss on assets sale, and so forth. Some systems are integrated with customer relationship management, e-commerce, project management, sales force automation, and work order management (*http://www.findaccounting-software.com/software/search/form.aspx?submittedfor=1&industry=Utilities&x=62&y=7* and *http://en.wikipedia.org/wiki/Comparison_of_accounting_software*).

The management accounting Information system (MAIS) is mainly dedicated in cost and inventory control and planning. The system collects, classify, and reports information that assists in financial planning and control of production activities (Bruggeman & Slagmulder, 1995; Flamholtz & Das, 1985). The system provides expost data for performance evaluation against predetermined goals and standards by the financial system. The financial part of MAIS can be grouped into traditional cost control information systems (TCCI) and advanced cost control information systems (ACCI) (Abernethy & Brownell, 1997; Chenhall et al., 1998; Govindarajan, 1984). One form of the advanced cost control information system is the design of activity based costing (ABC) (Foster & Swenson, 1997; Ittner et al., 2002; Krumwiede, 1998). TCCI systems are managing cost by means of standards, variances, and other metrics based at the individual level (Miller, 1992). In TCCI organizational performance is increased by maximizing individual efficiency (McNair, 1990) in relation to ACCI systems where interrelationships among function and group cooperation is of higher importance for performance (Choe, 2004). The critical attributes of those systems are the level of detail, the ability to disaggregate costs according to behavior, the frequency with which information is recorded, and the extent of calculation of variances. The more functional the type of MAIS the greater detail it provides, the better behavior classification it provides, as well as frequent reporting, and calculation of variances. The level of detail is analyzed by Chenhall and Morris (1986), Felthan (1977), Kaplan and Norton (1992), and Karmarkar et al. (1990). The system, in order to supply detail, must separate and classify cost according to behavior in fixed and variable, direct and indirect, controllable and noncontrollable (Feltham & Xie, 1994), and so forth.The greater the detail of MAIS, the greater the flexibility that it generates to analyze the cost for different purposes (Shank & Govindarajan, 1993). Feltham (1977) as well as Chenhall and Morris (1986) point out that decisions that are based on more detailed information are capable for performance increase in relation to decisions which are based on more aggregated information due to accuracy. Aggregations can be made in relation to the procedures, where direct costs are traced to the procedure and indirect, fixed, and variable costs allocated to the procedures. This requires a meaningful classification of cost according to behavior and activities (activity based costing system) (Cooper & Kaplan, 1992). The correct identification of cost behavior ensures the accurate information at all levels of detail (Cooper & Kaplan, 1991; McGown, 1998).

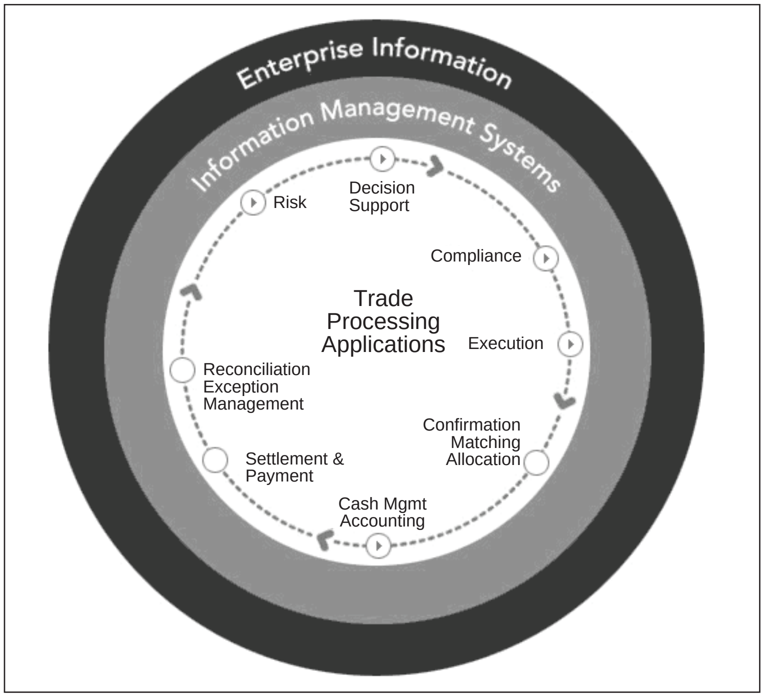
Cost reporting frequency enables the early recognition of problems in order for management to take corrective actions and accomplish fit with the environmental changes (i.e., takes advantage of opportunities and avoids threats). Chenhall and Morris (1986) found that frequency has a positive impact on performance for firms that operate in uncertain environment. Frequent reporting of the MAIS to the financial modeling system has found to have positive impact on financial performance. Hilton (1979) modeled the value of an MAIS in a cost volume profit decision setting where higher frequency of reporting increased the performance of the system.

The cost system trait, through variance analysis, determines the gap among expost and exante financial proforma estimations in order to resolve the causes of difference (Cooper & Suver, 1994; Feltham & Xie, 1994; Hilton, 1979; Johnson, 1992; Karmarkar et al., 1990; Khandwalla,1972; Simons, 1987). Variance analysis feed the financial information system with appropriate data in order to achieve budgetary control and help the administrative monitoring. Furthermore, inelastic pricing and contracts increase the need for variance analysis as they force firms to adopt risk of unexpected cost and utilization. Finally, variance analysis is extremely useful for the appropriate allocation of resources through measuring performance in relation to predetermined targets (Abernethy & Stoelwinder, 1996; Cooper et al., 1981; Covaleski et al., 1993; Lawrence, 1990; Ouchi, 1979; Preston, 1992).

The External Financial Information Systems

Market data that will feed the financial information system are obtained through external database management system (DBMS). Those external financial information systems keep track of market data, like prices, indices, interest rates, and other macroeconomic data as well as published information of financial accounts of other firms. Some of those databases need registration while others are free of charge. Examples are Bloomberg, Datastream, Hoovers, Yahoofinance, Plats, Edgar, Ibbotson, Reuters, and so forth. In this category we can refer interbank systems like Society for Worldwide Interbank Financial Telecommunication (SWIFT) as well as stock exchange information systems provided from various brokers. Those systems monitor and report the results of the stock exchange markets. The Electronic Data Gathering Analysis and Retrieval System (EDGAR) automates the collection, validation, indexing, and forwarding of data for companies required by the law with Securities and Exchange Commission (SEC). EDGAR, among others, delivers fundamental data, global annual reports, aggregated information, SEC fillings plus comparison, and searching and screening tools. Moreover, EDGAR with I-Metrix Professional offers analytical tools for fundamental, market data, and earnings forecasting, peer analysis, benchmarking, valuation, and so forth. Ibbotson, founded in 1977, offers tools and information for asset allocation, investment management, forecasting, education, and National Association of Securities Dealers (NASD)-reviewed presentation material. Presentation material is used to explain and demonstrate asset allocation strategies and investment concepts. Ibbotson offers software and data for investment planning, analysis, and asset allocation. EnCorr Analyzer accesses a central database to perform historical capital market data analysis, while EnCorr Input Generator refines and generates the necessary forecasting and optimization analysis. EnCorr also has an optimizer to test and analyze portfolios on frontiers, created using resampling methodology. EnCorr Attribution is used to analyze management style and attribute performance to investor decisions. EnCorr Allocator is used to implement asset allocation policy and Ibbotson Scenario builder is used toanalyze what-if scenarios. These database offers access to 3500 domestic and international macroeconomic indices and performance data series with monthly and quarterly Internet updates since 1926. Investment Planning Software and Data includes the Portfolio Strategist and Analyst, the Security Classifier, and the Investment Planning Data module. The software determines the optimal asset mix with the higher return and minimum risk. Find portfolios with the highest chance to obtain desired returns. Account the impact of taxes and create comparisons of multiple portfolio allocations on the efficient frontier. Moreover, examine the effect of changing assumptions (like taxes, interest rates, inflation, etc.). Classify security holdings to recommend an asset allocation to implement the plant with mutual funds and look at historical be-

Figure 2. The Reuters enterprise financial information systems



havior. With historical analysis, rank performance and examine risk/return trade offs. The Security Classifier defines the allocation of the portfolio and maintains a database of over 21,000 mutual funds, annuity subaccounts, and stocks. In the Ibbotson database, more than 5,800 mutual funds, 7,200 annuity subaccounts and 8,350 individual securities have been classified. Finally, service extends to security classifier, risk assessment, mean variance optimizer, historical calculations, wealth forecasting using straightforward analytical model and Monte Carlo simulation, and fund optimizer that determines the portfolio of mutual funds and subaccounts that most closely matches a target asset allocation.

The Reuter systems deliver financial information generated by exchanges, over-the-counter markets, price contributors, research services, and news. Also included are real-time prices, price histories and news, statistics, broker research and company fundamental data, and estimates. The financial information system of Reuter enables the market analysis and trading and investing opportunities identification, risk assessment of different strategies, ability to communicate with other market participants, direct trading, and access to executable prices and trading tools. Reuter premium financial information system incorporates trading functionality of the equity, fixed income, foreign exchange, and commodities from the desktop system of the company. Regarding the front office, Reuter offers pretrade analysis, limits checking, real time positioning, pricing analytics, tactical risk management, and profit and loss reporting. Regarding the middle office, it offers limits management, market risk and credit risk management, back testing, enterprise wide risk management, regulatory reporting, double validation, and market conformity check. In the back office, prevalidation is offered along with back validation, settlement, cash management, accounting, reporting, and messaging.

Bloomberg provides real-time and archived financial, market data, pricing, trading news, and communications tools. Platts is a division of McGraw-Hill Companies dedicated to energy financial information for oil, electricity, gas, coal, nuclear, petrochemicals, and metals. Platts offers energy benchmark pricing, forward curves, oilgrams, and real-time market news and industry analysis.

All the data and information collected from internal and external FIS are processed further in the processing box in order to advise and support decision making. In the following paragraph we will present the processing box operations along with the quantitative methods used to solve specific problems.

CORPORATE FINANCIAL INFORMATION SYSTEM: PROCESSING BOX AND QUANTITATIVE METHODS OF ANALYSIS

External databases provide the financial information system with inputs such as: YTM of the long-term bond (risk free rate), level of inflation, GDP growth, exchange rates, interbank rates and spreads (cost of debt), prices of commodities (metals, fuels, electricity, etc.) that determine the manufacturing cost, and so forth. The internal database and mainly the MAIS will provide FIS with the inputs relative to the unit cost classified according to behavior and activities. AIS will provide the relevant inputs for the financial statement forecasting and for the estimation of pro-forma financial statements. Sales and marketing information systems will provide the relevant forecasts for the sales budget. In the processing box, budgeting analysis will determine future needs for sales and capacity additions as well as investment needs. Future capacity investments will be selected according to the required returns (internal rate of return (IRR), net present value (NPV), return on invested capital (ROIC)). Material needs and their costs will be determined in conjunction with material requirements planning I (MRPI) systems. Sales budget, production budget, and inventory budget along with former financial statements (provided by AIS) will determine the forecasted pro-forma financial statements upon which further analysis will be contacted (i.e., ratio analysis, determination of additional required funds, etc.).

Portfolio management, financial, and specifically credit risk analysis will also be used for working capital and current assets management. Trading department will bargain and insure the price of both materials and end products on the spot and secondary markets wherever are organized otherwise in over-the-counter. FIS will determine metrics like earnings-at-risk (EaR), value-at-risk (VaR), and so forth to impose trading limits and define trading and hedging strategies. The operations will be accomplished by the coordinative effort of two functions: the front/middle office and the back office. Fundamental, technical (trends, support and resistance levels, reversal and continuation patterns, head and shoulders, triangles, pennants, flags, candlesticks, point and figure charts, etc.) and quantitative analysis (statistical, artificial intelligence and simulation techniques like Monte Carlo, and relevant software like @ Risk and Crystal Ball, EaR, PaR, CaR, etc.) will be accomplished by the front/middle office functions, while the operation of back office will be only supportive and mainly focused on matters of accounting. In the front and middle office the operations of market analysis, risk hedging, and trading monitoring will be accomplished while back office operations will include, risk measurement and reporting, accounting handling, and credit risk control. Various quantitative techniques are employed to model credit ratings using artificial neural networks (ANN) and sovereign credit ratings to model credit risk evaluation, to forecast financial risk, to model sock selection, to model failure and bankruptcy prediction, and so forth. All of these models employ statistical and artificial intelligence techniques to solve different financial problems. In the first case techniques such as linear and nonlinear regression, probit regression, logit analysis, linear or quadratic multivariate discriminant analysis, multidimensional scaling, simulation techniques, logistic regression and linear programming, WMA, ARCH-GARCH, and so forth can be seen. The category of artificial intelligence consists of artificial neural networks, case base reasoning, genetic algorithms, and genetic programming. Each of the above techniques has been used so as to provide solutions in different financial topics and will be presented in the following paragraphs along with their usage in financial modeling.

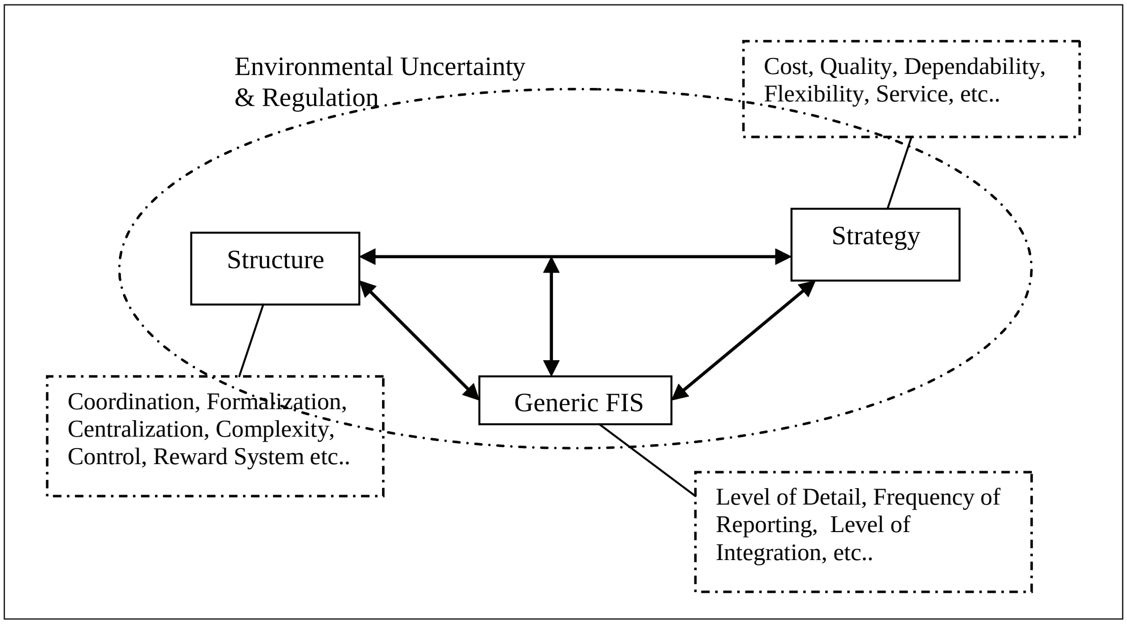
The linear regression technique, although trivial, can efficiently solve many forecasting problems. Multivariate linear regression was used by J.D. Jobson (1982) to test the arbitrage pricing theory and by Horrigan (1996) to find a link between the utility of the accounting data and the long-term credit administration. Schwartz (1988) identified four determinants of bid-ask spread (activity, risk information, and competition) and McInish and Wood (1992) used multivariate linear regression to demonstrate the relation among spreads and those factors. Prediction regressions and autoregression models have been applied by Keim and Stambaugh (1986) to predict the excess returns by some lagged variables: (a) the difference between the yield on long-term BAA underrated corporate bonds and the short-term Treasury bill rate; (b) the level of the S&P 500 index; and (c) the level of the small firm stock index. Using the same technique, Fama and French (1998) estimated the effect of the lagged dividend-price ratio on the stock returns. Additionally, Campell and Shiller (1988) found that the lagged dividend-price ratio and lagged dividend growth rate have a significant relation with stock returns. The same technique was applied by Hodrick (1992) to predict stock returns by the dividend-price ratio. Lewellen (2004) used the book-to-market ratio as a predictor while Kothari and Shanken (1997) have used the lagged book-to-market ratio. Predictive regression also was used by French, Schwert, and Stambaugh (1987) (predictor was the return variance obtained from an autoregressive integrated moving average (ARIMA) model). Linear regression finally could be found in popular studies of the capital asset pricing model (CAPM). Black et al. (1972) and Fama and McBeth (1973) have used the two-stage cross-sectional regression method. Finally, we can refer the work of Cantor and Packer (1996) and Trevino and Thomas (2000a, 2000b). Another type of regression which is also used in FIS is that of probit and logit. This technique has been used to examine the decreasing trend of firms to pay dividends (Baker & Wurgler, 2004; Ederington, 1985; Fama & French, 2001; Trevino & Tomas, 2000-2001). Linear multivariate discriminant analysis was used by Altman (1968), Belkaoi (1980), and Taffler(1983), and quadratic multivariate discriminant analysis was applied by Prinches & Mingo (1975). Mar et al. (1996) applied multidimensional scaling for bond ratings. Logistic regression was used by Wiginton (1980) to compare logit and discriminant models of consumer credit behavior. Linear programming techniques have been used by Mangasarian(1965), Freed & Glover (1981), and Hand (1981). Finally, simulation techniques have been used in economic analysis, decision making, and operational research. Simulation techniques have been applied in financial based computer systems, management games, for decision making, and operational research. Simulation procedures have been used by Kothari and Warner (2001) for the study of empirical properties of performance measures for mutual funds.

Genetic algorithm as a search algorithm is used to find solutions in complex optimization problems. Genetic algorithm offer advantages over the usual optimization techniques. Mahfoud and Mani (1996) say that the traditional optimization techniques “are of no use” if the problem that we want to solve is nondifferentiable. Genetic algorithms do not require gradient information, so there will be no problem in such optimization. Moreover, genetic algorithms are more likely to find a global optimum, as they search many points at once. The global optimum is more difficult to be found by other optimization techniques which do not search as genetic algorithms. Finally, genetic programming is a methodology that executes a procedure which guide automatically to the solution of the defined problem. Neural network applications can be found in financial topics such as financial and economic forecasting, data mining and target marketing, bankruptcy prediction, credit evaluation, portfolio selection/diversification, simulation of market behaviour, corporate loan portfolio risk evaluation, risk assessment, and pricing financial derivatives. Brown et al. (1995) talk about FALCON, a financial information systems that use ANNs by large credit card companies to screen transactions for potential fraud and credit advisor that accord credit for automobile loans. Furthermore, extensive literature can be found concerning the topic of pricing options using artificial neural networks. Malliaris and Salchenberger (1993a, 1993b) compare the performance of the Black-Scholes model and an ANN showing that the ANN model was superior for out-of-the-money options and the Black-Scholes model better for in-the-money options. Hutchinson, Lo, and Poggio (1994) compare three ANNs with Black-Scholes formula in pricing American call options on S&P100 futures. All three networks were better than the Black-Scholes model. Qi and Maddala (1996) compare the performance of an ANN in pricing European call options and found that the ANN produces better results. Alike to Qi and Maddala, Geigle and Aronson (1999) examine the performance of ANNs in pricing options. They have indicated that ANNs were better than Black-Scholes formula. The superiority of ANNs is shown also by De Freitas et al. (2000) who applied ANNs and Black-Scholes model to price Financial Times Stock Exchange (FTSE) 100 (United Kingdom) call and put options. Kelly (1994) shows that the ANN was superior than the binomial model in a study to price American-style put options on four U.S. firms. Healey et al. (2002) show that ANNs are well enough in pricing options. Bennell and Sutcliffe (2004) compare the performance of Black-Scholes model with an ANN in pricing European-style call options on the FTSE100 index. They provide an extensive study on the performance of ANNs in pricing UK options. The results have shown that ANNs were superior and they mentioned that this superiority "suggests that ANNs may have an important role to play in pricing other options." Another application of such networks is the use of Bayesian networks in financial analysis. Gemela (2001) studied the use of probabilistic Bayesian networks in fundamental financial analysis. They present the construction of a Bayesian network for the financial analysis of specific firms and sectors of the Czech economy. A survey of ANN applications in forecasting mentions that extensive literature can be found in financial applications of ANNs. ANNs have been used for forecasting bankruptcy and business failure (Tsakonas et al. 2006). Zhang, Hu, Patuwo, and Indro (1999) use neural networks for modelling bankruptcy and they linked to the Bayesian classification theory. Ahn, Cho & Kim (2000) presented a combination of rough sets and neural networks. Parag & Pendharkar (2004) proposed a threshold-varying artificial neural network for binary classification. Comparisons of results with other techniques such as inductive machine learning and genetic algorithms are also performed. In bankruptcy prediction the work of Odom and Sharda (1990) Tam and Kiang (1992), and Fletcher and Goss (1993) can be referred to. ANNs have also been used as a prediction and forecasting tool for exchange rates, stock prices, and volatility. The work of Casdagli and Eubank (1992), Hlupic, Walker, and Irani (1998), Refenes (1993) and Wu (1995) explores exchange rate forecasting. White (1998), Schoneburg (1990), Bergerson and Wunsch (1991) apply ANNs for stock price prediction. Kaastra and Boyd (1994) provide a procedure to design a neural network forecasting model for financial and economic time series. Kim (2006) proposes a genetic algorithm approach in ANNs for financial data mining. Hamid and Iqbal (2004) use ANNs to forecast the volatility of Standard & Poor's (S&P) 500 index futures prices. They present that the volatility forecasts from neural networks with realized volatility are about the same. Finally, Chen and Leung (2005) suggest that "neural networks are a better tool to forecast the exchange rate correlation." They compared the forecasting performance of neural networks with that of implied volatility and random walk models. Applications of ANNs could be found on predicting sovereign credit ratings. Bennell et al. (2006) believe that neural networks are superior to ordered probit models which have been used for credit rating. They found that ANNs, which are used by major rating agencies (e.g., Standard & Poor's and Moody's), can be used to predict sovereign credit rating. ANNs have also been applied in marketing problems. Bentz and Merunka (2000) showed that the neural network can be used as a generalization of the multinomial logit model which is used for brand choice modelling. Techniques such as genetic algorithm have also been used for financial forecasting. Mahfoud and Mani (2002) presented a genetic algorithm system to predict future performances of stocks. They tested the genetic algorithm system and a neural network system on 5,000 stocks where genetic algorithm systems produced better final results. Adaptive genetic algorithms have been used for construction finance decisions. Lam, Hu, NG, Yuen, Lo, and Wong (2001) propose adaptive genetic algorithms as an alternative method for modelling financial decisions. In this field, many optimization techniques have been used, such as heuristic method, linear programming, and neural optimization networks. The technique of genetic programming has been used in financial topics, such as option pricing. Chen, Lee, and Yeh (1999) use data from S&P 500 index options and distinguish them in in-the-money and out-of-the-money categories. They compare the genetic programming tree with the Black-Scholes model in its capability to hedge. Finally, we could find applications of machine learning techniques in financial topics, such as portfolio optimization problems. Ince and Trafalis (2006) developed a short-term management model based on the volatility around the earning announcements.

CONCLUSION AND FUTURE TRENDS: MANAGERIAL DECISION

The performance of a FIS as any other advanced IT system should be examined under the strategic alignment perspective (Theodorou, 2005, 2003, 1996; Theodorou & Giannoula, 2008). Otherwise performance comparisons and benchmarking practices will lead to wrong conclusions. Specifically, FIS should be aligned with the organizations' structure and strategy which is determined by the environment's uncertainty and volatility where the business operates under certain regulations (Chenhall, 2003; Theodorou, 2003). Performance achievements should be judged in relation to an alignment model in control of contingencies such as firm size, age, and so forth. Theodorou (2004) presents in detail the alignment model and its' variables with the relevant literature. The frequency of FIS reporting, the level of FIS detail, the level of integration among internal, and external financial information systems should be decided in relation to the strategic alignment mechanism (Figure 3) in control of contingencies such as size and age of the firm. The more volatile the environment where the firm operates the greater the need for the FIS to generate frequent reporting and higher level of detail in order for management to take corrective actions (Theodorou, 1996). Thus, decision making needs to do frequent corrective actions in a volatile environment. Rigid structure for firms working in a stable environment directs competitive strategy toward cost. Level of detail and frequency of FIS were kept at low level along with low level of integration among FIS and internal and external financial information systems.

Figure 3. Alignment of FIS



The FIS model previously presented should be examined on the previous characteristics but this must be done under the “umbrella” of strategic alignment theory. Decision making in a more detailed FIS model is also another topic that has to be examined using the criterion of performance. Sometimes potential benefits of frequent reporting, greater detail, and integration do not exceed the cost of the system. Implementing a sophisticated FIS system entails costs of consulting, training, and maintenance, but not the cost of investing. For example, if the firm has no significant number of counterparts than the cost of a credit risk system may exceed the benefits realized. Finally, further research can be conducted regarding the commonly adopted quantitative methods by successor firms.

FUTURE RESEARCH DIRECTIONS

Future research for the design of a financial information system must make use of the alignment framework (Theodorou, 2005, 2003, 1996) and the contingency approach (Figure 3), especially for the processing box and the quantitative methods. The components of the financial information system (described in the previous sections) should be chosen according to the environment where the firm operates and its existing structure. Increased performance and competitive advantage by the system will be expected only if modifications of business structure and the systems design are aligned with the environment. For example, a business with a flexible structure designed around risk management can better operate in a volatile environment. The financial information system of this business should incorporate modules of risk management (calculations of VaR, EaR, etc.) and hedging techniques, to help management eliminate the variability. In such an environment where nonstationarity of the mean exist, the computational averaging techniques (simple/centered/doubled/weighted moving averages, exponential smoothing, ARIMA, etc.) may be obsolete. More advanced computational methods must be applied, such as random walk models (RWM), stochastic volatility (SV) models, models that use stochastic processes, and computational intelligence of nonlinear artificial neural networks (S-E-TAR ANNs). Moreover, the computational techniques of autoregressive and generalized autoregressive conditional heteroscedasticity (ARCH-integrated-GARCH, fractionally integrated-GARCH, etc.) should also be used in these FIS in order to better describe volatility clustering, excess kurtosis, and fat tailedness. Finally, there is no need to incorporate this computational intelligence and the structural processes of risk management in the financial information systems which operate in a stable and predictable environment. If we do so, than the return on the additional not needed invested capital will be decreased as well as the overall performance.

That is why future research must take into account the alignment framework (Theodorou, 2005, 2003, 1996) in order to decide about the design of an FIS as well as the computational intelligent which has to be employed by taking into account behavioral characteristics.

Finally, until now there is no research indicating which parts of the previously mentioned generic FIS model are adopted by the firms. Also there is nothing indicating how the effect of frequency of reporting, level of detail, and integration of the FIS model with enterprise resource planning systems (ERP) impacts business performance.

Chapter 6.10

The Impact of E-Commerce Customer Relationship Management in Business-to-Consumer E-Commerce

Pauline Ratnasingam
University of Central Missouri, USA

ABSTRACT

The growth of business-to-consumer (B2C) e-commerce has gained a lot of attention among SMEs. Most B2C firms are turning their attention on how to retain new customers and are left in a situation to compete with larger firms. This paper aims to examine the impact of E-Commerce Customer Relationship Management (ECCRM) in a small business firm that engages in B2C e-commerce. Drawing upon the theories of customer relationship management, e-commerce, trust and loyalty, we develop an integrated framework of ECCRM model to illustrate the impact of the hard and soft factors that reflect the level of transactional and relational components of communication thereby impacting the customers shopping time lifecycle experiences. We develop a number of hypotheses to facilitate testing of the framework via an exploratory case study. We then discuss the findings of the integrated framework leading to theoretical and practical implications of this study and directions for future research.

INTRODUCTION

The Internet has become the foundation for electronic commerce customer relationship management (ECCRM). ECCRM refers to the application of e-commerce using the Internet and Web applications to manage customers. Information Data Center predicts that e-commerce spending will reach $496.7 billion in the United States and $1.3 trillion globally by the year 2009. In recent years we have witnessed an increased growth of small businesses turning towards the Internet to market their products. Business to consumer

(B2C) e-commerce, a significant subset of total Internet business, can provide significant benefits to customers and small-medium enterprises (SMEs), including the ability to market their products and services online thereby achieving global connectivity, high accessibility, scalability, interoperability, interactivity, and greater information richness (Turban, Lee, King, & Chung, 2006).

SMEs are an important and integral part of every country's economy and have been long recognized as different from larger businesses (Street & Meister, 2004). The Internet helps SMEs to manage customer relationships effectively, as it provides an easy and inexpensive way to advertise, lowering the barriers to entry for SMEs. Despite that customers are now even more demanding than ever before and B2C e-commerce firms are challenged to keep pace with the changing customers needs in maintaining a competitive edge. Unlike traditional means of communication such as newspapers or television, the Web gives the customers control in choosing and processing informing about the firm. Web tools such as online feedback forms, 1-800 telephone numbers, help-desk operators assist customers in obtaining information and clarifying questions quickly. Products such as LikeMinds from Macromedia uses complex algorithms to create affinity groups for each customer, so that B2C firms can better understand their customers engaged in buying from their Web site. The Web overturns the traditional hierarchical system of distribution channels by allowing integration of systems and information between the marketing, sales and servicing activities thereby forcing SMEs to view CRM seriously. Beyond blogs, podcasts, and wikis, social media comprises social networks of all strips, social tagging that provides organized customer generated content for small businesses and customers to share views. The breadth of the medium allows wider availability, accessibility and selection of hard-to-find products and services. Web tools thus serve two purposes namely; to provide Web content and to manage customers' interactions.

Customer relationship management (CRM) is the ability of a firm to capture and integrate customer data from all over the organization and then consolidate, analyze and distribute the data to various touch points within the organization. In most cases CRM uses groupware software to enable these processes to occur. Alternatively, ECCRM uses the e-commerce system and the CRM system of the firm to integrate and consolidate both the firm's and customer's data in order to facilitate access to any type of information, anytime and anywhere using the Web. These Web-based applications enable firms to generate, aggregate, and analyze customer data, thereby employing the results to improve service and marketing activities. ECCRM relies on the Web interactions between the firm and its customers while supporting e-commerce that entails shopping online, thereby contributing to profitability. Thus, it is more than simply a sales or marketing automation tool. It is an end-to-end, company wide solution that integrates the marketing, sales, and service activities.

Despite the hype and growth of the Internet for e-commerce, the application of ECCRM in the context of SMEs is limited. In fact, previous research suggests that only 20% of the SMEs are deploying CRM applications (Markowitz, 2005). This study aims to examine the impact of ECCRM in the context of B2C e-commerce among SMEs. Drawing upon the theories of customer relationship management, e-commerce, and trust and loyalty, we develop an ECCRM model to illustrate the impact of the hard and soft factors that reflect the extent of transactional and relational components of communication thereby impacting the customers shopping time life-cycle experiences leading to four modes namely; learning, monitoring, collaborating and distancing modes. The rest of the article is organized as follows. The next section discusses the ECCRM and its impact on the hard and soft factors. While hard factors reflect the transactional component of communication including Web site's performance, user friendliness, quality of Web content, customer acquisition/search costs and perceived security. Soft factors reflect on the relational component of communication including the quality of products/services, satisfaction, trust, loyalty and reputation of the firm. We develop a number of hypotheses to facilitate testing of the ECCRM model via an exploratory case study with a small B2C e-commerce firm in the retail-marketing industry. We then report and discuss the findings of the study leading to theoretical and practical implications of the study and directions for future research. This study contributes to theory as we provide a holistic ECCRM model that incorporates both hard and soft factors and its impact on customers shopping time life cycle experiences. The study also contributes to practice as B2C e-commerce practitioners will be aware of the mechanisms used to achieve timely, cost-effective, scalable, manageable and reliable feedback on their customer relationship performance.

E-COMMERCE CUSTOMER RELATIONSHIP MANAGEMENT (ECCRM)

The term ECCRM refers to the application of e-commerce to manage customers using Web applications. ECCRM when incorporated properly into the daily business processes can:

- reduce the cost of communicating with customers;
- provide Web-based opportunities for self-service activities, thereby reducing administrative overhead;
- integrate delivery of services, production, and derive value chain cost savings;
- boost sales through Internet marketing; and
- improve customers, interaction with the firm, leading to service improvements (Burr, Patterson, Rolland, & Ward, 2007).

ECCRM allows firms not only to keep in contact with their customers but also to extend their relationships with customers (Tsikriktsis, Lanzolla, & Frohlich, 2004). In fact ECCRM is a revolving process as B2C e-commerce firms need to interact with their customers, thereby generating, aggregating and analyzing customer data from the results of their sales, marketing, and servicing activities (Romano & Fjermestad, 2001; Seybold, 2001). The certainty in ECCRM requires that both the technology and the firm's positive relationships with their customers' lead to successful CRM as in attracting new customers and retaining existing customers thereby increasing profitability. Yet, little attempt has been made to understand how firms that engage in B2C e-commerce attempt to manage their ECCRM. In the next section we discuss the hard and soft factors that impact ECCRM.

Hard Factors

B2C e-commerce is a socio-technical system used to advertise, sell and share business information and products by conducting business transactions over the Internet. We argue that it is critical to consider the role of the Internet and other Web applications that facilitate the *transactional component* of communication thereby contributing to the hard factors such as; Web site's performance as in increased sales, reduced complaints, user friendliness, quality of Web content, customer acquisition/search costs and perceived security. The transactional components include both the transactions of information and money pertaining to the purchasing process. The transactional component of communication is reflected in the more formal and precise reporting of outcomes and quantitative results such as sales figures. Transactional attributes of communication also refers to the accuracy, timeliness, adequacy, correctness, and credibility of information exchanged between the firm and their customers (Daft & Lengel, 1986; Huber & Daft, 1987; Mohr & Spekman, 1994).

Hard factors thus refer to the technological mechanisms that facilitate customers to use the B2C firm's Web site to engage in online shopping. They form the foundation for B2C e-commerce transactions to occur and are derived from the Technology Acceptance model (TAM), which is one of the most widely accepted models used for predicting e-commerce adoption. Drawing from the TAM, which has its origins in the theory of planned behavior (TPB) (Davis, Bagozzi, & Warshaw, 1981), and theory of reasoned action (TRA) (Ajzen & Fisbein, 1980), we propose that technical solutions and security solutions provide impersonal assurances that contribute to positive expectations, intentions, and behaviors in e-commerce relationships. This is consistent with Zucker (1986), who claims that trust is created in impersonal economic environment (without familiarity) and similarity (communality). Trust forms not because people know each other personally, but because institutional structures that are akin to policies, auditing, and recourse embedded in the e-commerce technology. McKnight and Chervany (2001, p. 13) advanced this argument in the context of B2C e-commerce, arguing that "beliefs that the Internet has legal or regulatory protection for consumers (institution-based trust) should influence relationship trust of a particular e-vendor (interpersonal trust)."

TAM thus posits that e-commerce adoption is affected by prior use related beliefs. It identifies two beliefs namely; perceived usefulness (as a response to the B2C firm's extrinsic value—accuracy, quality, timeliness of business transactions); and perceived ease of use (as a response from the customers pertaining to the intrinsic characteristics of the e-commerce system (ease of learning, flexibility, security solutions). E-commerce solutions and other third-party application providers inform the B2C firm's expectations of the transactional capabilities of the technology platform. Customers form beliefs regarding the accuracy and efficiencies of the system thereby reducing search costs. The e-commerce system is also used to support a wide range of applications including standing purchase orders, just-in-time sourcing, invoicing and payments, as well as collaborative design and development. The technology also provides a mechanism to monitor the customers' interactions and communications with the firm and ultimately the firm's economic performance. Further, best business practices as in IT solutions and proven problem solving methods are used to attract and retain customers. Best business practices also include enforcing governance mechanisms in the form of contracts, regular audit policies, top management commitment, high-quality standards, adequate and complete training of the employees, and enforcing risk-management procedures that impact and control the quality of the Web content, security and Web-site performance (Marcella, Stone, & Sampias, 1998).

Soft Factors

Soft factors are derived from the *interpersonal or relational component* of communication between the firm and their customers. They include quality of products/services, satisfaction, trust, loyalty, and reputation of the firm. McKnight and Chervany (2001, p. 13) advance this argument in the context of B2C e-commerce, arguing that "beliefs that the Internet has legal or regulatory protection for consumers should influence relationship trust of a particular e-vendor." Trust is frequently defined in the literature as (1) the confidence or predictability in one's expectations (Zucker, 1986), and (2) the confidence in others goodwill (Ring & Van de Ven, 1994). The benefits of trust in e-commerce relationships seem wide ranging, including lowering transaction costs (Gulati, 1995), promoting desirable behaviors, reducing the extent of formal contracts, and facilitating dispute resolutions (Ring & Van de Ven, 1994). The behaviors reflect integrity and dependability as well as the customers' knowledge of the products and satisfaction of the firm increases. Previous research suggests that customer loyalty increases profit and growth in many ways to the extent that increasing the percentage of loyal customers by as much as 30% to 85% depending on the industry (Gefen, 2002). This is evidenced by Keen (2000, p. 1) who noted: “We are moving from an IT economy to a trust economy.” Similarly, a significant number of studies support the underlying importance of trust in e-commerce relationships (Dyer & Chu, 2000; Hoffman, Novak, & Peralta, 1999; Jarvenpaa, Tractinsky, & Vitale, 2000; Keen, 2000; Sako & Helper, 1998).

Based on the hard and soft factors that impact the customers’ interactions and communications using the firm’s Web site, we identify four modes derived from the customers shopping time life-cycle experiences leading to the four modes namely; learning, monitoring, collaborating and distancing modes. A mode refers to the characteristics of a particular e-commerce customer relationship at any given moment in the life of the relationship and it represents a pattern of behavior reflecting the customers’ desire to improve predictability and reduce uncertainty in their relationship with the firm. The firm also monitors behaviors of their customers, assesses performance, identifies ways to improve their ECCRM strategies and adjusts their behaviors in order to retain and attract new customers.

Customers Shopping Time Life-Cycle Experiences and its Impact on ECCRM

The customers shopping time life-cycle experiences and its impact on ECCRM is based on the hard and soft factors reflected on the transactional and relational components of communication leading to the four modes, namely learning, monitoring, collaborating and distancing modes. ECCRM does not involve just the use of technology. It is a continual process and approach a firm takes toward its customers backed up by thoughtful investment in technology and business processes (Morrell & Philonenko, 2001). The firm monitors behaviors of their customers, assesses their shopping behaviors and identifies room for where the firm can improve, and adjusts in order to align it with their future intentions of their customers. The firm also focuses on the operations of their e-commerce system, to potentially reveal additional information about their needs and expectations of their customers (Dwyer, Schurr, & Oh, 1987). The communications the firm has with their customers will reflect their satisfaction and intentions to continue the e-commerce relationship. Previous research suggests that the quality of communication is related to satisfaction of the customers, intentions to continue a relationship, and a willingness to provide referrals (Dwyer et al., 1987; Morgan & Hunt, 1994; Sawhney & Zabin, 2002; Schurr & Ozanne, 1985). MacNeil (1981) acknowledges that honest and open lines of communication encourage continued growth and close ties between trading partners. The customers shopping time life-cycle experiences in ECCRM impacts both the hard and soft factors that are reflected in the transactional and relational components leading to the four modes discussed below.

Learning Mode

The learning mode in ECCRM occurs when the impact of the hard factors is low and the soft factors are high. Novice customers using the B2C firm’s Web-site experience a positive relationship with the firm (Vatanasombut, Stylianou, & Igbaria, 2004). During the initial stages of an e-commerce relationship, the firm encourages their customers to contact them via 1-800 call numbers and e-mail. The emphasis is on the relational component of communication and experiences the customers have with the firm and to what extent the firm will satisfy the customers’ learning curve in using their Web site. Because the B2C firm values the customers they will go out of their way to make additional investment in assuring that their customers are satisfied. The firm is tolerant of the initial mistakes made by their customers. The firm focuses on how to attract new customers and build customer relationships. By properly integrating the ECCRM systems the customers experience reduction in consumers search costs. Typically, the B2C firm will concentrate on negotiating and implementing technical security solutions so that their e-commerce system can provide speed, accuracy, privacy, and accountability, thereby reducing the customer acquisition/search costs. Furthermore, certain Web technologies such as search engines and intelligent agents directly reduce the customers' search costs by providing relevant information for consumer decision making at a much lower cost and time (Lager, 2005). The B2C firm will continue to attract sophisticated customers as the firm provides user friendly technical solutions in the form of security, privacy policy information, functionality of the Web site, warranty details and increase in both the ease and depth of navigation (Vatanasombut et al., 2004). It is essential for firms to offer online attractive promotions on their Web site backed with high-quality products and services in order to convert potential customers to actual sales. Therefore, we propose that *RH-1: The customers in a learning mode of an ECCRM are more likely to experience a positive relationship with the firm.*

Monitoring Mode

The monitoring mode in the ECCRM occurs when the impact of the hard factors is high and the soft factors are low. The situation occurs when the hard factors are not used in a proper manner by the customers in order to create a positive relationship. The emphasis is on the economic returns from the transactional components. Because the firm has confidence in the functionality of their e-commerce system, they increase the monitoring measures to their benefit and assess the performance of their customers. Novice customers who do not have sufficient experience with the Internet may feel comfortable and tend to use the Internet for simple tasks (Lager, 2005). Their concerns relate to the compatibility of the browsers, hardware/software, cookies, user friendliness of the Web site, and sometimes being unable to remember how to log onto the B2C Web site. Sophisticated customers on the other hand have a higher understanding of the Internet technology demand speed and timely information. Their concerns relate to search costs, timeliness and accuracy of information/transaction updates, system and transaction reliability, new features, Web site functionality and accurate, timely product information (Vatanasombut et al., 2004). The sophisticated customers who have become the firm's regular customers' may not purchase the firm's products and services if their concerns were not met. Therefore, we propose that: *RH-2: The customers in a monitoring mode in an EC-CRM are more likely to experience a negative relationship with the firm.*

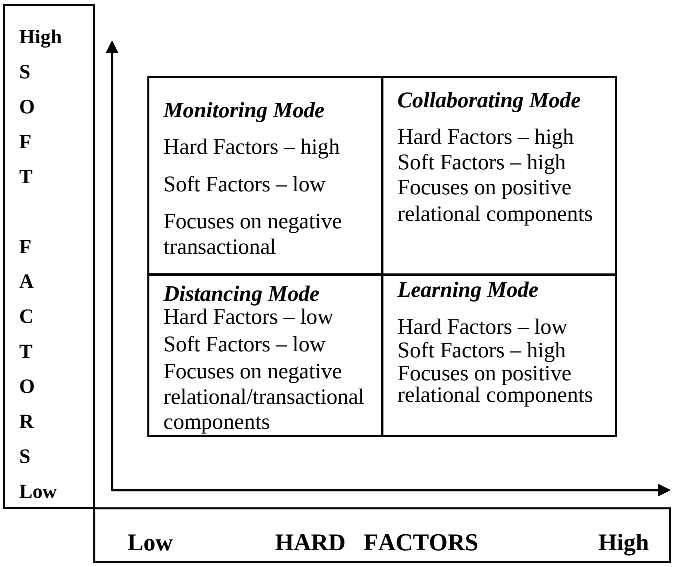
Collaborating Mode

The collaborating mode of the ECCRM occurs when the impact of both the hard and soft factors are high. The emphasis is on the relational component of the relationship between the customers and the firm. The customers experience cooperation, increased positive communications, trust satisfaction, and loyalty when interacting with the firm. Furthermore, the customers' positive experiences with the firm are associated with a willingness to recommend new customers derived from the reputation and image of the firm. Previous research suggests that there is a positive relationship between trust and commitment (Doney & Cannon, 1997; Ganesan, 1994; Lewicki & Bunker, 1996; Parasuraman, Zeithaml & Berry, 1985; Rousseau, Sitkin, Burt & Camerer, 1998). This, if reflected in current research, which suggests that ECCRM significantly impacts the level of trust of B2C e-commerce firms and their customers (Bunduchi, 2005). Trust can be achieved by providing customers with valuable information in a timely manner. According to Ganesan (1994), trust is the extent to which the customer believes that the vendor has intentions and motives that are beneficial to the customer. When customers trust a B2C e-commerce firm, they will share and communicate with the firm. Loyal customers are more tolerant when something goes wrong and are easier to satisfy because the B2C firms are aware of their customers' expectations (Gefen, 2002). Thus, loyal customers are satisfied and are more likely to continue shopping with the B2C firm thereby increasing both the number and/or frequency of purchases. Satisfaction with delivered products and services have been suggested and empirically documented as affecting the customers' intention to continue, thereby increasing the B2C firm's reputation. Therefore, we propose that *RH-3: The customers in a collaborating mode in an ECCRM are more likely to continue purchasing with the firm.*

Distancing Mode

The distancing mode in the ECCRM occurs when both the hard and soft factors are low. The customers perceive that the firm is not meeting their needs and are not keen to shop on their Web site. Because the customers lack confidence in the firm and their e-commerce system, they are more likely to encounter difficulties in trying to resolve issues and spending more time searching for their products and services. The customers lack trust and experience negative interactions with the firm. Most SMEs who conduct business over the Internet do not follow the robust technical, and security standards needed as they are challenged by financial resources, lower technical expertise, and limited management skills. They often do not have the time to gather customer information, which sometimes leads to poor decision making. The customers perceived the B2C firm to be untrustworthy, lacking quality service thereby leading to a negative image and poor reputation. The employees in a distancing mode wind up with reduced productivity and limited job satisfaction. The customers are inclined to distance themselves from this situation and are not willing to return to the Web site. The dissatisfaction of the customers' contributes to an inclination to withdraw from the firm. Previous studies suggest that customers are unlikely to purchase from a B2C e-commerce firm if they perceive their online experience is not

Figure 1. ECCRM research model



Monitoring Mode Hard Factors – high Soft Factors – low Focuses on negative transactional	***Collaborating Mode*** Hard Factors – high Soft Factors – high Focuses on positive relational components

sufficiently secured (Vatanasombut et al., 2004). Therefore, we propose that *RH-4: The customers in a distancing mode in an ECCRM are unlikely to continue shopping with the firm.*

RESEARCH MODEL

The ECCRM research model in Figure 1 illustrates the four modes and their impact on the both the hard and soft factors.

RESEARCH METHOD

An exploratory case study was chosen as an appropriate research method to examine ECCRM and the customers shopping time life-cycle experiences in a small business firm that engages in B2C e-commerce. The case study approach allowed us to ask *how-and-why* types of questions and enabled us to elicit subtle and rich data needed, thereby increasing our understanding of ECCRM. The questions pertaining to hard and soft factors were reflected in the transactional and relational components of communication leading to the four modes. This would be difficult if a survey research method was applied. We interviewed the manager of Firm A in the retail-marketing industry four times during the summer of 2007. Each interview lasted between 60 and 90 minutes. The manager is an IT consultant in the Institute of Entreprenurial Studies—Small Business Development Center at the University of Central Missouri, USA. Although two other employees did assist in providing us with relevant documents, the manager was the main person who contributed to the findings of this study. Evidence for the case study data was derived from the handwritten notes taken during the interviews and the tape recorded data. In addition, analysis of existing documents relating to ECCRM, day to day interactions, operating procedures, best business practices, and technical solutions were analyzed.

FINDINGS: BACKGROUND INFORMATION OF FIRM A

Firm A is an import export retail-marketing firm which conducts its business over the Internet. They sell unique accessories such as jewelry, artwork, handbags, and unique children books in Spanish and English. They cater to the needs of women, gay individuals, and young children in Spanish and African American communities. They have five full time employees, and their business transactions are conducted on their B2C Web site. They had at least 400 one-time purchase customers since they launched their Web site in 2001. Seventy percent of their customers are repeat customers today, and 90% of their customers are women whose ages vary between 30 and 50 years. Ten percent of their customers are men whose ages vary between 25 and 45 years. They come from all over the country in the United States and are average Internet users. They communicate frequently via e-mail, fax, 1-800 call centers, wireless phones, and a wireless LAN. They spent nearly $40,000 in initial IT implementation costs, and their annual IT maintenance cost varies between $4,000 and $5,000. The IT component of the Web site is transparent to the customers. Basically, customers browse the Web site, select the item they want, which then gets listed in their shopping cart. Once the shopping is complete, they hit *purchase*, and all the items in the shopping cart are listed on the sales receipt. Quickbooks is linked to Malsink, their shopping cart software. The shopping cart system allows their customers to place their orders and the bank to verify the credit of their customers. The customer is then charged the amount on his or her credit card. The system also automatically e-mails the customer and the firm acknowledging the order. Items are then shipped within 3 business days. Quickbooks is used to create the sales receipts issued to the customer. Inventory is controlled by Quickbooks as well. The Web site has databases that are linked to the product information. Firm A's business transactions include purchase order, e-mail acknowledgements, invoices, payment transactions, and delivery information. In the next section we report the findings of ECCRM on the four modes for Firm A.

Learning Mode

The learning mode in ECCRM occurs when the impact of the hard factors is low and the soft factors are high. The emphasis is on the transactional component of their e-commerce system focusing on how to attract new customers and building a relationship with the customers. The manager of Firm A commented that:

Our customers have shown a willingness to provide us information on what they need, and did provide support when we first implemented the B2C e-commerce Web site. Further, we trained our staff to exhibit care and concern to our customers when speaking on the telephone or via e-mail.

He went on to say that:

Although, initially, there were issues in the compatibility of the IT infrastructure and our e-commerce system, we relied on other forms of communication, such as the fax, telephone, and e-mail. We need to trust the customer keying in the data that the information is correct. The Web site enables us to log our customers so that we can contact them in the future.

The manager noted that:

Security was not a concern since the IT solutions were outsourced to an IS solution provider. We have a link that informs and describes our customers about the security features on our Web site. We used a third party trusting agency which prevents computer crimes and we adhere to the security principles.

The findings of the learning mode suggest the need for the firm to focus on the soft factors and facilitate the smooth flow of the transactional components. It was found that relying just on technology alone was not enough to build relationships as customers in the learning mode were keen to build credibility and trust in the firm that in turn motivated them to revisit the firm's Web site.

Monitoring Mode

The monitoring mode in the ECCRM occurs when the impact of the hard factors is high and the soft factors are low. The hard factors are not used in a proper manner thereby creating a negative relationship between the firm and their customers.

Firm A manager indicated that:

We have an account number assigned for each customer who shops on our Web site. All events are recorded against each order on a date/time basis, and memos are created and referenced/filed to each job for future reference, thereby enabling integrity of the business transactions and speed in the delivery process. This serves as a unique identifier thereby providing authentication. We believe that top management commitment is critical especially when it comes to investing in the e-commerce technical/security solution and search costs. Further, we undertake regular audit checks on our outcomes in order to manage risks.

The emphasis of the ECCRM is in the communications with the customers on identifying and resolving errors and delays. Conversations emphasize discussions on how to assure that the system performs correctly.

Of course, like any other new system we tried to simplify our business processes and provide a user friendly system for our customers. Initially there were errors, as both our employees and the customers had to learn to use Web site. There were customers e-mailing us on the functionality and errors they experienced when transacting on our Web site.

The findings of the monitoring mode suggest the need for the firm to focus on both the hard and soft factors that emphasized on the transactional and relational components of communication. It examines the customers shopping time life cycle experiences based on their ability to use the Web site correctly which will impact their intention to revisit the firm. This enabled the firm to identify their loyal and profitable customers versus the customers who have stopped shopping on their Web site.

Collaborating Mode

The collaborating mode of the ECCRM occurs when the impact of both the hard and soft factors are high. The emphasis is on the relational component of communication between the customers and the firm. The manager of Firm A indicated that:

Our employees were aware of the competitive market coverage and were confident in their capability in resolving standardized issues. The number of customers' visiting and shopping on our Web site has increased. When we first implemented e-commerce in 2001 we had between 30 to 40 regular customers, now after two years we have 300-400 regular customers and at least 4 new customers each month. Our main role is to establish the needs of our customers, and increase the variety of products and services we provide.

Firm A's manager also indicated that:

Positive feelings sometimes depend on whom you are speaking to, and can be a perception, which can change from one event to another. We are known to provide high quality products and services and our firm's image and reputation has contributed to an increase in our profits.

He added:

When you open a Web-site business, it is difficult for customers to know the firm size. Our customers thought that our business was big. A large image was impressive although in reality there were only five full time employees. The positive views, on our products, services, corporate initiatives and image, connected our customers on an emotional level as well as on an intellectual one.

The findings of the collaborating mode suggest the need for the firm to focus on the soft factors that enhances the relational components of communication and the customer shopping time life-cycle experiences. This will in turn increase the reputation and image of the firm thereby creating customer satisfaction and commitment of the customers to revisit the firm that in turn increased their profits.

Distancing Mode

The distancing mode in the ECCRM occurs when both the hard and soft factors are low. The customers do not perceive the B2C e-commerce firm to meet their needs.

Firm's A manager indicated that:

Although some of our customers were not novice customers, they continued to submit us incomplete purchase orders with errors. We had to spend a lot of time e-mailing and calling them back to explain the error. It created additional difficulties for us as we had to spend more time explaining the errors to our customers. Thus, a lack of positive behaviors demonstrated from the customers created a pattern and a situation of dissatisfaction. We used separate log-on procedures for these types of customers in order to ensure that different levels of service were provided to these customers.

The findings of the distancing mode suggest the need for the firm to focus on both the hard and soft factors exhibited by the customers that in turn impacted their transactional and relational components of communication. The firm experienced the need to spend unnecessary time on customers who were not abiding by the correct procedures that in turn created dissatisfaction for the firm and the customers.

DISCUSSION

The findings paved the way to some insights on the customers behaviors based on the impact of the hard and soft factors that were reflected in the transactional and relational components of communication leading to the four modes of the customers shopping time life-cycle experiences. The hard factors that reflected the emphasis on transactional components of communications were seen in the learning and monitoring modes, whereas the impact of the soft factors that reflected the emphasis on relational components of communications were seen in the collaborating and distancing modes. For example, while it takes time for a new customer to evolve from the learning mode to the collaboration mode the findings suggest that it may take only a couple of attempts for a customer to experience the distancing mode. We believe that the monitoring mode is the deciding stage for the customers whether to pursue the relationship with the firm leading to collaborating mode or to disband from the relationship leading to the distancing mode. Thus, each mode represents a broad reflection of the effect of both the transactional and relational components based on the hard and soft factors leading to relationship continuity. The findings suggest that although shopping online can be a simple process, firms must periodically survey their customers to determine the impact of their ECCRM solutions on customers attributes and behaviors. Based on these insights Firm A was able to identify their regular, profitable customers and customers who stopped shopping on their Web sites. Further the frequent communications with their customers via e-mail enabled Firm A to identify the needs, attitudes and behaviors of their customers thereby taking actions to increase their profit by meeting the needs of their customers.

CONCLUSION

This study expands upon the existing theory of ECCRM by explicitly considering the role of a B2C e-commerce firm in the context of CRM. The study contributes to theory as we suggest that the important characteristics of the hard and soft factors that are in turn reflected on the transactional and relational components of communication leading to the four modes of the customers shopping time life-cycle experiences. The hard factors that emphasized the transactional components focused on the outcomes of the exchange between the customers and their firms. Alternatively, soft factors that emphasized on the interpersonal relational components were characterized by conversations via the telephone and e-mail between the customers and the firm. At a simple level, we recognize that technology affects the transactional component and interactions between the customers and the firm. Technology provides a distinct basis for retaining customers that is separate from an assessment of the customers as it has an effect on profit. More importantly, we draw upon this expanded understanding over the *customers shopping time lif- cycle experiences* based on the impact of both the hard and soft factors that is reflected on the transactional and relational components of communication leading to the four different modes in ECCRM namely; learning, monitoring, collaborating and distancing modes.

This study contributes to theory as the ECCRM model provides a holistic view of the firm by simultaneously examining the customers shopping time life-cycle experiences and performances leading to the four modes. Further, the exploratory study contributes to practice as we discuss how firms that have adopted B2C e-commerce are likely to experience customers shopping time life-cycle experiences. Given that the model was tested as an exploratory study, future research should attempt to examine the ECCRM model via multiple case studies on how the hard and soft factors can impact the customers shopping time life-cycle experiences in ECCRM, thereby contributing to meaningful generalizations. We plan to pursue future research which aims to collect data from various stakeholders within and outside the firm. In conclusion, customer attraction and retention for B2C e-commerce firms remains a complex, elusive, yet extremely important phenomenon. The proliferation of the Internet has significantly threatened the ability of SMEs engaged in B2C e-commerce to retain their customers.

Chapter 6.11

Extending Relationship Marketing to Human Resources Management Using the CaRM Approach to Personnel Recruitment

Tobias Keim
Johann Wolfgang Goethe University, Germany

Kerstin Fritsch
Johann Wolfgang Goethe University, Germany

INTRODUCTION

Since the early 1990s, relationship-oriented approaches to product and services marketing have gained increasing interest by research and practice. While the overall approach of managing customer interactions has been inherent to the ways of doing business ever since, the recent change from transaction-oriented to relationship-oriented marketing is typically considered as a major paradigm shift (Grönroos, 2004). The current boom of customer relationship management concepts and solutions is only one indicator of this development. However, while relationship marketing has been discussed in various contexts such as business-to-business and business-to-consumer marketing, little attention so far has been paid to the question of what such an approach could add to the human resources field. This is astonishing as labor markets due to demographic effects and other changes in labor offer and demand tend to get increasingly narrow. Thus, traditional approaches to personnel marketing might no longer be sufficient and new concepts for the successful recruitment of qualified staff might be needed. Therefore, our research question is: How can we transfer the concepts of relationship marketing to personnel recruitment and what are potential benefits of such an approach? In order to answer this question, we present an approach for the IS-supported management of employer-candidate relationships. We outline two major dimensions of the approach together with selected validation results. The objective is to enhance human resources information systems (HRIS) research and to present an approach that could potentially assist employers in better facing mid-term shortages of qualified staff on a drastically changing labor market.

BACKGROUND

Information technology in recent years has drastically changed the human resources function. Providing support for mainly administrative activities such as payroll and attendance management at the beginning, the past decade has been characterized by an increased usage of information technology for the attraction of qualified staff as well as for the generation and the processing of applications. Online job ads on corporate websites or internet job boards, online CV databases, e-mail and form-based applications and applicant management systems are only few examples of this trend. While this development is assumed to provide employers with means to attract large volumes of candidates at low cost (Lievens & Harris, 2003), it has also increased the complexity within the recruitment function as job seekers show different propensities to use online information and application channels. Thus, for recruiters it has become more difficult to determine which channel to choose for the posting of a specific vacancy and what application channels to promote for the different target groups. To choose an unsuited personnel marketing channel for the posting of a job ad or restricting application channels to channels that are not preferred by the target group might limit the number of incoming applications and thus lower the possibilities of successfully recruiting a candidate coming as close as possible to the defined target profile. Posting a job ad in several or too many channels and offering a wide range or too many application channels, in turn, might result in such masses of incoming applications that a rapid identification, selection and hiring of the most suited candidate might be hindered, too. As a result, a deep understanding of the each specific target group and of the respective candidates' preferences is needed in order to assure an efficient recruitment process leading to the successful employment of a suited applicant.

In parallel to this development classical marketing in the past decade has seen a shift from a transaction- to a relationship-oriented marketing approach with customer relationship management (CRM) being only one example of this paradigm shift. By creating and actively managing long-lasting customer relationships and analyzing customer data supported by information systems, this approach has been shown to substantially increase companies' profitability (Wilson, Daniel, & McDonald, 2002). Typically, customer relationship management is separated into strategy-, process- and systems-oriented approaches. While strategy-centered approaches consider CRM as a customer-focused concept of the enterprise with the objective of identifying, winning and retaining customers (Wilson et al., 2002), the process-oriented perspective aims at analyzing and improving all processes and activities related to the interaction and contact with the customer (Schmid, Bach, & Österle, 2000). Systems-oriented approaches to CRM, finally, see an integrated information system as the basis for successful customer retention (Ryals & Payne, 2001). A common element, however, often lies in the fact that CRM is considered as a closed loop in which a company dynamically learns from its interactions with its customers and feeds this information back into the future management of its customer relationships (Selnes & Sallis, 2003; Zikmund, McLeod, & Gilbert, 2003). A customer segment in this context is considered as a group of customers that within the group are highly homogeneous but as much heterogeneous from other segments as possible. This process of customer segmentation serves at reducing the complexity in customer interactions by designing the marketing measures on the segment- and not on the customer-level (Wilson et al., 2002).

In addition to these distinctions, Hippner et al. (2004) in their work separate two major dimensions of a CRM system. These are the operational and the analytical customer relationship management. Operational CRM represents all activities dealing with the management of the customer contact. As an important element in this context lies in the integration of the various customer interaction channels and of the information transported over these channels, operational CRM is also referred to as communicative or cooperative CRM (Alt, Puschmann, & Österle, 2005; Chamoni, Düsing, & Stock, 2004). An additional activity within operational CRM is represented by the implementation of the insights gained from the analytical CRM with regard to the different customer segments' needs concerning marketing, sales and other related services. Different authors with regard to these activities have suggested different forms of IS-support. Hippner et al. (2004) and Berchtenbreiter (2004), for example, suggested supporting operational CRM by means of a content management system in order to represent the unstructured information that typically arises from the interactions with customers. Also, different software modules have been suggested to support front office activities thus allowing for marketing automation (Engelbrecht, Hippner, & Wilde, 2004; Schumacher & Meyer, 2003), sales automation (Winkelmann, 2004), and service automation (Schöler, 2004).

In separation from the operational CRM concept, analytical CRM deals with the analysis and mining of customer data in order to enable an improved operational CRM. Various kinds of data are cited in literature as being suited for such approaches. These data should be stored in an integrated data warehouse that serves as a basis for different retrieval and analysis tools (Alt et al., 2005). One means to analyze such data is online analytical processing (OLAP) that allows for the analysis of relevant indicators according to criteria previously known or defined (Gallegos, 1999). A typical example is the analysis of a company's turnover according to different products, regions or periods of time. Different data operations or manipulations provide different perspectives on the resulting data cube (e.g. by shifting between levels of aggregation). However, OLAP is not suited for the exploration of data as it assumes that the user is able to specify the dimensions of analysis in advance. This shortcoming is addressed by data mining methods that allow for the recognition of patterns or unknown interrelations within a given data set (Schumacher et al., 2003). Different methods such as data classification, regression, cluster analysis, and others support the extraction of information from the data stored (Chamoni et al., 2004). However, careful attention needs to be paid to the fact that some causalities might be extracted erroneously due to accidental patterns within the data; a situation that can be prevented by integrating theoretical or statistical considerations prior to the analysis (Schröder, 2002).

THE CaRM APPROACH TO RECRUITMENT

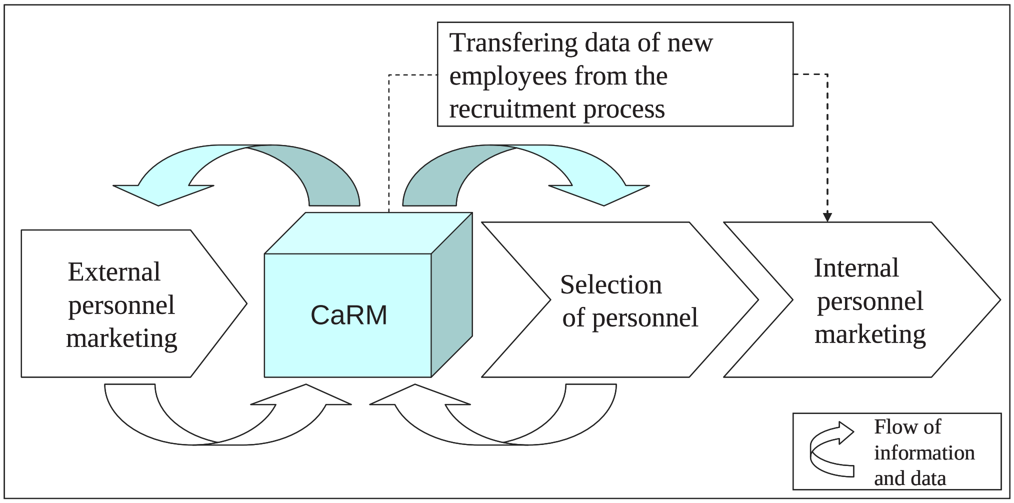
In analogy to these considerations, we designed a framework for a relationship management approach to personnel recruitment. We refer to this framework as the *Ca*ndidate *R*elationship *M*anagement or *CaRM* approach. We argue that conflating relationship marketing and personnel marketing might assist companies in facing the challenges of an increasingly competitive labor market. Of course, one could oppose that an applicant cannot be compared to a "repeat customer" or that many employers even prevent their candidates from "repeated" interactions (e.g., by sending multiple applications for the same position at different points in time or for several different positions at a single point in time). While this is certainly true, we consider the process of transforming external people into candidates and then into applicants as a relationship that is worth being managed. Also, as scarcities of different skill sets emerge on the labor market companies will be obliged to more frequently implement long-term approaches to the recruitment of highly qualified candidates for strategic positions. Finally, from the previous considerations on the increased complexity in personnel recruitment it has become clear that employers need to establish approaches that lead to a better understanding of the behavior and the preferences of their different target groups.

It is for these reasons that we consider the fusion of relationship marketing and personnel marketing as a promising goal. However, the CaRM approach is not limited to personnel marketing. It rather represents an approach that impacts the entire recruitment function and not solely the candidate attraction phase. By segmenting candidates according to their job search behavior as well as their informational needs and by systematically mining applicant data, we aim to provide the basis for a learning loop bridging personnel attraction and selection. Therefore, as depicted in Figure 1 below the CaRM approach is positioned right at the core of the recruitment function between the candidate attraction and the applicant selection stages.

Similar to customer relationship management, capturing and storing all relevant data within a single information system is critical to our CaRM approach. Therefore, we suggest enriching the candidate data provided as part of the application process by complementary data such as demographic and psychographic data and also by systemically capturing the data emerging from the interaction between an employer and its candidates. As employees dealing with personnel marketing, applicant screening and personnel selection are engaged in this process, HR experts and employees from specialized departments are in charge of gathering data. This is why the CaRM approach potentially impacts any employee involved in the recruitment process and not only the experts in charge of personnel marketing.

Once the relevant data are stored in the system, we in line with the above considerations sug-

Figure 1. The CaRM approach

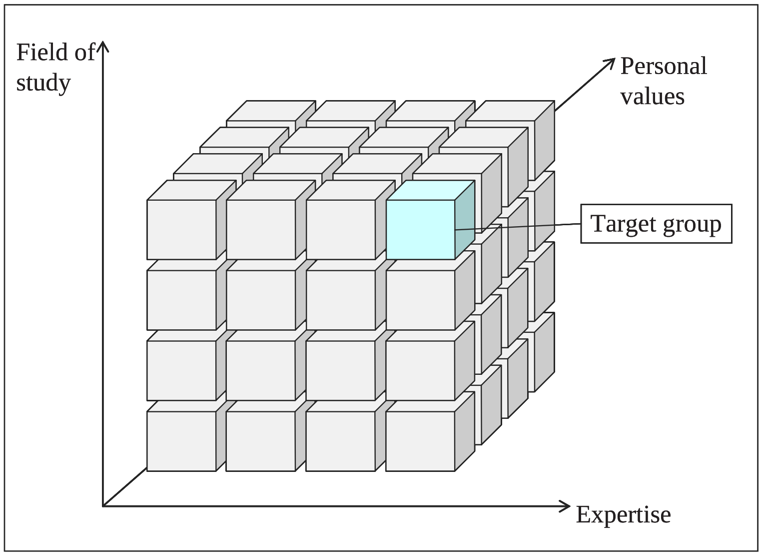


gest separating an operational and an analytical approach to the relationship management with candidates. While the operational CaRM supports activities such as the definition and implementation of the recruitment and application channel strategy for a specific candidate segment, the analytical CaRM provides the necessary information for these activities from the systematic analysis of the candidate data by means of OLAP and data mining methods. Figure 2 illustrates a sample data cube for candidate data.

In order to validate the approach, we carried out a survey with over 10,000 Internet job seekers. Data were generated in 2005 by means of a questionnaire publicly available on the internet. The questionnaire was promoted by means of e-mails, banners, and press releases. While the entire validation activities are out of scope of this article, we at least want to outline selected results from this research. The entire results from the survey can be found in Keim, König, Weitzel, Fritsch, and von Westarp (2005a).

In order to validate the approach, we used an online questionnaire containing 32 questions on the information and application channels currently used by job seekers in their job search activities. As part of the questionnaire, participants were provided with two sets of items concerning their personal values and their job or employer requirements. This list was adapted from Kirchgeorg and Lorbeer (2002). Following the data collection, we analyzed our survey data. In a first step, we considered our data on an aggregated level only. Then, we analyzed the data as part of an approach comparable to the above OLAP approach. We segmented our data according to three candidate segments being the candidates' career level, their field of studies and their occupational group. The analysis revealed that we were indeed able to identify interesting differences in the candidates' information and application behavior. Finally, in an attempt of data mining we clustered the candidates according to their personal values and job requirements. Similarly to Kirchgeorg et al. (2002), we were able to cluster our participants according to their personal values as well as their job requirements and to reveal interrelations between these clusters.

Figure 2. Sample OLAP data cube for candidate data



Despite the fact that many employers today might not feel to be in a position to capture candidates' personal values and employer requirements at the application stage, the results show that the overall CaRM approach and its methods are consistent and applicable. Also, the results already at this stage prove to be insightful for many HR experts desiring to understand the behavior of their target groups as well as the success or failure of their personnel marketing measures.

FUTURE TRENDS

Anticipating further future trends is difficult as we consider already the CaRM approach as one such potential future trend. As companies increasingly adopt applicant management systems, they in our eyes move one step toward the operational management of candidate relationships. Also, the adoption of company internal databases containing high volumes of candidate profiles provides the basis for an analytical processing of these data (e.g., see Keim, Malinowski, and Weitzel (2005b) or Keim and Weitzel (within this Encyclopedia) for the underlying adoption issues). Thus, from an adoption perspective we see strong arguments supporting the CaRM approach. Furthermore, we regard the development of IS support for personnel selection and team staffing as a major future challenge. We are convinced that such decision support will be a major element of a potential future analytical support for the recruitment function. First approaches to such decision support can be found in Malinowski, Keim, Wendt, and Weitzel (2005). Even the clustering approach previously presented could potentially be considered as such an approach as companies might want to define and recruit certain profile types from a specific subset of the data cube. Finally, the CaRM approach not necessarily needs to be limited to external candidates or applicants. We anticipate further potential in extending the approach to a company's current employees and thus by linking CaRM to the personnel development field.

CONCLUSION

In this article, we presented an approach transferring relationship marketing to the personnel recruitment field. We identified the operational and the analytical management of relationships with candidates as major dimensions of our CaRM approach. While the operational CaRM covers all aspects dealing with the direct contact between the candidate and the employer (e.g., the selection of targeted recruitment channels and instruments or the management of service-related processes and applicant touch points, the analytical CaRM comprises the systematic analysis of candidate data through data mining and OLAP methods). In order to implement such activities, companies need to pay special attention to three major and highly interrelated challenges. These are the capturing of comprehensive candidate data together with their storage in a single software system, the precise planning of operational and analytical measures and the careful implementation and analysis of these measures. Overall, a relationship-oriented approach to managing candidate relationships to us seems a promising path for any employer anticipating the future challenges of an increasingly narrow labor market.

KEY TERMS

Applicant: A person that has actively applied for a job within a specific company either by means of an application submitted for a specific job or by means of an unsolicited application. Therefore, an *applicant* can be separated from a *job seeker* by the fact that he or she has already progressed to a later stage of the job search process (e.g., from the sole search for information to the application action).

Candidate: A person that has applied for a job or that has been actively identified by the employer and that is considered relevant for a specific vacancy. Thus, not every applicant is necessarily regarded a candidate.

Candidate Relationship Management (CaRM): A candidate-centered approach to personnel marketing and even broader personal management that uses an integrated HRIS for capturing, storing and analyzing candidate data in order to enhance the cross-medial attraction, recruitment, and retention of candidates.

Candidate Relationship Management (CaRM), Analytical: Those activities within CaRM that systematically capture and store candidate data in a data warehouse to analyze them through methods of data mining and on-line analytical processing (OLAP) and, thus, to continuously increase the effectiveness of the recruitment activities.

Candidate Relationship Management (CaRM), Operational: Those activities within CaRM that deal with managing the direct contact and interaction with the candidates (e.g., applicant touch point management and the provision of other related services).

Employer Branding: Those activities within the long-term personnel marketing that aim at pro-actively positioning an employer as an employer of choice among its key target groups. Typically, such activities include image advertisements in various channels or media. Recently, however, employers have also begun to analyze the positioning of their employer brand by questioning their internal and external target groups to derive empirically grounded employer messages. Whilst the perception of employer and corporate brand may diverge, the employer brand needs to be positioned in consistency with the company's corporate brand and, further, in distinction from competition's employer brand on the labor market.

Personnel Attraction: Any activity within personnel marketing that aims at recruiting a candidate for a concrete vacancy in the short- or mid-term (e.g., either by posting job ads in one or more online or off-line recruitment channels or by actively identifying and contacting candidates in CV databases or by any other suited measure).

Personnel Marketing, Cross-Medial: Any measure aiming at recruiting qualified staff in the short-, mid-, or long-term. Therefore, the long-term personnel marketing or *employer branding* is separated from the short-term personnel marketing or *personnel attraction*. We refer to cross-medial personnel marketing as an approach that integrates different personnel marketing channels (Internet job boards, career sections of corporate Web-sites, print media, events, executive searchers) and application channels (Web forms, e-mail, paper-based) and adapts these channels so that a streamlined job search process for each of the target groups addressed is assured.

This work was previously published in Encyclopedia of Human Resources Information Systems: Challenges in e-HRM, edited by T. Torres-Coronas and M. Arias-Oliva, pp. 406-412, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 6.12

Approaches and Concepts to Restructuring Human Resources Management Functions

Peter M. Wald
University of Applied Sciences Dresden, Germany

Rainhart Lang
Chemnitz University of Technology, Germany

INTRODUCTION

Nowadays, most human resources (HR) managers are confronted with cost pressure, the demand for offering "high-quality-HR services" and the necessity for strategic contributions (Hewitt, 2004). Human resource management (HRM) with its current structures and tools is often unable to completely fulfill these requirements. Therefore, a strong need for reorganization of HR as a function is obvious. In the last few years, many efforts have been undertaken by HRM practitioners to re-structure HRM at the level of organizations as reflected in surveys or case studies from leading firms. Examples can be found in Som (2003) and Fairbain (2005). Moreover, the restructuring of the HR function has been the subject of a broad discussion among scientists and researchers in the field of management (Becker & Huselid, 1999; Caldwell, 2003, 2004; Truss, Gratton, Hope-Hailey, Stiles, & Zaleska, 2002). It is remarkable that this discussion has mainly focused on the strategic role of HRM (Lawler III, 2005), and consultants in the practical field have particularly given advice to improve the quality of HR services (Hewitt, 2004; Towers Perrin, 2005). A more complex view on the restructuring of HRM is rarely to be found.

BACKGROUND

Organizations often prefer an easy way of re-organization by simply cutting HRM costs. As

Capelli (2005) has stated when companies were downsizing, human resource functions capabilities were the first thing cut.

But, what does Restructuring of HRM functions imply?

Restructuring of HRM functions describes a more or less radical modification of roles, tasks and structures in all HR-related practices, like recruitment, placement, payment, development of human resources, and in structures and processes of the HR departments, and their co-operation with the top management, line managers, HR consultants, HR service providers, and employee representatives.

Starting from this broad view, it can be stated, that restructuring of the HRM function have to be seen as a normal part of its development. A view on the history of HRM reveals that at every developmental stage, specific roles, and tasks, and, moreover, a specific focus on restructuring of HR functions within each stage can be found (see Table 1).

The further text will focus especially on the ongoing development (i.e., the stage in which HRM acts as a "strategic business partner"). This stage can be identified in the extent to which newly structured HR departments and a new division of labor between HR-departments, line managers, and internal or external providers of HR services have been implemented.

The current reputation of HRM has been built generally upon excellent services and consulting processes as represented in stage 3. Now HRM is being increasingly asked for strategic contributions (Cascio, 2005; Lawler III, 2005; Ulrich & Brockbank, 2005). This article focuses on the "link" between the current reputations while focusing on the future role of HR.

Here, a framework will be introduced to enable an interdisciplinary and more complex approach on HR restructuring (see Table 3). It includes drivers, barriers, objects, pathways, and results

Table 1. Historical development of HRM (on the basis of Cascio, 2005)

Stages of the development of HRM	**Time period**	**Relevant tasks**	**Role**	**Focus of restructuring within the stage**
(1) HR-Partial/File-Administration ("File-maintance")	until mid of 1960s	Fulfillment of management information needs	Personnel Office	Focus on restructuring of HR data base
(2) HR-Full-Administration "Government accountability"	from the mid of 1960s until mid of 1980s	Compliance with legal & tax rules, fulfillment of administrative and legally mandated tasks	Personnel Administration	Focus on optimal, legal handling of a full range of administrative tasks, development of HR departmental structures
(3) HR Professionalization ("Organizational accountability"	in the 1980s and 1990s	Accountability for success (in single business units), effective use of HR-Tools (recruitment, development, etc.) for business success	Personnel Management	Focus on increasing professionalization of the HR departments, development of services and tools, optimizing the cooperation with other HR partners
(4) HR Strategic Integration ("Strategic business partner")	start in the late 1990s, ongoing development	"Add value to the business" (Cascio, 2005). Contributions with strategic impact, participative developed organizational strategy (strategic partnership)	Business partner and role sets, for example Ulrich (1997, 1998) and Lawler III & Mohrman (2003)	Focus on outsourcing, enabling of line managers to do HRM, inclusion of new fields (e.g., knowledge management, cultural development, creation of a new model of cooperation between HR partners)

Table 2. HRM functions and target groups

Groups of HRM functions	Target Groups
Strategic functions	Top-Management, Specific groups (high potentials, young managers)
Consulting functions	Line Managers and Employees
Service functions	All Employees

Table 3. Framework: Restructuring of HRM functions

Drivers
Globalization Need for Flexibility Intangibles Stakeholder demands IT-Technologies

Groups of HR functions	Objects of change	Pathways of change	**Results** (with sources)
Strategic Functions	Contributions to organizational success, Abilities, Skills, Values of HRM, Structures, Tasks, Activities, Tools, Quality, Costs	Change Management, Assignment of consultants, Improvement of service quality and delivery, Division of tasks, centralization, Cooperation (internal/external), Outsourcing, Cost cutting, Measurement of progress, Use of own concepts Self led/organized, Line manager responsibility, IT based services	Strategic contributions and takeover of strategic role (Cascio 2005; Lawler III et al., 2003; Ulrich. 1997, 1998) or role as strategic player (Ulrich & Beatty, 2001), support of organizational effectiveness (Lawler III, 2005), cultural change (Fairbain, 2005) or the change of mental methods (Pfeffer, 2005), "HR as key contributor to strategy planning" (Lawler III et al., 2004, p. 33)
Consulting (Consultancy Services)			Support of managers by realization of their business plans (Lawler III et al., 2003), new division of tasks--line-manager operate HRM tasks (Larsen & Brewster, 2003), the improvement of internal consultancy processes partly by means of modern HRIS, creating of HR policies (Lawler et al., 2004) or better consulting quality (Towers Perrin, 2005)
Services (Transactional services)			Centralization of transactional tasks/processes, implementation of Shared Services Centers (Bergeron, 2002; Lawler et al., 2004), specialized HR Shared Service Center, Outsourcing of transactional and consulting processes (Lawler & Mohrmann, 2003, Lawler et al., 2004) to new employee services companies (single HR service providers, consultants, employment services, and firms offering a full service in HRM), cost savings long/medium term (Towers Perrin, 2005), new vendor/ relationship management (Graddick-Weir, 2005)

Barriers
No sufficient abilities and skills for restructuring, Lack of available resources and tools, Divergent stake-holder interests, Quality externally provided solutions in HR consultancy and service conflicting interests in top management

as well as success factors and perspectives of restructuring of HRM function.

FRAMEWORK FOR RESTRUCTURING OF HRM FUNCTIONS

All activities of HRM restructuring must be aligned on the realization of the organizational strategy[1]. To differentiate activities, the framework is based on the different possibilities of HR to contribute to organizational success. It is proposed to use the widely known role set by Ulrich (as shown in 1997, 1998, and 2001) and to apply the concept of corporate value chain (Porter, 1985) to HRM (Becker, 2001). Taking this into account, three *relevant groups of HR functions* can be identified.

1. **Strategic functions:** Main objective is better strategy orientation of HR with the focus on strategic contributions. From this point, the corporate strategy should be defined collaboratively with HRM as a strategic partner (Broadly discussed by Ulrich & Brockbank (2001), Robinson & Robinson (2005) and Lawler III, Ulrich, Fitz-Enz, and Malden (2004)).
2. **Consulting functions:** Main objective is a stronger value orientation with the focus on value creation through HR activities. The relevant functions can be realized through professional consulting of line managers and employees by HRM and through facilitating and coaching line managers. These tasks were described by Ulrich (1997, 1998) as tasks of HR as a business partner.
3. **Service functions:** HRM contributes to cost reduction and proves its own efficiency. Main objective is here an improvement of service orientation with the focus on transactional processes or operational excellence. The potential to realize theses processes technically is very high. Actual examples are ESS and MSS, which allow employees/managers to do parts of HRM by themselves. These could be realized technically by human resources information systems (HRIS).

The potential for value creation is much higher by means of strategic functions as by means of administrative functions. The three groups of HR functions correspond with the three future HR product lines as defined by Lawler III et al. (2003). Moreover, different target groups could be addressed.

The drivers and barriers, objects, pathways and results of the ongoing HRM restructuring have to be seen as having a specific impact on these groups of HRM functions in order to achieve the planned service level, to create the planned value or to reach a specific strategic contribution.

Drivers of HRM Restructuring

Drivers of HRM restructuring are closely connected with the development in the corporate environment. These factors include current trends in the environment with more or less influence on the enterprises as

- **Implications of globalization**. Globalization leads to the development of supranational relation between people, falling relevance of physical locations, complex international supply links with deep effects on organizational culture and working practices as well as mergers, acquisitions, divestures change traditional structures dramatically.
- **Increasing requirements on flexibility and mobility of Human Resources**. Lifetime employment and seniority-based systems are no longer in use; due to rapidly changing market conditions actual topics are contingent work, independent contracting, and more free-market arrangements (Capelli, 2005).

- **Arising role of stakeholder issues**. Stakeholders like investors, customers, employees and their respective expectations play an increasing role for the success of restructuring processes. HRM must increasingly align its practices with the requirements of stakeholders (Lawler III et al., 2004, Ulrich et al., 2005).
- **Importance of highly committed employees and the knowledge of employees as intangible assets**. HRM must meet the relevant business demands (IBM, 2005) and the expectations of employees according to the specific business situation. Role of leadership and personal involvement as well as coaching and facilitating for the long-time commitment and retention of employees is evident.
- **Information and communication technology enable the permanent use and deployment of actual workforce information for HRM**. In 2001 Walker present technologies, which had been used for restructured HRM (elements of HRIS like work flow, manager and employee self services, interactive voice response, HR Service Center, HRIS and databases, stand-alone HR-systems such as data-marts and data-warehouses).

Barriers of HRM Restructuring

Barriers can be divided into personal, organizational, and resource related barriers. Personal barriers can be seen in lacking abilities and skills for restructuring of the concerned persons, e.g. HR manager, or responsible management staff. Organizational barriers are closely connected with interests and support of the top management teams, and other stakeholders; divergent interests may have a negative influence on the restructuring process. Moreover, lack of resources and change management tools can be seen as barriers. Last but not least, a minor quality of externally provided solutions of HR consultancy and services will have a limitation effect on an outsourcing oriented restructuring.

Objects and Pathways of Changes in HRM Functions

The changes in HR functions are targeted at the various contributions of HRM activities to organizational value creation and success, but include the skills of HRM, the structures, the tasks and activities, the used tools, but also the quality of the offered contributions, and the respective costs. They are objects of changes following different pathways.

The significant failure rate of corporate restructuring underlines the need of concept-based restructuring (amongst others Beer & Nohria, 2000). The following deficiencies are known: No clearly defined roles, no ongoing measurement of success, and no systematic application of modern tools. Noticeable is the absence of complex practical concepts (see recommendations in Hewitt (2004) and Towers Perrin (2005)).

Pathways of HRM restructuring mainly comprises:

- **Use of concepts and experiences/measurement:** The usage of new management concepts like process management, or blue prints with role and process models is often recommended. Experiences show that restructurings start regular with the **centralization of transactional tasks**. Design of the HR department is often process oriented and follows the groups of functions (transactional, consultancy and strategic processes = shared services, consultancy services and centers of expertise) and includes **outsourcing** of tasks. Objectives of restructuring (e.g., **improvement of service quality and delivery** or simple **cost cutting**, are permanently measured). Performance measurement for HRM seems to be one important way for restructuring HRM.

- **Change Management:** Restructuring of HRM is often planned and organized as specific change process and is based on **IT based remodeling** of HR-processes. Roles and responsibilities are more or less clearly defined. The shift of tasks to **line management** leads to a new shape of HRM. As a result of task centralization, outsourcing and line manager responsibility, the re-arrangement of **internal and external cooperation** marks another pathway or restructuring.
- **Self organized or self-led:** Restructuring of HRM is managed by HRM themselves (Som, 2003). By their opinions and their behavior, HR executives can effectively promote or impede restructuring. If the HR executives are not being gained as change agents, restructuring starts with a change of management. Often companies use **assignment of consultants** for the preparation of restructuring of HRM.

Actual Status and Success Factors

At the moment, it must be considered that most companies are at the beginning of restructuring the HR function (Towers Perrin, 2005). The previously mentioned pathways can be mainly found in large organizations.

A precondition for successful restructuring is the definition of the future role of HRM. The advanced role set (see Lawler III et al., 2004, p. 23; Ulrich, 2001/2005) should be considered. These new roles include on the one hand new roles for HR professionals as business strategist, coach, designer and deliverer, facilitator, and on the other hand, three roles as manager, business and strategic partner (Lawler III et al., 2004, p. 23-42). That means upcoming different contributions to organizational value creation.

First experiences of HRM restructurings show the following groups of success factors:

- **Cost handling and expectancies:** It seems that cost savings in transactional processes through HR outsourcing are possible, but only in a medium and long-term perspective (Towers Perrin, 2005). Costs are not the only reason for outsourcing of HR services; other considerations as service quality and accessibility to the latest technology are important too - a single focus on cost can sub-optimize the efforts (Lawler et al., 2004).
- **Quality of services:** The quality of transactional and consultancy HR services--often internally or externally realized by means of HRIS--must secured permanently, because success of HRIS and HRM in the field of administration and consulting are closely connected (Becker et al., 1999, p. 295; Lawler et al., 2004, p. 32).
- **Cooperation with external providers:** If HR processes are outsourced HRM have to manage the cooperation with external providers effectively. Only HRM could define and assess the service delivery level of HR services. The long-term success depends on the company-vendor relationship (Towers Perrin, 2005).
- **Importance of strong management:** A strong management of HR restructuring is necessary to meet the expectancies of stakeholders (Ulrich et al., 2005) as well as to reach the own objectives. Ongoing strategic contributions by HRM are expected. That means that companies have to design and retain expertise in relevant HRM fields. If they lose expertise, they will be unable to take strategic tasks (Som, 2003, p. 286).
- **Measurement of own restructuring:** Specific metrics can be seen as a fundamental basis for a successful restructuring. A professionalized HRM is able to do this task effectively. Without an accurate measurement, it may impossible to determine how successful the restructuring of HRM will

be (Hewitt, 2004), which will consequently lead to problems with the legitimacy of HRM activities.

FUTURE TRENDS

Restructured HRM increasingly and systematically influences leadership processes, organizational culture, and organizational effectiveness, especially by means of new management tools - which are developed, introduced, and controlled by HRM.

The ongoing outsourcing of transactional HR-processes will cover other HR-processes like recruitment and consulting processes, as shown for recruitment processes (Sommer, Brauner, & Simon, 2005). HRM must furthermore develop its own strategic competence to be able to give performance related contributions to realization of the corporate strategy with main fields in change management, intangibles, and new organizational capabilities.

Furthermore HRM measures and developments have to be based definitely on a HRM own operational model ("Value chain") as well as an own value base. That means the overall "Values" of HRM: Visibility, credibility, responsibility, and accountability will be more important. Future HRM must be based, developed, and measured increasingly on these basic values.

CONCLUSION

The linkage between HRM systems and company performance is evident (for further descriptions see Bowen & Ostroff, 2004, Pfeffer, 2005) characterizes the tasks of HRM more comprehensively as "important keepers and analysts of an organization's culture." Furthermore HRM has proved to be a key source of organizational effectiveness - organizational design, change management etc. (Lawler et al., 2004, p. 39-40; Lawler, 2005). In order to effectively manage the HR function, HR management needs to measure and report a broad range of indicators (Hewitt, 2004; Saratoga Institute, 2006).

A successful restructuring of the HRM function will support a fundamental change from service oriented personnel administration to strategy focused HRM. The quality of restructuring of HRM function builds therefore the basis for the future role of HRM.

KEY TERMS

Consulting Functions/HR Consultancy Services: HRM is accepted as business partner and key part of the management team. It provides services and tools that enable line managers to do HRM by themselves. HRM also provides coaching and knowledge support in the area of people development and other HRM subjects.

Delivery Models: Approach for restructuring of HRM. Applying of business principles to HRM, HR can be organized along lines of business principle, focusing on different activities and deliverables like service delivery, policy expertise & consulting processes ownership, business partnership.

Employee Self Services (ESS)/Manager Self Service (MSS): Employees are able to view company and personal information. They could change individual information, put in employment related enquiries, apply for new jobs internally, or book measures of HR development. Managers have access to specific applications, which enable them to retrieve information on HR issues (policies, manuals, plans, strategies etc). Managers are allowed to run scenarios to salary increases, personnel costs, skill development etc.

HR BPO (Human Resources Business Process Outsourcing): HR BPO occurs when an organization outsource specific HRM tasks, or processes to a vendor. One actual example is recruitment process outsourcing (RPO), which means outsourcing of all recruiting relevant processes to a (specialized) provider.

HR Center of Expertise: Provides high-quality services with strategic impact, like competency & knowledge development. This Center provides strategic value by experts, who can redesign HR related processes and are able to develop and implement new HR policies. The Center also ensures that all HR practices are strictly aligned with corporate strategy.

HR Shared Service Center: Centralization of HR processes in one entity. Enables companies to achieve economies of scale by establishing a separate entity within the company to perform HR services (payroll, payments of benefits, and other transactional services like travel and expense processing).

Human Resource Management (HRM): Involves all management decisions and actions that aim at gaining competitive advantage by using its human resources effectively. These include providing of capable, flexible, and committed people, managing and rewarding their performance and developing relevant competencies. HRM runs HR practices like recruiting, retention, development, and use of human resources. HRM is often realized by specific HR-departments.

Service Functions of HRM: HRM has to deliver HR services efficiently. It could be measured on customer/employee satisfaction and costs. These services are mainly transactional services (like payroll/benefits). At present many large companies have centralized (HR shared service center) or outsourced transactional services.

Strategic Functions of HRM: HRM is an important strategic partner of the top management and key contributor to strategic planning and implementation as well as change management. HRM must give impulses for value creation (strategic HR programs, talent development).

ENDNOTE

[1] We are aware of the fact that this claim is normative, as a lot of stage models of HRM growth.

This work was previously published in Encyclopedia of Human Resources Information Systems: Challenges in e-HRM, edited by T. Torres-Coronas and M. Arias-Oliva, pp. 48-55, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Section VII

Critical Issues

This section addresses conceptual and theoretical issues related to the field of strategic information systems, which include failures and successes in system implementation. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters also address service quality in supply chain management, petri nets, and privacy and security in customer relationship management. Overall, contributions within this section ask unique, often theoretical questions related to the study of strategic information systems and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1

Information System Development Failure and Complexity:

A Case Study

Abou Bakar Nauman
COMSATS Institute of Information Technology, Pakistan

Romana Aziz
COMSATS Institute of Information Technology, Pakistan

A.F.M. Ishaq
COMSATS Institute of Information Technology, Pakistan

ABSTRACT

This chapter examines the causes of failure in a Web-based information system development project and finds out how complexity can lead a project towards failure. Learning from an Information System Development Project (ISDP) failure plays a key role in the long-term success of any organization desirous of continuous improvement via evaluation and monitoring of its information systems (IS) development efforts. This study reports on a seemingly simple (but only deceptively so) failed ISDP to inform the reader about the various complexities involved in ISDPs in general, and in developing countries in particular. An existing framework from contemporary research is adopted to map the complexities found in the project under study and the critical areas, which lead to the decreased reliability and failure in Web-based information system development, are highlighted.

INTRODUCTION

Information and Communication Technologies (ICTs) are globally recognized as an enabler of economic and social growth, and Information

Systems (IS) can play a key role in accelerated growth and development if applied properly. In the developing countries, there is much talk of "development leapfrogging" by deployment of Information and Communication Technologies (ICT). Developing countries are making direct deployment of the latest technologies, techniques, and methodologies for the use of information systems without the step-by-step use of previous technologies already abandoned in the Western-developed countries. In this scenario, most development efforts in the field of Information Systems are overshadowed by organizational dissatisfaction and schedule and cost overruns resulting in project abandonment and failure. The following quote from a UN report (Gilhooly, 2005, p. 25), mentioning Least Developed Countries (LDC), sums up the severity of the situation:

> *Failure to urgently and meaningfully exploit the available means to bridge the digital divide may consign many developing countries, particularly LDCs, to harmful and even permanent exclusion from the network revolution.*

In this chapter, our focus is Information System Development Project (ISDP) failure from the perspective of a developing country. Learning from an ISDP failure plays a key role in the long-term success of any organization desirous of continuous improvement via evaluation and monitoring of its information systems development efforts. The "learning from failure" factor assumes a higher level of significance in the context of developing countries. In developing countries it is very important that the scarce resources are optimally utilized in such a way that the probability of failure is minimized. This study reports on a seemingly simple (but only deceptively so) failed ISDP to inform the reader about the various complexities involved in information systems development projects in general and in developing countries in particular.

This chapter is organized in five sections. In section two we describe the general information system development process and the associated rate of failure in this industry. Section three discusses the relationship between failure and complexity. A case study is presented in section four, followed by conclusions in section five.

BACKGROUND

Most of the IS research reported in the literature falls in three main categories, that is, positivist, interpretive, and critical, and there is widespread consensus that interpretive style with a critical stance is most suited for researching the IS-related issues in developing countries. The research is interpretive in nature, and an interview approach is used for investigations. The research is of significance to a wide audience in the IS community who are interested in understanding the impact and influence of various factors on failure of an ISDP in the peculiar environment of a developing country.

An organization may have one or many business processes (work processes) producing products, services, or information. In order to run properly, these processes need support from:

- **External environment,** including regulatory policies, supplier, and competitor behavior; and
- **Internal environment,** in the form of resources and managerial and organizational commitment.

Information systems support or automate the business or work processes by processing the information which is usually limited to capturing, transmitting, storing, retrieving, manipulating, and displaying information. An innovative information system usually changes the existing business/work processes in order to make them more suitable for automation.

A typical organization is created, established, and eventually evolved through a mix of indigenous factors like social, cultural, technical, and political mechanisms and interventions. IS are tools that contribute to the effectiveness and efficiency of the certain processes of an organization; therefore, IS development efforts in the organizations of a developing country have to be oriented towards local innovation needs and prevalent professional techniques and methods. These techniques and methods bear a strong influence of the above-mentioned indigenous factors. In order to understand and analyze information systems in organizational context, it is useful to first review the issues that cast a strong influence on the implementation and success or failure of an IS. The theory of information systems has discussed these issues in different pedagogical forms. For example, Alter's theory (Alter, 1999) defines an information system as a particular type of work system that "processes information by performing various combinations of six types of operations: capturing, transmitting, storing, retrieving, manipulating, and displaying information". The fourteen statements characterizing a work system in general and an information system in particular, as described by Alter (Alter, 1999, p. 8) are given below:

1. **Definition of work system:** A work system is a system in which human participants and/or machines perform a business process using information, technology, and other resources to produce products and/or services for internal or external customers. Organizations typically contain multiple work systems and operate through them.
2. **Elements of a work system:** Understanding a work system requires at least cursory understanding of six elements: the business process, participants, information, technology, products, and customers.
3. **Environment of a work system:** Understanding a work system usually requires an understanding of its environment, including the external infrastructure that it relies upon in order to operate and the managerial, organizational, regulatory, and competitive context that affect its operation.
4. **Fit between elements of a work system:** The smooth and painless operation of a work system depends on the mutual balance and alignment between the various elements of the system plus adequate support from the external environment.
5. **Definition of an information system as a work system:** An information system is a work system whose internal functions are limited to processing information by performing six types of operations: capturing, transmitting, storing, retrieving, manipulating, and displaying information.
6. **Roles of information systems in work systems they serve:** An information system exists to produce information and/or to support or automate the work performed by other work systems.
7. **Degree of integration between an information system and a work system it serves:** The information system may serve as an external source of information; it may be an interactive tool; it may be an integral component of the work system; the information system and work system may overlap so much that they are virtually indistinguishable. The information system may also serve as shared infrastructure used in many diverse work systems.
8. **Content vs. plumbing in information systems:** An information system can be viewed as consisting of content and plumbing. Its content is the information it provides and the way that information affects the business process within the work system. Its plumbing is the details that concern information technology rather than the way information affects the business process.

9. **Impact of an information system:** An information system's direct impact on work system performance is determined primarily by how well it performs its role in the work systems it supports.
10. **Definition of a project as a work system:** A project is a time-limited work system designed to produce a particular product and then go out of existence.
11. **Phases of a project that creates or significantly changes a work system:** A project that creates or significantly changes a work system goes through four idealized phases: initiation, development, implementation, and operation and maintenance.
12. **Impact of the balance of content and plumbing in a project:** For projects of any particular size, those in which both content and plumbing change significantly have more conceptual and managerial complexity than projects in which the changes are mostly about content or mostly about plumbing.
13. **Work system success:** The success of a work system depends on the relative strength of internal and external forces supporting the system versus internal and external forces and obstacles opposing the system.
14. **Inheritance of generalizations, truisms, and success factors:** Generalizations, truisms, and success factors related to work systems also apply to information systems and to projects (because these are work systems).

Information System Development Project

According to Alter, an Information System Development Project is also a work system, though a time-limited one. The development process of an information system incorporates a high level of innovation, and therefore inherently possesses uncertainty of results. Chris Sauer (1993) divides this process into four stages as shown in Table 1. These stages are identified by the objectives and problems they posses, and at each of the four stages there are some influences from supporters, users, and developers on this innovation process.

ISDP Failure, Definitions, and Classification

All human endeavors, scientific, technological, or other result in success or failure. This success or failure outcome is also related with technological and organizational efforts regarding development of information systems. Generally success is praised at every level, and itself defends its characteristics and long-term effects; however, it is considered better to disown a failure. In a particular project, both success and failure can be companions, that is, when the project is facing a status of partial failure. Richard Heeks (2000) describes these three statuses of an information system as:

- **Total failure:** In this type of failure, a system is either not implemented or it is discarded soon after the implementation.
- **Partial failure:** In some cases a system is implemented and used for some period of time; however, the system fails to meet some of its primary objectives. This type of failure can also result in producing some undesirable byproducts or features in that system. In other words, the system only covers a subset of its objectives. Partially-failed projects are also referred to as challenged projects in literature.
- **Success:** The success is straightforward, a status of project where all the objectives of all the stakeholders are fulfilled by the resulting system.

Many researchers have believed that the study of failed information system projects can enrich information systems' body of knowledge by making us aware of the dynamic and cross-

Table 1. Phases of information system development

Phase	Activities
Initiation	• Detection of performance gap • Formation of attitudes • Development of proposal • Strategic decision-making
Description: The efficiency of certain work/business processes and tasks can be improved with an information system. These candidate processes and tasks are identified in the initiation phase, and an analysis is carried out about the extent and nature of changes that are necessary for improved efficiency; also, the people likely to be affected by these changes are also considered. A cost benefit analysis is carried out to ensure that the benefits of the proposed information system outweigh its costs, and then necessary resources are allocated for the project.	
Development	• Development of abstract system • Development of concrete system • Establishment of project infrastructure
Description : In this phase, the information system and supporting documents are produced and the related procedures are defined.	
Implementation	Introduction of concrete system to operational and organizational context
Description: In this phase, the new system is introduced in the workplace and users are trained to use it.	
Operation	Operation, maintenance, and enhancement
Description: In this phase, the new system is accepted and is running smoothly in the work environment. In case a major change is required by the users, a new iteration of the four phases will start.	

cutting reasons that lead to partial or full failure. An information systems development project can fail due to any number of reasons and the possible list can easily stretch to triple figures. Therefore, in order to understand the reasons that lead to failure in information systems development it is important to first understand the different categories of failure. One classification of failures is proposed by Chris Sauer (1993) and it defines the following five categories of failure:

- **Correspondence failure:** When a particular ISDP is not able to achieve its predefined objectives, it is categorized as correspondence failure, for example, the selected project was not able to meet the objectives defined in the contract.
- **Process failure:** When a development process is not able to produce the desired system or could not meet the resource limitations, it is categorized as process failure.
- **Interaction failure:** Sometimes, it happens that the users are not satisfied with the delivered system or some portion of the delivered system, which leads the users to lose interest in that system, and hence the level of system use is decreased subsequently. This situation is referred to as interaction failure.
- **Expectation failure:** A project always starts with some tough and high expectations of its stakeholders; however, the resultant product may not be able to fulfill the expectations of any or all stakeholders, thus resulting in expectation failure.

- **Terminal failure:** This is the case when a project is abandoned or cancelled before the final delivery. Termination of a project is the last thing that can happen to a failing project, that is, when there are no hopes of meeting any of the objectives of the project, it is terminated.

ISDP Failure Statistics

Many researchers have attempted to study the extent of failure in the IS industry. A milestone study in this area is the Chaos Report of 1994 by the Standish Group (1994). They surveyed 365 companies and conducted a number of focus groups and interviews in order to determine:

- The scope of software project failures
- The major factors that cause software projects to fail

The Chaos Report stated that 16.2% of projects were successful, that is, these projects completed on-time and on-budget, with all features and functions as initially specified. 52.7% of projects were partial failures, that is, these projects were completed and they became operational, but were over-budget, over the time estimate, and offered fewer features and functions than originally specified. 31.1% of projects failed, that is, they were canceled at some point during the development cycle. This research survey also tried to determine the most important success, partial failure, and failure criteria. Table 2 lists the three criteria in descending order of importance.

Table 2. Criteria of success and failure

	Success	**Partial Failure**	**Failure**
1.	User Involvement	Lack of User Input	Incomplete Requirements and Specifications
2.	Executive Management Support	Incomplete Requirements and Specifications	Lack of User Involvement
3.	Clear Statement of Requirements	Changing Requirements and Specifications	Lack of Resources
4.	Proper Planning	Lack of Executive Support	Unrealistic Expectations
5.	Realistic Expectations	Technology Incompetence	Lack of Executive Support
6.	Smaller Project Milestones	Lack of Resources	Changing Requirements and Specifications
7.	Competent Staff	Unrealistic Expectations	Lack of Planning
8.	Ownership	Unclear Objectives	Did Not Need It Any Longer
9.	Clear Vision and Objectives	Unrealistic Time Frames	Lack of IT Management
10.	Hard-Working, Focused Staff	Use of New Technology	Technology Illiteracy

Table 3. Failure statistics

	The Robbins-Gioia Survey	The Conference Board Survey	The KPMG Canada Survey	The OASIG Survey
Year	2001	2001	1997	1995
Country	USA	USA	Canada	UK
Survey Size	232	117	176	45
Survey Method	Not Mentioned	Interview	Questionnaire	Interview
IS Type	ERP	ERP	Multiple	Multiple
Failure Rate	51%	40%	61%	70%

To emphasize the gravity of the prevailing problem of failure in IS projects, some more reports are examined and a summary of findings is presented in Table 3 (IT Cortex, 2005).

- The Robbins-Gioia Survey was primarily focused on studying the implementation of Enterprise Resource Planning Systems in 232 companies. Out of these 232 companies, only 36% had experience of ERP implementation. The success or failure of the ERP implementation was measured based on perception instead of some objective criteria. Fifty-one percent of the companies perceived their ERP implementation as unsuccessful.
- The Conference Board Survey also studied ERP implementation. The most important finding of this survey was that 40% of the projects failed to achieve the business case within one year of going live. Projects covered in this survey were 25% over budget.
- The KPMG Canada survey was focused on identifying the reasons that lead to failure of IT projects. The survey reported that 61% of the analyzed projects were judged as failure. In this survey, more than 75% of projects were late and more than 50% of projects were over budget.
- The OASIG Survey reported that 7 out of 10 IT projects fail in some respect.

These statistics show the edge of the iceberg in the ocean of information system developments. The above-mentioned reports are concluded in these statements:

- An IT project is more likely to be unsuccessful than successful;
- About one out of five IT projects is likely to bring full satisfaction; and
- The larger the project, the more likely the failure.

These surveys are from the developed economies of the world. The financial costs of these failed projects no doubt present a constant threat for the companies in these countries; however, these countries have a solid financial base. This solid financial base lets them absorb the losses incurred by the failed projects. Now let us see some of the statistics of developed countries where the financial base is not strong enough, and the impact of a single project failure can do a lot of damage.

ISDP Failure Statistics for Developing Countries

Information Technology (IT) innovation is now considered necessary for development; during the last two decades, an understanding has emerged that IT can effectively be used to narrow the gap between the industrialized and developing countries. Information systems are now an important part of the diffusion and implementation of IT. In developing countries, information system development efforts are most widespread in areas of governance, health care, education, finance, and poverty alleviation. The main thrust of these initiatives has been to apply technology appropriately in such a manner that its adoption brings the perceived socio-economic benefits. There have been cases where imported information system solutions have been used as a starting point for adaptation, but mostly developing countries and donors have focused on developing appropriate and sustainable local information systems. The emerging trend is that most of the information system initiatives have not been appropriately conceived or developed, and therefore they have failed to fulfill the desired outcomes. There is not much empirical evidence available on whether information systems failure rate is very similar or widely different in developing countries as compared with developed countries. Very little research has been conducted in general IS failure in developing countries, and in the particular area of information systems for e-government there are some statistics available.

In developing countries, e-government is a representative area of IS development as it involves sufficient financial and technical resources. Richard Heeks (2003) presents a generic situation in his report about success and failure rates of e-government projects in developing countries. This report presents findings of multiple surveys and studies which help to draw a wider picture. The estimates from past surveys present a situation that encourages Heeks to conclude that the failure rate in developing countries is higher than in the developed countries. The success and failure rates estimated in the Richard Heeks (2003) report from past surveys are in Table 4.

Results of some more existing studies from developing countries are summarized as:

- Braa and Hedberg (2000) have reported wide-spread partial failure of high-cost health information systems in South Africa;
- Kitiyadisai (2000) has concluded that in the public sector, IS initiatives failure cases seem to be the norm in Thailand;
- Baark and Heeks (1999) found that all donor-funded projects in China were partial failures; and
- Moussa and Schware (1992) concluded that almost all World Bank-funded projects in Africa were partial failures.

These findings tell us that at least one quarter of the projects in the developing countries tend to fail, and this rate may be as high as 50%. The success rate range is 15% to 20%. A majority of the projects tend to end in what is termed as partial failure where major goals of the project were not achieved or there were significant undesirable results. These statistics of success and failure in developing countries become even graver when other factors pertaining particularly to the underdeveloped world are also taken into consideration. For example, as a general rule the investments involved in big IS projects are always high from a developing country's perspective, and if the project fails, the resultant losses incur long-term

Table 4. Success and failure rates in developing countries

Classification	**Literature**	**Poll**	**Survey**
Success	15%-	20 %	15%
Partial Failure	60%+	30 %	50%
Total Failure	25%+	50 %	35%

negative effects on the progress of a developing country. Also, IS development companies in developing economies are small and do not have sufficiently deep pockets to survive the impact of a failed project. As a result, a high failure rate in the IS industry indirectly impedes the growth of the IS industry.

ISDP Failure and its Effects on Developing Countries

Information systems projects are initiated in developing countries typically in institutions like governance, management, healthcare, and education, and usually the general aims are to increase efficiency, introduce transparency in working, and improve accountability. The above-mentioned institutions in developing countries are very local in context and have deep historical roots. The evolution of these institutions has been different from that of the similar institutions in the developed countries. Information system projects in developing countries are usually perceived as pure technical initiatives aimed at making the functioning of an organization or institution more efficient and effective. The current prevalent IS strategies have matured in the developed countries and thus have a strong association with a particular way of management and administration style. It is difficult to embed these IS strategies in local institutions of developing countries without regarding social and organizational aspects.

The main objectives of an information system are to enhance capabilities of an organization and to help the organization save monetary resources by reducing workforce, travel, communication costs, and so forth (Mirani & Lederer, 1994). A good information system is expected to help an organization meet its information requirements at all levels and produce the appropriate information results. The information systems of e-government projects are meant to provide access to information at all levels of society with faster retrieval or delivery of information, with features like concise and better format, flexibility, and reliability. The aim is to improve the responsiveness of public organizations. These benefits are expected to fulfill the needs of a developing country, save its resources and provide better living standards to its society at minimum cost. This particular goal is an attempt to bridge the gaps of digital divide in the world and to compete in the race of progress. A typical IS project requires a high level of investment in terms of resources and efforts. Once a project is started, expected results are projected at all levels of society and stakeholders. Unfortunately, if a project fails, it generates much more relative damage in a developing country than in developed countries. With the failure, not only all the prestigious and scarce resources involved in that project are lost, but it is considered as a setback to the progress and development of the country. In the long run, this failure is considered as a bad example for future investments in that type of IS project. This scenario discourages further attempts to develop information systems projects in the developing country. Hence a developing economy takes a long time to fully recover from the effects of failure in a large-scale IS project.

Web-Based Information System and Reliability

The failure in Web-based information systems is an area which is being studied with great interest. The case study presented in this chapter provides us an in-depth analysis of the causes of deficiency in reliability of a Web-based application. This lack of reliability not only decreased the use of the application, but also made the higher management reluctant to enforce its use on a regular basis.

Web-based applications, like the academic records management portal in our case study, are a unique type of information systems which interconnect a large number of users with the organization and cater to variable access rates. As the pool of users is big, the variation of influences is also wide ranging, which makes the user preferences a significant factor in the development of such applications.

With the increasing use of Web interfaces across organizations, for example, corporate and supporting applications, comes a dramatic increase in the number of users of the resulting systems. Due to this trend of connecting more and more of an organization's staff and clients together via Web interfaces, the system design models are becoming more user-centric, and place user requirements higher on the priorities list. Moreover, user satisfaction is also a major performance and quality indicator. This trend is also evident in our case study. As we report, the development team tended to focus totally on the user satisfaction and kept on incorporating the new and changing user requirements in the project design even to the last stages of development. This factor brought the Web application closer to failure due to a decrease in reliability.

Learning Lessons from a Failure

The IS failure in developing countries carries more importance for learning and investigation of failure causes, as it not only wastes the scarce and precious allocated resources but also discourages further investment. The opportunity costs are certainly higher in developing countries because of the more limited availability of resources such as capital and skilled manpower. This situation is best described (Heeks, 2000, p. 4) in the following words:

The failures keep developing countries on the wrong side of the digital divide, turning ICTs into a technology of global inequality.

For these types of reasons, a failure in development of IS in developing country poses a significantly important area of study. In countries like Pakistan, where domestic market and domestic IS demand has traditionally been very low, ISDP failures discourage further demands and growth in IS industry. This scenario has established the need for studying ISDP in Pakistan, especially the failed ones. We believe that there are more opportunities and lessons for learning from failed IS projects, than there are from the successful IS projects. We are not aware of an existing study that has reported on the extent of failed IS projects in Pakistan. This chapter is a first step to fill this gap. We have chosen one small and simple IS project to study ISDP failure in Pakistan. We would also like to point out that a single case study can provide no basis for estimation of overall failure/success rates in Pakistan, and further work needs to done in this direction.

ISDP FAILURE AND COMPLEXITY

In this section we discuss the type of factors that can participate in an information system development failure and the associated role of project complexity in failure.

ISDP Factors and Dependencies

In this section we discuss what type of factors can participate in an information system development failure. During the four stages of the information system development process (initiation, development, implementation and operation), the development process is influenced by various factors; however, the degree of influence of these factors varies at different stages. There is no definite list of factors and no definite degree of influence which they make on the process. In order to understand the different possible factors, it is useful to discuss them from different perspectives. One perspective is that of the user factors (Havelka, 2002); these include:

- Biasness of users towards system performance;
- Commitment of users towards providing support to project;

- Communication skills of the users: whether or not the users can elaborate the needs and shortcomings of delivered system;
- Computer literacy levels of the users: whether or not the users can understand barriers and bottlenecks of common systems;
- Extent of users' participation in requirement gathering phase to the training phase;
- Users' know-how about the organizational processes and work flows; and
- Users' understanding of the requirements of the new information system.

Ananth Srinivasan (1987) has discussed organizational factors and the type of effects that these make on the IS development process. These include:

- Available resources (both human and financial): The human resources affect the development process positively, but increased financial resources are related to team disagreement;
- External influences on the development process: The degree of external influence on the system development effort needs to be carefully monitored and controlled; and
- Project team's exposure to information systems: Systems exposure in the firm allows an increase in the degree of awareness among project group members about the different problems encountered by users and systems staff.

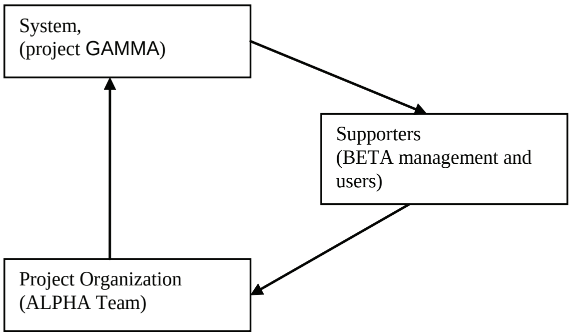
There are also some exogenous factors involved in influencing the development process as discussed by Chris Sauer (1993). These factors are cognitive limits, technical process environment, organizational politics, structure, and history. The environment is a collection of some other factors such as suppliers, technology, customers, competitors, interests, regulators, and culture.

All of these factors exist in their respective contexts and influence the information system development project. This is not a definite list; however, it helps to understand that there exist different factors when the system is studied with different perspectives. To examine the roles and dependencies of these factors in an integrated environment of information system development project, Chris Sauer presented Triangle of Dependencies (Sauer, 1993). The triangle of dependencies presents a cycle of interaction between supporters/users, the project development organization, and the system (under development) itself.

Model of IS Project: Triangle of Dependencies

The project organization (ALPHA in this case study) is defined as a group of people who, at a particular point in time, are occupied with the development, operation, or maintenance of a given information system (project GAMMA in this case). The information system must serve some organizational stakeholders and thereby function

Figure 1. Triangle of dependencies



as a resource for the project organization in gathering support. Supporters (BETA and its employees in this case) provide support in terms of monetary resources, material resources, information, and so forth. This triangle is depicted in Figure 1, and it is not a closed triangle. Each relationship is subject to a variety of exogenous factors which influence how it will affect the rest of the triangle. It was obvious that some resources were given to ALPHA development team by BETA management and the development of project GAMMA started. ALPHA delivered documentations and presentations on the working and status of the project to BETA at different milestones, to win the support from them by satisfying their needs.

It is important to keep in mind that information systems are developed and exists to fulfill the needs of stakeholders, and it is important for stakeholders to support the system in return. As the project organization plays the creator role for the system development, it is not possible to do it without any support from the users. Thus this situation exists like a triangle where the user organization supports the developers so that they can develop a system which fulfills their needs. If the system satisfies the users, they support the developer's organization in the development process, which enhances the system for further needs.

Dependencies of the Factors

This triangle clearly presents three sides of the software development process. It starts with the flow of support from supporters to project organization, the second side is the relation of system to supporters and the third side is the relationship of project organization to the information system. In the next paragraphs, the sides and corners of this triangle are discussed in detail.

The project organization is the group of people who are involved in the development of the system. Different people play different roles in the complete information system process, for example, development, implementation, and maintenance. The team leader plays an important role; he guides the whole team towards a particular goal. The competency of the team in understanding the problem and scope of the problem, as well as the development model they follow, are two of the major factors beside many others which influence the project.

The supporters are the people who support the project organization by providing them with resources as well as problem scope and definition. The resources, including monetary resources, material resources, information, social legitimacy, and control of strategic contingencies, are provided by the supporters to the project development organization. The supporters can also be categorized as funders (because they provide financial resources), power brokers (because they exert influence on project organization), and fixers (because they provide information and control decisions) (Sauer, 1993). Users of the system are an important part of the supporters as they not only provide basic information and requirements but also provide feedback to the funders and power brokers to make long-term decisions. It is important to note that the factors like organizational politics, nature and sources of power, history, and environment of the organization are the factors which make direct influences on the triangle.

The relationships among the system, project organization, and supporters are also interesting to examine. Each relationship contains different types of characteristics and factors which also influence the whole system. For the supporters-project organization relationship, the most significant thing is the flow of support. If the system satisfies the supporters, then the support for the system is there; if the system does not meet the goals, as perceived by the supporters, then the flow of support becomes problematic. The supporters-project organization relationship is based on human cognitive behaviors and is directly affected by organizational structure and politics. The second relationship is the system-supporters relationship, which also depends on the organizational factors. The needs of the organization for the system may change with time, due to which the system may become unacceptable. There can be some political changes due to which the degree of satisfaction may diminish. Factors related to users (biasness, skills, commitment, and understanding of needs) as well as the technical process by which the system is being evaluated directly influence this relationship. The relationship between project organization and system has a technical orientation, as it mainly consists of a technical process of information system development. This process consists of designing, creating, implementing, and making changes as required by the supporters. In this relationship, factors like communication and cooperation among team members, tools for development, requirement specification, the team's exposure to information systems, development process, and skills have influences. There are also some factors which come from the other sides of triangle to affect this relationship, for example, structural changes in the user organization can cause changes in requirements, and the system may need to be modified accordingly. The project organization might be at a stage where it cannot afford any shortage of support from the supporters, and the system may also be at a stage where it needs major changes and as a result may overshoot schedule. These types of problems demand a great skill set from the team leader.

Flaw

As discussed in the previous section, there are many factors which influence an information system development project, and these factors have different dependencies among each other. Every factor influences the project, and its effect is important for the success or failure of the project. Thus one cannot say that a particular factor should be ignored or its influence should be negated. These influences create a state of balance between different stakeholders and can make a project successful. However, at some stage the effect of these influences makes some aspects of the process uncontrollable, but at the same time, helps other factors to render positive influences. These unbalanced influences create flaws in the process, and the result is a flawed system/project (Sauer, 1993). The factors which highly influence a system and then tend to create flaws and make hurdles in the success of an IS project are termed as risks (Ward, 1995).

Information systems development process is open to flaws, and every information system is flawed in some way. However flaws are different from failure. Flaws are a characteristic of the system itself and also of the innovation process. Flaws are never desired by any stakeholder, for example, project organization, users, or supporters. Flaws are corrected at a cost or are accepted at some other cost. One technical type of flaw is a bug, which either stops a running program or destroys the results. Another type of flaw is any system characteristic which the users find inconvenient or otherwise undesirable, for example, a particular data entry form. This kind of flaw can also be corrected or accepted at a cost. There may also be flaws in the development process that are introduced by a decision about how to proceed in a particular step in the process. A particular decision may give the desired result with perhaps a greater cost, or may produce some other flaws.

Thus flaws are problems which occur as a consequence of events in the development process. Unless there is support available to cope with them, they will have the effect of reducing the system's capacity to serve its supporters or of resulting in further flaws. As this capacity to serve the supporters decreases and cost of managing the flaws increases, the project becomes more prone to failure. No stakeholder can continue to support the costs of flaws forever. In the long run, they will start to take notice of rising costs and undesirable results and reduce their support. When the support dries up, the system lacks the necessary resources and tends towards failure.

Complexity

We have discussed flaws in information systems and their negative effects on information system development, and one may reach the logical argument that flaws of a system should be removed. However, as these flaws are caused by interconnected factors, removing a flaw can generate negative effects on other parts of system. This situation renders complexity into the information system development process, where removing one flaw can develop other flaws. The definition of complexity varies in different contexts. Baccarini (1996, p 202) defines complexity as:

The complexity can be defined as an interaction of several parts which can be made operational differently and in interdependent ways.

Suppose we have a particular system in which there are many components. All these components have some intra-component dependencies. Each component may be independent and may have a particular behavior and influence in the whole system. Every component is not only dependent on its internal dependencies but is also affected by other components. These inter-component dependencies help the components to make a complete system for a particular purpose. All these components interact with each other to fulfill requirements and dependencies of other components. As all the components are independent, and have their own intra-component structure, they can work and behave differently if some changes occur in their internal composition. When these components work in a system, they can operate in different ways, and can have different effects on the system at different times. One or more than one independent component can lead to a situation where it has different effects on the system, and these influences can create an imbalance in the system's working. Now the problem solving can produce a complex situation, that is, which factors of a component should be negated to let the system keep working?

A similar situation arises in an information system development project, where the project is a collection of many different sub-processes and components. Each sub-process is not only separate but also dependent on the other components of project. In this type of system, the complexity is a situation where we have to leave a negative effect of a component on the system to let the system not be destroyed due to negative effects of other components. Thus the complexity of most information systems means that:

Cost of leaving a flaw uncorrected may be significant because of consequential effects it might have on other parts of system. (Sauer, 1993, pp. 63-64).

Suppose in a particular project a new requirement is made by the user and the project is delayed because of this particular requirement. Now if the requirement is not provided in the system, the user is not willing to accept the project, and if the requirement is fulfilled the project is delayed. This is a complex situation where we need to leave one flaw to avoid consequential cascading effects on the project. The factors involved in creating imperfection lead toward increasing the complexity of an ISDP and subsequently decrease its probability of success.

Complexity and Failure Relationship

Although flaws are in every system, they are not the cause of every failure; however, flaws lead a system towards failure. The relationship between flaws and complexity has been discussed in the previous section, and we saw that complexity also leads an information system towards failure. The complexity which is caused by the flaws is one of the major risk factors involved in the failure of information system development projects. Presence of complexity is considered one of the biggest risk factors involved in project failure (Barki, Rivard, & Talbot, 1993). Level of complexity and time duration of project are directly related to failure. As the complexity of the project increases, the time duration needed to solve the problems also increases, and on the other hand the sense of urgency also creeps up and wrong decisions are made. One way to reduce the level of project risk and failure is to reduce the level of complexity (Murray, 1993). British Computer Society (2003) found that the most common attribute underlying the failed projects was the high level of inherent complexity in the failed projects. Thus it is obvious that to improve ISDP success rate and the rate of return on IS investment, organizations must address the problem of complexity in ISDP and reduce it within manageable limits (Xia & Lee, 2004).

Virtually every IS project will increase in complexity once it has been initiated. Sense of urgency in announcing the end date and addition of post-initiation components/technology are two major causes of complexity for an IS system (Murray, 1993). Size is also a source of increasing complexity, because to solve a bigger problem the project is decomposed in smaller components, and thus complexity of interaction between the components increases (AlSharif, Walter, & Turky, 2004). This implies that complexity is one of the major causes of failure of information systems, thus studying the complexity of an information system can reveal the causes of failure. Dissecting a particular failure in the light of complexity will help us to understand the areas and flaws which should be provided more careful analysis in the development process.

Classification of Complexity

Complexity is one of the major reasons for information system development project failure, which encourages one to study an information system development project and analyze different complexities related to it. For this purpose we select a framework for ISDP complexity to classify different complexities. In this classification the ISDP complexity is divided into four different categories including technological and organizational factors. Xia and Lee (2004) classifies complexity in two major dimensions, organizational and technological, and then plots it against a third dimension called uncertainty for both the organizational and technological dimensions. As a result, four classifications emerge which are depicted in Figure 2.

Structural Organizational Complexity

A project always gets maximum influences from the organizational environment for which the project is being developed. The current organizational environment and the business processes present their own influences and complexities. This category of complexity presents the nature and strength of the relationships among project elements in the organizational environment, including project resources, support from top management and users, project staffing, and skill proficiency levels of project personnel.

Structural IT Complexity

The technology is itself a factor which causes many complex situations in the development project. Information technology not only includes the hardware, but also represents the software engineering and project development factors. This category represents the complexity of the relationships among the IT elements, reflecting

Figure 2. Taxonomy of ISD projects complexity

Organizational vs.	Structural Organizational Complexity	Dynamic Organizational Complexity
Technology	Structural IT Complexity	Dynamic IT Complexity

Structural vs. Dynamic

the diversity of user units, software environments, nature of data processing, variety of technology, need for integration, and diversity of external vendors and contractors.

Dynamic Organizational Complexity

As the time passes in the stages of development of an information system project, there come many changes in organizational environment and its business processes. The dynamic organizational complexity covers the pattern and rate of change in ISDP organizational environments, including changes in user information needs, business processes, and organizational structures; it also reflects the dynamic nature of the project's effect on the organizational environment.

Dynamic IT Complexity

Information technology is rapidly growing and changing. In the life span of an information system development project, there come many changes in the underlying information technology platform and tools for software engineering. This dimension of complexity measures the pattern and rate of changes in the ISDP's IT environment, including changes in IT infrastructure, architecture, and software development tools.

Now let us discuss some of the factors from each of the categories and understand their effect on increasing the complexities. In a particular project, the users may not provide the type of support needed by the project organization. In this situation, the requirements may not be provided correctly to the development team, which in turn may produce a faulty system which may not satisfy the needs of users or supporters. This situation can be worse if the top management does not give sufficient support, as the financial support is directly under the control of top management. The formation of the development team also plays a crucial role, as lack of team staffing or their skills can delay the time lines and lose further support. Then there are also some organizational factors from both of the users' and developers' organizations. As time progresses, there are some changes in the organizational environments and some new factors emerge from this situation. There may be some changes occurring in the organization itself, for example, the business processes of the organization are changed by the management. The management structure of the organization can also change; and this can cause changes in the organizational needs and rules. These changes can also be due to the new information system, and in this case the developer has to face an opposition from different sectors of the user organization. Some organizations do not have a defined set of business processes or have flexibilities in them; due to adoption of information systems, these flexibilities are limited and this scenario can also cause opposition from the users.

The nature of the project also poses its own complexities, for example, if the project involves multiple user units or involves different vendors and contractors. This type of project is open to different stakeholders to impose their decisions, and prone to different influences and flaws in return. These factors are summarized in Table 5.

THE CASE STUDY

In our case study, the developer is referred to as ALPHA and the client is referred to as BETA. ALPHA was one of the leading software houses in Pakistan operating as an independent business unit of a large and reputed international company. BETA was a top bracket public sector university. The ISDP was a Web-based portal for academic records management referred to as project GAMMA in this case study.

Research Methodology

In order to understand the factors which led the project GAMMA to failure, we conducted several

Table 5. Factors of ISDP complexity (Xia & Lee, 2004)

Complexity Factor
Structural Organizational Complexity - The project manager did not have direct control over project resources. - Users provided insufficient support. - The project had insufficient staffing. - Project personnel did not have required knowledge/skills. - Top management offered insufficient support.
Structural IT Complexity - The project involved multiple user units. - The project team was cross-functional. - The project involved multiple software environments. - The system involved real-time data processing. - The project involved multiple technology platforms. - The project involved significant integration with other systems. - The project involved multiple contractors and vendors.
Dynamic Organizational Complexity - The project caused changes in business processes. - Users' information needs changed rapidly. - Users' business processes changed rapidly. - The project caused changes in organizational structure. - Organizational structure changed rapidly.
Dynamic IT Complexity - IT infrastructure changed rapidly. - IT architecture changed rapidly. - Software development tools changed rapidly.

in-depth qualitative interviews. These interviews were flexible and exploratory in nature. In these interviews our later questions were adjusted according to the response of the interviewee in answering the earlier questions. Our aim was to clarify the earlier responses, to follow new lines of inquiry, and to probe for more detail. The overall interview style was unstructured and conversational, and the questions were open-ended and designed to elicit detailed, concrete information.

The persons interviewed included the ALPHA Project manager and the ALPHA technical team lead, and the BETA team lead, BETA coordinator, and a few users at BETA. The answers that warranted more clarification or were, to some extent, conflicting to the views expressed by the other side were further probed in the second round of discussions. ALPHA and BETA interviews were segregated from each other. Interview settings included individual and collective participation of the interviewees. The information collected was mapped on contemporary theoretical frameworks discussed in Sauer (1993) and Xia and Lee (2004) to analyze the responses and understand the role of different factors that led to the failure of our specific case under study. The information was then examined with the help of Taxonomy of ISDP complexities, and factors of each category were identified.

In the sections bellow, the process of different phases of information system development is discussed.

The Team from ALPHA

ALPHA had a team of skilled software engineers, and the average experience of team members was three-and-a-half years. The manager of the ALPHA team had software project management experience of six-and-a-half years. The ALPHA team comprised of a blend of analysts, designers, coders, and testers. ALPHA followed the incremental development approach for projects with a time period of more than eight weeks, and hence the same approach was followed in this case.

The Team from BETA

BETA made a focal team comprising of senior faculty members from different departments led by one Head of the Department. The focal team at BETA was mandated to collaborate with the ALPHA team. The responsibilities of the focal team were to help the ALPHA team to capture the information about policies and procedures of the academic and administrative departments and units of BETA. Its main role was also to help ALPHA understand the processes and verify the requirements against specific processes. The focal team acted as the client representative and in the later stages also tested the portal and gave feedback to ALPHA team.

The Complete Process

At the start of the project, a preliminary set of requirements was agreed upon between the BETA focal team and the ALPHA team. A total of eleven modules were identified, out of which eight modules were deemed to be more critical than others. The technological requirements were not rigid, and it was generally agreed to encourage the platform-independent technologies including Java and Linux. Regarding the choice of database, BETA preferred to use Oracle as it already had the license. Next the ALPHA team analyzed the preliminary requirements by collecting the data and observing the business processes and procedures. Both of the teams visited different academic departments and held meetings with the heads of the departments and different other employees. The same was done in the administrative units to record the data and procedures of different business processes. After analyzing the collected information and additional requirements, a standard requirement specification document was developed and agreed upon.

In the meanwhile, some significant changes occurred at BETA. Due to some routine and policy decisions, some of the members of the focal team from BETA were transferred, and newly-appointed persons took their place. As the people changed, the mindset changed and the vision about the project also changed. Changes at the organizational level of BETA led to some new requirements emerging from nowhere and caused frequent changes in the old requirements.

Surprisingly, ALPHA team had to face many objections on the already-settled requirements, which were conveyed from the user departments and the end users themselves. The new members of the BETA focal team were not clear about the scope and objectives of the project GAMMA, and they also did not agree with the version of the requirements provided by the former members of the BETA focal team. Due to this kind of divisive environment, a huge time was lost in the advancement of the project. ALPHA team was willing to work according to the satisfaction of the client organization and hence wanted to listen to the client's focal team members. As there was no consensus on requirements within the client organization, ALPHA decided to conduct some presentations and meetings with the representatives of all departments and the focal team.

After some presentation and discussion sessions, the analysis of the requirements with a conclusive set of requirements was presented, and the software requirements specification document was once again finalized after incorporating the revised requirements.

At this stage, in order to minimize the impact of organizational changes on the project, the management of BETA appointed a software engineer to lead the BETA focal team with the mandate that the newly-appointed lead person will work continuously in the next phases until the completion of project GAMMA. The new lead person coordinated with the ALPHA team and helped them to complete the trial version of the project. ALPHA finalized the trial version of the project and deployed it at BETA. In April, 2004, the first version of the project was deployed at BETA, and testing was done by ALPHA's testers using real data.

At this stage, training sessions were held by the ALPHA team members to guide the key potential users at BETA, with the objective that these people will use this portal and identify errors, bugs, and changes. As per the evaluation and trial report of the project, the users complained about a number of deficiencies. They reported variances in the expected and actual implementation of different functionalities. There were errors in data processing which caused the potential users at BETA to lose their interest. They also complained that the training was of very basic level and was not properly designed and executed. The ALPHA team was of the opinion that people attending the training sessions were mostly used to using an older existing IS system and thus were reluctant to shift to the new system. Their association and familiarity with the older system created hesitancy and an attitude of disinterest which prevented them from appreciating and exploring the full functionality of the new portal.

It was observed that for some particular processes there were no standard operating procedures, and different departments followed different procedures. This situation demanded flexibility in different data structures and functionalities of the GAMMA system. As an example, the pattern of student registration numbers varied in different departments. Such anomalies caused some requirements changes, even at the later phases, and delayed the implementation.

At this stage, the person who was hired earlier and was leading the BETA focal team through the development phase left BETA for another job. This particular development compelled BETA to restore the old structure of the focal team of BETA. Now the Head of the Department of Computer Sciences was assigned the role of team lead by the client organization. The project at this stage required transferring the existing data from the old system to the new system, and new data entry as well as testing the real-time application behavior. The developers from ALPHA provided scripts to convert data from the old system based on SQL server to the new system. However, according to BETA, the scripts did not work as per requirements which had to be modified time and again. BETA formed another team referred to as "Testing Analysis Team", to test the portal, and the team members were provided training by ALPHA. Moreover a person was selected from each faculty as master trainer, who was entrusted the task to further train the end users within his faculty. This task took another six months of time and further delayed the successful implementation.

The project started in September, 2002, with the planned completion date of December, 2003. A formal audit was conducted by the external auditors, engaged by ALPHA, in December, 2003, who found that the delay was justified as the requirement engineering phase took a much longer time as discussed above. The project took off a little in September, 2004, when the Head of the Department of Computer Sciences started to lead the team to implement the project. However, the project implementation came to a standstill in December, 2004, when the client organization desired deputation of full-time experts by the ALPHA organization to supervise the implementation, which included training of the end users to use the system and subsequently adopt it. ALPHA expressed their inability to depute an expert without charging further expenditure to BETA.

At present the status of the new portal is that it is being used as a passive repository of data. The new system has not been adopted by the end users, and the system that earlier existed is in use at the organizational level. ALPHA has received part of the agreed payment amount and has an outstanding claim for the balance payment from BETA. Both organizations consider it a failed project. BETA considers it a failure as it has not been implemented and adopted at the organizational level. ALPHA considers it as a failed project because, besides the financial loss, the product is termed unsatisfactory by the end users and has not been successfully deployed and adopted at organizational level.

The main reasons for the failure of this simple IS project can be summarized as follows:

- Adaptation and modification of underlying organizational processes in such a way that they become conducive for automation is an issue deeply intertwined with project definition and has to be tackled in the very beginning. Once the processes have been reengineered, only then the scope of an automation project can be fully visualized by all the stakeholders. This factor was initially ignored in the project GAMMA when the first version of project requirements was specified. Halfway through the development process of project GAMMA, the inadequacy of the organizational processes of BETA, in terms of their capacity to lend themselves to automation, was realized.
- The existing organizational processes of BETA were not fully mature. Introduction of a new organization-wide IS system for records management and decision-making implied a number of changes in the way things were done at BETA. Alignment of organizational processes and the IS systems was very important for successful implementation of GAMMA. The end users at BETA were not ready to adopt the changed organizational processes necessitated by the introduction of new technology.

The various complexity factors (Xia & Lee, 2004) and their impact on project GAMMA is summarized in Table 6 and Table 7.

CONCLUSION

The main aim of the GAMMA project was to implement a Web portal for the academic and administrative records management of BETA. Hence system GAMMA was required to capture, store, and process data for a number of departments within BETA. Each department had its own perspective regarding the policies and procedures of data and records management. Being in the same organization, these processes were interlinked and processed similar data.

The different departments of BETA created complexity for the requirement analysis team to decide on a particular set of requirement specifications. On the other hand, the users also did not provide sufficient support, and their behavior was

Table 6. Structural complexity categories and their impact on GAMMA

Complexity Factor	Effect in this case	Level of Risk
Structural Organizational Complexity	Yes/ No	
- The project manager did not have direct control over project resources.	No	
- Users provided insufficient support.	Yes	High
- The project had insufficient staffing.	No	
- Project personnel did not have required knowledge/skills.	No	
- Top management offered insufficient support.	No	
Structural IT Complexity		
- The project involved multiple user units.	Yes	High
- The project team was cross-functional.	Yes	Medium
- The project involved multiple software environments.	No	
- The system involved real-time data processing.	No	
- The project involved multiple technology platforms.	No	
- The project involved significant integration with other systems.	Yes	Low
- The project involved multiple contractors and vendors.	No	

Table 7. Dynamic complexity categories and their impact on GAMMA

Complexity Factor	Effect in this case	Level of Risk
Dynamic Organizational Complexity		
- The project caused changes in business processes.	Yes	High
- Users' information needs changed rapidly.	Yes	High
- Users' business processes changed rapidly.	Yes	Medium
- The project caused changes in organizational structure.	No	
- Organizational structure changed rapidly.	Yes	Medium
Dynamic IT Complexity		
- IT infrastructure changed rapidly.	No	
- IT architecture changed rapidly.	Yes	Low
- Software development tools changed rapidly.	Yes	Low

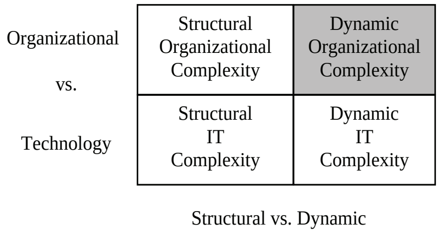
critical. The users from the lower management just pointed out the flaws in the system, even if they were because of flaws in the organizational processes of BETA. They did not accept the changes in business/organizational processes which were caused by the new information system. On the other hand, the business processes kept on changing due to their own needs as the people were also changing in the BETA organization. The changes in business processes caused the rapid change in information needs. At the technological dimension, there were also some changes in

IT architecture and software development tools, which caused more complexity in managing the project on target. The analysis shows that Dynamic Organizational Complexity, Figure 3, contributed most to the project failure in this case.

One of the important objectives of IS in developing countries is to bring about improvement in organizational and business processes. The information systems support the current processes to enhance the operations and improve information processing, which is helpful to the organization for making its business processes more efficient. These improvements are not without incurring any risk, as modifications or improvements are prone to introduce complexities (Heeks, 2000). However, this case study shows that the changes towards improvements in the processes caused by IS were not accepted by the supporters, which in turn increased the weight of various risk factors. On the other hand, the change in processes, due to the organization itself, caused delays and led the requirements to change significantly, which in the end proved fatal for the project. The inability of the development team to freeze the requirements and stick to the standard requirement specification is a major cause of the failure. However, the business scenarios, in developing countries like Pakistan, demand this type of flexibility in business agreements and job specifications.

With the help of this case study, we are able to identify a major problem area in the development of information systems in general and Web-based applications in particular. The lack of standard operating procedures in business processes and the evolution of new knowledge of business processes and technology encourage the managers of an organization to demand more features as well as the flexibility in them. The managers want to include many processes in the Web-based information system while these processes are either immature or are in phase of standardization; consequently, this demands extra flexibility from the developers and consumes more time. On the other hand, these immature processes are prone to changes as a result of political or structural changes. These business processes become the first target of new management to show that they are making changes in the organization. A weak legal environment in the developing countries like Pakistan does not allow the development team to challenge the client on the basis of service level agreement. This leaves only one choice for the developer's organization to adjust the demands (which look small as they come in pieces at a time) of the client, so that the support can be won from the client in the shape of financial resources. After some time it is realized by the developers that the small changes have combined, and there is a big requirement change demanding huge amounts of extra effort and time. The developers try to make these efforts and invest time in the project; however, at a certain moment it is realized that the complexities have been increased beyond control, and the project is heading towards failure.

Figure 3. Crucial area in ISDP complexity with respect to case study



Organizational vs. Technology	Structural Organizational Complexity	Dynamic Organizational Complexity
	Structural IT Complexity	Dynamic IT Complexity

The dynamic organizational complexities demand that a project should cover the business processes which have been standardized, or the information system should be allowed to standardize these processes. It is also the responsibility of the organization to show respect to the agreements and demand minimum changes in the requirements. In case of political and structural changes, a project should be owned by the organization, and the changes should not affect the project scope.

The responsibility of the developers is also high, as they should be aware of these complexities and adopt a strategy to cope with them. They should be able to take strong business and technical decisions to restrict the changes in requirements to a minimum level. On the technical end, they should be able to provide maximum flexibility in a minimum time frame. It can be concluded that responsibility of these types of failures cannot be given to one stakeholder; rather it is the responsibility of both the developers as well as the client organization to facilitate a project towards success.

Chapter 7.2

Critical Insights into NHS Information Systems Deployment

Rajneesh Chowdhury
CHR Global Consulting Services, India

Alan Nobbs
National Health Service, UK

ABSTRACT

This chapter discusses a systems methodology called strategic assumption surfacing and testing (SAST) that was used to understand the design and deployment of information systems in the healthcare context. It is based on the experiences of conducting SAST with a group of healthcare professionals, working in the National Health Service (NHS) in England. This application of SAST in the NHS setting highlighted deep politico-cultural concerns in the organizational setting, and it helped towards the conception of a normative inclusive approach for health informatics design and deployment. This approach introduces the understanding that the development of information systems in healthcare is a complex agenda, the success of which demands the active involvement of all stakeholders through all the key stages of the process. Critical perspectives on SAST have also been considered and the assumptions fostered towards arriving at the conclusions, have been highlighted.

INTRODUCTION

The responsibility of provision of healthcare services in England rests with the National Health Service (NHS). The NHS is the largest employer in Europe with an annual budget set to exceed £92 billion in 2007/08 (Department of Health, 2005). In October 2002, the NHS launched the National Programme for Information Technology (NPfIT) with the objective to create an integrated healthcare information system (IS) supported by information technology (IT). NPfIT has an anticipated investment of over £6.2 billion (Health

Informatics Community, 2004). However, there has been tremendous scepticism amongst key stakeholders regarding the success of NPfIT due to its lack of consultation with end users. The fundamentally top-down policy-led approach to the design and implementation of NPfIT and its lack of adherence to effective IS project principles have come under much spotlight as contributing to the feared failure of the project (Ballard, 2006).

This chapter argues that effective deployment of healthcare IS can be achieved by considering the interaction between a diverse range of factors within the organizational setting. This kind of an approach is inherent in the systems philosophy of management thought. Systems thinking has influenced a range of methodologies and techniques that facilitate stakeholder participation, boundary critique, and inclusive decision-making. Boundary critique (Midgley, Munlo, & Brown, 1998) is the idea that one's understanding of the world is bounded by the position and worldview they occupy. Therefore, the more one's boundaries are critiqued, the more informed and inclusive do understanding and perspective become. Strategic assumption surfacing and testing (SAST) is one such methodology that has been discussed in this chapter. Experiences from a SAST exercise with a group of NHS professionals and its resultant normative approach to health informatics has been illustrated.

HEALTH INFORMATICS AND THE SYSTEMS APPROACH

The NHS model of healthcare information system is epitomized in its NPfIT project, which in turn makes the promise to re-create the NHS as a high-tech environment. NPfIT aspires to deliver an integrated healthcare system for the NHS in England with its core in effective IS. The main elements of NPfIT are as follows:

- **NHS Care Record Service:** This is the central database of patients that will be available to authorized clinicians in the country, whenever and wherever required.
- **Choose and Book:** This is the electronic booking service whereby general practitioners (GPs) and other primary care staff are able to make hospital bookings at the convenience of their patients' date, time, and place.
- **Electronic Transfer of Prescriptions:** This service seeks to electronically link up the prescribers and dispensers of medicines in England. The objective is the connection between all GPs, community pharmacies and other dispensers.
- **Picture Archiving and Communication Service:** This enables medical images like X-Rays and scans to be stored electronically that can be viewed by clinicians in their video screens or computers. This is expected to eradicate hard films for recording radiographic medical images.
- **NHSmail:** This is the national e-mail and directory service that will be provided free of charge to NHS staff.
- **NHS Network (N3) Broadband:** This is the fast and reliable broadband service that will support the whole system. It is claimed to deliver the robust demands that will be made by the new system to deliver all the above services.

The previous developments, if implemented as planned, are set to pose the NHS as a truly high-tech organization with state-of-the-art IS support.

NPfIT and Related Challenges

Despite record levels of investments in NPfIT, there is considerable scepticism within the NHS and beyond that the project is heading towards failure. The Institute of Public Policy Research warned "that the program could be undermined by a failure to consult properly with medical professionals, a dearth of IT skills within the healthcare service and poor understanding of exactly what the health benefits are supposed to be" (Sherriff, 2004). Research and expert opinion suggest that core activities like clinical engagement, staff training, and system compatibility may have been compromised in the design and deployment of NPfIT. Gillies (2000) similarly notes that the primary reason why IT has not been a success in the NHS is that "IT has been technology driven not information driven" (p. 16). There are various factors resulting in this situation. Important ones among these may include the sheer size of the NHS, which posits tremendous challenges, management-clinician conflict where both perceive each other's roles as differing in common grounds, and underestimation on the complexity that IS projects have to deal with. For success in a project like NPfIT, clinical engagement and user commitment are paramount, along with the appreciation that different factors do not operate in isolation, but in interaction with one another. This kind of an understanding is the focus of the systems approach, which is discussed in more detail below.

The Systems Approach

Systems thinking is the philosophy in management thought that encourages holistic understanding. It supports the idea that organizations are constituted with elements that are in interaction with one another, and this interaction gives rise to the character and nature of the system (Jackson, 2003). Hence, emphasis is shifted from individual elements to the interrelationships between elements. Systems thinking encourages boundaries to be approached with criticality, and that boundaries can always adapt as a result of its interaction with its environment. Hence, a systems approach argues for the "sweeping-in" of immediate and non-immediate factors that influence the behavior of complex systems (Churchman, 1968). It therefore lends an inclusive and participatory perspective in the decision making process. As Hammond (2002) illustrates in Table 1, a systems approach has considerable implications for organizational planning and decision-making – those that are indicated in the left hand column; these ideas are in contrast to the ones in the right hand column:

Systems thinking can be of tremendous value in the design and deployment of IS. This is pertinent to the implications of considering the human, technological, and contextual factors in the conception and design of organizational IS. A systems approach can enable the understanding that IS of the present day are dominantly technology enabled human activity systems within specific contexts. Xu comments: "Systems science has been considered the basis of information systems. A wealth of research in information systems in the framework of systems science has produced an astonishing array of theoretical results and empirical insights, and a large suite of tools and methods" (Xu, 2000, p. 105).

The systems approach has influenced a wide array of methodologies and techniques to foster stakeholder involvement and facilitate participative decision making in complex situations. One of such methodologies is SAST. SAST has been discussed below in theory and practice in the context of IS design for the NHS. SAST has

Table 1. Social implications of systems theory: Contrasting views (Hammond, 2002, p. 431)

Participatory decision-making processes	Hierarchical decision-making processes
Self-organization	Externally imposed order and control
Free will, creativity, spontaneity	Determinism

been selected as an appropriate methodology in the current context as it facilitates decision making when there are two groups with distinctly opposing viewpoints. In this case, these are the management-led approach and the service provider-led approach in healthcare IS. This has been discussed in more detail below.

STRATEGIC ASSUMPTION SURFACING AND TESTING (SAST)

SAST is a methodology that was developed by Mason and Mitroff (1981) to enable managers to deal with complex situations in modern organizations. Mason et al. prefer to call complex problem situations "wicked problems" where issues are multidimensional, interconnected, and uncertain. Wicked problems that arise in these situations have social, political and organizational ramifications. Their understanding was governed by the idea that "in tackling wicked problems, problem structuring assumes greater importance than problem-solving using conventional techniques" (Jackson, 2003, p. 137). This leads to the understanding that unless the formulation and structuring of problems are addressed effectively in the beginning, we may end up tackling the wrong problems. SAST is therefore designed to formulate and explicate assumptions that people harbor in organizations.

SAST has been greatly informed by the following ideas of Rosenhead (1987), as described by Jackson (2003):

- A satisficing rather than optimizing rationale
- An acceptance of conflict over goals
- Different objectives measured in their own terms
- The employment of transparent methods that clarify conflict and facilitate negotiation
- The use of analysis to support judgement with no aspiration to replace it
- The treatment of human elements as active subjects
- Problem formulation on the basis of a bottom-up process
- Decision taken as far down the hierarchy as there is expertise to resolve them
- The acceptance of uncertainty as an inherent characteristic of the future and a consequent emphasis on keeping options open (p. 138).

Influenced by the philosophy of Churchman (1968)[a], Mason et al. embarked on a systems project that would accept the existence of a variety of worldviews, or *Weltanschauungen*, as an unavoidable prospect and embrace divergent subjectivity as a strength. Further, all worldviews are restrictive and a holistic perspective can only be achieved by synthesis of a variety of worldviews. A systems mindset would encourage one to question and formulate ones own assumptions and worldviews, and critically debate the same with opposing assumptions and worldviews (Churchman, 1968; Mason et al., 1981). Borrowing from Hegel, SAST is driven by the understanding that in any organization there would be a dominant set of worldviews--*thesis*, an opposing set of worldviews, *antithesis*, and there is always a possibility for the opposing worldviews to enter a state of constructive debate, and arrive at a higher level of understanding, *synthesis* (Jackson, 2003). This is however a never ending process, and the synthesis would always give rise to opposing set of beliefs. What is important for Mason et al. is that the worldviews and beliefs are derived from deep rooted assumptions that people hold in their minds. Management decisions are in turn dependent on these assumptions and beliefs. However, an effective organization is one that is able to formulate these assumptions and counter assumptions amongst its members and learn how it can behave differently from the knowledge that emerge. As Jackson notes:

> *An organization only really begins to learn when its most cherished assumptions are challenged by counterassumptions. Assumptions underpinning existing policies and procedures should therefore be unearthed and alternatives put forward based on counterassumptions.* (p. 141).

Constructive criticism and investigative debate is central to the previous philosophy. This philosophy is essential for "wicked problems" in complex organizations where not only there are a variety of opposing assumptions and beliefs, but also a tendency to subjugate the assumptions of the weak and the underdogs. SAST has therefore been designed to be participative, adversarial, integrative, and managerial mind supporting (Jackson, 2003). Decision-making process ought to involve different stakeholders with different assumptions and different ideas about how problems should be addressed. Hence, the situation should be adversarial, apart from being participative. Further, there ought to be the opportunity to bring together divergent views to a higher level of integrative understanding from which decision makers can gain deeper insights into wicked problems. Hence, this methodology has the potential to make a real contribution in the practical and operational level. The methodology of SAST follows four stages (discussed in detail in the next section): group formation, assumption surfacing, dialectic debate, and synthesis. The following is an account of SAST in action in the high-tech NHS environment.

A SAST exercise was conducted with a group of NHS professionals in June 2006. The purpose was to examine if the dominant and opposing viewpoints in the context of IS in the NHS can be brought together in synthesis. This was intended to inform the design of a route-map for IS in the context of UK public sector healthcare. This exercise was supported and funded by the NHS North and East Yorkshire and Northern Lincolnshire Network of Cardiac Care (NEYNLMCN).[b] The following discussion follows the methodology of SAST and the insights it generated in the exercise.

Group Formation

Group formation is the first stage where participants are divided into two distinct groups. The effort should be to "maximize convergence of perspectives" (Jackson, 2003) within each group and "maximize divergence of perspectives" between the groups. The result is two groups of opposing viewpoints with each group consisting of relatively like minded people.

There were eight participants in the exercise: one consultant clinician, one general practice manager, two nurses, one information support officer, one clerical staff, one service improvement facilitator, and one service improvement manager. The conflicting idea that was prevalent in the group was the design and deployment strategy of NPfIT and how a new health informatics strategy could be conceived and implemented. Certain participants believed that the prevalent top-down approach to the current NHS IS strategy was working and making progress. This was the dominant perspective overtly cherished by the NHS management. They believed that the new NPfIT system could be used for improvement in patient care and for the monitoring of clinicians' performance. They were of the opinion that there had been considerable consultation with frontline service providers before NPfIT was implemented. This represented the viewpoint of the management-led approach to health informatics. At the same time, there were other participants who believed that there had not been appropriate consultation before NPfIT was implemented. This was the opposing viewpoint. They believed that the NHS was wasting its resources in delivering functions that are not required by patients and the public. They were of the opinion that NPfIT was in a way imposed upon them by the management. This represented the service provider-led approach to healthcare information systems. They advocated that system specification and definition ought to come from frontline service providers like the clinicians, and that administrative staff should also have a say in the system as their role would radically change with the deployment of the new systems.

Considering the overt difference of opinion between the participants, they were divided into the following two groups, based on the approach they favored:

- **Group-1 (management-led approach)**
  - General Practice Manager
  - Service Improvement Facilitator
  - Service Improvement Manager
- **Group-2 (service provider-led approach)**
  - Consultant clinician
  - Nurse 1
  - Nurse 2
  - Clerical member of staff
  - Information support officer

The result was two groups where difference of opinion was maximized between the groups. However, as the following stages will show, this methodology facilitated the opposing groups to structure assumptions, many of which were quite similar instead of being opposing.

Assumption Surfacing

This is the second stage where the aim is to formulate and express key assumptions that members in the groups harbor. As Jackson (2003) notes, this should be done in a "supportive environment," where the aim should be as "imaginative and creative" as possible.

This stage may be facilitated with three methods: stakeholder analysis, assumption specification, and assumption rating. Groups can be asked to conduct a stakeholder analysis to identify who they think the relevant stakeholders in a particular project are, in terms of who the affected parties would be as a result of the implementation of a particular project. Groups may then be asked to specify their assumptions for each of their stakeholders. These specifications should be related to how these would influence the success of the project under consideration. Groups may then be asked to rate their assumptions in a chart rating them against two criteria: importance and certainty. A spokesperson from each group then has to make a presentation about the assumptions.

To facilitate this stage, both the groups were asked to state who they thought the stakeholders were in the implementation of IS in the NHS. The groups brainstormed their views in different rooms and agreed to a list of stakeholders. Following were the results:

- **Group-1 (stakeholders)**
  - Clinical professionals
  - Finance department of NHS
  - General public
  - Government, including the Department of Health (DoH)[c]
  - Healthcare IT Leads
  - IT Industry
  - Managers
  - Media
  - Patients
  - Regional and local NHS organizations
- **Group-2 (stakeholders)**
  - Administrative staff
  - Clinicians
  - General public
  - Government including the DoH and the Treasury[d]
  - Industry (Pharmaceutical and medical equipment companies)
  - NHS Management
  - Patients
  - Private healthcare providers
  - Suppliers (IT services including software and hardware and telecommunications)

  - Support staff (e.g. IT staff)
  - Universities (Research and epidemiology)

e

The groups were then taken forward to the method of assumption specification, where they had to state what their assumptions were. These assumptions were thought to effect the success of NHS IS strategies, with specific consideration to NPfIT. The responses were as follows:

- **Group-1 (assumptions)**
  1. IT industry has vested interest in personal gains.
  2. The media wants to portray a negative image and always wants to highlight problems.
  3. The media should be more positively engaged by NPfIT.
  4. The general public have a one-sided view, as portrayed by the media.
  5. The general public has a lack of confidence in NPfIT.
  6. The IT industry has a conflict of interest.
  7. The general public has a lack of understanding of the aims of NPfIT.
  8. The general public believes that money should rather be spent on healthcare and on professionals, than on IT.
  9. The government expects too much too soon from a complicated project.
  10. The government has an unrealistic timeframe for delivery of the project.
  11. The government is politically driven and does things that are locally irrelevant.
  12. The healthcare sector has a lack of expertise and lack adequate IT staff to deliver the project.
  13. The finance department underestimated resources needed for the national and local delivery of the project.
  14. Clinicians believe that they have not been consulted.
  15. Clinicians have an unrealistic expectation of participation.
  16. Clinicians have a fear of their IT skills.
  17. Patients are mostly not interested in getting involved.
  18. There is lack of training capacity to ensure skills for delivery.
- **Group-2 (assumptions)**
  1. NPfIT will go over cost. It is a white elephant.
  2. Administrative staff will be resistant to change.
  3. Administrative staff has no time to work with the new systems.
  4. Clinicians are not computer literate.
  5. Clinicians are time limited to work with the new systems.
  6. Patients are not computer literate.
  7. Clinicians are conservative to accept change.
  8. The government is control freak. It wants to control professionals with the information from NPfIT.
  9. Clinicians are sceptical about success of NPfIT.
  10. Patients want local treatment.
  11. Private healthcare services are only interested in profit.
  12. Clinicians are sceptical about patient confidentiality in the new system.
  13. NHS managers need numbers.
  14. Suppliers see NPfIT as an opportunity for profit.
  15. Administrative staff will find it difficult to use the new system.
  16. The treasury wants to keep costs under control.
  17. Patients lack knowledge about the system.
  18. The government wants to impose solutions all the time.

19. Universities need to do more research for information and funding.
20. Private healthcare services are always after more NHS work.
21. The government will blame someone else when the system does not work.

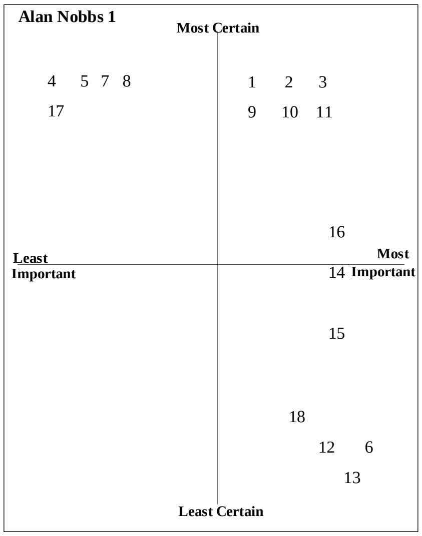
The groups then rated their assumptions in a chart against the axes of certainty and importance. A spokesperson from each group then presented their stakeholders, assumptions, and ratings to the other group. At this stage, it was interesting to note that although both the groups were supposed to be opposing in their viewpoints, there were many issues, which were common to both the groups. In addition to this, there were few elements, which both the groups seem to support as the root cause of many of the challenges faced by NPfIT. This is elaborated in more detail in the discussion below focusing on the presentation by each group.

Group-1 Assumptions

Group-1, which favored a management-led approach in healthcare information systems, believed that the IT industry had a vested interest in the implementation of NPfIT. The group however felt that this was a "gross assumption" in their part and they were not certain about it. The group felt that the media had a big role in portraying the NPfIT negatively. The media always highlighted problems rather than adopting a balanced position. This led to increasing scepticism of the project amongst clinicians and the general public. It was the view of group-1 that the media ought to be more "positively engaged" by NPfIT and the wider NHS as it is a "very important" stakeholder for the long term success of the project. This is because the media shapes public opinion. They also assumed that the general public had a fairly one-sided view about what NPfIT was, influenced purely on what they heard in the media. The public also suffered from a general lack of understanding about the aims and objectives of NPfIT. The public would rather be interested to see money being spent on healthcare *per se* and healthcare professionals, rather than support systems like healthcare IS.

The group thought that the government was to blame for making the project too complicated. This is because the government wanted too much sophistication in too little time. Therefore, the government had a "fairly unrealistic" time frame for delivery of the project. Moreover, it was the view of the group that the project was politically driven rather than being locally relevant to patients and clinicians. Members of group-1 also felt that there was a lack of expertise of IT skills in healthcare to realistically deliver the project. They felt that the finance for delivery of the project was also being underestimated. However, they were not certain about this as this may be the result of media reporting, and the way viewers, including the group itself, were picking up messages from the media. Regarding clinical consultation, the group felt that even it may have been misled by the DoH with the idea that appropriate consultation had taken place. The group was not sure whether or not clinicians were consulted appropriately. At

Chart 1. Assumption rating by group-1



the same time, they also felt that clinicians had an unrealistic expectation about what participation and consultation was supposed to mean, as consultation with every clinician is unrealistic. Fear of IT and skills deficit amongst clinicians was also featured as assumptions that came in the way of the success of NPfIT. Related to this, the group also featured that there was a general lack of appropriate IT training across all levels in the NHS.

Group-2 Assumptions

Group-2 favored a service provider led-approach to health informatics. Members of this group were certain that inspite of phenomenal investments in NPfIT, it was not yielding any of the anticipated benefits. However, at the same time, they also believed that administrative staff, patients, and clinicians may not be sufficiently IT literate to work with the new system. This may also have led to resistance to the change process, creating more challenges for the project. They also believed that patients lacked appropriate knowledge about the system and there was no appropriate initiative made to educate the public about the new system. The group highlighted that there was no realistic planning for training and development of clinical staff.

Group-2 was also critical of some of the objectives of NPfIT. For instance, one of the hallmarks of NPfIT is patient choice, but the group was confident that patients wanted local treatment. This discards one of the most important features of NPfIT itself. Members of this group also had grave concerns about patient confidentiality in the new system. They believed that the new system has been deployed without much consideration of security of access to patient details, which puts confidential patient information at risk.

This group also assumed that clinicians were conservative of change and not receptive to the new IS. This was creating grave challenges for the successful implementation of NPfIT. It was the view of this group that inspite of knowing about these challenges, the DoH did not take any specific measures to address them. The DoH rather proceeded with its own plan of deploying a system that would enable itself to have more control over the clinicians and management processes.

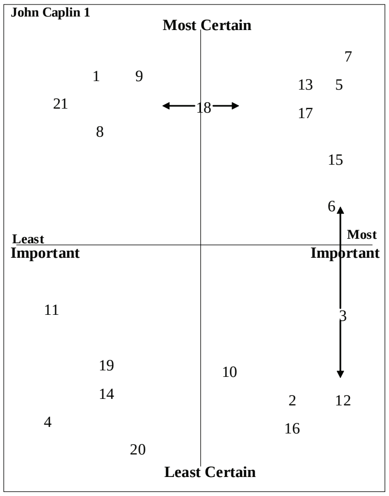
The previous insights interestingly shifted the blame from NHS managers to the government itself. This brought group-2 closer with group-1 in some of their viewpoints. The unintended consequence of these insights was that the groups already started to sympathize with each others' position within the organization.

Dialectic Debate

This is the third stage where both the groups are asked to debate the assumptions and viewpoints of each other. Whilst facilitating this stage, consideration should be paid to the following points (Jackson, 2003):

- How are the assumptions of the group different?
- Which stakeholders feature most strongly in giving rise to the significant assumptions made by each group?

Chart 2. Assumption rating by group-2



- Do groups rate assumptions differently?
- What assumptions of other groups does each group find the most troubling with respect to its own proposals? (p. 144)

After a certain period of time for which the debate has proceeded, groups can be offered an opportunity to modify its assumptions. This is called "assumption modification." However, as the following narration of this particular exercise will show, participants from both the groups were already beginning to see common grounds even before the following stage of anticipated consensus.

Group-1, that represented the management-led approach to healthcare information systems, was of the opinion that much of the resistance to NPfIT from clinicians was a generation issue. Members of this group felt that there was no problem with the younger clinicians accepting the new systems and they are more adept in using IT. They therefore felt that probably the problem would solve itself over time when the younger generation of clinicians would replace the older generation. This was however, taken with much contempt by group-2, who advocated that the main issue with NPfIT was its lack of consultation. This was immediately refuted by group-1 who was of the opinion that clinicians have never recognized their initiatives in helping them with service improvement.

As the debate progressed, the groups also began to see some common grounds. For instance, one of the key members of group-1 expressed scepticism of the DoH actually carrying out robust consultation with clinicians and patients about its IS strategies. They thought that they themselves might have been misguided by the DoH. In this regard, group-2 added that no one had actually ever approached them and asked what they really wanted. They felt that management would always make decisions about NHS reorganization or implementation of new strategies in complete isolation from clinicians. Identifying themselves closer to group-2, group-1 felt that there was always talk of a patient-led NHS, but the NHS never asked patients before it formulated its policies. Most of the consultation process in the NHS were actually "information giving" sessions, rather than consultation sessions, in which patients and the public are just informed about what the NHS was going to implement. When policies fail, management would try and backtrack the consultation process with patients and the public. This insight from group-1 immediately reflected a disparity between the NHS managers and the government, represented by the DoH. This disparity was more pertinent in discussions surrounding the choose-and-book feature of NPfIT, which offers choice of five treatment sites for patients in England. Group-1 felt that this was the "most ridiculous" feature as both patients and clinicians prefer local treatment. This view was immediately accepted by group-2. However, the managers felt that they had to work towards supporting Choose-and-Book as they had to deliver what they had been paid to deliver. Failure to do so would probably see their funding withdrawn. Hence, group-1 was surfacing frustration with their own position in the sense that they were implementing a strategy, some of its features they themselves did not support.

Both groups-1 and -2 expressed concern about the performance of the private companies that were contracted to deploy NPfIT. It was highlighted that there was considerable delay in the deployment of specific features of NPfIT, and some of the features that had been deployed were not functioning as expected, or not functioning at all. At this stage, it may be easy to blame the contracted companies for the fiasco. However, the participants suggested that there was a lack of realism that existed not only in the side of the NHS, but also in the side of the suppliers regarding what could be delivered and in what time scale the same could be delivered. However, at this stage, group-1 was again radical to question whether the contracted companies were failing to deliver due to their incompetence, or because the NHS did not clarify its specifications in the

Chart 3. Changed assumption rating by group-1

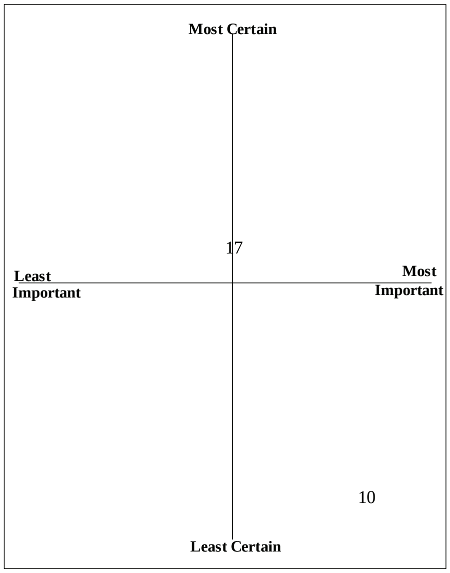


Chart 4. Changed assumption rating by group-2

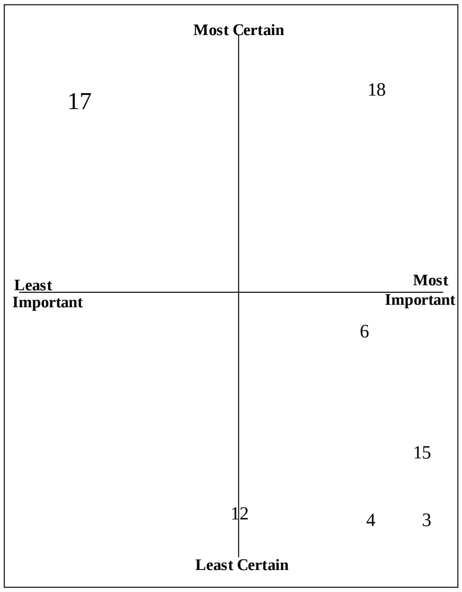


first place. One member of group-1 said: "If we can't tell them exactly what we want and stick to it, they are bound to go wrong."

However, it was stated by both the groups that people's expectations and demands change from time to time, and change is unavoidable. There was some agreement at this stage that IS should have built-in flexibility so that it can be adaptive to changing requirements. Group-1 believed that this can be possible only through true "partnership working" between management, clinicians and the public right from the beginning. Partnership working is about involvement of key stakeholders in the whole process of design and deployment of strategies. Certain comments from group-1 indicated that NHS management itself was operating under the pressures of DoH. This issue becomes more explicit in the discussions that followed.

After a lapse of time, the groups were asked if they would like to change ratings of any of their assumptions or the assumptions themselves. Participants returned to their own groups and spent sometime discussing how their assumptions have been informed and influenced after the debate and discussion. Both the groups decided to change how they rated certain assumptions initially. The following charts show the ratings that were changed.

The groups then discussed their assumptions again and started to consider how the present unwelcome situation in health informatics in the NHS could be addressed. This led to an interest to envisage a normative approach for health informatics that would be able to involve stakeholders in partnership, with the element of learning built into the model so that system flexibility and change is not seen as a challenge, but as an opportunity for the system to evolve. Working toward this approach was the final stage of this exercise.

Synthesis

This is the final stage of SAST where the previous stages are expected to lead to a synthesis of views. This will be the result of modification of assumptions, negotiation, and accommodation of viewpoints. Synthesis is expected to result in a reformed strategy for the organization to adopt. However, if the groups fail to arrive at a synthesis of views, the problematic assumptions and conflicting viewpoints should be taken up for further research and consideration.

In the exercise under consideration, the final stage was concentrated on both groups working towards overcoming their differences and envisaging a normative approach for public sector health informatics. This stage facilitated the groups to be critical of their own boundaries and perspectives. It implied the groups "sweeping in" the viewpoints of the opposing group and conceives a more inclusive approach towards healthcare IS. All insights in the discussion to follow have been the result of a synthesis of ideas of both the groups, and represent an approach conceived by the participants supported by the facilitator.

This approach to health informatics in the NHS ought to follow the following stages.

Needs Assessment

The conception of ideas for new IS emerges only from the need of such ideas to improve the operational situation. In the healthcare sector needs may be realized at the level of healthcare service delivery for the improvement of services and enhanced effectiveness in care delivery. If systems are introduced without any need these can be a dangerous toll on organizational resources and efforts. Once needs are realized, they have to be assessed to see if there is actually a requirement to introduce new IS or can those needs be met with existing facilities. Once needs are assessed and there is an agreement that new IS is a requirement, should service providers and management conceive of the new technology. If new systems are introduced without any need, they may come as a management-led initiative to cater to management needs. This can lead to members of an organization feeling imposed by new systems and not being committed to what has been introduced. Therefore, the conception of any new system is the realization and assessment of needs by members of the organization.

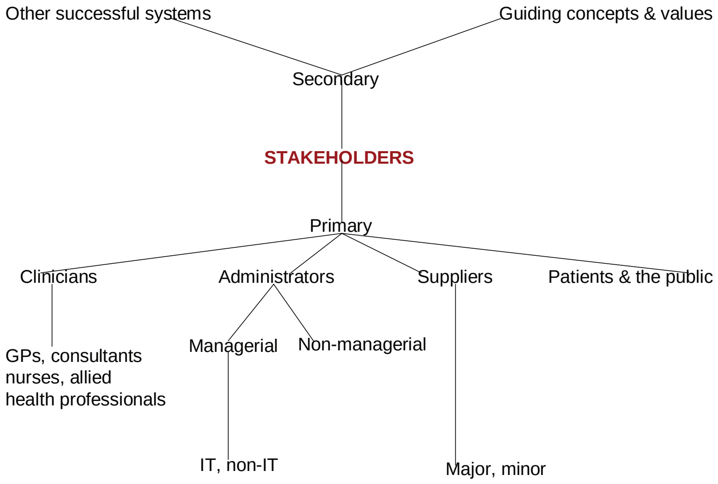
Stakeholder Analysis

Once management is convinced that there is a need for the introduction of new IS, there ought to be an understanding of who the stakeholders are in the new project. A thorough stakeholder analysis should be initiated to identify all those people who would be involved in the project or would be affected by it. Therefore, it goes beyond just the people who would use the system. A set of primary and secondary stakeholders were complied. This list was by no means meant to be exhaustive. For a health informatics project in the NHS, stakeholders would include what is detailed in Figure 1.

In the previous map, stakeholders are categorized into primary and secondary stakeholders. It was the view of the groups that other successful systems should be noted as secondary stakeholders. These are systems from where learning can be gained for the development of the new IS. This is because designing a system from scratch may lead to lack of realism in what can be achieved and how the system can be designed. This may further lead to lack of direction posing considerable challenges in the deployment of the system. Other successful systems would be specifically from the healthcare sector, but not confined geographically to the area for which the system is designed for. Insights may be drawn from successful systems in other countries. The guiding concepts and values that influence the new system and that which would be influenced by the new system have also been considered as stakeholder values. Primary stakeholders include clinicians, administrators, suppliers and patients and the public, who would be immediately effected by the new system (See Figure 1).

There should be a prime initiative to understand how the stakeholders should be involved in partnership right from the beginning. This should move beyond just information giving about the project, and there ought to be true consultation and partnership working from the beginning.

Figure 1. Stakeholder map for information systems in the NHS



System Specification

Needs assessment and stakeholder analysis may lead to the specification of what is actually desired from the system. This involves understanding of what the vision of the system is, what the vision of the organization is, and what can be realistically delivered. In a healthcare organization the vision may be to improve the quality of care; this will be supported by a whole gamut of technological activities and features. However, everything may not be possible to be delivered in a realistic sense. This was feared to have happened with NPfIT, in which the planners demanded too much within a limited time span. System specification should therefore be realistic and should be aligned with the organizational culture (discussed in more depth in the next stage). In another sense, this may also be called the stage of feasibility study to examine whether the whole idea is feasible or not. At this stage there may also be the requirement to go back to the first stage of needs assessment if there arise any scepticism about the success of the specified system.

It has to be realized that IS is integral to the process of healthcare service delivery. Therefore it has to be noted that the specified system is not treated as just one more piece of IT, but that which supports effective healthcare delivery underpinned by a systemic approach.

Context Analysis

Every organization is different. Design and implementation of any IS has to be suited to its context including the core business, the people and its culture.

The core business of the NHS include collating and dealing with confidential patient information. This entails that the nature of information that would be dealt with by the system is highly sensitive and confidential. This is a significant and decisive factor in the design of new systems. Any IS should regard confidentiality of patient information and safety of patients as its top priority. For instance, the NHS Care Record Service, in NPfIT, would record information for the whole population of England registered in the system. This sort of information is unlike of anything that can be found in other businesses. Security services and access criteria to manage and maintain this information is specific to the healthcare context.

If the system has to be developed effectively, it has to take the specific nature of this information into consideration.

In terms of people, the NHS employs highly qualified professionals. It has to be noted that these professionals cannot be forced by management to adopt an IS that the management wants. Any IS would have to prove its potential functionality and benefits to the professionals and patients. This is best achieved when professionals are directive of the design of the system. This takes us back to the first point of needs assessment, the primary impetus for the development of new IS. Due to the nature of work, it is the professionals who would normally recognize the need of new IS. Therefore, the participation and active involvement of professionals is paramount.

Organizational culture is important because any change not respecting culture may face stiff opposition to the change process. Organizational culture will include existing levels of receptivity of IT amongst staff, and also myths and stories associated with the same. The NHS finds itself in a unique position within healthcare as well, due to its sheer size and disparate organization. Myths and stories include comments such as one that was featured in the exercise by group-2: "we have not seen a single government IT project in a large scale succeed." This is an example of cultural scepticism of IS projects in the NHS. These feelings and opinions should be taken into consideration in the design of new IS. Scepticism ought to be understood and addressed in a manner that is culturally sensitive and appropriate to the organization.

Application of a generic IS model for the NHS will not be adequate, but any approach needs to be firmly based in the context itself including core business, people, and culture.

Risk Analysis

System specification may be followed by understanding the nature of risks the IS may face. Risks may be both technical and human. Following are some of the technical risks that may surface:

- Failure of the systems to be delivered on time
- Failure of the technology to deliver what has been aspired to be delivered
- Failure of suppliers to deliver what they have been contracted for
- The system failing to cope with changes in requirements and project specification
- Confidentiality of patient information breaking down
- Rapid change in technology rendering the original systems to be obsolete

Inspite of involving stakeholders appropriately, and considering the socio-cultural factors of new IS, there may still be human challenges in the way of implementing successful systems. Following are some of the human risks that may come with an IS project:

- Staff unwilling to use the new system
- Staff incapable to use the new system
- The system clashing with the organizational culture

The analysis of potential risks may even require designers to go back to the first stage of needs assessment and follow up the rest of the stages. Risk analysis is a crucial stage and if this is not undertaken in a detailed and critical manner, there will always be the fear that in spite of undertaking the rest of the stages effectively, the system may still fail.

Development & Implementation

The previous stages are expected to provide a robust background for the development and implementation of the desired IS. This is more the technical aspect of IS. The challenges here are to select the appropriate contractors and suppliers who will be able to technically deliver what they have been asked to. Success for the technical teams can be achieved with their work in partnership with the rest of the stakeholders.

It may not be appropriate to regard the implemented system as the final solution. Human expectation and system specifications are deemed to change. IS ought to be developed in such a way that changes do not threaten the existing system, but aids in the evolution of existing systems. This is what brings us to the overarching idea of cogenerative learning, discussed below.

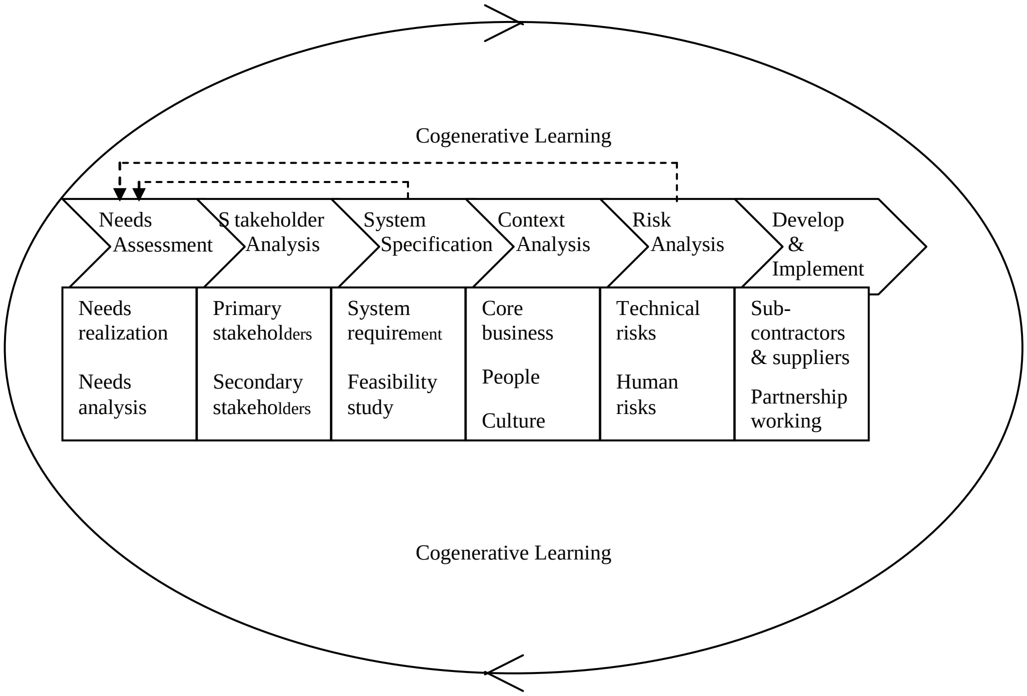
Cogenerative Learning

The idea of cogenerative learning is borrowed from Elden and Leven (1991) who talk of the term in the context of action research. They are of the opinion that cogenerative learning is the process where the power relations between the researcher and the research participants dilute, due to the active process the researcher involves the participants in. They note:

> *The insiders are not simply sources of data or sanctioners of studies and reports but actively help create and codetermine in every phase of the research process--especially in creating new meaning. They are not merely consulted in each phase of knowledge production; they participate as* cocreators. *We call this empowering participation.* (Elden et al., 1991, p. 133)

In the context of IS implementation, system designers, managers and planners ought to work cogeneratively with system users, "the insiders," to encounter challenges, learn from pitfalls and cherish knowledge. This has to be achieved in partnership and not in isolation between stakeholders. Constant learning ought to be integrated into IS so that the system is able to evolve from one stage to another and technology is designed to be adaptive. Cogenerative learning may be treated as the overarching philosophy. This lends the iterative angle to the IS design approach.

Figure 2. Normative approach to healthcare IS



The previous approach has been illustrated in Figure 2.

The previous model indicates a normative approach for healthcare IS, as informed by the SAST exercise. The insights that have been discussed in the above paragraphs are pertinent in the context of UK public sector healthcare. These insights were conceived by professionals working in a wide range of roles within the NHS. Hence, these insights and the resultant normative model for healthcare IS are invaluable for health informatics designers and planners in the context under consideration.

WEAKNESSES OF THE APPROACH

The previous discussion attempts to present SAST as an effective approach for the enablement of organizational decision making. However, taking a critical perspective, there may arise several aspects where the effectiveness of SAST can be called into question. This section highlights some of these critical aspects.

First, the methodology starts with the identification of participants into two diametrically opposing groups. However, it is not always necessary that even though participants are divided into two opposing groups, they will need to have radically opposing viewpoints. As this exercise shows, although there were two opposing groups, there were numerous instances where members of one group closely identified with the viewpoints from the ‘opposing’ group. The whole idea of maximising divergence of perspectives between the groups may be context dependent. Hence, although SAST aspires to unearth assumptions, it itself starts with an assumption that viewpoints of members from the two groups will always be radically opposing. This introduces a fundamental critique to the whole methodology.

Second, SAST has been portrayed above as an “ideal type” approach for management decision making, which has been aptly applicable in the context of healthcare IS. However, when it comes for the actual implementation of the approach in real life, SAST is best only as an “ideal type” approach. It has the limitation of optimistic simplification. Jackson (2000) notes that the methodology assumes that if the people’s attitudes change, so will the social system. This indicates to the methodology’s simplistic assumption that social systems are readily adaptable to human systems. However, given the tremendous complexity that gets incorporated into social systems once alterations and new structures are introduced, it may not be very simplistic to alter the same social systems. In the “ideal typical” approach previously taken for the formulation of a health informatics model, SAST has not allowed these challenges to be surfaced.

Third, the SAST approach does not pay due attention to the influence of power relations in the environment in which the exercise takes place. It presumes that in the dialectical debate stage every participant in the teams will present arguments and defend their own stands equally competently to arrive at an understanding. However, if participants come from a different set of hierarchy in the organization, certain members may be reserved about their participation. In the current case study, debating on the situation and arriving at a consensus inspite of radically opposing viewpoints was certainly possible. However, under what conditions this was made possible is also to be scrutinized. This stems from the feedback that was received after the exercise was conducted. One of the participants said that her inputs and vocal arguments were possible because she already knew the rest of the participants very well and felt comfortable to share her opinion; however if the group were different, her involvement could have been very different. A similar feedback was shared by another participant as well. Hence, the whole dimension of power and repression in the overtly consensual atmosphere needs to be considered. This may introduce a Foucauldian dimension of power into the methodology, which SAST very clearly does not consider.

Fourth, arrival at consensus in this particular exercise should not give the impression that consensus is a definite outcome of SAST. There may be cases where no consensus is arrived even after extensive deliberation, and that differences widen instead. This can happen due to a variety of reason including lack of enthusiasm of participants, power relations or simply because the methodology is not situated for that particular context. DP Dash (Dash, date not available) cites his experience of an instance where he applied SAST with two opposing groups, but could not reach a consensus. As he notes "Despite attempts at assumption negotiation and modification, it proved impossible to arrive at any overall synthesis during the final stage of the methodological process" (Dash, date not available). However, the whole idea of consensus is overplayed in the methodology and it gives an impression that a single or repeated deliberation of SAST will certainly lead to a consensus of opinion. Therefore, the idea of consensus at the end of SAST should be regarded with some criticality and it should be recognized that consensus is context and situation dependent.

CONCLUSION

Application of SAST in the context under consideration yielded interesting conclusions for IS design and deployment in the high-tech NHS environment, and for the methodology itself. These conclusions have been summarized in the next three levels.

Methodological

- The application of SAST was found to be a successful intervention strategy in the conflict situation of IS development in healthcare. SAST not only helped bringing the two opposing groups to a level of agreement, but it also identified the common grounds that both the groups had, but did not receive an opportunity to articulate prior to the exercise. Therefore, methodologically, SAST was found to be a useful tool in context under consideration. The systems approach was able to effectively consider a range of socio-technical factors in the design and deployment of healthcare IS.
- It was understood from the feedback that the effectiveness of SAST can be context and situation dependent. The impression that the methodology offers regarding the universal arrival at consensus at the end should be regarded with certain scepticism and consensus and for that matter the progress of the methodology is dependent on the kind of participants, the agenda, and the power relations between participants.

Organizational

- There was a new light on the often perceived conflict between management and clinicians in the NHS. It was understood that management itself had to operate within the pressures of the government. It was agreed in the exercise that many of the strategies adopted with respect to IS were not management led, but government led. Management itself did not agree with some of these strategies, but had to support these as they had no choice. This insight shed new light on how decisions were made in the high-tech NHS environment. This also carries great ramifications on organizational development factors in the context under consideration.
- It was the view of the groups that some of the decisions taken by the DoH were meant to meet political ends, rather than for the best interest of the NHS. As the groups suggested, NHS management itself may have been misled in many instances by the DoH with regard to the inclusiveness and robustness of planning for IS strategies. This portrays the NHS as organizationally fragmented and politically secretive.

Operational

- Healthcare IS is best supported by robust needs analysis, stakeholder analysis, feasibility study (system specification), context analysis, and risk analysis, before systems are designed and deployed.
- IS ought to be designed not as fixed solutions, but as systems that are capable to change and transform. This is specifically pertinent for healthcare due to its multi-dimensional and complex nature. Healthcare IS should be designed as complex adaptive systems, which is able to adapt to complexity and change in the wider environment. This character should be built into healthcare IS projects.

The previous conclusions carry pertinent implications for the design and deployment of healthcare IS. Introduction of new IS in a high-tech environment is not straight forward, but it has to be sensitive to a diverse range of factors. If this is neglected, the chances for success of the new IS may be compromised. A systems approach is vital in cases where issues are divergent and complexity is a rule rather than an exception. Application of systems methodologies like the one discussed in this chapter can be of immense benefit in understanding these issues and enabling variety to be addressed with variety for greater success in complex projects. It may be appropriate to conclude with the following quotation:

In information systems development, it is necessary to systematically view information systems as a socio-technical system and develop information systems using a wide spectrum of technologies, which is superimposed over the complex socio-technical interactions. Systems science provides the basis for taking such a broader view of information systems (Checkland, 1981, 1988; McLeod, 1995, Sommerville, 1996 in Xu, 2000, p. 106).

ACKNOWLEDGMENT

The authors would like to thank Dr Amanda Gregory from the University of Hull Business School, UK, for reviewing this chapter and for her valuable comments.

ENDNOTES

[a] Chuchman's (1968) fundamental idea is that every worldview is terribly restricted and to make sensible decisions for lasting beneficial effects, one needs to "sweep in" a variety of opposing perspectives and worldviews. He advocated that whilst it is not possible to know everything, it is indeed beneficial to understand the implications of the lack of comprehensive knowledge. Therefore, self criticality in theory and practice was central to the work of Churchman and his philosophy.

[b] NEYNLMCN is responsible for design and deployment of service improvement strategies for cardiac care in the North and East Yorkshire and Northern Lincolnshire region of England. This is headed by Alan Nobbs with a core team of four staff and representation from a range of service providing professionals.

[c] In the UK, the responsibility of the provision of health and social care welfare is under the Department of Health (DoH) and Social Security. DoH was formed in 1966 as a result of a merger between the Ministry of Health and the Ministry of Social Security. DoH is answerable to Parliament for the strategic control and direction of the NHS and social services. DoH is therefore the apex government body for healthcare matters in the UK (Source: Department of Health).

[d] The Treasury is the United Kingdom's economics and finance ministry. It is responsible for formulating and implementing the Government's financial and economic policy (Source: HM Treasury).

[e] Epidemiology is the scientific study of factors affecting the health and illness of individuals and populations, and serves as the foundation and logic of interventions made in the interest of public health and preventive medicine (Source: Wikipedia online dictionary).

Chapter 7.3

Quality Assurance View of a Management Information System

Juha Kettunen
Turku University of Applied Sciences, Finland

Ismo Kantola
Turku University of Applied Sciences, Finland

INTRODUCTION

Strategic management has been widely applied in public and private organizations. Strategic management adapts educational institutions to their environment, which includes the educational policy, local demand for labour and other circumstances. The increased autonomy of educational institutions has emphasised the role of strategic management. Quality assurance has also gained more attention in recent years when plans have been made to establish the European Higher Education Area (Berlin Communiqué, 2003).

European countries develop their own national solutions for evaluating and demonstrating the quality of degrees (FINHEEC, 2006). There are no European or national agreements that provide any specific approaches or tools for the management of higher education institutions (HEIs) (Maassen & Stensaker, 2003). Each HEI is responsible for defining its management and quality assurance systems. Strategic management is a strong candidate for the management system for Finnish HEIs, but there is more variation in the quality assurance systems. Quality assurance refers to quality management and improvement. Quality is understood as the ability of an institution to fulfill its mission or a study programme to fulfill its aims (Harvey, 2007; Harvey & Green, 1993).

The purpose of this chapter is to describe the management information system (MIS) which integrates strategic management and quality assurance. Institutional quality audits have shown that quality assurance is quite often separate from the general management system of HEIs. By contrast, a well-functioning quality assurance system produces evaluative information about results and processes and then management uses this information to develop processes. Management at each institutional level determines the corrective action. While providing support for strategic management, the management information system can also contribute to continuous improvement, which is the core of quality assurance.

The balanced scorecard approach developed by Kaplan and Norton (1996, 2001) translates the strategy into action and provides a framework to integrate the strategic management and quality assurance approaches. This chapter describes the case of the Turku University of Applied Sciences (TUAS). At the TUAS, the implementation of the strategic plan includes, among others, budgeting, action plans and HR plans, which are stored in the MIS portal. The balanced scorecard is used to create an understandable structure for the strategic and action plans which include quantitative measures. All these management and quality assurance tools are provided for the managers and personnel as the tools of the MIS portal.

BACKGROUND

Quality Assurance in Higher Education

The Bologna Process Finland has developed its own approach to quality assurance in higher education. The approach is based on the quality assurance systems of HEIs and external quality audits at the institutional level. The quality assurance systems of all Finnish HEIs will be evaluated by the Finnish Higher Education Evaluation Council (FINHEEC) by 2011. Each institution is responsible for the development of its own quality assurance system. HEIs have the responsibility to define what they mean by quality and how they manage and enhance quality. The external audits aim to evaluate how the quality assurance system of an institution performs as a tool for quality management and enhancement. The institutional quality audit ascertains whether a quality assurance system produces useful information for continuous improvement (FINHEEC, 2006).

When building a quality assurance system, the first step is to define the concept of quality. In everyday language, the word “quality” has been associated with excellence. However, fitness for purpose is the approach to quality accepted by most quality agencies. Fitness for purpose sees quality as fulfilling a customer’s requirements, needs, or desires. In higher education, fitness for purpose is understood as the ability of an institution to fulfill its mission or a study program to fulfill its aims (Harvey, 2007; Harvey & Green, 1993). This is the definition adopted in this chapter. At the institutional and faculty level, quality is defined in the institution’s mission, strategic plan, and annual action plans and evaluated against these plans.

The concept of quality assurance has various definitions in different contexts. According to Woodhouse (1999) quality assurance refers to the policies, attitudes, actions, and procedures necessary to ensure that quality is maintained and enhanced. Quality assurance is defined in this chapter to include strategic management and the performance of the internal processes. A similar interpretation is given by FINHEEC (2006), which states that quality assurance is part of strategic planning and includes the management process and the internal processes of HEIs. Quality assurance refers to the procedures, processes, and systems which safeguard and improve the quality of an HEI, its education, and other activities. At the level of HEIs, the quality assurance system refers to the entity composed of the quality assurance organization, the respective responsibilities, procedures, processes, and resources.

The relationship between the strategic management and quality assurance of higher education institutions could be interpreted as a new conceptualization for some of the most essential features of quality assurance. From our viewpoint, two basic ideas of quality assurance are continuous improvement and management's commitment. According to Beckford (2002), the principle of continuous improvement is an explicit part of the thinking of many quality gurus. Furthermore, John Oakland says, "Quality must be managed, it does not just happen", and Beckford argues that without adherence to the quality management system, it is impossible for the organization to know how well it is performing.

It is evident that management is an essential element of quality assurance. Mostly it is only the managers who possess the power and resources needed for carrying out the planned development steps (corrective action). One way to look more profoundly at the relationship between strategic management and quality assurance is to emphasise the fitness of purpose and use the phases: plan, do, check, and act (PDCA). This is known as Deming's cycle (Beckford, 2002). The cycle has been used in various quality awards. The Malcom Baldrige quality award has renamed it and uses the words: approach, deployment, results and improvement (ADRI) (Woodhouse, 2003).

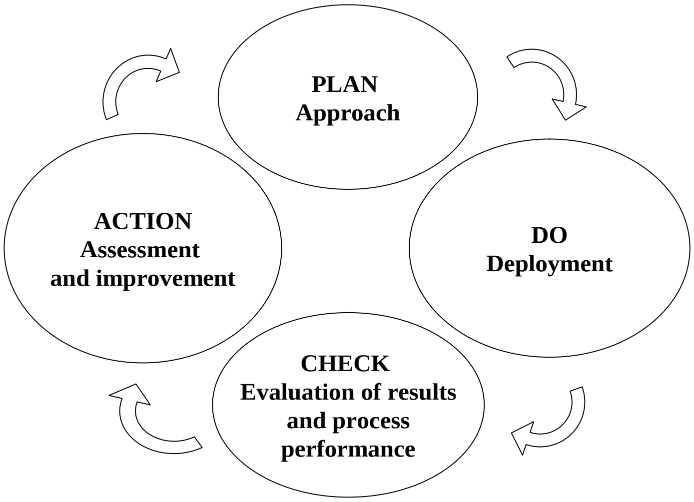
Figure 1 presents the quality cycle of continuous improvement. The approach is about planning what will be done and how it will be done. Deployment is about how to implement these plans. The results are the consequences of these actions. At this point, the results may be accepted as such and no changes are made to the approach or deployment. Often results are unsatisfactory and objectives have not been achieved. Then a systematic reflection about what approach and deployment led to these results may suggest useful improvement measures (Woodhouse, 2003).

MAIN FOCUS OF THE ARTICLE

The Quality Map

The concept of the quality map is introduced to describe the quality assurance of an organization. The quality map is a visual representation of the cause-and-effect relationships among the objectives of education policy, regional strategies and the institutional strategic plans. It provides an insight into the management, personnel and stakeholders to understand the main elements of quality assurance. The quality map is a graphical representation of quality assurance. We have

Figure 1. Quality cycle of continuous improvement



developed the concept of a quality map from the strategy maps introduced by Kaplan and Norton (2004). A quality map describes the essential characteristics of the quality assurance system like a road map, but omits all the minor details.

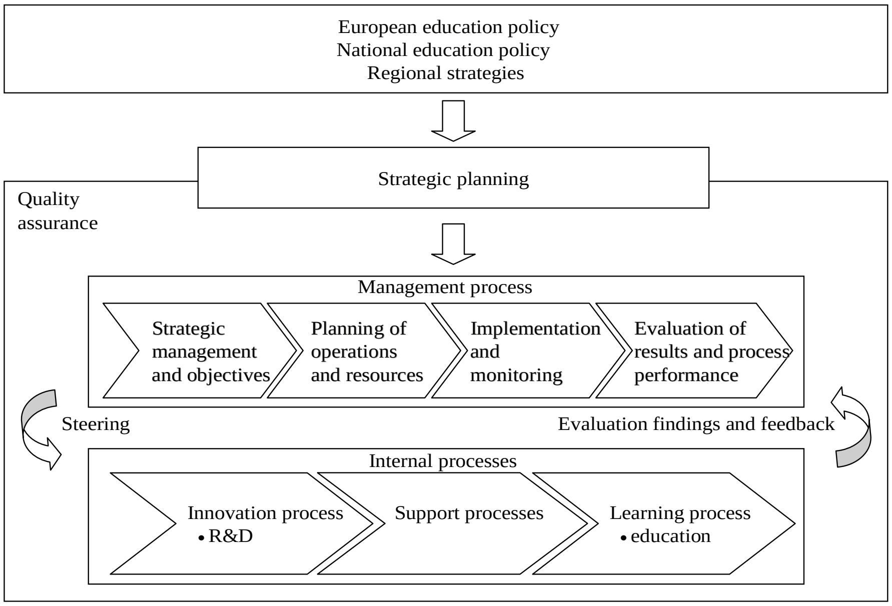
Figure 2 describes the quality map of the TUAS. The quality map shows that quality assurance is a comprehensive concept including the strategic planning, the management process and the internal processes and structures of the organization. There is a continuous flow of communication and interaction between these elements. The description of the quality assurance system is an attempt to formalize the diffuse knowledge and context-sensitive procedures.

The management process includes sequential planning and management activities. They include the strategic management and objectives, the planning of operations and resources, implementation and monitoring, and finally, the evaluation of results and process performance. The strategy process produces the strategic objectives for the planning period. The operations of the internal processes are aligned with budgeting and human resources planning. The achievement of results is regularly monitored and ensured to achieve the desired objectives during the planning year. Finally, the achievement of objectives is evaluated and reported to stakeholders.

The main internal processes include the innovation process (research and development), support processes (support services) and education (teaching and learning processes). The strategic planning and quality assurance overlap. The involvement of students, members of the personnel and external stakeholders in strategic planning is an important means of quality assurance.

The linkages between the management process and internal processes describe the guidance and information flows which have to be taken into account in the continuous improvement of activities. The aim of the management process is to steer the development of internal processes. Another linkage is the feedback and evaluation results from different sources, which include students, employers and self-assessments. The action plans

Figure 2. The quality map of the TUAS



located in the MIS are used to collect and store the steering information and development steps which may be based on self-assessment, feedback, or external evaluation.

The Management Information System

Without proper management tools it would be nearly impossible for administrators and evaluators to know how well the institution, department, or program is performing. The introduction of the balanced scorecard approach in 2002 laid the foundation for developing the management information system at the TUAS. Balanced scorecards were planned for all the administrative units of the institution. It was evident from the beginning that without any proper tools the maintenance of the scorecards was troublesome. The consistent aggregation of the scorecards to the upper organizational level needed automation. The data collection from the various data sources also needed automation. It was evident that the new MIS would provide clear benefits as required generally for development projects of this kind (Galliers & Sutherland, 1991; Galliers, Swatman, & Swatman, 1995).

The development and description of the management process started at the beginning of 2004. The entire management process was described in detail. About 700 concepts were defined and the data model was developed. More detailed process descriptions and specifications for the services provided by the portal were written to facilitate the automation of the process. It is important that the management process be entirely developed and described before the planning of the information system. It is also important that there is a well-defined and widely used approach to communicate and implement the strategic plans. The balanced scorecard approach clearly fulfills this requirement (Kettunen, 2004, 2005; Kettunen & Kantola, 2005). The first services of the portal were launched in the autumn of 2005 and the implementation continued through 2006.

The MIS portal was developed to support the management process. The members of the personnel have diverse user rights and roles in the interactive management tool. The administrative units are able to draft their strategic plans, action plans, budgets and human resources plans. The action plan of the units is important, because it describes the implementation of the strategic plan, timetables and responsibilities. The action plan also defines the development steps based on the evaluative information produced by the quality assurance system. The portal has been planned to be accessible to the personnel and to make the strategic planning understandable. The portal takes advantage of the data warehouse.

Data warehousing effectively utilizes the various data sources including personnel administration, financial planning, and student and study registers. The data warehouse captures data from data sources, makes transformations, and directs data to an integrated database (Guan, Nunez, & Welsh, 2002; Inmon, 1996). Sometimes these are called extract, transform and load (ETL) processes. Before the introduction of the data warehouse, the data were scattered and undocumented. Data collection was also unreliable because it was to a large extent collected manually from separate data sources or personal files.

The Management Information System Integrates Strategic Planning and Quality Assurance

The MIS is an electronic platform which effectively integrates the elements of strategic planning and quality assurance. The MIS provides strategic plans which are then implemented using the action plans and the tools for budgeting and human resources planning. This is evident when one compares the stages of the quality cycle (Figure 1) with the tools of the MIS portal. The strategic and action plans represent the approach stage of the cycle. The action plan contains reliable quantitative information about results and process performance. This information strongly supports management in the search for strengths and weaknesses. The MIS portal can be seen as an evaluation tool which supports the evaluation of the results stage of the quality cycle.

The action plan includes not only information about process performance but also about how to improve processes. The development steps on the basis of assessment are decided by the management at each institutional level. At the TUAS, the development steps are stored in the MIS as part of the action plans of the institution, its faculties and programmes. This is an illustration of how the portal supports the assessment and improvement stage of the quality cycle.

The action plan must identify the strategic initiatives and development steps at different organizational levels. The action plan must identify the timetables and individuals responsible for the planned tasks. All in all, the action plan is an electronic document where the implementation of strategic plans and development steps of quality assurance meet.

The effectiveness of strategic planning and quality assurance is crucial in how the strategic initiatives and development steps based on the evaluations and feedback can be integrated into the core institutional processes and functions. It is evident that these two approaches of management are most efficient when they are transformed into action close to teaching and learning. These approaches should be implemented at the different organizational levels of the institutions including the departments, degree programmes, teachers and students. Strategic planning and quality assurance must be implemented in the action plan, curriculum, course implementation plans, teacher workload plans and personal study plans of students.

FUTURE TRENDS

An obvious future trend is that electronic tools will be widely used in supporting the management process. The strategic plan is updated every fourth year at the TUAS, but the implementation of the strategy and detailed planning of activities are annually performed following the management process. The measures describing the strategic objectives are updated annually using the MIS portal and agreed in the internal target discussions. These group negotiations are led by the Rector and have strong steering elements, because the tasks are directly derived from the strategic objectives and written into the action plans. The target values of the measures are updated and agreed in these target discussions.

The second obvious trend is the harmonization of the MISs in the different HEIs. There are plans to collect a database of the process descriptions among Finnish universities. The concepts related to institutional management have also been defined and collected. A vision has been presented in the working group of the Ministry of Education that a national data warehouse should be planned to collect the information on students, degrees and ECTS credits in a common database to facilitate student mobility. There is also a need to integrate the national statistical databases of the universities and universities of applied sciences, which are separate nowadays and have different structures.

CONCLUSION

The concept of the quality map was introduced in this chapter to describe the integration of strategic management and quality assurance. The quality map is a visual description of how education policy and regional strategies are used to define the strategic objectives of the institution. The strategy map also describes the management process and the main internal processes of the institution. The visual representation of quality assurance helps the management, employees and stakeholders of an organization to understand the main elements and linkages of quality assurance.

This chapter shows that the different approaches of management can be integrated using an MIS. An advantage of the electronic management tool is that it supports the management process and the internal activities of the organization. It is a virtual platform for consistent strategic planning in the different organizational units. It is also a platform for quality assurance based on internal and external evaluations. This study also supports the view that the balanced scorecard is a useful tool for the basis of the MIS and the integration of different management approaches and tools.

The open MIS increases strategic awareness among managers and members of the personnel. The integration of management approaches and the alignment of the strategic objectives in the different organizational units help management to create a shared understanding among the personnel about the implementation of the strategic plan and the development steps based on the information produced by the quality assurance system.

KEY TERMS

Balanced Scorecard: The balanced scorecard approach is a framework for the communication and implementation of the strategy. The balanced scorecard approach translates the strategy of an organization into tangible objectives and measures and balances them typically into four different perspectives: customers, financial outcomes, internal processes, and learning.

Higher Education Institution: Higher education institutions include traditional scientific universities and professional-oriented institutions, which are called universities of applied sciences or polytechnics.

Management Information System: A proper management information system presupposes modelling the entire management process and tailoring all the necessary components of the information technology support system to meet the needs of the organization. The management information system should include a description and measures of how the strategic objectives will be achieved.

Quality Assurance: Assurance of quality in higher education is the process of establishing stakeholder confidence that provision (input, process and outcomes) fulfills expectations or measures up to threshold minimum requirements. Quality assurance refers to the procedures, processes and systems that safeguard and improve the quality of a HEI, its education and other activities.

Quality Enhancement: Enhancement is a process of improvement. In relation to higher education quality, enhancement may refer to: (1) individual learners when it means improvement of the attributes, knowledge, ability, skills, and potential of learners; (2) the improvement in the quality of an institution or study programme.

Quality Management: Quality management emphasises the importance of management's commitment to quality. Quality must be managed; it does not just happen.

Strategic Management: Strategic management is a matter of bridge building between the perceived present situation and the desired future situation. Strategy implies the movement of an organization from its present position, described by the mission, to a desirable but uncertain future position, described by the vision.

Chapter 7.4

Information Feedback Approach for Maintaining Service Quality in Supply Chain Management

R. Manjunath
Bangalore University, India

ABSTRACT

Maintaining the service quality in a supply chain has become a challenging task with increased complexity and number of players down the line. Often several supply chains cross over the common resources, calling for the sharing of resources and prioritization. This leads to the definition of pre-specified service quality as seen by the end user of the supply chain. In this chapter, a feedback mechanism that conveys the status of the supply line starting from the tail end is discussed. The advantages of using a predicted and shifted slippage or loss rate as the feedback signal are highlighted. Based on the feedback, the source is expected to change the rate of transfer of the commodity over the supply chain. With this, the resources would get utilized effectively, reducing the stranded time of the commodity down the line. The service quality in terms of delay and loss rate gets improved.

INTRODUCTION

The enormous business size in recent days call for distributed supply units to be located across the globe and connected through a sophisticated network. Throughout this work, these isolated business structures are referred to as mobile business units. They resemble the distributed computing environment in the sense that a time-bound, constraint-based command, signal, and information get exchanged among them.

In this work the concept of differential feedback is explored for the effective utilization of the information for the communication among the members of the supply chain. The model that translates individual behavior to the collective behavior of the chain is given. The resource contention for communication along the chain is addressed and the solution is modeled.

Maintaining a constant agreed ratio of defects or losses—quality of service (QoS)—in a supply chain is often tricky. The problem gets further complicated when the supply chain contains multiple source streams. In this work, a differential feedback-based model has been developed to predict the defects or losses. A shifted version of the same will be used as a feedback signal. Simulation results show that the number of defects observed at any point in the supply chain gets reduces with the shifted feedback signal. With the defects getting reduced, for a given demand at any point down the supply chain, the quantum of input may be reduced with differential feedback to achieve the same performance. The defense supply and deployment into the battlefield, the fair mixing of reactants in a chemical reaction chamber, and so forth stand as good examples.

The shifted feedback information from the end user or any other intermediate player in the line may be used to achieve some additional quality of service deadlines such as the absolute delay guarantee, fraction of the service loss, and so forth. The same would be agreed up on with the different units down the line, well in advance. Simulation results prove that the usage of shifted signals can stabilize the QoS and improve the service quality in terms of overall successful operations in a given time. This reduces the stranded time of the information or loss along the supply chain.

Analysis shows that a system exhibits self-similarity to maximize the entropy (Manjunath & Gurumurthy, 2005a). It is proved that, to maximize entropy, the system makes use of differential feedback of different degrees. They form various levels of abstraction and by and large carry redundant information (Manjunath & Gurumurthy, 2005a). The self-similar property has been exploited here to maintain the quality of service constraints

Because of abstraction and redundancy, even if a portion of the information is lost or if it is required to predict the future uncertainties with minimum available information, it can be repaired or re-synthesized using the available information.

The self-similar property of the component induces interesting properties into the system. This property may be used as lead-lag components in controlling the information transfer over the network. Closed-loop feedback is utilized to control the signals transferred over the network. Intermediate self-similar structures or switches may modulate feedback signals and control the system behavior.

In order to meet the real-time transfer of the signal, stringent service quality parameters are defined over the data transfers down the supply chain. This chapter provides techniques to meet these requirements with minimal resources. In-time flow of the commodities to the end user is the basic requirement in a supply chain. The tools and techniques used to meet this goal are different in different supply chains. The example of real-time transfer of information for the end user is considered throughout this chapter. The supply chain involves various routers, switches, and media in between. The goal is to get the real-time performance in the chain with minimal retransmissions. The concepts may be easily extended to any other form of supply chain.

A supply chain has four areas of decision: location, production, inventory, and transportation or distribution. It is known that the rate of production bears a direct relation with the rate of consumption. However, the other factors during the transportation, such as the influence of adjacent supply chains and the stranded time of commodities within the chain, need to be considered. In this chapter, these factors are explained in depth.

Simulation plays an important role in the modeling of a supply chain before it becomes operational. It provides a closer look at the issues that may crop up in a supply chain and handle them appropriately during the implementation.

Supply chains have to make two categories of decisions—he long-term strategic and short-term operational decisions. A lot of data is required for making decisions. A model-based approach is extremely helpful to reduce the sample size. The model consists of an auto regressive (AR) and a moving average (MA) part. The ARMA followed by a non-linear limiter can enhance the predictability in the data set. The model described here is called differentially fed artificial neural network (DANN) (Manjunath & Gurumurthy, 2002) and is a variant of ANN.

BACKGROUND

A supply chain is basically a network from production to the consumption, involving the producer, the end consumer, and the intermediate distribution agents or brokers. The underlying philosophy of a supply chain exists in diverse fields such as manufacturing industries, the troops deployed in the battlefield, and so forth.

In an industrial supply chain, the material undergoes changes metamorphically along the chain. The models that describe the supply chain are very specific in nature. In this work a more generic approach has been taken.

The literature in supply chain management dates back to the work of Geoffrion and Graves (1974). Their work describes an optimal flow of multi-commodity logistics from the plants to the end users. This model is further explored in Geoffrion and Powers (1995) as a review of the evolution of the distribution strategies.

In the supply chain the intervening agents can have distinct characteristics.

Cohen and Lee (1985) gave a framework for manufacturing strategy analysis, with several stochastic sub-models describing the supply chain. Finally these sub-models got integrated heuristically, which they presented in Cohen and Lee (1988). The other successful implementation of the supply chain model is at General Motors by Breitman and Lucas (1987). The optimal resource utilization in a supply chain has been considered by the work of Cohen and Lee (1989). Another cost and time optimization model has been considered in Arntzen, Brown, Harrison, and Trafton (1995).

Differential feedback of the status of the commodity that flows along the supply chain improves the performance of the supply chain. Here the differential feedback model is introduced (Manjunath, 2004).

The different components of an organization, such as marketing, distribution, planning, and production in the supply chain, operate quite independently with their own agendas and priorities. The marketing department targets maximum profit while the production division calls for more investment. The scientific way of bringing together these conflicting goals is the theme of supply chain management.

The real-time supply chain solution has to provide up-to-the-minute information for the end user. Hence the quality of the information is very important. The system cannot afford to undo the implications of usage of information of bad quality or transmit the data again. Stringent service quality parameters are imposed over the supply chain. Especially when multiple chains pass through the common resources in between, priority would come into the picture for the logical sharing of the resources.

INFORMATION FEEDBACK FOR SUPPLY CHAIN

When feedback information—that is, the information to the source about the status at the tail end of the supply chain—is provided, the system starts exhibiting interesting behavior (Manjunath & Gurumurthy, 2002). As a result of feedback that uses a set of previous values, the feedback signal exhibits multi-resolution property. That is, the output signal can be expressed as a weighted sum of a set of orthogonal signals, each of which is a replica of the other but for a scale (Manjunath & Gurumurthy, 2003). These replicas are called hyperplanes, as they form a linear transformation in the hyperspace. Any of these hyperplanes may be obtained from the other plane by convolving with a Gaussian pulse of appropriate scale factor.

The architecture is based on feedforward and feedback paths. The feedforward path consists of the actual information or data or commodity flow departing from the source depending up on the simulation application. It is data packets in a communication network, a commodity in a product supply chain, and investment in a finance supply chain. The feedback signal comprises the position and status of the commodity or information as observed at the destination. The differentially fed neural network sits as a controller in the loop comprising the source, the forward path, the destination, and the feedback path.

The presence of such a controller imparts all of its properties to the system. That is, the supply chain on either direction behaves as a system with differential feedback provided.

In general, when a controller is used as an estimator, it starts throwing the output depending up on the underlying algorithm and decision rules. An ideal estimator gives the weighted sum of the outputs from the different estimators. When the differentially fed controller is used as an estimator, there will be different output for each order of the differential feedback. The ideal controller is the one that corresponds to infinite ordered feedback. As the order of differential feedback is increased, it starts moving closer to the ideal estimator. Also, any of the estimators may be expressed as the weighted sum of other estimators.

The feedback information in a supply chain results in the reduction or increase of the source operation rate. It in turn helps in proper supply line scheduling. Based on the congestion status, different congestion control algorithms are used. Each one of them may be thought of as an estimator. A DANN works as an ideal estimator to replace all of them.

Since the differentially fed artificial neural network is a part of the loop, its presence has profound effect on the traffic in the loop. Traffic here refers to the movement of the commodity or the like. The DANNs make use of a large number of previous samples for decision making. Decisions thrown out by such a system contribute to long-range dependency in the movement of the commodity or the traffic. The abstract levels of hyperplanes of DANN contribute to self-similarity of the traffic when observed over different time scales.

In essence, insertion of DANN in the traffic loop makes the entire network behave as a differentially fed neural network, manifesting all its properties. The network here refers to the forward and feedback paths. Hence DANNs play a role more than replacing the conventional ANNs in traffic shaping. The traffic shaping involves maintaining the schedules, reduction in the delays, and reduction in stranded times or reschedules, while keeping up the agreed service parameters.

A multi-bit closed-loop feedback mechanism is assumed here, with the bits representing the drop or failure probability and express congestion status of the network. The notification signal or feedback signal is time shifted to get better performance. This algorithm is called random early prediction (REP) (Manjunath, 2004). Generally, feedback-based control is used in systems that need precise adaptive control. Any mismatch in the feedback would drive the system into an unstable region.

Models of the traffic are critical in providing a high quality of service. The complexity of traffic in a network is a natural consequence of integrating diverse ranges of members from different sources that significantly differ in their traffic patterns as well as their performance requirements over the same path.

Shifted Feedback in Data Network Supply Chain

The similarities between supply chain model and the data propagation over a network are exploited in this section. Basically the data network is a particular form of the supply chain. The concept developed with the networks is applicable for all variants of the chain. This perception throws all the associated problems of the network on to the supply chain. Consider two different classes of the data flow. It may be generalized for multiple classes. The relative service parameters come into the picture when the different classes of the flow contend for the common resources such as the operating path, buffering space, or docking space that tend to get choked and require the maintenance of a fixed ratio of the flow members.

The resource status in a network may be simulated with the DANN included. The application of a DANN component in network traffic shaping may be studied with this setup, and the parameters of the DANN may be fine tuned until the desired response is achieved. The simulations are basically used to analyze and tune the quality of service metrics and allow exploring different implementation options by conducting experiments.

The simulation setup and the underlying methodology is valid for other supply chains as well.

In the proposed scheme the predicted version of the probability of cell loss is given as feedback to the source. The DANN gets the training data from the background RED algorithm. For some time, the DANN will be in a learning phase. It then predicts the data and arbitrary k steps in advance. This is provided as the feedback signal to the source. The source then re-computes the transmission rate. It may be seen that the cell loss ratio has been reduced with feedback.

In a simulation, 42 data points computed with RED are used for training. The input consists of 20 sources supporting background traffic that exist over the entire simulation time. The maximum buffer size is 8,000 and the cell size is 512. The total cell loss ratio of an ordinary RED scheme is found to be 1.6. With a neural network prediction, it has been reduced to 0.05, and in a first-order differentially fed neural network, it is reduced further to 0.04.

It is desirable to keep the variance of the resource occupancy less. The variance can be brought down with the increase of the differential feedback order. The use of a differentially fed artificial neural network in Web traffic shaping has been explained at length in Manjunath (2006). As the order of differential feedback increases, the error reduces.

The proposed input rate prediction process captures the actual input traffic rate reasonably well. In the steady state, the average queue size changes more slowly compared to the instantaneous queue size. This means that the proposed active queue management method is successful in controlling the average size at the router in response to a dynamically changing load, and there is no global synchronization among the sources. There will be some large variation of mean queue length during the initialization phase. This is because it is assumed that the queue is initially empty and it takes some time for the proposed scheme to operate correctly.

Because the proposed scheme randomly drops incoming packets according to the severity of the incipient congestion, there is no global synchronization. The large variation of the transient queue size is due to the bursty input traffic.

With the number of traffic sources that exist from the start to end of the simulation increasing from 20 to 80, the total probability of cell loss or area under the error signal remains the same. However, the variance of the queue length is considerably reduced with the proposed scheme. The reduction in the variance is more pronounced with large traffic.

The variance will be reduced with increase in the prediction. This happens for some time. Again the variance shows upward trend. This is because the autocorrelation function of a long-range dependent series exhibits oscillations. As the number of sources increases, LRD is more pronounced, with peaks of correlation separated far apart.

RED detects incipient congestion by calculating the average queue size at each packet arrival. In other words, in RED, congestion detection and the packet drop are performed in a small time scale. On the contrary, in the case of the proposed scheme, the congestion detection and the packet drop are performed at different time scales. When network congestion occurs, it takes some time for a traffic source to detect the congestion and reduce sending rate to resolve the congestion situation.

The shift for which further increase of shift shows a reverse trend in the variance increases with the increase in the load.

The proposed scheme can reduce the time for a traffic source to detect congestion, because the congestion detection is determined in a large time scale. In case an incipient congestion is detected at a large time scale and a packet is lost within a sequence of packets, the successfully delivered packets following the lost packets will cause the receiver to generate a duplicate acknowledgement ACK. The reception of these duplicate ACKs is a signal of packet loss at the sender. So, the traffic sources can detect incipient congestion before it really occurs.

By using the proposed scheme, the source can respond to the incipient congestion signal faster than in the case of using RED gateway. Therefore, both the average queue length and the variation of the average queue length are smaller when the gateway uses the active queue management scheme proposed in this chapter rather than when the gateway uses RED. Because the proposed active queue management scheme can control the average queue size and the variation of the average queue size while accommodating transient bursty input traffic, it is well suited to provide high throughput, low average delay, and low average jitter in high-speed networks.

The variance of queue is found to vary linearly with the shift given to the feedback signal for different traffic loads. This confirms the existence of a constant term in the variance modulated by a variable term. The slope is independent of the load, while the constant depends on it.

Since the variance can be written as variance = k_1+k_2/shift, k_1 and k_2 being constants, the plot of variance against the reciprocal of shift is a straight line. The constant variance term represents the bias. The second term happens to be the multi-resolution decomposition of variance and is the sum of n terms, n being the order of differential. By the weighted averaging of hyperplanes, the two parts in the second term can be replaced by a single term of highest degree or shift**.** The plot of variance against load also behaves similar to variance against the shift. In both cases, the variance initially gets reduced and later increases.

The growth of buffer size is a reflection of the efficiency of the algorithm followed in routing the cells. When differential feedback concept is applied, the maximum buffer occupancy is reduced, resulting in reduced cell loss. Depending on the network condition and the kind of traffic, an appropriate algorithm or rule may be applied for packet scheduling and discard. A set of ANNs, each learning a different scheduling algorithm, may be used. Any of them may be triggered based on the cost function, once again decided by another ANN. Each scheduling algorithm is an estimator. A single differentially fed ANN may be used since an ideal estimator can replace all the Bayesian estimators. A differentially fed neural network can merge and learn the multiple rules in one shot. It results in reduced hardware as well as improved switching efficiency in routing of the cells. It may be observed that the differentially fed ANN-based estimator outperforms the multiple scheduling schemes.

The past history associated with the differential feedback imparts a kind of long-range dependency in the output. With this, the switch performance is found to be better in terms of maximum buffer size and the total time to flush the cells. The proposed algorithm is independent of the underlying scheduling algorithm. Green is another standard scheduling algorithm like RED. The proposed algorithm of random early prediction works well with Green. For small shift, variance is reduced with not much change in the cell loss. It is the reverse for large shifts.

The peak instantaneous value falls as the sources go off. When more sources come on, with shift, it builds slowly and thus reduces rapid fluctuations of Q size. When Q changes rapidly, queuing models do not work well.

When the optimization problem does not yield a solution, meaning that it is impossible to satisfy all service guarantees simultaneously, some of the QoS guarantees are selectively ignored, based on a precedence order specified in advance. Due to the form of the constraints, the optimization problem is non-linear and can be solved only numerically.

The computational cost of solving a non-linear optimization upon each arrival to the link under consideration may be prohibitive to consider the implementation of an optimization-based algorithm at high speeds. The REP algorithm is effective in providing proportional and absolute per-class QoS guarantees for delay and cancellation or reschedule. The closed-loop algorithm reacts immediately when the routes are going from underload to overload and reacts swiftly when the routes go from overload to underload. This indicates that the delay feedback loops used in the closed-loop algorithm are stable.

Proportional delay differentiation does not match the target proportional factors when the route is underloaded, due to the fact that the algorithms are work conserving and therefore cannot artificially generate delays when the load is small.

Results for ratios of delays indicate that proportional loss differentiation (i.e., schedule cancellation) is achieved when the outbound route is overloaded and traffic is dropped. However, it is not met in any of the algorithms when the queue falls to 0. This implies that the algorithms basically manipulate the queue of the flow members and scheduling of the members to meet the relative delay and loss guarantees. With this the REP feedback loops used in the closed-loop algorithm appear to be robust to variations in the offered load, and the results of the REP closed-loop algorithm are found to be better than the one without any shift.

The delays and losses experienced by classes are monitored. It allows the algorithm to infer a deviation compared to the expected service differentiation. The algorithm then adjusts service rate allocation and the drop rates to attenuate the difference between the service experienced and the service guaranteed. A prediction-based feedback control is used to achieve proportional delay differentiation. Absolute differentiation is expressed in terms of saturation constraints that limit the range of the controller. The control loop around an operating point is made stable through differential feedback, and a stability condition is derived on the linearized control loop. The stability condition gives useful guidelines for selecting the configuration parameter of the controller.

ISSUES AND SOLUTIONS

It is quite possible that the supply chains from the various producers to the consumers crisscross or intersect each other, calling for a kind of contention for the resources. The contention could be in various forms, in terms of financial investment or storage space.

The first step towards resolving this contention and optimizing the supply chains is to define service classes for each of the chains passing through the intermediate agents or the brokers. In addition, for each of the service classes, a set of quality parameters is defined. Both the absolute value and the relative value of these parameters are important for optimization. It is a requirement to keep the absolute parameters within a certain agreed limit and the relative parameters at a prespecified constant value. Various algorithms and implementation schemes exist considering the optimal utilization of resources.

In the REP method of meeting service quality parameters, a differentially fed artificial neural network is used as a system level controller.

The broker model, whereby the intermediate agents apparently shield the actual source from the destination and often act as virtual sources down the line, may be thought of as an extreme case of the supply chain. In such a scenario, the service quality constraints are to be met by all the agents in between.

The issues arising out of the transfer of commodity down the line and the solution based on shifted feedback were discussed separately in the previous section. The other issues in supply chain management (SCM) are highlighted here. Having a common goal among the players of the supply chain is a tough task. Each element down the line will have its own agenda. Appropriate common goals and interfaces need to be defined so that the individuals align themselves towards the goal. The interfacing can be meaningfully defined only if the units commit to adhere to some quality guideline. However, it requires some time.

Interoperability is a major issue in the communication along the supply line. It may be improved with a common protocol with a machine-independent language such as XML.

The language description would be bound to the commodity and would be interpreted by all the players along the line.

The SCM models are required to be scalable. The required scalability may be brought in with the help of a DANN. The model remains invariant with the inclusion of additional flows, the only change being that the loss rate would increase faster.

FUTURE TRENDS

The increased dimensions in the organization call for the usage of collaborative and Web-based technologies for data collection. The data handling and integration systems in a supply chain come with increased communication and quality capabilities. This happens through increased collaboration among the elements of the supply chain down the line.

Supply chain components make use of a variety of software. Integration of these components and software under one platform would gain momentum, paving a path for new software in the market.

The concept of distributed computing, multi-agent software and technology is getting in to the supply chain. The elements of the supply chain are quite often located at distinct physical and geographical locations. The data or commodity exchange among them can happen through a shift-based protocol. The protocols of distributed computing are expected to bring some order into the data exchange within the supply chain.

Advanced prediction of end user behavior would continue to contribute to the success of the manufacturing supply chain: it reduces the overhead on inventory. Further, development and usage of the customized prediction software tools as a part of the SCM suit would gain momentum. The usage of prediction of the health of the supply line has been explained in the previous sections.

Supply chain automation would be a common call in the future. The usage of automation software would enter into all forms of the supply chain. With the SCM software, it would be possible to automatically route the commodities all along the line. A variant of the software is electronic shopping, where the end user can directly negotiate with the distributor over the Internet and bypass the supply chain. This results in faster movement of the commodities. The Web services are coming along the supply chain. With this, it is possible for all players of the supply chain to get into a common platform and instantly interact over the Internet.

With supply chains involving digital contents, it is possible to specify the distribution patterns and rights through the associated meta-languages. The contents would be sold as commodities involving various middlemen like distributors and resellers, each having a specific rights over the contents.

The nature of the supply chain gets complex with the inclusion of more players. Often the chains would contain branches or mergers down the line. Some of the chains could include parallel paths in between and increase the complexity further. The SCM software has to consider all these scenarios.

CONCLUSION

The timely management of an end-to-end supply chain has become a challenging task in large and medium enterprises with distributed units scattered across the globe. In this chapter, the supply chain has been treated in a generic way, and no assumption has been made on the nature of the chain. It could be the data transferred over the Internet or the supply of arms to the ground troop deployed in the war field.

The different issues of the supply chain including the secure and timely movement of the commodities are addressed, and a solution has been sought based on a type of feedback from the tail of the supply chain to the head. The feedback includes a time-shifted version of the extrapolated loss or delay parameter of the commodity as seen by the destination. The feedback signal controls the overall flow in the supply chain.

The problem of resource contention at the intermediate nodes in the supply chain as a result of multiple flows has been defined, and the solution in terms of relative quality parameters has been explored.

Chapter 7.5

Supplier Capabilities and eSourcing Relationships:

A Psychological Contract Perspective

Vanita Yadav
Management Development Institute, India

Mahadeo Jaiswal
Management Development Institute, India

ABSTRACT

The forces of globalization have influenced organizations to extend the concept of IT outsourcing to IT-intensive business process outsourcing (eSourcing). Most of the research on managing outsourcing relationships has focused either on legal contracts or on strategic partnerships. Advocating a different viewpoint, researchers like Rousseau (1995) found that in reality everyday working of contractual relationships was governed by individual's subjective interpretation and was fundamentally psychological in nature. The objective of this paper is to posit a relationship step model which projects a vital relationship management capability plus psychological contract perspective for eSourcing. It incorporates the stance of relational contract, interorganizational relationship and psychological contract theories. Using the qualitative research paradigm, the research model is preliminarily explored with case studies of two eSourcing suppliers. The exploratory results of this research indicate that relationship management capability of suppliers is an important factor shaping the outsourcing value proposition. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

The concept of outsourcing has spread from traditional informational systems (IS) outsourcing structures into new outsourcing service configurations, like IT-intensive business processes. This kind of outsourcing has been defined as 'eSourcing' by Carnegie Mellon University's eSCM-SP. The primary drivers for this trend are increasing competitive pressures, a need to access world-class capabilities and a desire to share risks.

The eSourcing relationship begins with a contract between two parties - the client and the supplier. Both these parties must possess certain capabilities in order to make the engagement successful. Kern and Willcocks (2001) in their study on IT capabilities for clients found that supplier capabilities are critical for outsourcing success. Despite the growing interest in vendor capabilities, there has not been an in-depth examination of these capabilities and how they generate value in outsourcing relationships (Levina & Ross, 2003). Additionally, most of the prior research on outsourcing relationships has focused either on legal contracts or on advocating strategic partnerships for managing the relationship. But in reality, everyday working of contractual relationship is governed by individual's subjective interpretation, because all contracts, whether written or unwritten, are fundamentally psychological, i.e. existing in the eye of the beholder (Rousseau, 1995).

Rousseau's 1989 seminal research triggered much of the contemporary empirical work on the employment psychological contract. Adopting Rousseau's view, Koh, Ang and Straub (2004) have defined a new perspective on managing IT outsourcing relationships. They state that it is the individual's beliefs and perceptions of these obligations rather than written contract that drive their behavior. Hence to get a complete picture, it becomes relevant to view the sourcing relationships from the psychological contract perspective. Addressing these gaps, this paper aims to propose a relationship step model for eSourcing suppliers using a psychological contract lens. This study aims to explore how relationship management capabilities of suppliers help in fulfilling supplier obligations and hence add business value.

The paper proceeds as follows. In the next literature review section, we discuss the main concepts of the paper. We then move towards development of a model by delineating the theoretical foundations and the dimensions of relationship management capabilities. Next, we examine the relationship management capabilities via the psychological contract lens and posit a relationship step model for eSourcing suppliers. We then describe the methodology adopted for exploratory research and discuss the two case studies. We conclude with our initial findings, limitations and directions for future research.

LITERATURE REVIEW

eSourcing

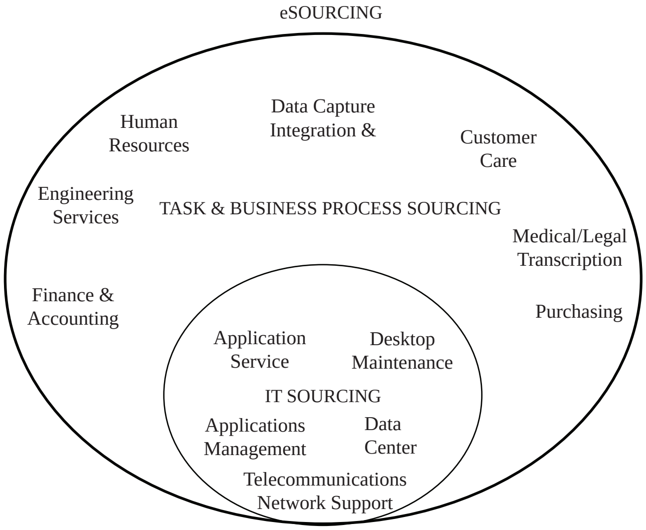
eSourcing or IT-intensive sourcing, uses information technology as a key component of service delivery or as an enabler for delivering services (Hyder, Heston & Paulk, 2004). It includes traditional IT sourcing, and task and business process sourcing (see Figure 1).

eSourcing is often provided remotely, using telecommunication or data networks. Carnegie Mellon University's eSCM-SP states that these services range from routine and non-critical tasks that are resource intensive and operational in nature to strategic processes that directly impact revenues. Adopting this view, we define eSourcing as "the delegation of one or more IT-intensive business processes to an external provider that, in turn owns, administers and manages the selected processes based on defined and measurable performance metrics."

Capabilities

Organizational capabilities are the abilities underlying high performance in specific spheres of business (Dawson, 2005). They are the result of deliberate investments in organizational structure and systems to make important improvements in those routines and practices (Zollo & Winter, 2002).

Figure 1. Types of eSourcing Services (Source- Hyder et al. 2004)



Client-Supplier Relationships

Outsourcing relationship can be defined as a state where client and supplier organizations are connected or related to via individual managers for the duration of the contract period of an outsourcing venture (Kern & Willcocks, 2001). A survey based study conducted by Goles (2001) highlights that higher vendor-client alignment, teamwork, balance of control, and process agility in the relationship will lead to more successful outcomes. Most of the research on managing outsourcing relationships has focused either on legal contract, with tight contractual mechanisms recommended to reduce opportunistic behaviors (Ang & Beath, 1993; Lacity & Hirschheim, 1993) or on advocating strategic partnerships for managing the relationship (Kern & Willcocks, 2001). *Relationship management* depends on carefully planning and formulating the contract, devising operational structures, outlining the interactions and leveraging and forming relational behaviors (Kern & Willcocks, 2001). From literature we learn that informal (interpersonal trust) and formal (contractual) aspects of the relationship are equally important (Poppo, 2002; Sabherwal, 1999) and need to be developed (Levina & Ross, 2003).

Business Value

IS research on the value generation potential of an outsourcing relationship has considered three factors: client characteristics, vendor characteristics, and the vendor-client relationship (Goles, 2001). An important factor shaping the outsourcing value proposition is the vendor's own capabilities (Goles, 2001; Saunders, Gebelt & Hu, 1997). Thus from the supplier perspective, business value addition would depend, to a great extent, upon the relationship management capabilities.

Business value addition can be operationalized via overall *satisfaction* with the contract, the *desire to retain* the outsourcing partner (Saunders, Gebelt & Hu, 1997) and increase in the level of *trust* (Lee & Kim 1999). Satisfaction is a common measure of success in IT outsourcing research (Susaria, Barua & Whinston, 2003; Koh, Ang & Straub, 2004), and is used as a proxy for the perceived effectiveness of the relationship. Satisfaction is also predictive of future actions (Poppo & Lacity 2002), and is closely related to the parties' intention to continue the relationship, either in the current contract or in subsequent repurchase (Koh, Ang & Straub, 2004). Also, it is more costly for suppliers to acquire new customers than to retain existing ones (Koh, Ang & Straub, 2004).

Trust is an indicator of partnership quality (Lee & Kim, 1999) and can be used to measure business value addition as the increase in the level of trust is more likely to result in the increase in the success of the relationship. Trust has been defined by Mayer, Davis and Schoorman (1995) as the "willingness of a party to be vulnerable to the actions of another party, based upon expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party". In simple words it is an expectation that a certain party can be relied upon even if there is a possibility of opportunism. Trust is rather an abstract and intuitive construct which is individual centric and is likely to have psychological connotations.

THEORETICAL FOUNDATIONS

Client and supplier relationships can be studied from varied theoretical perspectives. In this research paper we focus on three theories from literature. These are – relational contract theory (RCT), interorganizational relationship (IOR) theory and psychological contract theory. Together these theories cover an organizational, behavioral, legal and psychological perspective of the sourcing relationship:

i. **Relational Contract Theory (RCT):** RCT states that all contracts include contractual relations (Macneil, 1974). The core of the theory contains two key elements: the description of contract behaviors, which are the norms that arise in exchange relations and the dimensions of contract discreetness, which can be from discrete to relational.

ii. **Interorganizational Relationship Theory (IOR):** IOR is concerned with the reasons and conditions for forming relationships (including socio-political and economic aspects) and their structural behavioral and process dimensions (Oliver, 1990; Van de Ven & Ring, 1994). IOR theory provides a useful approach for understanding and analyzing the causes and conditions for the formation of a relationship, and the structural behavioral and interaction dimensions (Kern & Willcocks, 2001).

iii. **Psychological Contract Theory:** A psychological contract refers to an individual's mental beliefs about his or her mutual obligations in a contractual relationship (Rousseau, 1995). Koh, Ang and Straub (2004) assert that a psychological contract perspective offers a more inclusive view of mutual obligations between the contracting parties in outsourcing. Mutual obligations imply that the supplier agrees to make specific contributions to the customer in return for certain benefits from the customer. Their research findings highlight that fulfilling customer-supplier obligations explained a significant amount of variance in outsourcing success.

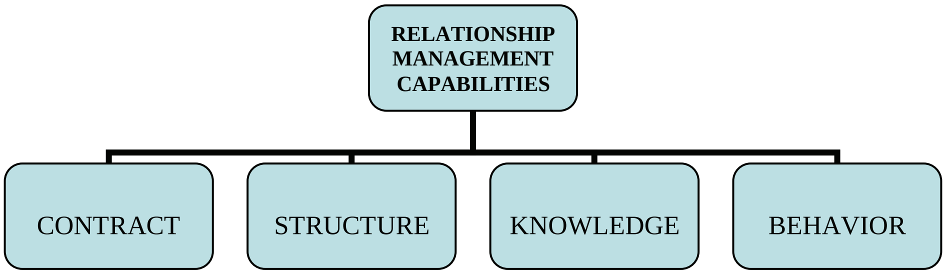
TOWARDS DEVELOPMENT OF A RELATIONSHIP STEP MODEL

Relationship Management Capabilities

We extend and adapt some of the IT outsourcing relational dimensions, identified by Kern and Willcocks (2001), to eSourcing relationships and posit the following four dimensions of relationship management capabilities of eSourcing suppliers (see Figure2).

i. **Contract:** Contracts are essentially vehicles for 'relational development' (Macaulay, 1963). RCT offers the theoretical foundation for investigating the contract dimension of eSourcing relationships. Ang and Beath (1993) in their study of outsourcing contracts demonstrate that unlike the sug-

Figure 2. Relationship management capabilities of eSourcing suppliers



gestions of discrete contracts, parties in real-life dynamically interact, commit to, and reinterpret their agreements with one another to assure necessary flexibility. Further, depending upon the complexity of the contract, anticipating all future events and covering them by making them present is impossible (Macneil, 1974).

ii. **Structure:** IOR theory offers a lens for examining the structural dimension of an eSourcing relationship. Buyer-supplier relationships entail a set of structural properties such as, size, centralization, specialization and configuration (Hakansson & Snehota, 1995). In outsourcing several individuals from different functional areas, at different levels in hierarchy, and fulfilling different roles generally become involved (Kern & Willcocks, 2001). Therefore, the interface points of the supplier and customer should be clearly defined. For the supplier interface roles of SLA management, leadership and business understanding are critical for coordinating, developing and facilitating the relationship (Kern & Willcocks, 2001).

iii. **Knowledge:** IOR theory says that exchange is the dominant process underpinning interorganizational relations (Kern & Willcocks, 2001). Exchange does not necessarily involve elements of economic value, but may also include services, information and knowledge. The knowledge dimension can be described in terms of sharing service related knowledge and industry best practices with the client.

iv. **Behavior:** Both RCT and IOR theories identify the major elements in representing behaviors in interorganizational relationships. Interactions among cooperating parties may cast a positive, neutral, or negative overtone on the relationship, influencing the parties' behaviors toward each other (Kern & Willcocks, 2001). The behavior dimension can be described in terms of taking ownership, supplier-client business goal alignment and a good working relationship.

Applying the Perspective of Psychological Contract

Psychological contract theory focuses on the contracting parties' mental beliefs and expectations. Using grounded theory approach Koh, Ang and Straub (2004) generated a list of customer-supplier obligations and identified six major components of what clients' believe are supplier obligations (see Table 1).

The supplier obligations were drawn from the customer sources and they point out precisely '**what the customers expects**' from their suppliers. If the supplier is able to fulfill these obligations it is more likely to lead to customer satisfaction. This would in turn help in adding business value. Next, we map the supplier obligations with the relationship management capabilities required to fulfill these obligations (see Table 2).

Table 1. Supplier obligations (psychological contract dimension)

	Supplier Obligations (Psychological Contract Dimension)
1.	**Project Scoping:** Clear definition of the nature and range of the services covered in the contract and flexibility in handling clients' requests for changes in the scope of the services
2.	**Clear Authority Structures:** Delineation of the decision-making rights and reporting structures in the project, in terms of the roles and responsibilities of all the parties involved.
3.	**Dedicated Project Staffing:** Assignment of high quality staff to work on the project, and minimization of staff turnover during the project.
4.	**Effective Knowledge Transfer:** Educating clients in terms of the necessary skills, knowledge, and expertise associated with using the outsourced system or service.
5.	**Taking Charge:** Completing the job and solving problems independently, with minimal customer involvement.
6.	**Building effective interorganizational teams:** Investing time and effort to foster a good working relationship among the team of customer and supplier staff working on the project

Table 2. Mapping relationship management capabilities with supplier obligations

Relationship Management Capability	Supplier Obligation(Psychological Contract Dimension)
1. Contract	1. Project Scoping & Flexibility
2. Structure	2. Clear Authority Structures 3. Dedicated Project Staffing
3. Knowledge	4. Effective Knowledge Sharing & Transfer
4. Behavior	5. Taking Charge 6. Building Effective Interorganizational Teams

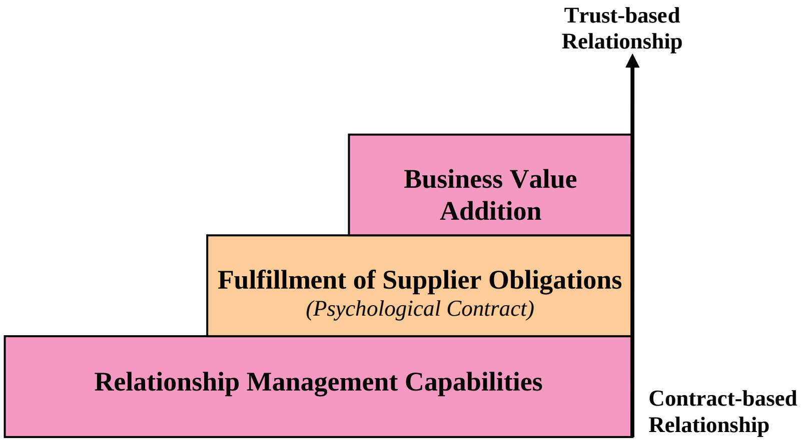
Contract capability is required to fulfill project scoping and flexibility obligation. Structure capability is required to fulfill clear authority structures and dedicated project staffing obligations. Knowledge capability is required to fulfill effective knowledge sharing and transfer obligation. Finally, behavior capability is required to fulfill taking charge and building effective interorganizational team obligations.

Relationship Step Model for eSourcing Suppliers

After combining the relational capabilities and psychological contract dimensions we posit that eSourcing suppliers possessing relationship management capabilities (input) are more likely to fulfill supplier obligations (intermediate outcome). As a result, the service provider will be more likely to achieve business value addition (final outcome). Figure 3 displays the relationship step model for eSourcing suppliers.

The first step is the achievement of relationship management capabilities. These relationship management capabilities would help the service provider to proceed to the second step of the model, which is the fulfillment of supplier obligations (intermediate outcome). After fulfilling the supplier obligations, the service provider ascends to the third step of the model, which is the achievement of business value addition (final outcome). As we move up in the vertical axis, the level of relationship also increases from a contract-based relationship to a trust-based relationship between the service provider and the client.

Figure 3. Relationship step model for eSourcing suppliers



METHODOLOGY

Case study research method was adopted for this study to carry out two exploratory case studies. Case study has been a common and widely accepted research strategy in psychology, sociology, political science, social work (Gilgun, 1994) and business (Ghauri & Gronhaug, 2002; Yin, 2003). Yin defines case study as an empirical inquiry to investigate a contemporary phenomenon within its real life context. Following Yin's (2003) approach, we included all the five components of research design:

i. Research Questions (RQ)
  RQ1: How do the relationship management capabilities help in fulfilling the supplier obligations (psychological contract dimension)?
  RQ2: How does the fulfillment of supplier obligations help in adding business value for the suppliers?
ii. Research Propositions (RP)
  RP1: eSourcing suppliers who possess relationship management capabilities are more likely to fulfill supplier obligations.
  RP2: eSourcing suppliers who fulfill supplier obligations are more likely to achieve business value addition.
iii. *Unit of Analysis*: a relationship/engagement between the supplier and the client
iv. *Logical linking of data collected with the propositions*: pattern matching
v. *Criteria for interpreting the findings*- logic model for analyzing case study evidence

DATA COLLECTION

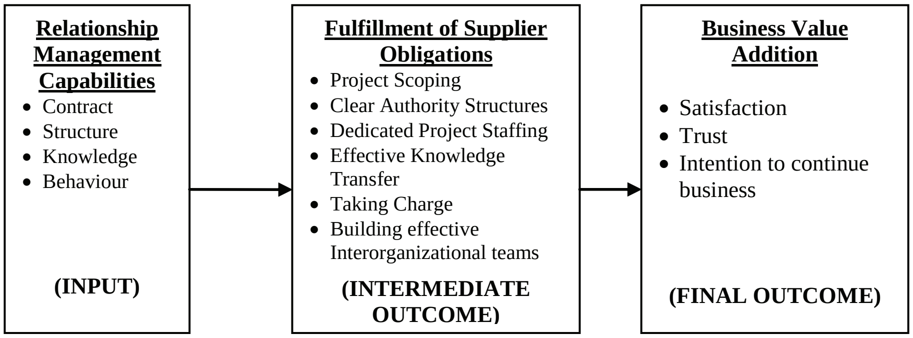
In the last decade, the information technology and business process outsourcing industries have seen substantial offshoring. Two eSourcing suppliers were selected from India for the purpose of data collection. India has established itself as a popular outsourcing destination as it offers and delivers the best 'bundle' of benefits sought from global sourcing (NASSCOM, 2006; Yadav, Bhardwaj & Saxena, 2006). India has successfully leveraged its advantages of abundant talent, a keen focus on quality and low costs coupled with an enabling business environment to attain leadership position in the global sourcing space ((NASSCOM, 2006). According to NASSCOM's report India accounts for 65 per cent of the global industry in offshore IT and 46 per cent of the global Business Process Offshoring (BPO) industry. Given trends in globalization and the increasing prevalence of offshore outsourcing (Carmel & Agarwal, 2002) and the relative dearth of eSourcing research outside the United States and selected parts of Europe (Barthelemy & Geyer, 2001; Koh, Ang & Straub, 2004), we believe that this dataset is useful in helping the Information Systems (IS) community understand eSourcing practices in other countries like India.

The two organizations selected for the study are well-established eSourcing suppliers based around the National Capital Region of India. Both service different domains- one provides knowledge-intensive eSourcing services in the Telecom domain and the other provides operational eSourcing services in the Travel Services domain. Their clients are located in USA. Due to high level of confidentiality and legal clauses involved in offshore outsourcing contracts the names of the organizations have been disguised in the paper. Hence in the rest of this paper Travel Services supplier will be addressed as *TravelWiz* and Telecom Services supplier will be addressed as *TeleWiz*.

We conducted interviews with the senior level managers from operations, finance, and business development; and middle-level project managers. Two members from the research team (one of the authors and one research assistant) took extensive field notes at the interview session to make the transcripts as complete as possible. During the interviews, the first author focused on conducting the interview using an interview script, which was transcribed from interview notes the same day. The interview questions (see Appendix 1) of the script were guided by our research propositions. Our research propositions provided the theoretical orientation to guide our case study analysis. Secondary data from sources such as company documentations, company press releases, presentations, official websites, news articles etc were also collected. Notes from informal observation were also taken during the site visits. All relevant information was stored as softcopies and hardcopies to create a case study database.

The case study evidence was analyzed using the 'logic models' data analysis technique. The use of logic models as an analytic technique consists of matching empirically observed events to theoretically predicted events. The events are staged in a repeated cause-effect-cause-effect pattern (Figure 4), whereby a dependent variable (event) at an earlier stage becomes the independent variable (causal event) for the next stage (Yin 2003). Thus according to our relationship step model (Figure 3), the presence of relationship management capabilities (input) leads to fulfillment of supplier obligations (intermediate outcome) and eventually to business value addition (final outcome).

Figure 4. Case analysis model

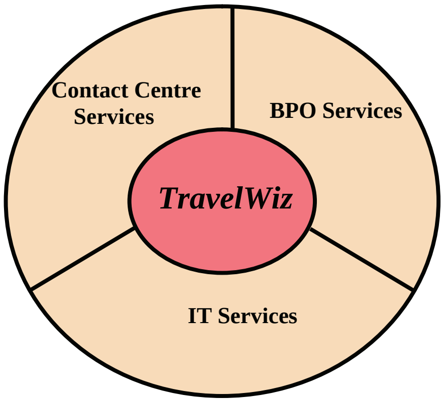


Case Study- TravelWiz

TravelWiz is a fully owned subsidiary, set up in India in 2001, of world's leading Travel and Real Estate Corporation based in USA. The parent company is listed among the fortune 500 companies and has clients in over 100 countries around the world. The offshore eSourcing unit in India provides a myriad range of services to its parent company. It operates as a niche player in the eSourcing arena and provides end-to-end solutions in the travel vertical.

The outsourcing services provided by TravelWiz fell under three categories: Contact Centre Services, IT Services and BPO Services in the travel domain (Figure 5). The Contact Centre Services included customer-facing (pre and post sales) services. Customer support was provided via email and phone in the caller's native language, e.g., calls from France would be routed to the agent in India handling French calls. IT Services included web design development and maintenance. This included support for enterprise management packages; website content management system; and ticketing engine used by the company and its clients. BPO Services covered back office administrative services and financial services. TravelWiz provided seamless integration of all these three services. Thus providing end-to-end travel domain specialized services which would help in achieving higher revenues and savings.

Figure 5. Services provided by TravelWiz



TravelWiz had a multicultural staff of over 1500 people with about 12% of them being Europeans. The expatriate staff was from 9 different countries in Europe. This offered unique opportunity to the Indian as well as expatriate staff to indulge in cross-cultural knowledge sharing. The expatriate staff was recruited and trained by TravelWiz clients from their native countries through advertisements posted on websites and employee referrals. During the span of six years TravelWiz had developed a robust multi-lingual support model to service voice and non-voice processes.

TravelWiz had signed detailed contracts with its client which allowed minimum flexibility related to scope changes. The process to be handled and the services to be provided by TravelWiz were defined in a very structured manner. The client and TravelWiz identified the interfaces in their relationships even before the project started. A formal organizational structure of their outsourcing value chain was drawn up to track the flow of the project. TravelWiz worked in a 24/7 mode and staffing was based upon seating capacity of their unit. For every project people were assigned based upon the required expertise and availability. The roles and responsibilities were clearly explained to the staff and were also documented in the company manuals. There were in-house ad-hoc training programs for new staff that joined in the middle of a project when there were situations of staff turnover or changes in the project scope. The services provided by TravelWiz were operational in nature and there were formally documented standards for every process and its delivery methodology.

TravelWiz had a formal relationship management team assigned to the eSourcing project. They interacted with the client on a regular basis via various modes- online chat, email, and videoconferencing. Scheduled face-to-face client meetings were also planned to report progress to the client and handle any project-related issues. This team was responsible to oversee any bottlenecks that would occur during the project and acted as a link between the client team and supplier team.

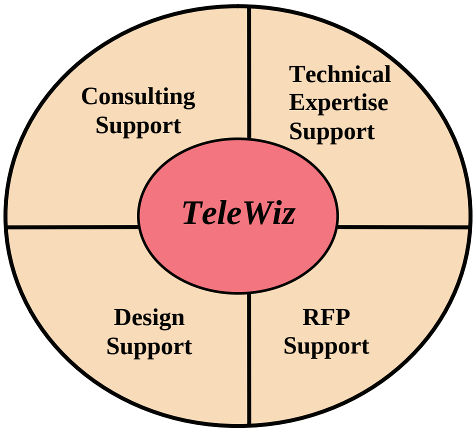
Case Study- TeleWiz

TeleWiz was a 60 percent owned subsidiary, in India, of a leading Telecom Corporation based in USA. TeleWiz was setup in the year 2002 as a technology and consulting group to provide pre-sales support on new technology to its parent company and business partners. The parent company was a global leader in communication systems, applications, and services. They designed, built, deployed and managed networks for enterprises. Customers ranged from small businesses and nonprofit agencies to the FORTUNE 500 companies, and the government.

TeleWiz provided knowledge-intensive eCommunication services to its parent company which included consulting support, technical expertise support, design support and request for proposal (RFP) support (see Figure 6). These services fell under the pre-sales category. TeleWiz provided these specialized services through a team of area specialists.

TeleWiz signed contracts with its client on basis of the nature of services and the range of services required. As a result, flexibility in contract scope changes was allowed to a great extent. The client team and TeleWiz team had clearly identified the interface structure for every project. Staff assignment for outsourcing projects was based upon the required expertise and availability of human resources. This was more critical in this case as the task at hand was highly complex and required expertise of specialized people. Communication skills of the team members were also considered as an important factor in staff assignment. The roles and responsibilities were clearly defined and documented in the company manuals. In-house extensive training programs for new staff were conducted for every project. People with prior experience in such projects were used as trainers in such programs. They motivated people to invest time in documentation by offering awards and prizes for building documentations during and after the projects.

Figure 6. Services provided by TeleWiz

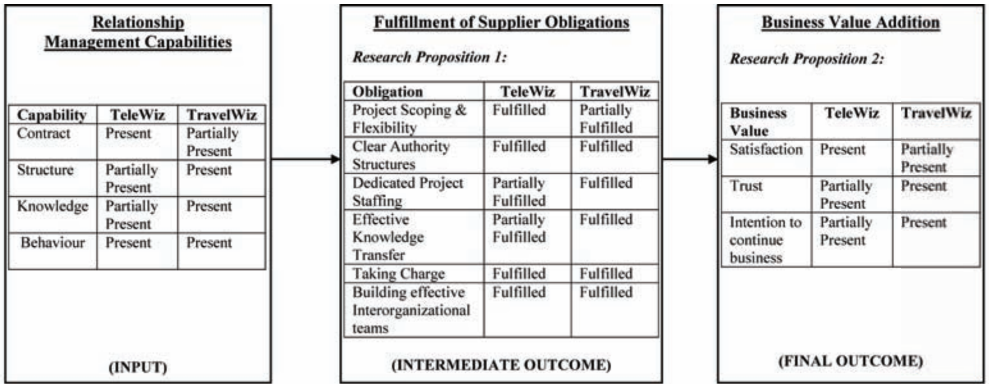


TeleWiz did not have a formal relationship management team assigned to the projects. But their team leads interacted with the client on a regular basis via various modes- email, teleconferencing and videoconferencing. Scheduled face-to-face client meetings were planned by senior project managers to report progress to the client and handle any project-related issues. Thus the structure of the relationship management team was defined as ‘informal in nature’ by TeleWiz. They informally spent time in educating the project team regarding the client’s business goals and work culture. This was conducted during project meetings which were attended by team members, team leads and project managers. They emphasized that the service being provided by them was highly specialized in nature and there were no industry best practices available.

RESULTS

Data analysis was guided by our case analysis model (Figure 4). The summary of the results for

Figure 7. Results summary



Relationship Management Capabilities

Capability	TeleWiz	TravelWiz
Contract	Present	Partially Present
Structure	Partially Present	Present
Knowledge	Partially Present	Present
Behaviour	Present	Present

(INPUT)

Fulfillment of Supplier Obligations

Research Proposition 1:

Obligation	TeleWiz	TravelWiz
Project Scoping & Flexibility	Fulfilled	Partially Fulfilled
Clear Authority Structures	Fulfilled	Fulfilled
Dedicated Project Staffing	Partially Fulfilled	Fulfilled
Effective Knowledge Transfer	Partially Fulfilled	Fulfilled
Taking Charge	Fulfilled	Fulfilled
Building effective Interorganizational teams	Fulfilled	Fulfilled

(INTERMEDIATE OUTCOME)

Business Value Addition

Research Proposition 2:

Business Value	TeleWiz	TravelWiz
Satisfaction	Present	Partially Present
Trust	Partially Present	Present
Intention to continue business	Partially Present	Present

(FINAL OUTCOME)

each research proposition are outlined in Figure 7 and explained as follows:

RP1a: eSourcing suppliers who possess 'contract' capability' are more likely to fulfill 'scoping & flexibility' obligations

Both the eSourcing suppliers believed that the project scope in the contracts should be clearly defined covering the nature and range of the services to be provided. They both also believed that some amount of flexibility should also be present in the outsourcing contracts. TeleWiz believed in signing very flexible contracts to the extent that project monitoring was loosely stated as per mutually agreed processes in the contract whereas TravelWiz believed in lesser amount of flexibility and greater amount of formality in the contracts. Both the suppliers had signed long term contracts which were reviewed on a yearly basis. Greater flexibility in the TeleWiz case can be attributed to the fact that the nature of the job was complex and was difficult to state explicitly beforehand whereas the TravelWiz case was more operational in nature that required lesser amount of flexibility.

Thus the presence of contract capability in the case of TeleWiz helped in the fulfillment of project scoping and flexibility obligations whereas the partial presence of contract capability in the case of TravelWiz resulted in partial fulfillment of the project scoping and flexibility obligations.

RP1b: eSourcing suppliers who possess 'structure' capability are more likely to fulfill 'clear authority structure & staffing' obligations

Both the suppliers assigned dedicated staff with the required expertise to the projects. An interesting finding was that even in highly technical roles, as in the case of TeleWiz, it was mandatory to possess good communication skills apart from having the required technical expertise. People were kept on-bench to mitigate the risk of staff turnover in the projects. Additionally, both companies had good HR practices consisting of a good salary structure and a healthy work environment. The interface points and roles and responsibilities were clearly defined for both the companies. But only TravelWiz had a dedicated relationship management team. The presence of structure capability in the case of TravelWiz helped in the fulfillment of clear authority structure & staffing obligations whereas the partial presence of structure capability in the case of TeleWiz resulted in partial fulfillment of clear authority structure & staffing obligations.

RP1c: eSourcing suppliers who possess 'knowledge' capability are more likely to fulfill 'effective knowledge sharing & transfer' obligation

The level of service related knowledge sharing with the client was high for both the companies. TeleWiz also offered awards for documentation and building content on service related knowledge. Industry best practices were shared by TravelWiz with its client (parent company). But TeleWiz shared none as they believed that there were no industry best practices in such a specialized domain. The services of TravelWiz were delivered with comprehensive and complete documentation whereas the services of the TeleWiz were delivered with brief and to-the-point documentation. It can be attributed to the fact that they were providing highly customized services and building extensive documentation separately every time could have cost implications in terms of time and effort. On the other hand TravelWiz tasks were mainly operational and repetitive in nature. This brought in a great amount of standardization and easy documentation for TravelWiz. Hence the presence of knowledge capability in the case of TravelWiz helped in the fulfillment of effective knowledge sharing & transfer obligations whereas the partial presence of knowledge capability in the case of TeleWiz resulted in partial fulfillment of effective knowledge sharing & transfer obligations.

RP1d: eSourcing suppliers who possess 'behavior' capability are more likely to fulfill 'taking charge & building effective interorganizational teams' obligation

Both the companies scored high on this dimension and believed in taking ownership of the project by completing the job and solving problems independently, with minimal client involvement. Also, both the companies invested time and effort to develop business understanding and a good working relationship. The team members working on the project were also given informal training on client-supplier goal alignment. Thus the presence of behavior capability in the case of TravelWiz as well as TeleWiz helped in the fulfillment of taking charge & building effective interorganizational teams obligations.

RP2: eSourcing suppliers who fulfill supplier obligations are more likely to achieve business value addition.

Fulfillment of most of the obligations for both the companies illustrated high level of satisfaction in the relationship with their respective clients. Also, both believed that the business with their client is likely to grow in future. The level of trust at the time of commencement of the eSourcing relationship was low in both the cases and was mainly contract–based. In the case of TeleWiz there were negative feelings about the project's success initially. The level of trust had risen in both the cases and was rated as very high in the present scenario by TravelWiz. This research proposition is strongly supported in the case of TravelWiz and partially supported in the case of TeleWiz. It is important to bear in mind that TravelWiz was a 100 percent owned subsidiary engaged in the relationship for the past six years whereas TeleWiz was a 60 percent owned subsidiary engaged in the relationship for the past five years. Trust had grown in both the cases but with varying levels. The ownership structure could have also impacted the level of trust.

DISCUSSION

Overall our exploratory results show considerable agreement in terms of our research model and propositions. They also highlight that the levels of the capability dimensions may vary from case-to-case. Researchers such as Poppo (2002) and Sabherwal (1999) stress on the importance of formal (contractual) as well as informal (interpersonal) aspects of the relationships. Our research model adds an interesting element of psychological contract to the informal aspect of the relationships. Further, our study revealed that communication skills of employees involved plays a major role in building relationship management capability.

Our results support Koh, Ang and Straub's (2004) view of psychological contract in outsourcing arrangements. Our research is advancement in this regard as it has moved beyond IT outsourcing and has studied the psychological contract perspective in eSourcing arrangements. Another important contribution of this study is that using the unique lens of psychological contract we were able to explore the gap between possession of a capability and achievement of business value for the firm.

In literature outsourcing value proposition in terms of vendor's own capabilities was stressed by Goles (2001) and Saunders et al. (1997). Our findings clearly indicate that relationship management capability of suppliers is an important factor shaping the outsourcing value proposition. The suppliers possessing these capabilities are more likely to fulfill the supplier obligations and hence are more likely to develop trust-based relationships with their clients. This study provides practical contributions to the outsourcing industry by recommending a comprehensive, yet easy to apply, relationship step model. The model can act as a relationship-checklist for the contracting process starting from planning for eSourcing contracts to post-contract management.

LIMITATIONS

Like most qualitative studies, this research has some limitations. Firstly, the study tries to derive results from two exploratory case studies. Yin (2003, pp. 10) clearly highlights a question posed frequently for case study research - "How can you generalize from a single case?" The answer, as argued by Yin (2003, pp. 10), is that "case studies like experiments are generalizable to theoretical propositions and not to populations or universes". We adopt Yin's viewpoint and try to generalize our results to our theoretical propositions and not to the population in general. Hence the results of this exploratory study should be considered as probable indicators for the phenomenon under study. Secondly, due to time constraints for the interview sessions, the authors had to focus their questions strictly around the theoretical propositions. As a result, other dynamic and static perspectives of eSourcing relationships could not be explored. We would like to put forward this as a future research direction for researchers examining sourcing relationships.

Thirdly, the research is purely from a supplier's perspective. Hence results from this study should be treated with caution. An ideal condition would be to study the client-supplier dyad. However, we would like to state that since this is one of the initial steps in this direction, insights from the supplier perspective are also important. The insights from this research can be taken forward to study the client's perspective to get the complete picture. Finally, the case studies were of successful eSourcing suppliers. An alternate viewpoint is also essential for progress of research. The case studies do not highlight negative examples of eSourcing relationships. Future research in this area can explore such dimensions as well.

FUTURE RESEARCH DIRECTIONS

The outsourcing industry is posed for phenomenal growth and this area has high potential for research. Future research in this area can involve further validation of the proposed relationship step model by undertaking case studies of third party eSourcing suppliers in India. Additionally, the framework proposed in this paper can be used by other researchers to carry out empirical research from the vendor perspective in other popular service provider countries, like China. An ideal endeavor would be to have client-supplier dyads as the unit of analysis.

An alternative viewpoint for looking at our research model (Figure 3) can be by viewing it in the reverse direction. In other words, what are the likely consequences of moving down the steps of the relationship step model? In what situations can this occur? A probable situation can be a case where projects do not reach their intended targets. Simulating such an example, a client and supplier start an outsourcing venture on a high note but due to high attrition at the supplier's end a large pool of team members engaged in the project leave in the middle of the project. With the urgency to meet deadlines the supplier hires a new talent pool. The new employees are unfamiliar with the current project and hence take more time in understanding the process and completing the project deliverables. As a result the supplier organization is unable to fulfill some of the supplier obligations which instigate dissatisfaction within the client team. In such situations, does a trust-based relationship collapse? Does it result in a stricter contract–based relationship? Or there exists a middle path. How can suppliers ensure that they move up the steps and not down the steps of the relationship step model?

An interesting extension of our research would be to compare and contrast our case studies with companies that have failed in outsourcing ventures using the relationship step model. Additionally, comparison between companies in a more variegated spectrum of industries can be carried out. Further, longitudinal studies can be carried out to establish causality effects in the proposed model. Future research can also explore other obligations that are important from the service provider perspective. Also, whether the supplier obligations evolve or change over time can be examined. Additionally, the impact of communication skills on relationship building can be studied by researchers.

APPENDIX 1. CASE STUDY QUESTIONNAIRE

Research Dimension	**Interview Questions**
Capability Dimensions	
Contract	o Why did the client decide to outsource? o What is covered in the contract?
Structure	o What is the governance structure? o What is your outsourcing team structure?
Knowledge	o How critical is the process to the client's business? o How do you deliver services to the clients? o What kind of knowledge transfer takes places?
Behaviour	o How do you manage the relationship with your client? o How much client involvement do you require/expect during the project? o How does the client hope to benefit from the arrangement? o How do you, as a service provider, hope to provide benefits to the client?
Obligation Dimensions	
Project Scoping	o How do you define the contract scope for an outsourcing project? o How much flexibility do you incorporate into the contract to accommodate contract scope changes?
Clear Authority Structures	o How do you define roles and responsibilities for the team members? o How are the interfaces points for the project defined between the client organization and your organization?
Dedicated Project Staffing	o How do you assign staff for a project? o How do you deal with staff turnover, for example, situations where people have left in-between projects?
Effective Knowledge Transfer & Sharing	o How do you share service related knowledge with your client? o Do you share industry best practices with your client? How do you share them? o How do you educate the client in terms of the necessary skills, knowledge, and expertise associated with using the outsourced system or service?
Taking Charge	o How do you tackle problems encountered during the projects? o How involved is the client in the project functioning in terms of: ▪ Monitoring ability ▪ Monitoring frequency ▪ Task observability ▪ Outcome measures
Building effective Inter-organizational teams	o Do you spend time in understanding the client's business? o What steps do you take to understand your client's business? o Do you share the details of your client's business with the team members involved in the project? How does this take place?
Value Addition Dimensions	
Satisfaction	o How has been your sourcing experience with the client?
Trust	o How would you describe the level of trust between you and your client at the time of signing the contract? o How would you describe the level of trust between you and your client now?
Intention to Continue Business	o How do you foresee your business with the existing client? o How long is the relationship expected to last?

Chapter 7.6

A Strategic Framework for Managing Failure in JIT Supply Chains

Jaydeep Balakrishnan
University of Calgary, Canada

Frances Bowen
University of Calgary, Canada

Astrid L.H. Eckstein
Independent Consultant, Canada

ABSTRACT

Supply chains can be disrupted at both local and global levels. Just-In-Time (JIT) companies should be particularly interested in managing supply chain failure risk as they often have very little inventory to buffer themselves when their upstream supply chain fails. We develop previous research further and present a strategic framework to manage supply chain failure in JIT supply chains. We identify two dimensions along which the risks of failure can be categorized: location and unpredictability. We go on to identify strategies which companies can use either before (proactive) or after (reactive) the failure to manage supply chain failure. We support our framework with examples of actual responses to supply chain failures in JIT companies. It is also hoped that our strategic framework will be validated empirically in the future leading to specific guidance for managers.

INTRODUCTION

Just-in-time (JIT) manufacturing, with its focus on continuous improvement through waste reduction and problem solving, has been widely hailed as a philosophy that improves organizational performance. JIT principles include only having required inventory; improving quality; trimming lead time by reducing setup time, queue length, and lot sizes; and reducing costs in the process (Cox & Blackstone, 2002). The philosophy offers organizations some significant cost and quality benefits (e.g., Funk, 1995; Duguay, Landry, & Pasin, 1997; Claycomb, Germain, & Droge, 1999), so it is not surprising that large numbers of organizations around the world have implemented or are in the process of implementing JIT manufacturing.

However, there are several disadvantages and implementation difficulties associated with JIT (Im, Hartman, & Bondi, 1994; Inman & Mehra, 1989), including supply chain failure (Altenburg, Griscom, Hart, Smith, & Wohler, 1999; Zsidisin, Ragatz, & Melnyk, 2005; Kleindorfer & Saad, 2005; Craighead, Blackhurst, Rungtusanatham, & Handfield, 2007). The risk of supply chain failure refers to the combination of the probability that an element of the supply chain will fail, and the magnitude of the disruption caused by the failure throughout the remainder of the chain. A recent McKinsey survey found that managers face increasing supply chain risk (Krishnan & Shulman, 2007). Understanding supply chain failure is particularly important for JIT organizations because companies using JIT are especially susceptible to failures in their upstream supply chain as they have limited inventory to protect them if the parts do not arrive on time.

Tang (2006) categorizes supply chain risk as operational or disruptional. Operational risk refers to inherent uncertainties such as uncertain customer demand, uncertain supply, and uncertain cost. Disruption risks relate to natural and man-made disasters or economic crises. This article focuses on the disruptional risk aspect of JIT supply chains since, as Tang points out, the impact of disruptional risk is far greater than that of operational risk.

We begin by briefly outlining research on risk within supply chains, and on the particular challenges facing managers within JIT supply chains. We then go on to develop two dimensions of supply chain failure based on our inference from industry practice reported in the literature: (1) the location, and (2) the unpredictability of the supply chain failure (or unpredictability in recovering from failure). While others have focused on dimensions of supply chain failure such as controllability of the risk or severity of impact, we extend these treatments by emphasizing the location of the supply chain failure: whether the risk of supply chain failure is internal to the firm, external to the firm but internal to the supply chain, or whether it is systemic within an industry/region external to the supply chain. We illustrate the framework by categorizing some of the proactive and reactive processes used by companies to mitigate JIT supply chain failure. We conclude with a discussion of the implications of our framework for research on supply chain failure and JIT, and for practitioners. Our location-based view provides managers with an additional lens with which to view JIT supply chain risk, and an organizing framework to generate potential strategic risk management options.

It is hoped that this exploratory framework will lead to future studies using empirical approaches such as case-based research to validate the proposed framework. Case-based research (Miles & Huberman, 1994; Yin, 1994) can be used to explore in depth the use of different risk management approaches, among others. This type of in-depth research will allow the development of specific guidelines that managers can use to address supply chain risk within the enterprise.

SUPPLY CHAIN FAILURE AND JIT SYSTEMS

Sudden or catastrophic supply chain failure in JIT environments can have serious organizational impacts. The most common response has been to reduce or stop production until systems were operational again. The September 11, 2001 (9/11) terrorist attacks which delayed goods flowing between the United States and Canada, (Keenan, 2001), the 1995 stoppage of commercial traffic on the Rhine River in Germany due to flooding, the August 2003 power outage in the Northeastern and Midwest United States and Ontario, Canada, and the aftermath of the Kobe earthquake are examples.

Mitchell (1995) would categorize these examples as "performance loss" or "time loss" due to supply chain failure. However, the impact of supply chain failure does not end with merely immediate performance and time losses; they can extend to "financial loss" due to lost orders or the operational cost of remedying the failure, "physical loss" of facilities or supplies in cases of fire or flood, and even to "social loss" of the firm's reputation for reliability or "psychological loss" due to the stress of coping with the failure or damage to the organization's self-perception. It is therefore crucial that we better understand supply chain failure, and develop robust supply chain mechanisms and structures to cope with actual or potential failure.

Research on the supply chain design implications of following a JIT manufacturing strategy has tended to focus on "single sourcing, close supplier location, long-term relationships, schedule coordination and sharing, frequent deliveries of small lot sizes and stable supply-chain pipelines" (Das & Handfield, 1997, p. 246). Technical modeling on, for example, lead time uncertainty (e.g., Schwartz & Weng, 2000) has been complemented by survey-based research on the perceived cost reductions from implementing JIT purchasing and logistics (e.g., Dong, Carter, & Dresner, 2001). While some of these studies make passing reference to the risk of supply chain failure, research on JIT supply chains has contradictory messages on managing such risk. On the one hand, some JIT supply chain characteristics such as schedule coordination and long-term relationships encourage repeated interactions, trust, and increased information sharing, hence decreasing the likelihood of supply chain failure over time. On the other, increased strategic risk, or over-reliance on a single or limited number of suppliers (Sadgrove, 1996), can magnify the impact or outcome of any potential upstream supply chain failure since the JIT firm may have fewer alternative sourcing options.

Thus managerial recommendations for designing supply chains to handle failures are often complex or even contradictory. Mechanisms and structures to manage supply chain failure differ in their scope and timing. To take some examples from a recent list by Elkins, Handfield, Blackhurst, and Craighead (2005), some design strategies are implemented within a focal organization (e.g., training employees, including expected costs of failures in the total cost equation), some are implemented across the entire supply chain (e.g., enhancing system-wide visibility and supply chain intelligence by using near-real-time databases), and others require the involvement of supply chain members within particular industries or regions (e.g., gathering intelligence and monitoring critical supply-base locations). Similarly, some strategies are implemented before a failure (e.g., creating early warning systems to discover critical events outside normal planning parameters), and others are designed in response to a failure (e.g., conducting a detailed incident report and analysis following a major disruption). Further complicating the intervention suggestions is that some risks are much more unpredictable than others, and so need relatively more or less intensive monitoring and management.

Given the complexity of supply chain risk, many authors have developed two-dimensional frameworks for risk management. For example Meitz and Castleman (1975), Kraljic (1983), and Sheffi and Rice (2005) incorporate the probability that an element of the supply chain will fail and the magnitude of the disruption caused by the failure throughout the remainder of the chain as dimensions. Chopra and Sodhi (2004) examine 'level of risk' and 'cost of mitigating reserve' as dimensions in order to suggest risk mitigation strategies. Cavinato (2004) examines risk on the 'risk/uniqueness' and 'value/profit potential' dimensions. Kleindorfer and Saad (2005) examine supply chain risk management from a 'cost of disruption' vs. 'cost of risk mitigation' perspective. Thus the various two-dimensional frameworks have proved useful lenses for managers attempting to manage supply chain risk.

Recent treatments of supply risk also recognize the importance of both the source and outcome of the risk of failure (Zsidisin, 2003), and explicitly recognize that the source of supply chain failure can occur further away than the immediate buyer-supplier dyad (Zsidisin, 2003b; Spekman & Davis, 2004). Natural disasters, strikes, or fires can affect not only the first tier, but also second- or third-tier suppliers that are integrated within the JIT manufacturing system. Supply chain failures arising from apparently remote disruptions can have significant impact on an integrated supply chain, particularly within an increasingly uncertain, post-9/11 global environment (Spekman & Davis, 2004; Barry, 2004). Our framework will assist decision makers to develop appropriate responses to apparently distant supply failure risks by focusing on the location of the risk.

An important aspect of managing supply chain failure is to understand how and why supply chain disruptions occur. Chopra and Sodhi (2004) emphasize the importance of understanding the drivers of risk (labor disputes, inadequate capacity, and weather are some examples) and categorize them to help develop effective risk mitigation strategies. Kleindorfer and Saad (2005) suggest 10 principles to help understand and mitigate supply chain failure. Craighead et al. (2007) identify network density, network complexity, and node criticality as drivers of supply chain failure risk, and recovery and warning as drivers of supply chain failure mitigation.

While these are useful starting points for understanding the risk of failure in JIT systems, a framework is needed which helps managers deal with the complexity of risks arising in distant supply locations both before (proactive) and after (reactive) the failure. The research in *proactive* planning in supply chain disruption risk has paid insufficient attention to risk mitigation strategies based on location of the risk (i.e., whether the disruption risk is internal to the firm, external to the firm but internal to the supply chain, or external to the supply chain). This is an important oversight in our current understanding of the proactive management of supply chain failure since risks internal to the firm may be most controllable while disruption risk external to the supply chain may be least controllable. While focusing on the location of supply chain failure, our framework echoes previous research, which includes the unpredictability of the risk. We suggest that the proactive approach to JIT supply chain risk mitigation can be understood better if analyzed on the 'location of failure' and 'unpredictability of failure' dimensions.

In addition, while many articles discuss avoidance of disruption by upfront planning, only a few (Lee, 2004; Sinha et al., 2004; Zsidisin, Melnyk, & Ragatz, 2005a; Zsidisin, Ragatz, & Melnyk 2005b; Tang, 2006; Craighead et al., 2007) discuss *reactive* recovery in the case of supply chain failure. Since supply chain failures will take place occasionally even with the best of proactive planning, we should also address the reactive management of supply chain failure. We suggest that the recovery from JIT supply chain failure (reactive approach) can be usefully analyzed along the same two dimensions of location and unpredictability.

LOCATION AND UNPREDICTABILITY AS DIMENSIONS OF SUPPLY CHAIN FAILURE

While the risk of supply chain failure is influenced by many factors, we focus on two primary dimensions: location and unpredictability. To consider location first, supply chain failures may be classified as: internal to the organization, external to the firm but internal to the supply chain, or external to the supply chain. Internal organizational failures include strikes or chaos arising from internal reorganization. It is important to note that a focal firm's internal failures could affect other supply chain members (for the other members the risk is external to the firm but internal to supply chain situation). Conversely, suppliers might suffer performance loss due to their own internal reorganization or financial difficulties, but this could affect the focal firm and so is categorized as external to the firm but internal to the supply chain. External to supply chain failures are generally due to acts of God such as weather or natural disasters, or acts of human aggression such as terrorism, sabotage, or arson (though these could apply to the other two categories also).

Location as a dimension of supply chain failure is related with controllability to the extent that failures arising further from the firm are less controllable than the focal firm. The advantage of location over controllability is that if managers can understand the location of a given risk, then they are better equipped to find a proactive plan or reactive response based on the location. Highly uncontrollable risks have the implication of managerial impotence. However, as we argue below, risks in distant locations encourage managers to think of mitigation actions matched with the location.

Our second dimension, unpredictability, captures the extent to which the probabilities of a failure and its impacts are ambiguous. This extends from traditional notions of risk (where probabilities and variables are known) and uncertainty (where variables are known, but probabilities are not), to an extreme form of unpredictability where neither the variables nor probabilities associated with supply chain failures are known (Hall & Vredenburg, 2005). Thus highly predictable failures can be understood with traditional risk measurement and management techniques, whereas highly unpredictable failures can usually only be identified after the fact.

The location of supply chain failure is often correlated with unpredictability of occurrence (or the unpredictability of recovering from a failure), since in general, the nearer the failure is to the focal organization, the more information the focal firm may have of the variables or probabilities of failure. Usually, an organization has little visibility of external failures even though it still has to deal with the failure. Sometimes, there may be an indication that the failure will occur such as in the case of an impending hurricane, but at other times there may be no warning. However, even some potential failures internal to the firm are unpredictable, and other external failures may be predictable. Therefore our framework maps location against unpredictability in an orthogonal two-dimensional space, including the entire conceptual set of failures from internal to external and from high predictability to low.

Examples of external failures which have high unpredictability include natural disasters, which can have very far-ranging effects, like floods and earthquakes. In these instances, an entire geographic locale is affected, usually including transportation arteries and local suppliers. Major parts of the global supply chain can be affected for all companies, whether JIT or not, such as with the 1995 earthquake in Kobe, Japan (Forman, Williams, & Sapsford, 1995), the ice storm and resulting power outage of 1998 that produced chaotic conditions in eastern Canada (Chipello, 1998), the 9/11 terrorist attack (Ip, 2001), and the SARS epidemic in Asia (Young, 2003).

Supply chain failure internal to the chain can arise due to actions taken or occurring within the supply chain. Consequently, for the most part they have at least some predictability and can be prevented by better supply chain practices. However, when the supply chain fails due to a strike at the logistics provider, for example, the effect can often be widespread. In the United States, the United Parcel Service (UPS) strike greatly affected its customers, especially those who used UPS as their sole "rush goods" transporter. During the strike, because UPS handled such a large portion of the U.S. market (63% of all rapid deliveries and 80% of all ground deliveries), other companies like Federal Express and the U.S. Postal Service were not able to pick up all the slack. The competition also placed a number of restrictions on customers due to increased volume (Coleman & Jennings, 1998). Nonetheless, since everyone in the U.S. was dealing with the impact of the strike, customers had to be more understanding. Another example of a high-impact strike is when the major trade unions strike, such as the 2002 longshoremen strike on the U.S. West Coast (Cavinato, 2004).

Examples of predictable failures within the firm would be reorganization, including mergers and acquisitions, plant expansions, major supply chain software installations, and the like. When Union Pacific acquired Southern Pacific Rail Corporation, poor integration of the scheduling systems resulted in more than 10,000 rail cars a day stalled due to a shortage of locomotives, crew members, and track space. Union Pacific's customers, whether JIT or not, had to work around the supply chain failure (WSJ, 1997). Problems with an Enterprise Resource System (ERP) software installation resulted in shipment delays and incomplete order shipments at the Hershey Company (Stedman, 1999). While the company kept producing, the software implementation glitches resulted in chocolate piling up in warehouses instead of being shipped.

A less predictable failure within the supply chain would be if a supplier goes bankrupt or encounters financial difficulties, which can result in the work being stopped quickly. This can be a particularly serious failure, since there is a focus on single sourcing and small lot deliveries in JIT. Land Rover in the UK faced this difficulty when its only chassis supplier UPF-Thomson faced financial difficulties in 2001 (Meczes, 2004).

Sometimes, what starts as an internal failure can have far-ranging effects. Natural disasters can impact locally, as when a fire guts a building, though the impact may be significant when that building houses the sole supply for another organization, as in the case of a lightning-bolt-based fire at a Philips semiconductor plant that supplied Nokia and Ericsson (Latour, 2001) and at Aisin, a supplier of Toyota (Reitman, 1997).

Thus location and unpredictability of failure appear to be dimensions that warrant investigation. In the following sections we elaborate on the strategic issues in the proactive and reactive management of supply chain failure in JIT systems. As mentioned earlier it is hoped that this discussion will lead to future empirical research into this topic, leading to more specific management suggestions.

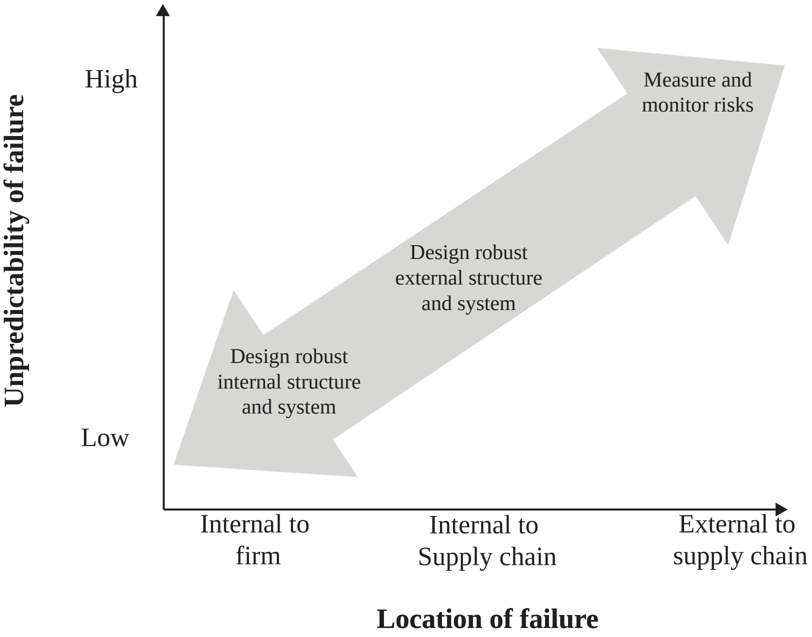
PROACTIVE MANAGEMENT OF SUPPLY CHAIN FAILURE

How can firms anticipate, avoid, or minimize supply chain failure before it occurs? In Figure 1 we map proactive risk mitigation strategies in our location/unpredictability framework (see Kelindorfer & Saad, 2004; Chopra & Sodhi, 2004; Lee, 2004; Johnson, 2001; Sinha et al., 2001). Based on examples of strategies and tactics that firms have adopted, and suggestions of strategies from the literature, we derive three main proactive options for firms along the shaded arrow depending on the location and unpredictability of the failure. These range from: (1) designing a robust internal structure and system, through (2) designing a robust external structure and system, to (3) measuring and monitoring risks in the external environment.

Robust Internal Structures and Systems

To manage highly predictable (i.e., low unpredictability) and internal potential failures, firms *design robust internal structures and systems.*

Figure 1. Proactive management of supply chain failure



For example, when companies believe that a supply chain failure may be coming, they may have a policy of stockpiling parts; that is, they implement failure anticipation inventory (Chopra & Sodhi, 2004; Sheffi & Rice, 2005). When GM speculated that its unions might go on strike, it tried to prevent supply chain failure; it stockpiled in advance, had contingency plans, and maintained backup data from the suppliers on the components of their products (Becker, 1998).

Another aspect of internal system design is business continuity planning (Zsidisin, Ragatz, & Melnyk, 2005; Zsidisin, Melnyk, & Ragatz, 2005; Sinha et al., 2004; Kleindorfer & Saad, 2004; Chopra & Sodhi, 2004). Steps such as risk analysis, contingency plans, logic charts and tabletop exercises, and failure modes and effect analysis (FMEA) would be useful in planning to deal with supply chain failure. This type of system planning becomes even more important when the company knows that the probability of a failure occurring may be higher than usual. For example, locations that suffer snowstorms, hurricanes, and the like with known probabilities can plan for disaster recovery within certain tolerances. Internally, if a strike is expected or if a labor contract is coming up for renewal, the company can choose to make "just in case" plans.

Lee (2004) emphasizes the great importance of agility, adaptability, and alignment in building robust supply chains (he calls it the Triple-A supply chain). Honda is a leader in flexible assembly plants, producing more than one model on the same line, and the same model at more than one plant. The Honda plant in Ontario, Canada, can build the Odyssey van and two types of SUVs on the same assembly line, while the Honda plant in Alabama can also produce the Odyssey (Keenan, 2003). While this increases Honda's flexibility from a competitive viewpoint, it also protects against supply chain failures. In case of a supply chain failure in Ontario, production at Alabama could be ramped up. Similarly Toyota is following a strategy of spreading out the location of its plants in North America to reduce what it teams as "geographic risk" (Shirouzu, 2005).

Another strategy is to minimize variability, that is, increase the ability to manage the process consistently. An example of variability would be the breakdown in machinery that might delay a shipment. Variance reduction and process improvement allow the organization to become better at supply chain management, which can result in fewer supply chain failures. If waste and variability can be removed (the JIT philosophy), the chain becomes more robust and it becomes easier to prevent problems from occurring. For example, the JIT practice of small batch sizes and reduced lead times helps reduce variability, or risk, in supply (Lee, Padmanabhan, & Whang, 1997). This could help avoid spikes in the supply chain that often creates a domino effect leading to supply chain failure.

Reducing the size of the product line through rationalization and the use of modularity will help duplicate production capacity (Kleindorfer & Saad, 2004; Chopra & Sodhi, 2004). This will allow production shifts in the case of supply chain failures. For instance, in 1999 Unilever made plans to trim away 1,000 of its 1,600 brands to focus on global/regional brands instead of local/national brands. The primary focus would become 400 brands that account for almost 90% of its annual revenue (Beck, 1999). Part of the rationale was to simplify the supply chain, which should make it more robust. When there are fewer products, it is also easier to duplicate production. Producing the same product at multiple locations allows the company to shift production when the supply chain fails at one facility. Even if a product is not duplicated, standardized components (modular design) and processes make it easier to locate an alternate source when the chain fails, as compared to totally customized components. An auto manufacturer was caught short recently because it failed to do this. It had a single supplier for rubber radiator gaskets that used unique machinery to produce these gaskets. When a fire destroyed the gasket supplier's machines, the only option left was to remanufacture the machines with much cost and time delay, as no alternative supplier could be found due to the uniqueness of the machines (Martha & Subbakrishna, 2002). In contrast, Toyota made use of the Aisin fire to improve its system by launching a project to increase parts standardization. In the case of the Philips fire, among its customers, Nokia was able to recover more quickly since it could find alternate sources of supply because its phone was more modularly designed than that of another customer, Ericsson (Tang, 2006).

Firms can also design their internal systems to manage product design and product portfolio for supply chain robustness. Innovative product manufacturers often use flexibility or postponement to deal with rapid changes in demand (Lee, 2004). Dell is able to circumvent the negative effects of components partially, by offering promotions and price discounts for other products for which components are available. Thus operations continue as normally as possible and the standardized modular components are being used rather than being left to accumulate dust and cost in inventory.

Other aspects of internal system design can include analyzing risk early in the product lifecycle. Teradyne Inc. incorporates supply chain analysis at the product design stage (Atkinson, 2003). The company tries to identify potential failures early in product design. The goal is to create a product sourcing plan that becomes a roadmap that anticipates and generates mitigation plans for every risk identified. Risks could relate to technology, suppliers, and parts. Naturally, suppliers should be involved in the product design stage to maximize the flexibility in the design for supply chain robustness (i.e., *external structure and system,* which is discussed later).

Designing a robust internal system can be helped by a formalized process (Hauser, 2003). Companies can seek to optimize supply chain performance by analyzing supply chain risk and making sound business decisions based on this analysis. This helps companies identify, quantify, and prioritize risks (sometimes hidden) in their supply chain and take proactive action to mitigate these risks. Hauser's model involves the following steps: (1) identifying risks, (2) understanding which risks can lead to significant supply chain disruption, (3) quantifying the economic impact, (4) determining the organization's desired risk profile, (5) conducting simulations and identifying key performance measures, (6) developing risk mitigation initiatives along with timing and sequences, and (7) measuring and monitoring performance. A similar process is used in business continuity planning (Barnes, 2001; Zsidisin, Ragatz, & Melnyk, 2005; Zsidisin, Melnyk, & Ragatz, 2005). A utility in the Midwestern United States was able to recover from the effects of a very major storm much better than other utilities in the same area because it had a plan in place that outlined what suppliers were to do in the event of a storm. While other utilities struggled to get power back to customers within four weeks, this utility was able to get power back to all its customers within two weeks. Other strategies to prevent supply chain failure could involve carrying critical parts at strategic locations (Atkinson, 2003; Aichlmayr, 2001).

Robust External Structures and Systems

The best defense when risk of failure is outside the firm but in the supply chain, and the risk is fairly predictable, is to *design robust external structures and systems* (Johnson, 2001; Kleindorfer & Saad, 2004; Chopra & Sodhi, 2004). This might include alternate sources of supply and distribution. A comparison of Japanese and American auto manufacturers in 1990 showed that while Japanese companies in Japan had about a third of the suppliers per assembly plant compared to their American counterparts, they only had 12% of their parts single-sourced compared to 69% for the Americans (Womack, Jones, & Roos, 1990, p. 157). This is confirmed by a study by Shin, Collier, and Wilson (2001) that found that dual or multiple sourcing was common. Increased globalization in the logistics industry and information technology is making it more feasible to find alternate sources of supply; not only are there more logistics providers, these providers are also global. This increases the chances of locating a supplier worldwide who is able to supply the affected facility.

Craighead et al. (2007) discuss the effect of supply chain density, supply chain complexity, and node criticality on the possibility of disruptions. Thus when one designs the supply chain structure, these factors must be analyzed in order to come up with a resilient design. Sinha et al. (2004) and Tang (2006) address external supply chain structure from a risk perspective.

Another example of a robust structure is the use of collaborative planning, forecasting, and replenishment (CPFR), which these days involves supply chain management (SCM) software and can help avoid problems (Tang, 2006). Greater visibility in the supply chain can be a successful mechanism to prevent disruptions (Christopher & Lee, 2001). If a supplier or one of its partners goes through a merger, acquisition, plant expansion, or software installation, operational planning with the supplier is critical. Texas Instruments uses CPFR to manage items on a JIT basis (Roberts, 2004). If disruptions do occur, real-time information available in SCM software also allows quick what-if analysis. This will help the organization make alternate plans to combat the disruption, whether it is alternate suppliers, routes, or logistics providers. Technologies like Internet marketplaces allow for quick identification of alternate sources of supply, while technologies such as Geographical Positioning Systems (GPSs) and Radio Frequency Identification (RFID) will allow companies to monitor the location of inventory within the supply chain, an important requirement in a JIT system where there is no excess inventory.

It is important to select supply chain partners carefully and strategically when structuring the supply chain based on their capability (Johnson, 2001). The partners in the supply chain, whether suppliers or customers, will have an impact on the chain. When their part of the chain fails, the whole supply chain is affected. Thus, the primary selection criteria should be their capability to maintain supply and their ability to respond in case of supply chain failure. For instance, it is important to examine a potential supplier's financial viability. In addition their plans in case of supply chain disruption should be examined. The example of the utility in the Midwest is a good illustration of this. When power fails, manufacturing will be significantly affected. Thus even the capability of utility partners within the supply chain is important.

Measurement and Monitoring

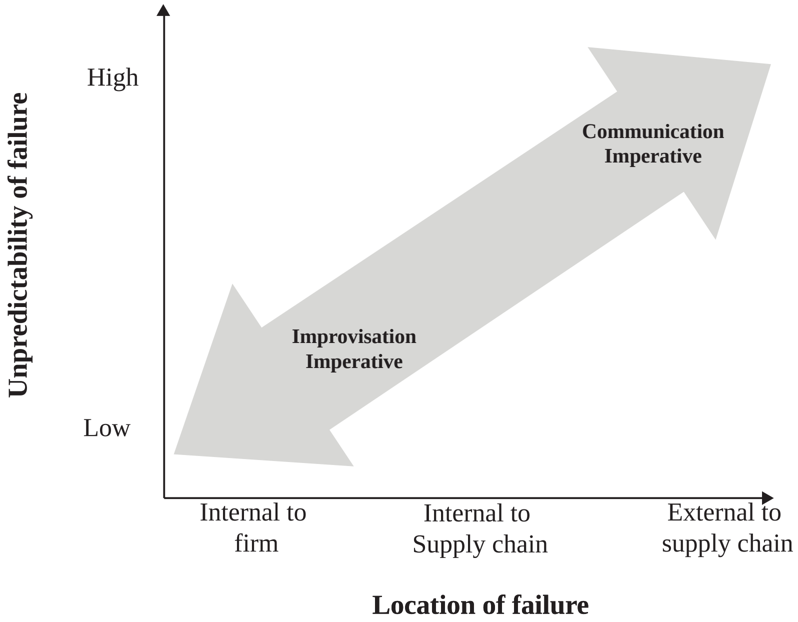
Prescription from the literature is weakest on how to deal with highly unpredictable events, especially those events external to the supply chain. Perhaps the best solution for highly unpredictable failures is consistent *measurement and monitoring.* Authors such as Hauser (2001), Zsidisin, Ellram, Cater, and Cavinato (2004), and Sinha (2004) include monitoring as part of their risk management process. In highly unpredictable situations this takes on added importance since it is difficult to plan ahead for something that is not known. Such monitoring can include early warning systems to discover internal system operations that exceed normal planning parameters (for internal to the firm); screening and regularly monitoring current suppliers for possible supply chain risks (for external to the firm, but internal to the supply chain situations); and scanning the external environment possibly through the use of scenario analysis (for external to the supply chain situations). The most recent literature in this area has begun to develop prescriptions on how to manage highly unpredictable failures (e.g., Rice & Caniato, 2003; Zsidisin, Ragatz, & Melnyk, 2005; Zsidisin, Melnyk, & Ragatz, 2005; Sinha et al., 2004; Craighead et al., 2007). The emphasis in these prescriptions is on upfront planning and monitoring so that the firm is in a good position to improvise if the unpredictable does occur. For example, one company seeing the potential for disruption in the supply chain leased additional transportation equipment, just in case (Craighead et al., 2007). While the inability to predict or take proactive action may be frustrating, it is important to note that highly unpredictable failures such as weather, acts of war, and other natural causes are likely to be more widespread with wide-ranging effects. So partners in the supply chain as well as customers themselves may be affected and are more likely to be understanding. In this situation the focus moves to reactive options in the post-failure stage outlined below, where it is important to be able to respond quickly to restore the supply chain.

Planning and buffering can be useful in managing failure. Though it is easier to buffer when the unpredictability is low, it has been used in highly unpredictable situations if the situation warrants it. During the Y2K warnings, the Cap Gemini Group commissioned a survey; it found that about 40% of the U.S. companies surveyed planned to stockpile inventory. Xerox Corp. built up a month's supply of raw materials (about four times the usual amount) and made sure suppliers were Y2K compliant (Aeppel, 1999). Similarly, when Toyota expects major demand changes within the year, it knows that its supply chain needs to be more responsive than usual. It sets the load of the machine at half of its future capacity; each worker operates several machines. This gives the capacity flexibility and buffer.

REACTIVE MANAGEMENT OF SUPPLY CHAIN FAILURE

What can companies do in the immediate aftermath of the failure to mitigate the damage? We suggest that it should vary according to the location and unpredictability of the recovery from failure (see Figure 2). The two core strategies

Figure 2. Reactive management of supply chain failure



suggested are communication and improvisation. Companies can also use a combination of these two core strategies.

The appropriateness of each strategy depends on the location of the failure. In Figure 2 as the location of the failure moves closer to being internal to the supply chain and unpredictability is lower, customers may feel that the failure could have been predicted and so be less forgiving. Thus they would expect the company experiencing the failure to act quickly to fix the problem (an 'improvisation imperative'). On the other hand for failures that are more external to supply chain and are more unpredictable, customers would be more willing to accept slower improvisation, but will expect communication on progress toward normalization (a 'communication imperative').

Consider two examples of internal failure discussed earlier. In the case of failure due to new software implementation, customers might expect that those problems were predictable (as there are many cases of firms experiencing this type of disruption). So they expect the company to have done some proactive planning to prevent such failures and to have recovery plans. In this situation, firms need to improvise quickly to fix the software problem. On the other hand if the failure was due to a factory fire resulting from a freak lightning strike, customers may be more forgiving and be satisfied with immediate communication and later improvisation.

The Communication Imperative

A example of the *communication* imperative situation due to freak events was experienced by Mitel Corp. (a semiconductor manufacturer) in 1998 during the ice storm. Mitel had to rent generators to produce electricity; even so, it could not recover lost time, as it was a 24-hour-a-day operation. So, Mitel communicated with its customers daily on the telephone to update them on the situation, and rescheduled production and shipment carefully to satisfy their customers as much as possible (Chipello, 1998). Kleindorfer and Saad (2004) and Craighead et al. (2007) also emphasize communication and information sharing in these circumstances.

Communicating with downstream customers helps alleviate the customer's anxieties, and they may be more likely to be willing to accept delays. If there is no communication, then their supply chain could also be severely disrupted, giving rise to strained relationships with their customers. Customers understand that supply chains do not always run smoothly and thus are going to be more forgiving if they are kept informed rather than if they are left in the dark. This communication strategy is particularly effective when the failure has its origins external to the supply chain. Customers may be more understanding if the whole system is down due to events external to the supply chain such as a flood, earthquake, or Teamsters Union strike, since many companies in the industry would be affected.

The Improvisation Imperative

As mentioned, when the failure is more predictable, the core strategy is to *improvise*. This relates to the business continuity planning (BCP) process discussed in Zsidisin, Ragatz, and Melnyk as well as Zsidisin, Melnyk, and Ragatz (2005, 2005). Sometimes companies will find room for additional capacity through improvement within the current system (*internal improvisation*). Tri-City Heat Treat Co. is a tier-two automobile supplier of heat-treated wheel nuts. To satisfy its customers' needs, it agreed to increase production, but the ordered equipment became delayed. Tri-City did its best to cope; besides asking customers with less pressing orders to wait, it worked round the clock to generate ideas to increase capacity. It used process improvement to eliminate gaps in a production line, turning the batch process into a continuous process (Petzinger, 1995). Similarly, Nishin Kogyo, a minor supplier of valves to Toyota, found a way to increase its efficiency permanently by 30% during the Toyota-Aisin crisis (Reitman, 1997).

Alternatively, companies can increase capacity by increasing labor hours (a type of *internal improvisation*). Many JIT plants tend to have excess capacity (Knod & Schonberger, 2001; Korgoankar, 1992), which allows time for activities such as maintenance, process improvement, and employee training. So if a crisis hits, it is possible to use this as a temporary alternate source to make the required parts or to increase production after the failure is rectified. This can be done by using a third shift, by working overtime, or by hiring temporary workers.

Another option to improvise internally is to not waste existing capacity. Such improvisation might include producing incomplete units. For example, when Johnson Controls went through a strike, it produced seats with management and temporary workers to maintain production. Multifunctional workers also help manage supply chain failure since production may be shifted to other products when one product's supply chain has failed. Demand shifts from one model to another can be influenced through the use of promotions and price incentives, as was done by Dell during a parts shortage (Martha & Subbakrishna, 2002).

Alternately a firm can *improvise externally* around the failure. One way to do this is to find an alternate source of supply and delivery. Although this may be more costly than the normal source, it still can be less expensive than the chain not functioning. This may include shifting sourcing locations, finding alternate routes, and using alternate modes of transportation (Aichlmayer, 2001). Naturally, this would have to involve the cooperation of the logistics provider. After the Kobe earthquake, some companies considered altering their supply routes. Nissan Motor Co. and others investigated costly new alternate routes to avoid supply bottlenecks. Seven-Eleven Japan Co. considered using helicopters to supply convenience stores in the region (Shirouzu, Williams, Sapsford, & Reitman, 1995). If the failure is likely to delay the shipment enough that it will miss a crucial deadline, one may have to find faster alternatives. For example, when a shipment of Sony PlayStations being transported by sea got delayed at the Suez Canal, the company chartered Russian cargo aircraft in order to deliver to customers on time for the crucial Christmas season (Maitland, 2005).

EXTENSIONS AND CONCLUSION

In the past two decades many organizations have embraced JIT and faced challenges of operations protection during supply chain failure since there is little inventory buffer. We presented an organizing framework for some of the structural designs and mechanisms that companies have used to prevent supply chain failure, and to mitigate the effects when the supply chain has broken. We have illustrated that many successful strategies and tactics used by firms, together with several risk mitigation strategies from the literature, can be usefully mapped on a two-dimensional framework anchored on the location and unpredictability of the failure. Since companies plan to persist with JIT even with the possibility of supply chain failure, we hope that our framework will be useful in positioning risks of failure and mitigation options.

While we have initially separated proactive from reactive responses, these may be dynamically connected over time. Firms may learn based on reactive experience. Gulliver (1987) discusses British Petroleum's appraisal of the management of the completed projects so that the lessons can be applied to future projects. The same principle could be applied in the case of supply chain failure. Through reactive improvisation, firms could learn which types of improvisation were effective, and use this to improve the proactive tactics in the future.

Similarly, it is important to note that the ability to reactively manage the supply chain failure is contingent on proactive planning. For example the ability to rely on suppliers to improvise depends on the relationships built within the supply chain. If the company's supply chain structure was not built on long-term strategic relationships, the ability to rely on suppliers to react may be diminished. Within the company, the ability to improvise may be improved by ensuring that employees are trained in process improvement and critical analysis skills, and if crisis planning is done up front.

Even after the fire at the Aisin plant, Toyota plans to keep its policy of single-source suppliers for certain parts despite the dependency, or strategic risk, to which this exposes them. However, the company is building fail-safe mechanisms such as improving the ability of the supplier to shift production to another site if a disaster strikes (Reitman, 1997). Hajime Ohba, general manager of the Toyota Supplier Support Center in Kentucky, publicly responded with Toyota's rationale for JIT after the fire. He said that a better solution is to keep the company's resources at a consistently low cost level, and then rely on the cooperative relationships in the supply network if anything does go wrong (Ohba, 1997). In fact JIT also helps maintain supply chain flexibility when deployed properly. Toyota believes that small lot production allows for flexibility to meet changes in demand, regardless of the cause. This flexibility develops the capability of the supplier to rapidly respond to any crisis (Ohba, 1997).

The evidence points to the fact that over the long term, the benefits of reduced waste and variability through JIT more than offset the disadvantages of being caught without inventory in the unlikely event of a supply chain failure. Accordingly, consultants such as Mercer Management Consulting still advise clients to carry on with JIT since it is estimated that in the auto industry alone, companies are saving $1 billion in carrying costs due to JIT policies (Aichlmayer, 2001). What is required is to make the appropriate adjustments for any unreliability in supply that cannot be avoided. Even from an insurance perspective, implementing JIT systems can have benefits. While some premiums may increase due to increased risks such as that of non-conformance in a supply contract and the increase in road accidents due to more frequent deliveries, the philosophy of focusing on perfection can reduce the premiums related to the risk of product liability and warranty claims (McGillivray, 2000). Also the lack of inventory means lower losses in the case of disasters such as fires.

Given the fact that JIT is likely to be a popular philosophy in the foreseeable future, it is important to provide guidance to organizations using JIT to manage the risk of failure in their supply chains effectively. The proposed framework should help companies manage the risk in JIT-based supply chains. We suggest that managing supply chain failure within JIT systems involves a two-pronged approach. Before the event, JIT involves making the production system as foolproof as possible and forming close relationships with capable suppliers. We have argued that a variety of structures and mechanisms can be used to mitigate the low-to-medium unpredictability events at the firm, supply chain, and external locations. However, some highly unpredictable events can occur despite a well-functioning JIT system. Before the event, firms can monitor and measure events in their internal system, supply chain, and external environment. After a failure occurs the options are more limited to a combination of improvisation and communication with the supply chain. In the ideal case, a well-designed JIT supply chain can use its high visibility, communication, and group problem-solving approach to cooperate to quickly find solutions to supply chain failure. In this article we have illustrated the framework using company experiences and previous supply chain risk research. Further research could attempt empirical validation of the proposed framework.

In the meantime, we hope that our strategic framework encourages managers to consider the location and unpredictability of supply chain failure as they devise strategies to cope with this crucial decision arena in JIT systems. We also hope that researchers will explore the framework using empirical research to validate it, and provide specific guidance to managers regarding the management of location and unpredictability issues in JIT supply chain failure.

Chapter 7.7

Towards Stable Model Bases for Causal Strategic Decision Support Systems

Christian Hillbrand
University of Liechtenstein, Liechtenstein

ABSTRACT

Most decision support systems (DSS) based on causal models fail to analyze the empirical validity of the underlying cause-and-effect hypotheses, but instead concentrate on numerous analysis techniques within the method base. However, the soundness of these cause-and-effect-relations as well as the knowledge of the approximate shape of the functional dependencies underlying these associations turns out to be the biggest issue for the quality of the results of decision supporting procedures. Therefore this article strives towards an approach to prove the causality of nomologic cause-and-effect-hypotheses by empirical evidence as a prerequisite for the approximation of the mostly unknown causal functions. Since the latter very often show non-linear influences, it is necessary to employ universal function approximators for this purpose: consequently the proposed approach adopts artificial neural networks (ANN) as an inductive method to learn a calculational model of cause-and-effect functions from empirical time series.

INTRODUCTION

One critical challenge in planning and implementing corporate strategies is deriving appropriate decisions and measures from an uncertain and diffuse informational background. Therefore, a crucial requirement for any application supporting this type of decisions is necessary to tackle at least two elementary issues. First, the decision maker has to be supplied with appropriate data about the underlying relevant key figures and business drivers as well as environmental information related to the market or competitors. This first function of data support as outlined before is the main focus of so-called management information systems (MIS). These tools usually employ powerful techniques to gather the necessary figures as a basis for strategic planning efforts.

Second, this raw data has to be arranged within decision models in order to reduce the variety and complexity coming with it. One characteristic of a complex strategic decision that is it is influenced by an immense set of business variables which have to be analyzed in this context. As a consequence, data supporting tools do not provide appropriate aids for this type of entrepreneurial function. It is to reduce the complexity emerging from this amount of data which becomes the principal task of decision support systems (DSS). Hence it can be observed that the architecture of any arbitrary DSS is highly dependent of the managerial approach it is designed to support. It necessarily incorporates the notion of a mental model underlying the respective decision theory as well as techniques to derive decisions from these assumptions. Sprague & Carlson (1982) specify these two core components of a DSS as model base and method base, respectively. The former defines the structure of the decision model, which arranges the raw data provided by a data support component, whereas the latter encompasses decision theoretic methods specifically designed to operate on the given decision model. According to the type of the model base, analytic techniques, like optimization as well as statistical methods or stochastic approaches, like simulation, are used to draw decisions from the raw data organized in the decision model.

A considerable number of recent approaches within the domain of strategic decision making propose to organize business indicators in the form of causal models. The main task of these models is to visualize the cause-and-effect relations which the decision maker assumes to exist between the given variables and/or goals (Hillbrand & Karagiannis, 2002a).

One well-known example for this type of strategic decision methodologies is the balanced scorecard approach (Kaplan & Norton, 1992): The main idea behind this concept is that short-term goals of financial nature like the improvement of profitability measures are usually influenced by long-term objectives of non-financial type. Therefore Kaplan and Norton (1992) postulate a balanced selection of strategic goals out of (at least) four distinct dimensions: financial-, customer-, process- and, development-specific perspectives should be included in the strategic process. Between the goals and measures of these dimensions the decision maker has to make hypotheses about the underlying cause-and-effect relations. Subsequently they can be used to disaggregate main strategic goals into tactical objectives and measures.

Similar principles are encompassed by the French tableau de board methodology (Mendoza et al., 2002) as well as by cybernetic management principles as proposed for example by Vester (1988) in his biocybernetic approach, whose main concepts are reused in the St. Gallen management model (Gomez & Probst, 1999; Schwaninger, 2001; Spickers, 2003).

Although these managerial approaches for strategic decision support provide some practical approaches for the reduction of complexity coming with a sense-making process the implementations of these ideas in the form of DSS are rather weak. It can be observed that software tools supporting such approaches are focused on techniques out of the method base in order to draw conclusions from a hypothetically assumed cause-and-effect model as outlined before (Hillbrand & Karagiannis, 2002a, p. 368). Therefore most DSS of this type provide simulation techniques as well as how-to-achieve- and what-if-analyses. However, the model base usually remains unproven with respect to the empirical evidence of the hypothetically assumed cause-and-effect relations between the business variables. As a logical consequence, the overall quality of the decision support provided by such a system is directly related to the completeness and soundness of the underlying causal hypotheses. Moreover, these techniques are not able to provide quantitative forecasts for future impacts of an analyzed strategic scenario. The reason for this lack of approaches for causal proof and quantitative techniques for managerial cause-and-effect models can be traced back to a proposition of Kaplan and Norton (1996): In their book, they recommend "correlational studies" in order to infer causal knowledge from time series of business variables in the course of double loop learning. This postulate caused an intense discussion about the admissibility of such techniques with respect to the purpose as mentioned before: As for example Weber and Schäffer (2000) conjecture, the "basic problem of an analytic derivation of the `correct` cause-and-effect relations cannot be solved in this way" (p. 8). Horvàth & Partner (2001) come to a similar conclusion:

> *Cause-and-effect relations [...] do not describe arithmetical logics for example in the form of the known ROI-scheme [...]. The goals and for this reason also the measures are causally associated in a logical but not in a calculative sense. If the value of one goal changes, the impacts on another variable of the same system cannot be predicted exactly. (p. 44f.)*

Other authors only refer to the need for further research in this area (Probst, 2001, p. 81). However, this discussion and its limitation to the construct of correlation lead to a rather dogmatic conception that managerial cause-and-effect models must not be evaluated in a quantitative way, which is typical for the relevant managerial literature. According to Schneiderman (1999) this is one of the major reasons for the failure of balanced scorecard projects:

> *We all know that correlation does not mean causality. But try explaining these data to someone who has been only reluctantly convinced that the non-financial scorecard metrics are a leading indicator of future financial success.*(p. 10)

However, if we abandon the restriction to correlation as a concept for the proof of causality and a measure of association, it seems to be possible to infer further causal knowledge from empirical data and therefore improve the quality of the model base significantly. Hence, this article proposes an approach to automatically prove managerial cause-and-effect relations and to approximate the unknown causal function underlying these associations.

The rest of the article is organized as follows: section 2 provides a brief overview of causality concepts as proposed within the appropriate philosophic literature. Consequently, specific causality criteria are defined on this basis. This definition is employed in section 3 in order to establish an approach for the automated proof of nomothetic cause-and-effect hypotheses. Since every single of these proven causal relations are characterized by an arbitrary unknown cause-and-effect function, this function has to be approximated in order to build a quantitative model base for DSSs. Therefore, this article discusses appropriate approximation techniques in section 4 and proposes a nonparametric approach for the universal approximation of arbitrary cause-and-effect functions by the means of ANNs. This article is concluded by the presentation of experimental results in section 5.

CAUSALITY CONCEPTS

Since one main objective of this article is to provide an approach to proof hypothetically assumed cause-and-effect relations between managerial variables, it is necessary to define necessary and sufficient conditions for the concept of causality in this environment. As it has been outlined in the introduction, the mere correlation of two variables seems to be insufficient for this purpose. Moreover, causality per se cannot be observed or tested by objective means. According to Kant, it is a synthetic judgment a priori (Schnell et al., 1999,

p. 56). Causality must therefore be regarded as an assumption about the connection between cause and effect made by the human mind and based on a variety of experiences rather than some kind of natural phenomenon which can be observed in an objective manner.

The Notion of Causality within the Philosophy of Science

As a consequence of the lack of observability of causal relations, there has been a broad scientific dispute within the philosophy of science about the concept of causality. The beginning of this discussion can be traced back to the Humean regularity theory (Sondhauss, 1998). This notion of causality is founded mainly on the two concepts of contiguity and temporal succession (Hume, 1748), that is, two events always have to occur within temporal and or spacial limits and the effect *must* follow the cause in time. Although this theory does not seem to be fully sufficient to explain the concept of causality[1], it introduces an important property that is part of almost every causality theory. Causal relations are usually regarded as asymmetric associations of two events.

However, there are (at least) two objections regarding this basic theory of causation.

Firstly, representatives of probabilistic causality theories bring forward the argument that the deterministic association between cause and effect as an integral part of the regulatory theory represents a too rigorous characteristic. According to their notion, the occurrence of a cause only raises the probability of an effect but does not necessarily imply it.

Secondly, the Humean regulatory theory is criticized because of temporal precedence being the only characteristic to establish the necessary asymmetric property of a causal relation as for example Brady (2002) explains:

The Humean theory does even less well with the asymmetrical feature of the causal relationship because it provides no way to determine asymmetry except temporal precedence. [...] Causes not only typically precede their effects, but they also can be used to explain effects or to manipulate effects while effects cannot be used to explain causes or to manipulate them. (p. 18)

Approaches to overcome these shortcomings lead to the notion of causality as it is proposed by interventionistic theories. The central ideas of these theories are driven by human action as the definition of Gasking (1955) shows:

The notion of causation is essentially connected with our manipulative techniques for producing results. (p. 483)

According to this perception, a causal relation can only be verified in experimental settings where a response can be observed after a cause has been manipulated and the system can be isolated from other (unknown) influences. This is necessary because there exists situations where the essential for defining causation, and it is mere observation of cause and effect misleadingly suggest causality between two events where there is none. For example, the influence of an exogenous third variable U on two endogenous variables C and E can lead to correlation as well as to a temporal precedence relation between C and E although they are not causing each other. This example demonstrates the inability of mere temporal precedence to explain the asymmetry in causal relations quite graphically.

The restriction of interventionistic approaches to analyze the concept of causality only experimentally is the main reason for their failure to explain many real-life problems as it is also the case for managerial cause-and-effect relations: In an enterprise there is hardly any situation where an experiment-like situation can be created because the trial-and-error manner of these settings usually would inflict losses for the business and the response time of basic cause-and-effect relations can be rather long. As a consequence it seems to be too costly to prove causality in this way.

A Synthetic Concept of Causality between Business Variables

Applied to managerial cause-and-effect relations, an appropriate concept of causality must restrict itself to observational studies in terms of empirical data as a consequence. Therefore, we can summarize the previously mentioned disquisition of definitions for causality as follows: A cause should provide information which can be used to (partly) explain its effects. In case of linear cause-and-effect relations this property of informational redundancy is also known as correlation or covariance. However, as it has been shown in the introduction these concepts do not succeed to fully explain causality. According to Hume, there has to be a temporal precedence relation between a cause and its effects additionally to informational redundancy as for example Pearl and Verma (1991) state:

Temporal precedence is normally assumed essential for defining causation, an it is undoubtedly one of the most important clues that people use to distinguish causal from other types of associations.(p. 442)

Regardless of the ability of these two necessary properties to fully explain many causal relations there still remains the problem of an exogenous common cause to induce spurious associations between presumably causal variables. Therefore, the definition of causality has to be enhanced by the postulate to control for this type of association. This leads to a notion similar to the one of Suppes (1970):

X and Y must covary, X must precede Y, and other causes of Y must be controlled.

Based on these foundations the following definition of an appropriate concept of causality to analyze associations between managerial variables can be derived:

Theorem 1 (managerial causal relation): *A causal relation between variables of a managerial system exists if and only if there exist appropriate nomothetic (i.e., unproven) cause-and-effect hypotheses based on causal a priori knowledge where the following conditions are fulfilled:*

- The empirical observations of a potential cause provide informational redundancy regarding its potential effect.
- The variation within the time series of the potential cause must always precede the response of this variation within the time series of the potential effect.
- The three causality properties as defined above (causal a priori knowledge, informational redundancy and temporal precedence) must not originate from the influence of a known or unknown cause, common to the potential cause and the potential effect.

□

As seen in theorem 1, the underlying notion of causality follows the logic of logical empirism, which regards a hypothesis as true as long as it cannot be falsified. Therefore, it is the task of a causality proof to rule out non-causal associations according to the criteria from a given strategy model consisting of nomothetic cause-and-effect hypotheses. The next section develops an appropriate approach for the automated proof of causality.

AN EMPIRICAL VALIDATION APPROACH FOR CAUSAL STRATEGY MODELS

As the previous section provides a homogeneous notion of causality, it remains to identify an approach to apply this definition to the causal knowledge of an enterprise in order to distinguish between genuine and spurious cause-and-effect relations. The conceptual basis for the construction of proven causal models for strategic decision support is therefore represented by the necessary and sufficient properties of causality as previously defined.

Modeling Nomologic Cause-and-Effect Hypotheses

The starting point for this approach is the compilation of causal knowledge in the form of implicit mental models or corresponding data into an explicit model of nomologic cause-and-effect hypotheses. The latter are contained in a rudimentary cause-and-effect model which has to be given by strategic decision makers and represents the first necessary causal property of a priori knowledge.

One possible approach to model causal strategy maps has been proposed by Hillbrand and Karagiannis (2002b, p. 53). The meta-model of their modeling framework consists of indicators which can be of crisp or fuzzy type and two types of associations which connect a pair of indicators:

- *Defined influence relations represent causal associations between variables which can be fully explained by decision makers. Usually the target variable of this type of relation is some kind of synthetic ratio which has been axiomatically devised by a formula consisting of several input parameters. A well-established example for influence relations are profitability measures like ROI, ROCE, and so forth. As a consequence defined influences can only be modeled between crisp indicators where the values of the result variable can be fully explained by some algebraic function of input indicators.*
- *All remaining potentially causal associations between either crisp or fuzzy variables which do not fulfill both conditions for a defined influence relation are called undefined. For this type of relation it is not possible to assume causality a priori as in the preceding case. Rather, the decision makers are forced to rely on nomothetic cause-and-effect hypotheses. However, the empirical knowledge of past time-series enables managers to scrutinize the causal content of the interjacent potential cause-and-effect relation.*

Consequently, it is the focus of this section to provide appropriate methods in order to analyze the hypothetically defined model base of a strategic DSS with respect to its causal validity. This task of the proposed approach is to detect so-called α-errors[2] of nomothetic cause-and-effect hypotheses between variables. Therefore the starting point for the reconstruction of a proven causal model is a rather over defined rudimentary model as described above.

Identification of Temporally Lagged Informational Redundancy

The second necessary condition for causality—as defined in the previous section—is informational redundancy between a potential cause and its potential effect. As a consequence the time series of the dependent variable as the output of an unknown causal function associated with the respective relation must also reflect patterns or variations of independent time series. Very often these patterns are transformed by the underlying causal function and superposed by the influences of other exogenous or endogenous variables.

Therefore, they cannot always be detected a prima facie. If the causal function which transforms the values of a set of independent variables into the value of a dependent value is of linear type, the concept of correlation can be used as a measure for informational redundancy. In all other cases, one has to find other techniques to analyze whether two time series are informationally redundant or not. For the purpose of this approach it seems to be suitable to restrict to the linear case because the causality proof per se does not build the model base but is used to select variables for the following approximation of a nonlinear causal function. Therefore, it is not necessary to rule out all possibilities of α-errors because the ANNs—assigned to perform the causal approximation task—are supposed to detect the non existing influence of marginally spurious associations. The admissibility of this theory for different types of causal functions has been shown by Hillbrand (2003, pp. 299ff.).

When considering the third necessary condition for causality of temporal precedence of cause and effect, the inadequacy of the concept of correlation alone to prove cause-and-effect relations becomes obvious: The correlation of two time series would show that the variations of a independent and a dependent variable are similar and that they take place contemporaneously.

As this is mutually contradictory to the notion of causality as defined in the previous section, the concept of correlation has to be adopted to measure temporally lagged responses of the variation of an independent factor within the time series of the dependent variable. Therefore, cross-correlation $\rho_{X,Y}(\Delta t)$ implies a time lag (Δt) between a cause X and an effect Y in the following form:

$$\rho_{X,Y}(\Delta t) = \frac{\dfrac{\sum_{t=1}^{T}\left(y_t - \overline{Y}\right)\left(x_{t-\Delta t} - \overline{X}\right)}{T}}{\sigma_X \cdot \sigma_Y} \qquad (1)$$

Where y_t and x_t stand for the values of the variables Y and X at time t, $\overline{X}$ and $\overline{Y}$ stand for the average values and σ_X as well as σ_Y for the standard deviation of the respective time series. As it is evident from the previous expression, the upper part of the fraction is derived from the construct of covariance.

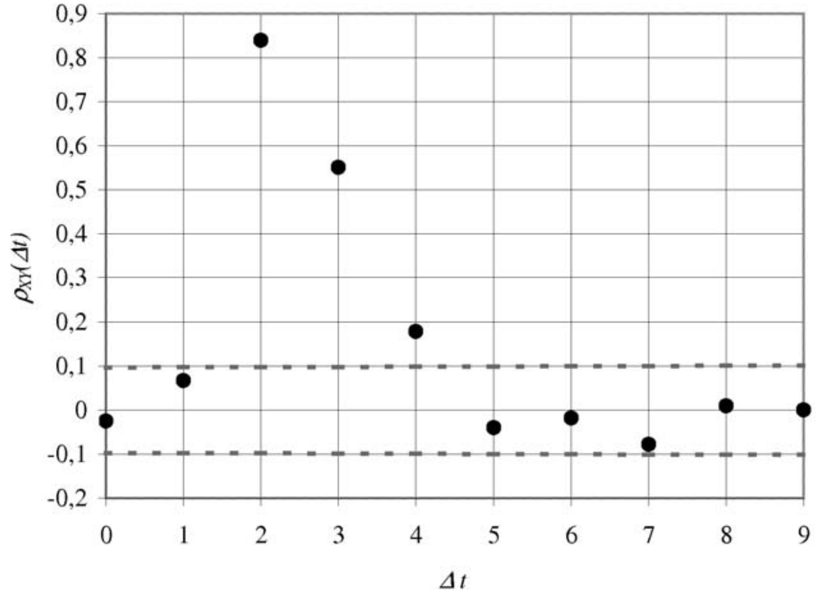
As a consequence, this approach employs this concept to identify the two causality conditions of informational redundancy and temporal precedence. By calculating the cross correlations for varying time lags it is possible to identify a window of impact between an independent and a dependent variable. This window of impact is characterized by a minimum time lag and a number of subsequent effects (i.e., the length of the window of impact). For this purpose it is necessary to identify the significance of a cross correlation at a given time lag. Therefore, this approach uses Bartlett's significance test (Bartlett, 1955) following the suggestions of the appropriate literature in this area (Levich & Rizzo, 1997; Makridakis & Wheelwright, 1978): The null hypothesis of this test is formed by the assumption that two given time series at a certain time lag are independent if their cross correlation shows a value of zero. This hypothesis has to be accepted if the cross correlation lies within the boundaries which are given by the standard deviation of the cross correlation. If it exceeds this critical value, the null hypothesis is rejected and it is said to be significant. Since the standard deviation of the cross correlation is usually not known a priori the critical test value is replaced by the following estimate (Bartlett, 1955):

$$\sigma_{\rho_{X,Y}(\Delta t)} = \frac{1}{\sqrt{n - |\Delta t|}} \qquad (2)$$

Where n stands for the number of samples in the time series of X and Y, respectively.

By increasing the time lag Δt by discrete steps beginning at a lag of zero time periods, it is possible to identify the minimum time lag by recording the first significant cross correlation between the time series.

Figure 1. Correlogram between two time series



This approach is illustrated in Figure 1 for the following synthetically generated time series:

$$x_t = \varepsilon_{U(0;\,1)}$$
$$y_t = 0.2y_{t-1} + 0.5x_{t-2} + 0.2x_{t-3}\ \varepsilon_{U(0;\,1)} \qquad (3)$$

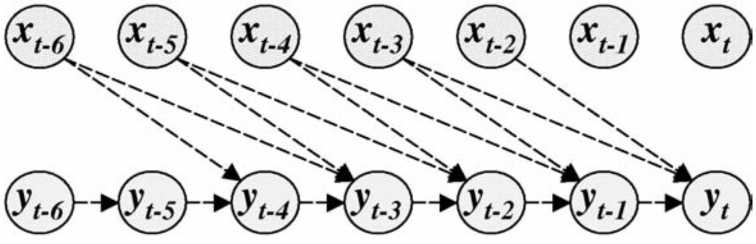
Where $\varepsilon_{U(0;\,1)}$ is a random variable, uniformly distributed between zero and one.

As it is obvious from the above equations, the time series y_t of the independent variable Y incorporates past values of the time series x_t with a time lag of two and three time periods, respectively. Therefore the correct window of impact is [2,3].

Figure 1 shows the cross correlations computed from the artificial time series x_t and y_t for the time lags $\Delta t = 0, ..., 9$ as well as the bandwidth of their standard deviation which lies between the dotted lines. The clear consequence which can be drawn from this correlogram is that the first significant correlation starting from zero occurs at a time lag of $\Delta t = 2$, which corresponds exactly to the generating function of y_t as stated above. Therefore, the minimum time lag for this potentially causal relation is $b = 2$ time periods. This means that the variation of the independent variable X is first repeated within the time series of the dependent variable Y after two time periods.

The first attempt to determine the appropriate length of the window of impact using the correlogram in Figure 1 yields time lags between $\Delta t = 2$ and $\Delta t = 4$ because the last significant cross correlation occurs with a time lag of four time periods. As this is not correct with respect to the generating function, one has to take the autocorrelation of the two variables into account. It can be shown that significant autocorrelation of the independent time series leads to the so-called echo effect (Hillbrand & Karagiannis, 2002b; p. 74), which describes the indirect effects of independent values prior to the window of impact through an autocorrelated dependent time series. In the example of Figure 1, this effect becomes evident when scrutinizing the generating function of the time series y_t. This function includes the term "… $0.2y_{t-1}$ …," which means that the actual value of the variable Y reflects also a fraction the preceding value y_{t-1}. As this in turn is influenced by the independent values x_{t-3} and x_{t-4} it becomes evident that the latter is reflected in y_t with the weight $0.2 \cdot 0.2 = 0.04$ (Figure 2). As the autocorrelation of the dependent variable can be regarded

Figure 2. Echo effect



as an infinite series, it can lead to putative random patterns for the echo effect.

Therefore, it is crucial for a correct identification of the impact window to eliminate any autocorrelation within the time series to be analyzed. This preprocessing of the time series is known as prewhitening in the appropriate literature (Makridakis & Wheelwright, 1978; pp. 382f.). As a prerequisite for this task, the order of autocorrelation for independent and dependent variables has to be determined by the use of the autocorrelation coefficient[3]. Thus this approach analyzes the autocorrelation coefficients for ascending orders which exceed the critical value of the Bartlett test (for details see above) and consequently are denoted as significant. This approach comes to reliable results for the analysis of independent time series. However, it does not perform well for result variables as a further disturbance effect can be observed in this context: Influences with a significant number of subsequent effects (i.e., the window of impact is larger than one time period) tend to induce an autocorrelation-like pattern in the dependent time series although there is no significant autocorrelation from the generating process of y_t. As a consequence, it seems to be necessary to identify the appropriate window of impact before analyzing the autocorrelation of the dependent time series. Therefore, a circular dilemma occurs because the autocorrelation of the dependent variable is a prerequisite for the prewhitening process, which is in turn necessary to avoid echo effects and to identify the appropriate size of the window of impact consequently.

Approaches for this dilemma include the solution of separated autoregressive generating processes for each time series, as well as iterative approximation techniques. The separated generating processes as mentioned previously are characterized by partial autocorrelation coefficients. The combination of partial autocorrelations of dependent and independent time series, as well as the cross correlation between the two of them, result in the specific cross-correlation pattern observable in the correlogram (Figure 1). Since the relevant literature knows solutions for this problem which are far from trivial, this article employs an approach which is based on an iterative approximation of an appropriate length for the window of impact:

1. Prewhitening of independent variables:
   a. Determine orders of significant autocorrelation within the time series of every independent variable X_t.
   b. For every order o of significant autocorrelation for every independent variable X_t determine the respective autoregression coefficient $\beta_{X,o}$.
   c. For every value $x_{i,t}$ of an autocorrelated independent variable X_t subtract past values of the same time series weighted by the appropriate autoregression coefficient in the following form: $x'_{i,t} = x_{i,t} - \sum_{\forall o} \left(\beta_{X_{i,o}} \cdot x_{i,t-o} \right)$.
2. Determine significant cross correlations between every prewhitened independent timeseries $x'_{i,t}$ and the dependent time series y_t for different time lags Δt.

3. Identify the windows of impact – determined by the minimum time lag b_i and the following effects s_i – from the the correlograms between every prewhitened independent variable X_i' and the dependent variable Y.
4. Determine the regression coefficients $\beta_{X'_{i,\Delta t}}$ between any independent variable X_i' and the dependent element Y for time lags Δt with a significant cross correlation.
5. Eliminate all impacts of independent variables on the dependent variable by subtracting the respective past values of the independent time series $x'_{i,t-\Delta t}$ weighted by the appropriate regression coefficient $\beta_{X'_{i,\Delta t}}$ according to the prewhitening procedure as described in step 1c.
6. The isolated dependent time series y_t^* resulting from the previous step is tested for significant autocorrelation.
    a. If no significant autocorrelation can be identified within the time series of y_t^*, the procedure terminates. Therefore the windows of impact for each independent variable X_i are given as determined in step 3.
    b. If the time series y_t^* is significantly autocorrelated, the raw time series y_t is prewhitened according to steps 1b and 1c. The procedure resumes with a new iteration at step 2 using the prewhitened dependent time series y_t'.

Having an appropriate algorithm to test the second and third necessary condition of causality (informational redundancy and temporal precedence) non-causal or spurious relations can be identified by the absence of an empirically significant window of impact.

Controlling for Third Variable Effects

The remaining potentially causal relations, which comply with the first three causality criteria, are subject to a further analysis of common causation by third variables. For this purpose Pearl and Verma (1991) propose an approach to distinguish spurious associations induced by a common cause from genuine causation:

Theorem 2 (Controlling for third variables): *One can assume a relation $X \rightarrow Y$ to be causal if and only if the time series of the potential effect Y incorporates not only patterns of its potential cause X but also those of the predecessors P (i.e., causes) of X in the cause-and-effect model. If X and Y as well as P and X are informationally redundant but P and Y are not, an unknown third variable U rather than a causal relation must be assumed to induce the informational redundancy between X and Y.*

□

As a consequence the patterns of P are reflected within the time series of X, but they are not passed on to Y due to the absence of a genuine cause-and-effect relation $X \rightarrow Y$.

A basic tool for the analysis of these assumptions within causal graphs is the concept of conditional independence: Two variables A and B are conditionally independent given a set of variables S_{AB} – written as $(A \perp B \mid S_{AB})$ – if A and B are informationally redundant but if the impacts of S_{AB} on B are eliminated, this property vanishes. Therefore S_{AB} is said to "block" the causal path between A and B.

Applying this concept to the previously mentioned theory, spurious associations between a potential cause X and a potential effect Y can be ruled out by the following observations:

- There exists a minimal set of blocking variables S_{PY} causing conditional independence between any predecessor P of X and the effect Y, denoted as $(P \perp Y \mid S_{PY})$.
- X is part of the set S_{PY}.

The theory to detect third variable effects as outlined in this paper is implemented by the

IC^4-Algorithm. For reasons of lucidity, this paper dispenses with a detailed discussion of these procedures but refers to the appropriate literature (Hillbrand, 2003, p. 198; Pearl & Verma, 1991).

Summarizing this approach, the mapping of nomothetic cause-and-effect hypotheses, by decision makers represents a prerequisite for their proof as well as the first causality criterion. The second and third condition for causality—informational redundancy and temporal sequence—are tested by analyzing the cross correlations between the prewhitened time series of the respective variables connected by a cause-and-effect hypothesis. To rule out a third variable inducing informational redundancy between two lagged variables, this analysis is completed by the application of the IC-Algorithm as outlined above. Only relations which pass all these tests satisfy the necessary causality conditions and are therefore said to be genuinely causal.

APPROXIMATION OF UNKNOWN CAUSAL FUNCTIONS

The proof of causality, as proposed in the previous section, is the main prerequisite for the approximation of the unknown causal function affecting the values of any arbitrary business variable within a cause-and-effect structure. This provides the necessary numeric properties for the causal model base of a DSS to run simulations as well as how-to-achieve or what-if analyses. One crucial issue of this task is that the form of these cause-and-effect functions cannot be assessed a priori. Therefore, three alternative approaches are to be considered in this context:

First, the base functions for the approximated associations have to be predetermined (e.g., linear, logarithmic, logistic, exponential, etc.). With this assumption, it is possible to approximate the unknown function by estimating the parameters of an appropriate regression model.

Second, a function can be locally approximated by developing an appropriate polynomial. This principle is used for the Taylor or Fourier series expansion. A disadvantage of these techniques is that their approximation is only accurate within local limits of the function.

Third, unknown functions can also be reconstructed without prior knowledge of their shape by so-called universal approximators (Tikk et al., 2001). Hence these techniques are able to learn a function from mere empirical observations without the need to narrow down some base function. This characteristic becomes increasingly important whenever the unknown function to be approximated is of nonlinear type. As it can be shown by numerous examples, microeconomic functions which usually underlie strategic reasoning are almost never of linear type (Hillbrand, 2003, pp. 201ff.). The reasons for this observation are manifold. Saturation as well as scale effects or resource limitations are only a few causes for the nonlinearity of relations between business variables. One well known example is the association between the market price and the customer demand for a certain product. Raising prices will not linearly result in an increasing demand. Rather it is likely that there is some maximum price level the customer is willing to pay, which therefore provides a limit for the demand. As an example Allen (1964) supposes demand functions to follow some S-shaped—also known as sigmoidal or logistic—pattern.

For these reasons it is essential to abandon all restrictions regarding a priori assumptions about the unknown function underlying a cause-and-effect relation. This postulate leads to the necessity to employ universal function approximators in order to identify the functional form of the causally proven associations. Therefore this approach studies the potential and limitations of artificial neural networks (ANNs) for universal causal function approximation. The theoretic foundations of this property of ANNs is the result of the endeavors to approximate an unknown mapping by the combination of known functions. The central theory in this area has been proposed by Kolmogorov (1957) who argued that any arbitrary unknown function *f* can be approximated by two nested known functions ϕ and ψ. This theory is usually regarded as the central concept for universal function approximation in the relevant literature (Tikk et al., 2001, p. 2):

Theorem 3 (Kolmogorov's superposition theorem): *For all $n \geq 2$, and for any continuous real function f of n variables on the domain [0, 1], $f: [0,1]^n \rightarrow \mathbb{R}$, there exist $n(2n+1)$ continuous, monotone increasing univariate functions on [0, 1], by which f can be reconstructed according to the following equation*

$$f\left(x_1, \ldots x_n\right) = \sum_{q=1}^{2n} \phi_q \left(\sum_{p=1}^{n} \psi_{pq}\left(x_p\right) \right) \square$$

Further enhancements of Kolmogorov's superposition theory are developed by several authors which lead to the notion of ANNs as universal function approximators (De Figueiredo, 1980; Hecht-Nielsen, 1987). Since the inner function of Kolmogorv's theorem can be highly nonsmooth it has to be weighted with a factor λ in order to use specific continuous functions (squashing functions) for this purpose. Therefore the resulting function can be represented by a multi-layer perceptron (MLP).

Separating Causal Function Kernels from Causal Strategy Models

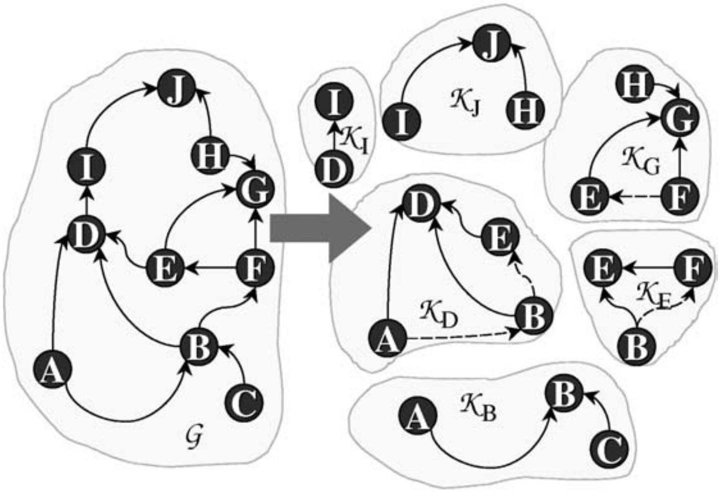
Since the universal approximation property has been proved for numerous types of ANNs, this approach focuses on the construction of MLPs out of empirically proven cause-and-effect hypotheses. Therefore the causal strategy model has to be separated into causal function kernels (CFK). The latter describe a set of variables and interjacent cause-and-effect relations, each of which consists of a dependent element and its direct predecessors. Therefore, the number of CFKs derived from a causal strategy model corresponds to the number of contained variables, which show an empirically significant influence by other elements. Following the theory underlying this approach, the total cause-and-effect relations within a causal function kernel represent the unknown causal function determining the values of the dependent variable. Taking the previous discussion into account, this function can be approximated sufficiently accurate by an MLP with the appropriate time series of the independent variables as input and those of the dependent element as output node.

Due to the possible existence of indirect associations between independent and dependent variables within a CFK it is likely that the overall effect between such two elements has to be separated in order to obtain the direct share of influence. This effect is called multicollinearity in the appropriate statistical literature and perturbs the approximation quality if it remains unsolved. Hence, it is necessary to extend the causal function kernels for cause-and-effect relations which directly and or indirectly link two independent variables $X_1 \rightarrow X_2$ and consequently induce an indirect effect between X_1 and the dependent variable *Y*. These auxiliary cause-and-effect relations accounting for multicollinearity can be discovered by analyzing the transitive closure[5] of each independent variable within the global causal system: For every pair of independent variables X_i and X_j within a causal function kernel K_Y there exists an auxiliary cause-and-effect relation $X_i \dashrightarrow X_j$ if and only if X_j is contained in the transitive closure of X_i according to the global model G. The procedure to construct extended causal function kernels (eCFK) from a causally proven global strategy model G is shown in Figure 3.

Temporal Disaggregation of Causal Function Kernels

Since an unknown causal function to be approximated does not exist between variables but rather

Figure 3. Separation of (extended) causal function kernels



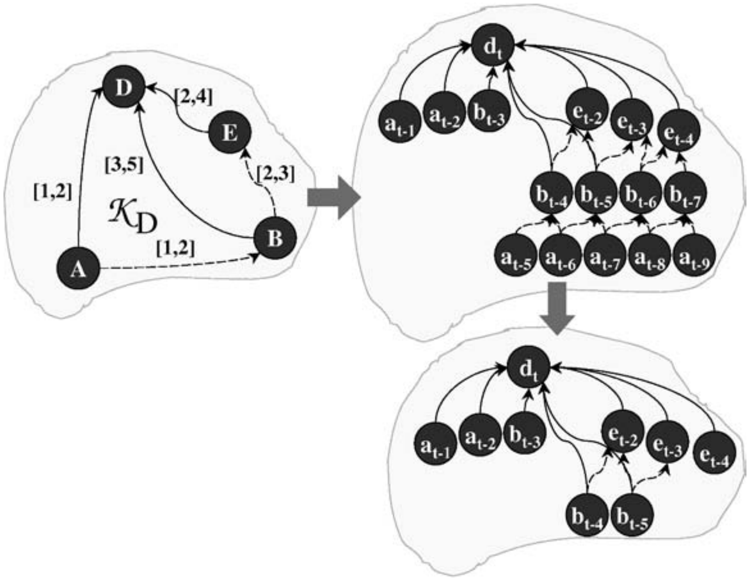
between their lagged time series, the eCFKs have to be temporally disaggregated. Therefore, this approach uses the window of impact as identified by the causal proof procedure (see section 3): While the dependent variable Y is represented by its instantaneous time series y_t as an output node, each independent variable leads to a number of input nodes corresponding to the length of the appropriate window of impact. These input nodes each represent one lagged independent time series within the window of impact. As far as eCFKs are concerned, it is necessary to introduce a second input layer which accounts for auxiliary cause-and-effect relations. The time series of the second layer are derived by the same procedure as described above taking the influenced indirect time series of the auxiliary association as output node and the influencing element as input node. Second input layer elements which affect first layer time series and the output node directly are of specific interest because they combine direct and indirect influence, as it is shown in Figure 4, for the extended causal function kernel K_D. All other second layer input elements where this overlap does not exist can be eliminated from the temporally disaggregated causal function kernel (dCFK) since they are already encompassed by another (d)CFK.

As temporal disaggregation delivers the appropriate input and output nodes for a neural function approximator in the form of temporally lagged time series there remains the issue to complete the model selection of the ANN. This includes an adequate dimensioning of the hidden layer(s) as well as the selection of input and transfer functions for all ANN-nodes.

Since the universal approximation property postulates a limitation of the inner function of Kolmogorov's theorem, it is necessary to use transfer functions which map the input values to a certain output interval. This class of so-called squashing functions encompasses sigmoid as well as logistic sine or heaviside functions (Hillbrand, 2003, p. 214). For practical reasons the use of an additive input function for hidden and output neurons is recommended.

The selection of an appropriate number of hidden neurons is directly related to the generalization ability of the ANN (i.e., to learn a certain function instead of memorizing input-output mappings). As this specific model selection task depends on a variety of influences which cannot be fully assessed a priori, it is necessary to rely on heuristics (for details see Hillbrand, 2003, pp. 226–230) and validate the prediction accuracy of the ANN by using a validation data set[6].

Figure 4. Temporal disaggregation of (e)CFKs



As it follows from the temporal disaggregation of eCFKs, the resulting auxiliary cause-and-effect relations between second-level and first-level time series have to be incorporated into the neural function approximator in order to account for indirect effects. Therefore, auxiliary sub-MLPs are introduced as symbolized by dotted connectors in the example of Figure 5.

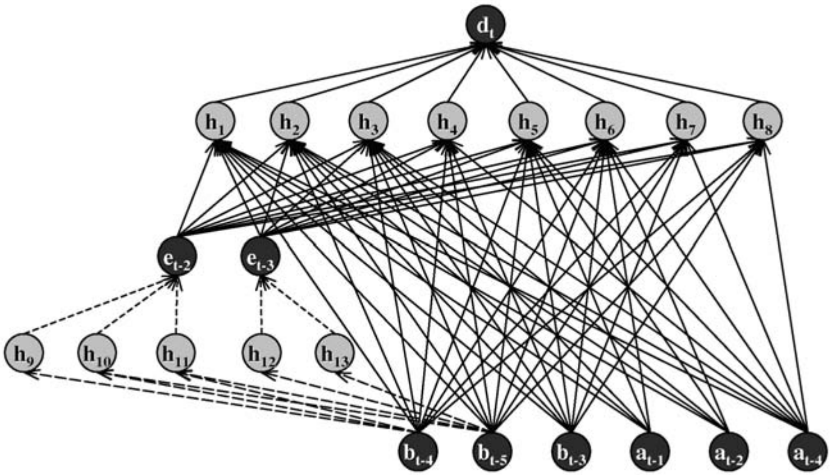
Before the training of the overall causal function approximator it is necessary to learn these correcting functions each of which has one first-level time series (e.g., e_{t-2} and e_{t-3}) as output node and one or more second-level time series as input nodes. The hidden layer of a correcting ANN is dimensioned by the same heuristics like the main function approximator. After the training of all correcting ANNs, their weights are kept fixed and included in the main neuron model. For the overall training of the causal function approximator it is necessary to equip first-level nodes with a specific input function since they are input and hidden nodes in the same way. Consequently, the input function of a first level node calculates the weighted output sum of all preceding nodes plus the respective input value of the node itself[7]. The ratio between these two shares of cumulative input is needed for training purposes when employing an error backpropagating algorithm. The same portion by which the overall input for a first-level node consists values from a lower network layer is used to distribute the output error—backpropagated from higher network levels (e.g., $h_1 – h_8$) —among lower level neurons (e.g., $h_9 – h_{13}$).

Since all further characteristics regarding layout and training of neural causal function approximators correspond with those of MLPs they are not discussed in further detail but referred to the relevant literature (e.g., Hillbrand, 2003).

EXPERIMENTAL RESULTS AND PROOF OF CONCEPT

The concepts to validate corporate cause-and-effect hypotheses and to approximate the underlying causal function from empirical evidence as proposed in this article have been implemented in

Figure 5. Neural function approximator for (e)CFKs



the form of a research prototype (Hillbrand, 2003, pp. 288–319). The latter has been implemented based on a modeling environment as described in section 3 provided by the metamodeling platform ADONIS (Karagiannis & Kühn, 2002). This provides the basis for an in-depth investigation about the admissibility of the proposed approach for real-world strategic scenarios as well as about its limitations with respect to several problem classes. Therefore, this proof of concept employs a causal system consisting of five variables each of which is described by artificially generated time series. According to the characteristics of these time series the respective CFKs are assigned to specific problem classes. Starting from a completely interlinked causal strategy model it has to be tested, if all spuriously inserted associations are detected and eliminated from the model. Furthermore the correct windows of impact have to be identified. Based on this reconstructed model the approach should construct appropriate causal function approximators which are trained subsequently. The superior prediction quality of the trained function approximator is then tested in comparison with similar techniques.

A Generating Causal System for the Proof of Concept

The causal system in Figure 6 is implicitly represented by the following functional associations:

$$as_t = \varepsilon_{N(1;\,0.50)}$$
$$rm_t = \varepsilon_{N(1;\,0.50)}$$

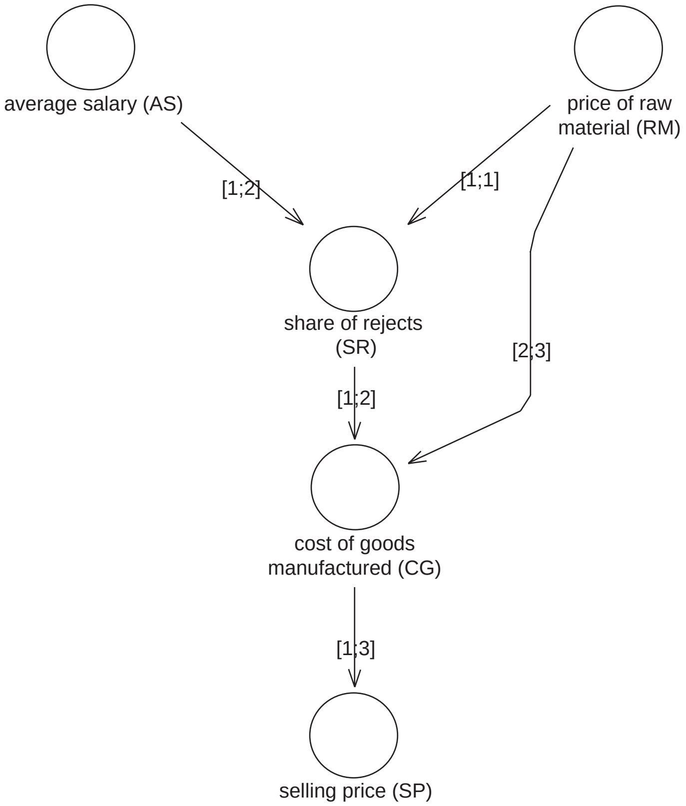
$$sr_t = 0.95 + \frac{1}{30 \cdot as_{t-1} - 23.5} + \frac{1}{6.66 \cdot as_{t-2} - 5} - \frac{7 \cdot as_{t-1} - 6}{8} + \varepsilon_{U(-0.15,+0.15)}$$

$$cg_t = -2.5 + 0.25\,(4 - \sin(4+5rs_{t-1}) + 0.2\,(4 - \sin(2 + 7rs_{t-2})) + 1.1rn_{t-2} + 0.8rn_{t-3}\,\varepsilon_{U(-.3;\,0.3)}$$

$$sp_t = \frac{\sum_{\Delta t=1}^{3} cg_{t-\Delta t}}{3} + \varepsilon_{U(-0.15,+0.15)} \qquad (4)$$

Where as_t, rm_t, sr_t, cg_t and sp_t stand for the values of the variables *average salary*, *price of raw material*, *share of rejects*, *cost of goods manufactured* and *selling price* in period *t*, respectively. The term $\varepsilon_{U(-0.15,+0.15)}$ stands for uniformly distributed random number within the interval [-0.15,+0.15]

Figure 6. Generating causal system



and $\varepsilon_{N\ (1;0.05)}$ represents a normally distributed random number with expectated value of 1 and a standard deviation of *0.05*.

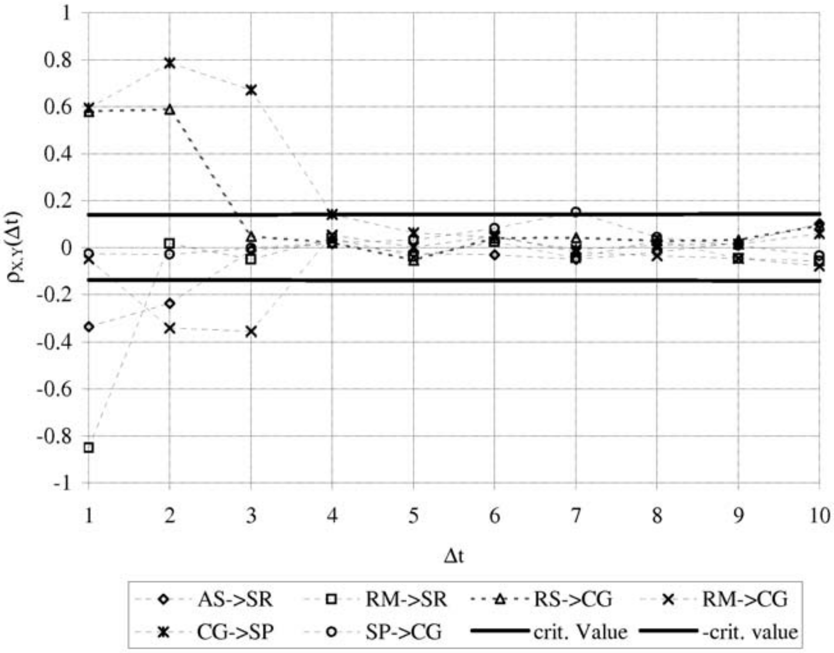
Identification of Spuriously Inserted Cause-and-Effect Hypotheses

Since the generating system of causally related time series does not exist explicitly in real-world scenarios, it is the aim of this approach to reconstruct the structure of the causal model as shown in Figure 6, to identify the appropriate time lags and to approximate the functional dependencies. The basis for the application of this approach is a rudimentary causal strategy model which comprises the nomologic cause-and-effect hypotheses as assumed a priori by decision makers. For this purpose, the functional proof of concept starts with a fully interlinked causal system consisting of the five variables already mentioned.

In order to rule out spurious associations according to the second and third causality criterion (informational redundancy and temporal precedence) the proposed approach analyzes the cross correlations for every link in the maximal strategic system model for different time lags. Since fourteen associations do not show a significant cross correlation at any Δt, they are marked as spurious. The remaining six potentially causal relations according to the second and third causality criterion yield cross correlation patterns as shown in Figure 7.

As it is obvious from this correlogram, the proposed proof of causality identifies the correct windows of impact of the five causal relations implicitly included in the generating system. However, this algorithm untruly identifies a sixth association ($SP \rightarrow CG$) to be potentially causal according to the second and third causality criterion because its cross correlation at a time lag of seven periods seems to be significant:

Figure 7. Cross correlations resulting from the verification algorithm



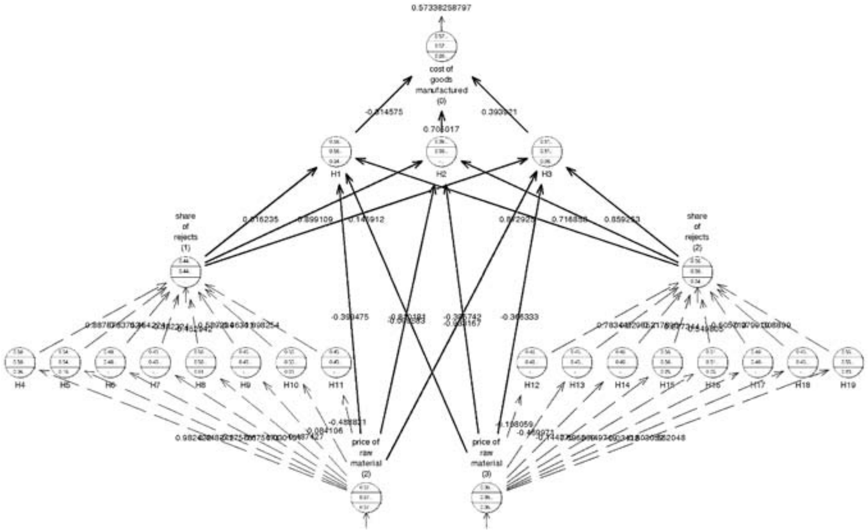
$$\rho_{SP,\,G}(7) = 0.1458 > \sigma_{\rho_{SP,\,G}} = 0.1411. \qquad (5)$$

The test for exogenous third variables inducing a spurious correlation between two elements of the causal system is performed by the principles as proposed in section 3 of this article. Since the variations of both, the variable *average salary* and *price of raw material* are not only reflected in the timeseries of their direct successor but also in those of the remaining elements it can be concluded that the potentially causal relations *SR* → *CG* as well as *CG* → *SP* are genuinely causal. As the latter proves that the direction of this relation is unambiguous, the potentially causal relation *SP* → *CG* is marked as spurious association.

Approximating Causal Functions

The next step, according to the proposed approach, is to approximate the unknown causal functions for each causal function kernel which consists of a positive number of proven causal relations. Therefore, this approach derives three multi-layer perceptrons (MLP) from the identified causal strategy model. For the K*SR* this neural network consists of the output node sr_t as well as of an input layer consisting of as_{t-1}, as_{t-2} and rm_{t-1} and a four-element hidden layer being dimensioned using a heuristic proposed by Baum and Haussler (1988). Another MLP—approximating the causal function of K_{SP}—is established with the time series cg_{t-1}, cg_{t-2} and cg_{t-3} forming the input nodes and sp_t as an output node. The input and output nodes of the causal function approximator for K_{CG} are derived analogously: The time series sr_{t-1}, cg_{t-2}, rm_{t-2} and rm_{t-3} representing the input layer and cg_t as output node. However, since this CFK contains the influence relation *RM* → *SR,* which causes multicollinearity, it is necessary to distinguish between first and second level input nodes and connect them with correcting function approximators. Therefore, the temporal disaggregation algorithm introduces two correcting MLPs. One of them contains sr_{t-1} as output and rm_{t-2} as input

Figure 8. Causal function approximator for K_{CG}



node and the other receives input values from rm_{t-3} and has sr_{t-2} as output element. The resulting MLP is shown in Figure 8, where dashed arcs represent auxiliary correcting MLPs accounting for the relation $RM \rightarrow SR$ and solid links are part of the main function approximator.

After deriving the three neural function approximators as shown in Figure 8, the latter have to be trained in order to inductively learn the unknown causal function from the empirical data. Therefore, the time series associated with each input and output nodes are split into a training and a validation set. If an MLP incorporates correcting function approximators, the latter have to be trained independently first. After reaching a global error minimum for these correcting ANNs, their weights are kept fixed and are included in the main function approximator as specified in section 4 including the special input functions for first level input nodes as well as its inverse function for error backpropagation purposes.

The training of these MLPs leads to an approximation of the causal function determining the values of the dependent variable of each causal function kernel. With the approximate knowledge of its functional dependencies in the form of the trained ANN, the causal strategy models can be enhanced by a prediction model which allows numerical analyses on future impacts of strategic scenarios. Since ANNs are known for their universal approximation properties in the relevant literature (cf. section 4), they are expected to yield better approximation results than other techniques. A comparison with linear forecasting models like multiple linear regression analysis shows a predominantly clear picture.

As it is shown in Table 1, the proposed approach enables decision makers to approximate a

Table 1. Prediction quality of linear regression vs. connectionist approximator

CFK	$MSE_{lin.}$	MSE_{ANN}	significant
K_{SR}	0.0048	0.0015	yes
K_{CG}	0.0143	0.0056	yes
K_{SP}	0.0022	0.0020	no

more precise causal function compared to linear regression in all cases. As the latter does not account for nonlinear functions, indirect effects, autocorrelation or noisy time series, it yields significantly[8] higher Mean Squared Errors (MSE) for the validation set than the connectionist approach especially for these problem classes. The only exception of this observation is CFK K_{SP}, which is not included in any of the problem classes: Only for these—strictly linear—functions, given the absence of other disturbances, it is not possible to achieve significantly better predictive results using the connectionist approach.

CONCLUSION

This article proposes a new approach to validate causal strategy models consisting of nomologic managerial cause-and-effect hypotheses as a prerequisite for the approximation of the unknown underlying functions: Therefore this paper focuses on artificial neural network models due to their universal approximation properties which explicitly dispenses with a priori assessments about the functional form of these associations. Therefore, this article presents techniques for the separation causal function kernels from causal models and their temporal disaggregation into multi-layer perceptrons. The article concludes with a functional review of the prototypical implementation based on these concepts. The main findings show that the assumption of linear causal function for model selection purposes within the stage of causal proof is admissible to a large extent. Merely the high noise level of one variable leads to the acceptance of a spurious cause-and-effect hypothesis for an intermediary result. However, this source of error will be one issue for future research: As Bartlett's significance test does not account for the noise level of a dependent variable this technique has to be enhanced in order to provide improved significance boundaries which are sensitive with respect to the predictive uncertainty.

In order to integrate this approach into a DSS it seems to be necessary to extend this approach for analytic techniques based on this improved model base like simulation, what-if- or how-to-achieve-analyses. These applications allow the quantitative anticipation and prediction of future impacts of strategic scenarios.

Another field of interest is the transfer of the approach—as proposed here—to other scientific areas. Basically, these techniques could be employed for every decision theoretic problem based on causal networks such as economic theories, medical diagnostics, etc.

ENDNOTES

[1] If the two Humean properties of causality would be sufficient to explain causal structures, a bad weather forecast would be the regarded as the cause for bad weather.

[2] An α -error or type-1-error denotes a cause-and-effect relation between two variables in a causal strategy model although the corresponding time-series are not causal. On the contrary the term β- or type-2-error is used if there exists a causal relation in reality (i.e., between the time-series of two variables but it is not represented in the causal strategy model).

[3] The computation of the autocorrelation of a variable X and a given order n corresponds to the one of the cross correlation $\rho_{x,x}(n)$. Hence it will be abbreviated by the symbol $\rho_x(n)$ for the rest of this article.

[4] IC = Inductive Causation

[5] The transitive closure is the set of all direct and indirect successors of a node within a directed graph (e.g., a causal strategy model).

[6] A validation data set is a subset of the empirical data which is not used to train the ANN

[7] e.g., $net_{e_{t-2}} = in_{e_{t-2}} + \sum_{i=9}^{11} w_{h_i, e_{t-2}} \cdot out_{h_i}$

[8] The statistical significance of this statement has been validated by testing the group average of the squared errors for both techniques using variance analysis.

ABSTRACT

Over the last 10 years, pervasive computing environments and mobile networks have become extremely popular. Despite the many end user benefits of pervasive computing, the intrinsic instability and context ambiguities of these environments pose impediments to data-oriented decision support systems. In pervasive computing environments where users, systems, and computing resources are distributed or mobile, the online or "available" state of decision support-related resources may be intermittent or delayed. Awareness or knowledge of these resources' online presence and availability can affect the decision making process. This article discusses issues related to data-driven decision support systems (DSS) in pervasive computing environments (PCE) and demonstrates that a decision maker's awareness of online status and availability can improve decision outcomes. A model for extending DSS resource presence and availability awareness to decision makers is presented and the impact of this knowledge on decision outcomes is evaluated using a management problem simulation.

INTRODUCTION

Technologies such as data mining and business analytics have seen explosive growth over the last 5 years in both research and industry. At the same time, advances in 3rd generation networks and communication have made the promise of pervasive computing environments a reality. With the convergence of pervasive computing environments and business analytics, now more than ever, greater volumes of data are available to decision support systems and subsequently decision-makers. One effect is the increase in data usage for both analysis and justification in decision making. In this context, the data is frequently assumed to be completely accurate and available. Moreover, it is also assumed that a decision support system would be available to assist with filtering, processing, analysis and other decision making tasks.

Despite the advances in technology, the fundamental characteristics of business decision making have not changed. Many business decision opportunities are time limited, and the phases of Simon's (1960) decision-making model still apply to business decision-makers. What has changed is industry's dependence on and related faith in data. There is an implicit belief that data is generally correct and that decision support systems can provide correct deterministic answers to decision problems. The data are used, not only as the basis to derive decision advice, but also to provide supporting justification. As evidence of this change, consider the North American business analytics market. Frost and Sullivan estimate that the enterprise analytics market generated $2.22B in revenue for 2005 and should increase at a Compound Annual Growth Rate (CAGR) of 10.8% from 2006 to 2012, reaching approximately $4.54B in 2012. Business intelligence (BI) is the largest single segment in this market, with $961.4M in revenues, which should reach $1.92B in 2012 at a CAGR of 10.4% (Frost & Sullivan, 2006).

The availability of decision support systems is integrally tied to industry's dependence on data. Gartner estimates that wireless voice and data will continue to displace wireline services, with voice and data services growing at a 6% CAGR - making wireless the fastest-growing segment of the communications services market (Flewelling, 2007). This demand for communication-enabling and data analysis products is clear evidence of businesses' interest and commitment to data-driven decision support and pervasive computing.

While data-oriented decision support and ubiquitous computing capabilities deliver many benefits to decision makers, in real world situations the availability of decision-related resources and support systems is not guaranteed. Moreover, data can be generally considered just one decision-related resource. Other types of computing resources, such as storage or processors must also be considered. What good is data without storage to hold it or a processor to process it? A great deal of research has been conducted to make systems highly available in pervasive computing environments (PCE) through redundant power and communications, data distribution and caching, and dynamic storage solutions. Much of the prior research has sought to address hardware limitations and ensure that computing resources are always available. In practice however, it is difficult, if not impossible, to ensure 100% availability. The telecommunications industry has a concept known as five nines (99.999% up time), which refers to system reliability of a copper-based telephone network. Five nines historically characterized the expected level of service availability that users could expect from a provider's communications network. With the advance of technologies such as digital subscriber lines (DSL), wireless, and packet-based voice communications, users are willing to accept increasingly lower standards of network quality (Lynch, 2002).

This acceptance of ambiguity in network and system availability conflicts with the increasing dependency on systems and data for decision making. Connectivity in pervasive computing environments is classically known to be intermittent and unstable. Intermittent and unstable communications and their underlying networks can have a significant impact on decision support systems, decision making, and decision outcomes. Moreover, time sensitive decisions, which often characterize business decision opportunities, can be even more susceptible to issues of availability. Extending knowledge of system and data availability to decision makers, who expect computer-aided support in these environments, may reduce uncertainty about the level of support available. This in turn, may improve the overall utility of decision support systems.

The relevance of research on resource and system availability becomes increasingly important as the popularity and availability of pervasive computing environments intensifies. However, little attention has been paid to the effects of data and system availability on decision making and decision outcomes. This article examines how decision maker's knowledge of decision support-related resources' or systems' online status (presence awareness) and readiness (availability awareness) can improve decision outcomes.

Following this introduction, the next section provides a discussion of prior work and background on presence and availability awareness. The third section illustrates presence and availability awareness in a decision making context and presents a model that incorporates these concepts in a traditional decision making support system. The third section is followed by the details of an experiment to evaluate the effects of availability awareness on decision making in a pervasive computing environment. The fifth section presents the results of this experiment, followed by a discussion of the implications for decision support systems. The article concludes with a summary and discussion of future work.

BACKGROUND AND PREVIOUS WORK

There is a significant amount of work on data and system availability. Much of this work focuses on hardware related issues. For example, Imielinski and Badrinath (1994) examined the challenges in data management for mobile computing. Their research identified several issues including bandwidth, location management, and power management. Imielinski and Badrinath's research has been supported by more recent efforts that provide solutions in each of these areas. Recent research has seen improvements in mobile power management that claim upwards of 35% improvement in battery lifetimes (Chakraborty, Yau, Lui, & Dong, 2006; Rahmati & Zhong, 2007) and redundant power has become a standard for data centers and servers (Bartlett & Spainhower, 2004). The concept of redundancy has also been applied to data storage (Muthian, Vijayan, Andrea, & Remzi, 2005).

Storage redundancy has implications for location management from the perspective of locating data closer to its users, thereby making it more available (Andreas, Alan, & Peter, 2005; Ruay-Shiung, Jih-Sheng, & Shin-Yi, 2007). Redundant storage can be very effective for local access, but the introduction of a network introduces other points of failure or interruption. Network latency is often a direct indicator of network congestion and problems (Shahram, Shyam, & Bhaskar, 2006). Roughan et al. (2004) propose how combining routing and traffic data can be used to detect network anomalies. Russello et al. (2007) provide a comprehensive hardware solution for managing network-distributed data that is policy based. Their approach allows application developers to specify availability requirements for data tuples, while an underlying middleware evaluates various distribution and replication policies to select the one that best meets the developer's requirements.

Research focusing on system and network hardware solutions provides a good practical foundation for addressing data availability in decision support systems. From the perspective of pervasive computing environments, extensive research has been done utilizing location as a context for how, when, and what device is interacting with computing resources. For example, Milliard et al. (2005) used wireless sensors, infrared, and accelerometers coupled with a semantic model to provide information on where a user physically was, in order to adjust resources and preferences accordingly. Perich et al's (2004) work is similar in that it combines semantic expressions to describe users' context and location. However, Perich's work combines the sensors and semantics with a caching algorithm to aid data management as users move about the computing environment.

The vision of true pervasive computing environments requires that pervasive data availability is essential for pervasive computing (Satyanarayanan, 2001). While this prior research goes a long way towards realizing the vision and promise of pervasive computing, these hardware approaches are not perfect and none of these solutions provide 100% data availability. Additionally, the focus of this research tends to concentrate on the system, network, or system administrators rather than on the end users.

There have also been efforts to apply these concepts specifically to decision support. This research is most frequently found in applications of distributed decision support systems and is divided into two different categories: decentralized systems and systems that support decentralized users. Both of these areas emphasize hardware approaches and collaborative components. For example, Du and Jia (2003) developed an enterprise network environment for cooperative problem solving. Compared to traditional client/server approaches, Du and Jia sought to provide a more efficient and secure solution by reducing network traffic and protecting private information. Recent work by Adla (2007) proposed a framework for a distributed cooperative intelligent decision support system. Adla's framework extends Soubie (1998) work for cooperative knowledge-based systems. The framework described components that effectively decomposed decision tasks and enabled collaboration amongst distributed decision-makers. Adla introduced innovation in his framework by including the concept of decision roles such as facilitator and considered the paradigm of distributed decision-support systems, in which several decision-makers who deal with partial, uncertain, and possibly exclusive information must reach a common decision.

In contrast to this other research, much of the work addressing data availability has focused on its psychological impact on decision-makers. Most significantly, data availability has been shown to be related to ambiguity, uncertainty, and risk (Kentel & Aral, 2007). The concepts of ambiguity, uncertainty, and risk should be considered as related, yet discrete concepts that may not necessarily be causal. For the purposes of this article, ambiguity is considered in the context of available data that has the capacity to reduce doubt regarding decision variables. Most of this work has studied user-centric perspectives of ambiguity in decision making, such as ambiguity tolerance. There have been several studies examining the effects of ambiguity (Boiney, 1993; Hogarth, 1989; Owen & Sweeney 2000; Shaffer, Hendrick, Regula, & Freconna, 1973) and ways to reduce ambiguity (Geweke, 1992; Hu & Antony, 2007; Pezzulo & Couyoumdjian, 2006) in decision making. This research has shown that a decision-maker's reactions to ambiguity are likely to be situation-dependent. Potentially relevant factors include not only the degree of ambiguity but also the size of the payoffs and the perceived role of individuals other than the decision-maker (e.g., the decision-maker's boss or spouse) (Winkler, 1997). Moreover, ambiguity may often be interpreted as risk and reduces a decision-maker's confidence (Ellsberg, 2001; Ghosh & Ray, 1997). In managerial contexts, the presence of risk and ambiguity may lead to suboptimal decision outcomes.

Some work has been done specifically examining the effects on decision making with and without having a DSS available for use. These efforts have evaluated the benefits of using decision support systems through simulations (Bricconi, Nitto, Fuggetta, & Tracanella, 2000; Forgionne & Russell, 2007), case studies (Alter, 2004; Keen & Scott-Morton, 1978), and empirical field studies (Holsapple & Sena, 2005; Sharda, Barr, & McDonnell, 1988). Unlike the work described in this article, these prior efforts examined the efficacy of decision support systems, themselves concentrating on the benefits resulting from the use of the system. Generally these studies have examined availability in absolute terms, either with or without a DSS; not the case where the system is intermittently available.

Unlike these previous efforts, the emphasis in this article is not on improving system/resource reliability or minimizing psychological effects of ambiguity resulting from data or system unavailability. In a pervasive computing environment, it is expected that reliability will be less than 100% and there will be occasions when data or systems are unavailable. The motivation behind the work in this article is to determine the effects of providing contextual details regarding when or if decision support-related resources will be available.

Context Aware Computing

Because the concepts behind presence and availability awareness are not new and have been applied in other domains, some attention must be given to the research conducted on these topics. It is important to begin with a definition, a**s** it is difficult to define presence awareness or characterize pervasive computing environment systems without some discussion of context. To be effective, PCE-based systems require some context aware components (Want et al., 1995). From a user's perspective, concepts that fall under context awareness include changes in a user's physical state and location, workflow, preferences, or resource interests. Context-awareness also includes environmental conditions. In recent years, there has been a significant amount of work on context aware computing. In this domain, research has been conducted examining aspects of users' physical environment (Yau & Joy, 2006), usability (Ho & Intille, 2005), system adaptation based on context (Baldauf, Dustdar, & Rosenberg, 2007), location modeling (Becker & Dürr, 2005; Satoh, 2005), personalization (Krause, Smailagic, & Siewiorek, 2006; Yang, Mahon, Williams, & Pfeifer, 2006), and presence (Brok, Kumar, Meeuwissen, & Batteram, 2006; Khan, Zia, Daudpota, Hussain, & Taimoor, 2006; Raento, Oulasvirta, Petit, & Toivonen, 2005; Sur, Arsanjani, & Ramanthan, 2007; Wegdam, 2005).

Within the broad domain of context aware computing, the concepts of presence and availability awareness can be grounded in location awareness research. Much of the research in location awareness concentrates on collaboration (Griswold, Boyer, Brown, & Truong, 2003; Holmquist, J.Wigstrom, & Falk, 1998) and commerce/service provisioning (Crow, Pan, Kam, & Davenport, 2003; Zeidler & Fiege, 2003). Knowing where a user or system is located and whether they are available for interaction can be particularly useful for these activities. While proximity is not a direct issue for availability awareness, it can allude to the quality of a resources' connectivity. Similarly, knowing the location of a user or resource can suggest when a resource will be available for interaction and it also implies its online state or presence.

Previous research in context and location computing provides a sound foundation for hardware and software approaches to capture and utilize information about where and how users use computing devices. However, the primary distinction between previous research in context awareness and that described in this article is that most of the previous solutions capture context information and utilize it within the system, rather than provide it directly to the end user. The solutions that do provide context information to the end user only provide presence (binary online/offline) status and not details about the likelihood of when resources will be available. Moreover, little of this research examined how availability contexts impact decision outcomes, either directly or indirectly.

Presence and Availability Awareness

This article does not address all of the issues with context awareness; instead, the focus is on presence and availability awareness, in terms of both data and system resources. A working definition of presence awareness in this article is: knowledge of whether data/system resources are online or connected for communication. Presence awareness provides knowledge of a resource's state, in terms of connectivity. Presence awareness is the basis for availability awareness, since knowing if a resource is online is the first step in determining availability for use. Succinctly, availability awareness is knowledge of a resource's readiness to be used.

Presence awareness has gained a great deal of popularity in real-time communication applications such as instant messaging (IM). All IM clients incorporate a form of presence awareness so that users can be made aware of when a potential communication partner, or "buddy," is online. Many of these clients also include availability awareness using techniques such as keyboard and screen saver monitoring. From a research standpoint, most of the studies on IM have been on its utility as a communications medium (Griss, Letsinger, Cowan, VanHilst, & Kessler, 2002; Kwon, Shin, & Kim, 2006; Wang et al., 2004).

Jesus Favela's research differs from the main body of instant messaging communication research. Favela's group embraces the concept of pervasive computing and has investigated using instant messaging, as a presence and availability awareness tool in agent-based systems. Favela (2002) created AIDA, an instant messaging and presence awareness client for handheld devices running PalmOS. Using this client, Favela created a pervasive computing communication application called DoMo. What is unique about Favela's efforts is his treatment of network resources, such as scanners and printers, as presence aware items. By extending the notion of presence to documents and other resources, AIDA offers new opportunities for casual encounters in a community of co-authors. For instance, when a user notices that a document has been locked, he/she might send a relevant message or even join his/her colleague in a synchronous collaborative authoring session.

Favela's work, while innovative and unique, did not focus on decision making. His application of presence awareness was much more practical in nature and concentrated on location contexts (i.e. proximity to resources and basic online-offline status of resources). His work did not examine how knowledge of presence and availability would affect users; rather his group studied the implications of a hybrid software-hardware architecture supporting document management and collaboration in a PCE. Particularly in a PCE, the implications of including presence and availability awareness of data in a decision support system can lead to improved outcomes for users and organizations. In contrast to Favela's work, the research described in this article differentiates itself by examining how a decision maker's knowledge of data's availability can affect decision outcomes.

PRESENCE AND AVAILABILITY AWARENESS FOR DECISION SUPPORT SYSTEMS

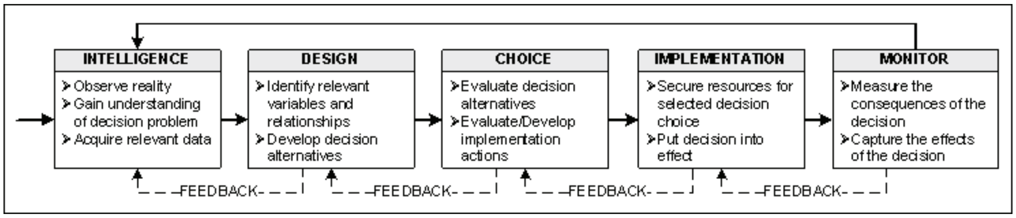
As data-driven decision support technologies become increasingly popular, the availability or knowledge of data's availability will become increasingly important. Even in situations where a model exists, the data for the model may often come from several systems. Pervasive computing environments will aggravate problems with data availability. Knowledge of when, or if, data will be available can impact the efficacy of a decision making support system that relies on data, particularly when the data come from multiple sources. If a decision support system requires data from external systems and the data from these systems were delayed or completely unavailable, the decision-maker would have to work around the lack of data, and the assistance provided by the system may be limited. Decision timing further complicates the effects of data availability. Depending on the time constraints for the decision, the data may not become available in a timely manner.

Figure 1 shows the phases and activities of the decision making process, adapted from Simon's (1960) model. If the decision opportunity has a time limit, then the intelligence, design, choice and implementation phases are also bounded by time constraints that must cumulatively be less than or equal to the opportunity time limit. Interruptions or delays occurring at any phase can affect any subsequent phases, constricting the time available for that phase. This constriction of time can have significant implications for the decision-maker, particularly if the causal delay is unknown. If the decision-maker does not have any understanding the delay duration, then he or she is left to either wait (possibly too long), skip that phase's tasks (no-wait), or improvise to accommodate the activities in the delayed phase. Decisions made under high pressure time constraints encourage a decision-maker to rely on heuristics and historical approaches that may not be appropriate for the current decision problem (Gonzalez, 2005; Ordonez & Benson, 1997). Moreover, these cascading effects can lead to reduced DSS effectiveness and sub-optimal decision outcomes.

In a pervasive computing environment, data may come from a variety of sources and are likely to be outside of the functional DSS itself. Environmental factors and the number of data sources required for the decision opportunity may have a direct impact on inputs, which then can affect processing and subsequent advice output. Moreover, in complex computing environments, the processing and output components may be distributed or physically separate from the other components. This consideration is particularly significant in a PCE because the DSS itself, users, or decision support-related resources may be mobile, have sessions interrupted, or have inconsistent network bandwidth.

When there is uncertainty about the availability of decision support-related data or the DSS itself, it introduces an additional decision within the core decision making process. Consider a simple example where someone wants to purchase a digital video disc (DVD) player and their only consideration for the decision is price. However, they want to use it to play a movie for some guests who will be arriving at their home in the next 90 minutes. The decision maker might use a DSS, which has a resource on the Internet that would identify the lowest price DVD available for local purchase. Now, what if the decision maker's Internet connection is down? The decision maker has an additional decision to make that stems from the original decision process. The decision

Figure 1. Decision making process steps



maker could wait for the connection to come back up and hope it comes back with sufficient time to identify a DVD and travel to make the purchase. The decision maker could try to get connectivity using another medium, such as an Internet-capable cell phone; or alternatively, the decision maker could forgo support altogether and drive to a local brick and mortar store and choose from the on hand selection of DVD players.

Figure 2 shows what happens to the traditional decision making process when availability is unknown at whatever step of the decision process. At each step in the primary decision process (shown as shaded boxes with dark arrows), there exists the possibility to spawn a secondary decision process (shown as lighter boxes and dashed arrows), due to uncertainty regarding the availability of resources necessary at that step. Moreover, these secondary decision processes may be terminal or create their own additional processes. To illustrate the effect of availability awareness and expand the previous example: what if the decision maker knew or was informed that the Internet connection would be available 10 minutes from the time the decision maker was made aware of the outage? The decision maker could make an informed decision about how to proceed and could weigh the previous alternatives with additional certainty.

Awareness information does not necessarily have to be limited to whether or not a resource is online/offline or when it will be available; it could also include probabilistic information as well. For example, the decision maker purchasing a DVD player could have been provided a probability that the Internet connection would be available within a certain amount of time and the likelihood that the connection will stay up, once it returns. To support the dynamic nature of pervasive computing environments, a DSS should incorporate interfaces that are capable of providing insight into components' and resources' online status and availability. Additionally, the DSS itself should provide status and availability information interactively directly to the decision-maker.

In order to meet these requirements in PCEs, a typical DSS architecture is adapted by considering resource characteristics that can cause delays (such as network bandwidth capacity and quality, storage failures, or extended processing loads). Figure 3 shows an architecture extending the typical DSS with an added layer of presence/availability awareness. The awareness layer delivers information and feedback from the functional DSS elements through the user interface and the dialog management directly to the decision-maker.

Examining this architecture from the inputs' perspective, the DSS would have information about the databases or data warehouses online status. Should the data or inputs not be online, the availability awareness layer would deliver details about when the data may be available. Similarly from the processing perspective, the decision-maker would have information about processor loading and subsequent task processing delays. Unlike architectures where the decision-maker has no knowledge of the DSS and its resources' availability, the decision-maker is provided the necessary information to evaluate the wait/no-wait, accommodate, or abandon secondary decisions resulting from system/resource delays or interruptions.

Figure 2. Decision making process with no presence and availability awareness

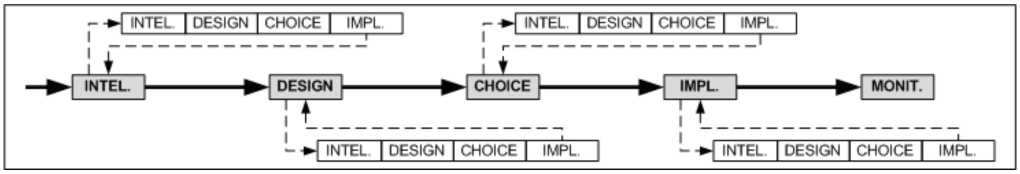


Figure 3. Typical DSS with awareness layer added

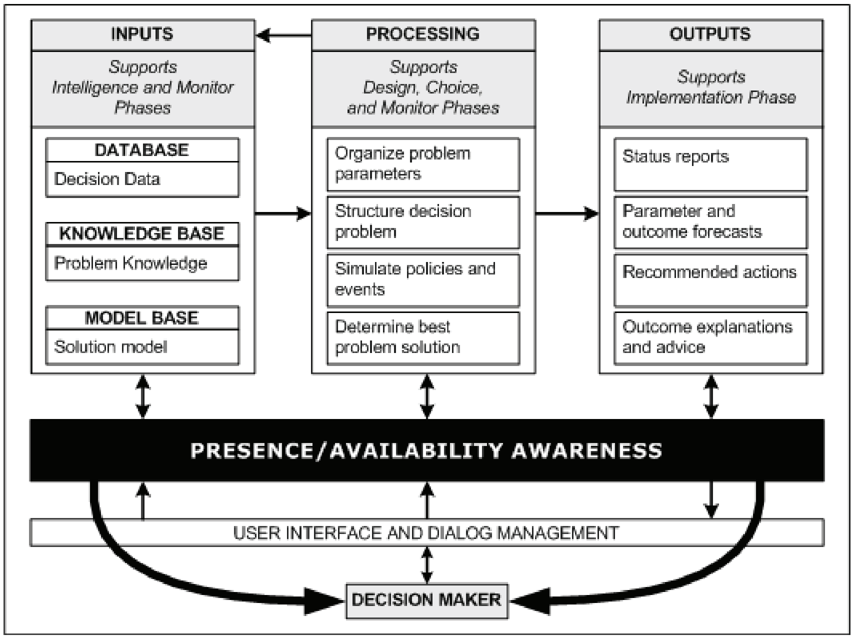
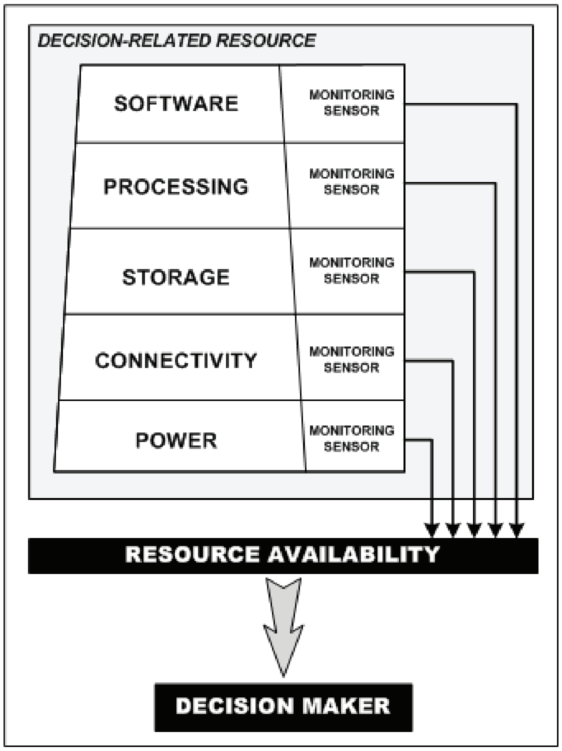


While shown as a monolithic layer in Figure 3 and centralized management of presence and awareness information is necessary, portions of the presence and availability awareness layer could exist within each functional DSS resource, e.g. as part of the database, as a process monitor, or as a function of a printer driver. If the DSS resources, including the DSS itself, are generalized they can be considered a hierarchical set of functions that are independent bottom up and dependent top down. Figure 4 illustrates a generalized hierarchy. While every level may not be necessary for every resource, the level dependencies are evident. Consider an example where a DSS provides guidance by presenting information on a graphical map, e.g. a spatial DSS. This DSS may require data from a remote website that converts street addresses to latitude and longitude. This remote website/data would be considered a resource. This resource depends on a hierarchy of dependent functions to be able to serve its purpose. Examining Figure 4, without power/electricity, there is no connectivity or anything else above power. Without connectivity the data in storage cannot be delivered. Without storage, processing cannot occur; there is nothing to process. Without processing, the software cannot operate, and if the software (web server, address-to-lat/long converter, or host operating system) fails, the resource cannot respond to the DSS's request. There is an implicit dependency from top to bottom but not the other way. It is possible to not have connectivity, yet have power and so on.

Each level has a sensor to monitor its own functions and the total availability of these individual levels comprises the resource's availability. The monitoring sensor at each level may take different forms as appropriate for that level. For example, the power monitoring sensor may be a hardware device that feeds data back to the DSS directly. In contrast, the software monitoring sensor may be software itself that monitors how well a service responds to requests, i.e. doesn't crash or stop running.

The obvious question is: *how might details about decision support-related resources' availability be obtained and quantified*? The hardware and software technology already exists to enable

Figure 4. Decision resource hierarchy



both new and existing DSS with presence and availability awareness. Hardware that monitors loading, power, outages, and interruptions have become standard in high availability environments. Research in high availability computing has already identified methods to evaluate, quantify, and monitor hardware related statuses such as power (Rahmati & Zhong, 2007), network characteristics (Shahram et al., 2006), computer components (Weatherspoon, Chun, So, & Kubiatowicz, 2005), processing/computing load (Zhoujun, Zhigang, & Zhenhua, 2007), and storage (Blake & Rodrigues, 2003).

Software presence and awareness solutions are broadly available and can be commonly found in server monitoring, instant messaging, and web service software. Moreover, research in the area of web service composition and quality of service (QoS) can provide solutions delivering awareness knowledge for general software-based resources. There is a significant amount of research studying applications using QoS monitoring for service level agreements, adaptation to changing system conditions, and web service composition (Ali, Rana, & Walker, 2004; Menasce, 2004; Thio & Karunasekera, 2005). Web service composition is a particularly active research area, rich with solutions for service availability, because of the critical nature of this information for process scheduling and execution planning (Peer, 2005; Pistore, Barbon, Bertoli, Shaparau, & Traverso, 2004).

These theoretical and accessible approaches provide a wide range of alternatives for implementing the collection, quantification, and monitoring of decision support-related resource presence and availability information. With regard to integrating resource presence and awareness in existing and future DSS, these technologies are well researched and readily available. The model discussed above maps presence and availability awareness information to decision support resources. This information can then be provided to decision makers. In theory, if presence and availability awareness is extended through a DSS to the decision maker, structured decision problems with deterministic outcomes should realize improved support. This theory suggests the following research question and hypotheses.

Research Question: Will decision support-related resource availability awareness improve decision outcomes?

- **Null Hypothesis**: Decision support-related resource availability awareness knowledge provided to decision makers will not improve decision outcomes.
- **Alternative Hypothesis**: Decision support-related resource availability awareness knowledge provided to decision makers will improve decision outcomes.

SIMULATION EXPERIMENT

To evaluate the above hypothesis a time constrained, deterministic, structured or semi-structured decision problem is desired. The experimental methodology consisted of two scenarios: one where the decision maker *is not* provided awareness information (control) and a second where the decision maker *is* provided this information (treatment). In order to isolate the effects of the resource awareness information, support from the DSS should provide specific and correct advice and the entire population of alternatives should be available to the decision maker whether the decision support-related resource is available or not. Figure 5 shows the control scenario and Figure 6 shows the treatment scenario; the decision maker is denoted as DM. The primary difference between Figure 5 and Figure 6 is the introduction of awareness information in the center of the flow diagram, where the DM has a choice to wait or not. To implement these scenarios a simulation experiment was created.

The simulation experiment utilized a complex semi-structured problem, frequently used in management training and evaluation and typically requiring decision making support (McLeod, 1986). This problem involves a market in which top management uses price, marketing, research and development, and plant investment to compete for a product's one-quarter total market potential. Demand for the organization's products will be influenced by: (1) management actions, (2) competitors' behavior, and (3) the economic environment. The decision objective is to plan a "next quarter" strategy that would generate as much total profit as possible. This profit is the deterministic quantitative result of the decision maker's choice.

Figure 5. Control experimental process

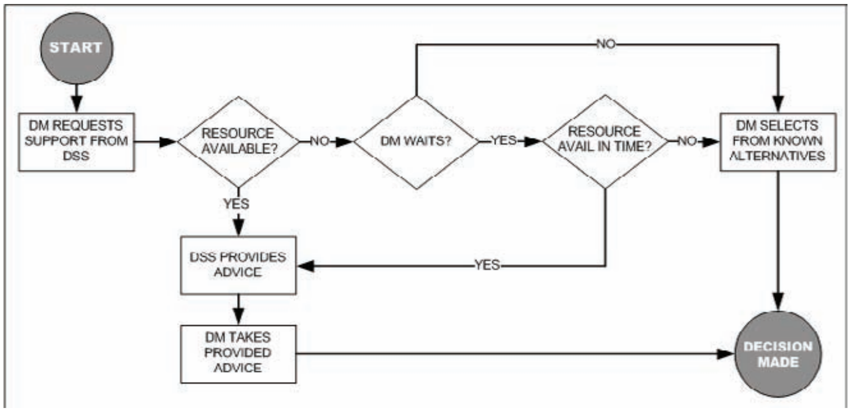


Figure 6. Treatment experimental process

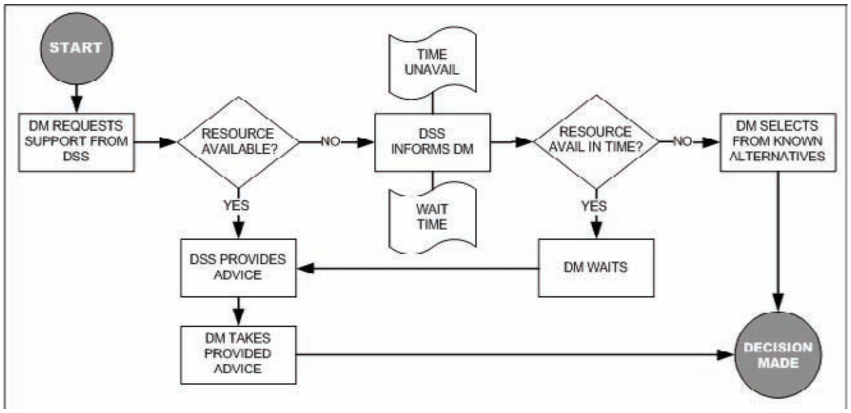

Strategy making requires: (1) setting the product price, marketing budget, research and development expenditures, and plant investment and (2) forecasting the competitors' price, competitors' marketing budget, a seasonal sales index, and an index of general economic conditions. Twelve additional variables, including plant capacity, raw materials inventory, and administrative expenses, were calculated from the strategy. Initial values for these twelve variables form the alternatives for decision-making. These twenty (controllable, uncontrollable, and calculated) variables jointly influence the profitability of the organization. This profit value is used as the key measure for decision outcome.

This management problem formed the core decision opportunity for the simulation, as it provides an explicit quantifiable measure of the decision outcome: profit. While the actual management problem used is considerably more complex (as described above), to illustrate the simulation and experimental methodology in a simple manner, let profit (P) equal forecasted sales (S) multiplied by forecasted price (PR) minus forecasted production cost (PC).

$$P = S * PR - PC$$

The data for forecasted sales, production cost, and price would consist of several historical values for each variable and be supplied by an external system. The data comprising the historical values are considered the decision-support related resource, as is the DSS itself. However, these resources may or may not be available within the time allotted for the decision. Within the DSS, there exists a model that would suggest the appropriate values, from all available historical data, that would provide the maximum profit value. This is the provided advice.

In strategy making, it is the decision-maker's responsibility to select which forecasted values to use, within a 5 minute time limit. The simulated decision-maker takes 3 forms: 1) where the decision-maker always takes the advice provided by the DSS, 2) where the decision-maker takes the advice a random number of times, 3) where the decision-maker never takes the provided advice. Using the simplified management problem here are three example simulation scenarios:

1. **The forecasted data *is* provided within the time allotted for the decision.** The DSS identifies the price, sales, and production cost that result in a maximum profit. Decision-maker (DM) 1 accepts the advice. DM-2 may or may not take the advice (randomly); if DM-2 does not take the advice, DM-2 chooses his/her own values. DM-3 does not take the advice and chooses his/her own

values. For all three DMs, the values for *S*, *PR*, and *PC* are applied to the management problem resulting in a profit value for each DM.

2. **The forecasted data *is not* provided within the time allotted for the decision.** All three DM choose their own values that are applied to the management problem, resulting in a profit value for each.
3. **The forecasted data *is delayed* and may or may not be provided within the time allotted for the decision.** If the data will be available within the allotted time, the DSS identifies the values that will result in maximum profit. If the data becomes available and DM-1 decides to wait, then DM-1 takes the advice. If the data are not available *or* DM-1 does not decide to wait DM-1 chooses his/her own values. If the data are available *and* DM-2 decides to wait *and* DM-2 chooses to take the advice then the DSS supplied values are used. If the data are not available *or* DM-2 decides not to wait *or* DM-2 declines the advice, DM-2 chooses his/her own value. DM-3 chooses his/her own values. The values for each DM are applied to the management problem, resulting in a profit value for each.

The simulation had 5 scenario variables that determined the conditions of the scenario, as shown in Table 1. All of these values were randomly generated for each run of the simulation. It was assumed that each input value would follow a standard normal distribution with a mean of 0 and a standard deviation of 1.

To evaluate the effects of data availability on decision making, the simulation was run with and without awareness of the data's availability, according to Figures 5 and 6. In one case, the decision-maker will be provided knowledge of the availability of the data (treatment) and in a second, the decision-maker has no knowledge of when or if the data will be available (control). For experimental purposes, the two simulations were run with two additional conditions that affected how values were handled when the decision-maker did not use the DSS advice. The first condition simulated the decision-maker choosing values from the forecasted dataset which consisted of the DSS advice values and 50,000 additional, sub-optimal input values. The second condition simulated the decision-maker selecting values without the forecast data dataset. Table 2 summarizes the simulations and conditions.

The first condition (A) represents the situation where the decision-maker has access to the data but may not have access to the DSS advice. Under condition A, the simulated decision-maker's values were randomly selected from the forecasted data. Condition B represents the situation where the DSS is available, but the data source may not

Table 1. Simulation scenario variables

VARIABLE	FUNCTION
Take_Advice	This is a 1 or 0 value determining if the DM who randomly takes the DSS advice decides to take the advice. If 1 then the DM takes the advice, 0 DM doesn't.
Data_Avail	This is a 1 or 0 value determining if the data is immediately available. If 1 then the data is available, 0 it is not. If this is 0 then the DM-Wait and Delay_Amt values are used.
DM_Wait_YN	This is a 1 or 0 value determining if the DM waits for the data to become available or decides to choose a value before it becomes available. This variable only applies to the simulations where the availability is unknown.
DM_Wait	Decimal value between 0 and 5 minutes that determines how long the DM waits. This variable only applies to the simulations where the availability is unknown.
Delay_Amt	Decimal value between 0 and 10 minutes that determines how long the data will be unavailable.

Table 2. Simulation decision-maker input value conditions

SIMULATION	CONDITION	DECISION MAKER INPUT VALUES…	CONTROL / TREATMENT
Simulation 1	A	Are randomly selected from dataset	Availability is unknown
	A	Are randomly selected from dataset	Availability is known
Simulation 2	B	Are randomly selected	Availability is unknown
	B	Are randomly selected	Availability is known

be. Under condition (B), the decision-maker's values were selected randomly based on formulas developed to ensure that input values would fall within the management problem's permissible ranges, according to a normal probability distribution.

For all randomly generated variables, to incorporate the diversity of inputs from a population of users and scenario conditions, each variable was assumed to follow a standard normal distribution with a mean of 0 and a standard deviation of 1. The choice of a normal distribution was based on the Central Limit Theorem, which roughly states that all distributions approach normality as the number of observations grows large (Barron, 1986; Davidson, 2002).

A precise and explicit model of the decision problem and simulation was programmed in Matlab. This software provided a robust programming environment where the simulation could be created and evaluated. Once programmed, 50,000 runs were conducted for each simulation and condition (4 sets as defined in Table 2 of 50,000 runs each). For every run, the run's scenario variables and resulting profit (decision outcome) for each decision-maker were recorded.

SIMULATION RESULTS

The results of the profit generated by the simulations were analyzed using SPSS and the hypothesis was tested for each type of decision maker and each condition. In summary, the results show that the runs where availability information was known performed significantly better for the simulated decision maker who took the DSS advice (either always or randomly). The decision maker who never took the advice had the lowest profits of all of the simulations. As might be expected, the availability awareness had no effect on the decision maker who never took the DSS advice and the simulation condition where the DSS (but not the data) was intermittently unavailable yielded higher profits. Table 3 shows a summary of the mean profit for all of the simulations.

The runs where availability was known (had awareness) had the best decision outcomes or highest profits, except in the case where the decision maker did not ever take the advice. Availability awareness had the greatest impact on the simulated decision maker who always took the advice. To evaluate the hypothesis, each decision maker is compared between the control and treatment groups using a paired t-test. Tables 4 and 5 show the results of the t-tests. The awareness-enabled runs outperformed the "unaware" runs. However, in the case of the decision maker never taking the advice, the difference was not significant (.558 for data intermittently available and .170 for DSS intermittently available) and subsequently the null hypothesis for this case must be accepted. The other two cases, where the decision maker either always or randomly took the DSS advice, were significant with alpha's lower than .025, rejecting the null hypothesis.

IMPLICATIONS AND LIMITATIONS

As this simulation study illustrates, awareness of decision support-related resources' presence and availability can lead to different decision

Table 3. Decision maker's average profit values (dollars)

DSS Advice:	**Always Accept**		**Randomly Accept**		**Never Accept**	
Availability:	**Aware**	**Unaware**	**Aware**	**Unaware**	**Aware**	**Unaware**

outcomes. In addition to presenting a model that maps presence and availability awareness to decision support resources, this study examined the effect of this awareness on decision outcomes augmented by DSS. In the cases where the decision maker always took the advice, having availability information provided delivered an average increase in profit of 17-56%. While more research may be necessary, this is significant. The research findings indicate that given time constrained, structured or semi-structured, deterministic decision problems supported by a DSS, resource availability information can have a dramatic impact on decision outcomes. Because the necessary resources need to be known before presence and availability information can be provided the benefit of this knowledge may be limited to structured and semi-structured decision problems. However, if the decision maker is able to provide structure during the intelligence or design phases of the decision making process, the benefits demonstrated in this study should translate to unstructured problems.

The benefits of presence and availability awareness are integrally tied to the architecture of the DSS and the support it provides. Other types of decision making support systems may offer different forms of support and guidance, changing the advice depending on the evolving circumstances in the decision situation. This research suggests that even in these other cases benefits can be gained by providing resource availability information to decision makers. Moreover, the technology to obtain availability information is mature, reducing the barriers for adoption; making practical implementations of this research immediately feasible. By applying this mature technology to existing and future DSS, the challenges of limited bandwidth, overloaded systems, and general delays in settings such as PCEs can be minimized.

Resource availability in a PCE is seldomly 100% guaranteed and delays/interruptions are likely. This study examined awareness benefits given a time constrained decision opportunity under conditions where resource availability was intermittent or delayed. The benefits of extending awareness information to the decision maker may be limited if the decision opportunity has a broad time window or delays resulting from unavailability are minimal. The issues of delay are significant, but pervasive computing environments may suffer from complete outages and interruptions where the disruption goes beyond the time boundaries of the decision opportunity. In this case, awareness of resource availability would have a limited effect, essentially mirroring the simulated decision-maker who never accepts the DSS advice. Further study is necessary to evaluate the implications of resource availability awareness in extreme cases of delay.

The awareness-enhanced model presented here sought to address the issues evaluated in the simulation experiments. Results from any simulation are only as good as the assumptions used in the analyses. This study assumed that scenario conditions, acceptance rates, and input values would follow normal distributions. A variety of other distributions are possible, including the uniform, binomial and Gamma, distributions. Further studies, then, should examine the sensitivity of the results to changes in distributions. This study also assumed that the management problem was a reasonable representation of many organizations' strategic decision making problem. Different organizations, however, may utilize different management philosophies, accounting principles, and decision objectives. If so, the decision model should be changed to reflect the organization's practices, philosophies, objectives, and decision environments. In particular, the profit equation may be replaced with an alternative measure or measures of performance, some tangible and others intangible. Variables and relationships may be defined and measured differently. Additional environmental factors may be added to the equations. While such alterations would change the specific form of the simulation model, the general model and experimental methodology would still be applicable.

CONCLUSION

This study presented a model that maps presence and availability awareness to decision support-related resources for use by decision support systems. A simulation was conducted to evaluate the effects of awareness on a data-driven DSS supporting management decision making. The results of this study confirm that extending awareness knowledge to decision makers through a DSS improves decision making when compared to DSS without this capability. In addition, these results suggest that availability awareness is important whether it supports data inputs or DSS advice. Since the results are expressed in dollars of net profit, the findings provide an objective measure of determining the relative decision value of presence and availability awareness. Moreover, as a large-scale simulation that approaches a census study, the evaluation results should be generalizable to other applications of DSS that decision problems in distributed or dynamic environments.

The results in this study suggest that the benefits of presence and availability awareness are most significant in environments where the reliability and accessibility of decision support resources are not 100% guaranteed; extending the findings of this study to most DSS in pervasive computing environments. With the advances in wireless and mobile networks, most modern computing settings have characteristics of pervasive computing environments. As a result, the benefits of generally extending resource presence awareness information to decision makers will be of increasing importance. Additionally, distributed computing resources, another characteristic of PCEs are already common. The research in this study implies relevance and applicability for these applications as well. However, further study is necessary to operationalize the model proposed in this work.

Future work is planned to implement decision support-related resource presence and availability awareness in an operational DSS. This future study will incorporate existing awareness quantification and monitoring solutions such as those discussed in the third section and will expand this study, examining the limitations noted in the implications section.

Chapter 7.9

Decision Support Systems and Representation Levels in the Decision Spine

Patrick Humphreys
London School of Economics and Political Science, UK

INTRODUCTION: DECISION-MAKING AS PROBLEM SOLVING

Problem solving has been defined as the complex interplay of cognitive, affective, and behavioural processes with the aim to adapt to external or internal demands or challenges (Heppner & Krauskopf, 1987). In the realm of organizational decision-making, Herbert Simon (1977) describes the problem-solving process as moving through three stages: intelligence, design, and choice. In this context, design focuses on "inventing, developing and analysing possible courses of action," where the design artefact being constructed for this purpose constitutes the "representation of the problem."

While a wide range of representation means and calculi have been proposed for decision problem solving purposes, practical implementations generally involve applying one or more of these means to develop the structure of the problem within one or more frames. Typically, these are future-scenario frames, multi-attributed preference frames, and rule base-frames (Chatjoulis & Humphreys, 2007). Simon (1977) characterized decision problems according to the degree of problem-structure that was pre-established (or taken for granted as "received wisdom," or "the truth about the situation that calls for a decision") at the time participants embark on the decision problem solving process. He placed such problems on a continuum ranging from routine (programmed, structured) problems with well-specified solutions to novel, complex (unprogrammed, unstructured) with ambiguous solutions.

System thinking and soft systems methodologies (Checkland, 1999) have provided ways of looking at problem solving as an integrated whole throughout this continuum by modelling the process within a problem definition cycle, moving from the awareness that a problem exists to the moment of choice. Central to these models is the specification of a sequence of stages that the decision-making group has to follow in order to reduce uncertainly and increase structure, in transforming an ill-defined problem into a well defined one (Humphreys, 1989; Phillips, 1992). A great number of decision support systems (DSS) have been produced with the goal of providing mechanisms to help decision makers get through such sequences in processing uncertain and ambiguous decisions (Silver, 1991). The majority of these DSS are intended to support decision makers by increasing the structure of decision problem representations situated in already semi structured decision situations (Keen, 1980). However, as Meredith (2006, p. 31) points out:

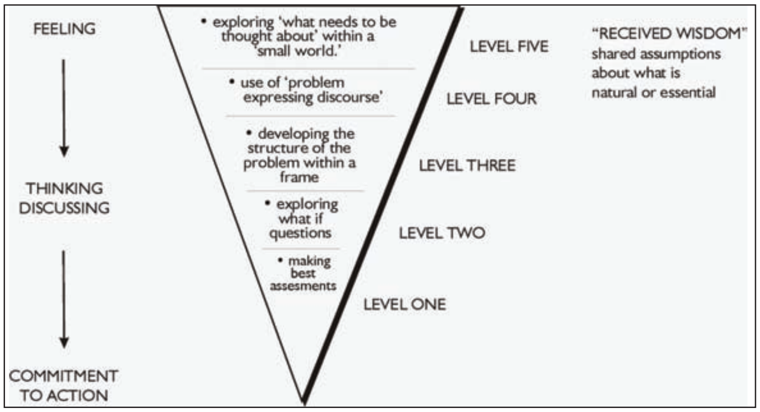
> *At the extremely unstructured end of the continuum sits a class of decision problems for which a pre-existing solution either does not exist or is inadequate. Such problems require creative decision-making. DSS designed to support decision makers with such a task face a dilemma: too much structure may stifle the creative process, while too little structure provides inadequate support.*

In such situations, participants embarking on the decision-making process can start out at the level of feeling, without being constrained (either explicitly or implicitly) by "received wisdom" about how the decision problem is already structured. Initially, participants have complete freedom and autonomy about how to think about translating this desire into action: all imaginable courses of action are candidates for implementation (Meredith, 2006). Conventional decision support methodologies, operating within the problem solving paradigm, intend to support a group process that aims at progressively strengthening the constraints on how the problem is represented at five qualitatively distinct levels, until only one course of action is prescribed: the one which should actually be embarked upon in the *real* (Humphreys & Jones, 2007).

LEVELS OF REPRESENTATION OF DECISION PROBLEMS

Each level of problem representation is associated with a different kind of discourse concerning how to structure the constraints at that level (Humphreys, 1998). The nature of the knowledge represented at each level and the cognitive operations involved in generating these knowledge

Figure 1. Five levels of constraint setting along the decision spine



representations has been discussed in detail elsewhere (Humphreys, 1984, 1989; Humphreys & Berkeley, 1986). These levels have been presented in a point-down triangle, or "decision spine" (Humphreys, 2007), as shown in Figure 1, indicating the progressive decrease in discretion in considering what knowledge can be included in the problem representation being developed as one moves downward from level 5 (exploring fantasy scenarios and dreams with conjecturality beyond formalization or structure) towards fixed structure (with all other knowledge now external to the representation of the problem), and zero discretion at level 1 (making "best assessments"). Three key formal properties of the 5-level scheme, taken as a whole, are as follows:

1. What is qualitatively different at each level are the cognitive operations carried out in thinking about the decision problem.
2. The results of the operations carried out on a particular level constrain the ways operations are carried out at all lower levels.
3. Any decision problem is represented at all levels, *doubled* in the symbolic/imaginary (where cognitive operations are carried out) and in the real (Deleuze & Guattari, 1988).

Therefore, we cannot treat levels like taxonomy, classifying decision problems as level 1, level 2, and so forth. We have to examine how each problem is handled at each level. In the actual decision making process, the sequence movement through the levels is not linear, but corresponds to a spiral through the circular logic of choice (Humphreys, 2007 ; Nappelbaum, 1997) to the point where a particular course of action is prescribed as the "true solution" to the decision problem. Decision conferencing methodologies essentially provide process designs to enable the decision making group to move efficiently and effectively through these levels within a general process which Phillips (1988, 1989) called "conferencing to consensus."

At Level 5

At the top level (level 5 in Figure 1), the roots of the decision problem are imagined through explorations carried out within a "small world" (Savage, 1955; Toda, 1976) whose bounds are defined by what each of the participants in the decision-making process is prepared to think about. However, small worlds complete with contents do not exist as complete entities pigeonholed away in a person's mind ready to be retrieved intact. From the outside, we infer the contents of the small world the person is using by looking at what he or she explores, and guessing its boundaries or possible holes within it by what he or she leaves out.

We are left with uncertainty concerning the actual boundaries of this structure in the same way cartographers of the physical world in the middle ages experienced uncertainty about where to draw bounds when they had access only to explorers' reports and guesswork to fill in the gaps. As they made the maps, they were, at the same time, exploring and creating a rhizome (Deleuze & Guattari, 1988; Humphreys & Jones, 2006).

From the standpoint of this analogy, though, the person doing the thinking is not the cartographer, but an explorer within the rhizome. Exploring alternative futures in a territory for which there are no maps except those made during the explorations and where there may be considerable uncertainty: not only about where the boundary limiting the explorations could be set, but also about what unforeseen successes—or terrors—lie along the route.

In decision making under conditions of uncertainty, at level 5, it is generally necessary to explore worst case scenarios, which can be an extremely frightening process when the worst case is unbounded: offering the possibility that in exploring it a participant could stumble upon all kinds of terrors which he or she otherwise succeeded in keeping out of consciousness. Hence explorations within these bounds are generally made within what Sandler and Sandler (1978) called "the background of safety,"[1] and are themselves beyond language (Lacan, 1977), which can only be used to describe the results of what is found during such exploration. These results constitute the contextual knowledge that is available in forming the content elements of problem representations that are manipulated in problem structuring at lower levels.

Attempts to improve or enrich this contextual knowledge, by persuading participants to explore beyond their background of safety can be highly distressing to them, and are usually countered with what others (who consider such exploration to be "safe") experience as *paranoid discourse* as described by Colby (1975): discourse aimed at preventing other participants from exploring in areas that the speaker considers could be "unsafe" for them. Hence effective decision support techniques, at level 5, should aim to extend the background of safety for all participants, creating an arena where communication can be innovative and creative rather than paranoid.

Techniques for doing this have been developed over many years in the field of drama. The role of the chorus in ancient Greek tragedies, providing ritualised, structured communication in unsafe areas where issues need to be resolved in coming to terms with tragedy, is one example; others involve improvisation techniques providing safe spaces for collectively acting out fantasies about alternative futures (Chatjoulis & Humphreys, 2007).

Humphreys and Jones (2006) describe how, within a flexible learning environment, a background of safety is created and maintained for participants through using dramatic techniques (construction and presentation of skits, enabling participants to explore future scenarios through the rhizome, enriching context, and allowing for more creative cognitive endeavours further down the decision spine).

At Level 4

At the next level down, (level 4 in Figure 1), problem-expressing discourse may be employed to make claims that particular elements of what was explored should (or should not) be included in the representation of the decision problem (Vari, Vecsenyi, & Paprika, 1986). This discourse determines the parts of the contextual knowledge, accessed by participants at level 5, which are expressed as "representatives in illocutionary acts" (Searle, 1979, following Austin, 1962) that will be proceduralised within the decision spine. This discourse is usually argumentative; *claims* about what aspects of context should be explicitly proceduralised. Claims are expressed by their advocates who support them with warrants and *backings* (Toulmin, 1958; van Eemeren, Grootendorst, Jackson, & Jacobs, 1997) in order to gain their acceptance by all participants in the decision making process.

The successful establishment of the claims of "what to include in the representation of the problem" is promoted and accepted through the use of *discourses of truth* (Foucault, 1981). These focus on establishing "unquestionable" or "natural" status for the backings for the claims made, in the minds of those participants in the decision making process who need to be persuaded to accept them. Thus problem-expressing discourse serves both to develop the proceduralised knowledge context within the decision spine and to define the constraints on what claims can be linked into frames so that their collective implications for potential prescriptions for action can be explored (Beach, 1990).

At Level 3

The claims thus established through problem expressing discourse need to be linked into frames so that their collective implications for the decision can be explored (Beach, 1990). Hence, at level 3, framing discourse is employed to develop the structure of the problem within a frame. Within "soft systems methodology" (Checkland, 1981; Checkland & Scholes, 1990; Humphreys, 1989), this process is described as "conceptual model building" and is located within proceduralised knowledge context established at level 4.

The problem structuring frames employed by participants developing problem structure within a decision spine usually fit into three principal categories (Chatjoulis & Humphreys, 2007). These are:

1. *Frames that structure future scenarios*, for example, through modelling act-event-sequences with decision trees. In this case, framing discourse serves to link imagined contingent acts and events in the future, forward through potential consequences of immediate acts, or backward from goals and imagined outcomes, with the aim of establishing course and action and investigating their potential consequences and side effects, usually under conditions of uncertainty.
2. *Frames that structure preferences between alternatives*, for example, through decomposition and recomposition within multi-attribute utility hierarchies. In this case, framing discourse seeks to identify value-laden attributes on alternative courses of action under consideration, (i.e., as explored within the other two categories of frames), and to make trade-offs (Keeney & Raiffa, 1976) or establish a dominance structure (Montgomery, 1983, 1989) between the alternatives to provide a rationale for "choice of the best alternative" (Berkeley, et al., 1991).
3. *Rule-based structures aimed at reducing the problem-solution search space*. In the extreme (bureaucratic) case, the framing discourse employed by participants tries to constrain possibilities for action by specifying a sufficient set of rules such that only one course of action is prescribed by the rule set, taken together.

Framing discourse is also employed to police the coherence of the material drawn from the proceduralised context into the frame until sufficient coherence is reached where it is possible to explore the structure so developed inside the frame.

Below Level 3

The result of the operations carried out at level 3 is a decision problem representation within one or more frames whose structure is conditionally fixed. Participants within the decision spine at this level no longer have any discretion over, say, which value-laden attributes may be considered within a preference structuring frame, but sensitivity analysis is possible within each frame, exploring what-if questions about the impact of changing values at nodes or reference points within structures developed at level 3. In this way it is possible to explore the decision problem within a frame. Hence at level 2, the content manipulated with the structured frames need not be represented as "facts" (where participants are expected to agree that there is a single "true" value), but as hypotheses (opinions, views, etc.). At this level, it is explicitly recognised, for example, that probabilities can vary according to individual participants' views on future states of the world and that utilities vary in reflecting the range of participants' interests and preferences.

Effective decision support systems, at this level, may employ "what-if" explorations to see the impact of changing the assessment of an element located at a particular node within the structure on the values of other nodes of interest within that structure. This kind of sensitivity analysis can discover points and areas within the frames where change of values across the range espoused by various participants makes very little impact on nodes of crucial interest, (e.g., those defining a choice between immediate courses of action) and so can be safely ignored. Conversely, where differences in espoused values are shown to have a crucial impact, a rationale is provided which could justify further effort in the *real* to refine participants' views on

At level 1, the only degree of discretion left for the participants in developing problem structure within the decision spine is to decide on how to make a "best assessment" of the of "the most likely value" at those points in the represented problem that have been represented as "uncertain" within the constructed decision-making frames, such that a particular course of action is prescribed.

If the resulting prescription is not acceptable to one or more stakeholders in the decision, this points to a re-examination of how the various higher- level constraints were set, to discover the level at which adjustment or negotiation is necessary, or for setting the constraints on how contextual knowledge is proceduralised in a new way, which will better reflect the interests of the parties to the decision.

DECISION SUPPORT WITHIN AND BEYOND THE DECISION SPINE:

From GDSS to GDACS

Figure 1 is not intended to indicate a prescriptive process model for decision-making (i.e., "start at level 5, establish constraints, then go down, one by one through the levels until action is prescribed at level 1"). All that can be established, *in general*, is that the employment, within the group decision-making process, of the discourses identified at each level in Figure 1 serves to constrain what can be explicitly considered, at the levels below it, in establishing the "truth about the decision situation" (Chatjoulis & Humphreys, 2007).

Group decision support systems (GDSS), following the approach instigated by the linear problem solving account of Herbert Simon, conventionally address the explicit modelling and support process at level 3 and below—working within one or more frames. What happens at levels 5 and 4 , in identifying what these frames might be and in proceduralising the context which specifies the material to be structured within the frames, is seen as something a *priori* and external to the decision-making process. The participants in the decision making process are expected to have shared assumptions about this (as "received wisdom"). Generation of "sufficient" alternatives (as can only be known with hindsight) is considered, within this paradigm, as a problem of creativity prior to the decision process itself, rather than intrinsic to it (Kleindorfer, Kunreuther, & Shoemaker, 1993; Meredith, 2006).

Elsewhere, Humphreys and Jones (2006) have proposed a fundamental evolution of the group decision support model from one that provides support at levels 3 and below, presuming a single, pre-existing proceduralised context (Brezillon & Zarate, 2007) to comprehensive group communication and decision support (GDACS) at all levels. GDACS supports creative decision-making at levels 5 and 4 through construction of narratives with the fundamental aim of enriching contextual knowledge within the *rhizome* (Deleuze & Guattari, 1988) which constitutes the body-without-organs of a *decision-hedgehog* (Humphreys, 2007). Localised processes within a plethora of decision spines, developing problem structure through the five levels described above with the aim of "pricking the real" at the tip of the spine, are rooted in this rhizome.

Chapter 7.10

Supporting Demand Supply Network Optimization with Petri Nets

Teemu Tynjala
Nokia Group, Finland

ABSTRACT

The present study implements a generic methodology for describing and analyzing demand supply networks, that is, networks from a company's suppliers to its customers. There can be many possible demand supply networks with different logistics costs for a product. Therefore, we introduce a Petri Net-based formalism, and a reachability analysis based algorithm that finds the optimum demand supply network for a user-specified product structure. The method has been implemented and is currently in production use inside all Nokia business groups. It is used in demand supply planning of both network elements and handsets. An example of the method's application to a concrete Nokia product is included.

INTRODUCTION

Logistics refers to the flow of materials, information, and money between the suppliers and customers. A *demand supply network* refers to the manner in which components flow from suppliers to the manufacturer's plants, and finally to the end customers. The logistics cost associated with a demand supply network include such costs as freight, warehousing, interest rate, duties, and taxes.

A typical problem that logistics professionals face in a global corporation is finding the cheapest and most reliable way of producing a product and delivering it to customers. Often, the product structures and supplier bases vary considerably during a product design phase. The logistics manager must decide the most economical component suppliers and the best-positioned assembly factories over the product's lifecycle. Typically there are hundreds or thousands of different demand supply network setup options for a given product. Therefore, manual analysis of demand supply networks is practically impossible.

Companies have considerable incentives to optimize their end-to-end demand supply chains. Firms approach this problem in two fronts: optimization of manufacturing functions on one hand and the demand supply chains on the other. As such, several methods for demand supply network analysis have been introduced in the literature. Most solutions use operations research paradigm—mixed integer programming—or discrete simulation to analyze demand supply networks (Bramel & Simchi-Levi, 1997; Simchi-Levi et al., 2003).

Recently, the industry has seen several examples of disasters brought up by broken demand supply networks (Norrmann & Jansson, 2004). A logistics manager must know all the demand supply network options available to reduce possible risks. This enumeration requires reachability analysis where each path (i.e., a possible demand supply network setup) is explored. Mathematical optimization may give the optimal setup quickly via analytic or heuristic methods. However, these techniques converge to the optimum, rather than enumerating the entire state space (including the costlier network possibilities). Discrete simulation, on the other hand, is excellent in dynamic analysis of a single demand supply network. Yet, it lacks the "helicopter view" of all demand supply network options which are possible to obtain using reachability analysis. Moreover, simulation and optimization software are costly in an environment with 200 potential users. It was realized that a reachability analysis-based solution, which solves small to medium size optimization problems in reasonable time, could be created in-house. The previous demand supply network analysis methods inside Nokia had relied on spreadsheets where each demand supply network setup was manually analyzed. In wake of increasing competition, the logistics team was looking for a powerful, yet cost efficient solution. Thus, I as a member of logistics team, started to consider the following research question:

How to apply reachability analysis in demand supply network analysis?

The result was a generic Petri Net model for describing arbitrary demand supply network options, and a reachability analysis algorithm that computes the network setups and costs from the Petri Net model. A Web-based analysis tool based on the methodology was constructed during 2004 and has been in production use since February, 2005.

The rest of the article is organized as follows: the remainder of the introduction reviews the current approaches to demand supply network analysis. The second section gives the generic Petri Net model for demand supply networks through example and formal definitions. The third section presents the reachability analysis algorithm for the model. The fourth section presents a concrete Nokia case for the tool use. The fifth section concludes with discussion and future work.

Literature Review

analyzing demand supply networks. Next, I describe operations research methods (Fandel & Stammen, 2004; Thomas & Griffin, 1996; Vidal & Goetschalckx, 2001; Zeng & Rossetti, 2003), analytic hierarchy processes (Dotoli et al., 2005;Wang, Huang,& Dismukes, 2004), control theoretical methods (Ortega & Lin, 2004), discrete simulation methods (Persson & Olhager, 2002), and workflow net related methods (vad der Aalst, 1998a; van der Aalst, 1998b; van der Aalst & ter Hofstede, 2005; Desel & Erwin, 2000). Each of these methods fits into one of four categories: deterministic analytical, stochastic analytical, economic, or simulation (Beamon, 1998). The five methods are briefly described along with their position in Beamon's categorization.

Operations research has been used to analyze demand supply network problems at least since the early 1970s (Thomas & Griffin, 1996; Zeng & Rossetti, 2003). The first mathematical programs had drawbacks, such as the possibility of analyzing only single transport modes, but the mixed integer programs have been developed to include multiple transport modes, transfer pricing (Vidal & Goetschalckx, 2001), development and recycling costs (Fandel & Stammen, 2004). Currently, mixed integer programs are the most powerful methods of finding the single best solution for very large problems. In finding the optimum, they converge to the result rather than enumerating the entire solution space. Operations research methods are deterministic analytical, however, so they must be augmented with simulation to understand the dynamic behaviour of solutions (Riddalls, Bennett, & Tipi, 2000).

Analytic hierarchy processes (Wang et al., 2004) can be employed in situations where each level in the product hierarchy has a large number of possible suppliers. Analytic hierarchy process uses balanced scorecard approach with set criteria to determine the best supplier choices (without regard to the complete product structure) for a single component. In the second stage of the analysis, the best supplier choices for each component are fed into preemptive goal programming for the entire product structure. This approach fits in situations where there are tens or hundreds of possible suppliers for each component, and a short list is needed first. However, it also requires expert knowledge to faithfully compare one supplier against another. Analytic hierarchy process is a deterministic analytical method.

Control theoretical methods for demand supply network analysis have recently surfaced as they provide an analytical method for estimating bullwhip effects in demand supply networks (Ortega & Lin, 2004). The demand supply networks are modeled in z-space, and z-transforms are used to arrive at Bode plots for dynamic behaviour. This method can analyze only one demand supply network setup at a time, but it has the benefit of estimating system dynamics without discrete simulation. However, the modeling of supply networks in Z-space requires expert knowledge, which may be a drawback in the business environment. Control theoretical methods of demand supply network analysis are stochastic analytical in nature.

Discrete simulation methods allows for dynamic analysis of a single demand supply network (Persson & Olhager, 2002). An arbitrary demand signal may be fed to the network, and simulation determines possible stockouts and order fulfillment lead time violations. The advantage of discrete simulation over control theoretical methods is the ease of specifying input signals, and the increasing processing power of computers keeps simulation runtimes reasonable. Discrete simulation is currently viewed as a de facto standard of analyzing dynamic behaviour of demand supply networks (Riddalls et al., 2000).

Workflow nets (Van der Aalst, 1998a; Van der Aalst 1998b; Van der Aalst & ter Hofstede, 2005) have been introduced in Petri Net community to analyze the dynamics of business processes. Workflow net is a stochastic analytical method for a single demand supply network. Each DSNnet setup (topic of the current article) may be refined to a workflow net for dynamic analysis. Process nets (Desel & Erwin, 2000) have also been used in Petri Net community to analyze business processes. In this technique, the user specifies demand supply network skeletons of interest, without any cost parameters. When the interesting skeletons are determined, actual cost parameters are inserted and analysis and simulation routines are run. This approach is useful when the number of possible demand supply network skeletons and suppliers is low. However, in situations where there are thousands of possibilities, the user involvement required may be too great. The DSNnet takes a different approach. The cost parameters are specified first for all possible suppliers of components, and the possible demand supply networks are determined via reachability analysis and are ordered by average cost.

Research Methodology

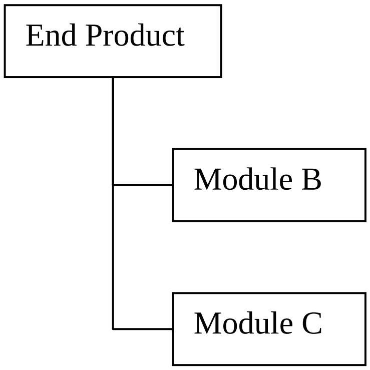
The current article uses constructive paradigm, where Petri Net theory is employed to solve a concrete business problem. The resulting solution was applied to solving demand supply network analysis problems more efficiently than earlier spreadsheet methodologies. The present work gives all the applicable decision algorithms and discusses validation issues. This research forms the foundation of an innovation diffusion study where the adoption of the presented method in Nokia is longitudinally followed. The research is done in the spirit of pragmatism (McDermott, 1976), where a theory's practical evidence is tested in real life: if it works, it is true.

DSN NET: NET FORMALISM FOR DEMAND SUPPLY NETWORKS

Introduction and Motivation

A demand supply network (DSNnet in the rest of this article) may be seen as a net whose topmost node is the combination of a product and its customer. All the nodes below contain the product's constituent modules (according to the product structure) and their alternative suppliers. Consider the simple product structure in Figure 1. The final product is called "end product," and it consists of two child modules, "Module B" and "Module C."

Figure 1. Simple product structure



An example of a scenario which a logistics professional may consider could be described as follows:

- End Product will have one customer
- End Product will have only one supplier, "End Product Manufacturer." In this case the end product is produced by the manufacturer itself, but the method also supports the analysis of contract manufacturers
- Module B can be sourced from two suppliers, and the sourcing options are:
    - Purchase all components from "Supplier 1 for Module B"
    - Buy 60 percent of the volume from "Supplier 1 for Module B" and 40 percent of the volume from "Supplier 2 for Module B"
- Module C has two suppliers and the sourcing options are:
    - Buy 100 percent of the volume from "Supplier 1 for Module C"
    - Buy 100 percent of the volume from "Supplier 2 for Module C"

Evidently the notion of choice and aggregation is vital in formalism for demand supply network options. Aggregation (AND logic) is needed for situations where a module has several parallel child modules. Choice (OR logic) is needed to describe alternative suppliers. Moreover, an OR may be immediately followed by an AND if two or more suppliers are simultaneously used to source a component in a given volume split.

The central idea of the DSNnet is to combine seamlessly the product structure and the associated demand supply network. The design of a product in parallel with its demand supply network renders a company's product design process more effective (Prasad, 1986). This mode of operation also requires specialized tool support. The logistics professional is looking for a tool where he can:

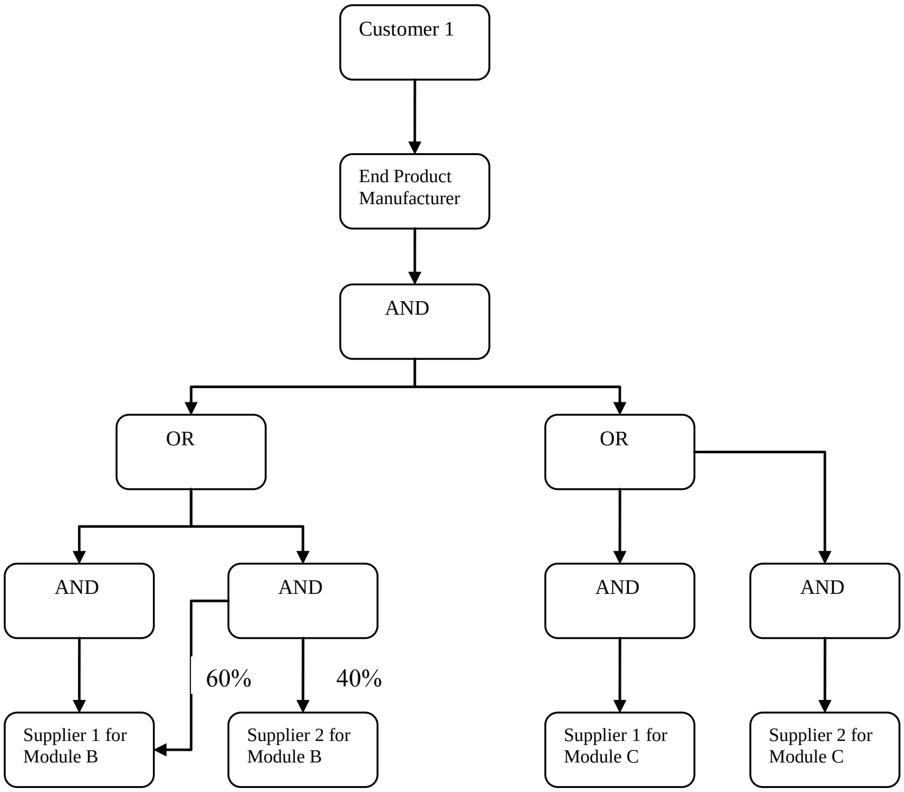
1. Choose the bill of materials for a product (key components)
2. Input the possible suppliers and associated costs for every component
3. Input the customers and their demand volumes

The logistics professional expects a computer to give all possible demand supply network combinations and associated costs for the input entered. The DSNnet instance in Figure 2 depicts the sourcing options for the product structure in Figure 1. Notice the inclusion of 'AND' nodes before single suppliers. Since volume splits between multiple suppliers are possible at every tier of the supply chain, the generic translation routine from product structure to DSNnet includes an AND-node after every OR-node. The AND node is really needed only in the 60/40 split of Suppliers 1 and 2 for Module B in Figure 2.

After the generation of DSNnet, a reachability analysis algorithm is executed to determine the demand supply network options and costs for each. For this example, there were no costs specified but the possible demand supply networks are:

1. End Product Manufacturer – 100% volume
   Supplier 1 for Module B – 100% volume
   Supplier 1 for Module C – 100% volume
2. End Product Manufacturer – 100% volume
   Supplier 1 for Module B – 100% volume
   Supplier 2 for Module C – 100% volume
3. End Product Manufacturer – 100% volume

Figure 2. DSNnet describing sourcing options for the product in Figure 1



Supplier 1 for Module B – 60% volume
Supplier 2 for Module B – 40% volume
Supplier 1 for Module C – 100% volume

4. End Product Manufacturer – 100% volume
   Supplier 1 for Module B – 60% volume
   Supplier 2 for Module B – 40% volume
   Supplier 2 for Module C – 100% volume

DSNnet does not resemble a Petri Net since the notion of transitions is missing as in Figure 2. However, between each pair of nodes a logistics network will incur , for example, freight and duty costs and these elements are included inside a transition. The transitions are not drawn in the figure for notational convenience, but Figure 3 shows an equivalent high level Petri net interpretation of a DSNnet instance. As indicated, the color of each place is the real number type and each arc contains a variable for a single real number token. Petri Net interpretations of AND and OR nodes are presented in Figures 4 and 5, respectively. AND-OR logic for Petri Nets was first introduced in (Agerwala & Flynn, 1973; Baer, 1973).

The formalism in Figure 5 satisfies the modeling requirements for network alternatives but the issue of data has not yet been addressed. The cost elements pertinent to logistics change from industry to industry, and some cost elements such as obsolescence rate per annum are very different for if one is selling bricks (low obsolescence rate) or mobile phones (high obsolescence rate). To address this requirement it is vital to have "metadata" on the types of cost elements as well as their values related to particular industry or firm. This metadata approach is adopted in the formal definitions described in the following pargraphs.

Formal Definitions

The definition of DSNnet is divided into three parts. First, I define DSNnet_skeleton (Definition 1), which gives the metadata for cost elements included in a particular company. Second, I define a particular DSNnet instance (Definition 2). Finally DSNnet system is defined in terms of high level Petri Net system with real number data types (Definition 3).

Definition 1

DSNnet_skeleton = { NodeTypes ∪{ AND_node, OR_node }, ArcTypes, ParameterPool, ParameterMap }, where

Figure 3. Showing equivalence between DSNnet and high level petri net

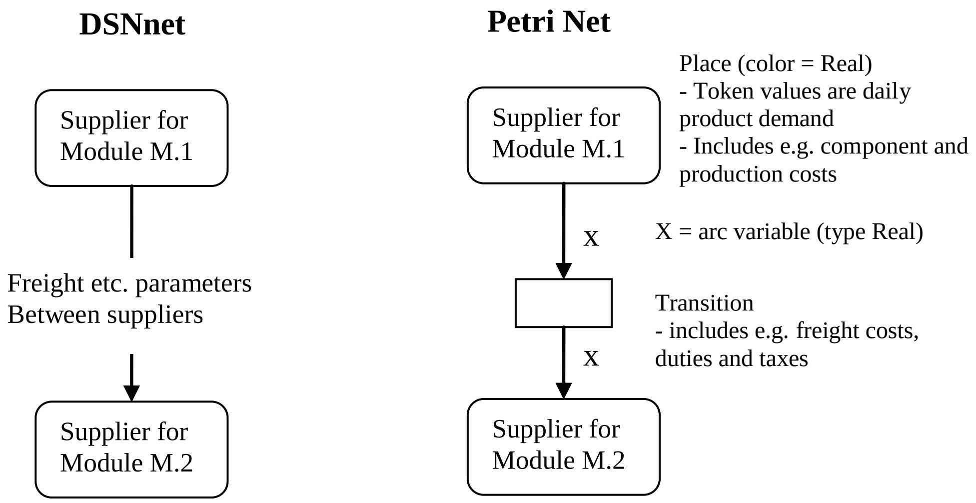


Figure 4. Semantics of DSNnet AND node

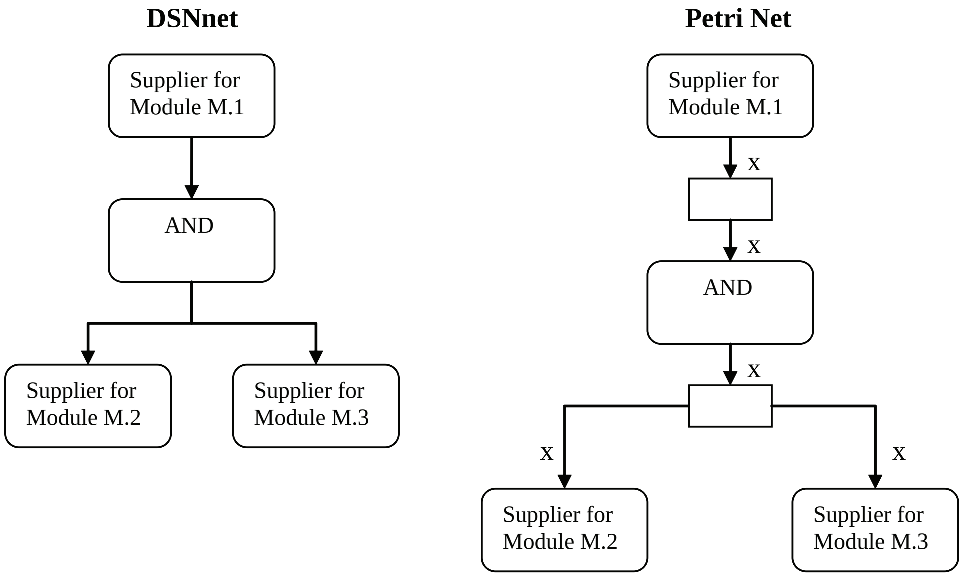

Figure 5. Semantics of DSNnet OR node

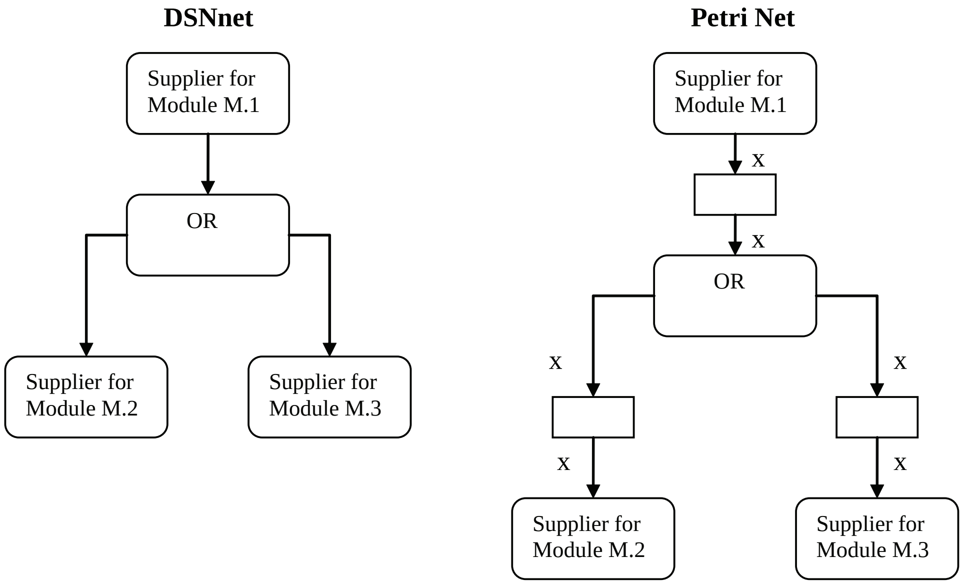

NodeTypes = types of nodes in analysis (e.g., customer, manufacturing, buffer)
ArcTypes = types of arcs in analysis (e.g., transportation arcs)
ParameterPool = collection of all cost parameters used in the analysis

$\mathit{ParameterMap} = \mathit{NodeTypes} \times 2^{\mathit{ParameterPool}} \cup \mathit{ArcTypes} \times 2^{\mathit{ParameterPool}}$

A company is responsible for defining its own DSNnet_skeleton. *NodeTypes* and *ArcTypes* are standard—customer node, manufacturing node, buffer node, and transport arc typically suffice. *ParameterPool* may differ greatly from company to company. For example, the percentage used to estimate stock obsolescence is different in ICT business as compared to construction business—value of bricks does not diminish as quickly in stock as that of unsold mobile phones or PCs. The companies in fast price erosion environments (e.g., Dell) have a stronger incentive to make their demand supply networks agile than construction material suppliers. ParameterPool may change during a company's lifetime. Finally, *ParameterMap* associates each NodeType and ArcType to the specific cost parameters associated with it. To illustrate, I show the DSNnet_skeleton in use inside Nokia Corporation.

Illustration 1 — *Nokia's DSNnet_skeleton*
{ NodeTypes = { Customer, Manufacturing, Buffer } ∪{ AND_node, OR_node},
ArcTypes = { DSNarc },
ParameterPool = { bill of materials cost, buffer inventory carrying cost, transport inventory carrying cost, freight cost, production cost, investment cost, duty cost, tax cost, manufacturing line verification cost, sales volume }, ParameterMap = { Customer node →{ sales volume }, Manufacturing node →{ bill of materials cost, production cost, investment cost, line verification cost },Buffer node →{ buffer inventory carrying cost }, DSNarc →{ transport inventory carrying cost, freight cost, duty cost, tax cost }}}

Definition 2 — *DSNnet*
DSNnet = { Nodes, Arcs, F, DSNnet_skeleton, Typing, Valuation}, where
Nodes = set of Nodes (Petri Net places, color = Real)
Arcs = set of Arcs (Petri Net transitions, transition guards are TRUE)
F = Nodes × Arcs ∪Arcs × Nodes, each arc's inscription is X, a Real number variable
DSNnet_skeleton = as defined above
Typing = Nodes × DSNnet_skeleton.NodeTypes ∪Arcs × DSNnet_skeleton.ArcTypes
Valuation = V(Nodes, Arcs, Typing) – a function that assigns relevant parameter values to each node and arc according to its type (joint responsibility of tool user and the user interface in real world)

Definition 3 — *DSNnet_system*
DSNnet_system = $\{ DSNnet, Nodes_0, M_0 : Nodes_0 \rightarrow Real \}$
A DSNnet_system has a valid DSNnet structure, a set of initial nodes (Customer nodes) $Nodes_0$*, and initial marking* M_0 *that maps a single token of type Real to each initial node (this value represents a customer's average daily demand for a certain product).*
The firing rule for DSNnet_system is that of High Level Petri Nets.

REACHABILITY ANALYSIS OF DSN NET

The traditional Petri Net reachability analysis algorithm computes all reachable system states. In DSNnet formalism, reachability analysis differs in two important points:

1. The algorithm computes all possible paths of a system (valid DSNnet structures are directed and acyclic, guaranteeing the absence of infinite paths)
2. The algorithm allows for several initial states, and aggregates the separate reachability graphs to a single result

The result of the reachability analysis is a list of complete paths in the DSNnet, each associated with a cost. The optimum path is the one with the lowest cost. In DSNnet context, a reachability graph is an array of arrays (matrix) where each component array (matrix column) is one demand supply network setup with its cost.

The pseudocode for the algorithm is presented next. RG is used as a shorthand for “reachability graph,” and arrays are indexed in C language style from 0 to array_size-1. The pseudocode uses four helper functions: *append_node*, *append_RG*, *aggregate_RG* and *add_per_item_costs*. *Append_node* appends a node (first argument) to all paths in the reachability graph (second argument). *Append_RG* joins two reachability graphs to form a single reachability graph—that is, the appending of RG1 with 5 paths and RG2 with 3 paths results in a single RG with eight paths. *Aggregate_RG* takes the Cartesian product of two reachability graphs, where each path in the resulting reachability graph has a cost equal to the sum of the two constituents. The Cartesian product of RG1 with 5 paths and RG2 with 3 paths has 15 paths. Finally, *add_per_item_costs* adds the costs of an arc or a node (the first argument) to each path in the reachability graph (the second argument). The preliminary version of the algorithm has been published in Tynjälä (2006).

Main DSNnet Analysis Routine

The main analysis routine is given in Figure 6. The investment costs are computed last because several customers can source their products from the same suppliers (manufacturing nodes). The total volumes for each supplier are known when the second for-loop has been executed. The second for loop—aggregation of individual customers’ reachability graphs—is also the source of the algorithm’s computational complexity. For, assume that we have C customers and P is the maximum of the number of DSN setup options for a customer. Then the size of the state space (and computation time) grows exponentially as $O(P^C)$. Parallelizing this part of the algorithm is included in the topics for future research.

Reachability Analysis Routine for a Single Customer Node

The algorithm that computes the reachability graph for one customer is presented in Figure 7. It follows the traditional reachability analysis algorithm with the addition of AND and OR nodes.

Computation of Investment Costs

This part of the algorithm computes investment costs that depend on production volume in a stepwise manner. For example, if a manufacturing line capacity for a particular phone is 7,500 phones per day, this algorithm computes the number of needed manufacturing lines based

Figure 6. Main analysis routine

```
RG_main(DSNnet_system — see Definition 3) returns all DSN setups with cost {
    RG[] = array of new Reachability Graphs;
    total_RG = new Reachability Graph;
    for each initial customer node do
        RG[i] = RG_1_customer(customer_node[i]);
    end
    for i = 0..number of customer nodes -1 do
        total_RG = aggregate_RG( total_RG, RG[i]);
    end
    for each path in total_RG do
        investment_cost = compute_investments(path);
        add investment_cost to the path’s cost;
    end
    return total_RG;
}
```

Figure 7. Reachability analysis routine for a single customer

```
RG_1_customer(Start Node with volume marking, Start RG) returns RG  {
    RG[] = array of empty Reachability Graphs;
    theChildNodes[] = Array for children of AND and OR nodes;
    theChildArcs[] = Array for arcs leading to theChildNodes;
    Add volume marking to Start Node's total volume;
    if Start Node has 0 children then
        append_node(Start RG, Start Node);
        Start RG = add_per_unit_costs(Start RG, Start Node, NULL);
        return Start RG;
    else if Start Node has 1 childNode then
        childArc = DSN Arc between Start Node and childNode;
        append_node(Start RG, Start Node);
        Add volume marking from Start Node to childNode and childArc;
        Start RG = RG_1_customer(childNode, Start RG);
        Start RG = add_per_unit_costs(Start RG, Start Node, childArc);
        return Start RG;
    else if Start Node is AND then
        total_RG = new Reachability Graph;
        append_node(Start RG, Start Node);
        Add the volume marking to theChildNodes[] and theChildArcs[];
        for each theChildNodes[i] do
            RG[i] = RG_1_customer(theChildNodes[i], RG[i]);
        end
        for i = 0..number of Child Nodes-1 do
            total_RG = aggregate_RG(total_RG, RG[i]);
        end
        total_RG = aggregate_RG(Start RG, total_RG);
        return total_RG;
    else if Start Node is OR then
        total_RG = new Reachability Graph;
        append_node(Start RG, Start Node);
        Add the volume marking to theChildNodes[] and theChildArcs[];
        for each theChildNodes[i] do
            RG[i] = RG_1_customer(theChildNodes[i], RG[i]);
        end
        for i = 0..number of Child Nodes-1 do
            total_RG = append_RG(total_RG, aggregate_RG(Start RG, RG[i]));
        end
       return total_RG;
}
```

on total volume throughput, and calculates the needed investments.

Algorithm Validation

The algorithm was validated in two steps. First, a series of tests with different product structures and customers was carried out to ensure that the paths were computed correctly. This step concentrated on the correct functioning of the AND and OR nodes which were our additions to the traditional reachability analysis algorithm. In the second phase, the cost figures obtained for a single setup were compared with those obtained from the previous spreadsheet-based tool. The second validation phase uncovered some errors in cost computation, which were corrected and revalidated.

Figure 8. Computation of investment costs

```
compute_investments(one DSN setup) returns InvestmentCost {
    for each manufacturing node in setup do
        determine total volume throughput;
        determine number of manufacturing lines;
        InvestmentCost = InvestmentCost + (no. of manuf. lines * investment per line);
     end
     return InvestmentCost;
      }
```

NOKIA IMPLEMENTATION AND CASE STUDY

Tool Implementation Method

The tool based on the previously mentioned formalism was developed in Java2 language, and embedded in the Oracle environment hosting demand supply planning data repository. The tool's Web user interface lets the logistics managers specify product structures, and costs for alternate suppliers. Common data such as transportation costs between cities, duty and tax rates are centrally updated by few key users. The Web UI has "analyze" button associated which invokes the Java algorithm. The Java algorithm first reads the database tables for product and supplier information, constructs the corresponding DSNnet instance, and runs the reachability analysis on it. Final results are stored in database tables and displayed in Web browser. Permissions to view data are granted in such a way that a normal user may see only his work when using the tool. Key users for each business group have view of all programs in that business unit. Finally, the global logistics directors see all programs in every business unit. The next subsection contains a real example of an analysis case for a product that started shipping in the summer of 2006.

Analysis of a New Handset

The product structure for the new handset that started to ship in the summer of 2006 is shown in Figure 9.

As indicated in the diagram modules A, B, and H had 2 supplier options, with the rest having a single decided supplier. For a single customer this product structure produces 8 (2*2*2) demand supply network setups. The analysis covered two customers, so the total number of demand supply networks came to 64 (8^2). Interestingly, the static costs for the alternative suppliers of modules A, B, and H (e.g., production costs, investment costs) were not radically different. However, their global position was such that the buffering and transportation costs associated with the total demand

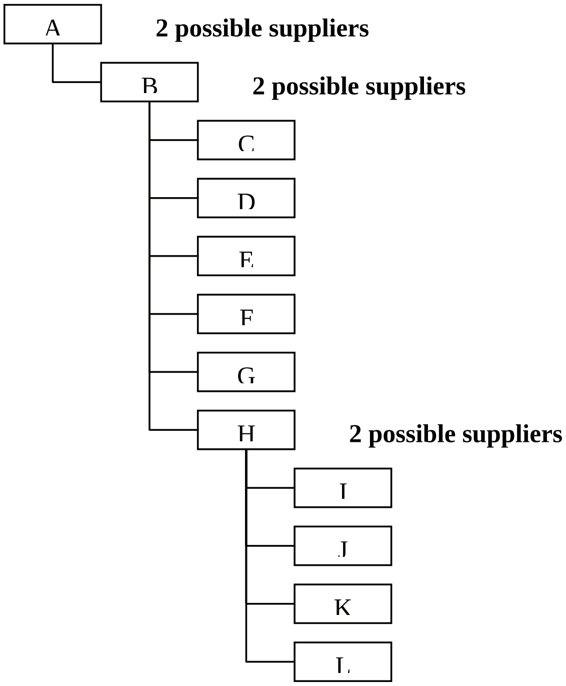

Figure 9. Product structure of a recently released Nokia handset

supply network were significantly different from one solution to another. For this product, whose expected lifetime is one year, the demonstrated cost differences from the cheapest to the most expensive demand supply network were ca. 15 Million Euros. The analysis tool was able to compute these 64 solutions in approximately 10 seconds, whereas the spreadsheet solution would have required several days (5 days with the optimistic target of 10 demand supply networks analyzed per day) to complete the job. The Nokia logistics team has established a target of one-week lead time for all demand supply network analyses (i.e., each week a new analysis report is generated based on the most current data). The spreadsheet method could not support this requirement because of time required for hand-generation of networks. With the new tool, this leadtime is feasible. The next subsection gives sample analysis times for problems of different complexity.

Usage and Performance Data in Nokia Environment

The tool has been actively used inside Nokia's business groups since February 10, 2005. The number of concrete product programs studied is over 200 at the end of July 2006. A product program represents a possible handset or network element under development that may or may not come to the market. The granularity of analyses is different in each business unit. The handset business units, where the volumes are large, consider few big customers, usually representing sales areas. The network business, where volumes are lower, relative logistics costs higher, and margins thinner, the granularity is more precise. The customers are modeled at least on a country level.

The typical performance of the tool is shown in Table 1. These measurements were single data points taken during a typical working day. The response times of the tool are practically the same globally, as the transport delays are small compared to the analysis time.

Table 1. Sample response times of Petri Net tool

Number of DSN Alternatives	Analysis time (sec)
4	0.5
16	2
64	7
256	40
1024	290

DISCUSSION AND FUTURE WORK

Applying Petri Nets and reachability analysis to demand supply network optimization has the benefit of exploring the complete state space of options. In wake of risks on the demand supply network, it is vital to explore also the expensive options for future contingencies.

I developed a high level Petri Net model expanding on the AND-AND, AND-XOR formalisms presented in (Baer, 1973; Agerwala, 1973), along with the associated reachability analysis algorithm. The Petri Net model is general and it may be employed in various types of businesses. In terms of expressive power, DSNnet stays within the normal Petri Net confines.

A tool based on the DSNnet methodology was developed during 2004 inside Nokia Corporation, and it has been in active use since February, 2005. The tool has been used in all business units and the results are very positive. The users have especially thanked the possibility of designing the product structure together with its demand supply network, which was not possible with the former spreadsheet methods.

The current reachability analysis algorithm is exponential, which may be a hindrance to some of the larger analyses, and finding the optimal supply network with mixed integer programming is much faster. However, a parallelized version of the reachability analysis algorithm could alleviate this problem and is part of the list of future research.

The work relating to DSNnet tool inside Nokia is ongoing, and the second release of the tool will become operational in October, 2006. This release enhances the tool with multimodal transport capabilities and improved duty and tax considerations. In the future, the tool is envisioned to become integrated to a data warehouse, which updates the cost and transport parameters automatically based on actual business transactions.

Chapter 7.11

Empirical Assessment of Factors Influencing Success of Enterprise Resource Planning Implementations

Fiona Fui-Hoon Nah

Zahidul Islam
Independent University, Bangladesh

Mathew Tan
Agilent Technologies, Malaysia

ABSTRACT

Enterprise resource planning (ERP) implementations in multinational manufacturing companies have experienced various degrees of success. This article investigates factors influencing the success of ERP implementations in multinational manufacturing companies in the Malaysian Free Trade Zone. The results indicate that enterprise-wide communication and a project management program are key factors influencing the success of ERP implementations, while other factors such as top management support as well as teamwork and composition are not as critical to the outcome. Organizational culture is a moderator of the relationships between enterprise-wide communication, a project management program, and the success of ERP implementations.

INTRODUCTION

Enterprise resource planning (ERP) refers to a seamlessly integrated family of software packages designed to integrate various financial, human resources, supply chain, and customer information functions. This system is a natural development and progression of Material Requirements Planning (MRP/MRP II) that was popular in the 1970's. Initially conceived to increase the efficiency of materials planning, the suite of software packages eventually evolved to cover a wide scope of organizational functions, including inventory control, finance, human resources, and manufacturing. Many companies experienced successes, but many more failed in their implementations. Some companies, such as FoxMeyer Corporation, experienced bankruptcy and resorted to suing the software company for failing to deliver the promises of the ERP system.

ERP implementation is a massive and costly affair (Davenport, 2000; Lee, Siau, & Hong, 2003; Siau, 2004). ERP implementations frequently consume a large portion of a company's time and resources (Siau & Messersmith, 2002, 2003). After more than twenty years of implementation and software development, much research has been gathered on the subject for developed nations (Bingi, Sharma, & Godla, 1999; Everdingen, Hilleegersberg, & Waarts, 2000; Kermers & van Dissel, 2000; Kumar, Maheshwari, & Kumar, 2003; Nadkarni & Nah, 2003; Scott & Vessey, 2002). However, the Southeast Asia region faced many challenges with ERP implementations (Davison, 2002; Soh, Sia, & Tay-Yap, 2000). The literature is scarce concerning ERP implementations and their success in this region (Tarafdar & Roy, 2003). The primary users of ERP systems are large multinational companies because local or regional small- to medium-sized companies have yet to fully embrace the benefits of ERP systems. In this research, we focus on investigating the factors contributing to the success of ERP implementations in multinational manufacturing companies in the Malaysian Free Trade Zone—a central zone in Southeast Asia.

LITERATURE REVIEW

ERP is a solution to fragmentation of information in large business organizations (Davenport, 1998). An ERP system typically comprises a central, state-of-the-art, comprehensive database that collects, stores, and disseminates data across all business functions and activities in an enterprise. By integrating all business functions, economies of scale are obtained and the business gains a significant operating cost reduction, in addition to improved capabilities and information transparency. The increased business trends of globalization, mergers, and acquisitions demand that companies must have the ability to control and coordinate increasingly remote operating units. An ERP system can help to achieve this by enabling the sharing of real-time information across departments, currencies, languages, and national borders.

The dream of creating an enterprise-wide system began in the 1970's, but was then unrealized due to the technological barriers at that time. Instead, most companies created what McKenney and McFarlan (1982) termed "islands of automation", which naturally evolved as new IT applications were introduced to fill the constantly-emerging business needs. This gave rise to a plethora of different systems that were loosely interfaced. As a result, information was scattered throughout an organization, and detailed analyses of an organization's performance across its business functions were not possible. Such information was impossible to obtain unless manual record-sifting or specialized programming requirements were carried out. In time, the organizational costs to maintain these "legacy" systems began to exceed the funds available for building new systems (Lientz & Swanson, 1980).

Enterprise systems provide a backbone of information, communication, and control for a company (Buckhout, Frey, & Nemec, 1999), and embody the current best business practices for organizational processes (Esteves & Pastor, 2000). Numerous benefits include improvements in:

- Cooperation between managers and employees;
- Consolidation of finance, marketing and sales, human resource, and manufacturing applications;

- Management information available—real-time information available anywhere, anytime;
- Informal systems for materials management/inventory/production control;
- Lead-times, manpower costs, overtime, safety stocks, work-in-progress; and
- Delivery times.

An ERP system is a set of customizable and highly-integrative real-time business application software modules sharing a common database and supporting core business, production, and administrative functions such as logistics, manufacturing, sales, distribution, finance, and accounting. Companies that are structurally complex, geographically dispersed, and culturally vibrant tend to present unique challenges to ERP implementation (Markus, Tanis & Fenma., 2000). Unique issues of change management are particularly important for multinational companies where their parent sites are geographically separate. This complexity involves several dimensions including business strategy, software configuration, technical platform, and management execution. Of these four, management execution contributes toward ERP implementation success to the greatest degree (Nah, Zuckweiler, & Lau, 2003). Different managerial reporting lines, languages, and national cultures also make managing a multi-site ERP implementation project challenging (Markus et al., 2000). Local management must therefore be prepared to deal with the issues of enterprise-wide implementation on a site level. In particular, companies in Asia confront issues substantially different from those faced by companies in the developed world (Tarafdar & Roy, 2003) due to the differences in sophistication of IT use and cultural influences.

THEORETICAL BACKGROUND ON FACTORS CONTRIBUTING TO ERP IMPLEMENTATION SUCCESS

To investigate specific metrics for ERP implementation success, we reviewed the literature and identified three sets of taxonomy or classification. They are: (i) the unified critical success factors model (see Table 1) proposed by Esteves and Pastor (2000), (ii) 22 critical success factors (see Table 2) identified by Somers and Nelson (2001, 2004), and (iii) seven broad categories of critical success factors (see Table 3) developed by Nah

Table 1. Unified critical success factors model

	Strategic	Tactical
Organizational	• Sustained management support • Effective organizational change management • Good project scope management • Adequate project team composition • Comprehensive business process reengineering • Adequate project champion role • User involvement and participation • Trust between partners	• Dedicated staff and consultants • Strong communication inwards and outwards • Formalized project plan/schedule • Adequate training program • Preventive troubleshooting • Appropriate usage of consultants • Empowered decision-makers
Technological	• Adequate ERP implementation strategy • Avoid customization • Adequate ERP version	• Adequate software configuration • Legacy systems knowledge

and Delgado (2006) which were derived from the 11 critical success factors (see Table 4) identified by Nah, Lau, and Kuang (2001).

Esteves and Pastor (2000) classify critical success factors into Organizational and Technological, and then further sub-divide them into strategic and tactical factors. By cross-referencing each of the factors with its citations in the literature, Esteves and Pastor (2000) derived the ERP implementation success matrix (also termed unified critical success factors model) presented in Table 1.

Somers and Nelson (2001) identified 22 critical success factors presented in Table 2 and evaluated them across stages of ERP implementation. The top six factors across the stages are: (i) top management support, (ii) project team competence, (iii) inter-departmental cooperation, (iv) clear goals and objectives, (v) project management, and (vi) inter-departmental communication.

Another comprehensive examination of the critical success factors of ERP implementation was carried out by Nah and her colleagues (Nah, et al., 2001; Nah, et al., 2003; Nah & Delgado, 2006). These factors fall into seven broad categories (see Table 3) and can be further broken down into 11 critical success factors (see Table 4).

Among the 11 critical success factors presented in Table 4, the top six critical success factors identified by Chief Information Officers of Fortune 1000 companies are: (i) top management support, (ii) project champion, (iii) ERP teamwork and composition, (iv) project management, (v) change management program and culture, and (vi) effective enterprise-wide communication (Nah et al., 2003).

Hence, top management support, project management, and enterprise-wide (or inter-departmental) communication are three common factors in Nah et al.'s (2003) and Somers and Nelson's (2001) "top factors" lists, whereas "ERP teamwork and composition" in Nah et al.'s (2003) list captures key aspects of project team competence and inter-departmental cooperation in Somers and Nelson's (2001) list. Therefore, we selected this set of four factors—top management support, project management, enterprise-wide communication, and ERP teamwork and composition—as independent variables for our study. These four factors are also ranked among the top five factors in Nah and Delgado's (2006) case study on ERP implementations in two organizations.

Figure 1 shows the research model, and the next section provides justifications for the hypotheses.

Hypotheses 1-4 specify the direct hypothesized effect of the independent variables—top management support, teamwork and composition, enterprise-wide communication, project management program—on the dependent variable—success of ERP implementation, whereas Hypotheses 5-8 state the moderating effect of organizational culture on these relationships.

Table 2. Twenty-two critical success factors model

Critical Success Factors
1. Top management support
2. Project team competence
3. Interdepartmental cooperation
4. Clear goals and objectives
5. Project management
6. Interdepartmental communication
7. Management of expectations
8. Project champion
9. Vendor support
10. Careful package selection
11. Data analysis and conversion
12. Dedicated resources
13. Use of steering committee
14. User training on software
15. Education on new business processes
16. Business process reengineering
17. Minimal customization
18. Architecture choices
19. Change management
20. Partnership with vendor
21. Use of vendors' tools
22. Use of consultants

Table 3. Seven broad categories of critical success factors

No.	Factor
1.	**Business plan and vision**
1.1	Business plan/vision
1.2	Project mission/goals
1.3	Justification for investment in ERP
2.	**Change management**
2.1	Recognizing the need for change
2.2	Enterprise-wide culture and structure management
2.3	Commitment to change—perseverance and determination
2.4	Business process reengineering
2.5	Analysis of user feedback
2.6	User education and training
2.7	User support organization and involvement
2.8	IT workforce re-skilling
3.	**Communication**
3.1	Targeted and effective communication
3.2	Communication among stakeholders
3.3	Expectations communicated at all levels
3.4	Project progress communication
4.	**ERP team composition, skills, and compensation**
4.1	Best people on team
4.2	Balanced or cross-functional team
4.3	Full-time team member
4.4	Partnerships, trust, risk-sharing, and incentives
4.5	Empowered decision-makers
4.6	Performance tied to compensation
4.7	Business and technical knowledge of team members and consultants
5.	**Project management**
5.1	Assign responsibility
5.2	Clearly establish project scope
5.3	Control project scope
5.4	Evaluate any proposed change
5.5	Control and assess scope expansion requests
5.6	Define project milestones
5.7	Set realistic milestones and end dates
5.8	Enforce project timeliness
5.9	Coordinate project activities across all affected parties
5.10	Track milestones and targets
6.	**Top management support and championship**
6.1	Approval and support from top management
6.2	Top management publicly and explicitly identifies project as top priority
6.3	Allocate resources
6.4	Existence of project champion
6.5	High-level executive sponsor as champion
6.6	Project sponsor commitment
7.	**Systems analysis, selection, and technical implementation**
7.1	Legacy system
7.2	Minimum customization
7.3	Configuration of overall ERP architecture
7.4	Vigorous and sophisticated testing
7.5	Integration
7.6	Use of vendor’s development tools and implementation methodologies
7.7	ERP package selection
7.8	Selection of ERP architecture
7.9	Selection of data to be converted
7.10	Data conversion
7.11	Appropriate modeling methods/techniques
7.12	Troubleshooting

Table 4. Eleven key critical success factors

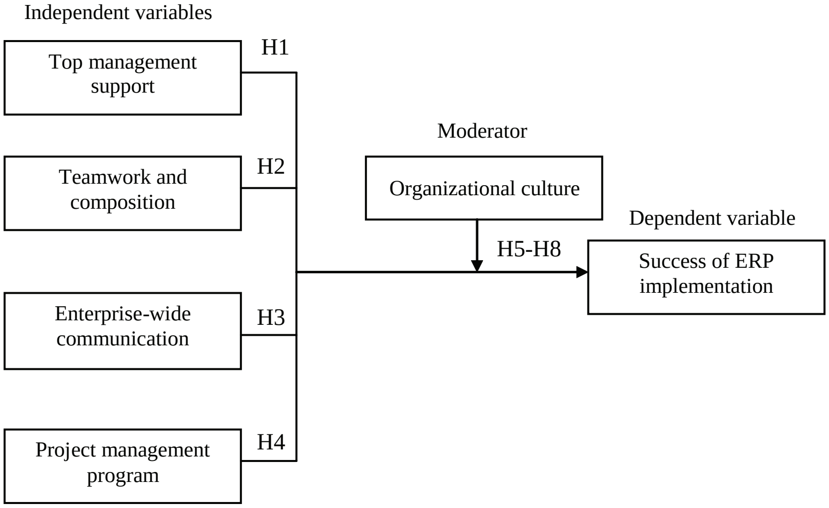
Critical Success Factors
1. ERP teamwork and composition
2. Change management program and culture
3. Top management support
4. Business plan and vision
5. Business process reengineering with minimum customization
6. Project management
7. Monitoring and evaluation of performance
8. Effective enterprise-wide communication
9. Software development, testing, and troubleshooting
10. Project champion
11. Appropriate business and IT legacy systems

ERP CRITICAL SUCCESS FACTORS

Rockart (1979) is one of the first researchers to study critical success factors of IT implementations. According to his account, these factors are the “areas in which results, if they are satisfactory, will ensure successful competitive performance for the organization” (p. 85).

Most of the literature in the MIS field list in excess of 20 critical success factors (Nielsen, 2002). Esteves and Pastor (2000) present a unified model of critical success factors, and further studied the effects of these factors in SAP’s ASAP

Figure 1. Research model



implementation methodology. To study key critical factors influencing ERP implementation success, we identified four "top" factors—top management support, ERP teamwork and composition, enterprise-wide communication, and project management program—that we examine in this research. Technological factors such as system configuration, customization, and legacy data migration are outside the scope of this research and are excluded from this study.

Top Management Support

Not only is the criticality of top management support widely cited throughout the ERP literature (e.g., Dong, 2001; Somers & Nelson, 2004), several studies (Akkermans & van Helden, 2002; Esteves & Pastor, 2000; Nah et al., 2003; Somers & Nelson, 2001) have also identified top management support as the top and most crucial factor in ERP implementation. Similarly, Sarker and Lee (2003) identified strong and committed leadership as a necessary condition for success in ERP implementation. Willocks and Sykes (2000) noted that senior-level sponsorship, championship, support, and participation is one of the critical enabling factors for success in an ERP project. Public, explicit, and sincere support for the project must be present to emphasize the priority of the project. Accordingly, commitment of valuable resources to the implementation effort (Holland, Light, & Gibson, 1999; Roberts & Barrar, 1992) provides the practical support that is needed to ensure success in an ERP project. Top management commitment is the most widely-studied factor in successful IS implementations (Dong, 2001) and is also the most severe source of difficulty in IS implementations. Top management support is even more important in the case of ERP because of the scale of the project and the amount of resources needed for the enterprise-wide project. Hence, we hypothesize that:

H1: *Top management support increases the level of success of ERP implementation.*

Teamwork and Composition

The ERP team should comprise the best people in the organization to maximize the chances of success of the project (Buckhout et al., 1999; Bingi et al, 1999; Rosario, 2000). The team should be cross-functional and possess the necessary technical and functional skills for design, implementation, and assimilation. The team will have to integrate business functions with the capabilities of the software as well as possess the necessary credentials to influence business process changes where necessary. The effective use of consultants also improves the likelihood of success of the project (Haines & Goodhue, 2003). Compensation, incentives, and the mandate for successfully implementing the system on time and within budget should be given to the team to foster teamwork in the project (Buckhout et al., 1999). It is also helpful to ensure that the ERP team is colocated to facilitate teamwork and coordination among the members. We, therefore, hypothesize that:

H2: *The use of cross-functional teams that comprise people with the best business and technical knowledge increases the level of success of ERP implementation.*

Enterprise-Wide Communication

Communication across the different levels and functions of an organization is necessary for success in ERP implementation (Akkermans & van Helden, 2002; Falkowski, Pedigo, Smith, & Swanson, 1998; Parr, Shanks, & Darke, 1999). Communication is a complex factor that includes, but is not limited to, specifications of individual roles and responsibilities, clear definitions of the project milestones, pre-implementation training, and unambiguous definition of the time horizon (Petroni, 2002). Monthly bulletins, newsletters, weekly meetings, and frequent e-mail updates are among the tools that can be employed. This communication needs to be two-way to avoid design gaps that can occur if the exact business requirements or comments and approval from the ground up are ignored. Esteves and Pastor (2000) also noted that both "outward" communication to the whole organization and "inward" communication to the project team are very important.

Rosario (2000) advocates an early "proof of concept" to minimize skepticism and sustain excitement. This kind of demonstration should be public and well endorsed by key project champions and top management. Keeping the morale high and convincing the users that the new ERP system is of benefit while convincing them to abandon the old, comfortable systems requires persuasiveness and acts of showmanship on the part of management and the implementation team. Users need to know that the feedback they provide will be considered and acted upon (Rosario, 2000). Among the stakeholders of companies studied by Holland et al. (1999), it was found that communication is a critical success factor of ERP implementation. For example, Shanks, Parr, Hu, Corbitt, Thanasankit, and Seddon (2000) found that the likelihood of ERP implementation failure increased when dates were not properly communicated well in advance to stakeholders.

Based on the above discussion, we hypothesize that:

H3: *Enterprise-wide communication during the implementation increases the level of success of ERP implementation.*

Project Management Program

The proper and effective management of an ERP project is essential for its success (Nah et al., 2003). An ERP project management program requires well-defined task assignments, accounting for resource allocations, project control-keeping, and avoiding "creep" (Bagranoff & Brewer, 2003; Rosario, 2000) which is the tendency of the project to acquire additional software requirements and customization and to uncover hidden issues as time goes by. Jiang, Klein, and Balloun (1996) found that a competent project manager is the second most important factor in an IS implementation. The scope of the project should be clearly established, managed, and controlled (Shanks et al., 2000). Ross (1999) indicated that establishing program scope is the key to successful ERP implementation. Proposed changes should be evaluated against business benefits, and scope expansion requests should be assessed in terms of the additional time and cost of proposed changes (Sumner, 1999). In addition, approved changes need to be coordinated across all affected parties (Falkowski et al., 1998). Schniederjans and Kim (2003) proposed that ERP systems implementations can be supplemented by Total Quality Management (TQM) and Business Process Re-engineering (BPR) programs to prepare an organization to be more receptive to the new ERP system. They suggested that the actual ERP implementation be preceded by BPR and followed up by a rigorous TQM program, to produce the effect of Lewin's (1951) recommended change criteria of unfreezing (BPR), change (ERP), and refreezing (TQM).

As discussed above, project management is essential to the success of ERP implementations. Thus, we hypothesize that:

H4: *A project management program increases the level of success of ERP implementation.*

ORGANIZATIONAL CULTURE

The organizational culture paradigm, as defined by Johnson and Scholes (2005), is a set of assumptions held relatively in common and taken for granted in an organization. It includes collective experience, values, beliefs, and behavioral norms. These assumptions exist at the organizational level, and they have worked well enough to be considered valid. An organizational culture that promotes learning and innovation can be especially influential to the success or failure of an organization's IT innovation or strategy (Johnson & Scholes, 2005; Sitkin, 1992). Scott and Vessey (2000) provide case study evidence to show that organizational culture can impact the success or failure of ERP implementation.

According to Sitkin (1992), the proximity of an organization towards a "learning" state would, in theory, greatly facilitate the process of change. An organizational culture that promotes learning encourages involvement/participation and adaptation. Edwards and Panagiotidis (2000) support the proposition that organizational culture is useful in understanding successful ERP implementations. They proposed a Business Systems Purpose Analysis (BSPA) methodology and recommended its integration into SAP's ASAP implementation methodology.

Skok and Legge (2002) highlight the importance of cultural as well as business process changes. According to them, ERP problems commonly lie in the employees feeling uncomfortable with the cultural changes, which follow from process changes in the ERP implementation. Thus, unless the organizational culture promotes openness in communication and facilitates learning, the employees may behave in a detrimental fashion towards the new ERP system, causing its failure.

Organizational Culture as a Moderator of ERP Implementation Success

A management team that readily accepts new concepts and is able to learn to accept and adapt to new tools as they become available is able to drive the implementation of a new enterprise-wide system more effectively, as opposed to a management team that prefers to maintain the "status quo" and is suspicious of progress (Dong, 2001). Since learning in an organization needs to be led from all levels of the organization, particularly from top-level management, a management team that is conducive to change (as in the case of an open and supportive organizational culture) is more likely to convince and persuade the rest of the organization to follow suit, which contributes toward the success of the ERP implementation.

H5: *Organizational culture moderates the relationship between top management support and the success of ERP implementation.*

ERP implementation teams are by necessity cross-functional, as the new system brings together and integrates the various functions within an organization. In order to derive the best benefits from the ERP system, the cross-functional teams working on the project should not only be able to work well together, but also understand and appreciate the different strengths and skills that each member brings to the teams. Closed or non-learning organizations are more prone to encounter difficulties in facilitating teamwork and coordination among members of cross-functional teams.

H6: *Organizational culture moderates the relationship between ERP teamwork-and-composition and the success of ERP implementation.*

An organizational culture that promotes openness in communication facilitates the process of organizational learning, which contributes toward ERP implementation success. An open and supportive organizational culture encourages increased interaction and improved communication, which help to facilitate communication of new and complex concepts of ERP systems to the end-users. Since the sheer scale and complexity of an ERP system will require almost all company personnel to learn new tools and new ways of working, organizational culture can facilitate the learning process involved in such implementations that are necessary for successful implementation.

H7: *Organizational culture moderates the relationship between enterprise-wide communication and the success of ERP implementation.*

Team leaders faced with the challenge of managing a project this massive typically face tight deadlines and a near-impossible means of disseminating all the required training to end-users. Furthermore, the leaders of the project team need to clearly specify responsibilities, establish and control project scope, evaluate any proposed change, assess scope expansion requests, define and set project milestones, enforce timeliness of the project, and coordinate project activities across all affected parties. Thus, a learning culture benefits these processes and increases the success of the implementation.

H8: *Organizational culture moderates the relationship between a project management program and the success of ERP implementation.*

SUCCESS OF ERP IMPLEMENTATION

The dependent variable in this study is success of EPR implementation. "Success" can be defined in several ways. For project leaders, a successful implementation means that the project is completed on time and within budget and where there is minimal disruption to product shipment and customer service during the cutover period. However, from a strategic point of view, success does not only refer to meeting the "Go Live" date, but also to the increased value of the business from usage of the new ERP system.

Markus and Tanis (2000) also pointed out that success means different things depending on the perspectives that one is taking and the person defining it. For example, project managers often define success in terms of completing the project on time and within budget. The business, however, takes the view of a smooth transition to stable operations with the new system, achieving intended business improvements like inventory reductions, and gaining improved decision-support capabilities (Markus & Tanis, 2000). Markus and Tanis define optimal success as the "best outcomes the organization could achieve with enterprise systems, given its business situation, measured against a portfolio of project, early operational, and longer-term business results metrics" (p. 186). Similarly, in this study, we will adopt the business value and performance perspective of success in ERP implementation. This perspective is also adopted by other researchers studying IS/IT success (Langdon, 2006; Mukhopadhyay, Kekre, & Kalathur, 1995; Tallon & Kraemer, 2006).

Petroni (2002) pointed out that simply asking users to rate their level of satisfaction would not be accurate or sufficient to assess success of an implementation. Neither would it be practical to ask a manager to define an implementation as anything less than successful, since no one is typically willing to shoulder the responsibility of failure. Petroni therefore suggests a set of criteria for judging the success of implementation (see Table 5) to help minimize respondent bias. We adapt Petroni's criteria, which include assessment of both performance and user satisfaction, to quantify optimal success from the business and strategic perspective. These criteria are also in line with Gable, Sedera, and Chan's (2003) measurement model for enterprise system success which covers organizational and individual impact as well as user satisfaction.

RESEARCH METHODOLOGY

The primary source of data collection was a survey, which was administered to both managerial and non-managerial staff from multinational companies in the Free Trade Zone of Malaysia. These companies had implemented ERP systems and were involved in distribution and manufacturing activities. The survey questionnaire was adapted from Nah et al. (2003) and Petroni (2002), and is presented in the Appendix. Pilot studies were conducted to validate these measures prior to finalizing the questionnaire. The primary means of distributing the survey questionnaire was via e-mail. The questionnaire was distributed after pre-contacting the recipients and informing them about the pending survey. Two hundred copies of the questionnaire were distributed, and the responses were collected electronically over a three-month period. A total of 110 questionnaires were returned. Hence, the response rate is 55%.

RESULTS

Respondents were asked to provide demographic information. Analysis of the demographic data indicates that 63% of the respondents were male and 37% were female. In terms of education, 66%

Table 5. Optimal success criteria

Improved ability	Ability to meet volume/product changes Capacity planning Cost estimation Inventory control Delivery dates Production scheduling
Improved efficiency and user satisfaction	Cooperation between managers and employees Coordination between finance, marketing, and sales
Reductions	Delivery or lead-times Informal systems for materials management Informal systems for inventory control Informal systems for production control Expediting of shipments Expediting of incoming materials Work in progress (WIP)

Table 6. Summary of reliability analysis

Variables	Number of items	Cronbach Alpha
Top Management Support	5	.82
Teamwork and Composition	5	.72
Effective Communication	5	.89
Project Management Program	5	.75
Organizational Culture	6	.83
Success of ERP Implementation	5	.83

reported holding a Master's degree and 14% have a Ph.D. Thirty-seven percent of the respondents reported holding managerial positions, while 54% were in non-managerial positions. A majority of the respondents (63%) have been with their companies for less than five years, and 18% of the respondents have been with their companies for 6 to 10 years. Eighty percent of the respondents were from companies that exceeded $4 million USD in annual revenue, and 64% have more than 3,000 employees in their organizations.

Table 6 shows the reliability assessments for both the independent and dependent variables. To assess the internal consistency and stability of data, Cronbach Alpha was used to establish the inter-item consistency. Since the Cronbach Alpha coefficients are all above 0.7 (Nunnally, 1978), it can be concluded that the measures are reliable.

Regression analysis was first carried out to assess H1-H4. Hierarchal regression was then used to test H5-H8, the moderating effect of organizational culture on the relationships between the independent variables and success of ERP implementation. We used a significance level of 0.05, or 5%, as the basis for accepting or rejecting the hypotheses.

As shown in the regression table in Table 7, the coefficient of R^2 is 0.389, indicating that the four independent variables explain 38.9% of the variance. Durbin Watson of 1.71 indicates that there is no auto-correlation problem. Tolerance and VIF values are also within the acceptable range indicating that there is no multi-collinearity problem.

The results presented in Table 7 prompted rejection of Hypotheses 1 and 2, and acceptance of Hypotheses 3 and 4. The results suggest that top management support (p=0.42) and teamwork and composition (p=0.42) did not influence success of ERP implementation. On the other hand, enterprise-wide communication (p<0.05) and project management (p<0.05) have significant impact on success of ERP implementation.

The results of hierarchical regression analysis for the moderating variable, organizational culture, are shown in Table 8. Recall that the R-square value is 0.389 when no moderating variable is taken into account. This value increases to 0.495 when culture is considered in the model and to 0.543 when culture is considered to moderate the interaction terms. The increased R-square suggests that organizational culture is a moderator in the proposed model.

Table 7. Summary of regression model output

PROJECT*CULTURE	2.850	**0.04***

* $p<0.05$

The model with organizational culture as a moderator explains 54.3% of the variance of success of ERP implementation. Durbin-Watson of 1.70 falls within the accepted range (1.5—2.5), indicating no auto-correlation problem. Condition index, VIF, and tolerance are all within the acceptable range (Condition Index < 40, Tolerance > 0.1 and VIF < 10), which means there is no multi-collinearity problem. Histograms for the regression model were plotted to validate that normality distribution is achieved and there is no heteroscedasticity problem.

The moderated relationship between enterprise-wide communication and success of ERP implementation is significant ($p<0.05$), which implies that organizational culture moderates the relationship between enterprise-wide communication and success of ERP implementation. We also tested the moderating effect of organizational culture on the relationship between project management and success of ERP implementation, and the result is significant ($p<0.05$), implying that organizational culture moderates the relationship between project management and success of ERP implementation. The results, however, indicate that organizational culture is not a moderator of the relationships between each of top management support (p=0.82) and teamwork-and-composition (p=0.68), and success of ERP implementation.

DISCUSSION OF RESULTS

The degree of enterprise-wide communication on the EPR implementation impacts positively on the success of the ERP implementation. This finding is also supported by the work of other researchers (e.g., Esteves & Pastor, 2000; Falkowski et al., 1998; Petroni, 2002; Rosario, 2000). Our research provides support for the importance of enterprise-wide communication and its purported benefits on ERP implementation in the context of multinational companies operating in Malaysia.

A project management program is also found to be important for ERP implementation success, which is consistent with the findings by Rosario

(2000) and Bagranoff and Brewer (2003). A project management program is essential for success, as it establishes project scope and ensures that scope expansion requests are carefully assessed before they are approved. An effective project management program defines and sets realistic milestones and enforces them. The success of ERP implementation also depends on coordination of project activities across the different parties involved, which is another important component of a project management program.

A surprising finding of this study is that top management support does not impact the success of ERP implementation. This contradicts findings of previous research (Dong, 2001; Esteves & Pastor, 2000; Nah et. al., 2003; Sarker & Lee, 2003) where top management support was cited as the top or a key factor influencing ERP implementation success. However, not all the previous studies run contradictory to this finding, as many studies have focused on different aspects of management involvement. For example, the unified critical success factors model by Esteves and Pastor (2000) examined *sustained* management support at all levels and phases of the implementation, which is conceptually different from top management support. Others, like Petroni (2002), found that top management support was a far more critical factor for small- and medium-sized firms than for large multinationals. Another possible explanation for this observed phenomenon lies in the nature of management style in multinational corporations operating in South-East Asia. Tarafdar and Roy (2003) indicated that management staff in developing nations confronted issues differently from management staff in developed countries. Hence, top management support may be more critical for ERP implementation in developed than developing countries. Power distance between top management and the employees could also account for the difference. In other words, with high power distance in Malaysia, the mandate for ERP implementation is strong across the different levels of an organization regardless of whether top management support is perceived to be present. Since the majority of the ERP literature has mainly focused on top management support in primarily developed nations, this new finding suggests that top management support may act more like an "enabling" rather than a "necessary" factor for the success of ERP implementation in developing nations. Another possible explanation is that top management support, when measured against optimal success from the business and strategic perspective, may not influence success. In other words, top management support may be necessary for the completion of an ERP project but may not directly affect the effectiveness of the system.

Another result of this study suggests that teamwork and composition of ERP implementation teams does not relate to ERP implementation success. This further contradicts previous findings (Bingi et al, 1999; Buckhout et al., 1999; Rosario, 2000). In the context of a multinational environment, it is likely that the selected teams might be too far removed from the actual implementation details and were focusing more on the system architecture rather than the change process, a phenomenon that is cautioned against by Davenport and Stoddard (1994). This is even more likely to happen if the company believes that the IS architecture is the most important aspect or if customization to suit existing business processes is given precedence (Brehm, Heinzl, & Markus, 2001) without due consideration of the pros and cons of customizing the software versus making changes to business processes to suit the new ERP system. It was established earlier that ERP systems are more about adaptation of business processes to the demands of the ERP system (Davenport, 2000) rather than the design of the ERP system to fit the demands of the business. It is also possible that the optimal teamwork and composition for ERP implementation is harder to achieve in developing nations due to limitations in human and technological resources.

The relationship between enterprise-wide communication and success of ERP implementation is positively moderated by the presence of a learning culture. A culture that is open to continuous learning and challenge, as evidenced in a “learning organization” (Senge, 1994), can help to facilitate effective communication across the enterprise, which is a key to success in ERP implementation. Similarly, an open and learning organizational culture also facilitates the execution of a project management program, which increases the chances of success in ERP implementation. These findings validate research by proponents of the learning culture theory (Edwards & Panagiotidis, 2000; Senge, 1994; Skok & Legge, 2002). In fact, the moderating influence of organizational culture was found to be so strong that it warrants cultural change programs as proposed by Schniederjans and Kim (2003) as the means to adjust the culture of an organization to one that is more receptive to changes.

CONCLUSION

From a comprehensive review of the literature on critical success factors of ERP implementation, Finney and Corbett (2007) identified a major gap in the literature, which is the lack of research to examine ERP critical success factors from the perspectives of key stakeholders. Our study is one of the few that examine success of ERP implementation from the perspectives of key stakeholders by assessing business value derived from ERP implementation. In addition, this is one of the few studies that examine ERP implementation in developing nations. Despite these strengths, our study also has limitations.

One of the limitations of this study is its generalizability. The findings of this study may be limited to multinational corporations operating in Malaysia. Follow-up work is needed to assess if the results are applicable to corporations in other developing nations. Another limitation is that a wider range of CSFs was not included due to practical constraints such as time and cost. The survey questionnaire spans several pages, and we were concerned that adding more factors would increase its length to the point where reliability of the responses would be affected (due to respondents’ fatigue) or participation would be discouraged/avoided. Some key CSFs that were deemed important but were not included in this study are:

- Comprehensive business process re-engineering (BPR),
- Project championship,
- ERP customization, and
- Adequate training program.

ERP implementation is a challenging task due to its complexity and cost. This research provides further insights into the critical success factors of ERP implementation, and presents some guidelines for organizations to focus their attention and resources in carrying out such implementations. This study has highlighted the significance of enterprise-wide communication and project management programs on ERP implementation success. It also reveals the importance and crucial role of organizational culture for ERP implementation success.

The findings of this study also suggest that the traditional views of change management are insufficient to influence success of ERP implementation. Businesses have to realize that their top managers, while functioning as leaders of the organization, are insufficient on their own to guarantee success. While continuous management support is required, more effort and focus on communication across the different functions and levels of the organization, management of the project, and the capability of the organization to learn are key considerations. In addition, due to the critical role of project management, it is recommended that businesses form a separate and formal project management team that works closely with the rest of the organization to manage both the implementation and the changes associated with the implementation.

Several studies have examined critical success factors across stages of ERP implementation (Holland & Light, 2001; Nah & Delgado, 2006; Somers & Nelson, 2001; Somers & Nelson, 2004). This is an important research direction, as it provides more specific guidelines on the key factors across the different stages of the implementation. However, since ERP implementation in most multinational companies is moving into the various stages of maintenance, it is also important to study and understand the various factors, issues, and activities in ERP maintenance to better utilize existing ERP resources and to further improve efficiency and effectiveness in organizations (Kang, 2007; Nah, Faja, & Cata, 2001). For example, data warehousing interoperability for extended enterprises (Triantafillakis, Kanellis, & Martakos, 2004) and challenges in upgrading ERP systems (Nah & Delgado, 2006) are also issues that warrant further research.

This study provides a unique view of multinationals operating in Malaysia's Free Trade Zone. It cautions us against assuming that best practices and success factors in developed nations will necessarily apply for developing nations. This is especially important for multinational companies intending to implement major changes to their operations in Malaysia or developing nations in the Southeast Asia. Accordingly, adapting to the ERP system environment can help to establish a win-win scenario for multinational companies, but management of the implementation is critical to achieve this goal.

APPENDIX

Questionnaire: Success of ERP Implementation

A. Top Management Support

Please indicate the extent to which you agree with the following statements by marking an "X" against the appropriate scale shown.	Strongly Disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
Sufficient incentive for ERP implementation was provided by top management.	☐	☐	☐	☐	☐
The ERP implementation is/was viewed as a strategic decision by (local) top management.	☐	☐	☐	☐	☐
There is/was sufficient top management commitment to this ERP implementation.	☐	☐	☐	☐	☐
The CEO, CIO, or COO is/was actively supporting this ERP implementation.	☐	☐	☐	☐	☐
The ERP implementation received explicit identification from (local) top management as a critical priority.	☐	☐	☐	☐	☐

B. Teamwork and Composition

Please indicate the extent to which you agree with the following statements by marking an "X" against the appropriate scale shown.	Strongly Disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
The people selected for ERP implementation teams had the best business and technical knowledge.	☐	☐	☐	☐	☐
A variety of cross-functional people were selected for the ERP implementation.	☐	☐	☐	☐	☐
Those selected for the ERP implementation were working on the project full-time as their only priority.	☐	☐	☐	☐	☐
Sufficient incentives or compensation were given to those selected for the ERP project.	☐	☐	☐	☐	☐
Those selected for the ERP project were relocated together.	☐	☐	☐	☐	☐

C. Enterprise-Wide Communication

Please indicate the extent to which you agree with the following statements by marking an "X" against the appropriate scale shown.	Strongly Disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
The project team or core design team was well-prepared to communicate effectively with the users.	☐	☐	☐	☐	☐
Persons involved in the ERP project clearly understood the goals/ objectives/purposes of the implementation.	☐	☐	☐	☐	☐
There were enough communication channels to inform the users of the stage of the ERP project and help users resolve problems.	☐	☐	☐	☐	☐
Enough reviews were conducted to ensure continued ERP end-user satisfaction.	☐	☐	☐	☐	☐
There were enough evaluations to assess the workings of the ERP system.	☐	☐	☐	☐	☐

D. Project Management Program

Please indicate the extent to which you agree with the following statements by marking an "X" against the appropriate scale shown.	Strongly Disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
During the ERP implementation, milestones were set with measurable results.	☐	☐	☐	☐	☐
There was commitment to promote and manage the ERP implementation project.	☐	☐	☐	☐	☐
Regular communication of expectation and challenges, education, training, and support were provided during the ERP implementation.	☐	☐	☐	☐	☐
Task assignments were well-defined during the ERP implementation.	☐	☐	☐	☐	☐
Customization of the ERP system was well-managed by the business team.	☐	☐	☐	☐	☐

E. Organizational Culture

Please indicate the extent to which you agree with the following statements by marking an "X" against the appropriate scale shown.	Strongly Disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
In my organization . . .					
Employees are supportive and helpful.	☐	☐	☐	☐	☐
Adequate organizational resources are available to the employees.	☐	☐	☐	☐	☐
There is willingness to collaborate across organizational units.	☐	☐	☐	☐	☐
Employees are encouraged or rewarded by their superiors to express and exchange their opinions and ideas regarding work.	☐	☐	☐	☐	☐
Opportunities are provided for individual development, other than formal training (e.g., work assignments and job rotation).	☐	☐	☐	☐	☐
Employees are encouraged to analyze mistakes that have been made and learn from them.	☐	☐	☐	☐	☐

F. ERP Implementation Success

Please compare the following statements to the situation before ERP/MRPII/MRP implementation and indicate the extent to which you agree with the statements by marking an "X" against the appropriate scale shown.	Strongly Disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
There is a reduction in informal systems for either materials management, inventory, or production control.	☐	☐	☐	☐	☐
Capacity planning, cost estimation, and inventory control has improved.	☐	☐	☐	☐	☐
Cooperation between finance, marketing, production, engineering, and sales have improved.	☐	☐	☐	☐	☐
Employee job satisfaction and morale has improved.	☐	☐	☐	☐	☐
There is a reduced need for "expediting" business requirements such as customer orders.	☐	☐	☐	☐	☐

G. Demographics

Your job position in your company:	Managerial	☐
	Non-managerial	☐
	Other. Please specify	☐
How long have you been in your company:	< 1 year	☐
	1-5 years	☐
	6-10 years	☐
	> 10 years	☐
Your education level:	PhD	☐
	Masters	☐
	Bachelors	☐
	Diploma	☐
	Others. Please specify	☐
Organizational annual revenue:	< USD 1.0m	☐
	USD 1.0-4.0m	☐
	> USD 4.0m	☐
Number of employees at your site:	<100	☐
	101-1000	☐
	1001-3000	☐
	3001-5000	☐
	>5000	☐
Gender:	Male	☐
	Female	☐
Thank you very much for spending your time to participate in this questionnaire. Your inputs are of tremendous importance to my research. Any constructive feedback would be very much appreciated.	☐

Chapter 7.12

Federated Enterprise Resource Planning Systems

Nico Brehm
Carl-von-Ossietzky-Universität Oldenburg, Germany

Daniel Lübke
University Hannover, Germany

Jorge Marx Gómez
Carl-von-Ossietzky-Universität Oldenburg, Germany

ABSTRACT

Enterprise resource planning (ERP) systems consist of many software components, which provide specific functionality. As ERP systems become more complex, the financial expenditures that are associated with the application of such systems dramatically increase. Furthermore, ERP system development of nowadays is product-oriented and coordinated by only one instance at any one time. Consequently, each product has a separate data model, which is the basis for the integration of various types of business applications. Based on this fact, the selection of the covered functional enterprise sectors as well as the implemented functions is controlled by the respective vendor, too. Thus, enhancements and modifications of the standard software product are incumbent upon the software vendors. A cross-vendor standardization of data models for ERP systems and the establishment of unified architectural model, however, would change this situation. The new idea is to develop a novel ERP system architecture, which facilitates an overall reusability of individual business components (BC) through a shared and non-monolithic architecture based on Web services. The presented approach uses Web services to wrap up ERP components that are provided within a distributed system, which appears as an ERP community and serves as a vendor-independent platform.

INTRODUCTION

Since the advent of Web services during the last years, software components can be easily distributed and remotely accessed. These components become small services, which provide clients with specific functions. These can be invoked using standardized protocols like simple object access protocol (SOAP) (Gudgin, Hadley, Mendelsohn, Moreau, & Nielsen, 2003). The goal is to create an infrastructure allowing business applications to seamlessly discover and use Web services. This will hopefully make the integration of different applications and the development of distributed applications easier. This kind of architecture, called service oriented architecture (SOA), provides a transparent environment in which applications can be composed out of services.

Some hopes and visions are associated with SOA, for example, enterprise application integration (EAI) strives to seamlessly connect different systems in an enterprise mainly by utilizing Web service standards. While EAI has become an objective for larger enterprises due to the huge number of deployed systems, small- and medium-sized enterprises (SME) still struggle to support business processes using integrated IT systems. SMEs compete against larger corporations utilizing their flexibility and their ability to innovate. In order to compete better, these SMEs need to deploy ERP systems to support their business processes. But to stay as flexible and competitive as today, SMEs have to customize their ERP system each time the business processes change. However, ERP systems are complex and their customization as well as maintenance is costly. Therefore, investments into large and powerful ERP systems often do not pay off financially for SMEs who do not have the necessary financial resources to deploy and maintain such systems at all.

Two approaches try to fill this gap: Cheaper ERP systems with less functionality have been offered and the concept of application service providing (ASP) has emerged. However, both solutions have their drawbacks. ERP systems offering less functionality do not realize all possible opportunities and do not address maintenance costs. Even worse, ASP (i.e., the operation of systems by a third party in an external data-center) has been rejected by the market because enterprises are not willing to store their valuable data externally and the distribution of responsibilities creates management problems (Walsh, 2003). Our aim is therefore a solution, which combines local data management with reduced costs and flexible support for changing and optimizing business processes.

The result is an ERP system whose logic is completely composed of Web services called federated ERP (FERP). The Web services are dynamically arranged to support the company's business processes (Krüger, Marx Gómez, Rautenstrauch, & Lübke, 2004). Such an ERP system has the advantage of storing all relevant data in-house as well as being extensible by integrating as many Web services as required for realizing the desired functionality. For implementing these ideas, some challenges have to be overcome. In course of this chapter, we will focus on the following problems:

- Management of user interfaces in highly dynamic, model-driven environments.
- Server-side data-management.
- Organization and standardization of Web services for the envisioned FERP system.
- Security considerations.

This chapter is structured as follows: Within the next section, we present background information and definitions of the most important terms. In the third section, we discuss the four main points as previously presented. The open research questions and future problems are presented in the fourth section. Finally, a conclusion is given.

BACKGROUND

An ERP system is a highly integrated software system representing different types of business application systems. In the majority of cases, there is a smooth transition between these system parts whereby it is almost impossible to locate isolated components. In fact, ERP vendors provide packages of business functions, which can be associated to different enterprise sectors. These functions are interwoven, which means that a function can invoke another function without a central control instance. This characteristic causes the problem that it is difficult to isolate a group of functions as a discrete component. With the intention of a sustainable reusability of discrete software components, ERP vendors started redesigning their products step by step. The main objective is to achieve a component-oriented software design. One example for this phenomenon is the company SAP®AG with their ERP system SAP®/R3™. Earlier versions of this product appeared as a monolithic solution. With the BAPI technology (business application programming interface) (see SAP Library, 2005), it is now possible to encapsulate single business functions in business objects. Furthermore, there is the possibility to remotely access these business objects or to recombine them within business workflows.

This chapter introduces the conceptual foundation of FERP systems and shows how a component-oriented ERP solution is transferred to a Web service-based FERP system. The visionary development process of such a system is supposed to be pushed by a community of ERP software vendors whereby the degree of implementation varies according to the different entrepreneurial motives of different developers.

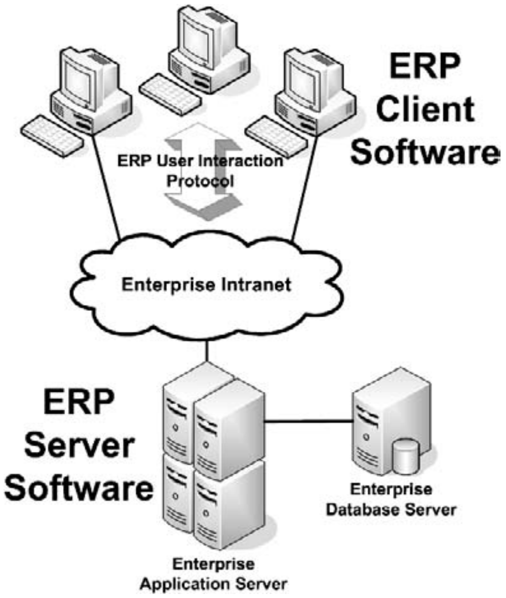
Definition 1

An *ERP system* is a standard software system, which provides functionality to integrate and automate the business practices associated with the operations or production aspects of a company. The integration is based on a common data model for all system components and extents to more than one enterprise sectors (see Rautenstrauch & Schulze, 2003; Robey, Ross, & Boudreau, 2002).

Conventional ERP architectures are based on n-tier models including presentation tier, potentially different application tiers, and a database tier. The functional software components of ERP systems are administered on a central application server, which is responsible for the coordination of interactions with end users, for the execution of business logic, and for the communication with the enterprise database server. The communication between the application server and GUI clients can be either based on standard protocols like HTTP or proprietary protocols like the DIAG protocol, which was developed by SAP® in order to exchange requests and responses between SAP®GUI and SAP®R3 servers or in later versions SAP® enterprise central component servers, which act as applications servers in this context. In cases where different application servers have to be interconnected (e.g., in order to invoke remote functions calls), protocols like RFC or also HTTP are used. Figure 1 shows the architecture of today's ERP systems.

ERP system development of nowadays is product-oriented and coordinated by only one instance at any one time. Consequently, each product has a separate data model, which is the basis for the integration of various types of business applications. Based on this fact, the selection of the covered functional enterprise sectors as well as the implemented functions is controlled by the respective vendor, too. Thus, enhancements and modifications of the standard software product are incumbent upon the software vendors. Various managerial motives (e.g., actual situation of the company, missing know-how, strategic objectives, or inadequate empathy for cooperation) are the deciding factors for the mostly compromise-driven orchestration of ERP system components.

Figure 1. Conventional ERP system architecture



A cross-vendor standardization of a data model for ERP systems and the establishment of unified architectural model, however, would change this situation. Thus in theory a cross-vendor composition of ERP functions becomes possible whereas the coordination of this process is individual and vendor-independent.

Definition 2
A *federated ERP system* (FERP system) is an ERP system that consists of system components that are distributed within a computer network. The overall functionality is provided by an ensemble of allied network nodes that all together appear as a single ERP system to the user. Different ERP system components can be developed by different vendors.

Definition 3
An *ERP system component* in this case is a reusable, closed, and marketable software module, which provides services over a well-defined interface. These components can be combined with other components in a not foreseeable manner (see Turowski, 2003, p. 19).

Figure 2 shows the two approaches in comparison to each other. The left hand side represents the architecture of a conventional ERP system where a closed amount of ERP components (C1, C2, …, C6) are installed on the same application server and were developed by the same software vendor. The right hand side shows an open ERP network where each node is assigned to one ERP component, which is provided as service (S1, S2, …, Sn). This network consists of allied network nodes that all together represent a federated ERP system. New components are added as new network nodes that provide corresponding services.

The main disadvantages of conventional ERP systems are that in most cases, not all of the installed components are needed, high-end computer hardware is required, and that the customizing of such systems is very expensive because product specific know-how of experts is necessary. Due to the expensive proceedings of installation and maintenance, only large enterprises can afford complex ERP systems, which provide business logic of all sectors of the functional enterprise organisation. Contrary to these aspects, FERP systems allow the separation of local and remote functions whereby no local resources are wasted for unnecessary components. Furthermore, single components are executable on small computers and due to decreasing complexity of the local system also installation and maintenance costs subside. Figure 3 shows how the ERP system is supplied by a network of FERP business logic components, which provide all potentially needed business functions.

ARCHITECTURE OF FEDERATED ERP SYSTEMS

Overview

The federated ERP-system as presented in the second section is a distributed system composed of

Figure 2. Conventional ERP system with ERP components (C1-C6) vs. a federated ERP system that provides its ERP components as services (S1-Sn)

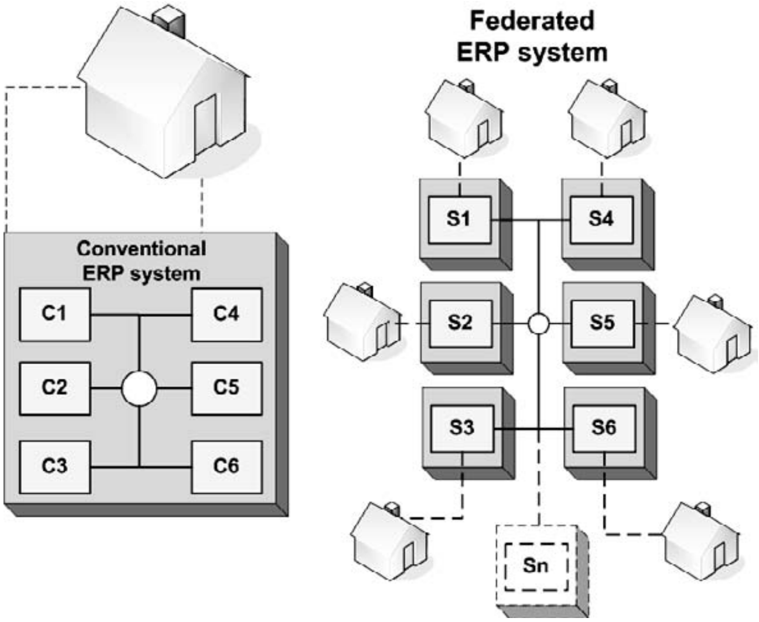


Figure 3. Vision of a federated ERP system landscape where ERP software components can be developed and provided by different software vendors

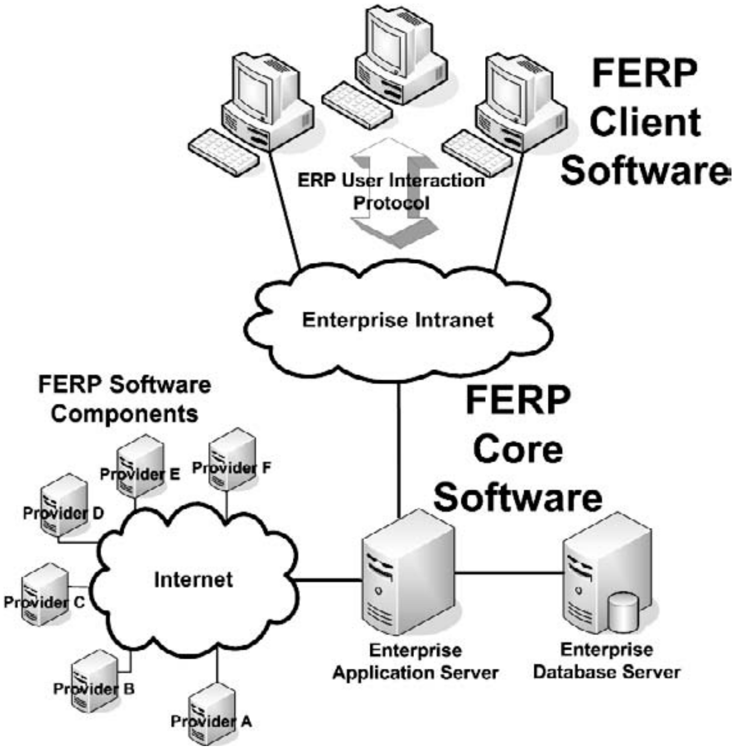

Web services. Therefore, the underlying architecture needs to fulfill the following requirements:

- Integrate the Web services to provide the needed functionality.
- Execute and control the workflow.
- Manage data access and storage.
- Authenticate and authorize users.
- Provide usable interfaces to the users.

For minimizing customization effort and reduction costs for changing business processes, the following non-functional requirements hold:

- Changes in business processes should be easy to introduce into the system.
- Changes in the federated ERP-system should be easy to incorporate.
- Changes in the federated ERP-system should require minimal software distribution effort for changes.

Requirements were grouped and assigned to layers resulting in a three-tier system design (see Figure 4):

1. Web services are the standard logic components of the system and the set of all Web services forms the first layer.
2. The Web service orchestration and business process layer is in charge of managing the data and control flow of the application through the business processes.
3. The presentation layer generates user interface descriptions for interactive steps in the business processes.

We decided to use an application server infrastructure in order to be able to centralize many tasks. Thus, many updates need only be done on the application server and do not affect clients. For our prototype implementation, we used the J2EE platform represented by a Tomcat Web container and the AXIS Web services framework. The clients were implemented in Java Swing.

For better explanation of the concepts, we will use the same example process throughout the next sections (the process is taken from Lübke, Lüecke, Schneider, & Marx Gómez, 2006). The example is a simple process of an order acceptance. The profit margin of an incoming order is checked. If the profit margin has been breached, a manager must decide if the order is accepted or not. For example, some orders of important clients can be seen as advertising and therefore, need to make not as much profit as orders normally would do. If the order is accepted, it is forwarded to production. The whole process is illustrated as an event-driven process chain (EPC) in Figure 5. EPCs consist of so-called events symbolizing the state of an organization and functions representing actions taken within the process. A function is triggered by a certain state and results in a new state. A whole process is triggered by events as well and results in a changed overall system. Therefore, an EPC is roughly an alternating event-function sequence starting and finishing with an event. To control the execution of process connectors can be added for splitting and joining the control flow as illustrated in the example process. EPCs are used for modeling all business processes in the Federated-ERP project and are stored at the application server in EPML (Mendling & Nüttgens, 2005).

User Interface Generation

Every ERP system needs to be operated by users. In the end, they need to make decisions, retrieve data, or enter new records. While classical ERP

Figure 4. Layers of a federated-ERP system

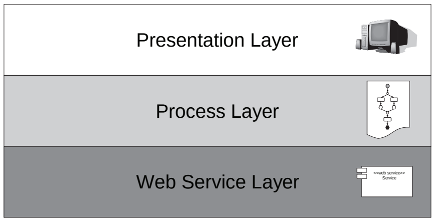

Figure 5. Example order process

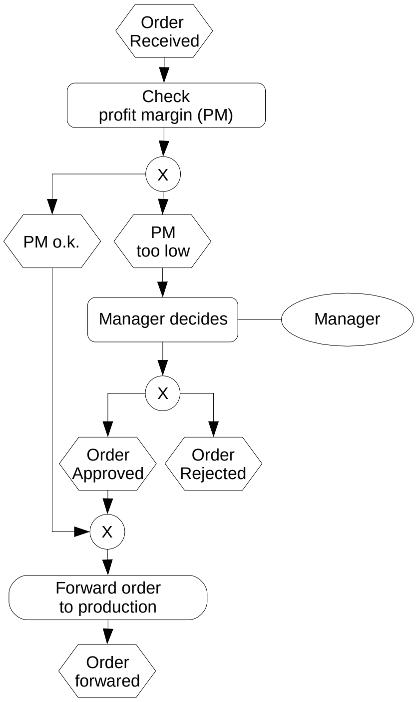

systems offer clients for personal computers only, now mobile devices, like handhelds and mobile phones, are emerging. Because of this situation, the federated ERP system will face many types of clients. Furthermore, these clients need to be easily updatable. For a simple process change, it is not feasible to update hundreds of possibly mobile or distributed computers. Thus, the user interface must be managed on the server-side and must be platform-neutral.

Our approach for minimizing the effort needed to develop and customize the user interface is to automatically generate the interfaces from the business process descriptions. Much research has been done in the field of model-based user interface (MB-UI), which aims to model user interfaces in the way program logic is modeled in UML. Research in these fields has been going on for more than a decade. For example, Paterno (1999) gives an overview over of the field of MB-UI. Numerous design environments have been proposed as result of MB-UI. Each differs in the number and type of models used (for a thorough overview the reader is referred to da Silva (2002). However, most approaches share a common element: the task model. Fortunately, this task model is easily related to our approach. The business process model is in fact a task model on a very high abstraction level (see Trætteberg, 1999). Furthermore, the field of MB-UI has matured; especially insight into reasons for failure of some approaches has been beneficial for our research. Common mistakes and problems concerning practical adoption of MB-UI techniques are listed by Trætteberg, Molina, & Nunes, 2004): The biggest problem has been the complexity of the introduced models. While complex and detailed models give the designer the best level of control, such models are difficult to learn, time-consuming to design, and hard to maintain. Therefore, our approach particularly strives to reduce the inherent complexity. This is especially important for being useful for the targeted, non-expert audience.

Because we assume the business process to be already modeled, the user interface is expressed by stereotyping business functions. Four stereotypes have been introduced:

- **Selection:** The user shall select data from a collection of possible choices. For example, select product from a catalogue.
- **Edit:** The user shall edit some information object from the data model. For example, edit order.
- **Control:** The user wants to explicitly invoke some action. This is used to model navigational decisions. For example, “Accept order.”
- **User:** The user has to do something by himself (e.g., planning, comparing, etc.).

These four actions can be attached to a business function and are visualized by small icons on the left-hand side of the function. The annotated business processes are downloaded by the client software, which generates user interfaces from these models and sends the data and user decisions back to the server. This way, the user interface can simply be edited by installing new business process models on the server. For generating the user interfaces, the data types are used to create matching editors: Because Web services are based on XML, the data types are represented by XML Schema definitions. XML schema recursively defines data types: Primitive types can be grouped to complex types. Complex and primitive types can be grouped to new complex types and so on. Editors are created by traversing this tree-structure and look for matching editors registered in the system. At least for each primitive type, like integers and strings, an editor is provided by the system. Therefore, a (possibly primitive) editor can be generated for each XML Schema. Figure 6 shows a simple generated editor for a customer record.

Figure 7 shows the hierarchical refinement of the example process with user interface stereotypes and the resulting user interface using a custom editor. The client application shows the processes needing further action by the user and the processes, which are currently executed by someone else. This information is given on the right hand side.

Since the user interface generation is based on the business process description, context information can be given to the user. For example, descriptions of the currently active business function can be displayed. In our prototype, these are realized by giving tool-tip information. At this point, it is even possible to integrate experience bases to facilitate the communication between developers, process designers, and end users.

Since this approach is based on the process description only, it is possible to generate user interfaces for different target platforms. For example, a connector for XForms—an XML standard for describing input forms—is under development and generation of HTML pages is possible as well for integration into intranet and portal applications. For further discussion on the topic of generation of user interfaces from EPC models see Lüecke (2005) and Lübke et al. (2006).

Server-Side Data Management

When executing a process model, which can not only include user interfaces but also Web service calls, corresponding data in terms of business objects needs to be managed. If a process shall be started, the application server creates a new process instance. The instance represents a running process including its whole state. The state is comprised of the data objects currently in use and the statistics which business functions have already been executed in order to evaluate the joins in the control flow. The data management currently follows the blackboard approach as presented by Alonso, Casati, Kuno, and Machi-

User manager connected to: Tomcat@Eclipse [http://localhost:8080/DERP-Server/services/DERPServer...

raju (2004). All process instance data is stored as XML at the process' instance. The advantages of the deep usage of XML are:

- Consistent use of XML between the whole platform.
- Efficiency during development because powerful XML technologies like XPath and XSLT are available.
- Easy user interface generation through XML schema.

Using XML throughout the application has the advantage that Web services' parameters can be simply extracted from the blackboard by use of XSLT. The Web services' output can be stored after XSLT transformations to the native XML Schema, too. The application server needs to offer local services for data management. The business processes need to be able to store and retrieve persistent data. The corresponding functionality is offered by the means of services. Data objects referenced by XPath expressions can be used from the business processes. The application server must retrieve the matching business objects from the database and save any changes made.

However, some disadvantages are also connected to this approach:

- XML processing is not efficient. Using plain objects would increase performance.
- If non-XML technologies are to be used like relational database systems or CORBA services instead of Web services, the XML data need to be transformed, which is an expensive operation.
- The XML data format is very space-consuming hindering replication within cluster environments.

These weaknesses can be addressed by building scalable applications, which can be distributed to many servers in order to improve performance. To overcome the third disadvantage, "sticky sessions" can be used in which a process instance is always run on the same server. Thus, replication is minimized.

Organization and Standardization of Web Services

Starting from the syntactical standardization approach of FERP systems as proposed in Brehm & Marx Gómez, 2005), it is possible to define dependencies between the different operations of FERP Web services. This structure is based on the preliminary idea that FERP Web services are classified according to the enterprise sector which their offered operations belong to. The basis of the FERP Web service specification model is the summarization of all functions (Web service operations) that belong to the same sector of the functional business organization. Functions of the same sector are assigned to the same FERP Web service. In this first proposal, we classify the following Web service types in the context of FERP systems whereas we have to mention that this classification is incomplete and only serves as an example:

- Production planning and controlling.
- Accounting.
- Logistics.
- Sales and distribution.
- Materials management.
- Quality management.
- Project management.
- Human resource management.

According to a literature review in the area of component standardization models as Turowski (2003) described, the standardization of FERP Web services must include the following levels:

- Syntactic level
- Behavioral level
- Synchronization level
- Quality-of-service level

Figure 8 shows an uncompleted example syntactic specification of a production planning and controlling (PP) Web service as presented in Brehm et al. (2005). Based on the specification of data types (e.g., BOM, work plan, operation, etc.), message types are specified. These message types are used to describe the functions of the PP Web service. Out of this functionality specification, different Web services can be derived, which implement the overall component functionality in a different completeness. The Web service descriptions are expressed in the Web service description language (WSDL).

Semantic Web services are Web services whose properties, capabilities, interfaces, and effects are encoded in an unambiguous, machine-understandable form (see McIlraith, Son, & Zeng, 2001). Research works that deal with semantic Web services aim at the provision of a comprehensive Web service description, discovery, and mediation framework. Because UDDI, WSDL, and SOAP are not sufficient, other specification languages like Web ontology language (OWL) (see W3C, 2004) and the resource description framework (RDF) (see W3C, 2004a) are used. This approach is more abstract then the presented proposal because the efforts within the scope of semantic Web services do not concentrate on a specific type of Web service. The shown proposal is based on XML schema to define a fixed language for ERP systems as basis for the communication between software components of a distributed application.

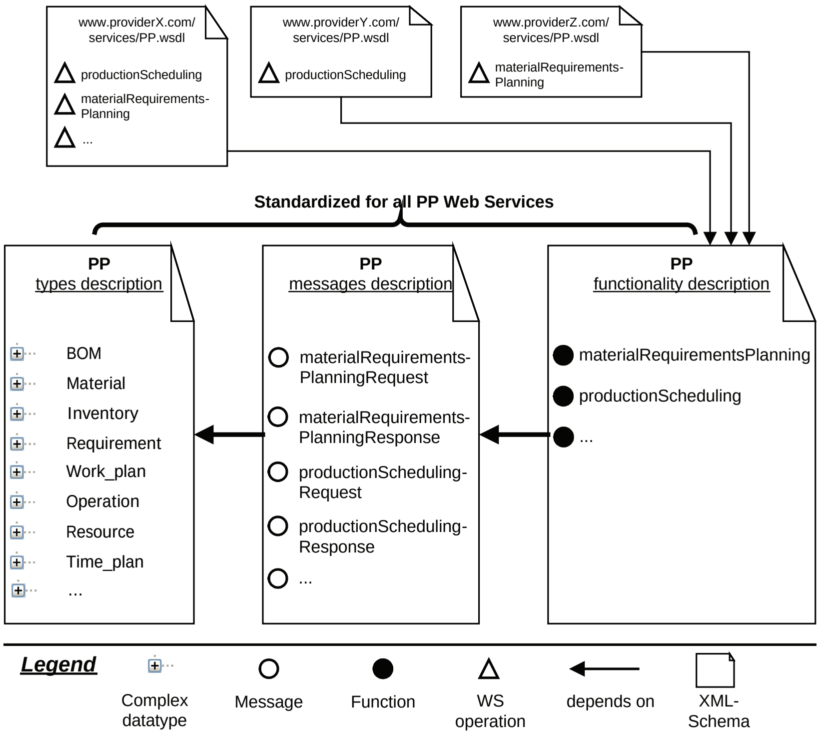
Security Considerations

Security Model and Requirements

In connection with the common use of distributed applications, several *security problems* exist. The most important security objectives in the case of distributed ERP systems are:

- *Confidentiality* of transmitted data.
- *Integrity* of transmitted data.
- *Authenticity* of communication partners.
- *Availability* of data and functionality.

Figure 8. Uncompleted example FERP Web service specification and three possible Web service descriptions (see Brehm et al., 2005)



- *Anonymity* of communication partners against unauthorized parties.
- *Non-repudiation* of transactions.
- *Reliability* (trustability) of communication partners.

Constructing a security layer and involving it into the already existing architecture, attention should be paid to the different specifications of individual security requirements of different companies. Within the shown context of a shared ERP system, those requirements commonly correspond to message integrity, authenticity, and data confidentiality of all interface calls and responses and thus, of the whole network traffic. As these strategic security objectives differ from each utilizing enterprise to another, it is essential that the security model is open for virtually all security mechanisms and standards, which allows the processing of generic definitions of security policies. Referring to the existing security mechanisms, security policies describe the concrete security requirements of the appropriate network node including the respective configuration parameters. Based on this approach, a suitable policy processor is able to audit all incoming messages for security conformance on the enterprises security policy and to extend all outgoing messages according to the security policy of the remote network node, which is commonly the service provider as proposed by Brehm, Marx Gómez, and Rautenstrauch, 2005b). Attributes of such security policies can partly be modeled directly in the EPCs. Functions in EPCs can be assigned to security mechanisms like encryption or decryption algorithms or user roles (e.g., the manager role in Figure 5).

Local and Remote Security

Within the context of FERP systems, local and remote security considerations have to be differentiated. Concerning this matter, the primary tasks of the FERP system core component, which is installed on the application server of an enterprise, can be split into responsibilities regarding access control and the assurance of confidentiality. Local access control mechanisms use role-based authentication and authorization models (e.g., passwords or public key infrastructure (PKI) elements like certificates) as to authenticate local users and to permit or deny their requests accordingly. Therefore, the system is equipped with a user management module, which maps possible activities to user permissions. A typical requirement in this case is that only users in the corresponding role can invoke a function or may access the corresponding user interface. However, in some situations the roles must be fine-grained. For example, it may be necessary to have a special manager who has to approve the order. In our example, it may be necessary that the manager of the customer's consultant must approve the order. For realizing this functionality, conditions can be appended to the roles: These conditions can access the process' instance data. In this case, the order is assigned to a customer who is assigned to his consultant. Therefore, the manager role can have the restriction of being accessible only to the consultant's manager. This security information can be used during run-time to control the access to ERP functionality.

Contrary to conventional ERP systems, FERP systems have to access functions of potentially not well-known component providers whereas the authentication of these providers and the establishment of a secure communication channel are not sufficient. Following the vision of a flexible and open FERP network where FERP component vendors can provide their functionality to all participating network nodes as straight forward as possible, it is not practicable to establish trust relationships, which are exclusively based on directly applied human intelligence (e.g., by persons who are talking to each other). This aspect is still unsolved and shows a frequently discussed research question. A number of trust models as for instance centralized rating systems as applied in *Ebay* and *Amazon* auctions or social network analysis techniques (e.g., Friend of a Friend (FOAF) networks) have been developed in e-commerce, e-business, security, and multi-agent systems, which have to be investigated according to their practicability in future research work.

FUTURE TRENDS AND RESEARCH

Many options concerning process modeling and service composition have to be researched. While SOA promises to better integrate software with its underlying processes, the models are still not integrated well nor even are unified. Our approach so far has been to simply use and extend EPCs, which are a business process modeling language. However, they are not as powerful as some workflow languages. If in practice, these additional abilities of workflow languages like Petri nets are needed, much research has to be done how to synchronize between different models. Business models are an important part of the software requirements and therefore often need to be traced forward and backward during the development. If EPCs cannot be used everywhere, a mapping between EPCs and the workflow language used needs to be established. However, tracing problems still arise if only using EPCs; Software requirements are more than business processes. For example, use cases are a very beneficial way of documenting software requirements. These need to be linked to the processes. The same holds true for test cases, which are based on requirements and the executable processes.

On the technical side, the internal modeling and mapping between business objects and their external representation in XML can be improved.

While the deep use of XML and the blackboard approach is sufficient for use within our prototype, this approach is not well suited for productive use. XML processing is very slow in contrast to the use of native objects like Java Beans. Furthermore, other types of services like those offered by Enterprise Java Beans via RMI and CORBA cannot be called with XML data. However, the migration to an object-oriented approach for data management results in the need for converting huge amounts of data from and to XML. Furthermore, the use of practical techniques like XPath has to be emulated. The system's user interface part can be extended with modules for generating interfaces for mobile devices and Web applications. The necessary infrastructure is already existent making these tasks easy to solve.

Chances, Problems, and Risks

The difficulties of the application of conventional ERP systems are based on the complexity of the currently available products. The ERP market offers small, medium, and large ERP systems, which can be classified by the amount of covered enterprise sectors and the amount of included functions. Starting from the general statement that small- and medium-sized enterprises (SME) have almost the same functional ERP system requirements like large enterprises have, a dilemma opens up. Because SME cannot afford large ERP systems such as SAP®R3, Oracle®E-Business Suite, or SSA®Baan ERP 5, choices are based on compromise-driven decisions. Contrary to conventional ERP systems, FERP systems feature the following advantages, which aim at the solution of these problems:

- Due to the provision of isolated components, it is possible to charge the utilizing enterprises according to their needs and by this to decrease the overall ERP system application costs.
- Enterprises do not have to run high-end hardware in order to meet the requirements related to the application of complex ERP systems. Hardware can be made available by service providers.
- ERP service providers only have to make a part of the total system available, which reduces their time to market and their financial investment.
- A distributed system architecture is more scalable then a monolithic system.
- Distributed systems may be more reliable then monolithic systems. If one service goes down, then other services might continue to work. Moreover, it might be possible to replace the service with another one.

Beside this advantages various disadvantages, problems, and risks exist:

- Security considerations play an important role when a public network is used as communication basis. Particularly confidentiality of enterprise data is a critical aspect, which has to be considered in this context. Furthermore, a distributed access control model has to be developed in order to ensure the protection of local and remote resources, which means that only authorized users are permitted to access these resources. A federated identity management provides a solution of this problem (see Siddharth et al., 2003).
- The relationships between the different participating parties are based on different trust levels. Trust not only refers to misuse aspects but also the professional correctness of the provided functionality has to be secured. This was already discussed in Brehm and Marx Gómez (2005a), but trust measurement techniques deserve closer attention in this case.

- Performance problems will arise because the volume of data to be submitted is going to be immense in many cases (e.g., a large number of input and output data has to be exchanged between accounting-service consumer and service provider in order to calculate an actual target report).

Data models, interfaces, and architectural components have to be standardized in order to make FERP services interoperable. A solution for this problem was already previously shown and proposed in Brehm et al. (2005).

CONCLUSION

Comparing distributed ERP systems and ERP systems running on only one computer, distributed systems offer a lot of advantages. However, the design and development of such architectures are subject to a number of problems. The chapter presents a basis for the introduction of FERP Web services and discusses the pros and cons of an ERP solution as part of a service landscape where different vendors are appealed for the implementation and provision of ERP Web services in a federated manner. The proposed approach tunes in to the vision of a development process, which abstracts from concrete implementations. Nevertheless, there are a lot of open questions left which hinder machines to interact as providers of ERP software based on a process model even if ERP Web services act on standardized requirements. Because ERP systems process confidential enterprise data, security considerations play an important role when an open network like the internet is used. The future work must pick up these problems to realize the vision of a loosely coupled ERP system, which allows the combination of software components of different providers.

Chapter 7.13

Integrated Product Life Cycle Management for Software:

CMMI[1], SPICE, and ISO/IEC 20000

Dirk Malzahn
OrgaTech GmbH, Germany

ABSTRACT

This chapter describes how models for software development and service delivery can be integrated into a common approach to reach an integrated product life cycle for software. The models covered by this chapter are the capability maturity model integration (CMMI), SPICE (software process improvement and capability determination, ISO 15504) and ISO 20000 (service management). Whilst the CMMI constellation approach delivers an integration perspective defined in three models (development, acquisition and services), SPICE and ISO 20000 need additional alignment to be usable in an integrated approach.

INTRODUCTION

The focus of the market for IT solutions has changed. Whilst many companies and organizations followed the latest "hype" several years ago, they now trust in reliable and sustainable solutions.

To ensure this, standardization of quality evaluation becomes more and more important. For supplier selection, make-or-buy decisions and outsourcing strategies, a powerful set of procedures, that can help to assess the capability of internal and external software processes, is required. These procedures have to be based on best practices and must be widely accepted.

On this basis, standards offer the best possibilities: they are usually defined by a wide group of experts, which all contribute their experiences and best practices. Standards are either sponsored by an industry or by national bodies—therefore making these standards de facto mandatory for an industry, nation, or combination of both enforces the acceptance. If a significant group uses a standard, market dynamics have an additional impact. Official certificates, levels, and so forth can be and are used for marketing activities.

In the field of software related standards, lots of different standards have been defined for special topics, but one standard is still missing: a standard that covers a software product from the very beginning—the first idea—up to the very end—the retirement of the software.

On the one hand powerful standards, for example the capability maturity model integration (CMMI) or SPICE (ISO 15504), have been defined for software development. On the other hand, standards for service delivery, for example ITIL or ISO 20000, have been well established; but there is still a wall between the worlds of software development and service delivery. Even though some standards – like SPICE – take a look over the wall, an integrated approach has not been delivered yet.

The need for this integration is obvious. A customer is not interested in having some quality for development and some other quality for service delivery—the customer needs one quality approach that covers the full life cycle of a software product.

BACKGROUND

The Wall Between Software Development and Service Delivery

When IT systems are planned, the focus of the planning is mostly restricted to software development. Topics like operation environment or data management are discussed, but the strategy usually ends with the delivery of the software product.

On the other hand, service-delivering organizations mostly just provide "services" and are not really interested in the software development process.

This behavior leads to multiple difficulties and inefficiencies:

- Software developers and service people do not understand each other. They work in different worlds and have their own "language" and processes.
- The efficiency and effectiveness of service delivery highly depends on the architecture of and assumptions for the software, therefore the service organization has to be integrated early into the software development.
- Service level agreements can be optimized, when both sides reach a common understanding. The development of service level agreements is often based on the "what we need" position of both sides and not on the "what will be best for the customer" position.
- Problem Management is not transparent to the customer. The customer is not interested whether he has a service problem or a software problem—the customer wants a quick and reliable solution. If the software side does not understand the service side, problems often become ping-pong balls.
- Software usually lives longer than the original developer intends. Systems often have to be enhanced just to fulfil the requirements of a new service platform. If this is not taken into account when the software is developed, the effort for updating software may become enormous. Sometimes software has to be retired, just because it is not executable on the new platform!
- New approaches like service oriented architectures (SOA) demand the high integration of software and service elements. Future trends will rather lead to small combined software/service environments than to big software solutions operated by massive computer environments.

Just to ensure that I am not misunderstood: software developing and service delivering organizations will still deliver and operate solutions with high quality—but the will not do it in the most efficient and effective way. Organizations and companies aiming for the delivery of sustainable and reliable solutions have to ensure, that the solutions are not only developed in the best way but will meet the requirements of the future efficiently, effectively and still with high quality.

Standards for Software Development and Service Delivery

Regarding software development, two standard are widely accepted all over the world: the Capability Maturity Model Integration, published by the Software Engineering Institute (SEI) at the Carnegie Mellon University, and SPICE (Software Process Improvement and Capability Determination), which is published as ISO standard 15504. Both standards define a process framework based on best practices and provide an assessment model to evaluate process capability.

A process reference model (PRM) and a process assessment model (PAM) usually characterize a process framework. The PRM defines processes that have shown evidence to support high quality for the defined domain – in our case software development. The PAM builds the basis for collecting evidence that the PRM is adhered to and to evaluate the capability of the processes defined in the PRM.

In the world of service delivery, ITIL (IT Infrastructure Library) is the most acknowledged standard. To make ITIL assessable, the ISO 20000 standard was developed.

But as it was said before, none of these standards cover the complete software life cycle. This gap is seen by the SEI and discussed by relevant contributors to the ISO standards. In this article two approaches for this integration are discussed—one based on the CMMI and the other based on the connection of SPICE and ISO 20000.

CMMI INTEGRATION PERSPECTIVE

CMMI is one of the best-established process frameworks for software development. Starting with the publication of Watts Humphreys book “Managing the Software Process” in 1989, the CMM and its successor—the CMMI—nearly became a synonym for process improvement in the software world.

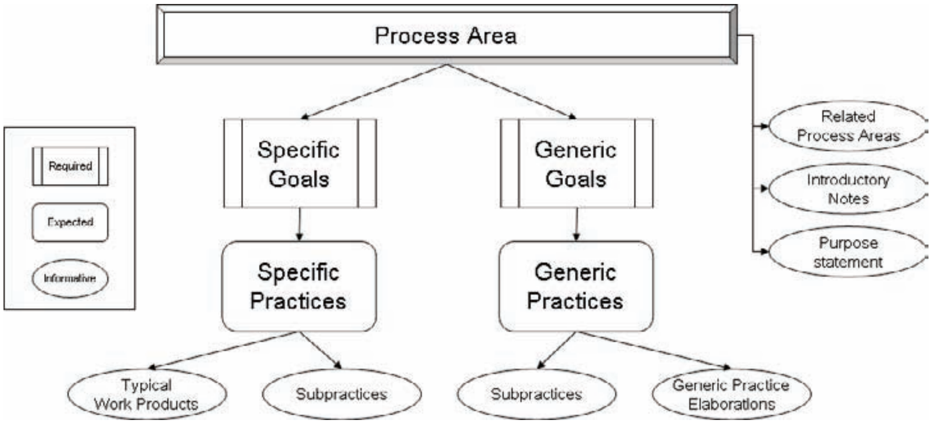
Nevertheless, until 2006, the CMMI was restricted on software and systems development. Since then a new initiative has been started to further develop the CMMI in the direction of acquisition and service processes. If one is talking about “CMMI” mostly the CMMI-DEV (for Development) is meant. This is the classical CMMI stream that covers service development. Other ideas concerning the usage and benefits of the CMMI for organizations that only acquire software, lead to the CMMI-ACQ (for Acquisition), which was published in November 2007. In 2006 and 2007 a CMMI for Services (CMM-SVC) has been developed to close the gap between software development and service delivery. The CMMI-SVC awaits publication in 2008.

CMMI Basics

Independent from the different CMMIs each of these models follows the same structure as shown in Figure 1.

In each CMMI a set of process areas is defined. For each process area the purpose is described, some introductory notes are given and other process areas which have a relation to this process area are listed. To satisfy the process area, goals must be fulfilled. Each process area has specific goals which are unique for this process area. Additional generic goals are defined, which are common for all process areas. For each goal a set of practices is defined, which are considered important for reaching the goal. For each practice subpractices, typical work products and elaborations are defined.

Figure 1. CMMI structure



From an evaluation perspective, only the goals are required. To reach a so-called "level" an organization has to fulfil the goals of the processes for this level. Nevertheless it is expected, that the defined practices are also fulfilled.

Process Capability vs. Organization Maturity

Talking about the CMMI always means talking about "level". But before the different levels can be explored, the different representations have to be discussed. CMMI knows two different representations, staged and continuous. In the staged representation each process area is assigned to a specified maturity level. To reach a maturity level, all specific goals of the assigned processes and a subset of generic goals have to be fulfilled.

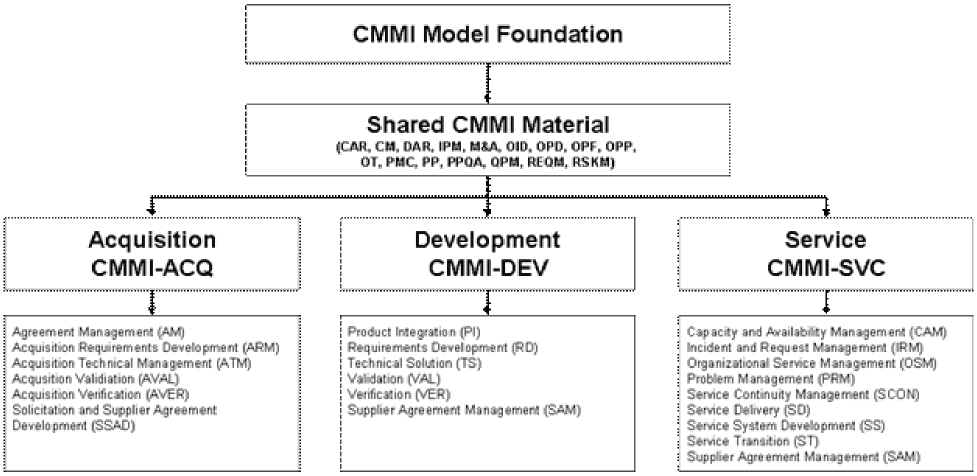
In the continuous representation, each process area is evaluated separately by fulfilling generic goals for this process area. Based on the set of generic goals that are fulfilled, the capability of the process area is measured.

In both representations, the generic goals have high importance. In total 5 generic goals are defined:

- **GG1:** The process supports and enables achievement of the specific goals of the process area by transforming identifiable input work products to produce identifiable output work products[2].
- **GG2:** The process is institutionalized as a managed process.
- **GG3:** The process is institutionalized as a defined process.
- **GG4:** The process is institutionalized as a quantitatively managed process.
- **GG5:** The process is institutionalized as an optimizing process.

In the staged representation 5 levels are defined. The lowest level is level 1, which means that the processes of the organization are still overwhelmingly chaotic. Goals for process maturity start with the definition of maturity level 2. For this level the specific goals of the assigned process areas and generic goal 2 have to be satisfied. For maturity level 3 the specific goals of the process areas assigned to level 2, the specific goals of the process areas assigned to level 3 and the generic goals 2 and 3 have to be satisfied. For level 4 and 5 specific goals of other process areas are added, but even for these higher levels, only generic goal 2 and 3 have to be satisfied.

Figure 2. CMMI constellation approach



In the continuous representation, 6 levels are defined, starting with level 0 and ending with level 5. Remembering, that a capability level is evaluated for each process area, the level is given by the fulfilment of the generic goals. On level 0 no generic goal is satisfied. On level 1, GG1 has to be satisfied, on level 2 GG1 and GG2 have to be satisfied and so on.

As this article is focused on the integration of activities and not mainly on evaluation issues, we will restrict the following chapters to the parts specific to certain process areas. For more information on the generic parts and evaluation procedures the CMMI itself should be used (Software Engineering Institute, 2006a).

The Constellation Approach

As said before, there is not the "one" CMMI. The idea of the current CMMI version is to have different constellations which share some process areas that are common for all constellations and have additional process areas that are unique for the constellation.

Currently, three constellations are published or planned to be published in 2007:

- **CMMI-DEV:** For development (June 2006) (Software Engineering Institute, 2006-1)
- **CMMI-ACQ:** For acquisition (November 2007) (Software Engineering Institute, 2007)
- **CMMI-SCV:** For services (2008, initial draft September 2006) (Software Engineering Institute, 2006b)

These constellations only differ in the number and content of process areas. All other contents of the CMMI, for example generic elements, level definitions, typographical conventions, build the model's foundation and are identical for all constellations.

In a first overview the constellation approach can be structured as shown in Figure 2.

The purposes of all process areas are explained in the next chapter.

Shared Process Areas

Causal Analysis and Resolution

The purpose of causal analysis and resolution (CAR) is to identify causes of defects and other problems and take action to prevent them from occurring in the future.

Configuration Management

The purpose of configuration management (CM) is to establish and maintain the integrity of work products using configuration identification, configuration control, configuration status accounting, and configuration audits.

Decision Analysis and Resolution

The purpose of decision analysis and resolution (DAR) is to analyze possible decisions using a formal evaluation process that evaluates identified alternatives against established criteria.

The IPPD Addition (Integrated Product and Process Development)

Before describing the next process area, a new term has to be defined: the "IPPD addition". In CMMI, "additions" are used to include material that may be of interest to particular users. The IPPD group of additions covers an IPPD approach that includes practices that help organizations achieve the timely collaboration of relevant stakeholders throughout the life of the product to satisfy customers' needs, expectations, and requirements (Department of Defense, 1996). If you apply the CMMI, you are free to add the IPPD addition or not.

Integrated Project Management + IPPD

The purpose of integrated project management (IPM) is to establish and manage the project and the involvement of the relevant stakeholders according to an integrated and defined process that is tailored from the organization's set of standard processes.

IPPD Addition: For IPPD, integrated project management +IPPD also cover the establishment of a shared vision for the project and the establishment of integrated teams that will carry out objectives of the project.

Measurement and Analysis

The purpose of measurement and analysis (MA) is to develop and sustain a measurement capability that is used to support management information needs.

Organizational Innovation and Deployment

The purpose of organizational innovation and deployment (OID) is to select and deploy incremental and innovative improvements that measurably improve the organization's processes and technologies. The improvements support the organization's quality and process-performance objectives as derived from the organization's business objectives.

Organizational Process Definition + IPPD

The purpose of organizational process definition (OPD) is to establish and maintain a usable set of organizational process assets and work environment standards.

IPPD Addition: For IPPD, organizational process definition +IPPD also cover the establishment of organizational rules and guidelines that enable conducting work using integrated teams.

Organizational Process Focus

The purpose of organizational process focus (OPF) is to plan, implement, and deploy organizational process improvements based on a thorough understanding of the current strengths and weaknesses of the organization's processes and process assets.

Organizational Process Performance

The purpose of organizational process performance (OPP) is to establish and maintain a quantitative understanding of the performance of the organization's set of standard processes in support of quality and process-performance objectives, and to provide the process-performance data, baselines, and models to quantitatively manage the organization's projects.

Organizational Training

The purpose of organizational training (OT) is to develop the skills and knowledge of people so they can perform their roles effectively and efficiently.

Project Monitoring and Control

The purpose of project monitoring and control (PMC) is to provide an understanding of the project's progress so that appropriate corrective actions can be taken when the project's performance deviates significantly from the plan.

Project Planning

The purpose of project planning (PP) is to establish and maintain plans that define project activities.

Process and Product Quality Assurance

The purpose of process and product quality assurance (PPQA) is to provide staff and management with objective insight into processes and associated work products.

Quantitative Project Management

The purpose of quantitative project management (QPM) is to quantitatively manage the project's defined process to achieve the project's established quality and process-performance objectives.

Requirements Management

The purpose of requirements management (REQM) is to manage the requirements of the project's products and product components and to identify inconsistencies between those requirements and the project's plans and work products.

Risk Management

The purpose of risk management (RSKM) is to identify potential problems before they occur so that risk-handling activities can be planned and invoked as needed across the life of the product or project to mitigate adverse impacts on achieving objectives.

Acquisition Process Areas

Solicitation and Supplier Agreement Development

The purpose of solicitation and supplier agreement development (SSAM) is to prepare a solicitation package and to select one or more suppliers for delivering the product or service and establish and maintain the supplier agreement.

Acquisitions Management

The purpose of agreement management (AM) is to ensure that the supplier and the acquirer perform according to the terms of the supplier agreement

Acquisition Requirements Development

The purpose of the acquisition requirements development (ARD) is to produce and analyze customer and contractual requirements.

Acquisition Technical Management

The purpose of the acquisition technical management (ATM) is to evaluate the supplier's technical solution and to manage selected interfaces of that solution.

Acquisition Validation

The purpose of the acquisition validation (AVAL) is to demonstrate that an acquired product or service fulfils its intended use when placed in its intended environment.

Acquisition Verification

The purpose of acquisition verification (AVER) is to ensure that selected work products meet their specified requirements.

Development Process Areas

Product Integration

The purpose of product integration (PI) is to assemble the product from the product components, ensure that the product, as integrated, functions properly, and deliver the product.

Requirements Development

The purpose of requirements development (RD) is to produce and analyze customer, product, and product component requirements.

Supplier Agreement Management

The purpose of supplier agreement management (SAM) is to manage the acquisition of products from suppliers.

Technical Solution

The purpose of technical solution (TS) is to design, develop, and implement solutions to requirements. Solutions, designs, and implementations encompass products, product components, and product-related lifecycle processes either singly or in combination as appropriate.

Validation

The purpose of validation (VAL) is to demonstrate that a product or product component fulfils its intended use when placed in its intended environment.

Verification

The purpose of verification (VER) is to ensure that selected work products meet their specified requirements.

Service Process Areas

As mentioned before, the CMMI-SVC has not been published yet. Nevertheless, it is available as initial draft (Software Engineering Institute, 2006b) and was already widely discussed on several conferences (Hollenbach & Buteau, 2006).

Capacity and Availability Management

The purpose of capacity and availability management (CAM) is to plan and monitor the effective provision of resources to support service requirements.

Incident and Request Management

The purpose of the incident and request management (IRM) process area is to ensure the timely resolution of requests for service and incidents that occur during service delivery.

Organizational Service Management*

The purpose of the organizational service management (OSM) process area is to establish and maintain standard services that ensure the satisfaction of the organization's customer base.

Problem Management

The purpose of the problem management (PRM) process area is to prevent incidents from recurring by identifying and addressing underlying causes of incidents.

Service Continuity*

The purpose of the service continuity (SCON) is to establish and maintain contingency plans for continuity of agreed services during and following any significant disruption of normal operations.

Service Delivery

The purpose of the service delivery (SD) process area is to deliver services in accordance with service agreements.

Service System Development*

The purpose of the service system development (SSD) process area is to analyze, design, develop, integrate, and test service systems to satisfy existing or anticipated service agreements.

Service Transition

The purpose of the service transition (ST) process area is to deploy new or significantly changed service systems while managing their effect on ongoing service delivery.

Supplier Agreement Management

The purpose of supplier agreement management (SAM) is to manage the acquisition of products from suppliers.

The process areas marked with an asterisk (*) are additions (like IPPD in the CMMI for Development) and therefore optional.

CMMI Process Categories

In order to develop a better understanding for the dependencies between the process areas, the CMMI-DEV defines 4 categories which are applied to the other constellations below, and collect process areas with a similar focus. Therefore, 3 categories are identical for all constellations. These are

- Process management
- Project management
- Support

The fourth category is focussed on the field of application of the constellation and is labelled

- Acquisition (in CMMI-ACQ)
- Engineering (in CMMI-DEV)
- Service Establishment and Delivery (in CMMI-SVC)

Based on this categorization the complete set of CMMI process areas can be categorized as follows.

For shared process areas see Table 1; for CMMI-ACQ see Table 2; for CMMI-DEV see Table 3; for CMMI-SVC see Table 4.

Constellation Based Maturity Levels

As described before, each process area is assigned to a defined maturity level. Whilst on level 4 and

5 only shared process areas are assigned, the assignment on level 2 and 3 is dependent on the constellation (see Table 5).

The shared processes assigned to level 4 are

- Organizational process performance
- Quantitative project management

The shared processes assigned to level 5 are

- Causal Analysis and Resolution
- Organizational Innovation and Deployment

A CMMI Based, Integrated Product Life Cycle

Even though the CMMI provides 3 different constellations, these constellations can be used to define 2 different integrated product life cycles:

- Organizations which provide service delivery for acquired software products should use the process areas of the CMMI-ACQ in combination with the process areas of the CMMI-SVC.
- Organizations which develop software and provide service delivery should use the process areas of the CMMI-DEV in combination with the process areas of the CMMI-SVC.

Even the combination of all three constellations is thinkable, when a service delivering organization partially acquires and partially develops the software.

SPICE / ISO 20000 INTEGRATION PERSPECTIVE

Besides the CMMI world, another possibility for an integrated product life cycle is the combina-

Table 5. Maturity level 2 and 3 for CMMI constellations

	Maturity Level 2	Maturity Level 3

CMMI-SVC	Supplier Agreement Management, Incident and Request Management	Capacity and Availability Management, Service Continuity Service Delivery, Service System Development, Service Transition, Organizational Service Management, Problem Management

tion of two ISO standards: the ISO 15504—better known as SPICE—and the ISO 20000.

SPICE Basics

The ISO 15504 (SPICE) is structured in 5 parts. Part 1 defines the basic concept and the vocabulary. In part 2 rules for performing an assessment are defined, and in part 3 guidance for the assessment is given. Part 4 gives additional guidance on the use for process improvement and capability determination.

The interesting part under the integration perspective is part 5. This part defines an exemplar process assessment model.

Whilst the capability determination is widely similar to the approach of the CMMI continuous representation, the process model is different from the CMMI.

SPICE defines 3 categories. These categories are structured in groups and each group has several processes (ISO/IEC, 2006). The categories with their groups are:

- Primary life cycle processes
  - Acquisition process group (ACQ)
  - Supply process group (SPL)
  - Engineering process group (ENG)
  - Operation process group (OPE)
- Organizational life cycle processes
  - Management process group (MAN)
  - Process improvement process group (PIM)
  - Resource and infrastructure process group (RIN)
  - Reuse process group (REU)
- Supporting life cycle processes
  - Supporting process group (SUP)

Comparing the SPICE categories with the CMMI constellations, strong connections can be identified between the process groups of the primary life cycle processes and the CMMI constellations. The acquisition process group and supply process group have the same focus as the CMMI-ACQ as well as the engineering process group and the CMMI-DEV. Only the CMMI-SVC does not have a counterpart in SPICE. The operation processes group and some processes of the supporting process group address service related topics, but a common approach is not delivered.

To better understand the content of the SPICE process groups each group with its processes should be further described—as defined in SPICE (ISO/IEC, 2006):

Primary Life Cycle Processes

The primary life cycle processes consist of processes that serve primary parties during the life cycle of software. A primary party is one that initiates or performs the development, operation, or maintenance of software products. These primary parties are the acquirer, the supplier, the developer, the operator, and the maintainer of software products.

- The acquisition process group (ACQ) consists of processes performed by the customer, in order to acquire a product and/or a service. The processes of this group are:
  - ACQ.1: Acquisition preparation
  - ACQ.2: Supplier selection
  - ACQ.3: Contract agreement
  - ACQ.4: Supplier monitoring
  - ACQ.5: Customer acceptance
- The supply process group (SPL) consists of processes performed by the supplier in order to propose and deliver a product and/or a service. The processes of this group are:
  - SPL.1: Supplier tendering
  - SPL.2: Product release
  - SPL.3: Product acceptance support
- The engineering process group (ENG) consists of processes that directly elicit and manage the customer's requirements, specify, implement, and/or maintain the software product and it's relation to the system. The processes of this group are:
  - ENG.1: Requirements elicitation
  - ENG.2: System requirements analysis
  - ENG.3: System architectural design
  - ENG.4: Software requirements analysis
  - ENG.5: Software design
  - ENG.6: Software construction
  - ENG.7: Software integration
  - ENG.8: Software testing
  - ENG.9: System integration
  - ENG.10: System testing
  - ENG.11: Software installation
  - ENG.12: Software and system maintenance
- The operation process group (OPE) consists of processes performed in order to provide for the correct operation and use of the soft-

ware product and/or service. The processes of this group are:

- OPE.1: Operational use
- OPE.2: Customer support

Organizational Life Cycle Processes

The organizational life cycle processes consist of processes employed by an organization to establish and implement an underlying structure made up of associated life cycle processes and personnel and continuously improve the structure and processes. They are typically employed outside the realm of specific projects and contracts; however, lessons from such projects and contracts contribute to the improvement of the organization.

- The management process group (MAN) consists of processes that contain practices that may be used by anyone who manages any type of project or process within a software life cycle. The processes of this group are:
    - MAN.1: Organizational alignment
    - MAN.2: Organizational management
    - MAN.3: Project management
    - MAN.4: Quality management
    - MAN.5: Risk management
    - MAN.6: Measurement
- The process improvement process group (PIM) consists of processes performed in order to define, deploy, assess and improve the processes performed in the organizational unit. The processes of this group are:
    - PIM.1: Process establishment
    - PIM.2: Process assessment
    - PIM.3: Process improvement
- The resource and infrastructure process group (RIN) consists of processes performed in order to provide adequate human resources and necessary infrastructure as required by any other process performed by the organizational unit. The processes of this group are:
    - RIN.1: Human resource management
    - RIN.2: Training
    - RIN.3: Knowledge management
    - RIN.4: Infrastructure
- The reuse process group (REU) consists of processes performed in order to systematically exploit reuse opportunities in the organization's reuse programmes. The processes of this group are:
- REU.1: Asset management
- REU.2: Reuse program management
- REU.3: Domain engineering

Supporting Life Cycle Processes

The supporting life cycle processes consist of processes that support another process as an integral part with a distinct purpose and contribute to the success and quality of the software project. A supporting process is employed and executed, as needed, by another process. The processes of this group are:

- SUP.1: Quality assurance
- SUP.2: Verification
- SUP.3: Validation
- SUP.4: Joint review
- SUP.5: Audit
- SUP.6: Product evaluation
- SUP.7: Documentation
- SUP.8: Configuration management
- SUP.9: Problem resolution management
- SUP.10: Change request management

Each SPICE process has a well-defined structure. After the process ID (e.g., SUP.10) and the process name (e.g., change request management), the purpose of the process is described. Then the process outcomes are defined. These process outcomes—plus process attributes—have to be achieved to reach a capability level in SPICE. Afterwards base practices for each process are defined and work products of the process are listed.

Table 6. CMMI and SPICE process structure

CMMI	SPICE
Acronym	Process ID
Process Name	Process Name
Purpose Statement	Process Purpose
Specific Goals	Process Outcomes
Specific Practices	Base Practices
Generic Goals	Process Attributes
Typical Work Products	Work Products

Comparing the structure of a CMMI process area and a SPICE process, there are lots of similarities (see Table 6).

All in all, SPICE has 48 processes that mainly cover software development and have only small focus on service delivery. For this part, the ISO 20000 seems more applicable.

ISO 20000 Basics

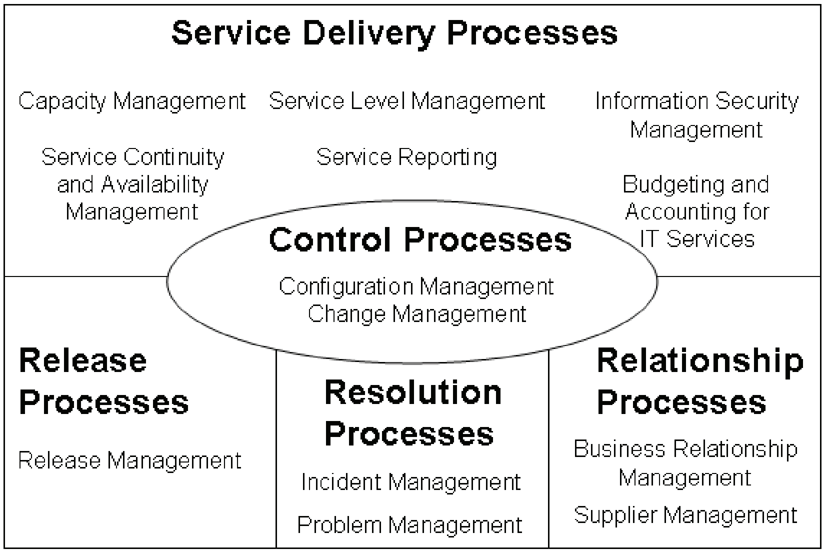
ISO 20000—Service Management covers the classical service delivery processes. Regarding the scope of ISO 20000, this standard represents "an industry consensus on quality standards for IT service management processes. These service management processes deliver the best possible service to meet a customer's business needs within agreed resource levels" (ISO/IEC, 2005b).

ISO 20000 defines 13 processes in 5 process groups.

Regarding each process group,

- The objective of the service delivery process group is to define, agree, record and manage levels of service, and consists of the processes
    - ◦ Capacity management
    - ◦ Service continuity and availability management
    - ◦ Service level management
    - ◦ Service reporting
    - ◦ Information security management
    - ◦ Budgeting and accounting for IT services
- The objective of the relationship process group is to describe the related aspects of supplier management and business relationship management, and consists of the processes
    - ◦ Business relationship management
    - ◦ Supplier management
- The objectives of the resolution process group are to restore agreed service and minimize disruption to the business, and consists of the processes
    - ◦ Incident management
    - ◦ Problem management
- The objective of the control process group is to define and control the components of service and infrastructure, and consists of the processes
    - ◦ Configuration management
    - ◦ Change management
- The objective of the release process group is to deliver, distribute and track changes, and consists of the process
    - ◦ Release management

Figure 3. ISO 20000 processes



Those who know ITIL may have found lots of similarities in the process names and structure of ISO 20000. The ISO 20000 is well aligned with ITIL. Whilst ITIL is a collection of best practices, ISO 20000 defines specifications to support a service provider in delivering high quality services. The other way round, ITIL best practices help to achieve the quality of service management as defined by ISO 20000. It has to be recognized that ISO 20000 and ITIL are developed in strong connection, often impacted by the same persons.

Interfaces Between SPICE and ISO 20000

Trying to integrate SPICE and ISO 20000 it has to be taken into account, that both standards cover similar or identical elements in some processes. If an integrated product life cycle should be defined, these interfaces have to be harmonized.

First of all, the operational process group of SPICE has to be analyzed. This process group consists of two processes, operational use (OPE.1) and customer support (OPE.2).

The operational use process has the purpose to ensure the correct and efficient operation of the product for the duration of its intended usage and in its installed environment. Topics like operational risks, operational testing, criteria for operational use and the monitoring of the operational use are covered by this process.

The customer support process has the purpose of establishing and maintaining an acceptable level of service. Topics of this process are establishing of product support, performance monitoring and customer satisfaction.

Even though these processes address service aspects, they only deliver a high level overview. Nevertheless these topics address similar elements as the ISO 20000 processes service level management and business relationship management.

Other service delivery related processes can be found in the group of the supporting life cycle processes. The processes in focus are:

- SUP.8: Configuration management
- SUP.9: Problem resolution management
- SUP.10: Change request management

With configuration management the integrity of work products is established and maintained and these work products are made available to parties concerned. The problem resolution management process focuses on identification, analysis, management and controlling of discovered problems, while change request management ensures that change requests are managed, tracked and controlled.

Some other useful information for service delivery can be found in the process related to supplier management (acquisition / supply process groups).

Integration of SPICE and ISO 20000

To reach a fully integrated product life cycle, two requirements have to be satisfied:

- A set of processes has to be defined, which covers all stages of the life cycle—a so called process reference model (PRM)
- A model to evaluate the process capability has to be defined and must be applicable to all processes—a so called process assessment model (PAM)

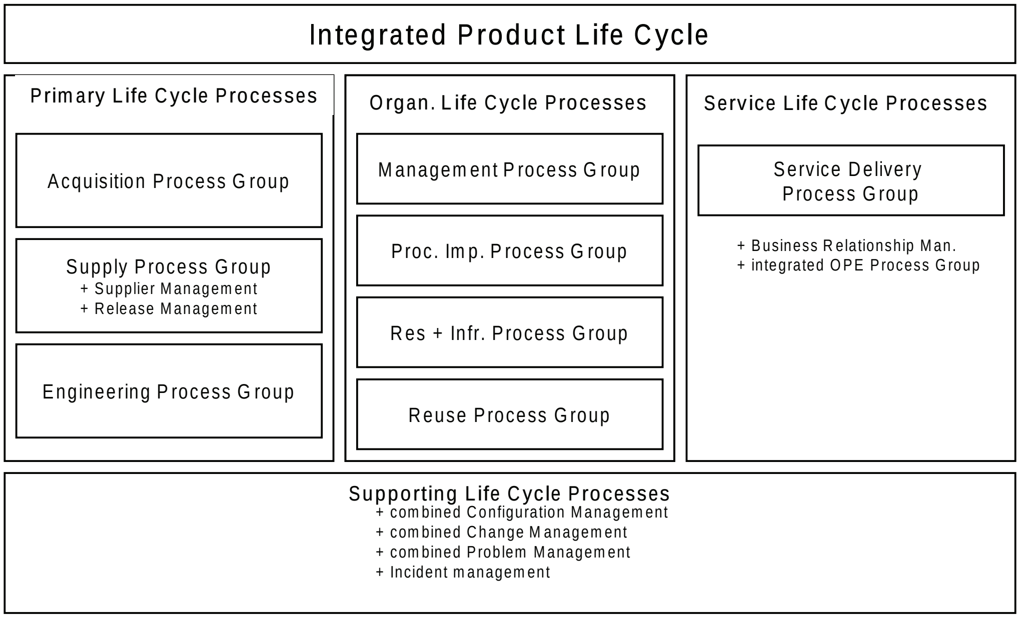
Both requirements are satisfied by the CMMI constellations: the PAM is defined in the model foundation which is mandatory for all constellations and the PRM is given by the defined process areas.

For the SPICE and ISO 20000 integration, this is not that easy. On the one hand SPICE and ISO 20000 address identical topics in different processes, on the other hand, only SPICE has an assessment model. A way to solve this problem was defined in early 2007 (Malzahn, 2007) and should be described in the following chapters.

A Combined PRM for SPICE and ISO 20000

As described before, double definitions in SPICE and ISO 20000 have to be eliminated and all processes need to have an identical structure. Therefore in a first step, the ISO 20000 processes have to be restructured into the SPICE process

Figure 4. Integrated Product Life Cycle based on SPICE and ISO 20000



structure. In a second step, processes with a similar focus must be aligned.

For the first step, the ISO 20000 process groups and processes become process groups and processes of the combined model. For each ISO 20000 process the defined objective becomes the process purpose. For the rest of the text it has to be decided, which text passage becomes an outcome, a base practice, or a work product.

In the second step, all processes with a similar focus have to be aligned. Concerning SPICE and ISO 20000 it is proposed to

- Integrate the SPICE OPE process group into the service level management, service reporting and business relationship management processes of ISO 20000,
- Combine configuration management
- Combine problem resolution management and problem management,
- Combine change request management and change management.

Other possibilities for further alignment are e.g., given by the combination of the ISO 20000 release management process and the SPICE product release process, and by integrating the relationship processes into the acquisition / supply process group.

After this integration and combination, the process groups may be restructured as follows:

- The ISO 20000 control processes become part of the support process group,
- The ISO 20000 release management process becomes part of the Supply process group,
- ISO 20000 problem management and incident management become part of the support process group,
- Business relationship management may become part of the service delivery process group.

In the very end, a combined PRM for SPICE and ISO 20000 may consist of the SPICE process categories and a new service life cycle category with the following amendments:

A Combined PAM for ISO 20000 and SPICE

The definition of a process assessment model for the integration of SPICE and ISO 20000 is easy to define—it is the approach defined for SPICE. Regarding ISO 20000, no measurement framework is defined. The requirements concerning measurement are given in part one of the ISO 20000 as follows:

"The service provider shall apply suitable methods for monitoring and, where applicable, measurement of the service management processes" (ISO/IEC, 2005a). Therefore no inconsistencies in the measurement and rating can occur. The SPICE definitions are applicable because each ISO 20000 process was restructured in the PRM and therefore all contextual and structural requirements are satisfied.

COMPARISON OF BOTH APPROACHES

Regarding both approaches—the CMMI constellations and the integration of SPICE and ISO 20000—there are pros and cons for each approach:

- The CMMI constellations are highly integrated by using the same model foundation, but CMMI-SVC will not see the light of day before 2008
- SPICE and ISO 20000 require additional effort to be integrated, but both are ISO standards and therefore widely accepted—especially if legal matters have to be taken into account.

Other impacts may be the region or industry of the organization. The CMMI is very strong in the United States; SPICE is heavily used in Europe. Most defence industry companies are interested in CMMI, whilst major parts of the automotive industry prefer SPICE.

FUTURE TRENDS

This article covers two possible integration approaches. Nowadays more and more approaches see the light of day. Especially the integration of ITIL and CMMI or SPICE is widely discussed (Barafort, Di Renzo, Lejeune, Prime & Simon, 2005; Foegen & Graumann, 2007). Nevertheless ITIL is a best practice collection and not a measurement framework and therefore we still see some problems in the ITIL integration.

Hopefully the CMMI-SVC proves that it is a powerful tool for this intended integration and maybe at some point in time the ISO will find a way to publish an assessment model that covers the complete product life cycle for software.

Another promising approach will be the Enterprise SPICE initiative. The goal of this initiative is to “integrate and harmonize existing standards […] to provide a single process reference model and process assessment model that addresses broad enterprise processes. Enterprise SPICE will provide an efficient and effective mechanism for assessing and improving processes deployed across an enterprise” (SPICE User Group, 2007).

Using Integrated Models

Defining an integration approach is only a short part on the way to software development and service delivery integration. Even though it builds the indispensable basis, integration only works, if it is accepted by organizations, teams, and people. To reach this, some simple rules of the thumb should be followed:

- Integrate the working level of development and service delivery at least in the review of an integrated model – preferably in the development. If the working level understands the need for integration and is part of the integration process, the integrated model is better accepted.
- Provide translation between the development, service delivery and integration approach. Only if software development and service delivery people reach a common understanding, an integrated approach can be established.
- Provide training on the approach. Training must not be focused on “we combine standard A with standard B” but on “we define an approach for the complete life cycle”. There is no longer “their work” and “our work” but a common responsibility from first idea to retirement.

If and only if the need for integration is understood and accepted by people on working level, integration can be established – otherwise there will still be two worlds with all their differences and borders.

CONCLUSION

The decision, which approach may deliver the best benefit, must be taken by the organization itself. But one thing is inevitable: if the capability of the processes of an organization is not evaluated against accepted standards and for the complete life cycle, the organization keeps the back door open for chaotic elements in their process suite and therefore has an open door for abusing strategies, processes, and procedures.

Chapter 7.14
Customer Relationship Management (CRM) Metrics:
What's the Holdup?

ABSTRACT

Adopting a focus on CRM has been an industry standard for nearly two decades. While evidence suggests that a majority of the attempts to implement CRM systems fail, no single reason for the failures has been identified. Assuming that CRM implementation is an extension of a customer-oriented business strategy and assuming successful integration with Enterprise Information Systems such as Enterprise Resource Planning (ERP) systems, the authors contend that the lack of valid and reliable CRM metrics leads to the perception of failed CRM implementation. Only through the development, application, and use of CRM metrics can organizations hope to achieve their CRM goals.

INTRODUCTION

For nearly two decades, businesses worldwide have sought a means to connect meaningfully with their customers. For many, the integration of information technology and marketing has provided a platform on which to build this connection. Thus, Customer Relationship Management (CRM) has emerged as the strategic bridge between information technology and marketing strategy (Wehmeyer, 2005). CRM is a customer-centric business strategy in which an organization seeks to increase customer satisfaction and loyalty by offering customer-specific services (Kristoffersen & Singh, 2004). CRM allows companies to collect and analyze data on customer patterns, interpret customer behavior, develop predictive models, respond with timely and effective customized communications, and deliver product and service value to individual customers (Chen & Popovich, 2003). Acquiring a better understanding of existing customers allows companies to interact, respond, and communicate more effectively with them in order to improve retention rates, among other things. The goal is to return to the feeling of yesteryear, when small business owners and customers knew each other intimately and shared a sense of community (Chen & Popovich, 2003).

Since CRM requires an integration of information technology and marketing, cross-functional cooperation becomes mandatory for success (Nairn, 2002). But this cooperation isn't the only prerequisite for success. Two other critical success factors have been identified: (1) a customer-centric business model (Chen & Popovich, 2003) and (2) appropriate business processes and integrated systems (Bull, 2003). In addition, resource constraints impact CRM implementation. It is estimated that the average investment in CRM applications per company is U.S.$2.2 million (Chen & Popovich, 2003). Estimates of 2004 global corporate expenditures on CRM range from U.S.$23.5 billion (Bull, 2003) to U.S. $125 billion (Adebanjo, 2003; Winer, 2001).

OVERLAP BETWEEN ENTERPRISE RESOURCE PLANNING (ERP) AND CUSTOMER RELATIONSHIP MANAGEMENT (CRM)

Many CRM packages were developed by legacy systems vendors (ERP) to be seamless additions or modules (Adebanjo, 2003). ERP systems are thought of as back-office systems, whereas CRM systems are thought of as front-office systems (Corner & Hinton, 2002). ERP systems address fragmented information systems, while CRM systems address fragmented customer data. The two systems work together interactively in order to produce data on which managers are able to increase competitiveness by reducing costs and increasing sales. The goal of CRM technology is to link front-office (i.e., sales, marketing, and customer service) and back-office (i.e., financial, operations, logistics, and human resource) functions with the company's customers (Chen & Popovich, 2003).

The importance of integrated corporate applications such as ERP and CRM is increasing despite reports of negative experiences and failed implementations (Huang, Yen, Chou & Xu, 2003). But prior to focusing on the pitfalls of CRM implementation, the following sections offer the potential benefits sought by businesses that pursue CRM as an active business strategy.

POTENTIAL BENEFITS OF CRM

There are many potential benefits of integrating ERP and CRM systems (Huang et al., 2003). Some of the possible outcomes of successful CRM implementation include increased competitiveness through higher revenues and lower operating costs; increased customer satisfaction and retention rates; increased customer value; potential to assess customer loyalty, profitability, and ability to measure repeat purchase; dollars spent;and customer longevity (Chen & Popovich, 2003; Ling & Yen, 2001).

Companywide, CRM systems provide each employee with a tool to manage contacts, activities, documents, and the information necessary for personalizing or customizing marketing efforts in order to meet individual consumer needs (Bygstad, 2003). The most frequently cited critical success factors for implementation include defining a CRM strategy that is consistent with corporate strategy and determining the scope and scale of the cross-departmental infrastructure changes needed (Kotorov, 2003). Finally, all businesses seeking to develop and implement a CRM system would be wise to realize that the goal of developing a perfect CRM system is unattainable (Corner & Rogers, 2005).

THE DARK SIDE OF CRM

CRM implementation is hard work (Bygstad, 2003). By some estimates, 75% to 85% of the CRM systems implementations either are outright failures (Bygstad, 2003; Earley, 2002; Tafti, 2002) or disappoint to the level that CRM frequently has come to mean "Can't Recover Money." In a recent study of Australian businesses that adopted CRM systems, 60% were less than satisfied with the results achieved to date (Ang & Buttle, 2005).

Therefore, it is safe to say that many of the companies who have implemented CRM systems have failed to realize the potential benefits sought (Kristoffersen & Singh, 2004). The question is why? Many companies underestimate the complexities of CRM, lack clear business objectives, and tend to invest inadequately in implementation (Bull, 2003). Others fail because they assume that the same methodologies used for implementing ERP systems are suitable for implementing CRM systems (Corner & Rogers, 2005). Still others fail because they do not successfully integrate with ERP systems (Chan, 2005). To be fair, the failure rate is consistent with the implementation success rate of other Enterprise Information Systems such as ERP systems. How can we improve the situation? One interesting area to investigate is the use, or lack of use, of CRM metrics. Chan (2005) contends that the inability to align the correct metrics across business activities is a critical reason for CRM failure.

THE CURRENT STATUS OF CRM METRICS

In a sample drawn from Fortune 1000 companies, 39% had no CRM metrics, 48% had internal metrics, and only 12% had external goals and metrics (Rogers, 2003). The need for valid and reliable metrics is clear. In order to optimize CRM performance, metrics need to be enterprise-wide, customer-centric (Chan, 2005), and relevant (Rogers, 2003). Metrics from sales, marketing, customer service, and operations should be unified in order to drive measures of customer profitability, customer satisfaction, and market share (Chan, 2005). The disconnect between CRM and CRM metrics negatively impacts marketing effectiveness, customer retention, and loyalty (Chan, 2005). The problem with CRM metrics today is that they mostly are focused internally, measuring items such as increase in sales revenue, improved sales productivity, reduction in marketing waste, reduction in costs in call centers, reduction in sales cycle time, increase in campaign response, and decrease in cost of response. In order to be useful, metrics are needed that focus on the customer's experience, measuring items such as improvement in first contact resolution or improved speed of order fulfillment (Rogers, 2003).

BUILDING THE CASE FOR THE DEVELOPMENT OF CRM METRICS

The emergence of the quality movement in the 1980s in the United States, spurred on by Edward

Demming's mantra "You can't manage what you can't measure," helped energize the push for performance management, benchmarking, metrics, and the like. While initially focused on financial and non-financial measures for manufacturing, performance measures have evolved to include the full range of activities within a company, including service activities and even strategic activities. The Metrus Group (2002) is one of many to document the effectiveness of performance management.

At the same time, as already addressed, there is also considerable evidence that CRM implementations today are not very good at measuring their impact or the benefit to the company, and the company often lacks an established approach to metrics or analytics. Granted, like other new technology waves, the CRM wave began with too many vendors promoting flash over substance. However, now that we are about 10 years into the wave and have the benefit of thousands of ERP and CRM implementations, what's the holdup? Why are we still fumbling with metrics?

It is true that metrics simply cannot be slapped on to the front bumper and be expected to provide value. A company needs to know what it is trying to accomplish with its CRM before developing metrics. That is, a company first needs to have an overall strategic plan as well as an enterprise-wide CRM strategy that integrates information needs, technology needs, and alignment with company processes and goals. The CRM should have organizational goals, technology goals, and goals for customer offerings (Sawhney, 2001). A company with many legacy systems that make it difficult to integrate across various information silos will have a slow start.

Others have suggested that people, culture, and processes also are factors that can inhibit a company from adding value across its customer value chain from the integrated information that a CRM can provide. Put a slightly different way, we suggest it is not the technology anymore, be it data communications issues or application maturity; it is people, culture, and change. A simple example is a new CRM system that identifies problem areas. Who wants to be the messenger to deliver the bad news in a corporate culture that does not support such activities?

Distance learning technology was at a similar point about five years ago. For a number of years, people had plenty of legitimate complaints about distance learning technology: it doesn't work, the server is down too often, the connection is too slow, the software is too frustrating and doesn't do what I need it to do, it takes too much time, and so forth. Over a few short years, connection speeds even to the home became fast and reli-

Table 1. Benefits of strategic performance management (© Metrus Group, 2002)

Measure of Success	Measurement-Managed Organizations	Non-Measurement-Managed Organizations
Industry leader over the past three years	74%	44%
Three-year return on investment (ROI)	80%	45%
Success in last major change effort	97%	55%
Clear agreement on strategy among senior management	93%	37%
Effective communication of strategy to organization	60%	8%

able, the learning management software matured, and adequate infrastructure such as servers was in place. Seemingly in a flash, the discussions moved from technology to pedagogy and assessment. Likewise, we believe the maturity of CRM applications available today and the experience of companies using CRM applications are now permitting companies to move from a technology focus to an application focus as well as the evaluation of CRM's performance and benefits.

We believe it is time to revisit and reinvigorate efforts to develop, implement, and research CRM metrics. Some CRM metrics, such as developing useful measures to support return on investment (ROI) or using the balanced scorecard technique, can take time to learn and implement. One such metric proposed is the Customer Value Scorecard (CVS). The CVS is a customer performance metric that looks at transition rates from stages and segments that affect the value of the customer base (Hansotia, 2002). However, many current CRM metrics exist today that can be applied quite readily to help demonstrate value and profitability. Metrics such as Relative Customer Satisfaction, Customer Retention, and Customer Lifetime Value provide valuable benchmarks for managers (Rogers, 2003). The following suggested metrics assume a full CRM implementation, integration with ERP reporting, and data mining capabilities. CRM metrics include the following:

- **Changes in Conversion or Sales Rate.** An increase in the number of opportunities vs. the number of wins can show growth. Data-mining techniques can show conversion results in specific markets or within a range of customers.
- **Changes in Cross-Selling Rate for Existing Customers.** Silos often are built in organizations between diverse product offerings. The ability to show an increase in cross selling to existing customers provides many intrinsic returns in an organization's ability to maximize its share of customer wallets.
- **Evaluating Marketing Campaigns.** The ability to measure the productivity of a campaign with hard numbers and trend data is especially important to organizations in which larger individual investments in marketing are needed to produce a win.
- **Predicting Future Sales.** Over time, an integrated CRM system can provide more information about future sales and more accurate probabilities about potential wins.
- **Evaluating the CRM System.** The data documenting the effectiveness of the customer life cycle for customers, including order and supply process improvements, customer support, sales, sales and marketing expenses, and customer satisfaction, can document the value of the CRM system.
- **Bringing New Marketing and Sales Personnel up to Speed.** Staff transition is a fact of doing business, especially in today's dynamic environment. CRM systems metrics as well as the valuable history of past and present interactions with customers can significantly speed up a new employee's productivity learning curve.

The following do not require an integrated, full CRM implementation. They just some time and, for most of them, an Excel spreadsheet:

- **Cost Per Acquisition.** Customer acquisition costs are the costs associated with convincing a consumer to buy a product or service, including marketing, research, advertising costs, and Web content. It is calculated by dividing the costs by the number of acquisitions. Customer acquisition cost should be considered along with other data, especially the value of the customer to the company and the resulting return on investment (ROI) of acquisition.
- **Customer Lifetime Value.** Loyal customers mean future revenues. Customer Lifetime Value (CLV) is the present value of the future

revenue generated from a customer for as long as you retain that customer. If CLV is an indication of the value of a relationship, companies must find ways to maximize CLV by utilizing strategies that maximize incremental sales and by launching effective customer loyalty programs. The formula for CLV is Customer Lifetime Value = Revenue from initial purchase + Present Value of Future Revenues over the Projected Lifetime—the Acquisition Cost of the Customer

- **Changes in Customer Satisfaction.** While satisfaction measures may not provide verifiable results as quickly as other metrics, they provide important overall, long-term trends as well as valuable feedback on the organization's most important customers.
- **E-mail Effectiveness.** E-mail effectiveness can be measured a number of ways. The Return on Investment (ROI) of a particular e-mail campaign can be calculated by dividing the total cost of the mailing into the net income produced. A monthly e-mail churn rate (number of undeliverable e-mail names plus the names deleted from the list during the month divided by the total number of e-mail names on your list at the end of the month) measures how much your customer base rolls over every month.
- **Web Traffic Analysis.** There are a number of Web traffic analysis packages available, many of which are very affordable (e.g., ClickTracks, Hitslink, FastCounter Pro). They can support Web marketing through ROI analysis, detailed visitor analysis, content performance, and ad tracking.

SUMMARY

For some, the development and use of CRM metrics is a case of too little too late and can only confirm that the organization is already in trouble (Rogers, 2003). But this should not dissuade organizations from the pursuit of the development of well-defined CRM metrics. Metrics provide actionable data, either positive or negative, and have the ability to help to demonstrate the value and profit attributable to a CRM implementation. Our hope is to illustrate that an opportunity exists for developing customer-focused CRM metrics and that starting down the road of CRM metric development does not require either a Ph.D. in statistics or even a full CRM implementation.

It is clear that just as the implementation of a CRM system is a cross-functional endeavor, so is the development of the metrics needed to manage these systems. We are attempting to walk the walk: one author is a management information systems professor, two are marketing professors, one is an accounting and finance professor, and the final one is from the CRM industry. Our goal is to promote and reinvigorate the CRM metrics conversation. We issue a challenge to our colleagues in the academy to join us in our pursuit of the development of valid and reliable CRM metrics that have broad applications. Do you measure up?

Chapter 7.15

Security Policies and Procedures

Yvette Ghormley
Saint Leo University, USA

ABSTRACT

The number and severity of attacks on computer and information systems in the last two decades has steadily risen and mandates the use of security policies by organizations to protect digital as well as physical assets. Although the adoption and implementation of such policies still falls far short, progress is being made. Issues of management commitment, flexibility, structural informality, training, and compliance are among the obstacles that currently hinder greater and more comprehensive coverage for businesses. As security awareness and security-conscious cultures continue to grow, it is likely that research into better methodologies will increase with concomitant efficiency of security policy creation and implementation. However, attacks are becoming increasingly more sophisticated. While the human element is often the weakest link in security, much can be done to mitigate this problem provided security policies are kept focused and properly disseminated, and training and enforcement are applied.

INTRODUCTION

In the days of mainframes, users were given a username and password, and perhaps an electronic badge to admit them to a computer facility. Those days have long evaporated. With the advent of private broadcast networks, intranets, portable media devices, laptops, and the commercial development of the Internet, security for any kind of business has become a lot more complicated. Moreover, it is costing more. The average loss from unauthorized access to data increased by 488 percent from $51,545 in 2004 to $303,234 in 2005, according to the most recent Computer Security Institute/FBI Computer Crime and Security Survey (McFadden, 2006). For larger companies, recent security breaches were estimated by Ernst and Young to range from $17 to

$28 million per incident (Garg, Curtis, & Halper, 2003), and Austin & Darby (2003) reported that the cost of security breaches to businesses in the USA was $17 billion. Further, correcting the long-term damage, which includes loss of customer confidence, damage to the company's image, and financial consequences, such as stock devaluation for public companies, can be extremely costly, although difficult to estimate. Therefore, developing an effective security policy, implementing it, and ensuring that it is understood and practiced by all employees is essential.

The Approach to Security Policies and Procedures

Companywide policies should be initiated and enforced from the top, and that includes IT security policies. That does not mean to say that technical policies, such as those developed by IT departments, cannot have a specific focus, but the level of technical complexity itself should not be regarded as a barrier that top management can ignore. Tuesday (2002) cites a case study in which an old approved policy was updated at a lower level but ignored by a CEO's assistant, who was essentially acting as the gatekeeper. The eventual result was that the CEO applied for an exception dispensation; however, the antics of the assistant probably caused sufficient disruption that enforcing the updated policy was difficult.

Policies must focus on the most important aspects of security rather than comprise a long list of laundry items in a 200-page manual. For example, one of the most productive ways to review security from scratch is for each business unit to determine what devices and associated data (digital assets) are the most important (Austin & Darby, 2003). From this data, common policies can be formulated, with the establishment of exception procedures for those groups that are not impacted, or who require a different solution.

The creation of simple, nonspecific technology-dependent policies allows for the possibility of change, and flexible approaches. Tomorrow's security problems are not necessarily going to be solved by today's solutions. Both threats and technology change, and policies should be broad enough to accommodate these facts.

Enforcement of policies is also important. Policies can be written and implemented, but if breaches occur, they must be addressed. Not reacting to breaches in policy causes employees to think that a policy can be safely ignored, and increases the risk that real damage will be done the next time an incident occurs.

Last, the roles of individuals in shaping, implementing, and enforcing security policies must be delineated. If responsibilities are not created, there is a tendency for some individuals to assume roles and proceed unilaterally, and others to ignore situations that must be addressed.

This chapter comprises six main sections: (a) methods to determine the constitution of security policies (frameworks, scope, and creation), (b) adoption and implementation of policies into specific procedures, (c) exception procedures, (d) training in security policies, (e) enforcement of security policies, and (f) leadership roles in security policies. Rather than focusing on specific technologies, the intent of the chapter is to create a framework from which security policies and procedures can be derived for any type of business entity. These elements, with emphasis on the constitution of security policies, are discussed in terms of (a) the research that has been conducted, and (b) practical advice that can be utilized.

BACKGROUND

Constitution of Security Policies

Developing Frameworks

Many IS (information security) researchers express skepticism about the use and effectiveness of security policies (Höne & Eloff, 2002), citing perception of security controls as barriers to efficiency and progress, which leads to circumvention (Wood, 2000). To be effective, IS security policies depend must on the specific organization and its environment (Karyda, Kiountouzis, & Kokolakis, 2005). These twin issues must always be borne in mind when creating security policies.

Several approaches have been taken regarding frameworks for security policies. Baskerville (1993) notes that the development of information security systems (ISS) in general has proceeded by generation, starting with the first generation, which relied upon checklists or security management standards; the second, which were mechanistic in nature, focusing on functional, technical, and natural science factors in ISS design, and neglecting the social nature of organizations; and the third, comprising logical modeling methods that abstract ISS problems. Siponen (2005) advances these concepts, describing five paradigms in modern ISS approaches, which include the viable and survivable, security-modified, responsibility modeling, business process, and information modeling. The reader might ask what relation this fundamental research has to do with security policies, and the answer is that the future fifth generation, which Siponen (2005) advocates, incorporates the use of social techniques, such as user participation to ensure the social acceptance of security techniques and procedures. In addition, although the use of sanctions and deterrents needs justification, such practices should be accepted by all the employees of an organization. In other words, future ISS designs will be synonymous with security acceptability. Details of these ISS approaches can be found in the papers by Baskerville and Siponen (2002), and Siponen (2005).

Karyda et al. (2005) base the framework of their approach to security policies on the theory of contextualism (Pettigrew, 1987). In essence, contextualism seeks to analyze the relationship and interaction between the content of strategic change, the context of that change, and the process involved in managing that change (Pettigrew & Whipp, 1993). The interrelationships transform dynamically over time, as a result of both outer contexts, such as the economic, social, competitive factors found in an organization's external environment, and inner contexts, such as the structural, political, and cultural factors present within an organization. By investigating security policy content, formulation processes, implementation, and adoption in this manner at three levels—organization, work system, and information technology—Karyda, et al. (2005) made four crucial findings in two case studies. First, employees with increased responsibilities and varied activities have higher security awareness. The corollary to this is that organizations with rigid, hierarchical structures will likely develop problems in the application of security policies. Second, organizations with coherent cultures, especially codes of ethics, have an easier time of adopting and implementing IS security policies. Third, the more management participates and visibly supports security policies, the better the outcome. Finally, security awareness and security policy evaluation programs assist in promoting successful adoption and implementation.

Alignment is another concept that has implications for the development of security policies. In her case study of eight companies Chan (2002) discovered that aligning IS and business strategies improved IS performance, but another key finding was that informal organization mattered more than formal structure. These results bear on another alignment, that between information security policy (ISP) and the strategic information systems plan (SISP), of which the latter is aligned with corporate strategy (Doherty & Fulford, 2006; Doherty, Marples, & Suhami, 1999). According to Doherty and Fulford (2006), the traditional method of SISP is to assemble a team, conduct a situation analysis, formulate, and then implement a strategy, and modify it as necessary after review. These researchers suggest that during the formulation phase, the SISP should be created or modified, and when the review is phase is conducted, the ISP should then be reviewed and modified in parallel. This linkage ought to provide several benefits: (a) imbue the ISP with a stronger business orientation; (b) provide advance warning of security risks or the need for new controls when new SISP directives are initiated; (c) move the security culture from one of reactive to proactive; (d) incorporate security management issues into user manuals, training, and procedures prior to the introduction of new systems; and (e) raise awareness of security breaches in management. The findings of Chan (2002) suggest that this process is best carried out using maximum flexibility and informal structure, rather than a rigid, completely defined structural organization.

Maynard and Ruighaver (2001) adapted software quality factors to create a framework for the quality of information security policies, utilizing measures of functionality, reliability, usability, efficiency, maintainability, and compliance. Functionality focuses on the appropriateness of security policies, whether the policies operate as intended in "real life," avoidance of contradiction (corollary harmony), and a careful balance between unintended disclosure of sensitive information versus the need by employees to comprehend all policies. Reliability highlights the developing maturity of security policies as they are reviewed and modified, and the ability of the policies to tolerate faults and not "fail hard." Usability is the ability to easily comprehend the policies, obtain them in a variety of formats, and execute them without going against psychological norms. Being able to easily update and implement policies without inordinate consumption of time or resources constitutes efficiency. Measures of maintainability focus on the ease with which deficiencies can be analyzed, rectified or changed, while compliance tests the ability of the policies to adhere to the standards of the organization, as well as legislative or regulatory requirements.

Scope of Security Policies

Baskerville and Siponen (2002) have proposed three levels of security policies: high-level reference, lower-level reference, and meta-policies. High-level reference security policies emanate from and are written by top management. Lower-level reference policy documents address specific departments, areas, or processes and are more concrete in nature, describing specific procedures to control authorization, protect assets, or minimize vulnerabilities. Security meta-policies are concerned with policy-making—for example, which entities or individuals are responsible for making policies, or when activities should trigger policy-making.

In practice, the scope of security policies is linked to the perceived strategic importance of information and security management practice. Some research shows that this is influenced by the risk perceptions of senior management and board of a company, and by internal or external events that are deemed significant by a company's decision-makers (Ezingeard, Bowen-Schire, & Birchall, 2004). In support of their findings, Ezingeard et al. (2004) also cite the novel security issue, which reduces to difficulty in judging the impact of a security problem if it has never been experienced (Frank, Shamir, & Briggs, 1991). There is also the sequential attention to goals issue, which manifests itself in change as a result of a major incident, and reversion to old practice for other reasons some time later (Cyert & March, 1992). This occurrence has been used to explain paradoxical decision in IS strategy (Hirscheim & Sabherwal, 2001). In addition, Doherty and Fulford (2005), who surveyed IT managers of large UK organizations, found no statistical association between the adoption of information security policies and the incidence or severity of security breaches. Distilled, this research intimates that both the scope and development of security policy content as currently practiced have a long way to go to reach maturity.

Security policy content has often developed from the BS 7799 standard that became the ISO 17799 standard in 2000. Doherty and Fulford (2006) have elaborated individual components of this standard as follows: personal usage of information systems (rights and responsibilities), disclosure of information (restrictions), physical security of infrastructure and information resources, violations and breaches of security, prevention of viruses and worms, user access management (who has access to what), mobile computing (security controls), Internet access, software development and maintenance, encryption (when and how), and contingency and continuity planning. Based on a validated survey of large UK companies, Fulford and Doherty (2003) determined that ≥ 89 percent of these components were covered in security policies, with the exception of software development, encryption, and contingency planning, with figures of 27 percent, 55 percent, and 18 percent, respectively. The factors affecting the success of information security policies identified as most important by respondents, which are listed in ISO 17799, were visible commitment from management, a good understanding of security risks, distribution of guidance on IT security policy to all employees, and a good understanding of security requirements. However, adoption of these success factors appears to be substantially lacking and worrisome (Fulford & Doherty, 2003).

Dhillon and Torkzadeh (2006) proposed a value-focused assessment of information system security as the baseline for developing an instrument for measuring IS security concerns. According to Keeney (1992; 1999), by identifying values, individuals can decide what they want and how to obtain it. The methodology involves three steps: (a) interviews with appropriate individuals to elicit values in the decision context, which typically produces long lists of wishes; (b) conversion to a common format (object and preference); and (c) classification of objectives into fundamental with respect to context, or a means to support/inform fundamental objectives (means objectives) (Dhillon & Torkzadeh, 2006). Based upon this approach, these authors interviewed 103 user managers from a broad range of industries and obtained 86 objectives, which were grouped into 25 clusters. Fundamental objectives included maximize awareness, maximize data integrity, maximize organizational integrity, whereas means objectives included improve authority structures, understand work situation, maximize access control, and maximize fulfillment of personal needs. What is most interesting is that this approach could be used to define the scope of security policies that moves beyond the ISO standards.

Security Policy Creation

Baskerville and Siponen (2002) advocate three imperatives for the creation of security meta-policies: flexibility (responsiveness), political simplicity, and criterion-orientation. Political simplicity in this context refers to due consideration of compliance by policy makers so that exceptions to policies can be explicit and reasoned, and criterion-orientation to the focus on the organization's priorities without exact specification on how the criteria should be met. In addition, the objective of such policies is to identify and classify security subjects and objects, which are the employees, business partners, and third parties associated with the organization, and the organization's assets, respectively (Baskerville & Siponen, 2002). Further, meta-policies are concerned with what type of access security subjects have to security objects.

In general, formulation of a security policy according to Karyda et al. (2005) is accomplished at three levels: organizational level, works system level, and the information technology level. The organizational level embodies structure, management style, norms and culture, defines the role and support of management, and describes both internal and external relationships. The work system level encompasses IS users, business processes, customers or users, and the technology and information utilized. Finally, the information technology level elaborates the specifications and configurations of technical components, as well as the software and hardware for implementation. The process of security policy creation follows the input → activities → output schema, in which input is typified by risk evaluation assessment, legal requirements, structural and cultural characteristics of the organization, existing security practices, knowledge of IT technology and security controls, and management standards and best practices. Activities constitute the identification of security requirements and controls, compilation of the policy document, the writing of individual procedures, and assemblage of the specifications for technical security controls. Finally, the output is in the form of a security policy for information systems and specifications for countermeasures. Separating IT security policies that are focused toward IT employees from those targeting all employees (Vijayan, 2006) can be easily accomplished using this methodology.

Adoption and Implementation of Security Policies

While creation of a security policy is the first step, is must be adopted and implemented or it is useless. Recent research in the UK shows that 60 percent of all companies surveyed have still not implemented a security policy (DTI, 2006), and even among larger companies, adoption is still an issue (DTI, 2006; Fulford & Doherty, 2003). May (2003) suggests that this is a result of security policies not being placed high enough on the agenda of company boards.

Karyda et al. (2005) suggest that the activities involved in adoption of a security policy include establishing norms that support security management, promoting the issue of security to IT users, and resolving conflicts and difficulties found in the application of security controls. They also suggest keeping users and management informed regarding IS security agenda. Through their contextual analysis, these investigators also studied two organizations, following security policy creation, adoption, and implementation. In one of these case studies, the Social Security Institute in the UK, management supported the creation of the security policy but failed to provide a linkage between security and the overall strategy of the organization. After creation of the policies, adoption and implementation stalled. Lack of flexibility in organizational structure and employing qualified personnel, competitive relationships, unbalanced workload in the IT department, and lack of understanding by users on security issues, as well as the security policy were among the reasons cited for the lengthy delays.

Behavioral research can provide insight into adoption and implementation. For example, by creating responsibility and accountability in structures, management can ensure that employees have a sense of ownership regarding security measures (Mishra & Dhillon, 2006). However, if these “top-down” directives are absent or half-hearted, one can see why members of an organization might not take security policies seriously. Other behavioral facets impinging on security concerns include alignment (if the goals of individuals are not aligned with those of the organization, security threats from the “inside” are likely) (Loch & Conger, 1996; Stanton, Stam, Mastrangelo, & Jolton 2005); ownership (employees should be treated as owners of information assets) (Adams & Sasse, 1999); and environment (a proactive environment promoting the importance of security behavior is important) (Dhillon & Torkzadeh, 2006; Vroom & Solms, 2004). All these factors are likely to enhance the goal of adopting and implementing a security policy once it has been formulated.

Physical implementation of IT security policies occurs at the works system or information technology levels. Although a technical discussion is beyond the scope of this chapter, the modeling approach exemplified by the work of Nagaratnam, Nadalin, Hondo, McIntosh, and Austel (2005) will be used as an illustration. Initially, a security policy officer and business analyst translate the security policy and using a business model, analyze and design the security requirements for the application, with the assistance of security and application architects. Implementation begins by writing the application policy, followed by building and testing the secure application. Deployment of the policy follows under the auspices of the application or security administrator by configuring the infrastructure for the application security, customizing the policies, and developing a list of subscribers who will utilize the policy. Finally the specific policy is managed and monitored under IT administration, with changes as necessary. Ultimately, many IT security policies depend on the utilization of service-oriented architecture templates for process mapping, efficiency, and elimination of redundancy in conjunction with mark-up using the appropriate machine language, for example, BPEL (Business Process Execution language). Once a specific policy is in place, it should be periodically audited. Bishop and Peisert (2006) caution that because of the complexity of modern systems, it is not always apparent that the low-level policy actually reflects the high-level policy. This could be the result of a "lost-in-translation" problem because "not only must a higher-level policy language be transformable into an implementation of a policy (or set of policies) on systems, but also deriveable from the existing configuration of systems. This means that mechanisms to handle contradictions must be defined, as must syntax and semantics to handle procedures external to the computer" (Bishop & Peisert, 2006, p. 1).

Exception Procedures, Training, Enforcement, and Leadership Roles

Exception Procedures

A good security meta-policy attempts to maximize compliance without outlawing noncompliance (Baskerville & Siponen, 2002). Following this, while adherence to security policies is important, cultural, legislative, and technological factors might make full compliance difficult to achieve (Maynard & Ruighaver, 2006). These are instances in which exceptions or deviations from policy can be created. In each case, a formal request for exemption should be made with documented reasons. An example of this would be the adoption of handheld BlackBerry 7200s by Unilever for their top executives, in which an exception from the policy of using the BlackBerries for both voice and data was granted in the form of permitting executives to use cell phones or smart phones for telephone conversations (McFadden, 2006).

Another historical example of the development of exceptions was reported by Couger (1986), which was a case study that involved approaches to configuration control of desktop computers. Three approaches were categorized: laissez faire (basically a free hand), hard controls (no exception to standardized configuration, under penalties), and soft controls (encouragement of desktop technology acquisition through a centralized agency by the addition of supplementary budgets). The first two approaches resulted in incompatible desktop technology, but the third did not, because of incentives and market-driven standards, and the fact that internal economics forced exceptions to be well justified (Baskerville & Siponen, 2002). However, if the number of exceptions reached critical mass, the central standard was changed.

Training

McCarthy (2006) reported that in a survey conducted by the Computing Technology Association in 2006, just 29 percent of respondents indicated that information security training was required at their companies. Yet of those 29 percent, 84 percent indicated that such training had reduced the number of major security breaches since implementation. Further, those respondents that did not mandate security training said that it was not a departmental or business priority or top management support for it was lacking.

Training has been referred to as a key ingredient to ensuring that a security policy is successful by a number of researchers. Maynard and Ruighaver (2006) link training to the learnability element. Besides the learning of the security policy itself, the complexity or simplicity of the policy will dictate the amount of training required. Overly complex policies can fail because users do not understand them no matter how much training they receive. Training is also one of the five emergent themes found in behavioral analysis of information systems security governance research and helps the implementation and communication of policies, as well as raising awareness of security issues, and improving efficiency (Mishra & Dhillon, 2006). Additionally, it results in improved internal control management. In their case study of the Social Security Institute, lack of training was also cited by Karyda et al. (2005) as a prime cause for failure to implement a security policy.

Enforcement

The foundation for any kind of enforcement policy as it pertains to security policies, whether it contains deterrent action, sanctions, or punishment are the various behavioral theories borrowed from psychology and the social sciences (Mishra & Dhillon, 2006). Foremost are the deterrence theories (Straub & Welke, 1998; Theoharidou & Kokolakis, 2005) that discuss individual and group behavior, and relate to the intention to commit crime. In our context, this would be breaking the rules embedded in the security policy. Theories of reasoned action (Loch & Conger, 1996; Park, 2000) and planned behavior try to understand how individuals react to security issues in a behavioral context and how superimposed control is perceived. Research from social bond theory (Lee, Lee, & Yoo, 2004; Theoharidou & Kokolakis, 2005) suggests that strong normative pressure forces individuals to behave correctly, while results from social learning theory (Hollinger, 1993; Theoharidou & Kokolakis, 2005) provide insight into why peer pressure can force individuals to do certain things that they would not otherwise do. In connection with this concept, the research conducted by Milgram (1963), suggests that certain actions can be brought about when the agent for instruction is perceived as an authoritative figure. Mathias (2004) describes such a real-life incident involving the installation of unauthorized application processors that occurred due to lack of policy awareness and because a supervisor told an employee “it was okay to do it.” Finally, social engineering, based on a knowledge of the beliefs, values, and attitudes of individuals seeks to impose a set of values or beliefs to given situations and is commonly used in the security industry (Loch & Conger, 1996).

In an ideal world, security policy enforcement would not be necessary. However, enforcement is necessary in order to reinforce a normative culture that “security policies matter.” What form enforcement takes is a matter for discussion within an organization, and should be predicated on an assumption that (a) security policies are widely available via a number of media types within an organization; (b) that all employees have received training in security policies (initial and recurrent as necessary); so that (c) there is not only an awareness, but a comprehension of such policies as they apply to individuals within organizations. Enforcement can take forms of reminders or reprimands for “first offenses,” or mandatory retraining or dismissal for severe breaches of security policy and repeated offenses.

Leadership Roles

Throughout this section, the recurrent theme of leadership has been emphasized with regard to the formulation and implementation of security policies. Many case studies have amply demonstrated that if senior management and the board of a company are not actively involved in security policies, the result will either be no security policy or one that takes an inordinate amount of time and resources to become operational. However, leadership roles do not cease with senior management. Lower and middle management must also be on board. This helps develop a security-conscious culture and prevents conflicts from emerging or behavior that runs contra to the security policy.

PRACTICAL GUIDANCE FOR SECURITY POLICIES

Creation, Adoption, and Implementation

Earlier it was indicated that IT-related policies should be separated from non-IT-related security policies targeting all employees. However, that should not imply that there would be two entirely separate "teams" dealing with such policies. Top management, and/or the board of an organization should kick off the security policy initiative in a variety of ways via companywide memos, meetings with employees, and use any available intranet. The point is to instill into the organization a firm top-down commitment to the project, begin the process of building a security-conscious culture, and delineate the general procedures by which the security policies will be created, adopted, and implemented. This should not be a one-time event for top management, especially for those companies that are not heavily invested in IT operations. Indeed, the involvement of senior management in all phases of the project is encouraged.

How should the security policy teams be constituted? This will depend on the size of the organization, its complexity, as well as its level of IT operations. One answer is to create the position of a security officer (if such a position does not already exist), a tsar-like figure who will guide the whole process and be answerable to the board or top management (Karyda et al., 2005). Another solution might be to appoint co-team leaders, one of whom is familiar with the strategic goals of the organization, the other an individual from the IT department who has a detailed working knowledge of its operations. One or more teams might necessary in large organizations, but if this route is chosen, it will be crucial to have a coordinator (who could also be the security officer) to ensure that all policies are harmonized and interoperable.

Although it is important to outline the structure of teams and identify the roles of members, it should be remembered that flexibility and informality are the keys to success. Rigidity and inflexible hierarchies can at best impede progress, or worse cause the project to languish. The composition of teams should reflect all interests of departments, divisions, or groups within an organization so that end users of the security policies—also the equivalent to all stakeholders—are not ignored. In some cases, the creation of meta-policies, with active direction from senior management might precede the creation of individual security policies in order to provide guidance on what is permissible.

In consideration of the content of security policies, while the overall accent is on the protection of assets, it is crucial not to be overly swayed by security incidents that have happened within the company. Such a view can produce bias. On the other hand, team members should be aware of incidents that have happened industrywide and have kept abreast of industry developments in order to achieve a balance. Case studies have shown that attitudes of "It can't happen here," or "We don't have the budget for that kind of security," or not uncommon. If consensus cannot be achieved within the company on what should be protected and to what degree, it might be useful to hire an outside expert to obtain a second opinion.

Drafts of security policies must be modeled or tested to ensure that they will work "as advertised." Assuming that a given procedure will work as written is likely to create a false sense of security, which is why the emphasis in this chapter has been on iterative processes in which review, feedback, and modification are important elements. Once the procedures have been tested, policies can be written and organized into manuals for dissemination.

The methods by which security policies are disseminated have been criticized as being insufficient and based too often on only one method (Fulford & Doherty, 2003). Consider not only using paper manuals but web-based applications, which have the option of being interactive to facilitate learning. For larger organizations pilot schemes can also be utilized in which security policies are implemented for small units to determine factors or modes of success or failure.

Other Factors

One of the essential factors to the success of security policies is training. Too many case studies have shown that failure was the result of lack of employee awareness. In addition, training can assist in building a security-conscious culture in which security of assets and data is considered a norm. Training should be thorough, companywide (which also includes all levels of management), and conducted during the implementation phase. Recurrent or refresher training is also smart as it keeps the skills of individuals better honed. Training after major configuration changes or the adoption of new infrastructure developments is also vital. The take-home message is that training should not be a one-time event. Most organizations are dynamic in structure, responding to new developments, and both security policies and the training associated with them should reflect this state.

Security policies must be enforced and individuals who willfully break security policies should be reprimanded. Without internal controls, it is unlikely that individuals will take security policies seriously, and will likely think that small transgressions are permissible. The majority of security breaches are caused by human error—that it to say from the failings of individuals rather than equipment or faulty procedures. If that error can be minimized, the security policies in place will succeed.

Even with internal controls present, errant human behavior will occur. Some individuals will perceive the security policy as too onerous, or "not applying to him or her." This kind of behavior is risky for the organization in that it can be contagious—"If she's doing it, so can I"—and can also facilitate attacks from outside the organization. However, the most dangerous individuals are those who have an axe to grind, and have the access authority to wreak havoc on security controls from within the company. Investing in monitoring equipment is a good idea, although if it is done with a heavy hand it might lead to resentment by individuals. The bottom line of an organization, however, is that the breaching of security policies should not be tolerated under any circumstances.

Finally, the issue of exception merits comment. Onerous processes—and security policies are no exception—often provoke an attitude of "that doesn't apply to me," particularly if the individual is at a high level within the organization, or commonly operates outside of the physical structures of the organization, such as a salesperson. Problems with security policy compliance should be reported to the individuals responsible for security and promptly, whether they are bona fide problems or gripes. It might be that a given procedure is poorly written, does not reflect original intention, or is simply too arduous, and is affecting a large group of individuals, in which case the procedure needs to be rethought. Individual or group exceptions to a stated policy should be decided upon by the security officer or other authority in a fair, rational manner without granting special status because of rank, power, or situation.

CONCLUSION

Security policies are a must for all organizations conducting business regardless of size or type. By protecting assets—human, physical, electronic, and digital—in a systematic way, organizations can focus most on what they do best: their business. Research shows that the creation, adoption, and implementation of security policies, however, is still lacking in many aspects. Issues of lack of management commitment, training, flexibility, and poor alignment with business strategic goals, as well as "knee-jerk" reflex action toward major security breaches are identified as the "usual suspects." Nevertheless, progress is being made in both the scope and execution of security policies in business today.

KEY TERMS

Alignment: The degree to which strategic or corporate goals are in harmony with security policies.

Information Security (IS): The securing of information identified as confidential by computer-based and human-based procedures.

Information Security System (ISS): A framework that encompasses the methodology by which information will be identified as confidential and kept secure.

Information Security Policy (ISP): A written document specifying how the digital and electronic equipment assets of an organization will be protected through the use of individual procedures.

Information Technology (IT): The technology that supports access, processing, and dissemination of data (information).

Security Awareness: The perception by individuals within an organization that security is important to the conduct of business.

Security Meta-Policy: A policy that describes what is permissible in broad terms of security issues without specifying exact technological solutions.

Security Policy: A written document specifying how all assets of an organization will be protected through the use of individual procedures.

Strategic Information Systems Plan (SISP): A plan that describes how information will be collected, processed, and disseminated within and outside of an organization.

Chapter 7.16

Privacy and Security in the Age of Electronic Customer Relationship Management

Nicholas C. Romano, Jr.
Oklahoma State University, USA

Jerry Fjermestad
New Jersey Institute of Technology, USA

ABSTRACT

This article presents a value exchange model of privacy and security for electronic customer relationship management within an electronic commerce environment. Enterprises and customers must carefully manage these new virtual relationships in order to ensure that they both derive value from them and minimize unintended consequences that result from the concomitant exchange of personal information that occurs in e-commerce. Based upon a customer's requirements of privacy and an enterprise requirement to establish markets and sell goods and services, there is a value exchange relationship. The model is an integration of the customer sphere of privacy, sphere of security, and privacy/security sphere of implementation.

INTRODUCTION

New technologies have fostered a shift from a transaction-based economy, through an Electronic Data Interchange (EDI) informational-exchange economy, to a relationship-based Electronic Commerce (EC) economy (Keen, 1999). We have moved from "*first order*" *transactional* value exchanges through "*second-order*" *informational* value exchanges to "*third-order*" *relational* value exchanges (Widmeyer, 2004). Three important types of EC relationships have been identified: between enterprises and customers (B2C); between enterprises (B2B); and between customers (C2C) (Kalakota & Whinston, 1996). Additional relationships between Governments (G2G), enterprises (G2B), and customers (G2C) have become more important as EC and e-government have matured, and legislation, regulation, and oversight have increased (Friel, 2004; Reddick, 2004); however, these are not the focus of this article. Relational value exchanges have become central to success and competitive advantage in B2C EC, and it is here that we focus on privacy and security in the age of virtual relationships.

Both enterprises and customers must carefully manage these new virtual relationships to ensure that they derive value from them and to minimize the possible unintended negative consequences that result from the concomitant exchange of personal information that occurs when goods and services are purchased through EC. The need to manage these relationships has resulted in the development of Electronic Customer Relationship Management (e-CRM) systems and processes (Romano & Fjermestad, 2001-2002). E-CRM is used for different reasons by enterprises and customers. It is important to understand how and why both of the players participate in "*relational value exchanges*" that accompany the economic transaction and informational value exchanges of EC.

Enterprises use e-CRM to establish and maintain *intimate virtual relationships* with their *economically valuable* customers to derive additional value beyond that which results from economic value exchanges to improve return-on-investment (ROI) from customer relationships.

Customers obtain goods, services and information (economic value) through EC for purposes such as convenience, increased selection and reduced costs. EC requires customers to reveal personal information to organizations in order for transactions to be completed. The exchange of information between customers and organizations leads to the possibility of privacy violations perpetrated against the customer. It is the responsibility of the organizations to provide privacy policies and security measures that will not endanger customer trust.

In this article, we present a series of models "*sphere of privacy model,*" "*sphere of security model,*" "*privacy/security sphere of implementation model,*" and then integrate them into the "*relational value exchange model*" to explain privacy and security in the context of e-CRM, from the perspective of both customers and enterprises, to provide guidance for future research and practice in this important area. It is important for both customers and firms to understand each others' vested interests in terms of privacy and security, and to establish and maintain policies and measures that ensure that both are satisfactorily implemented to minimize damage in terms of unintended consequences associated with security breaches that violate privacy and lead to relationship breakdowns.

The remainder of this article is structured as follows: First, we explain why privacy and security are critically-important issues for companies and customers that engage in EC, and the consequences that can result from failure to recognize their importance or poor implementation of measures to ensure both for the organization and its customers. Second, we define privacy and security and their interrelationship in the context of CRM. Third, we present our relational value exchange model for privacy and security in e-CRM.

Customer Relationship Management Privacy and Security: Who Cares?

The data contained within a CRM application is often a company's most critical asset, yet because of the pivotal role this information plays in day-to-day business activities, it is also often the most vulnerable to security breaches and disruptions (Seitz, 2006 p. 62).

Before we explain and define privacy and security in detail and present our models and the relational value exchange model, we will describe the costs associated with failure to understand these concepts and failure to effectively ensure that both are protected in terms that firms and customers can understand: dollars and lost customers.

Economic Cost of Customer Security Breaches

The economic cost of security breaches, that is, the release or loss of customers' personal information, has been studied in a number of surveys over the past decade; while some studies show declines in the total and average losses over time, the costs are still staggering for many firms. New threats and vulnerabilities have arisen in the recent past, and these lower costs are most likely offset by increased expenditures to implement security measures and training.

The Computer Security Institute (CSI) and the Federal Bureau of Investigation (FBI) have conducted eleven annual surveys of computer crime and security since 1995. Some of the results of the last seven are presented (Gordon, Loeb, Lucyshyn, & Richardson, 2004, 2005, 2006; Power, 2002; Richardson, 2003). The Ponemon Institute also conducted two surveys on the costs and effects of data security breaches (Ponemon, 2005a, 2005b), and we will also present a portion of their results as well.

The CSI/FBI surveys have tracked the costs (losses) associated with security breaches for thirteen years; we focus on summary data from the last seven years to illustrate trends and changes in the economic costs of security breaches for organizations that responded with loss data. Table 1 reveals some interesting aspects about security breach costs over the past seven years. Several types of costs have been reported across all the years of the survey; these include: theft of proprietary information, sabotage of data or networks, system penetration, insider abuse of network access, financial fraud, denial of service, viruses, unauthorized insider access, telecom fraud, and laptop theft.

Other types of losses were reported in early years of the period but not in later periods or were reported in only the last three or even only the final survey in 2006, indicating that some threats have been better managed and new ones have arisen or been identified and quantified. Specifically, losses from telecom eavesdropping were reported to be on average from a high of $1.2 million in 2002 to a low on $15,000 in 2003; however, there were no reported losses in 2004, 2005, or 2006. Active wiretapping is another loss that was reported as an average of $5 million in 2000 and $432,500 in 2003, but not reported in any of the other years. Theft of proprietary information was reported as the highest loss for the four years from 2000 to 2003; then viruses took over the top spot in 2004 and remained the highest loss in 2005 and 2006. The results also show that between 2002 and 2003, there is a 62% reduction in the reported losses and, between 2003 and 2004, there is a 90% reduction in the losses. Thus, the enterprises are responding to the need for privacy and security. In 2004, three new loss types were reported: Web site defacement, misuse of a public Web application, and abuse of wireless networks. All three of these losses were also reported in 2005 and 2006. Six new losses were reported in 2006: bots (zombies) within the organization; phishing in which your organization was fraudulently represented as sender; instant messaging misuse; password sniffing; DNS server exploitation; and a general category of other.

The time-series results reveal the dynamic nature of the security environment and the threats and costs over time as companies identify them and take actions to try to minimize or eliminate losses. Figure 1 reveals that losses from security breaches appear to be going down over time, which is a positive finding; however, they do not tell the whole story, because the same surveys from which the data in Table 1 are taken also found that budgets in terms of operating expenses and capitol investment for security and training also rose at the same time.

Figure 2 shows the reported average expenditure per employee for operations, capitol investment, and awareness training from 2004 to 2006 for four different-sized companies based on reported revenues. It is important to keep in

Table 1. Average loss per year per loss type

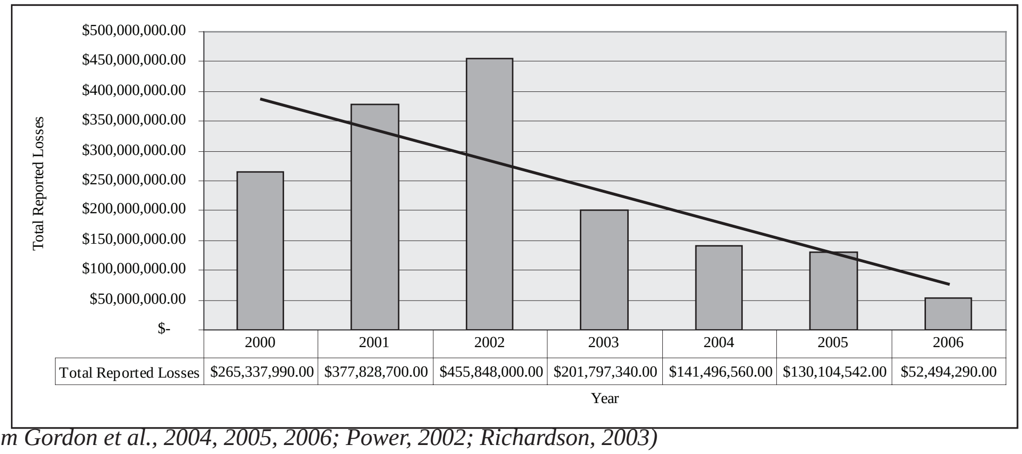
	2000	2001	2002	2003	2004	2005	2006
Theft of proprietary info.	$3,032,818	$4,447,900	$6,571,000	$2,699,842	$42,602	$48,408	$19,278
Sabotage of data or networks	$969,577	$199,350	$541,000	$214,521	$3,238	$533	$831
Telecom eavesdropping	$66,080	$55,375	$1,205,000	$15,200			
System penetration by outsider	$244,965	$453,967	$226,000	$56,212	$3,351	$1,317	$2,422
Insider abuse of Net access	$307,524	$357,160	$536,000	$135,255	$39,409	10,730	$5,910
Financial fraud	$1,646,941	$4,420,738	$4,632,000	$328,594	$28,515	$4,014	$8,169
Denial of service	$108,717	$122,389	$297,000	$1,427,028	$96,892	$11,441	$9,335
Virus	$180,092	$243,835	$283,000	$199,871	$204,661	$66,961	$50,132
Unauthorized insider access	$1,124,725	$275,636	$300,000	$31,254	$15,904	$48,878	$33,920
Telecom fraud	$212,000	$502,278	$22,000	$50,107	$14,861	$379	$4,033
Active wiretapping	$5,000,000	$-	$-	$352,500			
Laptop theft	$58,794	$61,881	$89,000	$47,107	$25,035	$6,428	$21,223
Web site defacement					$3,562	$180	$519
Misuse of public Web application					$10,212	$3,486	$861
Abuse of wireless network					$37,767	$852	$1,498
Bots (zombies) within the organization							$2,951
Phishing in which your organization was fraudulently represented as sender							$2,069
Instant messaging misuse							$931
Password sniffing							$515
DNS server exploitation							$288
Other							$2,827
Totals	$12,886,153	$10,688,458	$14,702,000	$5,557,491	$438,809	$203,661	$167712

(Data from Gordon et al., 2004, 2005, 2006; Power, 2002; Richardson, 2003)

mind that these are ***average*** expenditures ***per employee,*** so for any given company the total outlay would be calculated by multiplying the number of employees in the organization by their actual expenditures, which could be higher or lower than the average.

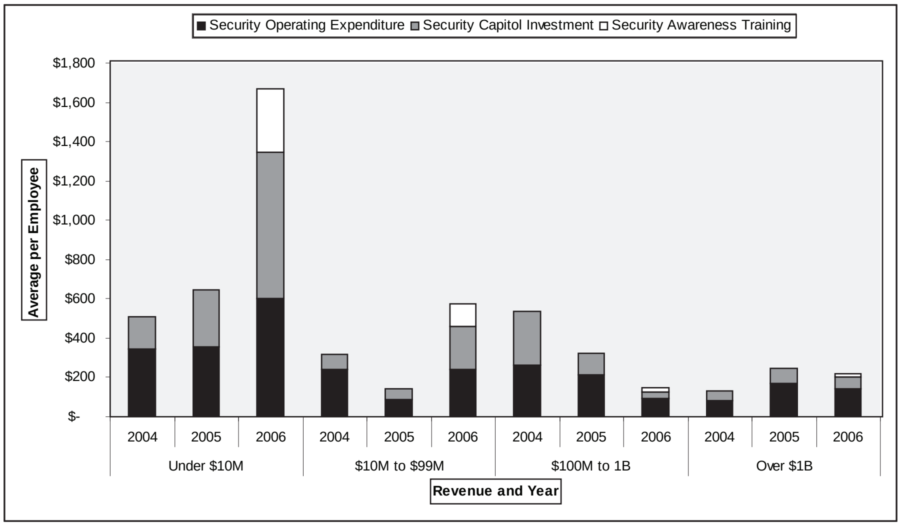
This time series of expenditures for security reveals interesting trends as well. One is that

Figure 1. Total reported losses per year across seven CSI/FBI surveys



(Data from Gordon et al., 2004, 2005, 2006; Power, 2002; Richardson, 2003)

Figure 2. Reported average expenditure per employee



(Data from Gordon et al., 2004, 2005, 2006; Power, 2002; Richardson, 2003)

there appears to be economies of scale for security measures, that is, organizations with higher revenue seem to have smaller expenditures per employee (Gordon et al., 2006), but that may not translate into smaller overall expenditures. A second similar trend is that lower revenue firms seem to have had increases in security expenditures while higher revenue firms have seen decreases. Regardless of these trends, the reduction in losses due to security breaches and attacks have been accompanied by increased investment in security software, hardware, and training; therefore, it is logical to conclude that either through losses or through increased defense expenditures, security continues to have a large economic impact on firms. Finally, it also reveals that in 2006, firms began to spend funds for security awareness training that were not reported in the previous years of the CSI/FBI surveys.

In November, 2005, the Ponemon Institute (Ponemon, 2005a) surveyed the costs incurred by 14 firms in 11 different industries that experienced security breaches. The size of the breaches in terms of customer records ranged from 900,000 to 1,500 for a total of 1,395,340 records and an average of 99,667 per breach.

Table 2 summarizes total average cost (including direct, indirect, and opportunity costs) for all 14 firms. The average total cost per company was $13,795,000 or $138 per lost customer record. These 14 firms had total losses of $193,103,545.

The economic cost of security breaches is still a staggering amount of money. Many enterprises have been able to reduce the losses by expending large amounts of resources. However, as shown in Table 1, new threats and vulnerabilities are being unleashed on enterprises every year. The lower costs are most likely offset by increased expenditures to implement new security measures and training. These economic costs are only part of the story, because there are also costs associated with lost customers, and opportunity costs associated with potential customers going elsewhere due to the security breach publicity. The next section discusses losses in these less tangible, but critically-important areas.

Cost of Security Breaches in Terms of Lost Customers

The Ponemon (2005a) survey found that security breaches have potentially severe costs to organizations in terms of lost customers and decreased customer trust in the organizations' ability to secure data and maintain the levels of privacy and confidentiality that customers expect. Ponemon also found that roughly 86% of security breaches involved loss or theft of customer information.

Ponemon (2005b), in "The National Survey on Data Security Breach Notification", polled 9,154 adult-aged respondents in all major U.S. regions, and found that damage to corporate reputation, corporate brand, and customer retention was very high among affected individuals:

- 1,109 (11.6%) reported that an organization had communicated to them a loss or theft of their personal information;
- upon receipt of a notification of a breach, nearly 20% of respondents reported that they had terminated their relationship with the firm;
- 40% of those that received notification reported that they might terminate the relationship due to the breach;
- 58% reported that they believed that the breach had lowered their confidence and trust in the organization that reported it;
- 92% of respondents blamed the company that notified them for the breach;
- only 14% of respondents that were notified of a breach were not concerned; and
- greater than 85% of all respondents reported they were concerned or very concerned about the effect that a data breach would have on them.

Table 2. Costs of security breaches for 14 firms in 2005

	Direct Costs	Indirect Costs	Lost Customer Costs	Total Costs
Total Cost for All Companies	$49,840,593	$123,262,952	(factored into indirect costs)	$193,103,545
Average Cost Per Company	$4,990,000	$1,347,000	$7,458,000	$13,795,000
Average Cost Per Lost Record	$50	$14	$75	$138

(Data from Ponemon, 2005a)

Furthermore, the National Survey on Data Security Breach Notification (Ponemon, 2005b) reported that the majority of respondents were not satisfied with the quality of the notification and communication processes. This is where CRM becomes important, and how enterprises communicate security breaches to their customers has an impact. The survey highlighted the following communication experiences:

- Companies that reported breaches to consumers were more than four times (417%) as likely to experience customer churn if they **failed** to communicate to the victim in a clear, consistent, and timely fashion;
- Companies that sent e-mails or form letters to communicate a breach of consumer data were more than three times (326%) as likely to experience customer churn than companies that used telephone or personalized letters (or a combination of both);
- Over 82% of respondents believed that it is always necessary for an organization to report a breach even if the lost or stolen data was encrypted, or there was no criminal intent. The type of information involved in the breach was also not a factor; and
- About 59% of respondents do not have confidence in U.S. state or federal regulations to protect the public from data security breaches by organizations.

The high cost of security breaches comes from efforts to prevent them and the cost of the aftermath of a breach. Customers appear to be more likely to terminate their relationship with an enterprise after a security breach. In addition, the timeliness and manner in which a breach notification is delivered is important. It appears that telephone calls immediately after (or at least before a public disclosure) followed up with a personal letter, is best to maintain trust and manage the relationship with the customer. Customers are concerned about protecting their privacy and identity, and they expect companies to be vigilant in securing any data they share. In the next two sections, we discuss and define both privacy and security within the context of EC and e-CRM.

PRIVACY DEFINED

The concept of privacy dates back into antiquity: For example, Aristotle (384–327 BCE) made explicit distinctions between a public sphere and political life, ‘πολιχ’ (*polis,* city) and one’s private sphere or family life, ‘οικοχ‘ (*oikos, home) that refers to a separate private domain (DeCew, 2002; Roy, 1999; Rykwert, 2001).*

DeCew (2002) explains that privacy does not have a single shared definition:

> *The term ‘privacy’ is used frequently in ordinary language as well as in philosophical, political and legal discussions, yet there is no single definition or analysis or meaning of the term. The concept of privacy has broad historical roots in sociological and anthropological discussions about how extensively it is valued and preserved in various cultures. Moreover, the concept has historical origins in well known philosophical discussions, most notably Aristotle’s distinction between the public sphere of political activity and the private sphere associated with family and domestic life. Yet historical use of the term is not uniform, and there remains confusion over the meaning, value and scope of the concept of privacy.*

DeCew (2002) further explains that there are several specific types or meanings of privacy that include control of information, human dignity (individual dignity and integrity, personal autonomy, and independence), degrees of intimacy, social relationships, and unwanted access by others. Each of these conceptualizations of privacy is important and meaningful; however, within the scope of this article, information systems (IS) research and practice in general, and EC specifically, we adopt the concept of "*informational privacy*" (DeCew, 2002). Privacy is an important issue for EC because new technologies have enabled personal information to be communicated in ways that were not possible in earlier time periods. Next we discuss the historical background of informational privacy and define privacy within the scope of this article.

Informational Privacy

Warren and Brandeis (*later Supreme Court Justice Brandeis*) (Warren & Brandeis, 1890) in their well-known essay "*The Right to Privacy*" cited "*political, social, and economic changes*" and recognized "*the right to be let alone*" to argue that extent law at the time did afford for protection of individual privacy. In 1890, technologies such as newspapers, photography, and others had led to privacy invasions through dissemination of details of peoples' private lives (Warren & Brandeis, 1890). They argued that the right to privacy is based on the general principle of "*the right to one's personality*" and the more specific principle of "*inviolate personality*" (Warren & Brandeis, 1890).

They asserted that the privacy principle was a part of the common law and the protection of a "*man's house as his castle*"; however, they also argued that new technologies had changed how private information was disseminated and thus required recognition of a separate and explicit protection of individual privacy (Warren & Brandeis, 1890). Their essay laid the foundation for what would become the idea of privacy as a person's control over information about themselves.

Two theories of privacy have stood the test of time and also have figured prominently in major privacy reviews in the 1970's, 1980's, and 1990's (Margulis, 2003): Westin's (1967) four states and four functions of privacy and Altman's five properties of privacy. We focus here on Westin's theory.

Westin (1967) defined four states of privacy; that is how privacy is achieved (Margulis, 2003) and four functions (purposes) of privacy; that is why one seeks privacy (Margulis, 2003):

States of Privacy

1. **Solitude**: an individual separated from the group and freed from the observation of other persons;
2. **Intimacy**: an individual as part of a small unit;
3. **Anonymity**: an individual in public but still seeks and finds freedom from identification and surveillance; and
4. **Reserve:** based on a desire to limit disclosures to others; it requires others to recognize and respect that desire.

Functions of Privacy

1. **Personal Autonomy**: desire to avoid being manipulated, dominated, or exposed by others or control over when information is made public;
2. **Emotional Release**: release from the tensions of social life such as role demands, emotional states, minor deviances, and the management of losses and of bodily functions. Privacy, whether alone or with supportive others, provides the "time out" from social demands, hence opportunities for emotional release;
3. **Self-Evaluation:** integrating experience into meaningful patterns and exerting individuality on events. It includes processing information, supporting the planning process (e.g., the timing of disclosures), integrating experiences, and allowing moral and religious contemplation; and
4. **Limited and protected communication**: limited communication sets interpersonal boundaries; protected communication provides for sharing personal information with trusted others.

Westin's (1967) definition is the one that we adopt for this paper and that we think is the one that should be adopted by IS researchers and practitioners as well as EC customers:

Privacy is the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others. (p. 7)

Westin (1967) also pointed out that privacy is not an absolute but that:

Each individual is continually engaged in a personal adjustment process in which he balances the desire for privacy with the desire for disclosure and communication…. (p. 7)

With this definition in mind, we again turn to recent surveys of consumers and businesses to gain an understanding of how security breaches that violate privacy are perceived and handled. Ackerman, Cranor, and Reagle (1999) surveyed consumers to learn how comfortable they were with providing different types of personal information with businesses, while Ponemon (2005b) gathered data on actual breaches. Table 3 illustrates that data from the Ackerman et al. (1999) survey of consumer concerns and the Ponemon (2005b) survey of actual data breaches reveals that there may be a mismatch in terms of what information consumers would prefer not to have revealed and what has actually been lost or stolen. Ponemon (2005b) surprisingly found that some of the more sensitive information that consumers are most reticent to reveal and that could result in the most damage are the ones that are most often released.

Only 1% of consumers surveyed were comfortable always or usually with providing information such as their Social Security numbers (Ackerman et al., 1999), yet 38% of all breaches reported in another survey involved SSNs (Ponemon, 2005b). Similar types of mismatches can be seen for several other data types in Table 3. These results illustrate that companies may not secure the types of personal information that consumers are most concerned about well enough (SSNs, credit card numbers, and home telephone numbers) and may place too much emphasis on the security of information that consumers are more willing to share (i.e., e-mail addresses and mailing addresses). This leads us to question whether firms take into consideration the privacy expectations of consumers when they decide how to protect different types of data. We think that firms should take consumer expectations and willingness to reveal information into account when establishing security measures to protect different types of information, as this would focus resources in such a way as to engender trust from the consumer and also to minimize potential losses due to breaches.

Table 3. Comparison of actual data types released and consumer concern

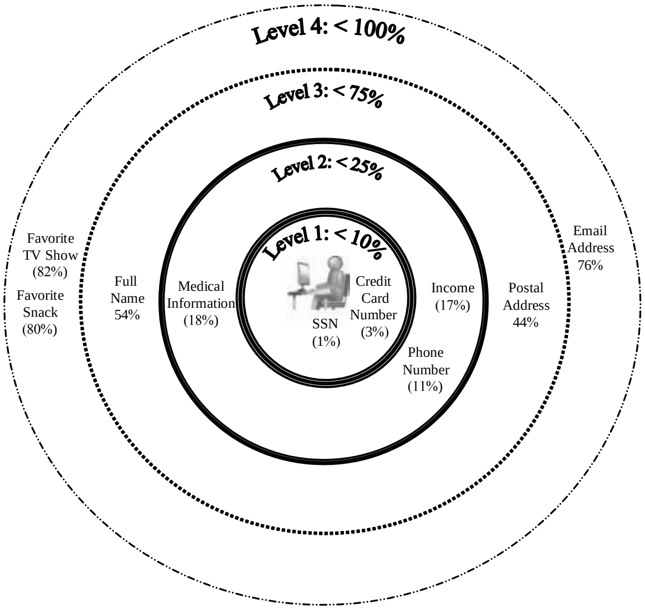
Data Type	Data Released	Consumer Comfort Level
Name	54%	54%
SSN	38%	1%
Credit Card Number	37%	3%
Home Telephone	36%	11%
Mailing address	23%	44%
E-mail Addresses	10%	76%

(Data from Ackerman et al., 1999 and Ponemon, 2005b)

Figure 3 presents our model of the personal "sphere of privacy" based on Ackerman's findings that illustrates how firms might establish levels of security that are consonant with both consumer willingness (comfort) to reveal information and also with the potential amount of damage that could occur from a breach of specific types of customer information.

We argue that firms should be most vigilant in securing information that consumers would

Figure 3. Model of the customer "sphere of privacy"



(Data from Ackerman et al., 1999)

most like to protect and should establish levels or zones of security of different strengths. Later in the paper we will tie this model to security strategies and technology implications.

Based on Ackerman et al. (1999) and Ponemon's (2005b) data (see Table 3), it is clear that consumers want their SSNs, credit card numbers, and telephone numbers kept private. In other words, consumers place maximum value on these data items in contrast to their mailing address and their e-mail address. Enterprises need to be sure and recognize what information is critical so as to protect it and ensure business continuity (Gordon & Loeb, 2002).

This leads us to the next section on security. Security is the technology and policies that an enterprise and consumer have to keep their valuable information secure.

SECURITY

Security breaches affect most enterprises and government agencies. A recent survey reports that 84% of all enterprises will be affected by a security breach, which is a 17% increase over the last three years (2004-2006) (Ferguson, 2006). Those enterprises and government agencies in the survey reported that when a security breach happened, 54% lost productivity, 20% reported lost revenue, and 25% claimed to have suffered some sort of public backlash with either damage to their reputation or loss of customer trust. Thirty-eight percent of these organizations reported that the breach was internal. Furthermore, according to the survey, many of them did not take the issue seriously enough. Only one percent of those surveyed thought IT security spending was too high, while 38% said it was much too low (Ferguson, 2006). The results suggest that even though organizations are investing in security technologies, they still are not achieving the results that they seek.

Security Defined

The term security can be used in reference to crime and accidents of all kinds. Security is a vast topic including security of countries against terrorist attack, security of computers against hackers, home security against burglars and other intruders, financial security against economic collapse, and many other related situations.

Following are four definitions that provide a narrower focus:

1. **Security**: a very general term covering everything;
2. **Computer Security**: "the discipline that helps free us from worrying about our computers" (Landwehr, 2001, p. 3). Computer security is the effort to create a secure computing platform, designed so that agents (users or programs) can only perform actions that have been allowed. This involves specifying and implementing a security policy. The actions in question can be reduced to operations of access, modification, and deletion. Computer security can be seen as a subfield of security engineering, which looks at broader security issues in addition to computer security;
3. **Information Security**: the protection of information systems against unauthorized access to or modification of information, whether in storage, processing, or transit, and against denial of service to authorized users, including those measures necessary to detect, document, and counter such threats (**NSTISSC,** 1999). IS security has previously concentrated on confidentiality of information stored electronically. The rapid growth in the volume of such information and the uptake of e-commerce within organizations have heightened the need for increased security to protect the privacy of this information and prevent fraudulent activities (Spinellis, Kokolakis, & Gritzalis, 1999); and
4. **Data Security**: the most important part of security - securing the data from unauthorized use.

From the point of view of e-CRM, the above definitions do not help us much. In the section on privacy, information such as SSN and credit card numbers were more critical to consumers than an e-mail address. Thus, we need to look at the security components.

Security Components

A recent meta-analysis of critical themes in electronic commerce research by Wareham, Zheng, and Straub (2005) identified security as an underserved area in IS research. They suggest and support Gordon and Loeb's (2002) assertion that information is an asset of value to an organization and consequently needs to be suitably protected in order to ensure business continuity, minimize business damage, and maximize ROIs and business opportunities (BSI, 1999). The purpose of information security could be characterized as the preservation of confidentiality, integrity, and availability for information assets to keep business value (BSI, 1999; Gordon & Loeb, 2002; Sheth, Sisodia, & Sharma, 2000). Then, in general, IS security is the effective implementation of policies to ensure the confidentiality, availability, and integrity of information and assets to protect from theft, tampering, manipulation, or corruption (Smith & Jamieson, 2006). This also follows from the International Standards Organization (ISO) 17999 Information Security Standard (ISO/IEC, 2005).

The ISO 17799 standard is an internationally-recognized information security management guidance standard (ISO/IEC, 2005). ISO 17799 is high level, broad in scope, and conceptual in nature. This approach allows it to be applied across multiple types of enterprises and applications. It has also made the standard controversial among those who believe standards should be more precise. In spite of this controversy, ISO 17799 is the only "standard" devoted to Information Security Management in a field generally governed by "Guidelines" and "Best Practices" (ISO/IEC, 2005).

ISO 17799 defines information as an asset that may exist in many forms and has value to an organization. Thus, the goal of information security is to suitably protect this asset in order to ensure business continuity, minimize business damage, and maximize return on investments. The objective of the standard is to safeguard:

- **Confidentiality** - ensuring that information is accessible only to those authorized to have access;
- **Integrity** - safeguarding the accuracy and completeness of information and processing methods; and
- **Availability** - ensuring that authorized users have access to information and associated assets when required.

Thus, our basic definition of security in the e-commerce environment is the necessary hardware, software, network controls, data encryption, policies, and procedures in place for an enterprise to ensure that a consumer's information is confidential, has integrity, and is available for e-commerce use.

Enterprise and Consumer Views of Security

Enterprises and consumers will view the security components somewhat differently. Table 4 shows the enterprise and the consumer view. For confidentiality, both the enterprise and consumer expect the security features to prevent unauthorized access to the data. For integrity, the enterprise must use the data supplied by the consumer only for business purposes and must not sell or release the personal data to other enterprises without authorization from the consumer. It is the consumer's obligation to assure that the data is correct. For availability, it is the enterprise's responsibility to assure that the data is available for the consumer and for e-commerce. From the consumer's point of view, the data needs to be available for modification (*i.e.*, change of address, change of preferences).

IS security has previously concentrated on confidentiality of information stored electronically. The rapid growth in the volume of such information and the uptake of e-commerce within organizations has heightened the need for increased security to protect the privacy of this information and prevent fraudulent activities (Spinellis et al., 1999).

Computer security is the effort to create a secure computing platform, designed so that agents (users or programs) can only perform actions that have been allowed. This involves specifying and implementing a security policy. The actions in question can be reduced to operations of access, modification, and deletion. Computer security can be seen as a subfield of security engineering, which looks at broader security issues in addition to computer security.

Table 4. Security components

Security Components	Enterprise/Organization	Consumers
Confidentiality	Prevent unauthorized access Secure all personal information	Prevent unauthorized access How my data is being protected
Integrity	Data used for only business purposes Data not sold without authorization	Data is correct
Availability	Data available for customer Data available for e-commerce	Data available for modification

Security Threats and Vulnerabilities

Table 5 highlights the major threats and vulnerabilities of enterprise networks and consumer use. Threats are any type of unwanted or unauthorized intrusions, attacks, or exploitations into the system (Volonino & Robinson, 2004). Vulnerabilities are twofold: from the consumer point of view - human error, using poor passwords, or participating in chat rooms; from the enterprise side - the complexity of the software which results in misconfigurations, programming errors, or other flaws. The major Internet security breaches are presented in Table 5 (Volonino & Robinson, 2004).

In a recent trade press article (August 29, 2006), AT&T revealed (Preimesberger, 2006) that an undisclosed number of unauthorized persons had illegally hacked into one of its computer systems and accessed the personal data, including credit card information, of about 19,000 customers who had purchased DSL equipment through the company's online store. The unauthorized electronic access took place over the weekend of August 26-27, 2006, and was discovered within hours, according to a company spokesperson. The electronic store was shut down immediately and remained off-line as we write this article. The cost of this security breach has not been disclosed; however, the company is also working with law enforcement to investigate the incident and pursue the perpetrators. The 19,000 customers are being notified by e-mail, phone calls, and letters. Furthermore, AT&T intends to pay for credit monitoring services for customers whose accounts have been impacted. Clearly breaches are still occurring, even to the largest companies that we would expect would have adequate security in place.

Security: No More than Managing Risk

Gordon and Loeb (2002) suggest that the optimal amount to spend on information security is an increasing function of the level of vulnerability of the information. However, the optimal amount to spend on information security does not always increase with the level of vulnerability of such information. They further suggest that managers should budget for security on information that is in a mid-range of vulnerability to security breaches. Furthermore, managers may want to consider partitioning information sets into low, middle, and high levels of security breach vulnerability. Some information may be difficult to protect at a high security level and thus is best defended at a more moderate level. Their findings suggest that the optimal amount to spend on information security never exceeds 37% of the expected loss resulting from a security breach.

Table 5. Security threats and vulnerabilities

Internal Threats		External Threats	
Organizations	**Consumers**	**Organizations**	**Consumers**
• Illness of personnel • Temporary staff • Loss of key personnel • Loss of network service • Disgruntled employees • Disgruntled consultants • Labor dispute • Malware • Software bugs	• User misuse • Malware • Software bugs • Poor passwords • Chat room participation	• Severe storms • Utility outage • Natural disasters • Theft of hardware • Software compromise • Hackers • Adversaries	• Severe storms • Utility outage • Natural disasters • Unauthorized access • Unauthorized sale • Theft of computer • Hackers • Denial of service

Smith and Spafford (2004) also suggest that security is managing risk. In addition, they suggest that the major security challenges are:

1. Stop epidemic-style attacks;
2. Build trustworthy large-scale systems;
3. Make quantitative information systems risk management as good as quantitative financial risk management; and
4. Give end users security that they can understand and privacy that they can control.

Kuper (2005) suggests that the sole reason that information technology exists is to leverage the critical asset of data. Thus, security is data and network integrity, the protection of and access to the data. Also, (Kuper, 2005) from 2000 to 2005, enterprises have spent $15 billion on perimeter level security (antivirus, firewal1s, and approximately $1.5 billion on encryption software,) one of the more obvious technologies for protecting the data. This supports Gordon and Loeb's (2002) assertion that the amount spent does not always match the required level of vulnerability.

Kuper (2005) suggests several new approaches to data security:

1. Data and network integrity - protecting access to data;
2. Inclusion/exclusion security - trusted, known users are handled differently than unknown users (nodes);
3. Embedded security - more security into all aspects of IT components (hardware, software, or service); and
4. Improved approaches - dynamic XML and Web service architectures.

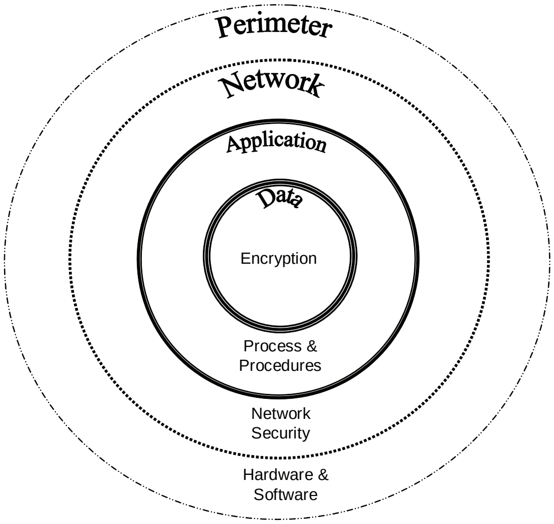
In this regard, enterprises need to work at the data level (using encryption) to secure the most critical data. The second element is that of trust; trusted consumers should be treated differently than unknown consumers. This is one of the objectives of CRM. Next, embedded security for the enterprise at the hardware/software and server level can help to minimize security breaches. Last, new dynamic approaches can be used.

Table 6 illustrates how privacy and security are interrelated in terms of the levels of data, security strategy, and technologies required to achieve appropriate vigilance. Our model of the sphere of privacy suggests that some information is not as critical to secure (i.e., e-mail address), while other information (consumer's SSN) is critical to secure. Kuper (2005) suggests that initially enterprises focused security at the perimeter, but as they learned from persistent attacks they moved from the edge down deeper, layer by layer, to secure the very data itself through encryption. We rename this as the Enterprise "Sphere of Security" model (see Figure 4). Different technologies are required at the different levels, and the most crucial-level data requires encryption to ensure that it is not released (Volonino & Robinson, 2004). At the perimeter (level 4), firewalls and malware

Table 6. Complementarity of privacy, security, and technology

Sphere of Privacy (Ackerman, 1999)	Sphere of Security (Kuper, 2005)	Technology (Volonino & Robinson, 2004)
Level 4: E-mail	Perimeter	Hardware/Software
Level 3: Full name	Network	Network Security
Level 2: Phone number	Application	Process and Procedures
Level 1: SSN	Data	Encryption

Figure 4. Model of the enterprise "sphere of security"



prevention software may offer enough protection for data that is not as sensitive.

Enterprise Privacy/Security Sphere of Implementation

There is an adage that you cannot ensure privacy if you do not first have security. Thus enterprises and consumers need to be prepared for an increasingly hostile public network. Both must provide the right (and updateable) hardware control, data and software controls, and encryption controls to ensure optimal security. Both must also consider the risks, costs, and possible consequences of releasing private information.

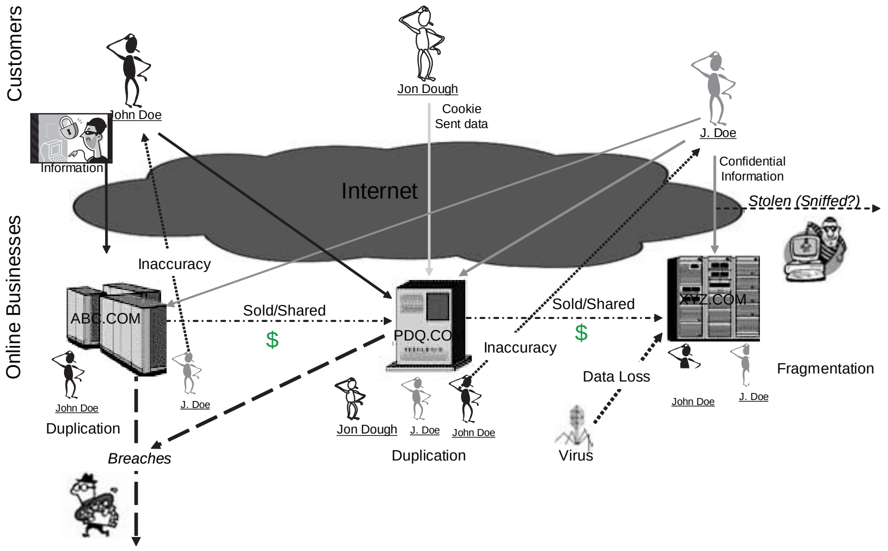
A complete solution to either the security or the privacy problem requires the following three steps which become our privacy/security sphere of implementation model:

- **Policy**: The first step is to develop a security or privacy policy. The policy precisely defines the requirements that are to be implemented within the hardware and software of the computing system and those that are external to the computing system, including physical, personnel, and procedural controls. The policy lays down broad goals without specifying how to achieve them.
- **Mechanism**: The security or privacy policy is made more concrete with the mechanism necessary to implement the requirements of the policy. It is important that the mechanism perform the intended functions.
- **Assurance:** The last step deals with the assurance issue. It provides guidelines for ensuring that the mechanism meets the policy requirements with a high degree of assurance. Assurance is directly related to the effort required to subvert the mechanism. Low-assurance mechanisms are easy to implement, but also relatively easy to subvert; on the other hand, high-assurance mechanisms are notoriously difficult to implement.

CONDITIONAL RELATIONAL "VALUE EXCHANGE" MODEL

Figure 5 illustrates customer data flow and some privacy and security issues related to e-CRM.

Figure 5. Customer dataflow and privacy and security issues



The Figure shows that each customer has their own personal identity as well as personal and confidential information that they may choose to share, or unknowingly (unwittingly) share with online businesses with which they interact, or with others that obtain the information through some other mechanism than a known direct transfer. The Figure illustrates both intentional and unintentional information transfer from customers to other entities. Three representative customers interact with one or more of three online businesses, as well as other players. Several different scenarios that can affect privacy and security are depicted in the Figure.

Scenarios for Customer John Doe: Mr. Doe interacts with online businesses ABC.COM and PDQ.COM and reveals “some” personally-identifiable information to both, but not necessarily the same information. Once this data is revealed, ABC.COM and PDQ.COM have a responsibility to keep it secure and accurate; however, both may fail in these responsibilities. If they share or sell the information to other companies, there will then be duplicate copies of the information in multiple systems, each of which has different levels of security and protection, and the risk that John Doe’s information may be used for purposes other than he intended increases. Additionally, duplicate copies may not be updated if Mr. Doe changes his address, e-mail, or phone number, and thus inaccuracies due to redundant data that is not synchronized can and do multiply. Another possible security and privacy issue is that data from other customers with similar names to John Doe may be inaccurately associated with him, or he may be inaccurately associated with their data. This can result in unwanted offers being sent, invalid information being released, or even inaccurate information that changes the customers’ status and affects their credit score, ability to purchase, or reputation. The complex data exchange environment and the increase in the number and types of attacks and threats makes it very hard for customers to be confident that their data will be secured and their privacy not violated.

Figures 6 and 7 present our conditional relational “value exchange” model. The basic value exchange model (Figure 6) integrates our customer sphere of privacy with our sphere of security model and the enterprise privacy/security sphere of implementation. If an enterprise is to succeed in

Figure 6. Conditional relational "value exchange" model

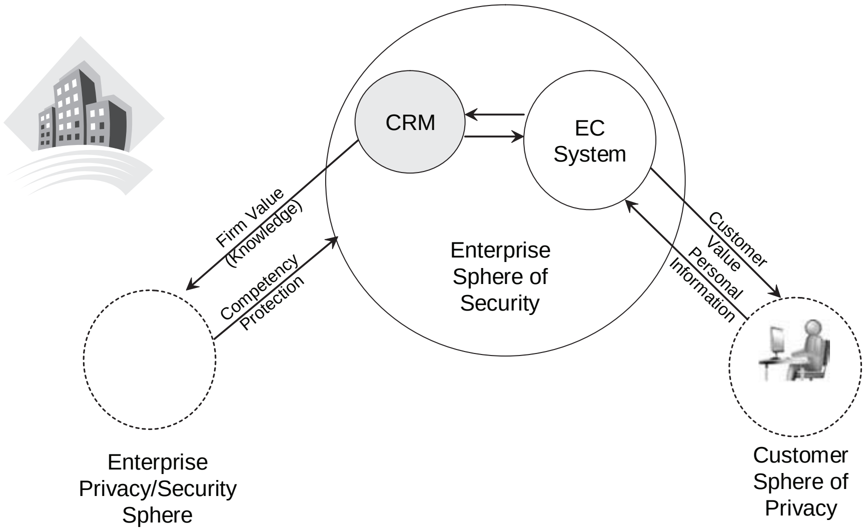


Figure 7. Extended model with watchdogs, government, society, and standards organizations

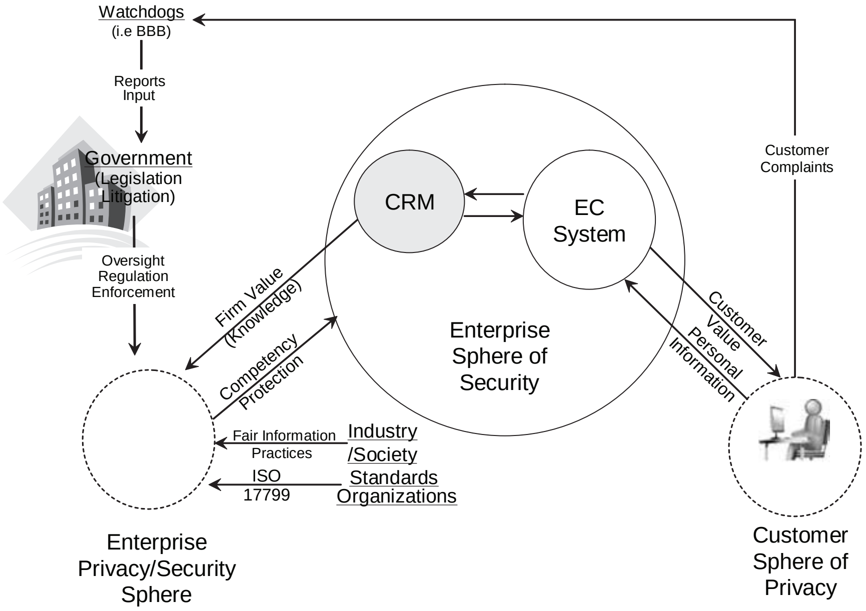

the EC environment, it must provide the necessary security to attract and retain customers. Surveys have shown that (Ackerman et al., 1999; Ponemon, 2005a) customers will churn if they feel that their privacy has been or may be violated.

The value exchange model works through the EC system. The customer interested in obtaining information, evaluating a product or service, or even buying a product or service connects with the EC system and then provides the information that is required from their sphere of privacy. Simultaneous with the customer's inquiry or purchase (the customer's value exchange) the e-CRM system is updated. This in turn becomes the enterprise's value exchange. Then, based upon detailed internal and external analysis, the enterprise's privacy/security policies, assurances, and mechanisms should be modified.

Clearly this is a value exchange model. Prabhaker (2000) suggests that businesses can add value to their EC offerings by leveraging Internet technology (the sphere of security) in coordination with proactive measures (privacy/security sphere of implementation) to preserve consumer privacy (the customer sphere of privacy). This is further supported by Schoder and Madeja (2004), who suggest that e-CRM built upon knowledge about their customers and their ability to serve their customers based on that knowledge has proven to be a key success factor in EC. They also suggest that the most effective way to collect customer data online is through an interactive, feature-rich environment that matches the customers' expectations of an enterprise. In other words, there should be a match between the enterprise's sphere of security and the customer's sphere of privacy.

Figure 7 is the extended value exchange model. This model adds in the interrelationships between the customers, the enterprise, the government, standards organizations, industry and society, and watchdog agencies (i.e., the Better Business Bureau, or BBB). This is a very complex open model. Fletcher (2003) suggests that consumer backlash to perceived invasions of privacy is causing government agencies, standards organizations, industry, and other watchdogs to be more proactive in developing guidelines and policies. Most major EC companies have a detailed privacy statement on their home page. For example, Amazon.com has 11 major items from "What personal information about customers does Amazon.com gather?" to "Examples of information collected". Their objective is to assure that the information that they collect from customers helps them personalize and continually improve the customer's shopping experience at Amazon.com (2006).

IMPLICATIONS FOR ENTERPRISES AND CUSTOMERS

Enterprises continue to collect more and more personal information from online transactions and are using this data to improve sales and service effectiveness (Fletcher, 2003; Romano & Fjermestad, 2003); this is e-CRM in the e-commerce environment. This has become one of the most significant issues confronting enterprises in the electronic age. The issues are securing privacy and security of consumer data while using advanced information systems technology (i.e., e-CRM, business intelligence, data warehousing, and data mining) to sell more goods and services to the consumer.

Consumers, on the other hand, want to get benefits (i.e., reduced time and reduced costs) from e-commerce; however, they are not willing to sacrifice data items such as SSN and credit card number to achieve these benefits. Consumers require that the enterprises safeguard their data.

CONCLUSIONS AND DIRECTIONS FOR FUTURE RESEARCH

The objective of this article was to develop an integrated value exchange model for enterprises and consumers in an e-commerce environment. Enterprises want to attract and retain economically-valuable customers (Romano & Fjermestad, 2001-2002). Typically this is through e-CRM. However, the prime ingredient is customer data. Thus, an enterprise must employ the right levels of privacy, security, and policy spheres to enable the continued collection and use of consumer data. Gordon and Loeb (2002) suggest that information is an asset of value to an organization and consequently needs to be suitably protected in order to ensure business continuity, minimize business damage, and maximize ROIs and business opportunities. Information security is then characterized as the preservation of confidentiality, integrity, and availability of this information asset to maintain business value (BSI 1999; Gordon & Loeb, 2002; Sheth et al., 2000). IS security is the effective implementation of policies to ensure the confidentiality, availability, and integrity of information and assets to protect it from theft, tampering, manipulation, or corruption (Smith & Jamieson, 2006).

Enterprises can lose customers if they do not respond quickly enough and through the right communication channel after a security breach. Research suggests that this is best handled with personal telephone calls and follow-up personal letters (Ponemon, 2005b). The use of spam e-mail will not be effective and can, in fact, make customers more upset due to feeling disrespected in addition to their personal information being lost.

Our contributions are fourfold. First is our model of the customer sphere of privacy adapted from Ackerman et al.'s (1999) survey findings. This model presents the idea of levels of privacy for a consumer in terms of how willing they are to reveal personal information of different types. The highest level, level 1, corresponds to any personal information that consumers are almost never comfortable revealing, such as their Social Security Number or credit card numbers. Consumers will not reveal such information unless they fully trust the recipient. The lowest level, level 4, corresponds to personal information that many consumers are very comfortable revealing, such as their e-mail address. These levels also correspond with the potential seriousness of consequences from the consumers' information getting into the wrong hands. Release of an SSN or credit card number can result in identity theft or monetary losses, while release of an e-mail address may only result in additional spam e-mail. Both are negative consequences, but clearly the former is much more serious than the latter.

The second contribution is our enterprise sphere of security derived from Kuper's (2005) levels of security. This model represents the level of security required to support customer privacy ranging from the deepest internal data level to the externally-focused perimeter level. Accompanying this model is the technology required to support it. At the perimeter level, hardware and software (i.e., routers and firewalls) provide a modest level of protection, while at the data level more secure technologies such as encryption or perturbation are required to more vigilantly ensure protection of consumer privacy. The third contribution is the enterprise privacy/security sphere of implementation. These are the policies, mechanisms, and assurances to support privacy and security. Many enterprises provide such a policy statement on their Web site.

Our fourth contribution is the integrated value exchange model and the extended model. This model is built upon the interrelationships among the three spheres. The model proposes that both the enterprise and the customer exchange information when they transact via EC. The customer exchanges personal information in order to obtain customer value (reduced time and cost, as well as the goods, services, or information purchased). The enterprise gains customers and, via aggregation and data mining, competitive advantage from the knowledge about their customers. In order to keep their customers, the enterprise must provide competent protection for the customers' information. The extended model shows that there is substantial input from industry, standards organizations, the government, and other watchdog organizations.

In many cases, the major asset of an enterprise is its customers and data about them. There is a delicate balance (as the value exchange model illustrates) that must be maintained. The customers are only a mouse click away from an enterprise's competitors. Customers also have responsibilities to be careful and vigilant in that they must give up personal information in order to receive the benefits of EC. They must provide accurate and reliable information and also verify that a firm is trustworthy and employing adequate levels of security before revealing personal information. They should also think carefully about what information is required for a given transaction and not provide additional information that is not necessary. This can assist customers to make more informed queries and purchases and, at the same time, helps the enterprise market to them and to other customers more effectively through new mechanisms such as recommender systems, cross-selling, and preference discounts.

In the age of e-CRM, Enterprises and Customers have vast new opportunities to exchange value more quickly and effectively than ever before; however, along with these come new vulnerabilities and responsibilities to secure and protect privacy. Enterprises that fail to protect the privacy of their customers may find that many leave for the competition that will do so. E-CRM is about establishing and maintaining intimate relationships with customers to generate additional value and long-term loyalty; enterprises cannot do this if they do not provide the security required to protect their customers' privacy at the level of vigilance they expect. It may be necessary to provide personalized levels of security for the very best customers if they demand it. Just as investors can choose the level of risk they are willing to take for a potential return on investment, consumers will also choose which firms to do business with via EC based on the level of perceived risk they associate with them. Future research and practice in Information Assurance (Security and Privacy) will have to take the consumer's perspective more into account than at present.

Section VIII
Emerging Trends

This section highlights research potential within the field of strategic information systems while exploring uncharted areas of study for the advancement of the discipline. Chapters within this section highlight advancements in enterprise resource planning, strategic technology planning, and strategic decision making for Green IT. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Chapter 8.1

Patterns for Organizational Modeling

Manuel Kolp
Université catholique de Louvain, Belgium

Stéphane Faulkner
University of Namur, Belgium

ABSTRACT

Organizational modeling is concerned with analyzing and understanding the organizational context within which a software system will eventually function. This paper proposes organizational patterns motivated by organizational theories intended to facilitate the construction of organizational models. These patterns are defined from real world organizational settings, modeled in i* and formalized using the Formal Tropos language. Additionally, the paper evaluates the proposed patterns using desirable qualities such as coordinability and predictability. The research is conducted in the context of Tropos, a comprehensive software system development methodology.

INTRODUCTION

Analyzing the organizational and intentional context within which a software system will eventually operate has been recognized as an important element of the organizational modeling process also called early requirements engineering (see e.g., Anton, 1996; Dardenne, van Lamsweerde, & Fickas, 1993; Yu, 1995). Such models are founded on primitive concepts such as those of actor and goal. This paper focuses on the definition of a set of organizational patterns that can be used as building blocks for constructing such models. Our proposal is based on concepts adopted from organization theory and strategic alliances literature. Throughout the paper, we use i* (Yu, 1995) as the modeling framework in terms of which the proposed patterns are presented and accounted for. The research reported in this paper is being conducted within the context of the Tropos project (Giorgini, Kolp, Mylopoulos, & Pistore, 2004; Giorgini, Kolp, Mylopoulos, & Castro, 2005), whose aim is to construct and validate a software development methodology for agent-based software systems. The methodology adopts ideas from multi-agent system technologies, mostly to define the implementation phase of our methodology. It also adopts ideas from Requirements Engineering, where actors and goals have been used heavily for early requirements analysis. The project is founded on the premise that actors and goals are used as fundamental concepts for modeling and analysis during all phases of software development, not just early requirements, or implementation. More details about Tropos can be found in Giorgini, et al., 2005. The present work continues the research in progress about social abstractions for the Tropos methodology. In Kolp, Giorgini and Mylopoulos (2002a), we have detailed a social ontology for Tropos to consider information systems as social structures all along the development life cycle. In Giorgini, Kolp, and Mylopoulos (2002); Kolp, Giorgini, and Mylopoulos (2002b); and Kolp, Giorgini, and Mylopoulos (2006), we have described how to use this Tropos social ontology to design multi-agent systems architectures, notably for e-business applications (Kolp, Do, & Faulkner, 2004). As a matter of fact, multi-agent systems can be considered structured societies of coordinated autonomous agents. In the present paper, which is a extended and revised version of Kolp, Giorgini, and Mylopoulos (2003), we emphasize the use of organizational patterns based on organization theory and strategic alliances for early requirements analysis, with the concern of modeling the organizational setting for a system-to-be in terms of abstractions that could better match its operational environment (e.g., an enterprise, a corporate alliance, etc.).

The paper is organized as follows: The second section describes organizational and strategic alliance theories, focusing on the internal and external structure of an organization. The third section details two organizational patterns—the structure-in-5 and the joint venture—based on real world examples of organizations. These patterns are modeled in terms of social and intentional concepts using the i* framework and the Formal Tropos specification language. The fourth section identifies a set of desirable non-functional requirements for evaluating these patterns and presents a framework to select a pattern with respect to these identified requirements. The fifth section overviews the *Tropos* methodology. Finally, The sixth section summarizes the contributions of the paper and provides an overview of related work.

STRUCTURING ORGANIZATIONS

Organizational structures are primarily studied by *organization theory* (e.g., Mintzberg, 1992; Scott, 1998; Yoshino & Rangan, 1995), that describes the structure and design of an organization and *strategic alliances* (e.g., Dussauge & Garrette, 1999; Gomes-Casseres, 1996; Morabito, Sack, & Bhate, 1999; Segil, 1996), that model the strategic collaborations of independent organizational stakeholders who have agreed to pursue a set of agreed upon business goals.

Both disciplines aim to identify and study organizational patterns that describe a system at a macroscopic level in terms of a manageable number of subsystems, components, and modules interrelated through dependencies.

In this article, we are interested in identifying, formalizing and applying organizational modeling patterns that have been already well-understood and precisely defined in organizational theories. Our purpose is neither to categorize them exhaustively nor to study them on a managerial point of view. The following sections will thus only insist on patterns that have been found, due to their nature, interesting candidates, also considering the fact that they have been studied in great detail in the organizational literature and presented as fully-formed patterns.

Organization Theory

"An organization is a consciously coordinated social entity, with a relatively identifiable boundary, that functions on a relatively continuous basis to achieve a common goal or a set of goals" (Morabito et al., 1999). Organization theory is the discipline that studies both structure and design in such social entities. Structure deals with the descriptive aspects, while design refers to the prescriptive aspects of a social entity. Organization theory describes how practical organizations are actually structured, offers suggestions on how new ones can be constructed, and suggests how old ones can change to improve effectiveness. To this end, since Adam Smith, schools of organization theory have proposed models and patterns to try to find and formalize recurring organizational structures and behaviors.

In the following, we briefly present organizational patterns identified in Organization Theory. The structure-in-5 will be studied in detail in the next section.

The Structure-in-5

An organization can be considered an aggregate of five substructures, as proposed by Minztberg (1992). At the base level sits the *Operational Core*, which carries out the basic tasks and procedures directly linked to the production of products and services (acquisition of inputs, transformation of inputs into outputs, and distribution of outputs). At the top lies the *Strategic Apex* which makes executive decisions ensuring that the organization fulfils its mission in an effective way and defines the overall strategy of the organization in its environment. The *Middle Line* establishes a hierarchy of authority between the Strategic Apex and the Operational Core. It consists of managers responsible for supervising and coordinating the activities of the Operational Core. The *Technostructure* and the *Support* are separated from the main line of authority and influence the operating core only indirectly. The Technostructure serves the organization by making the work of others more effective, typically by standardizing work processes, outputs, and skills. It is also in charge of applying analytical procedures to adapt the organization to its operational environment. The Support provides specialized services at various levels of the hierarchy, outside the basic operating workflow (e.g., legal counsel, R&D, payroll, and cafeteria). We describe and model examples of structures-in-5 in the next section.

The Pyramid Pattern

A well-known hierarchical authority structure. Actors at lower levels depend on those at higher levels. The crucial mechanism is the direct supervision from the Apex. Managers and supervisors at intermediate levels only route strategic decisions and authority from the Apex to the operating (low) level. They can coordinate behaviors or take decisions on their own, but only at a local level.

The Chain of Values

The chain of values merges, backward or forward, several actors engaged in achieving or realizing related goals or tasks at different stages of a supply or production process. Participants who act as intermediaries, add value at each step of the chain. For instance, for the domain of goods distribution, providers are expected to supply quality products, wholesalers are responsible for ensuring their massive exposure, while retailers take care of the direct delivery to the consumers.

The Matrix

The matix proposes a multiple command structure: vertical and horizontal channels of information and authority operate simultaneously. The principle of unity of command is set aside, and competing bases of authority are allowed to jointly govern the workflow. The vertical lines are typically those of functional departments that operate as ”home bases” for all participants, the horizontal lines represent project groups or geographical arenas where managers combine and coordinate the services of the functional specialists around particular projects or areas.

The Bidding Pattern

The bidding pattern involves competitive mechanisms, and actors behave as if they were taking part in an auction. An auctioneer actor runs the show, advertises the auction issued by the auction issuer, receives bids from bidder actors and ensures communication and feedback with the auction issuer who is responsible for issuing the bidding.

Strategic Alliances

A strategic alliance links specific facets of two or more organizations. At its core, this structure is a trading partnership that enhances the effectiveness of the competitive strategies of the participant organizations by providing for the mutually beneficial trade of technologies, skills, or products based upon them. An alliance can take a variety of forms, ranging from arm’s-length contracts to joint ventures, multinational corporations to university spin-offs, and franchises to equity arrangements. Varied interpretations of the term exist, but a strategic alliance can be defined as possessing simultaneously the following three necessary and sufficient characteristics:

- The two or more organizations that unite to pursue a set of agreed upon goals remain independent, subsequent to the formation of the alliance.
- The partner organizations share the benefits of the alliances and control over the performance of assigned tasks.
- The partner organizations contribute on a continuing basis in one or more key strategic areas, e.g., technology, products, and so forth.

In the following, we briefly present organizational patterns identified in strategic alliances. The joint venture will be studied in detail in the third section.

Joint Venture Pattern

The joint venture pattern involves agreement between two or more intra-industry partners to obtain the benefits of larger scale, partial investment, and lower maintenance costs. A specific joint management actor coordinates tasks and manages the sharing of resources between partner actors. Each partner can manage and control itself on a local dimension and interact directly with other partners to exchange resources, such as data and knowledge. However, the strategic operation and coordination of such an organization, and its actors on a global dimension, are only ensured by the joint management actor in which the original actors possess equity participations. We describe and model examples of joint ventures in the third section.

Arm’s-Length Pattern

The arm’s-length pattern implies agreements between independent and competitive, but partner, actors. Partners keep their autonomy and independence but act and put their resources and knowledge together to accomplish precise common goals. No authority is lost or delegated from one collaborator to another.

Hierarchical Contracting Pattern

The hierarchical contracting pattern identifies coordinating mechanisms that combine arm’s-length agreement features with aspects of pyramidal authority. Coordination mechanisms developed for arm’s-length (independent) characteristics involve a variety of negotiators, mediators, and observers at different levels handling conditional clauses to monitor and manage possible contingencies, negotiate and resolve conflicts, and finally deliberate and take decisions. Hierarchical relationships, from the executive apex to the arm's-length contractors, restrict autonomy and underlie a cooperative venture between the parties.

Co-Optation Pattern

The co-optation pattern involves the incorporation of representatives of external systems into the decision-making or advisory structure and behavior of an initiating organization. By co-opting representatives of external systems, organizations are, in effect, trading confidentiality and authority for resource, knowledge assets, and support. The initiating system has to come to terms with the contractors for what is being done on its behalf; each co-optated actor has to reconcile and adjust its own views with the policy of the system it has to communicate.

MODELING ORGANIZATIONAL PATTERNS

We will define an organizational pattern as a metaclass of organizational structures offering a set of design parameters to coordinate the assignment of organizational objectives and processes, thereby affecting how the organization itself functions. Design parameters include, among others, goal and task assignments, standardization, supervision and control dependencies, and strategy definitions.

This section describes two of the organizational patterns presented in the second section: the structure-in-5 and the joint-venture.

Structure-in-5

To detail and specify the structure-in-5 as an organizational pattern, this section presents two case studies: LDV Bates (Bates, 2006) and GMT (GMT, 2006). They will serve to propose a model and a semi-formal specification of the structure-in-5.

LDV Bates

Agate Ltd. is an advertising agency located in Belgium that employs about fifty staff, as detailed in Table 1.

The *Direction*—four directors responsible for the main aspects of LDV Bates's *Global Strategy* (advertising campaigns, creative activities, administration, and finances)—forms the *Strategic Apex*. The *Middle Line*, composed of the *Campaigns Management* staff, is in charge of finding and coordinating advertising campaigns (marketing, sales, edition, graphics, budget, etc.). It is supported in these tasks by the *Administration and Accounts* and *IT and Documentation* departments. *Administration and Accounts* constitutes the *Technostructure* handling administrative tasks and policy, paperwork, purchases, and budgets. The Support groups the IT and Documentation departments. It defines the *IT policy* of Agate, provides *technical means* required for the management of campaigns, and ensures services for *system support* as well as information retrieval (*documentation* resources). The *Operational Core* includes the *Graphics and Edition* staff in charge of the creative and artistic aspects of realizing *campaigns* (texts, photographs, drawings, layout, design, and logos).

Figure 1 models LDV Bates in structure-in-5 using the i* strategic dependency model. i* is a framework for organizational modeling (Yu, 1995), which offers goal-and-actor-based notions, such as *actor, agent, role, position, goal, softgoal, task, resource and belief, as well as* different kinds of social dependency between actors. Its strategic dependency model describes the network of social *dependencies* among actors. It is a graph, wherein each node represents an actor, and each link between two actors indicates that one actor

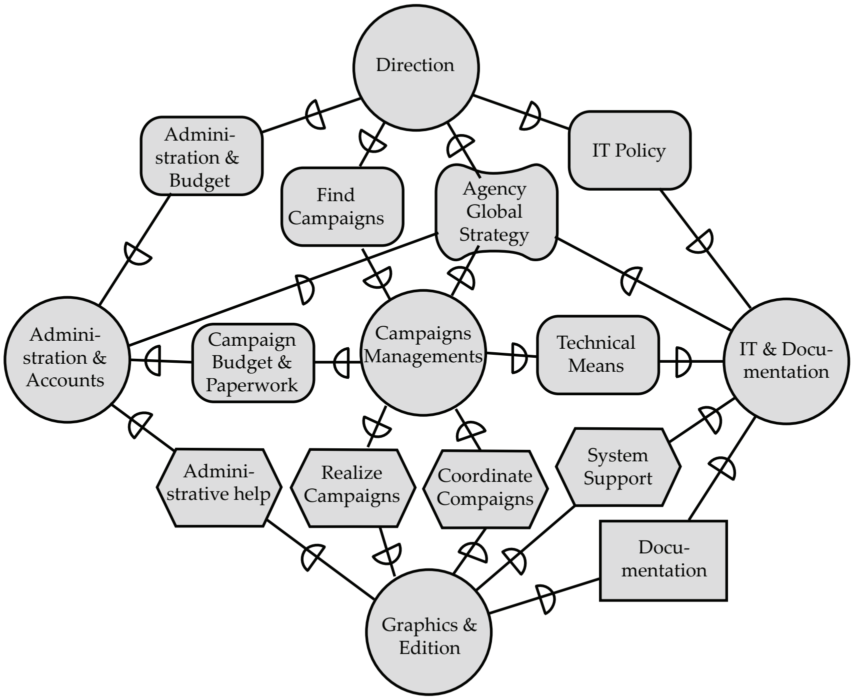
Figure 1. LDV Bates as a Structure-in-5

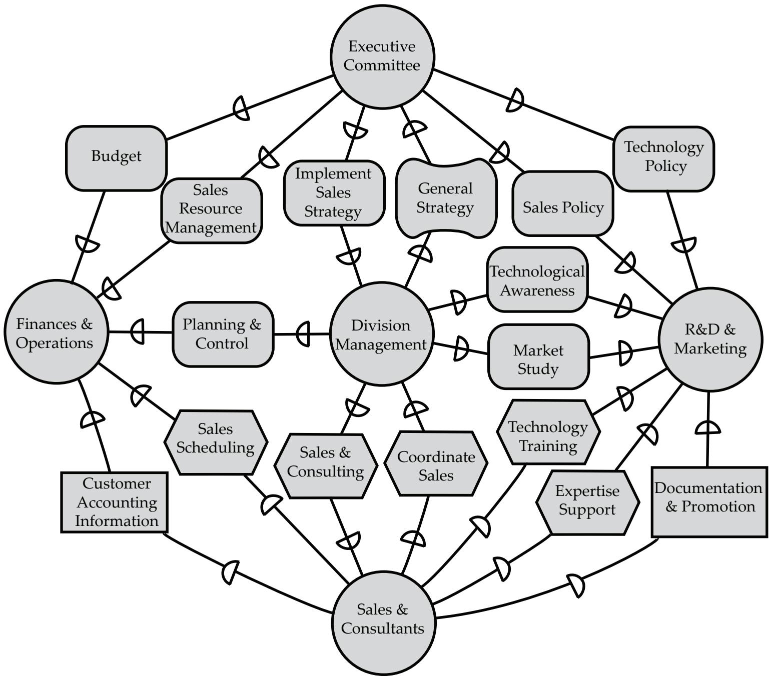


depends on the other for some goal to be attained. A dependency describes an "agreement" (called *dependum*) between two actors: the *depender* and the *dependee*. The depender is the depending actor, and the dependee, the actor who is depended upon. The type of the dependency describes the nature of the agreement. *Goal* dependencies represent delegation of responsibility for fulfilling a goal; *softgoal* dependencies are similar to goal dependencies, but their fulfillment cannot be defined precisely (for instance, the appreciation is subjective or fulfillment is obtained only to a given extent); *task* dependencies are used in situations where the dependee is required to perform a given activity; and resource dependencies require the dependee to provide a resource to the depender. As shown in Figure 1, actors are represented as circles; dependums–goals, softgoals, tasks, and resources–are represented as ovals, clouds, hexagons, and rectangles, respectively, and dependencies have the form *depender → dependum → dependee*.

GMT is a company specialized in telecom services in Belgium. Its lines of products and services range from phones & fax, conferencing, line solutions, internet & e-business, mobile solutions, and voice & data management. As shown in Figure 2, the structure of the commercial organization follows the structure-in-5. An *Executive Committee* constitutes the *Strategic Apex*. It is responsible for defining the *general strategy* of the organization. Five chief managers (*finances*, *operations*, *divisions management*, *marketing*, and *R&D*) apply the specific aspects of the *general strategy* in the area of their competence: *Finances & Operations* is in charge of *Budget* and Sales *Planning & Control*, *Divisions Management* is responsible for *Implementing Sales Strategy*, and *Marketing* and *R&D* define *Sales Policy* and *Technological Policy*.

The *Divisions Management* groups managers that coordinate all managerial aspects of product and service sales. It relies on *Finance & Operations* for handling *Planning* and *Control* of

Figure 2. GMT's sales organization as a structure-in-5



products and services, it depends on *Marketing* for accurate *Market Studies*, and on R&D for *Technological Awareness.*

The *Finances & Operations* departments constitute the *technostructure* in charge of management *control* (financial and quality audit) and sales *planning,* including *scheduling* and *resource management.*

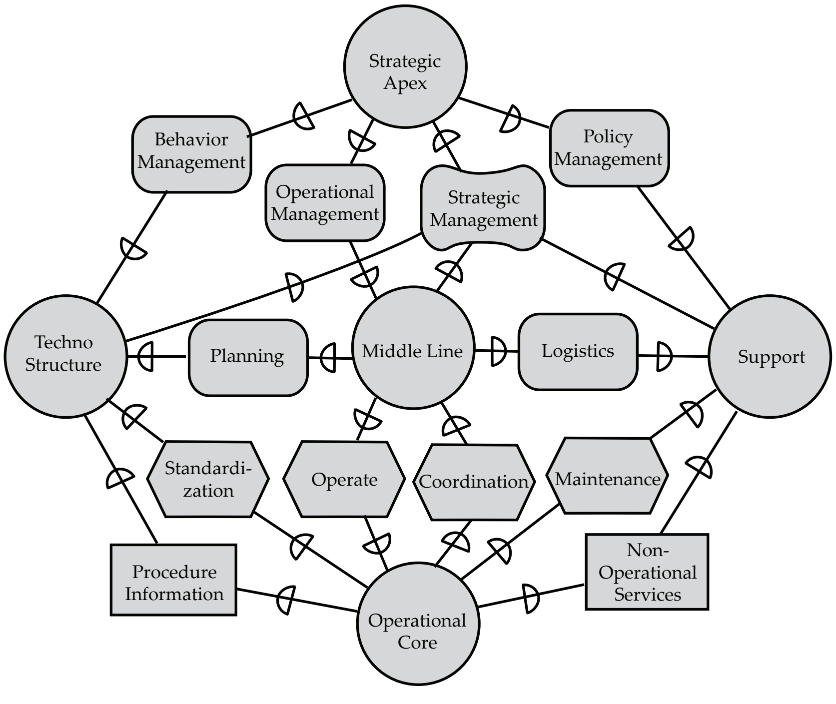
Support involves the staff of *Marketing* and *R&D*. Both departments jointly define and support the *Sales* Policy. The Marketing department coordinates *Market Studies* (customer positioning and segmentation, pricing, sales incentive, etc.) and provides the *Operational Core* with *Documentation* and *Promotion* services. The *R&D* staff is responsible for defining the technological policy, such as *technological awareness* services. It also assists *Sales people* and *Consultants* with *Expertise Support* and *Technology* Training.

Finally, the *Operational Core* groups *the Sales people* and *Line consultants* under the supervision and coordination of *Divisions Managers.* They are in charge of selling products and services to actual and potential customers.

Figure 3 abstracts the structures explored in the case studies of Figures 1 and 2 as a structure-in-5 pattern composed of five actors. The case studies also suggested a number of constraints to supplement the basic pattern:

- Dependencies between the *Strategic Apex* as depender and the *Technostructure*, *Middle Line,* and *Support* as dependees must be of type goal
- A softgoal dependency models the strategic dependence of the *Technostructure, Middle Line,* and *Support* on the *Strategic Apex*
- Relationships between the *Middle Line* and *Technostructure* and *Support* must be of goal dependencies
- *Operational Core* relies on the *Technostructure* and *Support* through task and resource dependencies

Figure 3. The structure-in-5 pattern



- Only task dependencies are permitted between the *Middle Line* (as depender or dependee) and the *Operational Core* (as dependee or depender)

To specify the formal properties of the pattern, we use *Formal Tropos* (Fuxman, Liu, Mylopoulos, Roveri, & Traverso, 2004), which extends the primitives of *i** with a formal language comparable to that of KAOS (Dardenne, et al., 1993). Constraints on *i** specifications are thus formalized in a first-order linear-time temporal logic. *Formal Tropos* provides three basic types of metaclasses: *actor, dependency, and entity* (Giorgini, Kolp, & Mylopoulos, 2002). The attributes of a *Formal Tropos* class denote relationships among different objects being modeled.

Metaclasses

Actor : = **Actor** name[attributes] [creation-properties] [invar-properties][actor-goal]
With subclasses:
Agent(with attributes occupies: Position, play: Role)
Position(with attributes cover: Role)
Role
Dependency : =**Dependency** name type mode **Depender** name **Dependee** name [attributes] [creation-properties] [invar-properties] [fulfill-properties]
Entity:=**Entity** name [attribute] [creation-properties][invar-properties]
Actor-Goal := (**Goal**|**Softgoal**) name mode **FulFillment**(actor-fulfill-property)

Classes: Classes are instances of Metaclasses.

In Formal Tropos, constraints on the lifetime of the (meta)class instances are given in a first-order linear-time temporal logic (see Fuxman et al., 2004 for more details). Special predicates can appear in the temporal logic formulas: predicate *JustCreated*(*x*) holds in a state if element *x* exists in this state but not in the previous one; predicate *Fulfilled*(*x*) holds if *x* has been fulfilled; and predicate *JustFulfilled*(*x*) holds if *Fulfilled*(*x*) holds in this state, but not in the previous one.

In the following, we only present some specifications for the *Strategic Management* and *Operational Management* dependencies.

Actor StrategicApex
Actor MiddleLine
Actor Support
Actor Technostructure
Actor OperationalCore

Dependency StrategicManagement
Type SoftGoal
Depender te: Technostructure, ml: MiddleLine, su: Support
Dependee sa: StrategicApex
Invariant

$$\forall dep : Dependency\ (JustCreated(dep) \rightarrow Consistent(self, dep))$$

$$\forall ag : Actor - Goal\ (JustCreated(ag) \rightarrow Consistent(self, ag))$$

Fulfillment

$$\forall dep : Dependency\ (dep.type = goal \wedge dep.depender = sa \wedge (dep.dependee = te\ dep.dependee = ml\ dep.dependee = su)) \wedge Fulfilled(self) \rightarrow \blacklozenge Fulfilled(dep)$$

[Invariant properties specify, respectively, that the strategic management softgoal must be consistent with any other dependency of the organization and with any other goal of the actors in the organization. The predicate Consistent depends on the particular organization we are considering and it is specified in terms of goals' properties to be satisfied. The fulfillment of the dependency necessarily implies that the goal dependencies between the Middle Line, the Technostructure, and the Support as dependees, and the Strategic Apex as depender have been achieved some time in the past]

Dependency OperationalManagement **Type** Goal
Mode achieve
Depender sa: StrategicApex
Dependee ml: MiddleLine
Invariant
$Consistent(self, StrategicManagement)$
$\exists\, c : Coordination\ (c.type = task \wedge c.dependee = ml \wedge c.depender = OperationalCore \wedge ImplementedBy(self, c))$

Fulfillment
$\forall ts : Technostructure, dep : Dependency\ (dep.type = goal \wedge dep.depender = ml \wedge dep.dependee = ts) \wedge Fulfilled(self)) \rightarrow \blacklozenge Fulfilled(dep)$

[The fulfillment of the Operational management goal implies that all goal dependencies between the Middle Line as depender and the Technostructure as dependee have been achieved some time in the past. Invariant properties specifies that the Operational Management goal has to be consistent with Strategic Management softgoal and that there exists a coordination task (a task dependency between MiddleLine and Operational Core) that implements (ImplementedBy) the OperationalManagaemnt goal.]

In addition, the following structural (global) properties must be satisfied for the Structure-in-5 pattern:

- $\forall inst1, inst2 : StrategicApex \rightarrow inst1 = inst2$

[There is a single instance of the Strategic Apex (the same constraint also holds for the Middle Line, the Technostructure, the Support, and the Operational Core)]

- $\forall sa : StrategicApex, te : Technostructure, ml : MiddleLine, su : Support, dep : Dependency\ (dep.dependee = sa \wedge (dep.depender = te \vee dep.depender = ml \vee dep.depender = su) \rightarrow dep.type = softgoal)$

[Only softgoal dependencies are permitted between the Strategic Apex as dependee and the Technostructure, the Middle Line, and the Support as dependers]

- $\forall sa : StrategicApex, te : Technostructure, ml : MiddleLine, su : Support, dep : Dependency : (dep.depender = sa \wedge (dep.dependee = te \vee dep.dependee = ml \vee dep.dependee = su) \rightarrow dep.type = goal)$

[Only goal dependencies are permitted between the Technostructure, the Middle Line, and the Support as dependee, and the Stategic Apex as depender]

- $\forall su : Support, ml : MiddleLine, dep : Dependency\ ((dep.dependee = su \wedge dep.depender = ml) \rightarrow dep.type = goal)$

  [Only task dependencies are permitted between the Middle Agency and the Operational Core]

- $\forall te : Technostructure, oc : OperationalCore, dep : Dependency\ ((dep.dependee = te \wedge dep.depender = oc) \rightarrow (dep.type = task \vee dep.type = resource))$

[Only resource or task dependencies are permitted between the Technostructure and the Operational Core (the same constraint also holds for the Support)]

- $\forall a : Actor, ml : MiddleLine, (\exists dep : Dependency(dep.depender = a \wedge dep.$

$$\begin{aligned}&dependee = \\ &ml) \vee (dep.dependee = a \wedge dep.depender = ml) \rightarrow \\ &((\exists sa : StrategicApex(a = sa)) \vee (\exists su : Support(a = su) \vee \\ &(\exists te : Technostructure(a = te)) \vee (\exists op : OperationalCore \\ &(a = op))\end{aligned}$$

[No dependency is permitted between an external actor and the Middle Agency (the same constraint also holds for the Operational Core)]

This specification can be used to establish that a certain *i** model does constitute an instance of the structure-in-5 pattern. For example, the *i** model of Figure 1 can be shown to be such an instance, in which the actors are instances of the structure-in-5 actor classes (e.g., *Direction* and *IT&Documentation* are instances of the *Strategic Apex* and the *Support*, respectively), dependencies are instances of structure-in-5 dependencies classes (e.g., *Agency Global Strategy* is an instance of the *Strategic Management*), and all above global properties are enforced (e.g., since there are only two task dependencies between *Campaigns Management* and *Graphics&Edition*, the fourth property holds).

Joint Venture

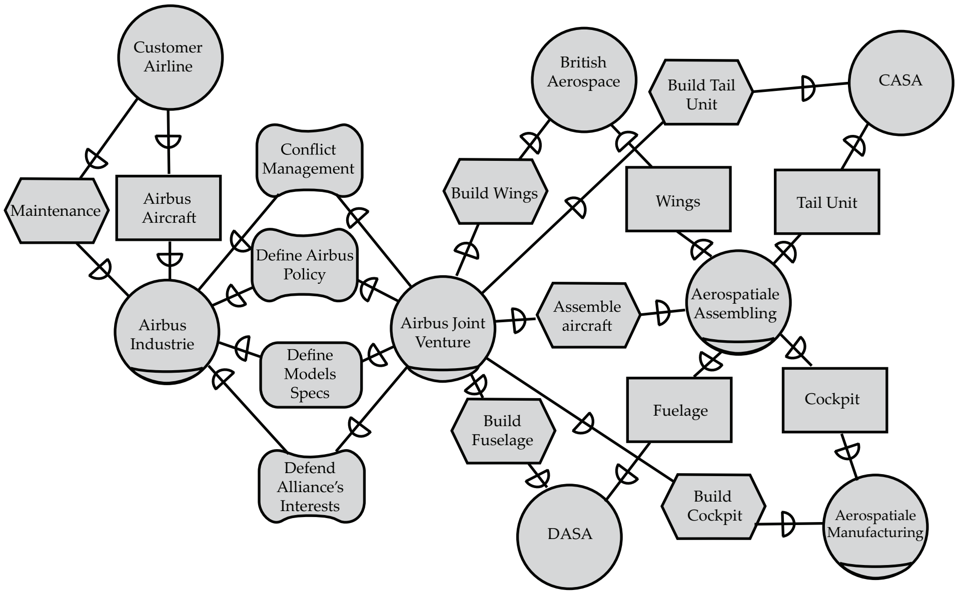
We describe here two alliances—Airbus (Dussauge & Garrette, 1999) and a more detailed one, Carsid (Wautelet, Kolp, & Achbany, 2006)—that will serve to model the joint venture structure as an organizational pattern and propose a semi-formal specification.

Airbus. The Airbus Industrie joint venture coordinates collaborative activities between European aeronautic manufacturers to build and market airbus aircraft. The joint venture involves four partners: British Aerospace (UK), Aerospatiale (France), DASA (Daimler-Benz Aerospace, Germany), and CASA (Construcciones Aeronauticas SA, Spain). Research, development, and production tasks have been distributed among the partners, avoiding any duplication. Aerospatiale is mainly responsible for developing and manufacturing the cockpit of the aircraft and for system integration. DASA develops and manufactures the fuselage, British Aerospace the wings, and CASA the tail unit. Final assembly is carried out in Toulouse (France) by Aerospatiale. Unlike production, commercial and decisional activities have not been split among partners. All strategy, marketing, sales, and after-sales operations are entrusted to the Airbus Industrie joint venture, which is the only interface with external stakeholders, such as customers. To buy an Airbus, or to maintain their fleet, customer airlines could not approach one or another of the partner firms directly, but have to deal with Airbus Industrie. Airbus Industrie, which is a real manufacturing company, defines the alliance's product policy and elaborates the specifications of each new model of aircraft to be launched. Airbus defends the point of view and interests of the alliance as a whole, even against the partner companies themselves when the individual goals of the latter enter into conflict with the collective goals of the alliance.

Figure 4 models the organization of the Airbus Industrie joint venture using the *i** strategic dependency model. Airbus assumes two roles: Airbus Industrie and Airbus Joint Venture.

Airbus Industrie deals with demands from customers, *Customer* depends on it to receive airbus aircrafts or maintenance services. The *Airbus Joint Venture* role ensures the interface for the four partners (*CASA*, *Aerospatiale*, *British Aerospace*, and *DASA*) with *Airbus Industrie* defining Airbus strategic policy, managing conflicts between the four Airbus partners, defending the interests of the whole alliance, and defining new aircraft specifications. *Airbus Joint Venture* coordinates the four partners, ensuring that each of them assumes a specific task in the building of Airbus aircrafts: wings building for *British Aerospace*, tail unit building for *CASA*, cockpit building and

Figure 4. The Airbus Industrie joint venture



aircraft assembling for *Aerospace*, and fuselage building for *DASA*. Since Aerospatiale assumes two different tasks, it is modeled as two roles: *Aerospatiale Manufacturing* and *Aerospatiale Assembling. Aerospatiale Assembling* depends on each of the four partners receiving the different parts of the planes.

Carsid (Carolo-Sidérurgie) is a joint venture that has recently arisen from the global concentration movement in the steel industry. The alliance, physically located in the steel basin of Charleroi in Belgium, has been formed by the steel companies Duferco (Italy), Usinor (France)—that also partially owns Cockerill-Sambre (Belgium) through the Arcelor group—and Sogepa (Belgium), a public investment company representing the Walloon Region Government. Usinor has also brought its subsidiary Carlam into the alliance.

Roughly speaking, the aim of a steel manufacturing company like CARSID is to extract iron from the ore and to turn it into semi-finished steel products. Several steps compose the transformation process, each step is generally assumed by a specific metallurgic plant:

- **Sintering plant:** Sintering is the preparation of the iron ore for the blast furnace. The minerals are crushed and calibrated to form a sinter charge.
- **Coking plant:** Coal is distilled (i.e., heated in an air-impoverished environment in order to prevent combustion) to produce coke.
- **Blast furnace:** Coke is used as a combustion agent and as a reducing agent to remove the oxygen from the sinter charge. The coke and sinter charge are loaded together into the blast furnace to produce cast iron.
- **Steel making plant:** Different steps (desulphuration, oxidation, steel adjustment, cooling, etc.) are necessary to turn cast iron into steel slabs and billets. First, elements other than iron are removed to create molten steel. Then, supplementary elements (e.g., titanium, niobium, and vanadium) are added to make a more robust alloy. Finally, the result—finished steel—is solidified to produce slabs and billets.
- **Rolling mill:** The manufacture of semi-finished products involves a process known as hot rolling. Hot-rolled products are of two

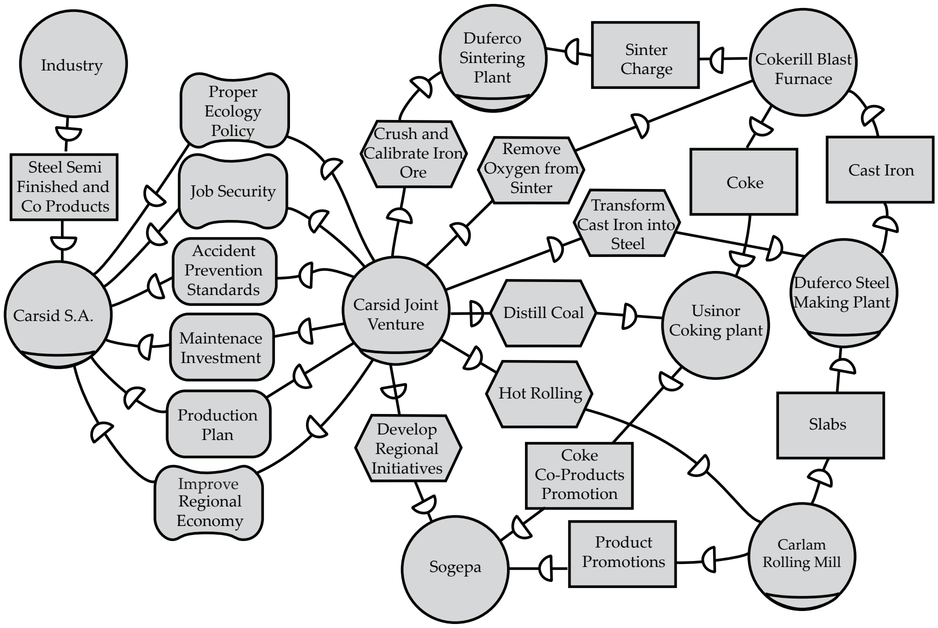
categories: flat (plates, coiled sheets, sheeting, strips, etc.) produced from steel slabs and long (wire, bars, rails, beams, girders, etc.) produced from steel billets.

Figure 5 models the organization of the Carsid joint venture in *i**. Carsid assumes two roles: Carsid S.A. ("Société Anonyme"–the English equivalent is "Ltd") and Carsid Joint Venture.

Carsid S. A. is the legal and contractual interface of the joint venture. It handles the sales of *steel semi-finished products* (bars, plates, rails, sheets, etc., but also slabs and billets) and *co-products* (coke that does not meet blast furnace requirements, rich gases from the different plants, godroon, naphtalin, etc.) to external *industries* such as vehicle manufacturers (e.g., automobiles, trains, and boats), foundries, gas companies, and building companies. It is also in charge of the *proper environment policy*, a strategic aspect for steelworks that are polluting plants. Most important, Carsid has been set up with the help of the Walloon Region to guarantee *job security* for about 2000 workers in the basin of Charleroi. Indeed, the steel industry in general and the Walloon metallurgical basins in particular are sectors in difficulty with high unemployment rates. As a corollary, the joint venture is committed to *improve regional economy* and maintain work in the region. Carsid has then been contractually obliged to plan *maintenance investment* (e.g., blast furnace refection, renovation of coke oven batteries, etc.) and develop *production plans* involving regional subcontractors and suppliers. Since steelmaking is a hard and dangerous work sector, Carsid, like any other steelworks, is legally committed to respect, develop, and promote *accident prevention standards.*

The *Carsid joint venture* itself coordinates the steel manufacturing process. The sintering phase to *prepare iron ore* is the responsibility of *Duferco Sintering Plant* while *Usinor Coking Plant, distills coal* to turn it onto *coke*. The *sinter charge* and *coke* are used by the Cokerill Blast Furnace to produce *cast iron* by *removing oxygen from sinter.* The *Duferco Steel Making Plant transforms cast iron into steel* to produce slabs and billets for the *Carlam Rolling Mill* in charge

Figure 5. The Carsid joint venture



of the *hot rolling* tasks. Carlam (Carolo-Laminoir). *Sogepa*, the public partner, has the responsibility to *develop regional initiatives* to promote Carsid activities, particularly in the Walloon Region and in Belgium.

Figure 6 abstracts the joint venture structures explored in the case studies of Figures 4 and 5. The case studies suggest a number of constraints to supplement the basic pattern:

- Partners depend on each other for providing and receiving resources
- Operation coordination is ensured by the joint manager actor, which depends on partners for the accomplishment of these assigned tasks
- The joint manager actor must assume two roles: A private interface role to coordinate partners of the alliance and a public interface role to take strategic decisions, define policy for the private interface, and represent the interests of the whole partnership with respect to external stakeholders

Part of the Joint Venture pattern specification is in the following:

Role JointManagerPrivateInterface Goal CoordinatePatterns

Role JointManagerPublicInterface
Goal TakeStrategicDecision
SoftGoal RepresentPartnershipInterests
Actor Partner

and the following structural (global) properties must be satisfied:

- $\forall$jmpri1, jmpri2 : J ointManagerPrivateInterface
  (jmpri1 = jmpri2)

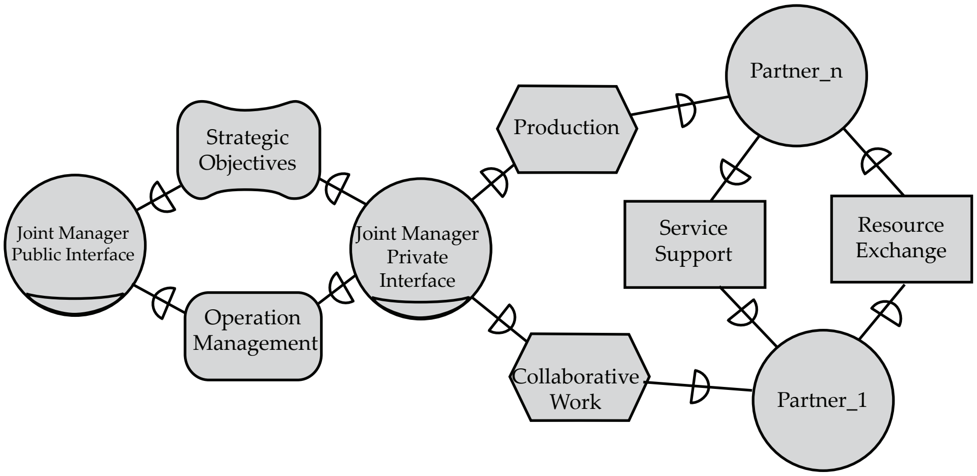
  [Only one instance of the joint manager]

- *$\forall$p1, p2 : P artner, dep : Dependency (((dep.depender = p1 $\wedge$dep.dependee = p2)$\vee$(dep.depender =
  p2 $\wedge$ dep.dependee = p1)) $\rightarrow$ (dep.type = resource))*

  [Only resource dependencies between partners]

- *$\forall$jmpri : JointManagerPrivateInterface, p : Partner, dep : Dependency((dep.dependee = p $\wedge$ dep.depender = jmpri)
  $\rightarrow$dep.type = task)*

Figure 6. The joint venture pattern



[Only task dependencies between partners and the joint manager, with the joint manager as depender]

- $\forall jmpri : JointManagerPrivateInterface, jmpui : JointManagerPublicInterface, dep : Dependency\ ((dep.depender = jmpri \wedge dep.dependee = jmpui) \rightarrow (dep.type = goal \vee dep.type = softgoal))$

[Only goal or softgoal dependencies between the joint manager roles]

- $\forall dep : Dependency, p1 : Partner\ ((dep.depender = p1 \vee dep.dependee = p1) \rightarrow ((\exists p2 : Partner(p1 \neq p2 \wedge (dep.depender = p2 \vee dep.dependee = p2)) \vee (\exists jmpi : JointManagerPrivateInterface\ ((dep.depender = jmpi \vee dep.dependee = jmpi))))$
  [Partners only have relationships with other partners or the joint manager private interface]
- $\forall dep : Dependency, jmpi : JointManagerPrivateInterface\ ((dep.depender = jpmi \vee dep.dependee = jpmi) \rightarrow ((\exists p : Partner((dep.depender = p \vee dep.dependee = p))) \vee (\exists jmpui : JointManagerPublicInterface\ ((dep.depender = jmpui \vee dep.dependee = jmpui))))$
  [The joint manager private interface only has relationships with the joint manager public interface or partners]

EVALUATION

Patterns can be compared and evaluated with quality attributes (Shaw & Garlan, 1996), also called non-functional requirements (Chung, Nixon, Yu, & Mylopoulos, 2000). For instance, the requirements seem particularly relevant for organizational structures (Do, Faulkner, & Kolp, 2003; Kolp, et al., 2006):

- **Predictability** (Woods & Barbacci, 1999): Actors can have a high degree of autonomy (Wooldridge & Jennings, 1995) in the way that they undertake action and communication in their domains. It can be then difficult to predict individual characteristics as part of determining the behavior of the system at large. Generally, predictability is in contrast with the actors' capabilities to be adaptive and responsive: Actors must be predictable enough to anticipate and plan actions while being responsive and adaptive to unexpected situations.
- **Security:** Actors are often able to identify their own data and knowledge sources and they may undertake additional actions based on these sources (Woods & Barbacci, 1999). Strategies for verifying authenticity for these data sources by individual actors are an important concern in the evaluation of overall system quality since, in addition to possibly misleading information acquired by actors, there is the danger of hostile external entities spoofing the system to acquire information accorded to trusted domain actors.
- **Adaptability:** Actors may be required to adapt to modifications in their environment. These may include changes to the component's communication protocol or possibly the dynamic introduction of a new kind of component previously unknown or the manipulations of existing actors.

Generally, adaptability depends on the capabilities of the single actors to learn and predict the changes of the environments in which they act (Weiss, 1997), and also their capability to make a diagnosis (Horling, Lesser, Vincent, Bazzan, & Xuan, 1999), that is, being able to detect and determine the causes of a fault based on its symptoms. However, successful organization environments tend to balance the degree of reactivity and predictability of the single actors with their capabilities to be adaptive.

- **Coordinability:** Actors are not particularly useful unless they are able to coordinate with other agents. Coordination is generally (Jennings, 1996) used to distribute expertise, resources, or information among the actors (actors may have different capabilities, specialized knowledge, different sources of information, resources, responsibilities, limitations, charges for services, etc.), solve interdependencies between actors' actions (interdependence occurs when goals undertaken by individual actors are related), meet global constraints (when the solution being developed by a group of actors must satisfy certain conditions if is to be deemed successful), and to make the system efficient (even when individuals can function independently, thereby obviating the need for coordination, information discovered by one actor can be of sufficient use to another actor that both actors can solve the problem twice as fast).

Coordination can be realized in two ways:

1. **Cooperativity:** Actors must be able to coordinate with other entities to achieve a common purpose or simply align their local goals. Cooperation can either be communicative in that the actors communicate (the intentional sending and receiving of signals) with each other in order to cooperate or it can be non-communicative (Doran, Franklin, Jennings, & Norman, 1997). In the latter case, actors coordinate their cooperative activity by each observing and reacting to the behavior of the other. In deliberative organizations, actors jointly plan their actions so as to cooperate with each other.
2. **Competitivity:** Deliberative negotiating organization (Doran et al., 1997) are like deliberative ones, except that they have an added dose of competition. The success of one actor implies the failure of others.

- **Availability:** Actors that offer services to other actors must implicitly or explicitly guard against the interruption of offered services.
- **Fallibility-tolerance:** A failure of one actor does not necessarily imply a failure of the whole organization. The organization then needs to check the completeness and the accuracy of information and knowledge transactions and workflows. To prevent failure, different actors can have similar or replicated capabilities and refer to more than one actor for a specific behavior.
- **Modularity:** (Shehory, 1998) increases efficiency of service execution, reduces interaction overhead, and usually enables high flexibility. On the other hand, it implies constraints on inter-organization communication.
- **Aggregability:** Some actors are parts of other actors. They surrender to the control of the composite entity. This control results in efficient workflow execution and low interaction overhead. However, it prevents the organization to benefit from flexibility.

As an illustration, we evaluate the patterns with respect to coordinativity, predictability, fallibility-tolerance, and adaptability. The evaluation can be done in a similar way for the other non-functional requirements. Due to the lack of space, we refer the author to the bibliography for the other attributes.

The structure-in-5 improves coordinativity among actors by differentiating the data hierarchy (the support actor) from the control hierarchy—supported by the operational core, technostructure, middle agency, and strategic apex. The existence of three different levels of abstraction (1) Operational Core; (2) Technostructure, Middle Line, and Support; (3) Strategic Apex addresses the need for managing predictability. Besides, higher levels are more abstract than lower levels: Lower levels only involve resources and task dependencies while higher ones propose intentional (goal and soft-goal) relationships. Checks and control mechanisms can be integrated at different levels of abstraction assuming redundancy from different perspectives and considerably increase fallibility-tolerance. Since the structure-in-5 separates data and control hierarchies, integrity of these two hierarchies can also be verified independently. The structure-in-5 separates independently the typical components of an organization, isolating them from each other and allowing them dynamic adaptability. But since it is restricted to no more than five major components, more refinement has to take place inside the components themselves.

The joint venture supports coordinativity in the sense that each partner actor interacts via the joint manager for strategic decisions. Partners indicate their interest, and the joint manager either returns the strategic information immediately or mediates the request to some other partners. However, since partners are usually heterogeneous, it could be a drawback to define a common interaction background. The central position and role of the joint manager is as a means for resolving conflicts and preventing unpredictability. Through its joint manager, the joint-venture proposes a central communication controller. It is less clear how the joint venture pattern addresses fallibility-tolerance, notably reliability. However, exceptions, supervision, and monitoring can improve its overall score with respect to these qualities. Manipulation of partners can be done easily to adapt the structure by registering new ones to the joint manager. However, since partners can also exchange resources directly with each other, existing dependencies should be updated as well. The joint manager cannot be removed due to its central position. Table 2 summarizes the strengths and weaknesses of the reviewed patterns.

Table 2. Strengths and weaknesses of some patterns

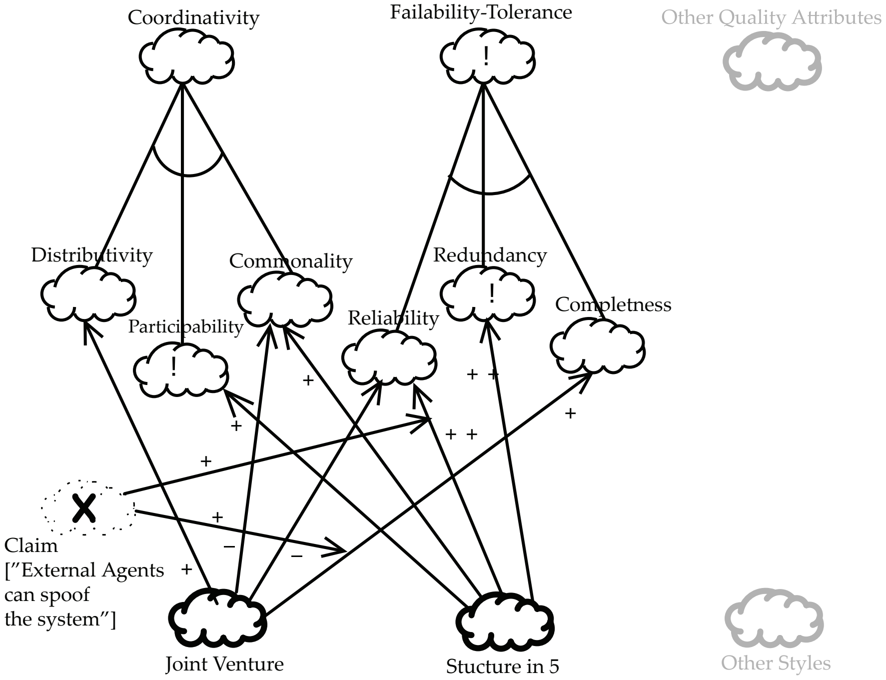
	Structure-in-5	Joint-Venture
Coordinativity	++	+
Predictability	+	+
Fallibility-Tolerance	++	+
Adaptability	+	+

To cope with non-functional requirements and select the pattern for the organizational setting, we go through a means-ends analysis using the non functional requirements (NFRs) framework (Chung et al., 2000). We refine the identified requirements to sub-requirements that are more precise and evaluates alternative organizational patterns against them, as shown in Figure 7. The analysis is intended to make explicit the space of alternatives for fulfilling the top-level requirements. The patterns are represented as operationalized requirements (saying, roughly, “model the organizational setting of the system with the *pyramid, structure-in-5, joint venture, arm’s-length* ... pattern”).

The evaluation results in contribution relationships from the patterns to the non-functional requirements, labeled “+”, “++”, “–”, “– –”. Design rationale is represented by claims drawn as dashed clouds. They make it possible for domain characteristics (such as priorities) to be considered and properly reflected into the decision making process, e.g., to provide reasons for selecting or rejecting possible solutions (+, –). Exclamation marks (! and !!) are used to mark priority requirements while a check-mark “√” indicates an accepted requirements and a cross “ X ” labels a denied requirement.

Relationships types (AND, OR, ++, +, –, and – –) between NFRs are formalized to offer a tractable proof procedure. AND/OR re-

Figure 7. Partial evaluation for organizational patterns



lationships correspond to the classical AND/OR decomposition relationships: if requirement R0 is AND-decomposed (respectively, OR-decomposed) into *R*1,*R*2,...,*Rn,* then all (at least one) of the requirements must be satisfied for the requirement R0 to be satisfied. So, for instance, in Figure 7 Coordinativity is AND decomposed into Distributivity, Participability, and Commonality. Relationships "+" and "–" model respectively a situation where a requirement contributes positively or negatively towards the satisfaction of another one. For instance, in Figure 7 Joint Venture contributes positively to the satisfaction of Distributivity and negatively to the Reliability. In addition, relationships "++" and "– –" model a situation where the satisfaction of a requirement implies the satisfaction or denial of another goal. In Figure 7 the satisfaction of structure-in-5 implies the satisfaction of requirements Reliability and Redundancy.

The analysis for selecting an organizational setting that meets the requirements of the system to build is based on propagation algorithms presented in Giorgini, Mylopoulos, Nicchiarelli, and Sebastiani (2002). Basically, the idea is to assign a set of initial labels for some requirements of the graph, about their satisfiability and deniability, and see how this assignment leads to the labels propagation for other requirements. In particular, we adopt from Giorgini, Mylopoulos, Nicchiarelli and Sebastiani (2002) both qualitative and a numerical axiomatization for goal (requirements) modeling primitives and label propagation algorithms that are shown to be sound and complete with respect to their respective axiomatization. The following is a brief description of the qualitative algorithm.

To each requirement *R*, we associate two variables. $Sat(R)$, $Den(R)$, ranging in $\{F, P, N\}$ (full, partial, none) such that $F > P > N$, represents the current evidence of satisfiability and deniability of the requirement *R*. For example, $Sat(R_i) >= P$ states there is at least partial evidence that A_i is satisfiable. Starting from assigning an initial set of input values for $Sat(R_i)$, $Den(R_i)$ to (a subset of) the requirements in the graph, we propagate

Table 3. Propagation rules for satisfiability in the qualitative framework. A dual table is given for deniability propagation.

	+ $G2 \rightarrow G1$	- $G2 \rightarrow G1$	++ $G2 \rightarrow G1$	-- $G2 \rightarrow G1$
$Sat(G1)$ $Den(G1)$	$min\{ Sat(G2), P \}$ N	$min\{ Sat(G2), P \}$	$Sat(G2)$ N	N $Sat(G2)$

the values through the propagation rules of Table 3. Propagation rules for AND (respectively OR) relationships are min-value function for satisfiability (max-value function) and max-value function (min-value function) for deniability. A dual table is given for deniability propagation.

The schema of the algorithm is described in Figure 8. *Initial*, *Current*, and *Old* are arrays of pairs $Sat(R_i)$, $Den(R_i)$, one for each R_i of the graph, representing respectively the initial, current, and previous labeling status of the graph.

The array *Current* is first initialized to the initial values *Initial* given in input by the user. At each step, for every requirement R_i, $Sat(R_i)$, $Den(R_i)$ is updated by propagating the values of the previous step. This is done until a fixpoint is reached, that is, no updating mode is possible (*Current* == *Old*). The updating of $Sat(R_i)$, $Den(R_i)$ works as follows. For each relation Rel_i incoming in G_i, the satisfiability and deniability values $sati_i$ and $deni_i$ derived from the old values of the source requirements are computed by applying the rules of Table 3. Then, it returns the maximum value between those computed and the old values.

Figure 8. Schema of the label propagation algorithm

```
Current=Initial;
do
    Old=Current;
    for each $R_i$ do
        Current[i] = Update label(i, Old);
until not (Current==Old);
return Current;

for each $Rel_i$ s.t. target($Rel_i$) == Ri do
    satij = Apply Rules Sat(i, $Rel_i$, Old);
    denij = Apply Rules Den($R_i$, $Rel_i$, Old);
return max($max_i$ ($sati_i$), Old[i].sat),
            max($max_i$ ($deni_i$), Old[i].den);
```

A REQUIREMENTS-DRIVEN METHODOLOGY

This research is conducted in the context of the *early requirements* phase of *Tropos* (Giorgini et al., 2004; Giorgini et al., 2005), a software development methodology for building multi-agent systems founded on the concepts of actor and goal.

The *Tropos* methodology adopts ideas from multi-agent systems technologies, mostly to define the detailed design and implementation phase, and ideas from requirements engineering and organizational modeling, where agents/actors and goals have been used heavily for early requirements analysis (Dardenne et al., 1993; Yu, 1995). In particular, the *Tropos* project adopts Eric Yu's *i** model which offers actors (agents, roles, or positions), goals, and actor dependencies as primitive concepts for analyzing an application during organizational modeling. The key assumption which distinguishes *Tropos* from other methodologies is that actors and goals are used as fundamental concepts for analysis and design during *all phases of software development*, not just requirements analysis. That means that, in the light of this paper, *Tropos* describes the organizational environment within which a system will eventually operate, as well as the system itself in terms of the same concepts and patterns. *Tropos* spans four phases of software development:

- Organizational modeling, concerned with the understanding of a problem by studying an organizational setting; the output is an organizational model which includes relevant actors, their goals and dependencies.
- Requirements analysis, in which the system-to-be is described within its operational environment, along with relevant functions and qualities.
- Architectural design, in which the system's global architecture is defined in terms of subsystems, interconnected through data, control, and dependencies.
- Detailed design, in which behavior of each architectural component is defined in further detail.

CONCLUSION

Modelers need to rely on patterns, styles, and idioms to build their models, whatever the purpose. We argue that, as with other phases of software development, organizational modeling can be facilitated by the adoption of organizational patterns. This paper focuses on two such patterns and studies them in detail through examples, a formalization using Formal Tropos and an evaluation with respect to desirable requirements. There have been many proposals for software patterns (e.g., Kolp, Do, & Faulkner, 2005) since the original work on design patterns (Gamma, Helm, Johnson, & Vlissides, 1995). Some of this work focuses on requirements patterns. For example, Konrad and Cheng (2002) propose a set of requirements patterns for embedded software systems. These patterns are represented in UML and cover both structural and behavioral aspects of a requirements specification. Along similar lines, Fowler (1997) proposes some general patterns in UML. In both cases, the focus is on requirements analysis, and the modeling language used is UML. On a different path, Gross and Yu (2002) propose a systematic approach for evaluating design patterns with respect to non-functional requirements (e.g., security, performance, and reliability). Our approach differs from this work primarily in the fact that our proposal is founded on ideas from organization theory and strategic alliances literature. We have already described organizational patterns, but to be used for designing multi-agent system architectures (Kolp et al., 2006) and e-business systems (Kolp et al., 2004). Considering real world organizations as a metaphor, systems involving many software actors, such as multi-agent systems, could benefit from the same organizational models. In the present paper we have focused on patterns for modeling organizational settings rather than software systems, and emphasized the need for organizational abstractions to better match the operational environment of the system-to-be during organizational modeling.

Chapter 8.2

Enterprise Resource Planning Under Open Source Software

Ashley Davis
University of Georgia, USA

ABSTRACT

Open source software is becoming more prevalent in businesses today, and while still a relatively immature offering, open source enterprise resource planning (OS-ERP) systems are becoming more common. However, whether or not an OS-ERP package is the right software for a given organization is a little researched question. Building on the current real options thinking about platform acquisitions, this chapter proposes the five most critical factors to consider when evaluating an OS-ERP package. To adequately do this, a great deal of detail about the current offerings in OS-ERP software is presented, followed by a review of the real options theory and thinking behind using these factors to evaluate OS-ERP options. The international implications of OS-ERP are presented in the "Future Trends" section.

INTRODUCTION

Open source software (OSS) is becoming a prominent part of the business infrastructure landscape. However, open source application software is still in its infancy. Success of open source enterprise resource planning (OS-ERP) systems will signify a coming of age of open source applications. There are many factors that will determine if OS-ERP systems are a valuable option for corporations, and thus whether OS-ERP systems will become as prominent as other open source offerings like Linux or JBOSS. This chapter will inform the reader of the current state of OS-ERP in the global context, and explain to potential adopters of OS-ERP the important factors to consider in evaluating an OS-ERP option.

First, a common language for defining OS-ERP systems will be developed. Second, the current state of OS-ERP software will be explored. Third, the business models of OS-ERP vendors will be exposed. Fourth, the advantages and disadvantages of customization of OS-ERP software will be explained. Fifth, the factors for valuing OS-ERP options using real options theory (Fichman, 2004) are defined. Finally, the global adoption of ERP software is explored.

BACKGROUND

The first necessary requisite for understanding OS-ERP systems is to define a common language for talking about OS-ERP applications. This includes defining exactly what an OS-ERP application entails and whether the software meets the definition of open source software. There is much ambiguity in the popular press about what is and is not OSS; this is only confounded when ERP systems claim to be open source. To clarify these issues, the next section will explain historical context of OSS. Secondly, open source licensing issues are explained. Then, the issue of open source ERP functionality is addressed. Lastly some examples of OS-ERP software are provided.

History of Open Source Software

Open source software has a rich history, from an initial chaotic beginning out of a hacker culture (Raymond, 1999) to its current manifestation as a foundation for profit-seeking corporations such as JBOSS (Watson, Wynn, & Boudreau, 2005), Compiere Inc., and Red-Hat Linux. As open source has evolved, the definition of open source software has changed and the open source ecosystem has grown. Previously, open source software was defined in terms of two characteristics: (1) licenses that give programmers the ability to view, change, enhance open source code, and distribute the source code without discrimination (Feller & Fitzgerald, 2000; Open Source Initiative, 2005); and (2) the software is free of cost. While this definition was sufficient, for pure open source initiatives of the past, it does not adequately cover all that "open source" includes today. This is in contrast to proprietary software where the license generally does not allow for distribution of the source code and is not free of cost. Evolution and commercialization of OSS have led to many products being labeled "open source" that are not free of cost. As well, proprietary software (software controlled and offered by vendors for a price) that give access to the code are termed open source, while there is no licensing to support the open source model of software development. Proprietary software that allows access to the source code still leaves the control of the source code, what is included in the source code in future versions, in the hands of the vendor, who may be less accepting of contributions of code than an open source community.

However, even under the most stringent of open source (OS) definitions, there have been many great open source successes. For example, MySQL is an open source database server that has grown phenomenally since its inception in 1995. MySQL AB is the company that supports the MySQL product. This product is free and the source code is available to everyone under the GNU General Public License (GPL). Licensing will be discussed in more detail in the next section.

MySQL is currently backed by several venture capitalists and is without debt (MySQL, 2007). There were over 12 million downloads of MySQL in 2006, and 2,500 new customers started using MySQL to power Web sites, critical applications, packaged software, and telecommunications infrastructure. MySQL is just one example of the success of OS software in the infrastructure space. Other examples in infrastructure offerings include JBOSS and Linux.

In terms of business applications, there are fewer major success stories. SugarCRM, however, is one of the most successful open source business applications. SugarCRM is a customer relationship management software package (packaged software is that which offers a "set of functionality" in a complete state that does not require programming) that is available under a "custom" open source license.[1] SugarCRM has over a million downloads and about 1,000 customers (SugarCRM, 2007). ERP systems—large packaged integrated business applications that include intensive functionality in the following areas: marketing and sales, accounting and finance, production and materials management, and human resources[2]—are relatively less prolific than these major success stories in the open source space. However, as the rest of this chapter outlines, there are several open source ERP offerings becoming available. It waits to be determined which of these applications will become widely used in businesses.

Open Source Licenses

Licensing plays a big role in definitions of OSS. As of 2006, the Open Source Initiative (OSI) recognizes nearly 60 different open source licenses (Open Source Initiative, 2006). Given this number of licenses, and that OSI is not the only organization that provides accreditation of licenses,[3] it is understandable that the definition of open source is not stable. Many companies have turned to a dual-licensing strategy, making their code available under general public license (GPL) but also offering a commercial license (Rist, 2005). Given this large number of licensing options and business models, it is understandable that there is confusion as to what software really is open source software.

Open source software still must allow access to the source code, as mentioned above. So, OS-ERP systems are defined to allow access to the code. However, under what terms this is available, including for what cost, is a question. For the purposes of understanding OS-ERP software, one must assume that the cost is not necessarily free. For the OS-ERP packages in this chapter, three general license types are utilized:

1. **Apache License Version 2.0:** "Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form." As with all licenses, it is recommended that a full review of the license is conducted before working with any open source software (Apache, 2007).
2. **Mozilla Public License 1.1:** This license allows for access to the source code for review and modification. This is a copyleft license, meaning that all modifications involving the original source code are sent back to the originator of the software. As with all licenses, it is recommended that a full review of the license is conducted before working with any open source software (Mozilla, 2007).
3. **GNU GPL:**"GNU is a recursive acronym for 'GNU's Not Unix'; it is pronounced *guh-noo*, approximately like *canoe*…the GNU General Public License is intended to guarantee your freedom to share and change free software—to make sure the software is free for all its users." Users of software under the GNU GPL can use, modify, improve, and redistribute such software. As with all licenses, it is recommended that a full review of the license is conducted before working with any open source software (GNU, 2007a, 2007b).

However, some software companies create their own licenses with their own implications for what "open source" means to their software. In the OS-ERP space, examples include:

1. **OpenMfg:**"…the license OpenMFG uses allows companies to view and modify

source code, as well as make contributions to the source code" (Caton, 2006). However, this license does not allow for distribution of the source code. So, by definition, this is not what is generally meant by "open source" software. As with all licenses, it is recommended that a full review of the license is conducted before working with any software.

2. **avERP:** This license includes no license fees, no charge for updates, no fees charged for own programming, no obligation to pay or purchase anything at anytime, no obligation for use of services, and it is possible to alter all program modules if wished and includes source code (HK-Software, 2007). It does not appear that redistribution of the software is allowed. As with all licenses, it is recommended that a full review of the license is conducted before working with any software.
3. **OpenPro:** This is software built on open source technologies that allows access to the source code. However, there is a license fee involved, and the right to distribute the software is not explained on the Web site (OpenPro, 2007). As with all licenses, it is recommended that a full review of the license is conducted before working with any open software.

Table 1 outlines current OS-ERP offerings, licensing, and Web sites where more can be learned about the software.

The popular press has referred to all of the software listed in Table 1 as OS-ERP, even those with cost. ERP systems are the backbone of an organization, and the cost of the initial license is

Table 1. Open source ERP licensing

GNUe	GNU GPL	http://www.gnuenterprise.org/
Value ERP	GNU	http://www.valueerp.com/

only part of the total cost of ownership (TCO) of an ERP system or any software package. Organizations cannot rely on vendors and analysts to provide accurate TCO estimates. One practitioner notes, "…no matter how honest they try to be, neither vendor nor analyst can ever fill in all the variables of the TCO formula…The unique combination of resources, both machine and human, at work within your organization is something only you can fully understand" (McAllister, 2005). One estimate of the costs that make up TCO includes hardware and software, technical services, planning and process management, finance and administration, training, user support, peer support, and application development (DiMaio, 2004). However, migration costs, testing, system integration, and so forth must be included in determining the total cost of switching to any software package. For a breakdown of some of the costs to consider, please see the cost comparison provided by Nolan (2005). The comparison of costs between proprietary ERP and OS-ERP systems is not readily known, as "the lack of large-scale implementations (of OS-ERP) eliminate a direct comparison with enterprise solutions, such as mySAP Business Suite or Oracle E-Business suite" (Prentice, 2006). However, even getting an accurate TCO is not adequate when deciding whether to use open source software (DiMaio, 2004, 2007). For OS-ERP software, the decision is more complex because this decision crosses the bounds of the entire organization. Decision makers involved in evaluating ERP systems are aware that even for proprietary systems, the cost estimates vary wildly (Cliff, 2003), and thus when considering OS-ERP solutions, TCO (as complex as it is) will be but one evaluative criterion. ERP evaluative criteria are often handled by complex request for proposal processes involving outside experts. Beyond this expertise, this chapter proposes factors for valuing OS-ERP options (see the "Real Options Value of OS-ERP" section) that should be considered in addition to these complex TCO estimates.

As well, the business model (see the "Open Source Vendor Models" section) behind open source offerings will explain why cost is not as much of an issue in the definition of OS-ERP systems. However, a pure definition of OS-ERP would not include AvERP, OpenPro, or OpenMFG because, although all allow access to modify and change the code, these packages either charge a license fee or do not allow for re-distribution of the software (as mentioned above).

Functionality of OS-ERP

For those interested in understanding the OS-ERP phenomena, a solid foundation of understanding the functionality of each ERP application is also important. The maturity of the proprietary ERP market has allowed convergence as to what constitutes ERP functionality. For most, an acceptable general definition of ERP systems is as follows: ERP systems are complex, modular software integrated across the company with capabilities for most functions in the organization. As mentioned in the "History of Open Source" section, ERP systems include functionality in the following areas: marketing and sales, accounting and finance, production and materials management, and human resources. Many times supply chain management and customer relationship management are also included in ERP packages. It is beyond the scope of this chapter to list and define whether each open source system that claims to be ERP actually contains ERP functionality. For practitioners looking to acquire OS-ERP software and academicians looking to do OS-ERP research, a thorough assessment of whether a particular system contains full ERP functionality is required. This is more of an issue in OS-ERP systems since most of these systems are fairly new and a consensus has not been achieved as to what is actually an OS-ERP system. In the OS-ERP market, many of the claims of what functionality constitutes an OS-ERP system is blurry:

One characteristic of open source is that different projects define their category's feature sets in different ways. This is especially true of ERP packages. Linux-Kontor, for example, defines ERP without accounting, focusing instead on customer management, order entry, invoicing, and inventory. TUTOS, on the other hand, calls itself ERP but more closely resembles a groupware suite. Clearly, some research is needed to make sure you're really getting what you expect in this category. (Rist, 2005)

Another concern with open source software is that the offerings are changing rapidly, so for up-to-date and complete information, the Web sites listed in Table 1 are the best sources for information about the offerings and the platforms on which the software is built/supports. However, just to provide a flavor of the offerings, Table 2 provides a cursory look at the functionality being offered by these software products (OS-ERP) at the time of this work. Again, since functionality is hard to pin down, (for example, if a package only lists "HR" as its offering, does this mean benefits administration is included?), those interested in this software should contact the company directly for the most accurate and up-to-date information.

OS-ERP Examples

There are many different flavors of OS-ERP packages, mostly because each package grew from a particular need (as OSS offerings often do). For example, Fisterra grew from a custom application built for an automotive glass replacement and repair company (Fisterra, 2007). Versions of the Fisterra product specifically intended for this industry are now called Fisterra Garage. This new name allows distinction from Fisterra 2—a generic ERP released in 2004. In this case, proprietary ERP definitions apply, in that the package has what most would define as full ERP functionality. However this is not always the case (as noted above).

The industry origins of the ERP package are important, as many times these are industry solutions that work best for the original industry. This is akin to SAP providing excellent manufacturing functionality because of its origins in the manufacturing industry. Another example of OS-ERP starting in a specific industry is OfBiz, which started with an emphasis on the retail industry (Adamson, 2004).

ASSESS THE OS-ERP LANDSCAPE

In the OSS arena, infrastructure products like Linux, Perl scripting language, and My SQL database management systems have been very successful and thus very prominent. Given that the developers of open source software were many times the users of open source software, this success is predictable. Less predictable is the success of open source software when used to develop applications. Most of the time, developers are developing the application for users that are very different from themselves. The users of applications are not technical, and their requirements are very different from those of technical users—thus the criticism that open source software is not "user friendly" or has a usability problem (Nichols & Twidale, 2003). This issue is important to OS-ERP, as possibly the entire organization will interface with the OS-ERP application, rather than only IT people directly working with infrastructure products.

OS-ERP is a quickly changing environment. For example, Compiere, one of the most well-known open source ERP companies, announced Andre Boisvert as chairman of the board and chief business development officer in May 2006. Jorg Janke (founder of Compiere) noted that Boisvert's success in "applying the open source business model to markets traditionally monopolized by proprietary software vendors is definitely a plus" (Compiere, 2006a). Then, in July 2006, Compiere added Larry Augustin to its board of directors. Mr.

Table 2. OS-ERP platform and functionality

Software	Platform	Functionality
Compiere	Independent	Quote to Cash, Requisitions to Pay, Customer Relations, Partner Relations, Supply Chain, Performance Analysis, Web Store/Self Service
OpenMFG	Linux, Apple Mac OS X, Windows	Manufacturing, Materials Management, Supply Chain (Sales Order, Purchase Order, CRM), Accounting
OfBiz	Linux, Berkeley Software Distribution	Supply Chain Management, E-Commerce, Manufacturing Resource Planning, Customer Relationship Management, Warehouse Management, Accounting
Tiny ERP	Independent	Finance and Accounting, CRM, Production, Project Management, Purchasing, Sales Management, Human Resources
OpenPro	Linux, Windows	Financials, Supply Chain, Retail and Manufacturing, CRM and E-Commerce, Warehousing, EDI
WebERP	Independent	Order Entry, Accounts Receivable, Inventory, Purchasing, Accounts Payable, Bank, General Ledger
ERP5	Linux, Windows (coming soon)	Customer Relationship Management, Production Management, Supply Chain Management, Warehouse Management, Accounting, Human Resources, E-Commerce
Adempiere	Independent or Linux on its site	Point of Sale, Supply Chain Management, Customer Relationship Management, Financial Performance Analysis, Integrated Web Store
avERP	Linux	Sales, Manufacturing, Purchasing, Human Resource Management, Inventory Control, CAD Management, Master Data Management, Business Analyses
Fisterra	GNU/Linux	Point of Sale, Other Business Processes Specific to Automotive Glass Repair Businesses
OpenBravo	Linux, Windows	Procurement, Warehouse, Project Management, Manufacturing, Sales and Financial Processes, Customer Relationship Management, Business Intelligence
GNUe	Linux, Microsoft Windows	Human Resources, Accounting, Customer Relationship Management, Project Management, Supply Chain, E-Commerce
Value ERP (Project Dot ERP) http://www.valueerp.net/catalog/index.php	Linux, Solaris, Berkeley Software Distribution, Microsoft Windows	General Ledger, Payable and Receivable, Invoicing, Purchase and Receiving, Time Sheet Management for HR, Inventory Management and Manufacturing

Augustin is founder of VA Linux (VA Software) and launched SourceForge.net, the largest open source development site on the Internet (Compiere, 2006b). These new additions to the board indicate an interest in growth by Compiere.

However, Compiere faces many challenges, for example a group of developers decided to "fork"[4] and created Adempiere ERP, CRM, & SCM Bazaar (commonly referred to as Adempiere). Forking (Raymond, 1999) is not unusual in the open source community. OFBiz also has a forked version called Sequoia. Sequoia in February 2006 was renamed Opentaps, meaning Open Source Enterprise Application Suite. The issue of forking is not new in open source software and thus is an issue in open source ERP applications as well. As mentioned earlier, forking usually occurs when a group of developers decides that the current direction of the project is not as they would like; take for example what happened with Compiere's fork Adempiere. Adempiere was started in September 2006 after "a long running disagreement between Compiere and the community that formed around the project" (Adempiere, 2006). The developers behind Adempiere felt that Compiere was focusing on "commercial/lock-in" aspects of the project, and decided to create a new version that could focus more on the community and the "sharing/enriching" aspects of the project. Jorg Janke refutes these allegations, nonetheless forking has occurred.

Geographic Origins, Age, and Networks of OS-ERP Projects

At this time, there is very little research (academic or practitioner) into the global status of open source ERP. It is clear that there are many vendors out there offering open source packages in multiple languages—indicating an international audience. Also, the packages analyzed for this research have geographically dispersed locations, if any location is listed at all. Many times in an open source ERP project, the Web serves as the primary location for the project, and there is no real geographic orientation associated with the project, as is indicated by "Web" in Table 3.

Most of the open source ERP companies are relatively new (see Table 3), though many have formidable numbers of partners (see Table 4). Part-

Table 3. Geographic origins of OS-ERP projects

Open Source Company	**Project Founded**	**Where**
Compiere Inc.	2001	Santa Clara, CA
OpenMFG	2001	Norfolk, VA
OfBiz	2001 (2003 migrated to java.net)	Web
Tiny ERP	2002	Belgium
OpenPro	1998 (1999 first release)	Fountain Valley, CA
WebERP	2001 (2003 first release)	Web
ERP5	2002	Web
Adempiere	2006	Web
avERP	1998 (2001 first installation)	Bayreauth, Germany
Fisterra	2002 (2003 first release)	Web
Openbravo	2001	Pamplona, Spain
GNUe	2003 (first release)	Web
Value ERP	2005	Sparta, NJ

ners are important in sustaining an open source project. Partners have some monetary interest in sustaining a viable open source offering, as they are often offering consulting services, implementation services, maintenance, or training. The number of customers is also important in assessing the maturity of the OS-ERP. As can be seen from Table 4, Compiere currently has more the three times the number of customers as any other OS-ERP application. However, it is hard to assess the number of customers because many of these open source projects have no central repository for keeping track of this information. Although partners that provide services for OS-ERP systems have some count of how many customers they currently have, they do not necessarily share this information. For assessing the value of OS-ERP software, the number of partners, customers, and developers provides a strong network and thus should provide greater value. More will be discussed on this topic in the "Real Options Value of OS-ERP" section.

Another important consideration in assessing the landscape of OS-ERP offerings is that most of these packages are targeted to specific audiences and may only be proven for specific sizes of organizations. Table 5 outlines the size of organization targeted by OS-ERP packages according to their Web sites.

From Table 5, it can be gleaned that most OS-ERP projects are targeting small and medium enterprises, with some targeting large organizations. With this target audience, the question of multinational implementation success with OS-ERP systems is raised. At this time, the limited and varying functionality (see Table 2), and lack of large-scale implementations precludes direct comparison with solutions like mySAP Business suite or Oracle E-Business suite (Prentice, 2006).

Venture Capital Funding and Project Activity in OSS and OS-ERP

The open source market is heavily funded by venture capital firms, Guth and Clark (2005) in the *Wall Street Journal* estimated that $290 million was invested in open source in 2004. However, open source ERP companies are lagging in maturity and thus their numbers for VC funding are much lower. Currently, two open source ERP companies are funded by venture capitalists: OpenBravo (Serrano & Sarriegi, 2006) and Compiere (Hoover, 2006). Both companies are funded with $6 million.

Given the importance of the community to open source project value, SourceForge.com tracks the most active projects daily. As of November

Table 4. OS-ERP network (partners, customer, and developers)

	Customers	Partners	Developers	Data Collected From
OpenBravo	15	*	*	Serrano & Sarriegi, 2006
Compiere Inc.	240	70	50	Ferguson, 2006

5, 2006, three OS-ERP projects fall in the top 15 most active: Openbravo ERP at #7; Adempiere ERP, CRM, & SCM Bazaar at #11; and Compiere at #14. There is clearly activity happening at the site that hosts these projects (http://sourceforge.net/top/mostactive.php?type=week). This is a sign of strength for these OS-ERP projects. Also, in trying to assess the value of OS-ERP options, VC funding and project activity would certainly positively impact the prospect for network dominance of the OS-ERP. More will be discussed on this topic in the "Real Options Value of OS-ERP" section of this chapter.

OPEN SOURCE VENDOR BUSINESS MODELS

Open source vendors have many different business models. When working with a piece of open source software, it is important to understand which type of organization/business model is in use by any particular vendor. Table 4 defines the business models that have been used to describe what is happening with open source firms in general. The most simple understanding of these models can be drawn from Bonaccorsi, Giannangeli, and Rossi (2006) with Pure OS and Hybrid business models. The Pure OS model includes firms that only offer OS products or OS solutions. The Hybrid business model includes all the others that play and profit in the OS space. Hybrid business models mix products, types of licenses, and sources of revenues. As academicians and practitioners, it is important to understand what type of vendor is included in any OS project undertaken. As can be seen from the plethora of business model types, the objectives and goals of each type of business will differ and may impact the quality of service or the types of products that the vendor offers. Organizations should consider the business model of any OS vendor with whom they engage in business, as the model and the viability of the vendor will impact the value of the OS-ERP option. Proprietary vendors do not have this range of business models, so this is not an issue with proprietary ERP systems. OS-ERP option value and its relation to business model will be discussed

Table 6. Open source business models

Business Models	Definition	Source
FOSS	Value-added service-enabling—sell support services and complementary software products Loss-leader/market creating—goal is enlarging the market for alternative closed source products and services	Fitzgerald, 2006
OSS 2.0	Includes FOSS, adds the following: Dual product/licensing—can download for free, small percentage of downloads purchase a commercial license Cost reduction—proprietary companies offer OS as part of their solution Leveraging the open source brand—as government agencies mandate that open source be a priority option for software solutions, the open source brand becomes more valuable	Fitzgerald, 2006
Software Producer GPL Model	Entirely open source offerings	Krishnamurthy, 2005
Software Producer Non-GPL Model	Incorporate source code into a larger code base and create a new product or take an entire open source product and bundle it with existing products	Krishnamurthy, 2005
The Distributor	Derives benefits by providing it on CD, providing support services to enterprise customers, upgrade services only to open source product	Krishnamurthy, 2005
Third-Party Software Provider	Provide services for all types of products	Krishnamurthy, 2005
Pure OS Business Model	Firms that offer only OS products and OS solutions	Bonaccorsi et al., 2006
Hybrid Business Model	"They (hybrids) distribute OS products but also develop customized solutions using OS software, for which they presumably offer installation, support, and maintenance. The large majority also actively supply complementary services such as consulting, training, and to a lesser extent research and development." (p. 1090)	Bonaccorsi et al., 2006
Professional Open Source (POS)	"POS combines the benefits of open source (OS) with the development of methodologies, support, and accountability expected from enterprise software vendors." (p. 329) Three features of POS: (1) separation of product adoption and purchase, (2) seed and harvest marketing strategy, and (3) dual growth of firm and ecosystem	Watson et al., 2005
Proprietary	Inability to view and modify the source code (regardless of price)	Watson, Boudreau, York, Greiner, & Wynn, 2006

continued on following page

Table 6. continued

Open Community	Volunteers develop and support code with limited or no commercial interest	Watson et al., 2006
Corporate Distribution	Organizations create value by providing complementary services such as: interacting with the community for support, supporting the software for customers, identifying appropriate OSS for customers	Watson et al., 2006
Sponsored OSS	Corporations act as primary sponsors of OSS projects. These corporations provide funding and/or developers to the project.	Watson et al., 2006
Second-Generation OSS (OSSg2)	This is a combination of corporate distribution and sponsored OSS (the OSSg2 company provides complementary services around the products, but OSSg2 companies also provide the majority of the resources needed to create and maintain their products). These types of corporations strive to provide accountability, talented programmers, and a healthy ecosystem.	Watson et al., 2006

more in the "Real Options Value of OS-ERP" section of this chapter.

CUSTOMIZATION OF OS-ERP

Proprietary ERP system customization has been explored extensively in the ERP literature (Gattiker & Goodhue, 2004; Levin, Mateyaschuk, & Stein, 1998; Nah & Zuckweiler, 2003; Soh & Sia, 2004, 2005; Soh, Siew, & Tay-Yap, 2000). OS-ERP applications are different from proprietary ERP applications in that they are closer to custom applications than to packaged software. For example, packaged software has limitations in terms of customization because the source code is not available. The issues with packaged software, as described by Gross and Ginzberg (1984) of "uncertainty about package modification time and cost, vender viability, and the ability of the package to meet the user needs," will apply differently to open source applications. Open source software has the code available, so the user is free to change (and many times is encouraged to change) the code as needed. Therefore, the issue of uncertainty about package modification time and cost depends solely on the skill of the programmers, not on some constraint that the modification may not be allowed by the proprietary software vendor. However, the ability to change source code raises a new set of problems. The efficiencies that we reap from packaged software (standards, easy maintenance, and upgrades) will not necessarily be available with open source software. Thus customization of OS-ERP is a double-edged sword. Although it is beneficial to adopters from a flexibility of the software perspective, maintenance, upgrades, and version control become new issues with which the adopting organization must contend.

Another issue that comes with OS-ERP is that the quality of the code will not always be similar to the acceptable quality of code required by the implementing organization (Spinellis, 2006). With proprietary code this is not as much of an issue, as you do not usually have access to all that code, and maintenance is definitely the duty of the vendor. In the OSS industry, it is many times expected that the skill for maintaining the code resides in the adopter's organization. Code of questionable quality will be harder to modify and maintain.

REAL OPTIONS VALUE OF OS-ERP

Much research has been done on real options theory as a way of evaluating platform change decisions (Fichman, 2004; Fichman, Keil, & Tiwana, 2005; McGrath, 1997; McGrath & MacMillan, 2000). In fact, a switch from SAP R/2 to SAP R/3 was considered a platform decision and evaluated in terms of real options (Taudes, 2000). These models and methods are useful, but seem to be missing some key variables that would influence the option value of OS-ERP.

Real options theory rests on the belief that limited commitment can create future decision rights. Real options theory has a rich history borne from the finance and economics literature, and has been applied to technology in a variety of ways. Real options theory, in terms of technology positioning projects, proposes that technologies are desirable if they provide opportunities for future rent creation. These investments require less commitment than if a full plan was created that did not allow for quitting midstream. Beyond the specific real options literature that supports the logic of committing to software with the intent of exercising some future option, the project management literature on management information systems (MIS) also supports this notion. In the case of ERP systems and large systems in general, organizations implementing technology have decided that a “staged” or incremental approach is preferable to “big bang” implementations. The staged approach allows for less radical change introduction in the organization. A logical extension of this trend in project implementation approaches to valuing technologies in the selection decision seems clear. If companies can commit to a technology, and yet have the option to proceed, as well as options for future rents, the technology is more valuable to the organization. ERP systems—and more specifically, OS-ERP systems—tend to allow for future options.

Option valuation will be performed multiple times throughout the life of a project. This is not a one-time pre-implementation exercise. This is important: as implementation techniques have changed, so have the options that are afforded by technology positioning investments. For example, a company may look at the option value of implementing specific modules of an ERP system. Future options may be to continue to implement other modules of this system, to implement an integrated best-of-breed addition, to use these modules as a stand-alone part of their system, to integrate this module back to existing legacy systems, and so forth. This approach would be in congruence with current project management practices, where the project is analyzed at different steps to ensure the project is proceeding satisfactorily. Likewise, the option value of investment should be analyzed periodically to determine how to proceed with the option[5]—the emphasis being here that option value does change with time and thus should be examined over time.

Most of the studies of real options in a technology context have used a rigorous finance-influenced quantitative methods for evaluating the value of real options (Benaroch, 2000, 2002; Benaroch & Kauffman, 1999; Clemons & Gu, 2003; Santos, 1991; Taudes, 1998, 2000). Table 7 provides important background information about these studies.

For valuing the option of OS-ERP, I propose thinking more in line with the thinking behind McGrath (1997), McGrath and MacMillian (2000), Chen and Chen (2005), and Fichman (2004). These studies apply real options thinking to a qualitative options valuation method. For example, McGrath (1997) provides factors that influence the option value of a technology positioning option. This framework was expanded with explicit items to characterize each factor in later work (McGrath & MacMillan, 2000). This theory of real options for technology positioning focuses on the factors that are necessary for specific domains: new product development and R&D type research. Although there are many similarities in R&D investments and IT platform investments, there are also many differences (Fichman, 2004).

Table 7. Finance-based studies of IT platform decisions as real options

Authors	Major Theme	Context	Case or Conceptual
Clemons & Gu, 2003	Strategic options in IT infrastructure	Credit card rates for Capital One (industry level)	Case
Benaroch, 2002	Manage IT investment risk that that helps to choose which options to deliberately embed in an investment	Internet sales channel	Case
Benaroch & Kauffman, 2000	Investment timing	POS debit market	Case
Taudes, 2000	Evaluates ERP platform change	SAP R/2 to SAP R/3	Case
Benaroch & Kauffman, 1999	Investment timing	POS debit market	Case
Taudes, 1998	Evaluates software growth options	EDI growth option	Case
Dos Santos, 1991	Applies real options theory to IT investments using two stages, where the first stage creates the option for the second stage	None	Conceptual

These differences are explained by drawing from four complementary perspectives: technology strategy, organizational learning, innovation bandwagons, and technology adaptation to develop 12 factors identified as antecedents of option value in IT platform investments (Fichman, 2004). As the focus of this book chapter is on option value of OS-ERP systems, the original factors proposed to explain option value of platform decisions (Fichman, 2004) are pared down to the most influential in this context, and the short definition is contextualized to OS-ERP option valuation. Then, several factors (see Table 8) are added based on the previous discussion of OS-ERP systems.

According to real options theory, options are valued more highly if limited commitment is required to take advantage of the option. In terms of OS-ERP options, less commitment will be required if the organization already possesses the resources to customize, maintain, and upgrade the OS-ERP software. Future rents may be created by customizing and upgrading the OS-ERP software. Less resources are required if the quality of the source code is high. As well, a fit between the business model of the OS vendor and the type of services and future solutions the organization might need would require less commitment in terms of gaining acceptance of the vendor. Future rents will be created if the business model of the vendor proves to be viable and the vendor is able to survive. This phenomenon is not unlike the dot.com era where the business model was as important as the technology. As was discussed earlier, these factors cannot be ignored in evaluation of an OS-ERP software option.

FUTURE TRENDS

Global Adoption of Open Source ERP

International research on open source firms is scarce (Bonaccorsi et al., 2006). Research in the area of OS-ERP packages is scarcer. Even scarcer still is international OS-ERP research. For that reason, some generalizations about the current state of "adoption of open source" research are attempted based on what is happening in open source software in general. As well, several open source ERP participants were asked their opinions of the international open source ERP market.

Table 8. Factors for valuing OS-ERP options

Factor	Short Definition
Susceptibility to network externalities (Fichman, 2004)	The extent to which a technology increases in value to individual adopters with the size of the adoption network. In the case of OS-ERP, this is particularly relevant as future versions of the software depend on the adoption network, the partners, and developers.
Prospects for network dominance of the technology instance (Fichman, 2004)	The extent to which the technology instance being adopted is likely to achieve a dominant position relative to competing technology instances within the same class. In the case of OS-ERP, a dominant position may be achieved by a large network of adoption, partners, and developers, as well as venture capitalists.
Customization	The extent to which an organization possesses the resources to customize, maintain, and upgrade OS-ERP software.
Quality of Source Code	The extent to which the source code associated with an OS-ERP is of high quality.
Business Model of OS Vendor	The extent to which the business model of the OS vendor is acceptable and viable to the organization.

There is clearly international activity in the open source arena, as is evidenced by a study performed by Lancashire (2001) where he showed that contributors to open source software development were shifting to an international origin. However, even this study had a very small sample (two projects) and there are questions as to the generalizability of these findings. More recently, evidence of the activity internationally in open source projects comes from the samples taken for some open source research. Bonaccorsi et al. (2006) performed a survey of 175 partners and system administrators of Italian open source[6] firms. Their sample was drawn using a snowballing technique where initial contacts refer other potential participants. This sample hints at the breadth of OSS in European countries.

Currently, several open source ERP participants based in the United States see potential for international growth. One open source ERP company estimates that about 15% of their business is from outside the United States and the CEO sees "enormous growth opportunity internationally." Another participant involved with an open source ERP package based in the United States reports that in 2005 about 80% of his income came from international sources. Then there are open source vendors that are based all over the world. The small sample of ERP vendors studied for this research shows that the base country for these organizations varies greatly (see Table 3).

There are many reasons that open source ERP is being developed internationally and development services sold internationally. The requirements of ERP systems vary from country to country. For example, China has different requirements of ERP packages than the U.S. (Liu & Steenstrup, 2004) . So, where certain packages dominate the U.S. ERP market, they are less diffused in the Asian market. Similar considerations will occur with open source ERP applications internationally. There is more room for competition from open source ERP packages in countries where the requirements are not as mainstream. This observation helps explain the proliferation of open source ERP developments around the world.

As for the services of U.S. developers being sold around the world, some U.S.-based open source

ERP participants feel that the international opportunity is greater because the dollar is weaker, and so development by U.S. programmers is more affordable to those outside the U.S. The economics of this assumption also work in the reverse. There are many instances of international partners to U.S.-based ERP projects that are called on to develop customizations for U.S.-based users of the software because this international labor is more affordable.

CONCLUSION

This chapter outlines the current state of several OS-ERP packages (see Table 1) along the dimensions of licensing, geographic origins, number of customers, number of partners, targeted organization size, and functionality. Then the several factors that are important to decision making about OS-ERP packages are discussed: susceptibility to network externalities, prospects for network dominance, customization, quality of the source code, and business model of the OS vendor.

These factors will be important to OS-ERP packages crossing the credibility gap. Currently, as companies scour the landscape looking for an ERP package, there are very few open source offerings that have established credibility as reliable, maintainable, and scalable. Once several OS-ERP packages cross this hurdle, more widespread use of OS-ERP can be expected. As well, since the cost of ownership of an ERP package is so complex, marketing OS-ERP packages as more affordable is probably not going to gain much traction or gain the attention of major decision makers in the ERP space. Other features of OS-ERP, like customizability (given an adequate upgrade path) and a strong OS-ERP network, most specifically customers and consulting partners, will be desirable to decision makers.

This chapter hopes to enlighten practitioners and academia about the growing field of OS-ERP systems and their role in the international ERP community. There are significant differences in the offerings of open source ERP packages, and theoretically grounded evaluation techniques of OS-ERP are little researched or published. The aforementioned topics are important for creating a clear picture of what is currently on the market and the future directions of the OS-ERP market. Given the data presented in this chapter, it is clear that while OS-ERP is entering the ERP market, OS-ERP is far from a strong player. Also, OS-ERP is currently marketed as a small and medium enterprise option, with some governmental agencies also considering its use. Future research should attempt to explore the value gained and experiences of organizations actually using OS-ERP systems.

FUTURE RESEARCH DIRECTIONS

OS-ERP is a very little researched area. Future research should be performed that rigorously interviews OS-ERP participants about motivation, as this will add to the current literature about OSS motivation (several motivation articles are listed in the Additional Reading section). Many open source software initiatives fill a gap in functionality and thus are interesting to programmers. ERP systems are mature enough to lack such gaps, and thus figuring out what interests programmers that take part in OS-ERP projects could shed more light on the issue of motivation. Also, OS-ERP in the global context is an area ripe for research. Case study research of a large multinational implementation of OS-ERP would inform academia as to how large organizations work with open source communities and whether the functionality offered by OS-ERP systems is adequate in such a setting. Survey research with global companies might shed light on the differences in companies that adopt OS-ERP solutions and those that choose proprietary solutions. Global public sector research is also needed, as the motivations and evaluation criteria for public sector organizations is noted in the popular press to be different from private companies.

To build on the ideas in this chapter, the five factors should be included in a survey of those that have adopted and not adopted open source research to determine how these factors impacted the decision, and whether there were future implications of any of these factors on the success of the OS-ERP implementation. Each factor should be further researched in terms of options evaluation in the OS-ERP domain. For example, the author has posited that OS-ERP is closer to custom software than to packaged software. This assertion should be tested through rigorous research. This could be done by looking at how much customization is actually done to OS-ERP packages, and how upgrades and maintenance are handled on these customized systems. ERP customization literature would benefit from such research. This is a partial list of possible future research directions. All of the topics covered in this chapter: factors for evaluating options, global OS-ERP systems, and OS-ERP organizations require much more research for academia to build a complete and coherent picture of OS-ERP and its impacts.

Chapter 8.3

The Dynamics and Rationality of Collective Behavior within a Global Information System

Jacek Unold
University of Economics, Wroclaw, Poland

ABSTRACT

The scope of interests in the area of information systems (IS) has focused mainly on technological aspects so far. If the human component were taken into account, it has been analyzed from the level of an individual. So have all new concepts of rationality. This chapter argues that collective behavior, which is a basic determinant of the global IS dynamics, does not proceed in a planned manner, but is adaptive and follows certain patterns found in nature. It follows that this behavior can be expressed in a model form, which enables to structure it. A model exemplification of a global information system is a modern, electronic, stock exchange. The identification of quantitative attributes of a social subsystem can provide substantial theoretical and methodological premises for the extension of the optimizing and individualistic notion of rationality by the social and adaptive aspects.

INTRODUCTION

General Perspective

One of the main issues, both in the theory and practice, of social and economic sciences is the question of integration, that is, how actions and interactions of individuals lead to the emergence of phenomena that characterize social entireties. This topic acquires particular importance in light of the dynamic integration processes of societies, for example, the recent enlargement of the European Union, when, in 2004, 15 new member states joined this commonwealth. The integration processes, aided with the most recent achievements in information technology (IT), harmonize with globalization and virtualization of human activity, from social to political to a business one.

The outlined issue is the background of two basic research threads proposed in this chapter.

The first part refers to the question of human behavior within an information system (IS). A fully integrated society of the future will make a fundamental, subjective element of a global information system. That global IS will be either a ubiquitous and wireless Internet, or some totally different, unknown yet, technological platform. And it is crucial that so far interests in the area of IS have concentrated mainly on technological aspects. The issue of human behavior within an IS has been generally omitted as one belonging to other disciplines. Admittedly, since the mid-1990s we have observed some growth of interest in the domain of social aspects of the IS development (Avison & Fitzgerald, 2003), but those interests have concentrated on the specificity of individual behavior. However, the nature of global phenomena and the features of dispersed collectivities denote a necessity of a new perspective on the society and organization. No longer can we perceive the human component of an IS as independent individuals. The users of local, regional and global telecommunications networks create a specific form of a *virtual crowd*, accessing the same sources of information and reacting to the same sets of stimuli. These users, through their interactions, compose the phenomenon of an IS dynamics. The dynamics not understood as one referring to the flow of energy (e.g., electrical impulses), but dynamics based on the collective information processes, reflected in collective actions. A phenomenon that was called by Simon (1955) "a collective mind."

And here we find the other research thread of this chapter: the issue of human rationality. The Western organizational culture still is based on three main determinants: individualism, competition, and a mechanistic-reductionist perspective. As a result, the essential body of scientific achievements in the area of human behavior concerns individuals (Nelson & Quick, 2005), and this is reflected in the paradigm of rationality. This depiction, known as rational choice theory (Alingham, 2006), assumes that individuals are perfectly rational, with clearly defined preferences, and optimizing their behavior at all levels of a decision-making process. Reductionism, which is related to it, postulates that collective behavior is composed of the sum of rational behavior of all individuals. Since this *sum* is purely theoretical and abstract, it generally is accepted that all phenomena concerning a collectivity are exclusively qualitative and cannot be structured.

The deficiencies of the traditional, idealistic approach to rationality have been known and discussed for a long time. Admittedly, since Simon's idea of "bounded rationality" it has been allowed that human actions can be more "satisficing" than "optimizing," but all new concepts of rationality still refer only to individual behavior (Halpern & Stern, 1998). At the same time, it has been emphasized that there is a need for such a formulation of the rationality principle so that it can take into account the specificity of collective behavior, so different from the individual one.

This chapter tries to briefly explore the existing possibilities of an effective modeling of collective information processes, and of structuring this phenomenon through the identification of its quantitative dimension. The potential findings should help formulate a new, wider, approach to rationality, which could respond to the integration and globalization trends of modern societies.

Objectives

The main objective of this chapter is a presentation of an innovative approach to the analysis and modeling of collective information processes and the mechanisms of collective behavior within a model global IS. This is the first such attempt in relation to the above-mentioned social aspects of information systems. Extensive literature studies helped formulate the following research questions:

1. Are information processes of collectivity and the resulting collective behavior, which

constitute the dynamics of an information system, phenomena of exclusively qualitative nature, impossible to structure?
2. Does irrationality or non-rationality, and unpredictability of individual actions determine irrationality and unpredictability of the whole social system within a Global IS?
3. Is there a research method allowing to identify and analyze a phenomenon of "social rationality," from its theoretical to methodological to empirical dimension?

These research questions produced the following theses:

1. Collective behavior, which is a basic determinant of the IS (global IS) dynamics, does not proceed in a planned and intended manner, but is adaptive and follows certain patterns found in the world of nature.
2. Collective behavior can be expressed in a model form, which enables to structure this phenomenon, otherwise considered purely qualitative so far.
3. The identification of quantitative attributes of collective behavior can provide substantial theoretical and methodological premises for the extension of the optimizing and individualistic notion of rationality by the social and adaptive aspects.

THEORETICAL BACKGROUND

Electronic Exchange as a Global Information System

The Notion of Information System (IS)

There are very many definitions of an information system. Some, such as the following example, emphasize the use of information and communication technology (ICT): "Any telecommunications and/or computer related equipment or interconnected system or subsystems of equipment that is used in the acquisition, storage, manipulation, management, movement, control, display, switching, interchange, transmission, or reception of voice and/or data, and includes software, firmware, and hardware" (National Information Systems Security Glossary, 1999, p. 31).

Others narrow it down to systems that support management decision making. This is typical for more recent approaches, which generally adopt a broader view. It goes well beyond the integration of hardware and software, and considers an information system to be any system that has collection, processing, dissemination, and use of information as a major component in terms of its purpose and the activities it carries out. Most modern information systems with any degree of complexity will, in practice, almost always incorporate ICT, but the technology is not the defining aspect. The significant issues are the generation, processing, and use of information.

For example, according to Vigden et al. (2002, p. 2), an information system is a set of interacting components—people, procedures, and technologies—that together collect, process, store, and distribute information to support control, decision making, and management in organizations. This definition stresses the mutual relation between an organization's management system and its information system.

Benson and Standing (2002, p. 5) identify the basic components of an information system: people, data/information, procedures, software, hardware, and communications.

Pearlson and Saunders (2004, p. 14), in turn, define an information system as the combination of people (the "who"), technology (the "what"), and processes (the "how") that an organization uses to produce and manage information. They also refer to information technology as the technical devices and tools used in the system.

The scope of this analysis makes one more definition of an IS especially useful for further considerations. Buckingham et al. (1987) define an information system as: "A system which assembles, stores, processes and delivers information relevant to an organization (or to society), in such a way that the information is accessible and useful to those who wish to use it, including managers, staff, clients and citizens. An information system is a human activity (social) system which may or may not involve the use of computer systems."

This definition is useful in that it emphasizes the human and organizational aspects of information systems. The definition also makes clear that not all information systems use information technology, and that an information system is in essence a human activity system situated in an organizational context—technology is important to information systems but must be considered jointly with human and organizational dimensions.

There are two clear examples of information systems, at somewhat different ends of the spectrum. A payroll system is an information system. This was one of the first applications to be computerized. Today, payroll systems are not simple, there exists a wealth of legislation with which the system has to cope and comply. A payroll system also must be flexible and maintainable, for almost every few days there are changes. It does not provide any competitive advantage to an organization, it is just a necessary system for an organization to have to enable it to be in business. It is what is termed, a mature application. There are many such mature systems in organizations, for example, invoicing systems, billing systems, order processing systems, inventory systems, and personnel systems.

The next example system is very different. It is an electronic auction house, such as eBay. It is relatively new (eBay started in 1995) and uses the World Wide Web as its user interface. Yet, essentially, it is just an information system. It matches buyers with sellers utilizing an auction concept. This concept is not new, there have been auctions for hundreds of years, but the electronic auction enables buyers and sellers to be geographically distributed across the world, whereas, the traditional auction required the buyers and sellers, and the product being auctioned, to be together in a particular place at a particular time. The electronic auction breaks the tradition in terms of both time and space. The auction house usually provides payment, insurance, delivery, security, and other services to its clients if required and, in general, provides an environment that enables people to participate easily and securely in an auction from the comfort of their home or workplace. So, the electronic auction is an information system, comprising people, rules, procedures, technology, software, communications and allied services.

IS Categories

There are different typologies and different levels of analysis within the area of information systems. Most generally, there are three basic categories of information systems:

- Simple manual (paper-and-pencil) IS
- Informal (word-of-mouth) IS
- Computer-based IS

Our concern in research today is with computer-based information systems. We must remember, however, that many information systems in organizations are informal—the office grapevine and conversations at the water-cooler are typical examples of these. Although the informal aspects of information systems are difficult to manage and are not amenable to an engineering approach, their influence should not be under-estimated.

This is consistent with the system's view presented by Thompson (1976, pp. 2-26) three decades ago. He argued that the organization consisted of two systems. The artificial system is the tool designed by the owner, managers, or both to accomplish a particular goal. The informal organization of social relationships constitutes a natural system whose goal is not entirely compatible with the artificial system's goal. The result is that the effectiveness of the artificial system is always limited by the natural one.

Thus, there are other forms of information systems. Organizations have always needed information systems, although the formal aspects of these information systems would have been implemented using paper-based filing systems (paper-and-pencil) in the pre-IT era.

One of the many ways to identify the development of IS/IT is using a three-era model (Ward & Peppard, 2002, p. 23). The prime objective of using IS/IT in the eras differs:

1. **Data processing:** To improve operational efficiency by automating information-based processes (from the 1960s onward—the DP era).
2. **Management information systems:** To increase management effectiveness by satisfying their information requirements for decision making (from the 1970s onward—the MIS era).
3. **Strategic information systems:** To improve competitiveness by changing the nature or conduct of business—from the 1980s onward (the SIS era).

Next, focusing, for example, on management information systems, they sit on the boundary between information and knowledge—MIS are really support tools providing management with the information needed to do the job. In essence, different kinds of information are able to be accessed and analyzed, and summarized reports produced. The reports are used at the highest levels of management to produce long-term strategic plans, and in middle management to improve the quality of service and employee efficiency, or for simple operational matters. MIS can be divided into five basic categories (Benson & Standing, 2002, p. 87):

- Management reporting systems (MRS)
- Decision support systems (DSS)
- Expert systems (ES)
- Executive information systems (EIS)
- Groupware

To conclude this brief overview of IS categories, let us concentrate on another important criterion. It is the range of applicability, and there are micro- and macro-economic information systems. In light of the dynamic growth of a global telecommunications network, we can complete this typology with a relatively new category of global information systems. Turban et al. (2005, p. 277) define global information systems as inter-organizational systems that connect companies located in two or more countries. There are three main categories of organizations that use global information systems: multinational, international, and virtual organizations. Companies that have global operations usually use the Internet. The major benefits of global information systems for such organizations include:

1. Effective communication at a reasonable cost.
2. Effective collaboration to overcome differences in distance, time, language, and culture.
3. Access to databases of business partners and ability to work on the same projects while their members are in different locations.

Global systems involve multiple organizations in multiple countries. Examples include: airline reservation systems such as Travelocity (www.travelocity.com) or Expedia (www.expedia.com), police and immigration systems, electronic funds transfer (EFT) systems (including networks of ATMs), and many commercial and educational systems for international organizations such as the European Union (http://cordis.europa.eu).

Also, the electronic auction house, described earlier, belongs to this category. We may posit, then, that a modern, electronic exchange (stocks, commodities, currencies) also constitutes a good example of a certain category of global information systems. Besides, the performance of capital markets is a typical example of group (crowd) reactions (Plummer, 1998), which will be especially useful in further analysis.

Another important observation from this brief analysis points to a certain structural characteristic of an information system. Regardless of different definitions and approaches, people constitute the basic component of any information system. We may assume, then, that the most important element of each information system is its social subsystem, which complies with the basic categorization of IS, and with the notion that IS do not have to use modern technologies.

The social subsystem of an electronic and virtual stock exchange will be the subject of further analysis.

IS Dynamics

Dynamics (Latin: *dynamikos,* "strong," "possessing strength") according to *Webster's Unabridged Dictionary* (2005, p. 564), refers to "that branch of mechanics which treats of the motion of bodies (kinematics) and the action of forces in producing or changing their motion."

According to Eden and Spender (2003), the dynamics of an organization represents changes in the various types of knowledge, in the learning and unlearning processes. The basic determinants of this phenomenon are thus:

- Knowledge
- Learning
- Unlearning

Organizational learning is a metaphor indicating the way an organization adapts to the constantly changing environment. Organizational learning occurs as knowledge, acquired and developed by individual members, is embedded in *organizational memory.* At the same time, collective knowledge cannot be understood without paying attention to the communication processes going on among the group's members (Weick, 2000). It follows that information and decision processes flowing in the social subsystem of a given IS condition the phenomenon of the IS dynamics, and learning and unlearning are a specific category of these processes. Decision processes usually precede taken actions, therefore, collective behavior, as a consequence of collective information and decision processes, is the next determinant of the IS dynamics.

The IS dynamics, generally understood as the systems ability to act, refers directly to a phenomenon defined as the "activity system" (Eden & Spender, 2003). The notion of activity system, jointly with the notion of the *organization's culture* point to the next determinant of the IS dynamics. It is the *collective mind,* which can only be identified in the practice of the activity system, and for many analysts the terms organizational culture and collective mind are scarcely separable.

As early as 1895, Le Bon (2006) in his classic "The Crowd: A Study of the Popular Mind" posited that a crowd is primarily a *psychological* phenomenon rather than a physical one (although the two concepts are not necessarily mutually exclusive). He considered that any number of otherwise independent and spatially separate individuals could form a crowd, provided that the members had a *common cause.* This implies that *crowd-type* pressures can be found in a large range of groupings. We can identify the occurrence of this phenomenon during football games, manifestations, and revolutions, in schools (peer pressure) and religious cults. We also can find it in many organizations, especially those, where the identification of an employee with the company is very strong. Le Bon argued that "whoever be the individuals, the fact that they have been transformed into a crowd puts them in possession of a sort of collective mind" (2006, p. 53).

A crowd is, then, something other than the sum of its parts—in particular, a crowd has an effective mind of its own, and each individual's behavior is altered by membership of a crowd. Generally, this phenomenon reveals how strongly a group influences its members and is described more precisely by the "social laws" (Pring, 1993). According to these laws:

- A group of people, or "crowd," is subject to instincts that individuals acting on their own would never be.
- People involuntarily follow the impulses of the crowd, that is, they succumb to the herd instinct.
- Contagion and imitation of the minority make individuals susceptible to suggestion, commands, customs, and emotional appeals.
- When gathered as a group or crowd, people rarely reason but, instead, follow blindly and emotionally what is suggested or asserted to them.

Today, it is assumed that an organism does not even need a brain in order to be intelligent. Intelligence is a property that emerges when a certain level of organization is reached that enables the system to process information. The greater the ability to process information, the greater the intelligence. If a system has the capacity to process information, to notice and respond, then that system possesses the quality of *intelligence* (Wheatley, 2005, p. 98). Any entity that has capacities for generating and absorbing information, for feedback, for self-regulation, possesses mind. This approach offers us a means to contemplate *organizational intelligence*.

The issue of human behavior within an information system is the most recent research trend in the area of information systems development (ISD). In 1994, Morita, the founder of Sony Corp., pointed to the constantly growing gap between the world of business, and generally a society, and the new world of information technology, and called it the "IT/business gap." Arguably, it was the first human aspect within the area of IS that was detected so clearly. The problem identified by Morita a decade ago concerned individual attitudes and actions. Today, the Internet revolution and an unprecedented growth of dispersed collectivities denote a necessity of a new perspective on the society and organization. No longer can we perceive the social subsystem of an IS as a set of independent individuals. The users of the global information system create a specific form of a *virtual crowd*, accessing the same sources of information and reacting to the same sets of stimuli.

The idea that behavior in financial markets is essentially a crowd phenomenon is the basis of this analysis. At one extreme, a self-aware individual is potentially unpredictable except within the very broadest of guidelines. However, at the other extreme, people as a group are predictable. This is the essence of the crowd phenomenon, and the main challenge is to find a quantitative measure of this phenomenon. It follows that the individualistic and optimizing approach to rationality has become insufficient in that new, virtual environment, and the next big challenge in the discussed area is an attempt to adapt the traditional paradigm of rationality to the new reality.

Rationality of Human Behavior

Traditional Approach to Rationality

Battram and Battram (2002, p. 94) argue that modern management thinking is underpinned by three myths. These are: the myth of the rational person, the myth of the economic person, and the myth of the scientific person.

The rational person is characterized by the property of perfect knowledge, and the ability to obtain and retain perfect information. Also it is assumed that people are always rational and logical, and all else being equal, decisions are always about selecting the best alternative. The myth of the economic person is that the market is perfect, free and open, and everyone behaves perfectly within it. Similarly, the myth of the scientific person tells us that our decisions are always logical, perfectly quantified, based on an understanding of cause and effect, and carried out in our mind, without any influence from emotions, and other distractions.

The key word of those three myths is "rationality." Rationality (Latin: *rationalis,* "reasonable"), according to *Webster's Unabridged Dictionary* (2005, p. 1193), refers to the "possession of," "agreeableness to," or "exercise of reason." Reason, in turn, is a "basis or cause;" or a "statement in justification or explanation of a belief or action" (2005, p. 1197).

Rational behaviors follow stable, consistent, and coherent beliefs or rules that enable individuals to understand what they are doing and why. The most clearly elucidated rules of rational behavior are based on self-interest. As early as the late 1800s, Edgeworth (1881/1974), in *Mathematical Psychics* asserted that the "first principle of Economics is that every agent is actuated only by self-interest." And so, Edgeworth's *first principle* of self-interest came to define the core of economic and political models.

Today, the notion of positive science is premised on a rational method, and social scientists have struggled continually with the concept of rationality, both in defending their methods and in describing human behavior. One side in the debate argues that the classical economists' model of rational decision making offers the best way to understand decision behavior. This model focuses on the value, or utility, of the decision outcome. And since the publication of Von Neumann and Morgenstern's (1944) seminal work, the concept of maximizing expected utility became synonymous with rationality. This axiomatic single-person decision theory considers only rational outcomes, those made based on maximization of expected utility, unencumbered by external pressures or cognitive limitations.

The second group of researchers, those concerned with decision processes, advocate identifying specific behaviors or concerns that characterize humans and incorporating their influences into the classical models.

A third approach to the debate advocates the inclusion of context, particularly social context, as an additional element influencing the decision maker (Halpern, 1997; Mele & Rawling, 2004). As this third, more recent, approach develops, it may either extend or repudiate the classic model.

Within economics a theory of rational choice developed, adding to the self-interest argument the notion of "revealed preferences" (Halpern & Stern, 1998). The theory assumes that people are capable of expressing both consistent preferences (evaluative judgments) and consistent beliefs (predictive judgments concerning cause and effect). This individual choice model combining self-interest with preference simplifies our understanding of decision making by offering maximization of expected utility as the sole criterion of a rational choice.

The economists' preference for investigating rationality in a vacuum emerged from their tendency to study an ideal market with perfect competition, which functions without prolonged human or social contact. As a result, the central assumptions of rational choice theory are powerful simplifications. Arrow (1990, p. 25), a Nobel-prize winning economist, argues that: "[The rationality assumptions] . . . imply an ability at information processing and calculation that is far beyond the feasible and that cannot well be justified as the result of learning and adaptation."

The critics of the classical rational choice structure, including anthropologists and some psychologists and sociologists, long have argued that decision making, even economic decision making, tends to occur in a social setting (e.g., Lichbach, 2003; Coleman, 1998). Recently, researchers, including some economists have agreed that rationality has a social component (e.g., Shi, 2002; Sato, 2006). The social context creates pressures of its own, influencing the decision process and outcome. Arrow (1990, p. 25) acknowledged the importance of context in this observation: "Rationality is not a property of the individual alone, although it is usually presented that way. Rather, it gathers not only its force but also its very meaning from the social context in which it is embedded." Recent laboratory work, based on these earlier empirical observations, suggests that the social context exerts its effects even when there is no communication between transactors (Halpern, 1997). This observation has a particular significance for further analysis, which concerns the rationality of collective behavior of investors taking actions in the virtual environment of present-day capital markets.

Alternative Notions of Rationality

The first response to Von Neumann and Morgenstern's formulation of rationality as maximization was Simon's (1955) idea of *satisficing*. Simon observed that human decision making is "boundedly rational": it is limited by our inability to process all the information that is available as well as by our inability to be consistent in our preferences. As a result, people tend to "satisfice" or use a variety of heuristics (shortcuts) in their decision-making process.

Simon's critique of the maximization principle was based on two issues. First, in order to maximize one has to have all the relevant information, and this usually is not the case. Second, people are limited in their ability to process information; hence, the chance that people would be able to maximize is rather small. According to this model, people select a subsample of the space of total relevant alternatives and search until they find a *good enough* alternative. Search is terminated when an alternative gets selected, and since the process does not continue to ensure the selection of the optimal alternative, it is defined as satisficing, which differs from maximizing.

Simon's analysis of bounded rationality treated individual and organizational decision making similarly. The development of behavioral decision theory over the last 30 years, however, has focused more on the individual level of analysis. Recent attempts have been made to link the two and over the last decade relationships between these two levels of analysis have been explored (e.g., Kahneman & Lovallo, 1993; Shapira, 2002).

In 1978 March proposed variants on the classical notion of rationality. In addition to the notion of *bounded rationality*, he suggested several alternatives. *Limited rationality*, describes the features of a process where decision makers try to simplify a decision problem because of problems associated with considering or anticipating all the alternatives and all the needed information. *Contextual rationality* highlights the effects of a social context where there are multiple other claims on decision makers' attention. *Game rationality* highlights the degree to which self-interests and calculation guide the behavior of a decision maker, while *process rationality* is the extent to which decision makers focus on the process of making choices, rather than on the decision outcomes. *Selected rationality* refers to the process of selection through survival or growth, while *posterior rationality* refers to the discovery of intentions after actions have been taken.

Last but not least, *adaptive rationality* was supposed to emphasize the experiential learning of individuals and the way experience affects learning. This was the first case of a usage of the term "adaptive rationality." This concept, however, related to individuals only and remained in the area of theoretical proposals. This chapter explores the possibilities of an extension of the notion of adaptive rationality to the whole social system within a given IS, and supports it with a practical case study.

In 1992, Mumby and Putnam unshackled rationality and expanded it to embrace emotionality. Their concept of *bounded emotionality* fuses the emotional foundations of the social phenomenon, rationality, with the currently reified perspectives. The boundedness stems from each party's mutual respect for the other's space and dignity (a choice that a person makes) rather than the boundedness of rationality that is treated as a constraint without choice. Originally, this approach was supposed to unite the concepts of *bounded rationality* and *emotionality*. The authors suggested acknowledging the *emotionality of rationality*, in order to create an appreciation of "intersubjective understanding, community, and shared interests" (1992, p. 480), recognizing not only the cognitive, instrumental dimensions, but also the social dimensions of human behavior, in which emotions play an important role.

Similarly to March's adaptive rationality, bounded emotionality still remains a theoretical concept, without any empirical achievements.

Finally, in 1998, the concept of *bonded rationality* was introduced (Halpern & Stern, 1998). Just as human cognitive limitations on our ability to process and use information lead us to have "bounded rationality," so also do our shared limitations on information processing and on our understanding of the evaluation of alternatives lead us to a "bonded rationality" based on our need to interact effectively with other people.

Bonded rationality is a model of human interaction that argues first, that we share ways of evaluating alternatives that may not be objectively optimal, and second, that we reason rationally about these shared evaluations. It follows that we should study evidence of suboptimal transaction behavior as elucidating shared ways of valuing alternatives rather than as evidence of nonrational reasoning.

Bonded rationality derives from the fact that our personalizations (individual acts of understanding alternatives) can be understood by others, and that we wish these personalizations to be understood by others. The decision maker who is bondedly rational usually is understood (although not necessarily agreed with) by peers because his or her personalized perceptions share common cognitive bounds and contextual references. Bonded rationality thus both derives from, and facilitates, social interaction.

What is important, bonded rationality argues that individuals reason rationally about alternatives as they personalize these alternatives, but this rational reasoning proceeds in terms of the axioms of rational choice theory. Nevertheless, the concept of bonded rationality explicitly adds social and cultural context to considerations of psychological influences in rational decision making. It is thus both more realistic than theories of rationality that ignore context, and a fertile source of research questions. By emphasizing the importance of how decision makers personalize alternatives, bonded rationality focuses attention on the influences of psychology, sociology, and anthropology on rational decision making.

This cursory survey of alternative notions of rationality shows that in spite of the development of diverse concepts, and a general consensus about the existence of many possible ways to describe rational behavior, still dominates the classic, single-person and optimizing, version of rationality. This creates a need to both continue research in the area of social and organizational aspects of rationality and search for empirical evidence for proposed theoretical concepts.

METHODOLOGICAL BACKGROUND

The Paradigm Shift

Most of today's organizations are designed and managed according to the assumptions taken from 17th century physics, from Newtonian mechanics. This machine imagery leads to the belief that studying the parts is the key to understanding the whole. These assumptions also are the base from which we do research in all of the social sciences. Intentionally, or not, we work from a world view that has been derived from the natural sciences. Even to this day, many scientists keep searching for the "building blocks" of matter, the physical forms from which everything originates.

However, we need to expand our search for principles of organization to include what is presently known about the universe. Only this can help us explain how to create structures that move with change, that are flexible and adaptive, even boundaryless, that enable rather than constrain.

One of the first differences between new science and Newtonianism is a focus on holism rather than parts. Organizations are understood as whole systems, and attention is given to relationships within those networks. When we view systems from this perspective, we enter an entirely new field of connections, of phenomena that cannot be reduced to simple and linear cause and effect, or explained by studying the parts as isolated contributors. In this new land, it becomes critical to sense the constant working of dynamic processes, and then to notice how these processes materialize as visible behaviors and forms. The most recent trend even goes as far as assuming that a system is a set of processes that are made visible in temporary structures (Wheatley, 2005, p. 23).

The new science research referred to in this chapter comes from the disciplines of quantum physics, biology, chemistry, theories of evolution and co-evolution, theories of complexity and chaos. They span several disciplines, so the proposed research approach is, by definition, multidisciplinary, and interdisciplinary.

For example, in physics, the search for radically new models is characterized by the major discoveries in quantum mechanics. In the quantum world, relationship is the key determiner of everything. In a homologous process, described as *relational holism*, whole systems are created by the relationships among subatomic particles. Subatomic particles come into form and are observed only as they are in relationship to something else. Electrons are drawn into these intimate relations as they cross paths with one another, overlapping and merging; their own individual qualities become indistinguishable. There are no *building blocks.* Many physicist nowadays describe elementary particles as, in essence, a set of relationships that reach outward to other things.

A new understanding of change and disorder also has emerged from chaos theory. Work in this field has led to a new appreciation of the relationship between order and chaos. These two forces are now understood as mirror images, two states that contain the other. A system can descend into chaos and unpredictability, yet, within that state of chaos the system is held within boundaries that are well-ordered and predictable. Chaos is necessary to new creative ordering.

In chemistry, Prigogine's and Nicolis's (1977) work confirmed that disorder can be the source of new order. Prigogine coined the term "dissipative structures" for these newly discovered structures. In a dissipative structure, anything that disturbs the system plays a crucial role in helping self-organize into a new form of order. Whenever the environment offers new and different information, the system chooses whether to accept it and respond. If the system brings the information inside, the information grows and changes. If the information becomes such a large disturbance that the system can no longer ignore it, then real change is at hand. At this moment, far from equilibrium, the system will fall apart. In its current form, it cannot deal with the disturbance, so it dissolves. But this disintegration does not mean the end of the system. If a living system can maintain its identity, it can self-organize to a higher level of complexity.

In this way, dissipative structures demonstrate that *disorder* can be a source of new *order,* and that growth appears from disequilibrium, not balance. The things we try to avoid in organizations-disruption, confusion, chaos-are thus necessary to awaken creativity. And so, our concept of organizations is moving away from the mechanistic creations that were useful in the age of bureaucracy. We now speak of more fluid, organic structures, of boundaryless and seamless organizations. We are beginning to recognize organizations as whole systems, construing them as *learning organizations* or as *organic* and noticing that people possess self-organizing capacity. Most importantly, however, organizations are living systems, possessing the same capacity to adapt and grow that is common to all life. And fluctuation and change are essential to the process by which order is created.

Scientists of chaos study shapes in motion. Wholeness is revealed only as shapes, not facts. Systems reveal themselves as patterns, not as isolated incidents or data points. Wheatley (2005, p. 125) raises a question: "If we were to understand organizations in a similar way, what would constitute the shapes in motion of an organization?" This chapter makes an attempt at answering, at least partially, this question.

Collectivity of Investors as a Complex Aadaptive System

The flow of collective information processes determines organizational learning, which is a useful metaphor describing the way an organization, including a virtual and global one, adapts to its environment. The research on collective mind and collective behavior can be conducted within a social subsystem of an electronic stock exchange, which was recognized as a model representation of a global information system. The performance of capital markets is a typical example of crowd reactions. After the memorable crash of world financial markets in August 1998, Alan Greenspan, chair of the U.S. Federal Reserve Bank, affirmed that "markets are an expression of the deepest truths about the human nature" (Ramo, 1999).

Financial markets are fast-moving, continually oscillating, reflections of the processes of transformation and change. Unlike any other crowd, the behavior of financial market crowds is clearly reflected in simple, and specific, indicators. These are the price movements themselves, and certain mechanical indexes of the underlying activity and energy of the crowd, such as trading volumes. Financial markets are, therefore, an ideal source of information about all crowd behavior.

The introductory analysis shows that the social subsystem of an electronic and virtual stock exchange reveals at least four characteristics of a nonlinear, complex adaptive system. Turniansky and Hare (1998, p. 106), analyzing the issue of self-organization, identify the main characteristics of a complex adaptive system. Such a system:

- Consists of a network of agents acting in a self-managed way without centralized control.
- The environment in which the agents find themselves is constantly changing and evolving since it is produced by the interactions with other agents.
- Organized patterns of behavior arise from competition and cooperation among agents producing structures arising from interactions and interdependencies.

The processes in a complex adaptive system are those of mutual adjustment and self-regulation. Each self-organizing structure is responsive to disequilibrium, is open to the environment for the exchange of information and energy, and is able to process information and energy. They are decentralized systems having a bottom-up direction from combining actions rather that top-down centralized control. The structure that emerges is not simply an aggregation of individual actions, but rather has unique properties not possessed by individuals alone.

Self-organization cannot be imposed from outside, but operates from within the system itself. Organization is not designed into the parts, but is generated by the interaction of those parts as a whole. The self-organizing form has implications for organizational learning. Self-organizing or self-renewing systems are characterized by system resiliency, rather than stability. When the systems have to deal with new information they recognize themselves in the ways needed to do so. Its form and function engage in a fluid process where the system may maintain itself in its present form or evolve to a new order. The system possesses the capacity for spontaneously emerging structures, depending on what is required. It is not locked into any one best form but, instead, is capable of organizing information in the structure that suits the present need. In other words, instead of making information fit the existing structure, structure is made to fit the information.

In a seemingly paradoxical way, openness to the environment, to information from outside, leads to higher levels of system autonomy and identification. Some fluctuations will always break through, but what comes to dominate the system over time is not environmental influences, but rather the self-organizing dynamics of the system itself. In response to environmental disturbances that signal the need for change, the system changes in a way that remains consistent with itself in that environment. The system is autopoietic, focusing its activities on what is required to maintain its own integrity and self-renewal (Cooper, 2006). As it changes, it does so by referring to itself; whatever future form it takes will be consistent with its already established identity.

Each element in the system influences other elements directly, indirectly, or both. The relationships are mutually determining and determined. As each agent (here: investor) tries to adapt to the others, it changes the environment of the others as well. Freedom and order coexist and support each other in autonomous systems. Wheatley (2005, p. 95) argues that "self-organization succeeds when the system supports the independent activity of its members by giving them a strong frame of reference. When it does this, the global system achieves even greater levels of autonomy and integrity."

Effective self-organization is supported by two critical elements: a clear sense of identity, and freedom. In organizations, if people are free to make their own decisions, guided by a clear organizational identity for them to reference, the whole system develops greater coherence and strength. The organization is less controlling, but more orderly. Jantsh (1980, p. 40) argues that "the natural dynamics of simple dissipative structures teach the optimistic principle of which we tend to despair in the human world: the more freedom in self-organization, the more order." This is precisely the case with the electronic stock exchange. The social subsystem of a modern stock exchange:

1. Consists of a network of investors (agents) acting in a self-managed way without centralized control.
2. The environment in which the investors operate changes and evolves constantly, which is the result of continuous fluctuations in the economy and market situation, but also is produced by the interactions among the investors.
3. Competition among the investors leads to a consensus, reflected by a current market trend.
4. This trend suggests the hidden existence of organized patterns of collective behavior, which is the result of the emergence of a natural dynamic structure of this social system.

The classification of the analyzed social system as a complex adaptive systems allows for the application of the most recent findings of many disciplines, considered to have no relations with the science of management and organization. For example, complexity theory can offer a range of new insights into the behavior of social and economic systems. The idea of self-organization and emergence can be used to identify and explain the dynamics of individual and collective behavior on the stock market. Thousands of independent and difficult to observe transactions, carried out by individual participants of the market, generate the emergence of specific and *predictable* patterns of collective behavior. These phenomena can only be identified on the higher, collective, not individual, level of social organization. Kauffman's (1996) famous phrase "order for free" describes that the process of "crystallization," also known as the emergence of complexity in complex adaptive systems. The fundamental challenge of such defined research would be to find a quantitative measure of that emergence.

Chaos theory, a sub-discipline of complexity theory, identifies, and analyzes the dynamics of nonlinear systems. In nonlinear systems, iteration helps small differences grow into powerful effects. In complex ways, the systems feeds back on itself, magnifying slight variances, communicating throughout its networks, becoming disturbed and unstable. Iteration launches a system on a journey that visits both chaos and order. The most visible consequence of iteration is found in the creation of *fractals*. The process of fractal creation suggests some ways organizations can work with the paradox that greater openness is the path to greater order. A fractal reveals its complex shape through continuous self-reference to a simple initial pattern.

To see how chaotic processes reveal the order inherent in a system requires that we shift our vision from the parts to the whole. Wholeness is what rushes in under the guise of chaos whenever we try to separate and measure dynamical systems as if they were composed of parts. For example, *strange attractors* are not the shape of chaos, but the shape of wholeness. When we concentrate on individual actions of individual investors, we see only chaos, emotions, and lack of rationality. But when we stand back and look at what is taking shape on the market, we see order. Order always displays itself as *patterns* that develop over time. Thus, the shape of the entire system is predictable or predetermined, which will be showed later on in this chapter.

There is a difference between *fractals* and *strange attractors*. Strange attractors are self-portraits drawn by a chaotic system. They are always fractal in nature, being deeply patterned, but they are a special category of mathematical object. Estimates are that there are only about two dozen different strange attractors (Posamantier & Lehman, 2007). In contrast, fractals describe any object or form created from repeating patterns evident at many levels of scale. There are infinite number of fractals, both natural and human-made. Fractals are everywhere around us, in the patterns by which nature organizes clouds, rivers, mountains, plants, our bodies. We live in a universe of fractal forms. Everywhere in this fractal landscape, there is self-similarity. There is pattern within pattern within pattern. There is no end to them, no scale small enough that these shapes cease to form.

Many disciplines have seized upon fractals, testing whether self-similar phenomena occur at different levels of scale in both natural and human-made systems. From architects who explain the beauty of building and towns as the repetition of harmonious patterns, to business forecasters who have observed a fractal quality in market behaviors. Fractals also have direct application for how we should understand organizations. All organizations are, in fact, fractal in nature. Each organization is deeply patterned with self-similar behaviors evident everywhere. These recurring patterns of behavior are what many call the culture of the organization. The organizational culture, as was noted before, is often identified directly with collective mind. Hence, if we could identify a specific fractal in the market behavior, we would be allowed to affirm that there is a sort of *collective mind* on the market. This, in turn, would indicate that there is a certain form of *collective*, or *social*, rationality, most likely quite different from the individual one.

Research Method

Three-Element Ecological Model

The idea of self-organization bears the notion of an "open system," contrary to the Newtonian "closed system." It also allows for the full utilization of the concept of "entropy" in social sciences. More than two decades ago Capra (1984, p. 32) argued that the new paradigm of rationality should take into account the fact that "an economy is a living system, and one of many aspects of a large ecological and social structure." And so, to model and structure the behavior of our complex adaptive system, we can use the elements of environmental economics—one of the most trendy areas in economics (e.g., Callan & Thomas, 2006). The general methodological concept proposed in this chapter is based on a three-element system, *society-economy-nature*, and it replaces the two-element system, *economy-nature*, which has been applied in economics since the 1960s. This will allow for the identification of the dependencies in its two-element subsystem, *society-nature*. This, in turn, will help identify and describe phenomena, which are observed in the surrounding world of nature and, to the same extent, are expected to regulate behavior of the crowd. This should be the actual, as opposed to only formal and declared, introduction of the ideas of open system and entropy to economic and social sciences.

Generally, the research method consists of the following stages:

identification-analysis-synthesis-exemplification-verification-interpretation-discussion

More accurately these stages are:

- Identification of the research area.
- Identification of the mechanism of collective behavior.
- Analysis of the identified mechanism.
- Synthesis, a mathematical description of the mechanism.
- Exemplification and verification of the mechanism.
- Interpretation and discussion: a new approach to rationality.

Next is a brief description of the main stages of the research method applied in this chapter.

Identification of the Research Area

The collectivity of investors composes a non-linear complex adaptive system. Each crowd can be defined in terms of its processes rather than its physical characteristics. The basic catalyst for the formation of a crowd is a condition of non-equilibrium. The presence of two crowds in a financial market (*bulls* and *bears*), ensures that a state of conflict of interest exists within the rules of the investment game. Such a condition creates stress and competition, and provides the purpose for the creation of a crowd. In order to achieve its objectives, a crowd must be open to the environment for the exchange of both energy and information. Crowd members of the financial market are in a constant state of expectant attention and are, therefore, vulnerable to suggestion. Moods, feelings, and ideas in such an environment are very contagious and they spread rapidly. Modern Internet communications ensure that the same effects can be quickly achieved even if the crowd is not assembled in one place. Crowd behavior ensures that a price movement triggers an emotional response among members of opposing crowds, and, thereby, ensures that the most recent movement in prices is continued into the future.

In this sense, change and progress within the analyzed system come about as a result of a dynamic interplay, both between individuals and the crowd to which they belong, and between a crowd and its environment. Independent fluctuations in the environment itself can lead to a number of different responses by a crowd. Ultimately, however, the crowd will always adapt to permanent changes in the environment. And all price movements are part of a very simple pattern, which is the response to information shocks, and prices oscillate rhythmically in response to the metabolic fluctuations of the crowd.

Identification of the Mechanism of Collective Behavior

The important feature of any self-organizing system, whether it be a crowd or a living organism, is that it *oscillates* during the transfer of energy and information. In fact, the presence of continuous fluctuations can be taken as a *prima facie* evidence of the presence of "mental activity." Once a crowd with common values and a common objective has been established, it will then respond positively to the input of new items of information from the environment. There is a great partnering that exists between the system and its environment. The theory of co-evolution relies on the fact that the relevant feedback loops generate stable fluctuations between a particular system and a higher-order system (Brand, 2006). Mathematicians call these stable fluctuations *limit cycles.* A limit cycle is defined as the isolated periodic oscillation between two variables, and is represented graphically by an isolated closed non-linear path (King et al., 2006). If the limit cycle is stable, the oscillations will spiral on to the solution path from a wide range of initial states. If, on the other hand, the cycle is unstable, a disturbance will cause the oscillations to spiral away from that solution path. It follows that co-evolving systems utilize stable limit cycles.

Figure 1 represents an idealized stable limit cycle. Within the context of this analysis, the *x*-axis on this figure represents an index of crowd behavior and the *y*-axis represents an index of environmental change. In reality, the two-dimensional limit cycle relating *x* and *y* (or the crowd and the environment) actually unfolds through *time*. For this part of the analysis, however, this factor can be omitted.

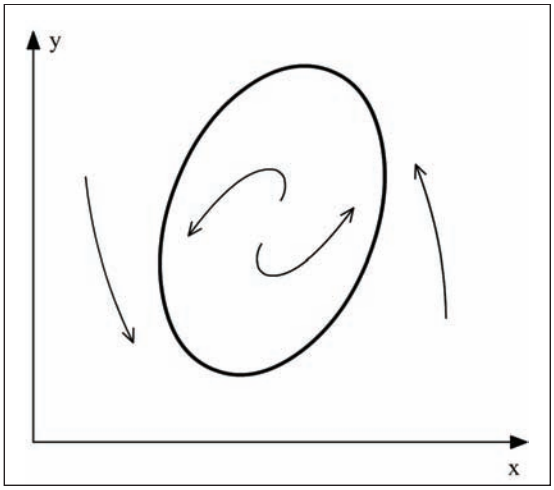
According to chaos theory, a limit cycle is one of the three possible forms of an attractor (Feudel et al., 2006). This observation is critical for further analysis and discussion.

Analysis of the Identified Mechanism

The viability and resiliency of a self-organizing system comes from its great capacity to adapt as needed, to create structures that fit the moment. Neither form nor function alone dictates how the system is organized. Instead, they are *process structures*, reorganizing into different forms in order to maintain their identity. The system may maintain itself in its present form or evolve to a new order, depending on what is required. It is not locked into any one structure; it is capable of organizing into whatever form it determines best suits the present situation.

Whenever a self-organizing system experiences any amplification process, change is at hand. If the amplifications increase to the level where they destabilize the system, the system can no longer remain as it is. At this moment, the system is at a crossroads, standing posed between death and transformation. In chaos theory, it is known technically as a bifurcation point. For the investors, it is either a moment of great fear (at the very bottom of a bear market) or great euphoria (at the end of a bull market). Abandoning its present form, the system is free to seek out a new form in response to the changed environment.

Figure 1. Idealized stable limit cycle



According to this analysis, the price-sentiment limit cycle operating in a financial market is also integrated with limit cycles relating that market to the wider economic, social, and political environment. Although limit cycles are the main mechanism whereby a self-organizing system copes with fluctuations in its environment, they do not fully represent the adjustment processes that are involved. In reality, bits of information become available only in discontinuous or discrete time intervals. The adjustment process depends on whether or not the recipient system is prepared for the information. If the information is unexpected, then the information impacts as a *shock*, and the system may have to change its dynamic structure in order to cope (Plummer, 2006, p. 50). Shocks occur because of a sudden divergence between current price movements and expected price movements, and may derive from two sources: first, they may be triggered by an unexpected movement in prices themselves; second, they may be precipitated by unexpected changes in the social, political, or economic development.

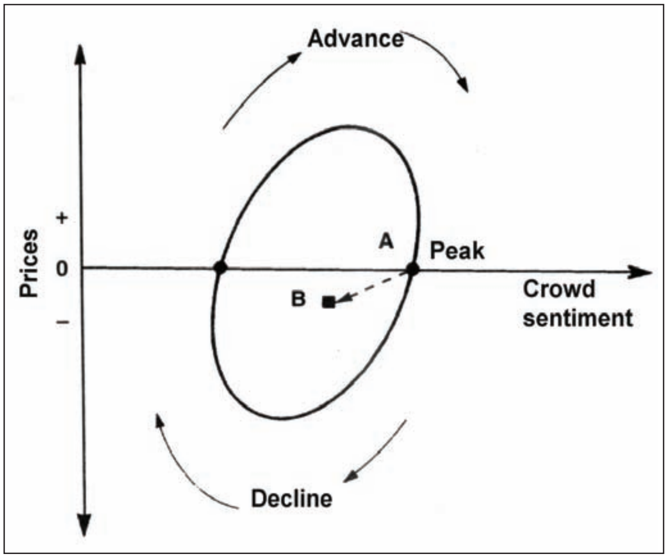
In practice, shocks are delivered to systems that already are oscillating in a limit cycle pattern with their niche in the environment. Divergences between lower-level cycles and higher-level cycles are rectified by those shocks, and the fluctuations will continue at least until the limit cycle of the next higher degree is able to reassert control. When an information shock appears, the process of adjustment begins (see Figure 2).

In this analysis, the limit cycle is biased to the right. This reflects a fact that sentiment usually turns prior to price reversals. Hence, prior to market peaks, sentiment will begin to deteriorate as the percentage increase in prices falls. On the other hand, just prior to market troughs, sentiment begins to improve and the percentage fall in prices decreases.

Whatever the source of the shock, the response of the market is essentially the same. The shock is represented here by a "jump" inward from the path of the limit cycle as the change in prices moves across the zero percent change line. Hence, in the case where a market is moving from bullish to bearish, the position on the phase plane will jump from point A to point B as the price moves into negative territory. There will be both a fall in prices and a drop in crowd sentiment (see Figure 2).

Since the limit cycle is essentially stable, it follows that behavior will try to return to the solution path. Technically it means that the fall in

Figure 2. Information shock and "jump" from the cycle path (Source: Based on Plummer, 2006)



prices begins to slow and lower prices encourage a return of "bulls." This, in turn, causes prices to rise and stimulates a reversal in sentiment. Eventually, however, higher prices encourage some profit taking or reducing the previous losses, and prices begin to slip again. The subsequent price collapse is very deep and painful, but it brings prices back to the solution path of the limit cycle, and this phenomenon is expressed by a spiral of the adaptation process of collectivity (see Figure 3).

The key question is: Since there are several different spiral movements what kind of a spiral represents these phenomena? The answer is found in the world, or even the Universe, surrounding us, because a *collectivity is also a natural system* (Frost & Prechter, 2001). And this is the stage when we can utilize the three-element system, *society-economy-nature*, and look for analogies between its two natural subsystems, *society* and *nature*.

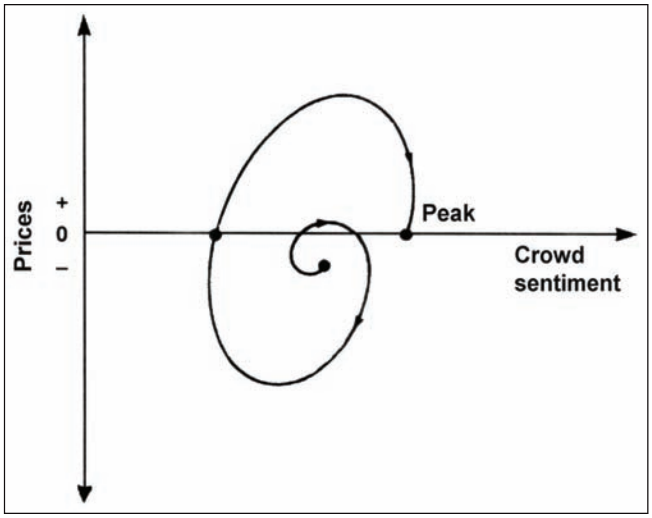
Synthesis: A Mathematical Description of the Mechanism

Contemplating the beauty and form of all the wonders of nature and giving further thought to the achievements of man in many fields, we learn that all of these have one thing in common—the *Fibonacci Summation Series* (Posamentier & Lehman, 2007). Long ago, Thomas of Aquinas described one of the basic rules of aesthetics—man's senses enjoy objects that are properly proportioned. He referred to the direct relationship between beauty and mathematics, which is often measurable and can be found in nature. Man instinctively reacts positively to clear geometrical forms, in both his natural environment and in objects created by him. Thomas of Aquinas was referring to the same principle that was a little earlier described by the 13th century mathematician, Fibonacci. He developed the summation series:

1,1,2,3,5,8,13,21,34,55,89,144, . . .

This mathematical series develops when, beginning with 1,1, the next number is formed from the sum of the previous two numbers. If each number in the series is divided by its preceding value (e.g., 21:13), the result is a ratio that oscillates around the irrational 1.618033988. . ., being higher one time and lower the next. But never in eternity can the precise ratio be known to the last digit,

Figure 3. Formation mechanism of a spiral of the adaptation process of collectivity (Source: Author's research based on Plummer, 2006)



therefore, for the sake of brevity, it is referred to as 1.618. Algebraically it generally is designated by the Greek letter phi (ϕ=1.618).

This ratio is known as the Divine Proportion, the Golden Section, or the Golden Mean. Kepler called the ratio, one of the jewels in geometry." Many people have tried to penetrate the secrets of the Pyramid of Gizeh, which is different from the other Egyptian pyramids. More detailed observations give a clue that the pyramid was designed to incorporate the phi proportion of 1.618. The same phenomenon is found in the Mexican pyramids. A different representation of Fibonacci numbers is found in the number of axils on the stem of a plant as it develops (Fisher, 2001).

The Greek mathematician Euclid related the Golden Section to a straight line (see Figure 4).

The line AB of length L is divided into two segments by point C. If C is such a point that L:AC equals AC:BC, then C is the Golden Section AB. In other words, the point C divides the line AB into two parts in such a way that the ratios of those parts is 1.618 and 0.618 (1:1.618).

The Golden Section occurs throughout nature. In fact, the human body is a tapestry of Golden Sections in everything from outer dimensions to facial arrangement.

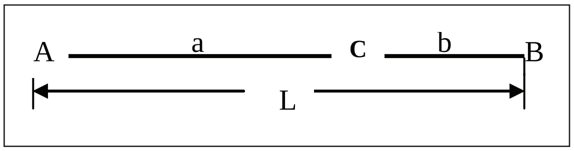
Another common occurrence of the Divine Proportion can be observed in the Golden Rectangle, which sides are in the proportion of 1.618 to 1 (see Figure 5).

According to Pythagorean theorem:

$CG = \sqrt{5} + 1$; $FG = 2$;
$CG : FG = (\sqrt{5} + 1) : 2 = (2{,}236 + 1) : 2 = 3{,}236 : 2 = 1{,}618$.

$DG = - 1$; $FG = 2$;
$DG : FG = (\sqrt{5} - 1) : 2 = (2{,}236 - 1) : 2 = 1{,}236 : 2 = 1{,}618$.

Figure 4. Golden section of a line



Works of arts have been greatly enhanced with the knowledge of the Golden Rectangle. Fascination with its value and use was particularly strong in ancient Egypt and Greece and during the Renaissance, all high points of civilization. But the value of it is hardly limited to its beauty, it serves function as well. Among numerous examples, the most striking is that the double helix of DNA itself creates precise Golden Sections at regular intervals of its twists.

While the Golden Section and the Golden Rectangle represent static pieces of natural and man-made aesthetic beauty and function, the representation of an aesthetically pleasing dynamism, an orderly progression of growth or progress, can be made only by one of the most remarkable forms in the Universe, the Golden Spiral.

To construct a Golden Spiral a Golden Rectangle can be used. Any Golden Rectangle can be divided into a square and a smaller Golden Rectangle. This process then, theoretically, can be continued to infinity. The resulting squares, which have been drawn, appear to be whirling inward. A spiral can be drawn by connecting the points of intersection for each whirling square, in order of increasing size. As the squares whirl inward or outward, their connecting points trace out a Golden Spiral (see Figure 6).

Figure 5. Construction of the Golden Rectangle

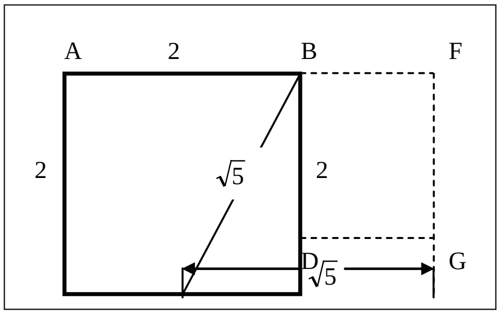


Figure 6. Geometry of the Golden Spiral (Source: Author's research based on Frost and Prechter, 2001)

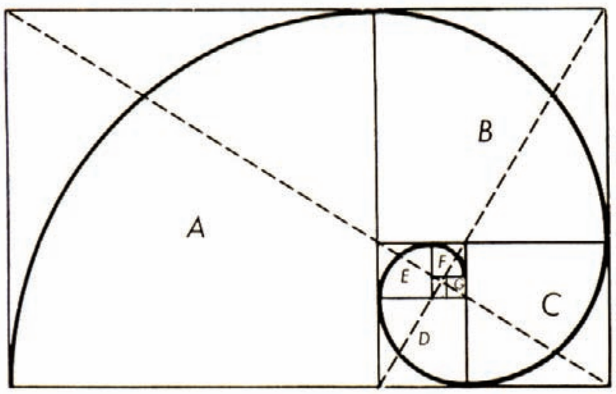


At any point in the evolution of the Golden Spiral, the ratio of the length of the arc to its diameter is 1.618 and the diameter is related to the larger radius just as the larger radius is to the smaller radius, by 1.618, as illustrated in Figure 7.

The Golden Spiral, which is a type of logarithmic or equiangular spiral, has no boundaries and is a constant shape. From any point on it, one can travel infinitely in either the outward or inward direction. The center is never met and the outward reach is unlimited.

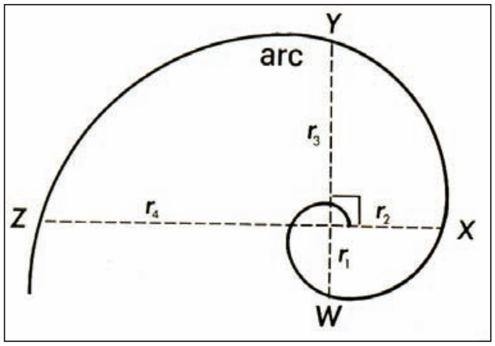
Now, the tail of a comet curves away from the sun in a logarithmic spiral. A spider spins its web into a logarithmic spiral. Bacteria grow at an accelerating rate that can be plotted along a logarithmic spiral. Meteorites, when they rupture the surface of the Earth, cause depressions that correspond to a logarithmic spiral. Pine cones, sea horses, snail shells, ocean waves, ferns, animal horns, and the arrangement of seed curves on sunflowers and daises all form logarithmic spirals. Hurricane clouds and the galaxies of outer space swirl in logarithmic spirals. Even the human finger, which is composed of three bones in Golden Section to one another, takes the spiral shape (Fisher, 2001). Everywhere, the design is the same: a 1.618 ratio, perhaps the primary law governing dynamic natural phenomena.

PRACTICAL VERIFICATION

Application of the Logarithmic Spiral on the Index Chart

According to the three-element model, this natural law, permeating the universe and described by the Fibonacci ratio $\phi = 1.618$, should refer to the dynamics of collective behavior as well. Since adaptations to the exchange of information spiral and financial markets reflect psychology and the dynamics of the crowd, the spiral identified in price formations also should be logarithmic.

Figure 7. Constant proportions in the Golden Spiral (Source: Author's research based on Frost & Prechter, 2001)



$r_2:r_1=r_3:r_2=r_4:r_3=...=r_n:r_{n-1}$
$d_2:d_1=d_3:d_2=...=d_n:d_{n-1}$
$(d_1=r_1+r_3,\ d_2=r_2+r_4,\ etc.)$

All technical approaches to understanding the stock market depend on the basic principle of order and form. No matter how minute or how large the form, the basic design remains constant. And the stock market has the very same mathematical base as do all those natural phenomena. It appears that the top of each successive wave of higher degree is the touch point of the logarithmic expansion. The spiral form of market action is repeatedly shown to be governed by the Golden Ratio, and even the Fibonacci numbers themselves appear in market statistics more often than mere chance would allow. Any point on the spiral represents the optimum price-time relationship.

The most challenging part of the spiral is to see it work in extreme market situations, when behavioral patterns are strongest. With the correct center and starting point chosen, the spiral can identify turning points in the markets with accuracy never seen before.

Examples from an Emerging Market

One of the examples of how to use the concept of the spiral to predict the basic market moves is shown in Figure 8. It represents a chart of the Warsaw Stock Exchange index.

The stock market in Poland was reopened in 1991 after more than half a century. The x-axis on the chart represents the dates of consecutive trading days, and the y-axis represents the value of the index in a logarithmic scale (albeit the scale can also be arithmetic).

A logarithmic spiral has been applied, with the center and starting point in the middle of an almost two-year base, preceding the sharp move upward. On the second ring of the curve, we can locate a point that approximately ends the long period of basing, on the third ring there is the end of the first wave of enormous gains, and a sharp and painful correction takes place (first days of June 1993). The fourth ring is the ultimate target of the bull market, and the beginning of a long and devastating bear market in March 1994.

The center of the spiral can be placed either in the middle of the market or at one of the extreme points (highs or lows). The spiral itself can be turned either clockwise or counterclockwise. The next important factor is the swing size, that is, the distance between the center and the starting point (Fisher, 2001). Once those parameters have been set, we can begin working with the curve. And the most important factor is the meaning of consecutive spiral rings. At this time no rules have been offered for investing when the first spiral ring is penetrated. Usually we may wait some important moments, when ring number two is reached. It is not often that the third ring of the spiral is penetrated in the same direction as the major trend. But when it happens a significant trend change should follow, as it took place in Warsaw in June 1993. A penetration of the fourth ring in the continuing trend direction must occur even less than any other ring penetration. But, it does happen, and it should indicate a dramatic trend change. These are moves such as the stock market collapse of October 1987 in New York, or March 1994 in Warsaw (see Figures 8 and 9). The fourth ring is the ultimate price target. When it is penetrated, the point of penetration can be used as an entry signal. There is no need to wait for a confirmation. Another good example of

Figure 8. Four spiral rings defining the Warsaw Stock Exchange bull market

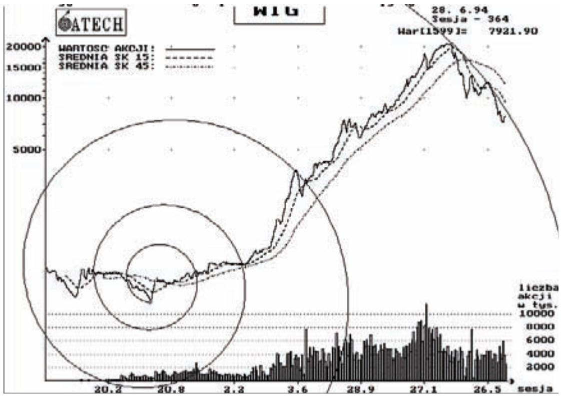


Figure 9. The fourth spiral ring as the ultimate destination of the bear market

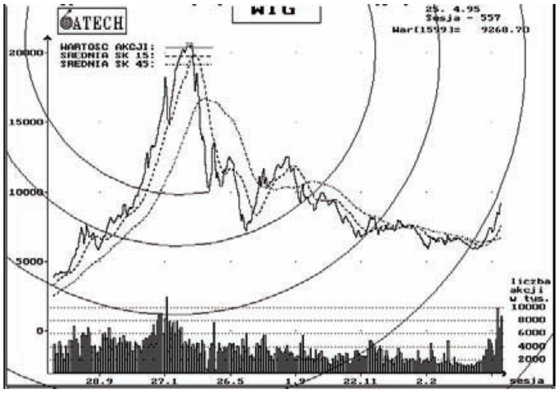


the importance of the four rings of the spiral is presented in Figure 9 on an arithmetic scale.

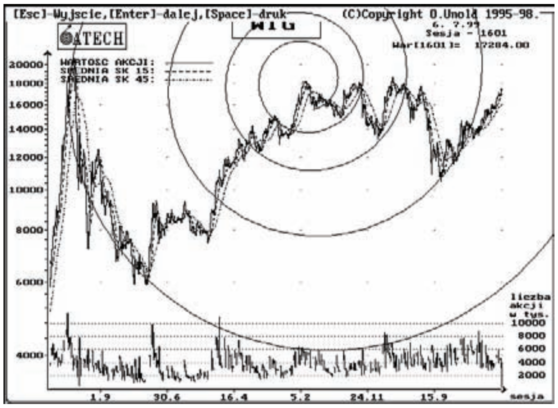
A long and painful bear market in Warsaw has its major turning points on the four rings of the spiral. On the second ring a dynamic and upward correction wave begins. The third ring points to the beginning of a consolidation phase, preceding the final shake-out. The fourth ring is the end of the bear market.

Figure 10 presents how the logarithmic spiral applies to the next stages of the development of Polish emerging stock market. The spiral embraces all the vital turning points of the index chart, starting at the peak of the first wave of the bull period in March 1994, through a year-long bear market in 1994 and 1995, the next, very extensive, bull market, to the end of the next corrective wave in July 1999.

Examples from Developed Markets

In the next step, the observations from one of the emerging markets should be confirmed at a few much more developed exchanges. And indeed, in all the following examples the development of the market trend proceeds according to the logarithmic extension.

Figure 10. Logarithmic spiral on the Warsaw Stock Exchange index chart



The next figure confirms the logarithmic extension of German DAX index, charted from January 2005 to March 2003 (see Figure 11).

Yet another one reveals a similar pattern at French CAC40, from January 1995 to March 2003 (see Figure 12).

Last but not least, the Hangseng index of the Hong Kong stock exchange, analyzed in the time frame June 1987-April 1999, follows the logarithmic expansion (see Figure 13).

The above examples, taken from a few of the world's best developed markets, confirm the universality of the analyzed mechanisms of collective behavior in complex adaptive systems.

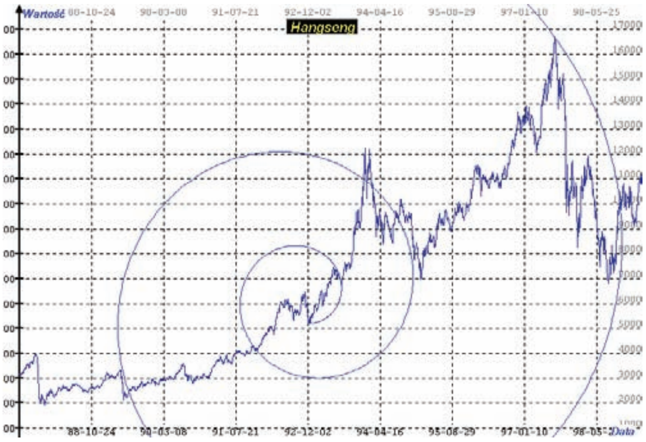
CONCLUSION: INTERPRETATION AND DISCUSSION

The most general conclusion drawn from this chapter is that the same law that shapes the spiraling galaxies mold the spirit and attitudes of men en masse. It shows up so clearly in the market because the stock market is the finest reflector of mass psychology. It is a nearly perfect recording of man's social psychological states and trends, reflecting the fluctuating valuation of his own productive enterprise and making manifest its very real patterns of progress and regress. What is more, the empirical evidence is available for study and observation. It seems that these parallels are too great to be dismissed. On the balance of probabilities, we may come to the conclusion that there is a principle, everywhere present, giving shape to social affairs. The stock market is no exception, as mass behavior is undeniably linked to a law that can be studied and defined. The briefest way to express this principle is by a simple mathematical statement: the 1.618 ratio.

The logarithmic spiral identified within the analyzed information system is self-similar and isomorphic. It follows that information processes

Figure 13. Logarithmic spiral on Hangseng index chart in Hong Kong



of collectivity also are isomorphic. The identification of isomorphism and self-similarity in the analyzed system is of great importance in the proposed research procedure. The spiral in Figure 3 represents a new, modified form of the attractor presented in Figure 1. This spiral is a metaphorical equivalent of a fractal attractor (strange attractor). This metaphor has deep theoretical grounds, as a logarithmic spiral actually is a fractal.

The identification of a fractal attractor (strange attractor) in a social subsystem of a model global information system carries far-reaching theoretical and methodological consequences. It implies self-similarity and recurrence of system behavior. Recurring patterns of behavior in an organization are called organizational culture, and the notion of "organizational culture" is used interchangeably with the concept of "collective mind" (Eden & Spender, 2003). Thus, the identification of a fractal attractor in the analyzed social system suggests, on the grounds of chaos theory, the occurrence of rationality of collective behavior and defines the model representation of the adaptability of collective behavior a spiral movement.

It is worth emphasizing that the concepts of *collective mind* and *organizational intelligence* add a crucial qualitative dimension to information systems analysis. They add the missing internal social dimension to the technical or mechanistic dimension, which is, generally, the focus of the classical theory of systems and organizations.

Another research thread that can be used to theoretically explain the identified phenomena and justify the method applied in this chapter is Heisenberg's uncertainty principle, with the example of the dual nature of electrons, that is, unpredictability of behavior on the individual level versus predictability on the collective level of an "electron cloud" (Heisenberg, 2000). The decision-making process of collectivity within a model global information system is adaptive and follows specific patterns found in nature. Therefore, unlike the decision-making process of an individual, this process can be expressed mathematically and, under certain conditions, ought to be predictable. In other words, individual behavior, which is often irrational and unpredictable, is expected to compose an adaptive, spiral, and thus, predictable process of collective decision making.

The main potential scientific result of the proposed research approach could be a new formulation of the rationality paradigm. In the era of globalization and virtualization, we shift our interest from traditionally perceived *physical collectivities* to a *dispersed, virtual crowd*, which is a totally new social phenomenon. The observations included in this chapter should allow us to identify the theoretical grounds of a new paradigm, which will refer to the behavior of crowd and the notion of adaptation as a more natural reaction to information stimuli than optimization. Moreover, adaptation would not exclude traditional optimization. Optimization would remain a specific case of adaptation, applicable to strictly deterministic decision situations.

The importance of the adaptation issue has been recognized in organizational sciences for a long time. The organization theorist Barnard held that adaptation was the central problem of organization. Barnard was concerned with cooperative adaptation, hereafter referred to as adaptation (C), which was accomplished in an intentional way. Formal organization, especially hierarchy, was the instrument through which the "conscious, deliberate, purposeful" cooperation was accomplished (Barnard, 1938, p. 4). Barnard's insights have had a lasting effect on organization theory.

A different approach to adaptation was presented by the economist Hayek, who emphasized autonomous adaptation of a spontaneous kind. He maintained that adaptation was the main problem of economic organization, and argued that it was realized spontaneously through the price system. Changes in the demand or supply of a commodity give rise to price changes, whereupon "individual participants . . . [are] able to take the right action" (Hayek, 1945, p. 527). Such price-induced adaptations by individual actors are referred to as adaptations (A), where (A) denotes autonomy. The conclusions of this chapter directly refer to Hayek's notion of adaptation, providing theoretical, methodological, and empirical framework for further research in this area.

This way, the above conclusions could contribute to an increased understanding of mutual interactions between societies and individuals in the era of birth and growth of the Global Information Society. These findings might help examine and structure the unique influence that social processes exert on the decision-making processes of an individual. In this sense, we would be able to speak of *system rationality*, which should not depend on the rationality or irrationality of the system's components.

FUTURE RESEARCH DIRECTIONS

The research method proposed in this chapter is interdisciplinary and intersectorial. It combines the theoretical and methodological principles of Information Systems with the most recent achievements in such new and progressive disciplines as chaos theory and environmental economics. On the level of theory, further research should look for deeper references between the behavior of dispersed collectivities in a model global IS and the principles of chaos theory. The identification of a fractal attractor in a model of collective behavior is just an initial step in this direction. This could overlap with methodology, when a more sophisticated mathematical apparatus would be used to describe these exciting phenomena.

The next step in the practical verification procedure could include other areas of collective activity. The global IS epitomized in this chapter is a modern, electronic, stock market. However, Fonseca (1989) already proved that a logarithmic expansion regulates the natural development of the urban populations, as well. The next case could analyze, for example, the behavior of social systems in medium and large size companies. The initial challenge here would be to find the proper indicators, which, in the case of a stock market, were the historic value of the index, represented by an index chart, or the volume of trading. Other areas of collective actions could include voting groups, but taken internationally and along a model dividing lines, for example, conservatives versus liberals. This case might be easier to structure, because of the well-known political marketing methods, and a well-developed research regarding the influence of modern IT on human behavior.

A very important research thread is the influence the global IT exerts on human behavior. While individual behavior already is pretty well described in the literature, the collective behavior still is mostly unknown. This issue could be related to the one of social rationality. For years, academics have been trying to formulate a new paradigm of rationality. All of these attempts, however, are highly theoretical and lack any practical verification. The notion of adaptive rationality, introduced in this chapter, could help construct a new approach to rationality, going well beyond the overused notion of bounded rationality, and being supported by a solid practical verification.

Chapter 8.4

Information Technology and Diversification:

How Their Relationship Affects Firm Performance

Namchul Shin
Pace University, USA

ABSTRACT

While the importance of IT coupled with organizational changes for business performance has been widely discussed in the information systems (IS) literature, there has been little empirical research on the issue. This research examines empirically the relationship between IT and diversification by employing multiple diversification measures. It also examines empirically the relative impact on performance of IT and diversification. Results show that diversification coupled with increased IT spending improves firm performance when its strategic emphasis is on related diversification. The results also show that firms place strategic focus on related diversification when they increase IT spending, and that they require more IT when their strategic emphasis is tilted toward related diversification. The findings imply that by providing a better means of coordination, IT enables scope economies, efficient utilization of business resources and collaboration across individual business units, eventually leveraging the benefits of diversification.

INTRODUCTION

Emerging technologies can often allow firms to reexamine how they do business, stimulate creative thinking, and ultimately create new opportunities. In the e-business environment, where process automation and digitization are critical for business success, efforts to redesign processes and effectively coordinate value chain-activities with customers and suppliers are ever more important. Information technology (IT), including the Internet and related technologies, can make its fullest impact on organizations when it is deployed in conjunction with changes in business processes, structures, and strategies.

While the importance of coupling IT with organizational changes for business performance has been widely discussed in the information systems (IS) literature (Brynjolfsson & Hitt, 1996; Brynjolfsson & Yang, 1998; Clemons & Row, 1991; Dewan, Michael, & Min, 1998; Rai, Patnayakuni, & Patnayakuni, 1997; Shin, 2001, 2006), there has been little empirical research on the issue. Brynjolfsson and Yang (1998) found that an increase of one dollar in IT capital was valued by the stock market at about ten dollars, and this extra nine dollars represented the value obtained from organizational changes to complement IT investments. Brynjolfsson and Hitt (1996) also found that IT had its greatest contribution to output in firms that adopted a more decentralized and human capital-intensive work system.

This research examines empirically the relationship between IT and diversification by employing multiple diversification measures. It also examines empirically the relative impact on performance of IT and diversification. Several empirical analyses in two stages attempt to answer the following questions:

1. Do firms increase their strategic emphasis on related diversification when they increase IT spending?
2. Is business performance improved by increased IT spending when firms place their strategic emphasis on related diversification?

By answering these questions, this study attempts to shed light on why the impact of IT on firm performance may not be constant across firms. It concludes that IT spending complements the strategic choices of firms, such as a strategic decision to focus on related diversification. The empirical aspects of this complementarity have received little attention from previous IS and economics research.

THEORETICAL BACKGROUND: PRIOR RESEARCH ON DIVERSIFICATION AND IT

Economics research posits that a firm is a collection of physical, human and intangible resources capable of undertaking a number of separate economic activities. Some resources may be relatively product specific, and thus utilized to produce a particular good or service through one business line. Other resources, however, may have the potential to increase production of goods or services in multiple business lines. When a firm has excess capacities that are insufficiently utilized in its current operations and cannot be sold in external markets, it will expand their use by diversifying its operations into multiple markets (Caves, Porter, Spence, & Scott, 1980; Clarke, 1985; Penrose, 1959; Rumelt, 1974).

A firm can diversify its operations into either related or unrelated markets. Related diversification means that a firm diversifies into business areas close to the one in which it originated (for example, computer and communications product manufacturing), while unrelated diversification refers to a firm diversifying into more distant areas unrelated to its current business (for example, computer product manufacturing and banking). When a firm pursues related diversification, its ability to achieve tangible economic benefits depends on increased coordination, communication, and collaboration among its different business lines (Hill, 1994; Hill & Hoskisson, 1987). Individual divisions share market information, managerial expertise, technical knowledge, and physical resources such as supply chains and distribution channels. Thus, when a firm pursues related diversification, it should consider the costs of coordinating resources, including the costs of information sharing, across related markets (Williamson, 1975). On the other hand, unrelated diversification is pursued with the goal of realizing economic benefits from the exploitation of an internal capital market in which capital can be more efficiently allocated than in external markets (Hill, 1988). Because there are no interrelationships among divisions, that is, no sharing of business resources, unrelated diversification does not require as much coordination and collaboration as related diversification (Hill, 1994; Hill & Hoskisson, 1987).

IT is widely used to share information and coordinate business resources across multiple markets (Clemons, Reddi, & Row, 1993; Gurbaxani & Whang, 1991; Malone, Yates, & Benjamin, 1987). Because IT provides a better means of coordination and collaboration across multiple markets, firms pursuing related diversification may require increased IT investment. Similarly, increased IT investment may facilitate diversification, particularly related diversification. A firm's IT investment, therefore, can be the cause or the effect of its diversification. In other words, IT can complement a firm's diversification strategy or vice versa.

The relationship between IT and diversification has been examined by previous IS research (Dewan et al., 1998; Hitt, 1999). Dewan et al. (1998) found that diversification, especially related diversification, was likely to increase a firm's demand for IT. They argue that their findings might reflect a greater need for coordination of assets and information processing within diversified firms. Working from similar findings, Hitt (1999) argues not only that diversified firms have a higher demand for IT capital, but that increased use of IT is associated with a slight increase in diversification. While Dewan et al. (1998) and Hitt (1999) have provided the implications of the complementarity of IT and diversification for firm performance, they did not empirically analyze the issue in their studies. The issue of how the complementarity of IT and diversification affects firm performance has been examined by several recent papers. Shin (2006) finds a positive interaction effect between IT and strategic direction, defined as the difference between related and unrelated diversification. Liu, Ravichandran, Han, and Hasan (2006) also find that the interaction effect between IT and diversification is positive only for related diversification.

This study is similar to the prior work done by Shin (2006) and Liu et al. (2006), but while the prior work focused on the interaction effect of IT and diversification, this study shows the directional effect of IT and diversification by performing empirical analyses in two stages. This study also examines lagged effects of IT, which was not done in Shin's study (2006).

DIVERSIFICATION AND PERFORMANCE IMPACTS OF IT

Diversification can increase the demand for IT because of the need for coordination and collaboration across multiple markets. In today's global economy in which firms can diversify across national borders, the use of IT for diversification has become ever more important since IT lowers the additional costs of coordination and collaboration, thereby augmenting the benefits of diversification. Thus, increased use of IT can improve the performance of highly diversified firms. However, the contribution of IT to firm performance may depend on the direction of the firm's diversification strategy (Shin, 2006). If a firm's strategic direction is oriented more toward related diversification, in which coordination and collaboration are critical for success, increased use of IT may improve the firm's performance by providing a better means of coordination and collaboration. However, if a firm's strategic direction is oriented more toward unrelated diversification, which does not require as much coordination and collaboration as related diversification, increased use of IT may have less impact on the firm's performance.

The strategic direction of diversification (strategic direction, in short) is defined here as the relative emphasis a firm places on related diversification relative to unrelated diversification.

A measure of strategic direction is constructed as follows:

Strategic Direction (SD) = Related Diversification – Unrelated Diversification

Positive scores indicate a firm's relative emphasis on related diversification; negative scores indicate its relative emphasis on unrelated diversification. It is expected that IT will improve the performance of firms when they place emphasis on related rather than unrelated diversification. On the other hand, IT is not likely to leverage the performance of firms when they place emphasis on unrelated rather than related diversification. This result does not negate the importance of unrelated diversification for firm performance, but rather highlights the importance of IT for leveraging the benefits of related diversification.

METHODOLOGY AND ANALYSIS: DATA SOURCES AND VARIABLE CONSTRUCTIONS

The study employs two data sources: *Information Week*'s annual data set of IS budgets for the three years from 1995 to 1997 and the Compustat database for the five years from 1995 to 1999.

IT intensity is calculated by dividing the IS budgets by the number of employees. As measures of diversification, we employ the Entropy indexes of total diversification, related diversification and unrelated diversification (Jacquemin & Berry, 1979). A measure of strategic direction is constructed by taking the difference between the Entropy index of related and unrelated diversification (i.e., related diversification – unrelated diversification). Two other diversification indexes—the Concentric index (Caves, et al., 1980; Montgomery & Wernerfelt, 1988; Wernerfelt & Montgomery, 1988) and the Herfindahl index—are also employed as measures of diversification.[1]

Data items such as sales, total assets, capital investment, the number of employees, and return on assets (ROA) are obtained from the Compustat database for the same firms included in the Information Week 500 data set. Tobin's q, ROA, gross margin, and revenue per employee are employed as measures of firm performance. To construct the measure of Tobin's q, we employ the same method used by Bharadwaj, Bharadwaj, and Konsynski (1999):

Tobin's q = (MVE + PS + DEBT)/TA
Where
MVE = (Closing price per share at the end of the fiscal year) * (Number of common shares outstanding)
PS = Liquidation value of the firm's outstanding preferred stock
DEBT = (Current liabilities – Current assets) + (Book value of inventories) + (Long-term debt)
TA = Book value of total assets

Tobin's q is defined as the ratio of the capital market value of a firm to the replacement value of its physical assets. This incorporates a market measure of firm value (Bharadwaj et al., 1999; Montgomery & Wernerfelt, 1988). According to Bharadwaj et al. (1999), Tobin's q is forward-looking, risk-adjusted, and less susceptible to changes in accounting practices, compared to accounting-based performance measures such as ROA. In other words, it reflects the ex-ante financial market valuation of the level and risk of future profitability. Tobin's q has been widely used in economics research to measure the intangible values of factors such as R&D and brand equity (Cockburn & Griliches, 1988; Simon & Sullivan, 1993). Some recent IS studies have also used Tobin's q to examine the intangible value created by IT (Anderson, Banker, & Nan, 2002; Bharadwaj, et al., 1999; Brynjolfsson & Yang, 1998; Tam, 1998; Tanriverdi, 2006). The use of Tobin's q for measuring intangible value is based on the assumption that the long-run equilibrium market value of a firm must be equal to the replacement value of its physical assets, giving a q value close to unity (Bharadwaj et al., 1999). Any upward deviation from this unity, where q is significantly greater than one, indicates that there is an unmeasured source of value, which is generally attributed to the intangible value created by the firm. Since IT creates significant intangible benefits such as improved market orientation, better coordination and collaboration, higher product quality, and more effective business strategies and processes, the use of Tobin's q as a measure of firm performance can provide a means of capturing IT's true value to a firm.

The sample includes 535 observations (267 different firms) for the three years from 1995 to 1997. The sample statistics are shown in Table 1.

METHODOLOGY

The basic methodology is to analyze the combined data set for five years (1995-1999) using an ordinary least squares (OLS) regression with lag variables: one-year and two-year lags. To analyze the relationship between IT and diversification, an analysis with IT and multiple diversification indexes is conducted. Then we analyze the performance impacts of IT and diversification. For the analysis with the one-year lag, IT intensity from 1995 to 1997 and diversification and firm performance from 1996 to 1998 are employed. For the analysis with the two-year lag, IT intensity from 1995 to 1997 and diversification and firm performance from 1997 to 1999 are employed.[2]

ANALYSIS OF IT AND DIVERSIFICATION

The Model

The model measures the relationship between IT and diversification, while controlling for industry- and year-specific effects.

$$DIV_{i,t} = \beta_0 + \beta_1 IT_{i,t-1} + \beta_2 DIV_{i,t-1} + \beta_3 CAP_{i,t} + \beta_4 Industry_{i,t} + \beta_5 Year_{i,t} + \varepsilon \quad (1)$$

DIV stands for the Entropy index of total diversification. It is replaced in turn by two other diversification variables: the Concentric and Herfindahl indexes. The model includes a one-year lagged variable of total diversification

Table 1. Sample statistics (1995 to 1999)

Variables and other data	Mean	St. Deviation	No. of Obs.
IT intensity (IS budgets/employee)	5,091.8	6,033.3	535
Related diversification (Entropy)	.1794	.2843	535
Unrelated diversification (Entropy)	.3713	.4146	535
Strategic direction	-.1919	.4993	535
Total diversification. (Entropy)	.5507	.5060	535
Concentric	.5214	.4932	542
Herfindahl	.3140	.2753	542
Capital intensity	.5579	.1570	535
Tobin's q	1.790	1.401	321
Return on assets (ROA)	.0911	.0951	366
Gross margin	.3409	.1722	394
Revenue per employee	268,713.4	218,208.5	393
Total sales (in million)	11,855.8	20,890.3	535
Total assets (in million)	15,852.5	35,926.9	535

($DIV_{i,t-1}$) because the analysis conducted without controlling for this variable may overestimate the significance of IT (Santhanam & Hartono, 2003; Tanriverdi, 2006; Zhu, 2004). It also helps reduce the adverse impact of serial correlation in the regression (Zhu, 2004). For the analysis of the two-year lags, the one-year lagged IT ($IT_{i,t-1}$) is replaced by the two-year lagged IT ($IT_{i,t-2}$). Capital intensity (capital investment/total assets) is included as a control variable for firm-specific effects. Because the model employs ratio variables for both dependent and independent variables, we do not include firm size as a control variable. Dummy variables for each industry categorized by the SIC code and for each year are also included in order to account for industry differences and macroeconomic (or market) trends. ε is the residual term with zero mean, which captures the net effect of all unspecified factors.

The differing impact of IT on related and unrelated diversification is estimated separately using the following two models:

$$RD_{i,t} = \beta_0 + \beta_1 IT_{i,t-1} + \beta_2 RD_{i,t-1} + \beta_3 CAP_{i,t} + \beta_4 DIV_{i,t} + \beta_5 Industry_{i,t} + \beta_6 Year_{i,t} + \varepsilon \qquad (2)$$

$$URD_{i,t} = \beta_0 + \beta_1 IT_{i,t-1} + \beta_2 URD_{i,t-1} + \beta_3 CAP_{i,t} + \beta_4 DIV_{i,t} + \beta_5 Industry_{i,t} + \beta_6 Year_{i,t} + \varepsilon \qquad (3)$$

RD and URD stand for the entropy indexes of related and unrelated diversification respectively. As in the model of diversification, each model includes one-year lagged variables of related ($RD_{i,t-1}$) and unrelated diversification ($URD_{i,t-1}$) respectively. Capital intensity and total diversification (entropy index) are included as control variables for firm specific effects. Industry and year dummies are also included as control variables.

We also estimate a model with strategic direction (the entropy index of related diversification—the entropy index of unrelated diversification) in order to directly examine if a firm places emphasis on related rather than unrelated diversification when it increases IT spending. A firm can direct its operations into both related and unrelated diversification. However, the important strategic decision is not whether to choose one or the other, but how much emphasis to place on one relative to the other. A firm can pursue both related and unrelated diversification for different reasons, but what really matters is the firm's strategic focus (Shin, 2006). Unlike models (2) and (3) shown earlier, which examine the impact of IT on related and unrelated diversification separately, the model of strategic direction captures both components at the same time. The model includes related diversification (one-year lagged), capital intensity, total diversification (entropy index), industry and year dummies as control variables.

$$SD_{i,t} = \beta_0 + \beta_1 IT_{i,t-1} + \beta_2 RD_{i,t-1} + \beta_3 CAP_{i,t} + \beta_4 DIV_{i,t} + \beta_5 Industry_{i,t} + \beta_6 Year_{i,t} + \varepsilon \qquad (4)$$

As discussed earlier, a firm's increased IT spending can be the result of its diversification: Namely, a firm that places emphasis on related diversification relative to unrelated diversification may require increased IT spending. In order to examine this reverse causality, we use a simultaneous regression model by taking IT as a dependent variable and strategic direction as an independent variable.

$$IT_{i,t} = \beta_0 + \beta_1 SD_{i,t} + \beta_2 IT_{i,t-1} + \beta_3 CAP_{i,t} + \beta_4 RDIV_{i,t} + \beta_5 Industry_{i,t} + \beta_6 Year_{i,t} + \varepsilon \qquad (5)$$

Unlike the other models, this one does not include a lagged variable of strategic direction, since a firm can adjust the level of IT spending relatively easily compared to strategic direction. A one-year lagged IT variable, capital intensity, related diversification (Entropy index), industry and year dummies are included as control variables.

Models 1 to 5 test the following hypotheses respectively:

H1: There is a positive relationship between IT and total diversification.
H2: There is a positive relationship between IT and related diversification.
H3: There is a positive relationship between IT and unrelated diversification.
H4: IT has a positive relationship with strategic direction.
H5: Strategic direction has a positive relationship with IT.

ANALYSIS FOR FIRM PERFORMANCE

The Model

The model measures the relationship between IT and firm performance as measured by Tobin's q, gross margin, revenue per employee, and ROA while controlling for diversification and capital intensity, as well as industry- and year-specific effects. The model also includes a one-year lagged variable of ROA to control for past performance since the performance impact of IT can be overestimated if there is no control for past performance (Santhanam and Hartono, 2003; Tanriverdi, 2006; Zhu, 2004).

$$\text{Performance}_{i,t} = \beta_0 + \beta_1 \text{IT}_{i,t-1} + \beta_2 \text{RD}_{i,t} + \beta_3 \text{DIV}_{i,t} + \beta_4 \text{CAP}_{i,t} + \beta_5 \text{ROA}_{i,t-1} + \beta_6 \text{Industry}_{i,t} + \beta_7 \text{Year}_{i,t} + \varepsilon \quad (6)$$

For the analysis of the two-year lags, the one-year lagged IT is replaced by the two-year lagged IT. When ROA is employed as a dependent variable, the one-year lagged variable of Tobin's q is employed as a past performance variable. The model is also estimated separately using the strategic direction variable instead of the diversification variables (RD and DIV).

$$\text{Performance}_{i,t} = \beta_0 + \beta_1 \text{IT}_{i,t-1} + \beta_2 \text{SD}_{i,t} + \beta_3 \text{CAP}_{i,t} + \beta_4 \text{ROA}_{i,t-1} + \beta_5 \text{Industry}_{i,t} + \beta_6 \text{Year}_{i,t} + \varepsilon \quad (7)$$

Models 6 and 7 test the following hypothesis:

H6: There is a positive relationship between IT and firm performance.

RESULTS: IT AND DIVERSIFICATION

As shown in Table 2, the current level of IT spending is strongly associated with an increase in diversification after two years. The coefficient of IT (two-year lagged) indicates that the null hypothesis of zero effect of IT can be rejected at a confidence level of .01 when the entropy index is employed as a measure of diversification. The F values suggest that the overall model is statistically significant at a level of .01. The results are the same for the Concentric and Herfindahl measures of diversification (Table 3). IT is also associated with an increase in related diversification, and the impact is stronger for IT spending that has been lagged for two years, with a coefficient of .065 ($p < .01$). As expected, IT is associated with a slight increase in unrelated diversification after two years. The coefficient of IT is .035 and significant at a .10 confidence level.

The model also explores the impact of IT on diversification by using the variable of strategic direction (Table 4). As expected, IT is strongly correlated with an increase in strategic direction, and its impact is stronger after two years, with a coefficient of .075 ($p <.01$). The results indicate that firms place their strategic emphasis (or focus) on related diversification when they increase IT spending.

Table 5 shows the results of a direct test of reverse causality with the simultaneous regres-

sion model. The results show that strategic direction is strongly associated with an increase in IT spending, with a coefficient of .139 ($p < .05$). The results in Tables 4 and 5 suggest that there is some causality in both directions between IT and strategic direction, which reflects a mutual reinforcement of IT and strategic direction.

Our results are consistent with the findings of previous studies done by Dewan et al. (1998) and Hitt (1999). However, this study is different from them since it examines lagged effects of IT and employs a measure of strategic direction, in addition to other diversification measures, which captures and quantifies the components of both related and unrelated diversification at the same time. It also employs a more recent data set (1995-1999), compared to the previous studies.[3] This study is also distinct from the two studies in that Dewan et al. (1998) analyzed the IT demand side only, and Hitt (1999) did not distinguish related and unrelated diversification in his analysis.

FIRM PERFORMANCE

As shown in Table 6, IT is positively associated with firm performance as measured by Tobin's q. The positive relationship is significant for both one and two-year lagged IT. The results are the same for models (6) and (7). Diversification is negatively associated with firm performance, while strategic direction is positively associated

with firm performance. However, the relationship is significant only for total diversification.

The explained variance (R^2) of the results is relatively low (in the ranges of 30 and 40 percent), compared to the one in the analysis of IT and diversification. This indicates that there might be some missing variables in the model. Previous research suggests that organizational resources and capabilities (e.g., R&D intensity, advertising intensity, and intangibles such as flexible culture, customer and supplier relationships, and human IT skills) can influence returns from IT investments (Bharadwaj, 2000; Wade & Hulland, 2004). On the other hand, there has been limited attention on strategic factors, such as diversification, and their importance for IT returns. Because of the focus of this research is on diversification and how it is related to IT payoffs, we do not include variables identified by previous research in our model. This might result in specification error and cause biased estimates of standard errors. However, specification error is not likely to be a problem if the included and excluded variables are independent; in that case, the estimates of included variables are not affected by variables excluded (Berry & Feldman, 1985).[4] Since the present research does not consider variables of organizational resources and capabilities, it would be valuable for future research to examine IT returns holistically by considering all the factors that affect firm performance, for example, both strategic factors and organizational resources and capabilities.

As shown in Tables 7 and 8, IT is positively associated with firm performance as measured by gross margin and revenue per employee, and its impact is significant. The results are the same for models (6) and (7). The impact of diversification, including strategic direction, is not significant, except for total diversification in Table 7. Its impact is negative as in the regression with Tobin's q.

IT is negatively associated with firm performance as measured by ROA (not reported here). However, the negative relationship is not significant, and the results are the same for models (6) and (7).

Table 9 summarizes our hypothesis test results.

The results indicate that increased IT spending improves firm performance as measured by Tobin's q, gross margin, and revenue per employee, but not by ROA. In the previous section, we found

that firms place their strategic emphasis on related diversification with increased IT spending (Table 4), and that firms require more IT when they are oriented more toward related diversification (Table 5). Overall, this implies that the economic benefits of diversification are leveraged by IT when its direction is oriented toward related diversification. By providing a better means of coordination, IT facilitates the coordination of diverse production activities and the collaboration of individual business units, eventually enhancing the benefits from this diversification. The summary of the overall findings is presented in Figure 1.

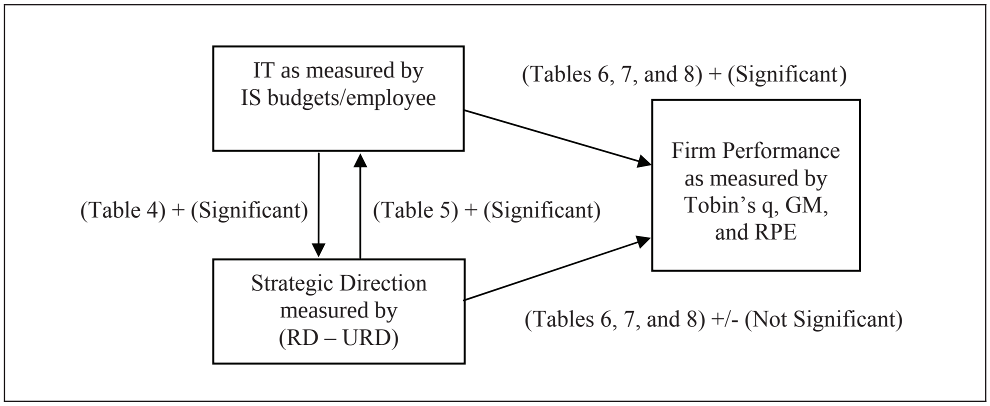
DISCUSSION AND CONCLUSION

By conducting empirical analyses in two stages,this research demonstrates that IT leverages the benefits of diversification (Figure 1). Based on the findings obtained from several two-staged empirical analyses, this research shows that IT improves firm performance when firms place emphasis on related, rather than unrelated, diversification. In other words, IT complements the strategic decision to focus on related diversification.

Replications and extensions can contribute to the accumulation of knowledge, and it is critical for the development of a discipline (Benbasat & Zmud, 1999; Berthon, Pitt, Ewing, & Carr, 2002; Santhanam & Hartono, 2003). This research contributes to the stream of IT business value research by extending previous IS studies by conducting several empirical analyses to explore: (1) the relationship between IT and diversification by employing multiple measures of diversification and (2) the impact of IT and diversification on firm performance as measured by Tobin's q, gross margin, revenue per employee, and ROA. Another contribution of this research is that it shows the mechanism of how firm performance is improved by IT and diversification by illustrating the directional effect of the two. The insignificant estimates of strategic direction in the performance analysis (Figure 1) indicate that on average technology-driven business strategy (diversification led by IT investments) has little performance impact, while business-driven technology investment has a significant performance impact. The results imply that our business strategy must guide our decisions on technology investment, not the other way around. However, the high standard errors of the estimates also indicate that some firms are obtaining a significant value from technology-driven business strategy, while others are not. This variation could be of significant interest for future research, for example, how to make technology-driven business strategy more successful.

Companies invest in IT to execute their strategies successfully, thereby creating value. In today's turbulent and fast changing global business environments, companies can create new market opportunities across national borders by developing new products or by finding new customer segments. IT is a critical strategic resource to help companies pursue these new market opportunities with low additional coordination and collaboration costs. By providing a better means of sharing information and coordinating business resources, such as supply chains, distribution channels, marketing expertise, managerial and technical expertise, market information, and other tangible and intangible resources, IT can enable scope economies and efficient utilization of business resources across multiple markets. However, when companies pursue diversification, they should be cautious not to lose their strategic focus and ensure that the new market opportunities do not impair their core strategic position.

Figure 1. Findings on IT, strategic direction, and firm performance



Note: RD (Entropy Related Diversification); URD (Entropy Unrelated Diversification); GM (Gross Margin); RPE (Revenue per Employee)

This research is not free from limitations: One limitation is that it does not consider all the factors that influence firm performance. Thus, as discussed earlier, there is considerable variance in the dependent variable (firm performance) left to be explained. However, since the focus of this research is on diversification and how it is related to IT performance, we would leave the elucidation of the unexplained variance of firm performance to future research.

ENDNOTES

[1] The Entropy index of total diversification is a weighted average of the sales shares of the different four-digit SIC code industries, where the weight for each industry is the logarithm of the inverse of its share. The Entropy index of related diversification (RD) measures the extent of diversification arising from operations in several industries of the same two-digit SIC code industry group. The Entropy index of unrelated diversification (URD) measures the extent of diversification arising from extending operations into different two-digit SIC code industries. It follows that total diversification is equal to the sum of RD and URD. Unlike the Entropy index, the Concentric and Herfindahl indexes do not distinguish between related and unrelated diversification. The concentric index measures the degree of distance or relatedness between industries. Weights are given based on industry sales shares. This value depends on the relations between the industries. On the other hand, the Herfindahl index measures industry concentration. This index is defined as one minus the sum of squared shares of a firm's activities in different industries (Dewan et al., 1998; Shin, 2006).

[2] We take a one-year and a two-year lag structure based on previous IS research (Brynjolfsson, Malone, Gurbaxani, & Kambil, 1994), which shows that the impact of IT is not fully realized immediately and is greatest after a lag of one to two years. We analyze with a one-year and two-year lag separately because they are highly correlated.

[3] Dewan et al. (1998) used a data set from 1988 through 1992, and Hitt (1999) used a data set from 1987 through 1994.

[4] The interaction between an independent variable in the model and a variable that has been left out often causes the problem of heteroscedasticity—the error term in a regression model does not have constant variance (Berry & Feldman, 1985). Heteroscedasticity does not influence the bias of regression coefficients, but it can bias the estimation of standard errors.

ABSTRACT

An accelerated scientific, engineering, and industrial progress in information technologies has fostered the deployment of Complex Information Technology (highly dependent) Organizational Systems (CITOS). The benefits have been so strong that CITOS have proliferated in a variety of large and midsized organizations to support various generic intra-organizational processes and inter-organizational activities. But their systems engineering, management, and research complexity have been substantially raised in the last decade, and the CITOS realization is presenting new technical, organizational, management, and research challenges. In this article, we use a conceptual research method to review the engineering, management, and research complexity issues raised for CITOS, and develop the rationality of the following propositions: P1: a plausible response to cope with CITOS is an interdisciplinary engineering and management body of knowledge; and P2: such a realization is plausible through the incorporation of foundations, principles, methods, tools, and best practices from the systems approach by way of systems engineering and software engineering disciplines. Discussion of first benefits, critical barriers, and effectiveness measures to reach this academic proposal are presented.

Businesses no longer merely depend on information systems. In an increasing number of enterprises, the systems are the business. (R. Hunter & M. Blosch, Gartner Group, 2003)

INTRODUCTION

An accelerated scientific, engineering, and industrial progress in information technologies and its convergence with communications technologies (the ICT concept) has fostered the deployment of Complex Information Technology (highly dependent) Organizational Systems (CITOS) in the last decade. The CITOS concept subsumes the well-known constructs of *mission-critical systems*, *large-scale information systems, enterprise information systems*, and *inter-organizational information systems.* Generic instances of CITOS are worldwide credit card systems, brokerage financial systems, military defense systems, large ERPs, governmental tax payment systems, and worldwide e-commerce and B2B supply-chain systems in automotive and publishing industries.

Empirical evidence, such as (a) the raising of the ICT budget (measured as a percentage of sales) to 5%-9% in the 2000s (Prewitt & Cosgrove, 2006); (b) the growing of world ICT trade from 8% in 1995 to 10% in 2001 with a 4% annual growth rate (OECD, 2004); (c) the IT commoditization or democratization phenomenon being more affordable the ICT infrastructure in midsized firms in the 1990s (Carr, 2003); (d) the maturing of the myriad of ICT in the last decade (e.g., mobile computing, wireless networks, Web services, grid computing, and virtualization services); (e) the new ways for performing business-oriented operational, tactical, and strategic organizational duties through ICT (e.g., workflow systems, business process management, and service-oriented management); (f) the several tangible and intangible organizational benefits from intra-organizational processes (as in Porter's value-chain activities) and inter-organizational activities (supplier-customer value chains, B2B, and e-government initiatives) leveraged by CITOS; and (g) the thousands of US dollars lost due to availability, continuity, and capacity failures in ICT services (van Bon, Pieper, & van deer Veen, 2006) because of an hour of system downtime. These factors and others show that CITOS are relevant for business and government organizations (as well as for nonprofit organizations).

Such systems are characterized by having (1) many heterogeneous ICT (client and server hardware, operating systems, middleware, network and telecommunication equipment, and business systems applications) (2) a large variety of specialized human resources for their engineering, management, and operation; (3) a worldwide scope; (4) geographically distributed operational and managerial users; (5) core business processes supported; (6) a huge financial budget for organizational deployment; and (7) a critical interdependence on ICT. Thus, these can be correctly labeled as "complex systems" (comprised of a large variety of components and inter-relationships in multiple scales generating unexpected emergent behaviors).

According to a systemic definition, the emergent properties from a system cannot be attributed to the individual actions performed from parts. Rather the interactions among people, machines, applications, procedures, data, policies, and the organizational setting and organizational environment are responsible for their coproduction. Consequently, and because of its raised engineering and management complexity, a holistic study of human and machine component inter-relationships and of its environment is needed when the efficiency and effectiveness of CITOS are considered. It could be expected that the current IS body of knowledge (IS BoK) addresses such issues. Nevertheless, because of the ICT technological progress, combined with the extended capabilities of CITOS services demanded in large organizations (Dougmore, 2006), have raised significantly the systems engineering, management, and research complexity for users, managers, engineers, and researchers, our premise is such a current IS BoK is insufficient and an extended (interdisciplinary) IS BoK is required.

According to the international expert in complex systems Bar-Yam (2003b), to design organizational complex systems, we must recognize that "the networked information system that is being developed, serves as part of the human socio-economic-technological system. Various parts of this system that include human beings and information systems, and the system as a whole, is a functional system" (p. 17). Also "the recognition that human beings and information technology are working together as an integrated system" (p. 25) should be an imperative consideration for its design. From a service oriented management and engineering perspective (Chesbrough & Spohrer, 2006), Dermikan and Goul (2006) suggest a similar finding:

> *A transdisciplinary education program needs to be developed by utilizing organizational sociology, law, services marketing, business strategy and operations, accounting and finance, information technology, and industrial and computer engineering to provide the knowledge necessary to equip new graduates to lead this culture change.* (p. 12)

Because the current typical IS graduate curriculum lacks most systems approach foundations and contains few, if any, truly systems perspective courses (e.g., most IS development methods do not use a well-defined systems perspective (Alter, 2007; Avison, Wood-Harper, Vidgen, & Wood, 1998; Checkland & Holwell, 1995)), we hypothesize (**H1**) that a deep "system" view has been scarcely deployed in the graduate IS curriculum. We also hypothesize (**H2**) that an IS holistic view is better able than a partial view to cope with the new technical and organizational complexity that large organizations show. Feigenbaum[1] (1968) foresaw similar ideas by identifying a partial using of the systems approach in the IS discipline. His perspective, a well-defined systemic view where man-machine systems are combined (with new roles such as CSD (chief systems designer), CSMO (chief systems manager officer), CBPO (chief business process officer), and CBAO (chief business architect officer)) and their inter-relationships with their environment are considered, offers an initial effort toward a holistic view of the firm and the information systems deployed.

To test **H1** and **H2** is the long-term aim of the research stream fostered by IJITSA. In this article, we focus on a more limited but still useful purpose: to develop the rationality of two conceptual propositions relevant for the progress of the information systems discipline, and outline plausible courses of action. **Proposition P1** (**the interdisciplinary IS BoK proposition**) argues that an interdisciplinary body of knowledge is called for in information systems because of the rising systems engineering, management, and research complexity of the emergent complex information technology-intensive organizational systems (CITOS). **Proposition P2** (**the systems approach foundation proposition**) poses that **P1** is plausible through incorporating foundations, principles, methods, tools, and best practices from the systems approach by way of systems engineering and software engineering disciplines.

To support **P1** and **P2**, we use a conceptual research approach (Glass, Ramesh, & Vessey, 2004) with a descriptive and evaluative purpose. A similar scheme is used by Goul, Henderson, and Tonge (1992) in the domain of artificial intelligence (AI). The units of study are abstract elements (BoK of SE, BoK of SwE, and BoK of IS). This article is structured as follows: first, we identify the emergent engineering, managerial, and research challenges raised by CITOS. Second, we compare the underlying foundations (core definitions, disciplines of reference, teaching themes, and research methods) of information systems and of the two most emergent related disciplines (software engineering and systems engineering) that are considered essential to address such rising complexity in CITOS, and report the knowledge gaps. Third, we discuss its benefits, the hard and soft barriers to deployment, and its effectiveness measures.

THE INCREASING ENGINEERING, MANAGEMENT/BEHAVIORAL, AND RESEARCH COMPLEXITY DEMANDED BY CITOS

Conventional systems are characterized by being architecturally and functionally cohesive (they have low heterogeneity, low dispersion, low autonomy of their parts, low functional variety, and manageable functional scalability) and for being highly predictable. The classic software engineering (SE), software engineering (SwE), and IS disciplines have largely provided the adequate knowledge to design, build, and deploy conventional systems efficiently in organizations. When these systems (originally planned as conventional well-controlled physical entities with core software and hardware components), are combined with intensive human-activity systems and telecommunications components from multiples sources, as is characteristic of CITOS, the systems exhibit characteristics of complex systems: *many components, rich interactions and loose coupling among the components, the system evolves, system characteristics emerge over time, and the system pursues a mixture of component goals and system goals* (Frank, 2001; Jackson, 1991; Keating, Rogers, Unal, Dryer, Sousa-Poza, Safford, et al., 2003). Thus, an engineering complexity (manifested as many alternative designs, components, assembly procedures, equipments, tools/languages, and standards available for their realization and operation) and a behavioral and management complexity (manifested as unexpected interactions and emergent behaviors during their project management and deployment phases that might lead to critical failures and the user demand for enhanced system capabilities and functionalities) are introduced in such systems.

The Engineering Complexity of CITOS

The *complex systems* concept has long been present in the systems approach. Von Bertalanffy (1972) reports that “modern technology and society have become so complex that traditional branches of technology are no longer sufficient; approaches of a holistic or systems, or generalist and interdisciplinary, nature became necessary” (p. 420). The software engineering (Glass, 1998) and systems engineering (Bar-Yam, 2003a, 2003b) domains have also been concerned with the engineering complexity of *complex systems* (Shenhar & Bonen, 1997).

A main effect of the engineering complexity of systems is a “system failure.” In the SE domain, failures occur during the operation of the system but also those taking place during the various development stages. A system failure, as distinguished from a local component-based failure, is a failure expressed in degrading system performance. The symptom of failure is seen or measured but its source is not clear. A “system problem" refers to another scenario. An example of a system problem is a user expressing dissatisfaction with the system because of unanticipated environmental changes. System problems and failures, in a most basic systemic perspective, are not single events but a messy system of problems (Ackoff, 1981). Sources of system problems come from the conflicts raised from the interactions between the system, subsystems, and suprasystem to reach their objectives and from changes in such objectives (Ackoff, 1976).

New concepts have been developed in the SE and SwE domains to cope with engineering complexity. In the case of SE, a few of the concepts are *system of systems* (SoS) (Keating et al., 2003), *federation of systems* (FoS) (Sage & Cuppan, 2001), and *complex system* (Mage & de Weck, 2004). A SoS exists if (1) its component systems have well-substantiated purposes even if detached; (2) its component systems are managed for their own purposes; (3) its component systems, functionalities, and behaviors can be added or removed during its use; and (4) it shows emergent behavior not achievable by the component systems acting independently (at least one emergent property must be present to be considered a system). When SoS are human-activity intensive, these become a FoS (Sage & Cuppan, 2001). SoS and FoS are comprised of component systems that individually provide user-oriented functionalities and for the whole system. Each SoS and FoS are implicitly complex *systems* but not the converse. Because of the ambiguity and uncertainty in SoS, the strong interaction of the SoS and its context, and the limitations for deploying partial solutions the classic SE for single-complex systems must be updated (Keating et al., 2003). A true *systemic worldview* (our philosophy), conceptualized as "a way to thinking, deciding, acting, and interpreting what is done and how it is done" (p. 44), as well as an action-research orientation that links theory building and theory testing, are the main updates suggested. Because SoS and FoS architectures are found in CITOS, these concepts cannot be omitted in an interdisciplinary IS BoK.

Complex systems can be classified to avoid inadequate deployment of engineering and management processes. Shenhar and Bonen (1997) derived a 4x3 matrix of instances of systems based on uncertain technological and system scope dimensions. Mage and de Weck (2004) developed a more detailed classification (also based on the Theory of Systems) of a 5x4 matrix of operators (transformation/process, distribution/transport, store/house, trade/exchange, and regulate/control) and operands (matter, energy, information, and value). Natural, noncomplex artificial, and complex (artificial) engineering systems are also differentiated by the authors. Noncomplex artificial systems have either technical or social complexity. Complex engineering systems have both. Similar to other studies, a complex system is defined as a system "with numerous components and interconnections, interactions or interdependencies that are difficult to describe, understand, predict, manage, design, and/or change" (p. 2). The engineering (and management) of CITOS can be based on these classifications. Other studies have also complemented such concepts to update the classic SE view (Calvano & John, 2004; Cleary, 2005; Franke, 2001).

In the software engineering discipline, concepts such as software-intensive systems (Andriole & Freeman, 1993; Boehm, 2000), sociotechnical software-intensive systems (Sommerville, 1998), and software-intensive systems of systems (Boehm, 2006; Boehm & Lane, 2006) are examples of research efforts for addressing the engineering complexity issue associated with CITOS from an information systems perspective.

For Andriole and Freeman (1993), the best engineering strategy to address engineering complexity involves unifying the SE and SwE disciplines. These authors argue (1993) that:

> *Our working premise is simple: software-intensive systems (regardless of their application domains) are among the most important, yet hardest to create and maintain artifacts of modern society. Thirty*

> *years ago, there were few large-scale software-intensive systems. Today they pervade the public and private sectors.*(p. 165)

Thus, as "both disciplines address the same subject, the creation of complex software-intensive systems, albeit from different perspectives" (p. 165), they pose a unified software systems engineering. A similar rationality is argued by Boehm (2000): "A unified culture of systems and software engineering can tame the rapid changes in information technology" (p. 114). For Boehm, "organizations can change from slow, reactive, adversarial, separated software and systems engineering processes to unified, concurrent processes. These processes better suit rapid development of dynamically changing software-intensive systems involving COTS, agent, Web, multimedia, and Internet technology" (p. 114). A software-intensive system of systems (SISOS) concept and other core trends for the mutual interaction of SwE and SE disciplines are also proposed in a later study (Boehm, 2006). The rationale for improving the SwE acquisition process in the new scenario of SISOS is expanded in Boehm and Lane (2006). For Sommerville (1998), engineering complexity is manifested through the sociotechnical software-intensive systems. These systems can be described as:

> *Systems where some of the components are software-controlled computers and which are used by people to support some kind of business or operational process …. [Such] systems, therefore, always include computer hardware, software which may be specially designed or bought-in as off-the-shelf packages, policies and procedures and people who may be end-users and producers/consumers of information used by the system …. Socio-technical systems normally operate in a "systems-rich" environment where different systems are used to support a range of different processes.* (p. 115)

Somerville argues that SE foundations are needed in SwE programs because a computer science approach is reductionistic and isolates students from the organizational and human-based complexities in developing large-scale software development. The SE discipline contributes to improve the engineering rigor of SwE practices. This enhanced curriculum then revalues the SwE methods and tools and incorporates well-tested management engineering approaches.

In the domain of information systems, most studies have been focused on behavioral and managerial perspectives (Hevner, March, Park, & Ram, 2004), rather than engineering complexity issues. A seminal study (Nunamaker, Chen, & Purdin, 1991) introduced the system development process, from the engineering and software engineering disciplines, as a research method for IS to be used jointly with theoretical, observational, and experimental research. But the proposal is focused in the study of the final artifacts rather than in the study of the engineering and design methods to cope with CITOS. Consequently, behavioral-oriented research is ultimately stressed, and the development engineering process is offered as a mediator rather than a primary research goal.

Other authors (Hevner & March, 2003; Hevner et al., 2004; March & Smith, 1995), using the core foundations for a design science established by Herbert A. Simon (1969), have formulated a design research paradigm in information systems, one different from a routine design paradigm based in the application of the existent knowledge for building an artifact. A theoretical framework that justifies behavioral (called *natural*) and design dimensions to study IT in organizations is reported by March and Smith (1995). The behavior (*natural*) dimension accounts for the formulation and testing (justifying) of theories about how and why IT works or does not work in an organizational setting. In the design dimension, the building and evaluation of IT artifacts are conducted. These authors classify IT artifacts (e.g., the research products) as constructs, models, methods, and instantiations. Hevner and March (2003) and Hevner et al. (2004) extend the study proposing design principles and research validation methods for the IS domain. They assert that the design issue is a core topic in the engineering discipline, but it has been rarely explored in the IS domain (the design references used by these authors come from the computer science, software engineering, artificial intelligence, and political science domains). Complexity and wicked problem concepts (Rittel & Weber, 1973) are also described by these authors. From a systems approach, a similar construct: messes as a system of problems, has also been defined (Ackoff, 1973).

These few studies, then, contribute directly to the IS domain introducing the engineering complexity issue of CITOS. Paradoxically, despite some SE literature reports that the incremental deployment of IT is generating SoS (Carlock & Fenton, 2001; Keating et al., 2003), CITOS as SoS are still not studied in the IS domain.

The Management and Behavioral Complexity of CITOS

According to Sterman (2001), managerial complexity is of two types: combinatorial or dynamic. Relevant for the IS domain is that combinatorial managerial complexity is most perceived by organizational managers but dynamic managerial complexity affects them more. As Sterman (2001) indicates:

> *Most people think of complexity in terms of the number of components in a system or the number of possibilities one must consider in making a decision. The problem of optimally scheduling an airline's flights and crews is highly complex, but the complexity lies in finding the best solution out of an astronomical number of possibilities. Such problems have high levels of combinatorial complexity. However, most cases of policy resistance arise from dynamic complexity—the often counterintuitive behavior of complex systems that arises from the interactions of the agents over time. Dynamic complexity can arise even in simple systems with low combinatorial complexity.* (p. 11)

This resistance (often occurring as a delay by decision makers to make critical managerial choices regarding courses of action and to intervene in critical situations) happens because complex side effects are generated in messy organizational systems. These complex organizational systems, characterized by an underlying structure of mechanisms that is highly coupled, dynamic, adaptive, self-organizing, and with emergent counterintuitive behaviors (Sterman, 2001), demand at least a similar complex systemic solution as the controller system (Bar-Yam, 2003b).

In the domain of information systems, the management complexity is manifested in failed IT projects (CIO UK Web site, 2007; Standish Group, 2003). Failed IT projects are defined as projects where there are cost over-runs, large schedule delays, incomplete delivery of systems, system underutiliztion, or cancellations before completion or early system disposal (Ewusi-Mensah, 1997; Wallace & Keil, 2004). A common issue reported in such studies is the critical influence of management inadequacies during the implementation life cycle. Management complexity is important for CITOS deployment because an information system comprises technology, procedures, data, software, and people. Moreover, the technical, socio-economical, and political-cultural components of the CITOS environment are factors whose influences must be identified for reaching a successful system deployment (Gelman, Mora, Forgionne, & Cervantes, 2005; Mora, Gelman, Cervantes, Mejia, & Weitzenfeld, 2003). This view is supported by a vast literature on IS implementation research (Kwon & Zmud, 1987). A holistic view of the phenomenon, then, requires the inclusion of managerial complexity and interactions with engineering complexity. Efficiency and efficacy engineering project success metrics (on time project completion, on budget, and with a high percentage of expected requirements delivered) must be complemented with system effectiveness metrics (associated to managerial complexity) to manage CITOS projects.

In the SE domain, managerial complexity is manifested when large-scale but simple systems become a SoS and when the usual technical, operational, economical, and political (TOEP) feasibility priority order shifts to a political, economical, operational, and technical (PEOT) order (Carlock & Fenton, 2001). Then, "seamless interoperability and acceptable performance to all users at an acceptable cost are the most important priorities" (Carlock & Fenton, 2001, p. 245). Managerial complexity can be addressed through enterprise systems engineering (a natural extension of SE) for an updated and adequate engineering management of SoS development or procurement. In a SoS, each system component is also conceptualized as a system comprised of hardware, software, facilities, procedures, and people. Such a whole SoS operating is linked to needed support systems. Facilities and support systems have usually been ignored in the IS literature. An exception is the "SERVQUAL" concept to measure IS service quality. Management complexity of SoS is then addressed through an extended management SE life cycle involving strategic, project management (midlevel), and implementation/operational levels. Recent evidence of managerial complexity issues manifested in large-scale software systems projects and solved through a SE enhancement is reported in Hole, Verma, Jain, Vitale, and Popick (2005). Critical deficiencies in the older SwE methodology are identified as follows:

> *In its existing state (pre-SE&A) this framework did not address requirements, architecture development, integration, and verification as part of a coherent Systems Engineering methodology. Existing descriptions of these SE&A practices were general and open to interpretations, and often "hidden" in broader activities and work products.* (Hole, Verma, Jain, Vitale, & Popick, 2005, p. 80)

Enhancements, such as project mission awareness over the traditional project objectives, non-negotiable mission-critical requirements, better requirements traceability activities, project manager and lead systems engineer roles, disciplined change impact analysis, and tangible scored reviews (also generated independently in the SwE domain but rarely used in the IS domain), are reported as contributions from the SE domain. IT and IS architecture views of the full enterprise, such as Zachman's Framework (Sowa & Zachman, 1992; Zachman, 1987), have received little attention in the IS domain.

The complexity behavioral dimension in the management of large-scale projects has been reported also in the SwE domain (Curtis, Krasner, & Iscoe, 1988). An implicit holistic multilayer model (business, company, project, team, and individual milieus) is used to study the behavioral interactions in the system. Findings suggest that large-scale software development demands that the learning, negotiation, communication, and customer interactions activities (that are not usually considered in SwE management projects) be accommodated explicitly in the process.

The Research Complexity of CITOS

Because CITOS is concerned with engineering and managerial/behavioral complexity, a research complexity inherently appears when CITOS are investigated. Comprehensive IS research frameworks that recognize behavioral and engineering perspectives are recent (Hevner & March, 2003; Hevner et al., 2004; March & Smith, 1995). As noted earlier, much research in the IS discipline dilutes IT artifacts and consequently their engineering characteristics or when focused on the computational view, this ignores the behavioral issues (Orlikowski & Iacono, 2001). CITOS' complexity demands mutual research interaction from both sides.

A comprehensive IS research framework (Mora, Gelman, Forgionne, Petkov, & Cano, 2007a) uses a critical realism stance (Bhaskar, 1975) and a multimethodology research worldview (rationalized by Mingers, 2000, 2001, 2002), to frame some core ideas of the Theory of Systems (Ackoff, 1971; Gelman & Garcia, 1989; Mora et al., 2003), as a proposal to accommodate the disparate and conflicting research stances (positivist, interpretative, and critical). Four postulates are articulated in Mora et al. (2007a) to frame such disparate philosophical stances. Postulate P4 posed as integrator and underpinned in critical realism says that:

> *The world is intelligible for human beings because of its stratified hierarchy of organized complexities—the widest container is the real domain that comprises a multi-strata of natural, man-made and social structures as well as of event-generative processes that are manifested in the actual domain that in turn contains to the empirical domain where the generated events can or cannot be detected.* (p. 3)

For Bhaskar (1975), reality is independent of human beings: "a law-governed world independently of man" (p. 26), but the social structures and their generative mechanisms are conditioned to the existence of human beings at first and then these really exist and can be studied and intervened. Bhaskar also explains that "it is not the character of science that imposes a determinate pattern or order in the world; but the order of the world that, under certain determinate conditions, makes possible the cluster of activities we call science" (p. 30). Accordingly to Mingers (2002):

> *CR (critical realism) recognizes the existence of a variety of objects of knowledge—material, conceptual, social, psychological—each of which requires different research methods to come to understand them. And, CR emphasizes the holistic interaction of these different objects. Thus it is to be expected that understanding in any particular situation will require a variety of research methods both extensive and intensive.* (p. 302)

Other IS frameworks and models based on the Theory of Systems as the most adequate models to cope with the complexities faced by IS practitioners and academicians have been reported (Alter, 2001, 2003, 2007; Bacon & Fitzergarld, 2001; Ives, Hamilton, & Davis, 1980; Nolan & Whetherbe, 1980). Such IS systemic research frameworks are usually ignored in IS research, which is still guided by a reductionistic view.

Thus, there is an extensive granularity manifested by a vast array of IS relevant topics, but the topics are disconnected as a whole. An IS body of knowledge from an accumulation research tradition is missing. A plausible reason, according to Mora, Gelman, Cano, Cervantes, and Forgionne (2006a) and Mora et al. (2007a), is that the holistic view of the IS discipline has been lost from its original conceptualization in the 1960s. Consequently, research topics appear disconnected from a general standardized research framework (as SE and SwE have through a BoK).

These large unconnected research topics, the infrequently-used underlying microtheories, the broad background of IS researchers, the lack of finding accumulation, and the engineering and managerial richness of the phenomena involved are also manifestations of research complexity in the IS domain.

Consequences and Initial Interdisciplinary Efforts for CITOS Complexity

Table 1 summarizes the new engineering, managerial, and research challenges faced by practitioners and researchers in CITOS (and from the software engineering and systems engineering disciplines oriented to CITOS).

Such challenges imply a need for human resources with the adequate competencies for the development (e.g., the engineering and research design view) and the management (e.g., the behavioral research view) of CITOS. Nevertheless, the IS curriculum literature has not addressed it enough. An OECD (2004) study, for instance, claims that most critical technical competencies in ICT must be learned directly from organizations:

> *The need for ICT skills can be satisfied in part through education and training. Full-time education does not appear to be the most important path to obtaining general and advanced skills. As schools become well equipped, however, students develop at least basic ICT skills, and ICT-related degrees can be obtained through formal education. For specialist skills, however, sector-specific training and certification schemes may be more effective, given the rapid changes in skills needs and the constant introduction of new technologies.* (p. 12)

Given such complexity, our position is that an interdisciplinary (e.g., a systemic integration of several disciplines) IS graduate curriculum is a plausible course of action that will enable practitioners and researchers to acquire a holistic view of such phenomena.

Proposals for a mutually enhanced SwE and SE curriculum (Bate, 1998; Brown & Scherer, 2000; Denno & Feeney, 2002; Hecht, 1999; Johnson & Dindo, 1998; Rhodes, 2002; Sommerville, 1998) and a new unified software systems engineering discipline (Andriole & Freeman, 1993; Boehm, 2000; Thayer, 1997, 2002) are initial efforts to cope with IT complex systems.

The SE discipline is also being fostered to extend its coverage from an enterprise level focused perspective (Farr & Buede, 2003) (taught in engineering management or industrial engineering disciplines) and to redefine its identity (Emes, Smith, & Cowper, 2001). Such expansion might enable SE to strengthen a systems view for managing the complete organization and the traditional technical processes for engineering a product or service (Arnold & Lawson, 2004; Bar-Yam, 2005; Emes et al., 2001). In particular, Bar-Yam (2005), using a trade-off design between the variety (number of different and highly-independent actions pursued by the components) and scale (number of elementary components performing the same core task) of a system, suggests an evolutionary SE to design and manage complex systems where simultaneous designs, competitive teams, and ongoing fielded and virtual tests are conducted. Other proposals argue for a new SE education focused on complex systems (Beckerman, 2000; Cleary, 2005; Franke, 2001) and the systems approach (Frank & Waks, 2001). For instance, Moti and Waks (2001) report: "technological systems grow larger, more complex, and interdisciplinary, electronics and high-technology industries face a growing demand for engineers with a capacity for systems thinking" (p. 361). These authors also suggest that the SE knowledge about domain specializations (software, computer systems, etc.) be about the (1) complexity of the system; (2) interconnections of lower and upper level systems; and (3) functional domains and constraints. In the IS domain, few similar direct or indirect arguments have been reported (Hevner et al., 2004; Mingers, 2001; Mora, Gelman, Macias, & Alvarez, 2007c). Hence, our **Proposition P1** (**the interdisciplinary IS BoK proposition**) that argues that an interdisciplinary body of knowledge is called for in information systems because of the raising of systems engineering, management, and research complexity of CITOS can be supported.

A COMPARATIVE ANALYSIS OF INFORMATION SYSTEMS, SOFTWARE ENGINEERING, AND SYSTEMS ENGINEERING DISCIPLINES

To support **Proposition P2** (**the systems approach foundation proposition**) that argues that **P1** is plausible through incorporating foundations, principles, methods, tools, and best practices from the systems approach by way of the systems engineering and software engineering disciplines, this article continues and enriches three recent reports (Mora et al., 2006a; Mora, Cervantes, Gelman, Forgionne, & Cano, 2006b; Mora, Gelman, O'Connor, Alvarez, & Macías, 2007b) and is developed under the following rationale: (1) the engineering, management, and research complexity of the issues involved with the emergent CITOS is beyond the scope of the traditional monodisciplinary and reductionistic view of IS (from proposition **P1**); (2) the IS discipline is so fragmented that it has become in disconnected islands in a knowledge sea; and (3) an interdisciplinary, systemic approach (Ackoff, 1960) provides the adequate philosophical paradigm and methodological research tool to cope with the phenomena of interest.

A historical review of the origins of the SE, IS, and SwE disciplines shows that SE is the oldest (from late 1930s) followed by IS (late 1950s), and then SwE (late 1960s). We consider SE the most mature discipline, as evidenced by the existence of large-scale projects using standardized theories, methods, and tools (Honour, 2004), followed by the IS discipline. SwE, by its separation from computer science (Denning, Comer, Gries, Mulder, Tucker, Turner, & Young, 1989) as an independent discipline, can be considered the newest and less mature area of study. Using several sources (Editorial policy statement, 2006; INCOSE, 2004; SEI, 2003) and the PQR concept (Checkland, 2000), it is possible to compare general definitions (shown in Table 2) for these disciplines. At first glance, the three disciplines study disparate systems: a well-defined physical system, a computer software system, and an IT-based organizational system.

Recent SE (Rhodes, 2002) and SwE (Boehm, 2000) literature has noted the increasing inclusion of software and IT components in current and emergent complex systems. Rhodes (2002), for instance, remarks that software is a critical component, like hardware and people, in the entire artificial organizational system developed by systems engineers. Also as mentioned earlier (Sommerville, 1998, p. 115), the SwE discipline has suggested that software systems must be considered as sociotechnical software-intensive systems. From an IS perspective, this definition of software systems corresponds to what is considered an information system (Mora et al., 2003). The SE discipline has also identified that the usual technical, operational, economical, and political (TOEP) order of priorities (Carlock & Fenton, 2001) has been changed to a political, economic, operational, and technical (PEOT) order when complex and large systems are designed. It is usually accepted that SE (Hitchins, 2003) can be deployed in different hierarchical levels: (1) the Artifact SE; (2) the Project SE; (3) the Business SE; (4) the Industry SE; and (5) the Socio-economic (environment) SE. Therefore, the increasing inclusion of software components suggests a needed interaction between SE and SwE, and between these disciplines and IS to cope with the same object of study under different systemic scales.

Table 3 updates the analysis (Mora et al., 2007c) of the relations of these disciplines with their reference disciplines. A qualitative 5-point scale from 1 (very low support) to 5 (very high support) is used to report the current support level assessed by the authors and based on the different studies reviewed (Buede, 2000; Emes et al., 2005 for SE; Glass, 2003; Sage, 2000; SWEBOK (IEEE, 2001) for SwE; and Culnan & Swason, 1986; Glass et al., 2004; Vessey, Ramesh, & Glass, 2002; for IS). A grey shading is also used in the cells to show the recommendations. Six relevant implications for an interdisciplinary IS BoK can be reported.

First, the SE and IS disciplines have been shaped by at least two basic disciplines (Industrial & Manufacturing Engineering Management Science & Operations Research for SE; Behavioral & Social Science and Business & Organizational Science for IS) while SwE has been formed from just one discipline (Computer Science). SwE has been largely considered as a research stream and body of knowledge for Computer Science (Denning et al., 1989). In the last decade, the usefulness of other reference disciplines for SE and IS (Fuggetta, 2000; Kellner, Curtis, deMarco, Kishida, Schulemberg, & Tully, 1991), has been recognized in SwE. A recommendation for the IS discipline is to lessen the variety of such interactions from a high (manifested by excessive MBA courses in the curriculum of graduate MIS programs) to a normal level of support. High-level support from multiple disciplines generates a loss of identity for the IS discipline when the IT artifacts are diluted (Orlikowski & Iacono, 2001). Given the managerial and engineering complexity shown in CITOS and their technical and sociopolitical inter-relationships with their upper and lower level systems, a holistic research approach that combines behavioral and design research approaches supported for the SE and SwE disciplines is encouraged.

Second, while systems science was a core discipline of reference for IS (Ives et al., 1980; Nolan & Wetherbe, 1980) and SE (Sage, 2000), now systems science is scarcely used in IS research. To cope with CITOS, recent proposals to re-incorporate this original foundation (Alter, 2001, 2003, 2007; Gelman et al., 2005; Lee, 2000; Mora et al., 2003, 2007a) have been reported. In the SwE discipline, there has been little evidence of such incorporation, but the recent unification efforts with SE could implicitly link SwE with systems science. Such support should be encouraged in SE and extended in IS and SwE. Third, management engineering and business process engineering, which has been typically incorporated in the SE and partly in SwE curriculum (through CMMI and ISO 15504 initiatives), has been largely ignored in IS with the exceptions of BRP, ERP process modeling, and emergent ITIL initiatives (Mora et al., 2007b). According to Farhoomand and Drury (1999, p. 16), the highest average percentage (25%) of the themes published in eight premier IS journals and the ICIS proceedings during the 1985-1996 period were from "reference disciplines" while the "information system" themes reached 14%. These authors also report that "there seems to be a shift from technical themes towards non-technical themes" (p. 17). Similarly, Orlikowski and Iacono (2001) found in 177 research articles (published in the ISR journal during the period 1990-1999) that the highest percentage (25%) of papers corresponds to a "nominal" view of IT (e.g., IT is absent). Although we accept the relevance of such domains for the IS discipline to understand the suprasystems served by CITOS, we suggest a better balance between organizational, behavioral, and social sciences and management engineering. This balance provides the IS discipline with new conceptual tools for CITOS management and engineering. Then, the server system (CITOS) and the served system (business process) are system components that are studied and designed or redesigned simultaneously.

Fourth, while the SE discipline is strengthened through the interaction of other engineering and management disciplines and permits a normal self-reference, the IS and SwE disciplines have been extensively self-referenced (Glass et al., 2004). We consider that it has had more negative than positive consequences when an imperialist and nonpluralist view of models, frameworks, and theories are encouraged. Self-reference in a domain is positive when there is an open interaction with related domains and when there is an evolutionary accumulation of knowledge rather an iterative decreasing increment of knowledge. The acceptance of qualitative and interpretative research methods was largely rejected in the IS discipline through the self-reference of repetitive specific quantitative methods. Another example is the service science engineering and management initiative (Chesbrough & Spohrer, 2006), rarely addressed in IS but incorporated in the SE and SwE domains in a seamless way.

Fifth, although IS and SwE have been outside the engineering specialties, such as electronic, electrical, and mechanical, CITOS demands at least knowledge on the foundations of such disciplines for IS researchers and practitioners to get an understanding of IT limitations. Consider, for example, developing automated vision recognition systems combined with RFID and secure mobile IT for airports, banks, or worldwide package delivering services. A CIO or research academic should be able to understand the scope, limitations, and costs of deploying such solutions and collaborating in their design (as systems engineers do). IT technical knowledge must not be diluted in IS research. Another example is the planning, design, and management of a data center where network-critical physical infrastructure (NCPI) issues include electrical power, environmental cooling, space, racks and physical infrastructure, cabling, grounding, fire protection, and other issues related to design security (Industry Report, 2005).

Sixth, while SE and SwE have mutually acknowledged the need for interaction, the IS discipline still ignores possibly beneficial interdisciplinary communications. New theoretical incorporations to the IS discipline from the design/engineering paradigm could be obtained by incorporating the systems science paradigm, including the complex systems intellectual movement.

Table 4 exhibits the BoK and general research themes derived for these disciplines. From Table 4, the first inference is that SE and SwE, by their engineering heritage, are most likely to interact in the next 25 years. The IS discipline, in contrast, seems to be unaware of the dramatic changes and challenges that world organizations are demanding due to complex sociotechnical information systems. In the cells with very low interaction (value of 1 point), more interaction is suggested to expand the body of knowledge. According to the systems approach, a system is understood only if it is studied: (1) from two perspectives (like a unitary whole and as a set of interdependent parts) and (2) within its wider system and comprising internal subsystems (Ackoff, 1971; Gelman & Garcia, 1989).

Details of the need for a systems approach in the IS discipline have already been reported (Alter, 2001, 2003, 2007; Bacon & Fitzgerald, 2001; Gelman et al., 2005; Lee, 2000; Mora et al., 2003, 2007a). A second finding from Table 4 is the lack of teaching and research of IS frameworks and standards/models of processes (e.g., CobIT, ITIL, ITSEC, and ISO 20000). The SE and SwE disciplines have developed their rigor through the development, deployment, and compliance with standards of process, but such a movement has largely been ignored in the IS discipline (Beachboard & Beard, 2005). A third finding from Table 4 is that SE has fewer missing interactions than the other two disciplines. A strong implication is that systems engineers are more holistically trained, studying and carrying out large-scale and complex systems (Frank & Waks, 2001), than software engineers and information systems practitioners (Mora et al., 2006b).

In Table 5, the research approaches used in the three disciplines are reported under the same scale. The main categories of research are adapted from Denning et al. (1999), Nunamaker et al. (1991), Hevner and March (2003), Vessey et al. (2002), and Glass et al. (2003, 2004). Theoretical, conceptual, and modeling approaches can be considered pieces of conceptual research that study concepts, constructs, frameworks, methodologies, algorithms, and systems without using data directly from real artifacts. Engineering and behavioral approaches, in contrast, are empirical research methods that take data directly for artifacts, people, or organizations. The holistic systems approach is considered a pluralist and multimethod research paradigm that uses diverse research approaches relying on the complexity of the research situation, goals, and availability of resources.

Table 5 shows that the SE research is conducted mostly through modeling, but it also uses the other research approaches in a more balanced way than the other two disciplines. According to Glass et al. (2004), theoretical/conceptual studies are more frequent than engineering studies in SwE.

For the case of IS, because of its strong historical dependence on business and organizational sciences, most studies are empirical (behavioral approach). Recent studies have argued the need for using modeling/simulation (Mora et al., 2007a) and engineering/design approaches (Hevner & March, 2003; Hevner et al., 2004; Nunamaker et al., 1991) in the IS discipline. In a similar way, other studies have suggested that SwE must conduct empirical research (Kitchenham et al., 2002) and expand the few modeling/simulation studies performed (Madachy, 1996).

Table 5 also shows a behavioral approach bias for the IS discipline, even though the table covers positive and interpretative stances. We believe that the understanding of, and the effective intervention in, single large scale and emergent CITOS demand an interdisciplinary and multimethodological research approach. Mingers (2001) has reported extensively the relevance and need of such an approach for the IS research stream through a critical realism philosophical stance (Mingers, 2002). Previous analysis for management science and operations research (highly linked to SE) has also been reported (Mingers, 2000, 2003). In this article, we support this proposal and believe that the systems approach can glue the disparate, conflicting, and still monodisciplinary views of our discipline (Mora et al., 2007a). In concordance with some SE and SwE studies, we also believe the IS behavioral approach can enhance the SE and SwE disciplines. For the IS discipline, a more balanced use of the engineering, modeling, conceptual, and formal theoretical and behavioral approaches under the holistic paradigm of the systems approach is encouraged.

DISCUSSION AND IMPLICATIONS FOR AN INTERDISCIPLINARY BoK IN INFORMATION SYSTEMS

To complete this proposal, we identify the investment resources required, the potential benefits, and the effectiveness measures for developing the aforementioned interdisciplinary IS BoK to cope with the emergent CITOS. In the investment dimension, hard and soft issues can be considered. Hard issues are the financial resources required to redesign a graduate curriculum, prepare new human resources, and deploy integrated labs for students. Under the assumption of an already existent common core engineering curriculum for SE and SwE, the challenge is the incorporation or adaptation of it to the IS domain. It is typical for academic institutions to share labs and library resources, so the new investments in better equipped and integrative labs would be a worthy investment. The virtualization and distribution of ICT resources actually can allow a large campus to share valuable ICT resources with small academic units. For instance, a small business data center lab (not a computer network lab) could be developed for training SE, SwE, and IS graduate students in different problem and solution domains. For the SE and IS disciplines, the ICT architectural planning of the data center as well as the managerial and financial operations of the ERP installed in the data center lab are adequate issues for several courses in the curriculum suggested in Table 4. For SwE students, the same lab can be useful to deploy and test service-oriented application software and middleware. An implicit benefit for SE, SwE, and IS graduate students is the interdisciplinary team interaction for solving problems under a systems approach. The investment needed will be determined by supply and demand. Regarding soft issues, the existence of such an interdisciplinary IS BoK—that should support the current IS 2006 curriculum (Gorgone, Gray, Stohr, Valacich, & Wigand, 2006)—with the SE and SwE foundations, principles, and methods also demands: (1) adjustments in the faculty power relationships; (2) the management risk of identity loss in the discipline; and (3) the compliance with national accreditation boards procedures. Soft issues, then, become the main barriers for this proposal.

The main benefits estimated from this interdisciplinary IS BoK are (1) the revaluing of the IS discipline as a core element in modern society and business organizations; (2) the update of the body of knowledge required by IS practitioners and academics to cope with the emergent CITOS; (3) the joint development under a holistic view of the rich and complex phenomenon of CITOS with the two highly related disciplines of SE and SwE; (4) the development of a shared mindset of concepts and worldviews with SE and SwE practitioners and academics; and (5) the increased supply of a new generation of IS professionals and researchers to meet growing organizational demands.

Figures of merit to evaluate the effectiveness of this proposal are the following: (1) trends of the critical failures reported in CITOS (similar to the measures reported in Standish Group (2003); (2) trends of the financial losses derived by failures in CITOS; (3) trends of the simplification and standardization of principles, foundations, and methods shared for the three disciplines used in organizations; (4) trends of the high-quality and relevant research conducted and published under the paradigm proposed in this article; and (5) trends in the enrollment of IS graduate programs under this new interdisciplinary IS BoK. Hence, we understand that this proposal is a challenge that will generate positive as well as negative reactions. However, our academic responsibility and final purpose is to strengthen the IS discipline to face the challenges of business organiztions and society. The IT artifact as an artificial symbolic processor for processing, storage, and transport data, information, and knowledge (Simon, 1999) has transformed the world. Now, the challenge for the IS discipline (Ackoff, 1967) will be to transform such IT artifacts and align them with the emergent CITOS concept.

Proposition P2 (**the systems approach foundation proposition**), that poses that **P1** is plausible through incorporating foundations, principles, methods, tools, and best practices from the systems approach by way of systems engineering and software engineering disciplines, can also be supported.

CONCLUSION

We have developed this article with the aim to improve and reposition the IS discipline to accommodate the emergence of CITOS. In this proposal, we articulate the rationale for two propositions. **P1** argues that a plausible response to cope with CITOS is an interdisciplinary IS, SE, and SwE engineering and management body of knowledge, and **P2** argues that such realization is plausible through incorporating foundations, principles, methods, tools, and best practices from the systems approach by way of the systems engineering and software engineering disciplines. We believe the evidence articulated from the comparison of the IS discipline with SE and SwE (through the structured systemic definitions, the disciplines of reference, the knowledge for research and teaching, and the main research paradigms used) supports our claim. It has also been argued that:

> *The ability of science and technology to augment human performance depends on an understanding of systems, not just components. The convergence of technologies is an essential aspect of the effort to enable functioning systems that include human beings and technology; and serve the human beings to enhance their well-being directly and indirectly through what they do, and what they do for other human beings. The recognition today that human beings function in teams, rather than as individuals, implies that technological efforts that integrate human beings across scales of tools, communication, biological and cognitive function are essential.* (Bar-Yam, 2003b, p. 1)

Thus, we believe that this position paper and the new *International Journal in Information Technology and the Systems Approach* are robust academic efforts toward this essential purpose.

The road, however, will not be an easy academic endeavor.

ACKNOWLEDGMENT

We thank the several senior colleagues that helped us with the insightful review, expertise, and wisdom in systems engineering, information systems, and software engineering, to eliminate conceptual mistakes, improve the clarity of the article, and focus on the relevant issues for IS, SE, and SwE disciplines from a systems approach.

Chapter 8.6

Strategic Technology Planning for the Techno-Global Economy:

Cities in the Market

Al D. McCready
McCready Manigold Ray & Co., Inc., USA

ABSTRACT

Indications are strong that globalization is an irresistible force, fomented by, or at the very least, enabled by technology. This chapter refers to the technology driven aspects of globalization as “techno-globalization” and describes the role of strategic technology planning in the marketing of cities in this global economy. It describes strategic technology planning for information and communication technologies and its intersection with marketing planning. It is intended to guide managers through the technology planning aspects of ICTs and city marketing. In addition to providing practical guidelines for preparing a technology plan that supports the organization’s strategic and marketing objectives, the chapter explains many of the nuances of the preparation and alignment of organizational strategic plans using current information systems and organizational theory concepts.

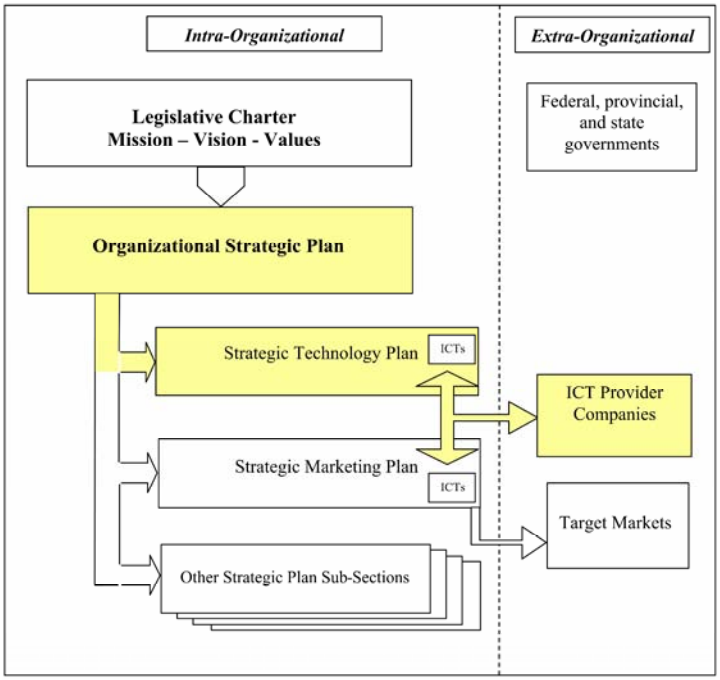
INTRODUCTION

Strategic technology planning is a specialized instance of strategic planning. Because of the particular nature of technology strategy, it embraces many elements of strategic planning, but necessarily includes technology planning considerations and technology evolution forecasting that are not normally part of standard strategic planning. Strategic technology planning can be thought of as a strategic view of the entity’s technology infrastructure and requirements that results in the identification of “best fit” technology initiatives in support of the entity’s overall strategic direction. In parallel, marketing planning takes the marketing perspective at both a strategic and tactical level. When viewed in relation to the marketing plan, the strategic technology plan moderates and supports the marketing plan at the tactical level and in its transition from a strategic perspective to a tactical focus. The chapter provides specific guidelines regarding the development and content of the strategic technology plan, but leaves the details of the actual plan preparation to each municipality's information technology governance and planning process. The chapter describes strategic technology planning, what it is, and how it properly integrates with the organizational strategic plan and peer strategic planning components.

Naturally, municipal organizations have many active plans in a multitude of areas. Some of these plans are strategic, some are financial and some are operational. The following chart, Figure 1, depicts some of the elements of the overall strategic planning process. This diagram shows the segments of the overall system of planning that are addressed by this chapter. The shaded areas are directly addressed and the areas without shading are not addressed or are mentioned only tangentially. The organizational strategic plan and the strategic technology plan are discussed. The role of strategic planning in marketing, the role of information and communication technologies (ICTs) in marketing, and the potential interactions with ICT providers are addressed.

This chapter is intended to provide useful information to people who have oversight or direct responsibility for a municipality's marketing planning and/or technology planning activities. The purpose of this chapter is to describe strategic technology planning and its intersection with ICTs, and their joint intersection with marketing planning as it relates to municipal marketing. Strategic technology planning is oriented to the specific requirements of planning technology to support the planning entity's overall strategic and tactical plans. Therefore, this chapter is a little less of a "what is" description and more of a "how to" explanation. The next sections will discuss strategic technology planning, the role of strategic technology planning in marketing planning, and, in parallel, the role of ICTs in marketing. This chapter also discusses the process of constructing the technology segment of your overall city marketing plan, and reviews certain tactical considerations related to successful implementa-

Figure 1. The overall system of planning



tion. It should be noted that, by their very nature, governmental entities are monopolies. However, when their considerations move beyond their geographic boundaries, they move from being the only one to being one of many. Planning, and specifically various types of strategic planning, is often couched in a "competitive" context. Within the monopoly, the competitive frame of reference has limited application. But outside the monopoly, in the "marketing as one of many" framework, the competitive frame of reference applies. It is from this perspective that commercial and quasi-governmental planning references are used in the following discussion.

STRATEGIC TECHNOLOGY PLANNING

The Techno-Globalization Planning Context

In many nations of the world, people are increasingly migrating into a technology laced way of being. The proliferation of Information and Communication Technology (ICT) is having an impact around the world, and the impact is not limited to the "industrialized nations" that are the usual suspects. Recent scholarly literature provides examples of the role of ICTs in many a far-flung place. Trinidad and Tobago have a national ICT plan (Warnaby & Bennison, 2006). There are examples in Mongolia (Amarsaikhan, Lkhagvasuren, Oyun, & Batchuluun, 2007; Uyanga, 2005), in Tunisia (Hulm, 2007), and the Philippines (Ramos, Nangit, Ranga, & Triñona, 2007). In his 2006 Nobel Prize acceptance speech, Muhammad Yunis (2007) describes how the success of his Grameen Bank in providing micro-credit to poor women in Bangladesh morphed into Grameen Phone. Grameen Phone, in what Yunis describes as the synergistic confluence of micro-credit and ICT, provides 300,000 women with mobile phones which they use to sell telephone services to villagers around Bangladesh.

Certainly many people in the world do not currently have access to technology. However, in many of the more industrialized nations of the world it appears to be mostly those who actively choose to avoid email and cellular phones that do not have them in their lives. For many people, the ubiquitous nature of ICTs makes them so much a part of daily life they are essentially invisible.

These contextual changes manifest themselves in international communications. The proliferation of ICTs worldwide now makes it possible to have a substantive virtually instantaneous document or data exchange with a person on the other side of the globe. This sort of instantaneous global communication is now many people's expectation. It is now of note when someone separates themselves from ICT connectedness by temporarily abandoning their technology devices or traveling to locations without connectivity. Techno-globalization is the proliferation of ICTs and the resulting information and communication exchange that has become institutionalized in much of the global society.

This institutionalization is the new personal existence paradigm for an increasing number of people. These are the digital aboriginals. There is a book (Tarlow & Tarlow, 2002) with these words in the title, but here we will use our own definition. Digital aboriginals are here defined as people who have grown up in a quasi-digital environment, and who consider solid state portable music/video players, computerized games, and handheld computing/telephone devices part of the wallpaper of their lives. These digital natives have ICT expectations that appear to exceed the capabilities of the extant ICT infrastructure and their numbers are growing throughout the world. Naturally, there really is no definitive line between digital aboriginals and those who are not. This is more of a continuum and we all exist somewhere along that scale. Furthermore, this is a multi-dimensional issue and we may be at different points on the continuum in our personal lives than in our professional lives. However, it is fair to extrapolate this line of thinking to the conclusion that increasingly, people move through their lives in a personal technological environment that might be referred to as a "techno-bubble," which is, of course, highly dependent on ICTs. A person's "techno-bubble" can be defined as that assemblage of technology that ranges from our mobile phones and mobile computing devices to automobiles with "brains" and their own mobile data connections. For many people this is the technological environment or even the techno-ecosystem in which they live, and, in many cases, move about. A question to consider is how this evolution and migration of peoples' expectations will impact geographically oriented marketing efforts.

The Planning Paradigm

Plans ranges from the very broad and high level mission statements that may be applicable over decades, down to very tactical task lists related to that day's events. There are an enormous number of documented approaches to sub-dividing and structuring every step along this planning continuum. In general, any planning that is prefaced with the word "strategic" differentiates itself by virtue of the fact that it relates more to strategy than it does to tactical or financial considerations. In different words, it relates to what are we intend to do and why are we doing it, more than it relates to exactly how we will do it or how much will it cost or how we will pay for it. The strategic planning process was explained well by Porter (1980; 1985) and has since been suitably elaborated by many other authors. When strategic planning is done in a governmental organization, public policy considerations often supplant, or at least supplement, the typical mission and purpose guidelines used in commercial strategic planning work. Naturally, this moderates the applicability of commercial sector planning approaches in governmental planning.

An interesting example of this difference is described by Davison, Wagner and Ma (2005) in their analysis of various paths that governments can take in the transition to e-government. They specifically address the somewhat pregnant pause between the adoption of web-based technologies for commercial B2B (business to business) and B2C (business to consumer) interactions and governmental adoption of the same for G2B (government to business) and G2C (government to citizen) interactions. These authors note that there usually is a significant difference between a commercial B2C website's interest in keeping the consumer on the site as long as possible and the governmental G2B or G2C website's interest in providing information or service quickly and allowing the citizen to go on their way as quickly as possible. It is a difference that is typical of the difference between commercial and governmental planning requirements. Beyond their useful explication of this differentiation, Davison, Wagner and Ma (2005) do a good job of describing the most successful paths to be taken in planning the transition from government to e-government. In a similarly insightful way Mason (2007) does a good job of using complexity theory to describe the external environment's effect on the development of strategic plans. Overall, the planning process often has multiple mediating, moderating and sometimes intervening factors that will influence the direction established by the plan. These influencing factors, in turn, are appropriately expressed in the follow-on tactical and operational plans.

Tactical plans address the implementation and operational issues, and financial plans address costs and funding issues. In order to avoid deadlocks or an excessive number of feedback cycles and iterations, many strategic plans include some high level revenue and expense projections thereby setting the direction and magnitude expected. Of course, one of the traps here is that operations oriented managers who have trouble dealing at the true strategic level will often turn a strategic planning process into a tactical or financial planning process. The balancing act of keeping the strategic planning strategic while also keeping it feasible and affordable benefits from the involvement of experienced executives whose accumulated experience helps guide the strategic with a practical and tactical perspective.

Guideline 1: *Keep the plan strategic, but include high level revenue and expense projections.*

The organization's strategic plan addresses the entire organization and properly sets the direction and overall bounds for all other organizational planning. Each significant organizational function or department could reasonably develop their own sub-strategy and prepare their own strategic plan. If a city is interested in marketing itself, for example, then a strategic marketing plan that is supportive of the direction established in the super-ordinate strategic plan is appropriate. Another area that very often warrants the development of a supporting strategic plan is information technology or information systems.

The Intersection of Strategic Planning and Strategic Technology Planning

A great deal has been written about strategic technology planning. Commercial organizations regularly prepare strategic information systems plans (SISPs) or strategic information technology plans (SITPs) as part of their strategic planning process. Information technology researchers, theoreticians and practitioners regularly write about the SISP/SITP process. From a taxonomical perspective, the scope of information systems (IS), information technology (IT), and information and communication technology (ICT) are, technically, all different, though they describe substantially overlapping domains. When these overlapping domains are raised to a strategic planning level, the differences begin to diminish. The choice between them is often driven by organizational history and the orientation of those managing the planning effort. The IS domain often includes data and processes not entirely computer systems based, where IT is usually essentially a technology oriented domain. The ICT domain is very closely aligned with the IT domain, but the term is more popular in countries other than the U.S.A. Since, at the organizational planning level, information systems, information technology, and communication technology all need to be addressed, this chapter will use the terms interchangeably in their more generic sense and abbreviate to SISP/SITP to refer to that strategic plan. The following paragraphs summarize some noteworthy thinking on these topics that is relevant to the planning process discussed in this chapter.

Malnight and Keys (2007) provide useful perspective on tuning the planning process to global change in their article entitled *Surfing the storm: Translating long-term global trends into today's decisions.* They discuss the advantages of taking a continuous and systematic approach to scanning the environment and collecting information about what it means to the organization. Applied here, their ideas indicate that there needs to be a continuous effort at gathering the relevant data, constructing shared insights, understanding the implications for the city and making appropriate decisions. This advice is particularly salient to the topic at hand given the fast paced changes in ICTs and the challenges of incorporating technology planning into the marketing planning and implementation process. It can be done. Wonglimpiyarat (2007) provides an example of how a similar process was successfully used by the country of Thailand. Wen and Shih (2006) describe how another large Asian country proactively managed strategic IT prioritization.

Guideline 2: *Make a practice of systematically and continuously scanning the environment.*

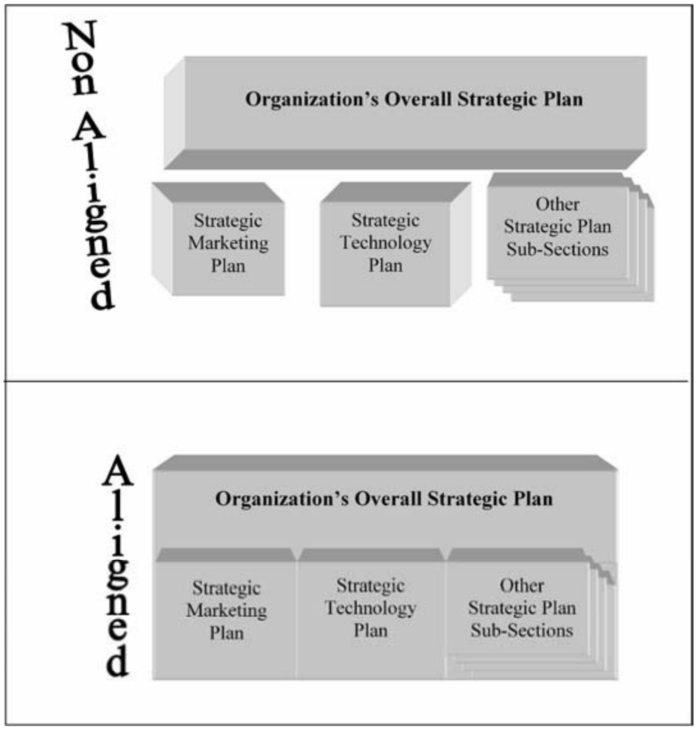
One aspect of the intersection of strategic planning and strategic systems planning is the need for alignment of technology planning with the organizational strategy. A great deal has been written about the need, and how it can be effectively accomplished. For example, in 1999 Henderson and Venkatraman wrote an excellent monograph presenting their "Strategic Alignment Model" (1999, p. 472). They parse the process into four domains, business (organizational) strategy, IT strategy, organizational infrastructure and processes, and IT infrastructure and processes. As you can see in their breakdown, organizational strategy and IT strategy are the first two essential components. They also take their alignment model to the next step and insightfully incorporate the organizational dynamics and the technology infrastructure. These second two are an important insight and are highly recommended for inclusion in the city marketing planning process.

Guideline 3: *Beyond alignment, also incorporate organizational and infrastructure considerations.*

The question of alignment is not always intuitively obvious. Even when the overall plan and various sub-parts are in place, they can have substantially different orientations. This can occur in various degrees and in some, or all, components. Figure 2 represents this concept diagrammatically. The plans need to be aligned under a single overall strategy. They need to be directionally aligned meaning that the route to achieve the organizational goals is coordinate. They need to be aligned in terms of scope; a narrow scope sub-section plan may not be out of alignment in any way other than the fact that it simply doesn't cover enough ground, or perhaps is overly ambitious. They also need to be aligned horizontally, meaning the peer-to-peer sub-sections are aligned.

Many other authors, researchers, and theoreticians have written about IT alignment. Peak and Guynes (2003) describe a successful IT alignment implementation at the Omaha Public Power District. Chan, Sabherwal and Thatcher (2006)

Figure 2. Alignment of plans



report on their research into factors affecting the IT alignment process at both business and non-profit organizations. Huang and Hu (2007) describe how to use the balanced scorecard system to achieve IT alignment. Kearns and Sabherwal (2007) present a knowledge based view of achieving IT alignment. These research articles and reports are a sampling of the broad range of available literature on IT alignment. Two observations are immediately evident. First, the need for, and benefits of, strategic technology planning alignment with the organizational plans are widely discussed and accepted as a necessary part of successful planning. Second, if your own organization has a unique need or a preferred approach, it is very likely you will be able to find specifically applicable literature to study.

It may also be helpful to note how other governmental organizations view the SISP/SITP question, and here are some examples. Thorogood, Yetton, Vlasic and Spiller (2004) describe an instance at a Southern Australian governmental organization where a public policy decision was successfully implemented through an SITP incorporating IT alignment. Another interesting example is the work by Holley, Dufner and Reed (2002; 2004) who have written two research articles. One addresses SISPs in U.S. state governments and the other addresses SISPs in county governments. Morton (2006) takes a social sciences perspective and uses critical realism to analyze IT alignment in a multi-department governmental organization.

And finally, Roge and Chakrabarty (2003) have written about their research into IT's integration with marketing strategy and operations. These authors indicate that their research shows the evolution and development of the integration or alignment of IT with marketing operations has progressed to the point that IT is now regularly integrated with marketing strategy. Taking the concept of alignment to the next logical step, we can now look at not only the vertical alignment of IT strategy with organizational strategy, but also the horizontal or peer-to-peer alignment of IT strategy with marketing strategy.

Guideline 4: *Be sure the SISP/SITP is fully aligned with the organization's strategy and the marketing strategy.*

How Strategic Technology Planning Integrates with Other Types of Planning

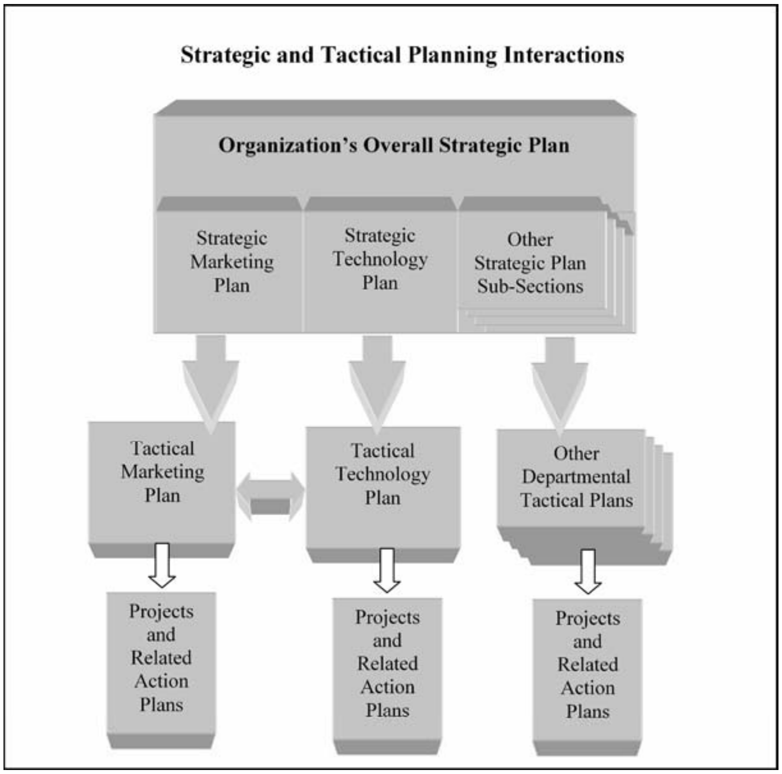
As was mentioned above, strategic technology planning is oriented to the specific requirements of planning technology in support of the overall strategic plan. One of the more challenging aspects of this process is lack of clarity, and sometimes the out-right absence (non-existence), of the overall strategic plan. The organizational strategic plan is often an emergent design, and even when brought to a firm conclusion, the best of them are immediately open to revision and improvement.

Consequently, a successful approach to strategic technology planning requires an element of simultaneous development with the overall plan and any concurrent peer-to-peer sub-section development. This process requires the technology planners to be ready to facilitate and enable the development of the grand plan. The questions asked, the ideas developed, and the documented progress can all help move forward a deficient or incomplete overall plan.

Guideline 5: *These plans are best done in a cooperative, simultaneous co-development mode.*

In addition, the technology planners must actively interact with any concurrent planning efforts, including the marketing plan development. As is depicted in Figure 3, below, there is a top level strategic planning component that defines organizational mission, purpose and overall direction. The supporting strategic plan sub-sections address strategic planning for the various major sub-sections or departments, such as the strategic marketing plan and the strategic technology plan.

Figure 3. Planning components and relationships



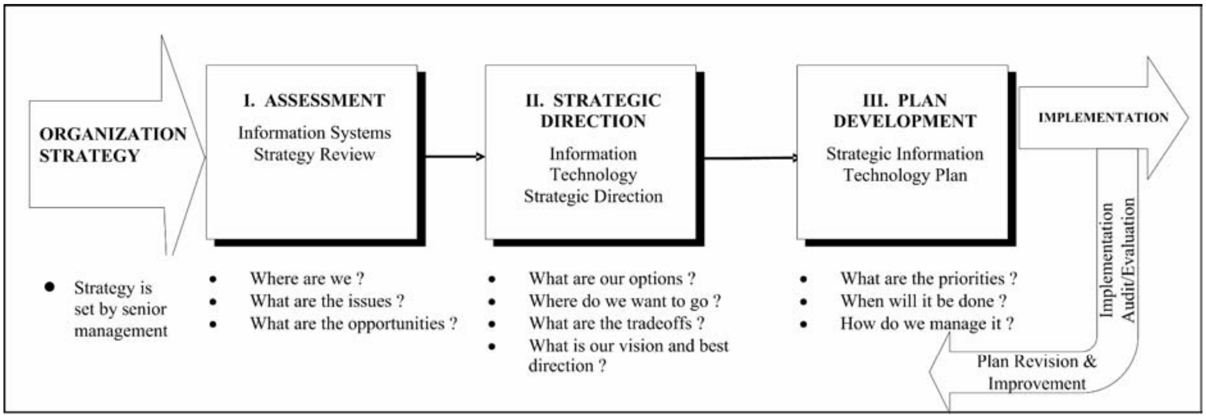
Key Elements of Strategic Technology Planning

Strategic technology plans usually incorporate the conceptual development of enterprise software, hardware, networking, and personnel plans. The plan typically includes identification of the preferred technologies, and a staged program for the acquisition, implementation, and support of various technological solutions. Technology planning also frequently incorporates consideration of external entities and their technological direction and potential for success. The reasons for this can range from a simple reliance on an external provider up to a tight lockup with a true technology partner. Unlike strategic technology planning for an enterprise with a more limited scope of activities, the strategic technology planning in support of a city, including its marketing planning can have a rather broad perspective and naturally it should address internal and external considerations of all major ICTs.

Guideline 6: *Setting the scope of the plan is very important and should receive careful consideration.*

The strategic information technology/systems planning process. Although there are many acceptable variations, the SISP/SITP processes generally have broad elements of similarity. It usually starts with an assessment that answers the question "where are we right now?" One aspect of this current assessment is the evaluation of both the state of the implemented technology and the organizational environment, including the status of the organization's strategic plan. The next phase of the planning process answers the question "where do we want to go?" This phase is typically the development of one or several systems and technology strategic initiatives that

Figure 4. The SISP/SITP planning process (© 2007 McCready Manigold Ray & Co., Inc.)



maintain alignment with the organizational strategy. The third phase, the "how will we get there?" phase is the plan development that structures the specifics and establishes priorities within the strategic direction and approach established in the second phase. The Figure 5 depicts the flow of the process.

The written plan combines the products of all three phases of the planning process. Naturally there are many variations on this planning process, but processes that do not incorporate all of these elements should be used with caution. Once the implementation process has been initiated, the quality of future planning efforts can be improved by a plan evaluation process. This process is based on the plan evaluation criteria established at the outset plus a practical ex post facto perspective. Following the principle of commensurate complexity (Thorngate, 1976; Weick, 1979), larger organizations require more detailed and complex plans, and typically will have multiple large subsections in each phase that deal with individual organizational subdivisions and major initiatives.

Guideline 7: *Establish the audit and evaluation criteria for the plan during Phase One and Two.*

The components of the plan document. Typically most SITPs or SISPs will have an outline that is reasonably similar. Once again, the size, complexity, and level of technology dependence of the organization will influence the number of sections and the complexity of the plan. An internet search for "SITP" or "SISP" or "ICT plan" will usually generate links to a few copies of governmental or quasi-governmental organizations' strategic plans. Acquiring some of these plans will provide some live examples to review and compare. Because many users of the SISP/SITP are not interested in reading all of the detail, the documents usually contain a fairly comprehensive executive or management summary.

Other key planning elements. A strategic technology plan in support of city marketing includes elements such as the technology infrastructure and governmental facilitations such as tax incentives and regulatory concessions. More specifically, a complete strategic technology planning process will address the target technological environment, the specific ICTs incorporated, the facilitating regulatory and taxation environment, the budgetary/funding strategy—including the revenue strategy, if any.

One significant point that should be brought up early in this discussion is a very real risk raised by Grenny, Maxfield and Shimberg (2007). Their research reports a problem noted by 85% of their participants in technology planning projects. It is referred to as "fact-free planning" by these researchers. In summary, it is the phenomenon of the people responsible for developing the plan acceding to the pressures and expectations of various managers and organizational stakeholders and thereby ignoring contravening facts. Based on the authors' explanations, the key to managing this risk is the ability of those conducting the planning functions to "confront, discuss and manage the phenomenon effectively" (p. 47). This point is further supported by Holley, Dufner and Reed. They make the following point: "When elected officials negotiate to set objectives, feasibility issues may not be considered fully. Setting an organizational objective without consideration of its information systems (IS) feasibility precludes SISP" (2002, p. 399).

Guideline 8: *Be alert to and attentively manage the "fact-free" planning phenomenon.*

The Connection Between Technology Planning and Marketing

The strategic technology plan and the strategic marketing plan can intersect in several ways. The marketing plan may anticipate the organization having a particular technological capability, like an internet website or an on-line system for employees to use in servicing customer/citizen requirements. If the marketing plan calls for advertising or marketing a particular technological capability to potential short term or permanent arrivals, the technology plan will need to assess the capacity and readiness of that capability if it exists, or how to put it in place if it does not.

For city marketing, where the marketing plan addresses a target market segment that is known to, or is likely to, desire or require a specific technological environment or capacity, inevitably that should become part of the technology plan. If the marketing plans target teenagers with iPod devices that play videos, then planning the capability to deliver iPod video broadcasts is important. Similarly, if the marketing plan calls for attracting a certain size or type of business that requires ICTs, planning the appropriate type and level of ICT infrastructure support is required. In a municipality, IT is a service provided to the organization. The SITP will need to be aligned with the organizational strategy in a vertical sense, and will also need to be aligned with the marketing plan from a horizontal or peer-to-peer perspective. The following section addresses that concept.

THE ROLE OF STRATEGIC TECHNOLOGY PLANNING IN MARKETING

Although Kavaratzis and Ashworth suggest that it is time to "transition from city marketing to city branding" (2006, p. 184), others appear to be looking even farther ahead. In an interesting article about technology marketing in this new era, Singer (2006) notes that "the paradigm of brand is worn out. Marketing and strategy must now be about shaping the competitive ecosystem" (p. 96). This raises a new standard that applies to the issue at hand. Through skilful representations of a city's advantages, interests, and facilities that substantially exceeds that of "competing" cities, the city marketing competitive ecosystem can evolve and be shaped to the advantage of the market leaders. The question to be addressed is that of an appropriate method to shape this particular competitive ecosystem.

Defining the Marketing Objective

The marketing objective explains the target and intentions of the marketing plan. It is a risky venture to undertake the development of a technology strategy to support an unknown or poorly defined objective. That applies to the objective and strategic direction provided by the superordinate organizational plan and the objective and strategic direction provided by peer plans like the marketing plan. This risk assessment is based on the obvious logic, recognized strategic planning theory, and the practical experience of having seen unsuccessful attempts to circumvent the inevitability of this requirement.

Guideline 9: *Be sure that the objectives of related plans have been developed and clearly set forward.*

In parallel with the strategic planning misfires mentioned above, there are times when those whose role properly includes the responsibility for planning the marketing objective don't fully understand or know what is required. When the strategic technology planner runs into that circumstance and it is exhibited as a lack of the recognition of the need for a clear marketing objective, the strategic technology planner can work to facilitate the development of enough of a marketing objective to support the strategic technology planning process. This can be done in several ways, and one successful approach is to lead others to the objective through a process of asking questions as Marquardt (2005) so effectively explains in his book *Leading with Questions*. Without a clearly defined marketing objective that has been properly vetted within the organization, the strategic technology planner is substantially constrained in producing a successful technology plan to support the marketing effort. In short, the marketing objective is a necessary, but not sufficient, condition for a successful technology plan.

Guideline 10: *The technology planners should support other organizational strategic planning teams in developing actionable objective statements.*

Assessing Strengths and Weaknesses

With an understanding of the marketing objective in hand, the strategic technology planner can move through a traditional strategic planning strengths and weaknesses analysis of the organization and the region's technological position relative to the marketing objective. If these concepts are a little rusty or perhaps somewhat new to the reader, a good place to start are the well-known books on the topic written by Porter (1980; 1985). In a subsequent section we'll describe the more tactical process of creating the ICT inventory and the related evaluation and planning. This assessment process is a review of the entity's general ICT strengths and weaknesses. Naturally it is important that this strength and weakness assessment be honest, without any boosterism. The extant weaknesses are not necessarily a liability, simply a fact that should be acknowledged and dealt with in the strategic technology planning process. As is often the case, properly identifying a problem here is some substantial part of the solution.

Technological Market Positioning

An important issue is how to position your organization from a technological perspective. For example, a city trying to attract technology businesses could promote both the availability of ICT infrastructure and the potential employees being trained by the city's educational system. If a marketing objective is to attract conventions and trade shows, having a convention center with a high capacity wireless network installed and ready for use can be a significant support. In instances like these the role of strategic technology planning is, obviously, to map out the ICT strategy to support the strategic marketing objective.

Another part of the marketing research the technology strategist will need to undertake is to develop an understanding of the technologies being offered or marketed by the likely municipal competitors. It is rare for a city to have such a unique offering to market that no competition exists. In this era of techno-globalization, the competition may be much more geographically distant than was historically the case. Outsourcing has crystallized many people's understanding of how a city a great distance away can be a viable competitor.

The strategic technologist's contribution to the development of the city marketing plan can be substantial. In the ideal situation, the overall strategic plan is completed first and then the marketing plan and the strategic technology plan are completed concomitantly and in concert. Most likely this will be done in an iterative fashion, as the two plans are taken to increasing levels of detail. In the implementation of this cooperative, iterative approach, the relevant sections of the draft marketing plan are provided to the IT planners who do the necessary data collection and evaluation. The IT planners, in turn, provide the marketing planners with their assessments that provide an initial reading on technical feasibility and perhaps order-of-magnitude costs. It certainly is possible to have a completed marketing plan, and then to undertake the supporting strategic technology planning process. However, experience indicates that the marketing plan will be richer as a result of an interactive process, and it is more likely to avoid revision detours generated by technology roadblocks. These occur when the technology required to support a marketing concept turns out to be unavailable, impossibly expensive, or otherwise untenable.

Guideline 11: *Ideally, the SISP/SITP and the marketing plan are developed cooperatively and iteratively.*

In this collaborative, iterative process, the technology planner will benefit from the creative and expansive thinking of a good marketing planning person or group. The inspiration generated can lead the technology planner to new insights into the marketing/branding process and perhaps contribute to "shaping the competitive ecosystem" as Singer suggests (2006, p. 96). Of course the same benefits can apply in the reverse direction when the channels of dialog are open and flowing. An exceptional job of market positioning can create new competitive dynamics in a world where strong and early market position can translate into competitive advantage. As was noted earlier, this is not necessarily based on unique capabilities, simply on unique marketing. However, when the marketing program lays claim to a capability, the capacity to deliver on that promise is essential in order to maintain both organizational credibility and any advantage gained. This next section discusses the role of strategic technology planning in setting forward the implementation framework.

Framing the Structure for Implementation

There is a reasonable possibility that the marketing objective and/or marketing plan will not explicitly call out specific technologies. It is entirely possible it will be a generic requirement. The strategic technology planners serve best when they apply their knowledge of the technological environment and offer up the leading alternatives with their advantages and disadvantages.

For example, if, as in our earlier hypothetical, the concept of a wireless network in a convention center is in play for attracting convention business, it would be the technology planner's role to provide the advantages and disadvantages of an quasi-open network with limits on internet browsing and email attachments, versus a fully open network free to everyone within range of its signal. The technology planner might contrast these to other options such as an array of "hotspots" or even a "walled garden" solution. Hotspots are small area open networks of the type common in the technological market positioning of some coffee shops. Walled garden networks are those that apply strict limits to the websites and content permitted on the network. These are common at kiosks and at public terminals in some hotels and airports. The user may be accessing the sponsor's selected website(s) via the internet, but is not able to get over the wall to the rest of the internet world.

All of these are viable options for our hypothetical convention center wireless network market positioning example. All of these options can reasonably be implemented, and the decision most properly is not left to the technology planner. When the marketing function eschews this sort of evaluation and interaction as "too technical" or not essential, the organization misses an opportunity to obtain significant advantage. Without input, the technology planner makes the decisions based on technology factors and/or their intuition about what the marketing planning group intends or can use to the city's advantage. The interaction described is an example of an effective healthy organizational interaction. The strategic technology planner, the marketing planner, and the senior municipal executives who oversee them are jointly responsible for enabling and ensuring this process.

After the alternatives are presented and discussed, and the choices or preferential rankings are done, the implementation framework can be completed. Naturally, even though we only discussed one example, that of the convention center wireless network, there will very likely be three to five, or occasionally as many as seven, technology elements included. If there are more than seven, it is likely that this stage of the planning is being done at too low or detailed a level. Larger more complex organizations may have more total elements in their planning, but their *strategic* technology planning and marketing planning will initially be done at a more general level, and subsequent efforts will take the plans to a more detailed level. A smaller municipality may have a complete plan with only three technology elements.

The strategic technology framework should lay out the elements required to achieve the technological market positioning described in the previous section, the ways that these elements interact and support each other, and should clearly state how they will integrate (or not) with the enterprise technology architecture in the final implementation. In addition, if any acquisition, development, or construction (hard or software) is required, the timing, sequence, and responsible agency should be set forward as part of the strategy. At this level of planning, the timeframes are broad estimates that are often stated in calendar quarters, and occasionally in months for smaller, short term, efforts. The strategic technology plan is a high level direction-setting plan and the particular technology being planned is one of its most tactical elements. In this current era, it is almost certain that every complete strategic technology plan will include consideration of communication and networking technologies. The next section reviews ICTs and their role in marketing and consequently strategic marketing plans.

THE ROLE OF INFORMATION AND COMMUNICATION TECHNOLOGIES IN MARKETING

As was mentioned in the previous section, writers and thought leaders in the field of "place marketing" or geography oriented marketing propose moving forward from marketing, to branding (Kavaratzis & Ashworth, 2006), to "shaping the competitive ecosystem" (Singer, 2006, p. 96). Many aspects of marketing and branding revolve around differentiation, and a city's ICT infrastructure certainly can be a differentiator. Furthermore, since perception is the most salient aspect of many of these efforts, promoting an ICT that competitors have, but do not present well, can result in a perceptual differentiation that provides a distinct advantage. This can be accomplished in part by removing an element of uncertainty in the marketing target's evaluation and assessment. If they have explicit assurance that a capability exists in one location, but no explicit assurance that it exists in another, the location that successfully marketed the capability will have the advantage. This can be as simple as making specific note of the geographic coverage of mobile telephone service, or as complex as promoting the existence of high capacity "backbone" data transmission capability.

When this concept is combined with the "techno-bubble" discussed earlier, the intersection is the opportunity to assure, or remove some uncertainty, regarding the ability to maintain connectivity when they come to the geographical area being marketed. So, one of the roles of ICTs in marketing is connectivity assurance for this increasingly technology dependent way of being.

Recognizing the Ubiquitous Nature of ICTs

Regarding the ubiquity of ICTs, think for a moment of a street corner in a moderately affluent larger city. Some percentage of the cars going by have a mobile phone based computer data connection. The people in the cars are likely to be carrying at least one mobile communication device on their person. A phone installed in the car may serve a dual purpose of allowing either the passenger or the vehicle to make a call. Some cars are programmed to automatically call for assistance when the crash-safety air-bags are triggered. The municipal bus passing by may have one or more communication devices installed, including a global positioning system and an emergency communication system. The police car passing by may have multiple instances of active ICT devices including a computer with an intranet and/or internet online research capability. The teenager passing on the sidewalk may be armed with multiple devices, but likely has a mobile phone at a minimum, and that phone provides voice, text messaging and probably internet access. In the apartment above, a grandmother may have her high-speed internet connection open on her computer while talking on her land-line telephone with her mobile phone in her purse. The utility meter at the rear may have a passive or active data connection. In the retail store across the street there may be corporate data connections via either satellite, fiber-optic cable, land lines (cable or telephone), and in a few cases, mobile phone technology.

This snapshot inventory of the pervasive presence of ICTs in many people's lives simply serves to remind that this connectivity is both fixed and mobile, transient and persistent, and personal and employment related. When a person or business is considering coming to your city, what role will the availability of these ICTs play in their decision-making process? Naturally that translates into the role of ICTs in city marketing. The following four sub-sections offer some practical suggestions for the next step is thinking through this aspect of information and communication technology planning.

A Framework for Analyzing the Role of ICTs in Marketing

When considering the role of ICTs in marketing planning and the related technology planning process, it may be helpful to parse the concepts to achieve greater specificity. Some ICT capabilities are simply basic infrastructure, like paved roads, traffic lights, water, and sewer. The data network at city hall is an example of basic ICT infrastructure. If it's not in place and functioning it gets attention, but otherwise is simply expected to be maintained in an adequate manner. On the other hand, a new initiative to put free public wireless internet service, like that in place in St. Cloud, Florida or downtown Hermosa Beach, California rises above the level of basic infrastructure. It is likely that residents of St. Cloud and Hermosa Beach will someday see the free wireless internet the same way the rest of us see our basic infrastructure, but until it is in place in a significant percentage of municipalities, it will be viewed as a special initiative. The continuum described here is one that ranges from very basic essential infrastructure to special technology initiatives that differentiate the municipality.

A second continuum to consider is the ownership and control of the infrastructure, in this case the ICTs. This range extends from municipally owned telephone equipment in city hall, through joint ventures with technology partners, to commercial ICT companies resident in or providing services to the community.

In the first continuum, concept of basic ICT infrastructure to special ICT initiative can be somewhat artificially divided into two halves, basic and special initiatives. In parallel, the second continuum can be divided into municipal ownership, partnership ownership, and commercial ownership. If these two continua are arrayed against each other in a matrix as in Figure 5, we get a view of some of the aspects of this topic that need to be assessed in planning the role of ICTs in city marketing. The St. Cloud, Florida and Hermosa Beach, California examples of free public internet access running on the municipal high speed internet access is a special initiative municipally owned ICT infrastructure from the top left box on the matrix. Commercial telephone company or cable fee-based internet access is basic commercially owned ICT infrastructure. This classification is very much context dependent. For example, the Grameen Phone project in Bangladesh that was described earlier is a special initiative in Bangladesh, but basic ICT infrastructure in other places. This extreme comparison is drawn to make the point that each city's environmental circumstances will be a little different and placement on this matrix is relative.

The value of the matrix is that it can be an aid to help parse your city's ICT infrastructure so you can assess, inventory, plan, and partner using an appropriate referential framework. Your city marketing plans may include elements from all six divisions in this framework. If your marketing plan includes partnership and commercially owned ICT infrastructure, you may find that you will need to move beyond the standard introspective model for municipal planning. This is not, in and of itself, problematic. It is simply a different requirement that enters into the equation as a result of the role of ICTs in city marketing.

Guideline 12: *An infrastructure ownership/type matrix helps analyze ICT's relationships to marketing.*

Assessing Your ICT Infrastructure

In an earlier section, we noted the importance of conducting an assessment of installed or current technological capabilities. The pace of change is too rapid to here provide an authoritative list of the ICT technologies to be included in your municipality's ICT infrastructure assessment

Figure 5. ICT infrastructure analysis matrix

	ICT Infrastructure Ownership		
Infrastructure Type	Municipal	Partnership	Commercial
Special Initiatives			
Basic			

and inventory. Therefore, the recommendations here regard the process more than they provide a sample inventory. As an example, the elements of the communications technology infrastructure assessment can be broken into three broad segments: high speed backbone, commercial grade, and consumer level.

High speed backbone capacity is the fiber optic, satellite, micro-wave, radio frequency, or other high-speed/high-capacity wholesale transmission capacity. Inevitably, this process requires some level of partnership information exchange with private enterprise organizations that own or manage this level of "backbone" transmission capacity. If marketing to businesses that have significant ICT demands is part of your marketing strategy, a thorough review of the availability of commercial grade service is essential. A marketing plan that can describe the area's overall high speed backbone capacity and also list multiple commercial grade service providers is a stronger presentation to today's technology savvy commercial decision-makers. The provision of consumer level service generally falls to private enterprise organizations, and thinking of the purpose here, city marketing at the consumer level might fall into three categories. Cities that are trying to attract new residents. Cities that trying to attract individual tourists. Cities that are trying to attract conference/convention/trade show business.

The assessment work product. Applying the results of the assessment of your ICT infrastructure in the framework suggested in Figure 5 should result in a reasonably complete inventory of the matrix of ICT capabilities and their capacity. As was described above, the first phase of the IT planning process is the assessment of the current environment. In order to develop the portion of that strategic plan which relates to ICTs and marketing, you will need to have an inventory the addresses both quality and quantity (or capacity) of your ICT infrastructure. This assessment should produce that inventory for both the governmental infrastructure and the relevant commercial capabilities.

Mapping Out Your Position

Once you have assessed the ICT infrastructure you will be able to engage in a strategic review of your city's ICT strengths and weaknesses. If the organization's strategic plan clearly sets an ICT direction or the marketing plan is sufficiently developed to indicate a planned marketing direction, you can use the inventory to analyze your strengths and weaknesses in light of those intended directions. This is often done using a "gap analysis." The gap analysis is exactly what the name implies. A list of requirements is compared to the existing capabilities and the magnitude of the "gap" between existing and required is documented. The obvious benefit of the gap analysis is that it results in the identification of the areas where current (and perhaps planned) capabilities don't meet expectations.

Guideline 13: *Conduct an assessment using gap analysis as a tool.*

When a municipality is planning to use ICTs as part of its marketing strategy, the ICTs fall into two categories. Those which the city owns or controls, and all others. Since the marketing plan may include the promotion of ICTs controlled by others, this process of assessment, inventory and analysis may require coordination or a partnership with private enterprise. The next section describes some elements of the tactical approach related to the role of ICTs in city marketing.

Planning Your Tactical Approach

When the cooperative or iterative process of reconciling and aligning the strategic technology plan and strategic marketing plan within the bounds and direction of the organizational strategic plan have been completed, the tactical action plan will be prepared. When you have completed the assessment, the inventory and the gap analysis described above, you may want to quickly assess whether there is any "low hanging fruit" in the results. These can be taken as an immediate tactical win.

CONSTRUCTING A TECHNOLOGY PLAN TO SUPPORT THE CITY MARKETING PLAN

This section addresses the amalgamation of these planning and strategy elements. The strategic technology plan and its coordination with the organizational strategic plan, support the city marketing plan. Knowing what the current and planned technology capabilities are, and the organization's strategic intentions as described in the city's overall strategic plan provides part of the framework for the city marketing plan. With these perspectives clearly in hand, the marketing plan can market to these strengths and intentions.

Multiple Audiences

As the reader can clearly see, the segmentation and construction of each city's plan will, of necessity, be different. In any event, there is a need to address multiple audiences. The choices made in this regard will depend on the city's planning orientation and the prioritization of the various audiences. To facilitate that process, some of the various audiences and typical reasons for interest are described here.

The first, and most obvious, audience is that of the elected officials. Generally the agenda here is fairly well known, and consequently a little easier to address and accommodate. It is an error to ignore this reality since many of these politicians are acutely conscious of the public positions they have taken during and after the election cycle and will apply that litmus test to their evaluation of the technology and marketing plans.

A second audience is that of the professional/career municipal managers. Support from the strongest and/or most influential members of this group is virtually a necessary condition for successful implementation of the plan, consequently the planning process and its interim results need to be fully vetted within this group.

Cities usually have business oriented groups, like a Chamber of Commerce or downtown business group that combines boosterism and perhaps some quasi-governmental role. Since some amount of boosterism is a natural part of their role, they have great potential to support the city marketing plan, but need to be included in the plan development.

Another audience that needs to be considered when ICTs are part of the city marketing plan is the ICT companies. Using a current example, if free internet service is to be provided through the city's broadband connection, the contractual provider may see this as an advantage in marketing to other municipalities, or may have concerns about the plan. This audience should be included in the plan development in an appropriate manner.

Of course a significant audience for the plan is the citizenry and their common proxy, the local mass media. It is unlikely that citizens will want to read the entire plan, and this leads to a specific requirement for dealing with this audience. The plan will need a clear, complete and succinct summary that both sells and informs. Individual communities will have different numbers and types of media that can be offered access to the plan summary (and the detailed plan). Local television stations may be receptive to a well prepared position piece. This quickly becomes an opportunity to demonstrate your city has examined the "competition" and is ready to move forward.

Guideline 14: *Be sure that your plan successfully addresses the many important audiences.*

Formulating Multiple Orientations of the Plan

In the discussion of the multiple audiences for the strategic technology plan, we reviewed various groups inside the municipal community who are mostly potential users of the plan, a somewhat introspective view. This section addresses a parallel, more outward looking perspective that may appropriately be implemented in summaries or abstracts of the plan for those who are more *readers* of the plan than they are *users* of the plan. In a sense, this is about marketing the strategic technology marketing plan.

Local stakeholders. The local stakeholders are primarily those addressed in the multiple audiences section above. However, local stakeholders also include the individual businesses in the hospitality or services businesses that may benefit from increased business driven by some aspect of the city marketing program. In some cases, these companies may have a marketing plan that could be adjusted to coincide with, or be supportive of the city's plan. Attention to these opportunities can strengthen both public support for the plan and a successful implementation. In addition, you should include in your considerations any local stakeholders that may see the plan as disadvantageous. As is usually the case, foresight and a specific plan of action is more likely to result in a better conclusion.

National targets. When a city's marketing plan includes an international orientation, there is a possibility that there will be an audience for the plan at the national level. When a municipal marketing plan is coordinate with national marketing plans, there is an opportunity for synergy and national level support. Whether the aim of the city marketing plan is tourist, conference/trade show, or commercial business, there may be potential support at the national level. This should be considered and where the opportunity exists, an appropriate nationally oriented summary of the plan should be prepared.

Consumer targets. At the consumer level, the city marketing plan can address tourists, transitory, or permanent visitors. Generally targets of this type will be offered some specific set of benefits in the marketing plan. As was discussed in the techno-globalization section at the beginning of this chapter, in this day and age, assurance of the opportunity to stay "connected" while visiting the city is an attractive feature and should be included in your ICT planning considerations. Overall, the consumer orientation of the plan, if any, may have the broadest range of potential messages. Once again, careful consideration of how and what message will be delivered is better than acceptance of a random or default choice in this matter.

Industry and commercial targets. This segment can be targeted with considerable precision. If the orientation of the city marketing plan includes commercial or industrial targets, writing an appropriate summary or applicable section of the plan can be a benefit. As was mentioned earlier, removing an element of uncertainty for a decision-maker can be advantageous. For example, if the plan is able to say that your city is interested in attracting businesses of a certain type and is willing to offer certain advantages or specific concessions, these give the corporate decision-maker both an assurance of a welcoming municipal climate and a referential authority to include in her/his explanation and justification of a decision to come to your city. This may be simply to hold a conference or trade show, or it may be to locate an office or other facility. If it is a trade association or travel/hospitality industry company, they may be interested in both the business climate and the tourist orientation and, as described above, the marketing plan should address both of these aspects.

Supporting Research

Because the field of technology is perennially fast moving and evolutionary, current research is inevitably required. As you might expect, the internet is an excellent place to get both current information and investigate what your city's "competitors" are doing and the state of the art. As an example, an internet search of the words "municipal wireless" will generate a significant list of results. It isn't possible to provide a comprehensive list of useful sites here, however, one example is a site named www.muniwireless.com founded by an attorney named Esme Vos. This is a commercial site with abundant advertising. However the advertising supports useful research. You can find lists of municipal wireless implementations, articles on current requests for proposals for municipal wireless networks, and articles on specific orientations like tourism and wireless municipal networks. In short, this website and other similar ones are a valuable source of information and research data. Naturally you will want to tailor your own searches to your specific needs, but your planning process will be richer and more complete with this important and useful internet based scan of the environment.

Once the strategic plan is complete, begin the tactical and operational planning process. One of the keys to the transition from a strategic plan to a tactical plan is having a skilled tactical planner working with the approved strategic plans and working in conjunction with the financial planners. The reality in governmental entities is often that the financial plan is produced through a combination of administrative recommendations/requests and a legislative/political process. The more closely the tactical, financial and implementation plans are aligned with a properly vetted organizational strategy, the more likely it is that they will be approved and successful.

CONCLUSION

The intersection of strategic technology planning and marketing is, inevitably, different for each municipality. This chapter surveyed the strategic planning paradigm, the role of strategic technology planning in marketing, and the role of ICTs in marketing. In addition, the chapter described the process of constructing and organizing both the strategic technology plan and the ICT marketing sub-plan.

What Can We Conclude?

A successful strategic plan depends on the existence of a clear organizational strategy, which is best captured in a written strategic plan document. If a written plan document doesn't exist, the strategic technology planner needs to invest the time and effort required to get a statement of strategic direction approved by top management. As we address the topic of the interaction of marketing and technology, the same thing applies to a strategic marketing plan. If one doesn't exist, then the technology planner needs to help guide those responsible for marketing the city to the development of a definitive statement of the marketing strategy. The strategic technology plan needs to be aligned with both the organizational strategic plan and the strategic marketing plan (and any other appropriate peer plans). Successful strategic technology planning generally involves a process of simultaneous development with peer strategic plans like the strategic marketing plan. The iterative co-development method is usually the shortest path to successful completion of both planning processes.

Lee and Bai (2003) captured these concepts well in their article discussing organizational mechanisms necessary for successful SISP/SITP plan preparation in the digital era. They trace the evolution of the SISP/SITP planning process over several decades. They explain the progression from "technology mode" to the "align mode" to the "impact mode" to the most developed, the current "fit mode" (p. 33). These four phases were driven by technology, business issues, competition, and organizational issues respectively. The approach described in this chapter intends to reflect the full range described by Lee and Bai (2003). Successful participation in the techno-global economy virtually requires this level of sophistication.

Organizational strategic technology plans incorporate conceptual development of enterprise wide software, hardware, networking, and personnel plans. They often incorporate consideration of external entities and their technology direction. This is especially true when marketing plans will include non-owned ICT capabilities. The objective of the intra-organizational aspect of the plan is to set the strategy and direction of the information and communications technology for the municipality and its delivery of service and support to its constituencies. The objective of the extra-organizational aspects of the plan will include identifying and assessing the technology and capabilities that are required to support the objectives of the strategic marketing plan.

The three phases of the strategic technology planning process are the assessment (Where are we right now?), setting the strategic direction (Where do we want to go?), and developing the plan (How will we get there?). In the discussion of this process, we noted the need to manage the fact-free planning phenomenon. In conclusion, with the organizational strategic direction clearly understood and the marketing objective documented and agreed upon, the scope and requirements for the intra-organizational and extra-organizational assessment should be very clear. The gap analysis technique is recommended as a useful tool to collect and present the differences between what is in place, and what will be needed. This level of sophistication is also essential to success.

What can we conclude the attributes of a successful final product are? The well-done strategic technology plan will address the multiple targets and audiences discussed in the previous sections. It will be aligned with both the organizational strategy and the marketing strategy. It will lay out the elements required to achieve the technological market positioning set forward in the marketing plan. It will clearly set forward the organization's technology strategy and plans for both internal and outward looking initiatives. It will exhibit a broad organizational perspective, result from good group interaction, capture the required organizational knowledge and incorporate organizational change management requirements.

Planning of this sort is almost always an iterative organizational learning process. The review, revision, and renewal of the plan in subsequent years is a natural part of the process and should, as was noted in Figure 4 and Guideline 7, be anticipated at the beginning of the effort. Wherever possible, the initial planning process should include measurement and evaluation metrics that can be used to assess how well your plan has succeeded in meeting your objectives.

With or without specific measurements, a frank assessment of the previous plan should be done before the next iteration of the planning process is undertaken. This can be done very successfully by convening a group of appropriately knowledgeable people. The charge given to this group should be to bring to the meeting their own list of the successes and failures of the prior plan. When these are discussed in the group setting, the individual perspectives get incorporated into the group understanding of the plan. When this group learning is recorded, it becomes a valuable organizational knowledge tool to guide those responsible for the development of the next planning iteration.

Guideline 15: *Consider using a peer-review group to help assess the success of the prior plan and recommend future improvements.*

FUTURE TRENDS

From 2000 through 2007 there was much discussion about municipalities providing free internet access to citizens. In spite of the existence of some free municipal networks, the current trend appears to be moving away from broad, free access networks. There are several factors which militate against free municipal networks. Free wireless service is not currently an essential municipal service, but more of a luxury. In the final analysis, it may be provided free to the users, but there are costs to building and maintaining the network. Some service providers who agreed to partner with cities and provide free access to citizens have found that advertising and other anticipated sources of revenue are really not sufficient to make it worthwhile at this current time. Some rather localized free municipal networks, like those at some airports seem more likely to survive and be replicated.

There is clear potential to capitalize on technology in addressing the city marketing challenge. The techno-global economy fosters an increasing reliance on and demand for technology infrastructure. In the future, technology infrastructure may come to hold the same position as an essential utility that water supply, sewer, land-line telephone, and electric utilities currently hold. As people come to see various aspects of technology infrastructure, especially communications capabilities, as increasingly essential and assumed, the future city marketing potential grows. Farsighted city marketing and technology plans can anticipate this future state and market toward it.

Chapter 8.7

Mission-Critical Group Decision-Making:

Solving the Problem of Decision Preference Change in Group Decision-Making Using Markov Chain Model

Huizhang Shen
Shanghai Jiaotong University, China

Jidi Zhao
University of New Brunswick, Canada

Wayne W. Huang
Ohio University, USA

ABSTRACT

Review on group decision support systems (GDSS) indicates that traditional GDSS are not specifically designed to support mission-critical group decision-making tasks that require group decision-making to be made effectively within short time. In addition, prior studies in the research literature have not considered group decision preference adjustment as a continuous process and neglected its impact on group decision-making. In reality, group members may dynamically change their decision preferences during group decision-making process. This dynamic adjustment of decision preferences may continue until a group reaches consensus on final decision. This article intends to address this neglected group decision-making research issue in the literature by proposing a new approach based on the Markov chain model. Furthermore, a new group decision weight allocation approach is also suggested. A real case example of New Orleans Hurricane Katrina is used to illustrate the usefulness and effectiveness of the proposed approaches. Finally,

the article concludes with the discussion on the proposed approaches and presents directions for future research.

INTRODUCTION

Mission-critical events such as hurricanes, terrorist attacks, fires, and earthquakes require different governmental departments to work together to respond to those emerging crises and reach consensus quickly to make effective decisions within a short time period. Traditional group decision support systems (GDSS) have not specifically addressed this important issue in the research literature (Fjermestad & Hiltz 1999; Huang, 2003; Huang & Wei, 2000; Huang, Wei, & Lim, 2003; Tan, Wei, Huang, & Ng, 2000; Zigurs, DeSanctis, & Billingsley, 1991; Vogel, Martz, Nunamaker, Grohowski, & McGoff, 1990). A special type of GDSS, mission-critical GDSS (MC-GDSS), can be designed to support this group decision-making process.

Mission-critical group decision-making has some important characteristics that are different from conventional group decision-makings (Belardo & Wallace, 1989; Beroggi, Mendonça, & Wallace, 2003; Huang & Li, 2007; Limayem, Banerjee, & Ma, 2006; Mendonca, Beroggi, Gent, & Wallace, 2006; Wallace & DeBalogh, 1985): (1) decision-makers have to make nearly real-time decision. Decision-making on emergency response has to be made within a short time because of the nature of critical mission, (2) mission-critical decision-making problem is unstructured, fuzzy and unexpected in nature, and (3) information available to decision-makers is insufficient and not always accurate because complete information may not be collected in a short time, thus the decision makers can only rely on such incomplete information to making decisions. Therefore, conventional decision support approaches may not well solve decision problems of mission-critical events.

Prior research studies mission-critical decision-making from different perspectives. LaPorte and Consilini identify two emergency response patterns based on frequency and scene information respectively (LaPorte & Consilini, 1991). Ody thinks that crisis decision-making task, one type of mission-critical decision-making tasks, consists of three segments, pre-incident identification of hazards, the use of agreed communications, and the introduction of a third party to promote the coordination of decision makers (Ody, 1995). Wilkenfeld, Kraus, Holley, and Harris design a decision support system, GENIE, and demonstrate the usefulness of GENIE to help decision makers maximize their objectives in a crisis negotiation. Experimental results show that GENIE users, as compared to non-users, are more likely to identify utility maximization as their primary objective and to achieve higher utility scores (Wilkenfeld, Kraus, Holley, & Harris, 1995). Papazoglou and Christou propose a method on optimization of the short-term emergency response to nuclear accidents, which seeks an optimum combination of protective actions in the presence of a multitude of conflicting objectives and under uncertainty (Papazoglou & Christou, 1997). Bar-Eli and Tractinsky explore psychological performance crises under time pressure towards the end of basketball games (Bar-Eli & Tractinsky, 2000). Zografos, Vasilakis, and Giannouli present a methodological and unified framework for developing a decision support system (DSS) for hazardous materials emergency response operations (Zografos, Vasilakis, & Giannouli, 2000). Weisaeth, Knudsen, and Tonnessen discuss how psychological stress disturbs decision making during technological crisis and disaster, at an operative level of emergency response and at the strategic and political level respectively (Weisaeth, Knudsen, & Tonnessen, 2002). Chen, Sharman, and Rao et al. develop a set of supporting design concepts and strategic principles for an architecture for a coordinated multi-incident emergency response system based upon emergency response system requirement analysis (Chen, Sharman, & Rao et al., 2005).

As Arrow points out, based on the construction of group preference, group decision-making is a procedure of synthesizing the preferences of each decision-maker in a group and sorting decision alternatives or choosing the best decision alternative from a decision alternative set (Arrow, 1963). Group decision preference relation of a group should satisfy five rational terms: preference axiom, impossible axiom, completeness, Pareto optimization, and non-autarchy (Arrow, 1963). Prior studies by Arrow (1963), Dyer (1979), Keeney (1975), and French (1986), and so forth, provide a theoretical foundation on group decision preference relation analysis in group decision-making research literature. Group decision preference is a function of individual preferences on group decision-making issues. Preference is a term originally coming from economics. In group decision-making research literature, it is used to represent decision-makers' partiality on value (Dyer & Sarin, 1979). The procedure of forming individual preference is a decision-maker's meta-synthetic thinking procedure of perceiving all the information relating to expectation, information, sensibility, creativity, and so on, which is a extremely complex procedure (Bordly & Wolff, 1981). Some prior studies try to explore these complicated issues from different angles, including Weighted Average Method, Bordly Multiplication (Bordly & Wolff, 1981), Bayesian Integration Method (Keeney & Kirkwood, 1975), Entropy Method (French, 1986), and Fuzzy Cluster Analysis (Dyer & Sarin, 1979). Generally speaking, a decision-making group's decision preference on decision alternative sets will change as decision-makers adjust their decision preferences after communicating with other group decision-makers through group interactions, which could lead to group decision-marking preference convergence.

In this article, how a group reaches decision consensus quickly and effectively in group decision-making on emergency response is focused on. Emergency response, as one type of mission-critical group decision scenario, requires an MC-GDSS to collect group members' decision-making choice preferences automatically and quickly determine a group's overall decision choice preference. Further, group members may also dynamically change their decision preferences after seeing other group members' decision choice preferences during group decision-making process. This dynamic adjustment of decision preferences will continue until all the group members do not rectify their preferences. After a few rounds of group interactions with decision preference adjustment, group consensus may be reached on the group's final decision choice. Prior studies in the research literature have not considered the preference adjustment as a continuous procedure and neglected its impact on group decision-making. This article intends to address this important group decision-making research issue and proposes a new approach based on the Markov chain model.

In addition, one central element of group decision-making is decision weight. Prior main solutions to decision weight allocation in the research literature can be summarized. The first solution is the authority allocation method (Mallach, 2000). An authoritative decision maker allocates decision weight for each decision-maker, which may be biased. Another solution is the Nominal Group Technique (Potter & Balthazard, 2004; Shyur & Shih, 2006). Nominal Group Technique is a kind of anonymous survey which should be done for some rounds. Each member of a group endows weight to other decision members according to his/her own experience, value system, and personal judgment. The anonymous survey process will continue until all decision-making members' opinions converge. These two methods largely involve subjective judgment on decision weight allocation (Chen & Fu, 2005; Williams & Cookson, 2006), which is likely to lead to subjective biases as well. Other methods are based on forecasting each decision-maker's weight according to historical experience and data, such as entropy method and fuzzy cluster analysis (French, 1986), where two disadvantages exist. First, those require a lot of historical data, which is not easy to collect in reality. Second, the external environment of decision-making is changing fast. Therefore, historical successful experience may not provide a good indication for successful current and future decision-makings. This article proposes a new decision weight allocation approach, which can help address the problems of prior methods in terms of subjective biases and requiring substantial quantity of historical data.

The remainder of this article is organized as follows: The next section proposes a new decision weight allocation method. The third section presents a new approach to construct a Markov state transition matrix in group decision-making, addressing the neglected research issue of dynamically changed decision preference in the group decision-making process. A real case example of New Orleans Hurricane Katrina is used to illustrate the usefulness and effectiveness of the proposed approach. Finally, the article concludes with the discussion on the research results and presents directions for future research.

PROPOSING A NEW DECISION WEIGHT ALLOCATION APPROACH FOR MISSION-CRITICAL GROUP DECISION-MAKING

This section proposes a new decision weight allocation approach for mission-critical group decision-making. First, a group decision preference judgment matrix is defined, followed by a quantitative consistence indicator to measure decision-maker's decision consistence. Second, a clustering method to analyze the distances among decision preferences in a decision-making group is put forward. Finally, a decision weight is determined by both decision preference consistence indicator and decision preference distance indicator.

Group Decision Preference Judgment Matrix

In this article, the concept of preference utility value from economics literature to quantitatively represent preference, which describes preference direction or priority of a decision-maker is used. It would be difficult for a group member to accurately judge which decision choice is certainly the best among those alternative decision choices, especially for mission-critical problems. In reality, group decision-makers do pair wise comparisons *on each pair of two decision alternatives (or decision choices)* and give their decision preferences using fuzzy terms like "equal, a little better, better, much better, absolutely better." *Based upon this line of logic thinking, each decision-maker's preference utility value can be generated.* The definition of preference utility value $\theta_r(x^i, x^j)$ *and its quantificational values are given in Appendix A.1.*

Thus, according to the r^{th} decision maker of a group, DM_r's pair wise comparison between each two alternatives on the set, we get a preference judgment matrix P_r. Apparently, it is a positive symmetrical matrix. Decision-makers only need to judge $s(s-1)/2$ times, which is equal to the amount of the elements of the upper or lower triangular matrix.

$$P_r = \begin{pmatrix} \theta_r(x^1,x^1) & \theta_r(x^1,x^2) & \cdots & \theta_r(x^1,x^s) \\ \theta_r(x^2,x^1) & \theta_r(x^2,x^2) & \cdots & \theta_r(x^2,x^s) \\ \cdots & \cdots & \cdots & \cdots \\ \theta_r(x^s,x^1) & \theta_r(x^s,x^2) & \cdots & \theta_r(x^s,x^s) \end{pmatrix} \quad (1)$$

Suppose there are l decision-makers, then there are l preference judging matrices altogether.

Decision Preference Consistence Indicator for a Preference Judgment Matrix

Although it is relatively easy for decision-makers to do pair wise comparisons and give the preference utility value, it may not be easy to derive sequential order of the decision alternatives from a preference judgment matrix. What is more, the derived order may often be self-contradictory. For example, analysis of a given preference judgment matrix may lead to a contradictory conclusion that A is more preferred than B, B is more preferred than C, and C is more preferred than A. This kind of contradiction indicates that a decision-maker may not always be consistent enough to make decision. As a result, a quantitative consistence indicator from AHP (Satty, 1988) is introduced to measure decision-maker's decision consistence. Let CI_r denote the r^{th} decision maker DM_r's consistence indicator. The larger the indicator is, the worse the consistency of the preference judgment matrix becomes. Based on the theory of matrix, the preference utility value of DM_r on x^i, denoted by $\pi_r(x^i)$ can be derived and the consistence indicator from a matrix' characteristic vector and characteristic value, as illustrated in the Appendix A.2.

Clustering Analysis and Decision Preference Difference

Besides the individual carefulness measured by the consistence indicator, the differences among the individual preference and other's preferences (preference distance d_r) also play an important role in reaching consensus in group decision-making. As to an individual decision-maker, the larger the difference is, the extremer she is, and the less contribution she makes to the group consensus, and vice versa. In this section, firstly, a clustering method to classify the group decision-makers' preferences is introduced. Secondly, each decision-maker's preference distance to measure the extremenesses among the group members is computed. The clustering method and the definition of preference distance (d_r) are illustrated in Appendix B. The Euclidean preference distance (d_r) between the preference utility value vector of DM_r on X and the specified cluster center shows the preference distance of the decision-maker under the average criteria. The smaller d_r is, the lower the decision-maker's preference distance is, and the more contributions the decision-maker makes to group consensus.

As to those clusters that only contain one element, the distances between the element and the cluster centers of all the other clusters are calculated and the minimum distance is chosen to represent the corresponding decision-maker's preference distance.

The Optimization of Decision Weight Allocation

The decision weight allocation for group decision-makers can be described as the following optimization problem.

$$\min F(w) = \sum_{r=1}^{l} [CI_r + d_r] w_r^2 \qquad (2)$$

Subject to:

$$w_r \geq 0 \ (r = 1, 2, \cdots, l)$$

$$\sum_{r=1}^{l} w_r = 1$$

where $CI_r = (\frac{\lambda_{\max}^{(r)}}{s-1} - \frac{s}{s-1})$ denotes the consistency degree of decision-maker DM_r and $\sqrt{\sum_{k=1}^{s} \left|\pi_r(x^k) - \pi(x^k)\right|^2} = d_r$ denotes that person's preference distance. Equation (2) shows that the higher an expert's consistency is, the lower her/his extremeness is and the larger weight she/he should be assigned. A solution of the decision weight vector assigned to a group of decision-makers, $W = (w_1, w_2, \cdots, w_s)$ is given in the appendix C. Thus we have:

$$w_r = 1 \Big/ \left[(CI_r + d_r) \bullet \sum_{r=1}^{l} 1 \Big/ (CI_r + d_r)\right].$$

This approach of allocating decision weighs has at least two advantages over traditional approaches. First, it is less subjectively biased because as the decision weight allocation is based on individuals' current objective decision information with less subjective factors. Second, the allocation approach may be more accurate because it considers both individuals' decision preferences and the differences between individual decision preferences and others' decision preferences of a group.

PROPOSING A MISSION-CRITICAL GROUP DECISION-MAKING SUPPORT APPROACH USING MARKOV CHAIN MODEL

This section proposes a mission-critical group decision-making approach to address the issue of the impact of dynamic decision-making preference change on group decision-making. More specifically, the Markov state transition matrix is used to determine the dynamic nature of group decision-making preference changes, decision-making convergence, and decision preference distance. The section on group decision-making and Markov chains presents how to construct this Markov state transition matrix. Based upon that, an optimal group decision-making choice can be generated.

Group Decision-Making and Markov Chains

After the t rounds adjustment, the preference utility values in all the rounds for decision-maker DM_r are:

$$\pi_r = \begin{Bmatrix} \pi_r^1(x^1) & \pi_r^1(x^2) & \cdots & \pi_r^1(x^s) \\ \pi_r^2(x^1) & \pi_r^2(x^2) & \cdots & \pi_r^2(x^s) \\ \cdots & \cdots & \cdots & \cdots \\ \pi_r^t(x^1) & \pi_r^t(x^2) & \cdots & \pi_r^t(x^s) \end{Bmatrix}.$$

In this matrix, each row stands for the preference utility value vector in each round. Comparing the k^{th} row with the $(k+1)^{th}$ row ($\{k = 1, 2, \cdots, t\}$), if there exists $\pi_r^{k+1}(x^i)\downarrow \Leftrightarrow \pi_r^{k+1}(x^j)\uparrow$, the state variable $E_{ij} = E_{ij} + 1$ is set, which shows that the decision-maker has ever changed her/his preference from the alternative x^i to x^j. For each decision-maker, there are at most $t-1$ times of adjustment. Packing all the adjustment for the group together, we have:

$$T_r = \begin{bmatrix} 1-\sum_{j\neq 1}\frac{E_{1j}}{E_r} & \frac{E_{12}}{E_r} & \cdots\cdots & \frac{E_{1s}}{E_r} \\ \frac{E_{21}}{E_r} & 1-\sum_{j\neq 2}\frac{E_{2j}}{E_r} & \cdots\cdots & \frac{E_{2s}}{E_r} \\ \cdots\quad\cdots & \cdots\quad\cdots & \cdots\quad\cdots & \cdots\quad\cdots \\ \frac{E_{s1}}{E_r} & \frac{E_{s2}}{E_r} & \cdots\cdots & 1-\sum_{j\neq s}\frac{E_{sj}}{E_r} \end{bmatrix} \tag{3}$$

where T_r is the preference state transition matrix for decision-maker DM_r, E_{ij} denotes the preference transition times from x^i to x^j and $E_r = t-1$ is the sample space for the state transition times.

For example, the preference utility value matrix for decision-maker DM_r is:

$$\Lambda_r = \begin{bmatrix} 0.1 & 0.3 & 0.2 & 0.4 \\ 0.2 & 0.2 & 0.3 & 0.3 \\ 0.2 & 0.3 & 0.2 & 0.3 \\ 0.2 & 0.4 & 0.2 & 0.2 \\ 0.3 & 0.3 & 0.2 & 0.2 \end{bmatrix}.$$

The first row of the matrix is the initial value and the sample space is $t-1 = 5-1 = 4$.

Comparing the second row with the first row, we have $x^2 \to x^1, x^4 \to x^3$.

Comparing the third row with the second, we have $x^3 \to x^2$.

Comparing the fourth row with the third, we have $x^4 \to x^2$.

And, comparing the fifth row with the fourth, we have $x^2 \to x^1$.

According to Equation (9), we have the preference state transition matrix T_r for decision-maker DM_r is:

$$T_r = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0.5 & 0.5 & 0 & 0 \\ 0 & 0.25 & 0.75 & 0 \\ 0 & 0.25 & 0.25 & 0.5 \end{bmatrix}.$$

In this matrix, $\frac{E_{11}}{E_r} = 1$ shows that the decision-maker never changes her preference on x^1.

Define the overall state transition matrix of the decision-making group in the t rounds adjustment procedure as:

$$T = \frac{1}{l}\sum_{r=1}^{l} T_r. \qquad (4)$$

In Appendix D, a review on discrete time Markov chains is given. It is also shown that the group decision-making procedure satisfies a Markov chain. Therefore, the Markov property can be used to predict adjustments of the decision-makers' preference.

Nine Implementation Steps of the Proposed Group Decision-Making Support Approach

The proposed approach for supporting mission-critical group decision-making works in following nine steps:

1. State a group decision-making problem and background information to each group member, including the mission-critical event, available information, constraints, decision alternatives, decision-making rules, the user handbook of a MC-GDSS that is being used, and so forth.
2. Each decision-maker gives her/his preference judgments between each two alternatives on the set of alternatives using the quantificational values given in Appendix A. The preference judgment values for decision-maker DM_r are presented in the matrix P_r. All the decision-makers can share their opinions, evidences, and explanations on the screen of the MC-GDSS system to support their view points.
3. Substituting the corresponding values into the approximate calculation algorithm presented in Appendix A yields the preference utility values for a decision-maker DM_r in the t^{th} round, $\{\pi_r^t(x^1), \pi_r^t(x^2), \cdots, \pi_r^t(x^s)\}$. As stated, the individual preference adjustment in group decision-making is a continuous procedure in which the decision-makers adjust their preference in each round respectively based on the communications among the group members. The continuous adjustments make group decisions converge gradually. The preference utility values vector $\{\pi_r^t(x^1), \pi_r^t(x^2), \cdots, \pi_r^t(x^s)\}$ for the decision-maker is used for constructing the Markov state transition matrix in step (8).
4. With the preference values worked out in step (3), the preference utility values matrix Λ^t for the t^{th} round are had. Using the Equation (-16), the preference distance d_{ij} between decision-maker DM_i and DM_j on X are had. Substituting these preference distances into Equation (17), the preference difference matrix D can be constucted. Furthermore, given $\varepsilon = \frac{\max d_{ij} - \min d_{ij}}{2}$, clustering analysis on the preference difference matrix D based on the definitions 3 and 4 can be done.
5. The MC-GDSS system displays the preference utility values and the clustering results on screen, which is a public communication space for group decision-makers to see and then maybe adjust their preferences. After that, members can go back to step (2) and begin another round of decision discussion with further preference judgment as well.
6. Repeat the above procedure from step (2) to step (5) for $t = 7 \pm 2$ times. The choice of $t = 7 \pm 2$ is based on two reasons. First, conventional Delphi method usually repeats more than four times (Giunipero, Handfield, & Eltantawy, 2006; Lao, Dovrolis, & Sanadidi, 2006). Second, empirical research in psychology shows that 7 ± 2 is a common experienced value for human being's thinking-span (My-

ers, 2005; Murphy, Roodenrys, & Fox, 2006; Over, Hooge, & Erkelens, 2006). In addition, the value for t can also be determined by a group decision meeting organizer according to the meeting time limit and other factors.

7. Calculating the weight assigned to each decision-maker with the solution given in the appendix C yields the weight vector $W = (w_1, w_2, \cdots, w_s)$ for the group.
8. Constructing the Markov state transition matrix T using Equation (3) and (4) with the saved preference values $\{\pi_r^t(x^1), \pi_r^t(x^2), \cdots, \pi_r^t(x^s)\}$.
9. Multiplying decision weight vector $W = (w_1, w_2, \cdots, w_s)$ by the preference matrix Λ in the last round, and then by the Markov state transition matrix T, we have Equation 5, seen in Box 1. Where $[x^1, x^2, \cdots, x^s]$ is the preference utility values vector on the decision alternative set X and $\max\{x^i\}$ $(i = 1, 2, \cdots, s)$ is the final decision made by the group.

Here some points on this group decision-making support approach are clarified:

1. The nine steps of group decision-making only need some interactions between group decision-makers and a MC-GDSS system, without additional interactions of group decision meeting's organizer as in traditional group decision-making setting. In this way, decision-making process may be sped up, which is important to mission-critical decision-making tasks.
2. Each decision maker can share her/his opinion, present her/his explanation, and browse other's opinions anonymously or with her/his identity.
3. The clustering analysis result of individual decision preference values in each decision round is displayed in public screen and used as a reference for decision preference adjustment for the next decision round.
4. Every decision-maker is encouraged to adjust her/his preference based upon the clustering analysis result of the previous decision round. If each decision-maker sticks to her/his initial decision position and does not adjust her/his decision preference at all in following decision rounds, the group will never reach consensus and such group decision-making makes no sense, which should be stopped. Otherwise, after a few rounds of group interactions, it could be possible for a group to reach consensus and final group decision can be achieved.

A Real Case Illustrating the Usefulness and Effectiveness of the Proposed Approach

Background Information

1. New Orleans is the largest city of the state of Louisiana in the USA and the second largest American port next to New York City. It is located at the southeast part of the state of Louisiana and at the lower part of Mississippi River near the sea. The city is next to Pontchartrain Lake in its north. The city is around 950 square kilometers with a population of 500,000. Moreover, the Great New Orleans District has a population of 1180,000.

In August 2005, Katrina, a category 5 hurricane called a "Perfect Hurricane" by meteorologists with its 280 kilometer-per-hour winds, lashed the city of New Orleans. New Orleans Mayor Ray Nagin of the city of New Orleans called for voluntary evacuation of the city's residents on August 27, 2005.

On August 28, New Orleans Mayor Ray Nagin sent down a compelling order of all-out evacuation of the city's residents and provided 10 refuges for the city's remaining residents. The Louisiana Superdome is assigned as an island refuge.

On August 29, Katrina made a landfall as a category 5 hurricane over the Gulf of Mexico and lashed Southern America. New Orleans's flood embankments could not withstand the ferocity of the hurricane and were breached at two sites. As a result, 80% of the city was flooded. In some parts of the city, the water continued to rise at a speed of one foot per hour.

Constraints

The New Orleans government assigned a 7000-people rescue army. For 700,000 refugees scattered in an area of 950 square kilometers, the rescuers were only one percent of the refugees.

The city was out of communication. Except the 10 refuges, the rescuers were not aware of the location or quantity of the refugees. The city was out of traffic transportation. The vehicles such as buses were not usable any more. Helicopters were the main transporters. Moreover, the city was out of clean water, power, and cooking. There have already appeared hostile looting and murders.

Decision Alternatives

x^1 (the first decision alternative for this mission-critical event): Search for the separated refugees. If the rescue is just in time, the death rate of the refugees can be reduced. Although people in refuges were besieged, they could be kept away from death.

x^2 (the second decision alternative for this mission-critical event): Evacuate those serious patients. Without clean water and power, they might die immediately.

x^3 (the third decision alternative for this mission-critical event): Evacuate people in refuges as there is no clean water, power, and cooking. Give up the search for separated refugees temporarily because they may not die in a reasonable time period.

x^4 (the fourth decision alternative for this mission-critical event): Arrest the looters in order to make the city safe, which can also help with the rescue work to be done in a safe context.

2. Assume that there are six decision-makers in the governmental rescue committee. Every decision-maker does pair wise judgments and gives her/his preference judgment according to the quantitative values given in Table 1 of the first section. The initial preference judgment matrix is illustrated in Table 1.
3. Substituting the corresponding values into the approximate calculation algorithm presented in the appendix A, we have the preference utility values for a decision-maker DM_r in the t^{th} round, $\{\pi_r^t(x^1), \pi_r^t(x^2), \cdots, \pi_r^t(x^s)\}$. The preference utility values for the six decision-makers in the first round are shown in Table 2.
4. With the preference utility values worked out in step (3), we have the preference utility values matrix Λ^t for the t^{th} round. Using Equation (16), we have the preference distance d_{ij} between decision-maker DM_i and DM_j on X. Substituting these preference distances into Equation (17), the preference difference matrix D can be constructed. The preference distances and the preference difference matrix are shown in Table 3.

Given $\varepsilon = \frac{\max d_{ij} - \min d_{ij}}{2}$, we have $\varepsilon^1 = 0.239$, as shown in Table 3 in bold font. Thus, we get $d_{31} \leq \varepsilon^1$, $d_{62} \leq \varepsilon^1$. According to the definitions 3 and 4, there are 4 clusters in this round, DM_1 and DM_3 belong to the same cluster in $\varepsilon^1 = 0.239$, so do the DM_2 and DM_6. DM_4 and DM_5 are independent clusters respectively. The cluster analysis result is shown in Figure 1. In Figure 1, the numbered black dots denote the current preference states of the decision-makers. The diameter of the circle is the clustering distance in this round, $\varepsilon^1 = 0.239$. All the dots that can be enclosed in a circle belong to a specific cluster, which shows that the decision-makers in the same cluster come to partial consensus in ε.

Table 1. Pair wise preference judgments and preference utility values on a set of alternatives

DM_1	x^1	x^2	x^3	x^4	π	CI	DM_2	x^1	x^2	x^3	x^4	π	CI
x^1	1.00	0.33	3.00	0.33	0.17		x^1	1.00	5.00	2.00	1.00	0.38	
x^2	3.00	1.00	2.00	1.00	0.36		x^2	0.20	1.00	1.00	0.50	0.12	
x^3	0.33	0.50	1.00	0.50	0.12		x^3	0.50	1.00	1.00	0.17	0.11	
x^4	3.00	1.00	2.00	1.00	0.35	0.097	x^4	1.00	2.00	6.00	1.00	0.39	0.087
DM_3	x^1	x^2	x^3	x^4	π	CI	DM_4	x^1	x^2	x^3	x^4	π	CI
x^1	1.00	0.33	2.00	0.20	0.13		x^1	1.00	5.00	3.00	2.00	0.50	
x^2	3.00	1.00	3.00	1.00	0.37		x^2	0.20	1.00	2.00	2.00	0.20	
x^3	0.50	0.33	1.00	0.50	0.12		x^3	0.33	0.50	1.00	0.33	0.10	
x^4	5.00	1.00	2.00	1.00	0.38	0.075	x^4	0.50	0.50	3.00	1.00	0.20	0.123
DM_5	x^1	x^2	x^3	x^4	π	CI	DM_6	x^1	x^2	x^3	x^4	π	CI
x^1	1.00	0.33	6.00	5.00	0.34		x^1	1.00	5.00	4.00	0.33	0.33	
x^2	3.00	1.00	5.00	3.00	0.48		x^2	0.20	1.00	0.50	0.33	0.09	
x^3	0.17	0.20	1.00	2.00	0.10		x^3	0.25	2.00	1.00	0.50	0.15	
x^4	0.20	0.33	0.50	1.00	0.08	0.139	x^4	3.00	3.00	2.00	1.00	0.43	0.132

5. The preference judgment results can then feedback to all the decision-makers based upon the results as shown in Table 3 and Figure 1. Decision-makers can make adjustments after seeing the first round of deliberation. The group then begins another round of decision-making (i.e., repeating the decision-making process starting from step 2).
6. Repeat step (2) through step (5) for five times, t = 5.

Table 2. The preference value for every decision-maker in the first round

0.17	0.36	0.12	0.35
0.38	0.12	0.11	0.39
0.13	0.37	0.12	0.38
0.50	0.20	0.10	0.20
0.34	0.48	0.10	0.08
0.33	0.09	0.15	0.43

7. Different preference difference matrices in each round are gotten. Here the difference matrix in the last round are only presented, as shown in Figure 2 and Table 4. The scales in Figure 1 and Figure 2 are the same.

DM_1 and DM_3 belong to the same cluster in $\varepsilon^1 = 0.239$, so do the DM_2 and DM_6. DM_4 and DM_5.

As shown in Figure 2, the clustering distance in the fifth round is $\varepsilon^5 = 0.143$. It can be seen that the individual preferences are clustered into three

Table 3. Preference difference matrix in the first round

0					
0.313	0				
0.054	0.353	0			
0.393	0.245	0.446	0		
0.347	0.486	0.383	0.350	0	
0.321	**0.071**	0.354	0.307	0.532	0

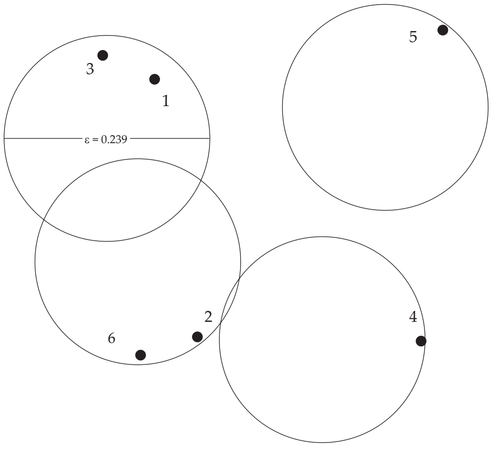
Box 1.

$$\left[w_1, w_2, \cdots, w_s\right] \begin{bmatrix} \pi_1(x^1) & \pi_1(x^2) & \cdots & \pi_1(x^s) \\ \pi_2(x^1) & \pi_2(x^2) & \cdots & \pi_2(x^s) \\ \cdots & \cdots & \cdots & \cdots \\ \pi_l(x^1) & \pi_l(x^2) & \cdots & \pi_l(x^s) \end{bmatrix} \begin{bmatrix} T_{11} & T_{12} & \cdots & T_{1s} \\ T_{21} & T_{22} & \cdots & T_{2s} \\ \cdots & \cdots & & \cdots \\ T_{s1} & T_{s2} & \cdots & T_{ss} \end{bmatrix} = [x^1 \quad x^2 \quad \cdots \quad x^s] \tag{5}$$

clusters. DM_1, DM_3 and DM_4 belong to the same cluster, DM_3 and DM_5 belong to the same cluster, and DM_2 and DM_6 belong to the same cluster. In Figure 2, the diameter of the larger circle is the clustering distance in the first round ($\varepsilon^1 = 0.239$). From this figure, it is easy to see that if we use this distance to cluster the individual preferences, five decision-makers have come to consensus in $\varepsilon^1 = 0.239$, that is, DM_1, DM_2, DM_3, DM_4, and DM_6. Thus the clustering distance is reduced gradually in each round and shows the convergence of the group preference and the procedure of reaching consensus.

Substituting the values into the solution given in the appendix C yields the weight vector for the decision-making group $W = (0.131 \quad 0.264 \quad 0.163 \quad 0.165 \quad 0.113 \quad 0.162)$.

Figure 1. Clustering result of the individual preference utility values in the first round



8. Construct the Markov state transition matrix T using Equation (3) and (4) with the saved preference utility values$\{\pi_r^t(x^1), \pi_r^t(x^2), \cdots, \pi_r^t(x^s)\}$. In this example, if $\pi_r^k(x^i) - \pi_r^{k+1}(x^i) > 0.01$ and $\pi_r^{k+1}(x^j) - \pi_r^k(x^j) > 0.01$ occurs, it is considered as an one time transition $\pi_r^{k+1}(x^i)\downarrow \Leftrightarrow \pi_r^{k+1}(x^j)\uparrow$, let the state variable $E_{ij} = E_{ij} + 1$, thus it indicates that the decision-maker DM_r transits from alternative x^i to alternative

x^j for one time. The final preference state transition matrix is

$$T = \begin{bmatrix} 0.333 & 0.417 & 0.0417 & 0.208 \\ 0.125 & 0.875 & 0 & 0 \\ 0.083 & 0 & 0.917 & 0 \\ 0.292 & 0.333 & 0.083 & 0.292 \end{bmatrix}.$$

9. Multiply the weight vector $W = (w_1, w_2, \cdots, w_s)$ by the preference matrix Λ in the last round, and then by the Markov state transition matrix T, we have

$$\begin{bmatrix} 0.131 & 0.264 & 0.163 \\ 0.165 & 0.113 & 0.162 \end{bmatrix} \begin{bmatrix} 0.23 & 0.32 & 0.19 & 0.26 \\ 0.33 & 0.23 & 0.13 & 0.31 \\ 0.22 & 0.40 & 0.15 & 0.23 \\ 0.28 & 0.35 & 0.15 & 0.22 \\ 0.21 & 0.50 & 0.11 & 0.18 \\ 0.31 & 0.20 & 0.17 & 0.32 \end{bmatrix}$$

$$= [0.273 \quad 0.314 \quad 0.148 \quad 0.262] \qquad (6)$$

$$\begin{bmatrix} 0.273 & 0.314 \\ 0.148 & 0.262 \end{bmatrix} \begin{bmatrix} 0.333 & 0.417 & 0.0417 & 0.208 \\ 0.125 & 0.875 & 0 & 0 \\ 0.083 & 0 & 0.917 & 0 \\ 0.292 & 0.333 & 0.083 & 0.292 \end{bmatrix}$$

$$= [0.219 \quad 0.476 \quad 0.169 \quad 0.133]. \qquad (7)$$

[0.219 0.476 0.169 0.133] is the preference utility values vector on the set of alternatives X and the alternative x^2, corresponding to $\max\{x^i\}$ ($i = 1, 2, \cdots, s$) = 0.476, is the final alternative chosen by the decision-making group.

Comparing the result of Equation (6) with the result of (7), it can be seen that if the possible decision preference changes are not taken into account (the dynamic nature of group decision-making process), it will come to the static conclusion $x^2Rx^1Rx^4Rx^3$ as shown in Equation (6) (i.e., the preferred decision alternatives are determined in following sequential order: the most preferred decision alternative x^2, followed by the decision alternatives x^1, x^4, and x^3). This conclusion is drawn by traditional meta-synthetic approaches on group decision-making, that is, after decision weights for every decision-maker are assigned and fixed, the group preference value on each decision alternative is determined by the sum of each decision-maker's decision weight multiplied by her/his *current preference value* of the alternative. Finally, all alternatives are sorted in the order of their preference values to derive the final group decision.

On the other hand, if the possible decision preference changes are not taken into account, the conclusion comes to the result $x^2Rx^1Rx^4Rx^3$ as shown in Equation (7), different from the result of Equation (6), which would be closer to group decision-making in reality. This difference shows the importance of considering dynamic decision preference change into group decision-making model.

The decision difference between traditional methods and the currently proposed one may not always ensure a better group decision result, which will be further discussed.

Considering an ergodic Markov chaie, let T be a probability matrix. If there exists a $m(m > 1, m \in Z)$, which makes all the elements of T^m positive, T is called a normal stochastic matrix. A probability vector π must exist, which makes

$$\pi = \pi T \text{ and } \pi_j = \lim_{n\to\infty} T_{ij}^n \text{ for all } i \qquad (8)$$

The probability vector π is called the steady state vector for the state transition matrix T.

It is easy to show that the preference state transition matrix in our example is a normal stochastic matrix. Thus there must exist a probability vector π, the steady state solution to the group decision-making problem on the alternative set. Therefore the following Equations are resolved.

$$\begin{cases} \pi = \pi T \\ \sum_{i=1}^{s} \pi_i = 1 \\ \pi_i > 0 \quad i = 1, \cdots, s \end{cases} \qquad (9)$$

or see Box 2.

Box 2.

$$\begin{cases} [\pi_1 \quad \pi_2 \quad \pi_3 \quad \pi_4] = [\pi_1 \quad \pi_2 \quad \pi_3 \quad \pi_4] \begin{bmatrix} 0.333 & 0.417 & 0.0417 & 0.208 \\ 0.125 & 0.875 & 0 & 0 \\ 0.083 & 0 & 0.917 & 0 \\ 0.292 & 0.333 & 0.083 & 0.292 \end{bmatrix} \\ \pi_1 + \pi_2 + \pi_3 + \pi_4 = 1 \\ \pi_i > 0 \quad i = 1, \cdots, s \end{cases} \tag{10}$$

We have

$$\pi = [0.161014988 \quad 0.663345006 \quad 0.128267958 \quad 0.047323744] \tag{11}$$

The result shown in Equation (11) represents the decision preference order $x^2Rx^1R\,x^4R\,x^3$, the same result derived from Equation (7). Note that now this conclusion in Equation (11) has nothing to do with the decision weight vector W and decision preference value matrix Λ in the last round, and only depends on the decision preference state transition matrix T.

Comparing the Equations (6), (7), and (11), several conclusions can be drawn:

1. The traditional meta-synthetic approaches on group decision-making, neglecting the dynamic nature of decision preference adjustments/changes of group decision-makers, can lead to the loss of important decision element/information for group decision-making.
2. The dynamic nature of decision preference adjustment/change is one important part of group decision-making process, which should not be neglected.
3. The conclusion drawn on Equation (11) merely depends on the Markov state transition matrix, not on the decision weight vector W and decision preference value matrix Λ in the last round. This shows that if there would be enough time for a group to continue group decision-making process, group consensus will be reached in the form as shown in Equation (11).
4. The static conclusion $x^2Rx^1R\,x^4R\,x^3$ derived from Equation (6) can be considered as a transient result that will change as group decision-making process proceeds.
5. The dynamic decision-making conclusion $x^2Rx^1R\,x^4R\,x^3$ derived from Equation (7) can be considered as a stationary result that includes the developing trend of group decision-making process. That is that, as group decision-making rounds continue ($t > 5 \to \infty$), group decision result will come to the conclusion as shown Equation (11), the same as being derived from Equation (7).
6. As a result, it is shown that the group decision-making steps based on the Markov Chain, can help a group derive decision conclusion, as shown by Equation (11), which could otherwise be achieved by a big number of (or even infinite) group decision-making rounds. Therefore, in mission-critical group decision-making situation with short response time, the proposed approach could help a group reach consensus on final group decision within a few decision-making rounds (usually 5~9 rounds), rather than a big number of decision-making rounds (or infinite decision-making rounds), which may lead to more efficient and effective group decision-making.

DISCUSSION AND FUTURE RESEARCH

Discussion and Implications

This study contributes to the research literature in three aspects. First, prior research does not consider group decision-making preference being dynamic, which would be fixed and not be changed in group decision-making process, neglecting its existence and its impact on group decision-making. The proposed approach in this article solves this problem using the Markov Chain model. Further, the proposed approach can automatically determine and present group decision-makers' decision preference distances as well as similar decision preference clusters they belong to, which clearly shows similar and different positions of group decision-makers on a given mission-critical decision-making task in its first round and subsequent decision-making rounds, which in turn may support group decision-makers in more effectively adjusting their decision preferences/positions to help reach group final decision more efficiently and effectively. This is very important to mission-critical decision-making tasks. Future studies can use empirical research methodologies to examine this research issue.

Second, the proposed group decision weight allocation approach solves the problems of traditional methods that require substantial historical decision data and largely involve subjective judgment.

Third, the proposed approach provides a solution to Coudorcet's group decision paradox. One commonly used group decision rule is group concensus or majority rule (Nunamaker, Briggs, Mittleman, Vogel, & Balthazard, 1997; Huang & Wei, 1997; Huang, Wei, & Tan, 1999; Watson, DeSanctis, & Poole, 1988). When there are more than three decision alternatives, it may be possible to generate a group decision cyclic loop, which would be theoretically impossible to read a group consensus or majority rule (Coudorcet, 1785). For example, there are three decision-makers (DM_1, DM_2, DM_3) in a group and three alternatives (A, B, C). Table 5 shows possible decision results for each decision-maker.

It is so-called the Voting Paradox (also known as Condorcet's paradox) (Coudorcet, 1785; Deemen, 1999; Nanson, 1882), as shown in Figure 3.

Let the number of decision-makers in a group be l, P denotes the probability of generating group decision circular loop based on majority rule. Prior studies report the relationship between l and P, as shown in Table 6 (Niem & Weisberg, 1968); but when l is large, the relationship between the number of alternatives s and P is shown in Table 7 (Niem & Weisberg, 1968).

In this research, each decision-maker's decision preference judgment matrix based on pair wise comparisons are had and the characteristic vector from AHP is introduced to derive the sequential order of decision alternatives of each decision-maker. When decision-makers do pair wise comparisons on decision alternatives, which leads to a group decision preference judgment matrix, this matrix might result in group decision

Table 5. Decision result for each decisoin maker

Decision Maker	Preferences

cyclic loops. However, this matrix is only used for determining group decision-makers' decision weights, not for determining group's final decision. So it will not lead to Condorcet's paradox. When a group comes to the final group decision, a group decision cyclic loop can be avoided because the group decision sequential order of decision alternatives from a decision-maker are gotten based upon the calculation of the characteristic vector of her preference judgment matrix, not the preference judgment matrix itself. Therefore, the group decision-making approach proposed in this research can avoid the possibility of group decision circular loop, which provides a solution to Condorcet's paradox in group decision-making.

In practice, incorporating the proposed approaches to an existing GDSS system, the system may have a potential to help a group reach group decision consensus faster and more effectively, which can be especially important to mission-critical decision-making tasks. While global terrorism currently becomes one major threat to all the countries of the world, and while more globalized world economy would possibly lead to one country's major economic problem quickly becoming an emerging mission-critical problem of other countries within days or sometimes hours, many of those cross-border mission-critical problems would require group decision-makers to respond quickly and make decisions quickly. The proposed approach provides a possible solution to those mission-critical group decision-making problems that may be faced by both developed and developing countries. Field studies can be conducted to further investigate the effectiveness of such proposed GDSS systems in the future.

Research Limitation

It should be noted that not all the Markov state transition matrices in group decision-making process, based on the Markov chain approach, would surely be normal stochastic ones, which can be shown in the example.

If decision preference adjustment only runs for a few rounds, for example, $t < 5$, the overall state transition matrix for a group can be shown in the matrix T:

$$T = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0.5 & 0.5 & 0 & 0 \\ 0 & 0.25 & 0.75 & 0 \\ 0 & 0.25 & 0.25 & 0.5 \end{bmatrix}.$$

It is clear that T is not a normal stochastic matrix, and its steady state solution can not be resolved using Equation (9). In this case, group decision-making result can be conducted derived from Equation (7) instead of Equations (8) ~ (11). As a result, the proposed approach, though being efficient and effective in most cases, may not be so in all cases. Future research can look at this limitation and provide further improvement.

APPENDIX A

A.1 Definition of Preference Utility Value and a Set of its Quantificational Values

Let G denote a decision-making group, DM_r be the r^{th} decision-maker of the group with l decision-makers, then $G = \{DM_r | r \in \Omega\}(\Omega = \{1, 2, \cdots, l\}, 2 \leq l < +\infty)$. Let X be a set of alternatives, x^i be the i^{th} alternative and there are s alternatives in the alternative set, then $X = \{x^i | i \in \Omega\}(\Omega = \{1, 2, \cdots, s\}, 2 \leq s < +\infty)$.

Definition 1. Preference utility value $\theta_r(x^i, x^j)$: *Let* R_r *denote the preference relation of* DM_r *on* X. *Let* $x^i R_r x^j$ *denote that comparing* x^i *with* $x^j (x^i, x^j \in X)$, DM_r *tends to choose* x^i. *According to the needs of the decision-making, let* $\theta_r(x^i, x^j)$, *a real number, denote the quantificational difference of* DM_r*'s preference degrees on the two alternatives* x^i *and* x^j.

Let's define the quantificational values of $\theta_r(x^i, x^j)$ as in Table 5.

$\theta_r(x^i, x^j)$	the signification to DM_r
1	x^i and x^j has equal preference degree
3	Compared with x^j, x^i is a little better
5	Compared with x^j, x^i is better
7	Compared with x^j, x^i is much better
9	Compared with x^j, x^i is absolutely better
2, 4, 6, 8	The middle state's corresponding utility values of the judgments
reciprocal	Compared x^j with x^i, the utility value of preference $\theta_r(x^j, x^i) = 1 / \theta_r(x^i, x^j), \theta_r(x^i, x^i) = 1$

A.2 The Solving Process of the Consistence Indicator CI_r

From the theory of matrix, the Equation $(P_r - \lambda I)\pi^T = 0$ has at least one group of solutions, where π^T is the characteristic vector, λ is the characteristic value. An approximate calculation algorithm is given to get the maximal characteristic value $\lambda_{\max}^{(r)}$ and characteristic vector $\pi_r = (\pi_r(x^1), \pi_r(x^2), \cdots, \pi_r(x^s))$ of P_r in Appendix A.

1. Calculate the geometric mean of all the elements in each row of the matrix

$$\bar{\pi}_r(x^i) = \sqrt[s]{\prod_{j=1}^{s} \theta_r(x^i, x^j)} \quad i = 1, 2, \cdots, s \tag{12}$$

We have $\bar{\pi}_r = (\bar{\pi}_r(x^1), \bar{\pi}_r(x^2), \cdots, \bar{\pi}_r(x^s))$

2. Normalize $\bar{\pi}_r(x^1)$

$$\pi_r(x^i) = \frac{\bar{\pi}_r(x^i)}{\sum_{j=1}^{s} \bar{\pi}_r(x^j)} \quad i = 1, 2, \cdots, s \tag{13}$$

Then $\pi_r = (\pi_r(x^1), \pi_r(x^2), \cdots, \pi_r(x^s))$ is the approximate solution of the characteristic vector. We call $\pi_r(x^1)$ the preference utility value of DM_r on x^1. The set $\{\pi_r(x^1), \pi_r(x^2), \cdots, \pi_r(x^s)\}$ denotes the preference utility values set of DM_r on the set of alternatives.

3. Calculate the maximal characteristic value $\lambda_{\max}^{(r)}$ of the matrix P_r

$$\lambda_{\max}^{(r)} = \sum_{i=1}^{s} \frac{(\mathrm{P}_r \pi_r)_i}{s\pi_r(x^i)} \tag{14}$$

where $(P_r \pi_r)_i$ is the i^{th} element of the vector $P_r \pi_r$.

The consistency test index CI from AHP is introduced (Saaty, 1988)

$$CI_r = \frac{\lambda_{\max}^{(r)} - s}{s-1} = \frac{\lambda_{\max}^{(r)}}{s-1} - \frac{s}{s-1} \tag{15}$$

Let CI_r denote the r^{th} decision maker DM_r's preference judgment consistency. CI_r is an indicator to measure whether the decision maker's judgment is careful. The smaller CI_r is, the better it is. Especially, when $CI_r = 0$, the preference judgment matrix P_r is a complete consistency matrix, which represents the complete consistency of DM_r's preference judgment. However, when people do pair wise comparisons they cannot ensure their judgments are completely consistent because of the complexity of the objective reality and the limitation of human thoughts. There usually exists error of estimation which makes CI_r larger than 0. The larger CI_r is, the worse the consistency of P_r becomes.

APPENDIX B: CLUSTERING METHOD AND DEFINITION OF PREFERENCE DISTANCE

Packing all the preference values $\pi_r(x^1)$ $(1 \le i \le s;\ 1 \le r \le l)$ from the l decision-makers in the group, we have the $l \times s$ preference value matrix Λ

Definition 2. *The Euclidean preference distance between decision-maker DM_i and DM_j on a set of alternatives X is*

$$d_{ij} = \sqrt{\sum_{k=1}^{s} \left| \pi_i(x^k) - \pi_j(x^k) \right|^2}. \tag{16}$$

The Euclidean preference distance d_{ij} also denotes the difference of consensus between decision-maker DM_i and DM_j on X.

Packing the preference distances of all the l decision-makers, we have the $l \times l$ preference difference matrix,

$$D = \begin{bmatrix} 0 & & & & \\ d_{21} & 0 & & & \\ d_{31} & d_{32} & 0 & & \\ \cdots & \cdots & \cdots & 0 & \\ d_{l1} & d_{l2} & d_{l3} & \cdots & 0 \end{bmatrix} \tag{17}$$

where d_{ij} is nonnegative. The closer DM_i and DM_j are to each other, the smaller d_{ij} is. As $d_{ij} = d_{ij}$ and $d_{ij} = 0$, we have the matrix as shown in Equation (17).

Definition 3. *Let* $C = \{c^{\omega}: \omega = 1, 2, \cdots, m\}$ *be the preference cluster of the group G on a set of alternatives X,* ε *be the given clustering distance. If the distance between each two elements in* c^{ω} *satisfies the constraint* $d_{ij} \leq \varepsilon \in c^{\omega}$*, we call that* c^{ω} *is a cluster, that is, the sub-group comes to consensus in* c^{ω}*.*

Definition 4. *With respect to the decision-makers* DM_i *and* DM_j*, if* $(d_{ij} \leq \varepsilon) \in c^{\omega} \subseteq C$*, we call that* DM_i *and* DM_j *come to partial consensus in* c^{ω}*. As to* $d_{rq} \leq \varepsilon^k \in c^k, (d_{ij} \leq \varepsilon^l) \in c^l$*, if and only if* $\varepsilon^k = \varepsilon^l = \varepsilon$ *and* $d_{ri} \leq \varepsilon$, $d_{rj} \leq \varepsilon$, $d_{iq} \leq \varepsilon$, $d_{jq} \leq \varepsilon$*, we call* $c^k = c^l$ *is the same cluster.*

Example 1. *Suppose there is an initial preference utility value matrix as follows,*

$$\Lambda = \begin{bmatrix} 0.1 & 0.3 & 0.2 & 0.4 \\ 0.2 & 0.4 & 0.1 & 0.3 \\ 0.3 & 0.1 & 0.4 & 0.2 \\ 0.4 & 0.2 & 0.3 & 0.1 \\ 0.3 & 0.3 & 0.3 & 0.1 \\ 0.2 & 0.2 & 0.2 & 0.4 \end{bmatrix}. \tag{18}$$

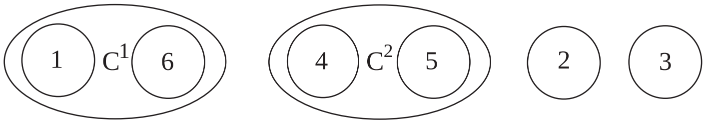
Substituting the values into Equation (16), the consensus difference matrix (the preference difference matrix) as follows is had,

$$d = \begin{bmatrix} 0 & & & & & \\ 0.2 & 0 & & & & \\ 0.4 & 0.447 & 0 & & & \\ 0.447 & 0.4 & 0.2 & 0 & & \\ 0.374 & 0.316 & 0.245 & 0.141 & 0 & \\ 0.141 & 0.245 & 0.316 & 0.374 & 0.346 & 0 \end{bmatrix}. \tag{19}$$

1. Given $\varepsilon^1 \leq 0.15$ thus $d_{61} = d_{54} = 0.141 \leq \varepsilon^1$

The results DM_1, $DM_6 \in c^1$ and DM_4, $DM_5 \in c^2$ can be had. Although $d_{61} = d_{54} \leq \varepsilon^1$, $\min\{d_{65}, d_{64}, d_{51}, d_{41}\} = 0.346 > \varepsilon^1$ thus c^1, c^2 are not the same cluster according to Definition 4 and the two clusters come to partial consensus separately. DM_2 and DM_3 have not come to consensus with others as shown in Figure 3.

Figure 3.



2. Given $\varepsilon^2 \leq 0.2$, we have $d_{21} = d_{43} = 0.2 \leq \varepsilon^2$ and $d_{61} = d_{54} = 0.141 \leq \varepsilon^1$, that is, $DM_1, DM_2 \in c^3$ and $DM_3, DM_4 \in c^4$ come to consensus respectively based on the consensus of $DM_1, DM_6 \in c^1$ and $DM_4, DM_5 \in c^2$. Here c^3 and c^4 are not the same cluster, as shown in Figure 4.
3. Given $\varepsilon^3 \leq 0.25$, we have $d_{61} = d_{54} = 0.141 \leq \varepsilon^1$, $d_{21} = d_{43} = 0.2 \leq \varepsilon^2$, and $d_{62} = d_{53} = 0.245 \leq \varepsilon^3$, that is, $DM_1, DM_2, DM_6 \in c^5$ come to consensus in c^5 and $DM_3, DM_4, DM_5 \in c^6$ come to consensus in c^6 as shown in Figure 5.

Assume k clusters are being sought after clustering with given ε and there are $\hat{l}$ elements in one of the k clusters, c^{ω}.

Definition 5. *To those clusters that have more than* 2 *elements, that is,* $2 \leq \hat{l} \leq s$*, the cluster center is defined as*

$$\hat{\pi} = \frac{1}{\hat{l}}\sum_{i=1}^{\hat{l}} \pi_i . \tag{20}$$

The Euclidean distance of preference between a decision-maker DM_r and the specified cluster center is then defined as

$$d_r = \sqrt{\sum_{k=1}^{s} \left|\pi_r(x^k) - \hat{\pi}(x^k)\right|^2} . \tag{21}$$

APPENDIX C: A SOLUTION OF THE DECISION WEIGHT VECTOR

Construct the Lagrange function for the optimization model,

$$L(w,\xi) = \sum_{r=1}^{l}[(\frac{\lambda_{\max}^{(r)}}{s-1} - \frac{s}{s-1}) + \sqrt{\sum_{k=1}^{s}(\pi_r(x^k) - \hat{\pi}(x^k))^2}\,]w_r^2 + 2\xi(\sum_{r=1}^{l} w_r - 1). \tag{22}$$

Figure 4.

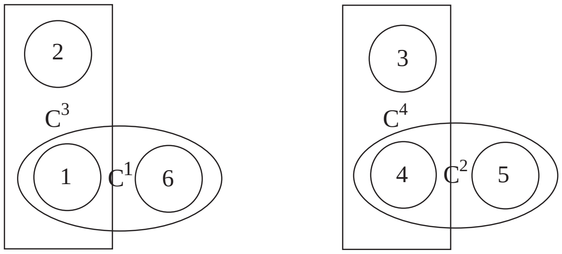


Figure 5.

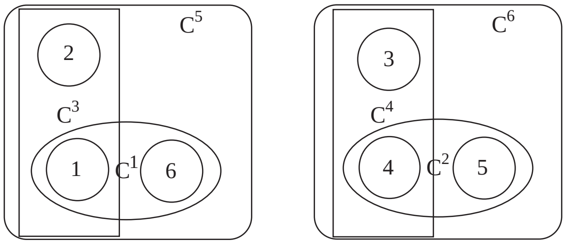

From the first-order condition of Equation (24), we have

$$\begin{cases} \dfrac{\partial L}{\partial w_r} = 2[(\dfrac{\lambda_{\max}^{(r)}}{s-1} - \dfrac{s}{s-1}) + \sqrt{\sum_{k=1}^{s}(\pi_r(x^k) - \hat{\pi}(x^k))^2}\,]w_r + 2\xi = 0 \\ \dfrac{\partial L}{\partial \xi} = \sum_{r=1}^{l} w_r - 1 = 0 \end{cases}$$

which implies that

$$\begin{cases} w_r = \dfrac{-\xi}{[(\dfrac{\lambda_{\max}^{(r)}}{s-1} - \dfrac{s}{s-1}) + \sqrt{\sum_{k=1}^{s}(\pi_r(x^k) - \hat{\pi}(x^k))^2}\,]} & (23) \\ \sum_{r=1}^{l} w_r = 1 & (24) \end{cases}$$

Thus, we have

$$\begin{cases} \xi = -\dfrac{1}{\sum_{r=1}^{l} 1 \Big/ [(\dfrac{\lambda_{\max}^{(r)}}{s-1} - \dfrac{s}{s-1}) + \sqrt{\sum_{k=1}^{s}(\pi_r(x^k) - \hat{\pi}(x^k))^2}\,]} & (25) \\ w_r = \dfrac{1}{[(\dfrac{\lambda_{\max}^{(r)}}{s-1} - \dfrac{s}{s-1}) + \sqrt{\sum_{k=1}^{s}(\pi_r(x^k) - \hat{\pi}(x^k))^2}\,] \bullet \sum_{r=1}^{l} 1 \Big/ [(\dfrac{\lambda_{\max}^{(r)}}{s-1} - \dfrac{s}{s-1}) + \sqrt{\sum_{k=1}^{s}(\pi_r(x^k) - \hat{\pi}(x^k))^2}\,]} & (26) \end{cases}$$

From Equation (26), the decision weight vector assigned to a group of decision-makers, $W = (w_1, w_2, \cdots, w_s)$ can be derived.

APPENDIX D: DISCRETE TIME MARKOV CHAINS AND MARKOV PROPERTY OF THE GROUP DECISION-MAKING PROCEDURE

A sequence of random variables $\{E_n\}$ is called a Markov chain if it has the Markov property:

$$T\{E_{n+1} = j \mid E_n = i, E_{n-1} = i_{n-1}, \ldots, E_0 = i_0\} = T\{E_{n+1} = j \mid E_n = i\}$$
$$T_{ij} = T\{E_{n+1} = j \mid E_n = i\} \qquad (27)$$

Here, E_i is an event and T_{ij} is the probability to transit from state i to state j of the event. The property is called Memoryless. In other words, “Future” is independent of “Past” given “Present.” Here the transition probabilities T_{ij} satisfy

$$T_{ij} \geq 0, \quad \sum_{j=0}^{\infty} T_{ij} = 1.$$

The Chapman-Kolmogorov Equation for a discrete-time Markov chain is as follows: If the distribution at time t_n is $\pi^{(n)}$, then the distribution at time t_{n+1} is given by

$$\pi^{(n+1)} \tag{28}$$

Because each decision-maker in the group independently puts forward her/his preference judgment matrix, the preference state E^r_n of decision-maker DM_r is independent of other decision-makers and the future preference state E^r_{n+1} is independent of other states except the current state E^r_n, thus the group decision-making procedure satisfies Equation (27).

Obviously, the transition probabilities T_{ij} constructed from Equation (3) satisfy

$$T_{ij} \geq 0, \quad \sum_{j=0}^{\infty} T_{ij} = 1.$$

Equation (4) shows that the overall state transition probabilities matrix is the mean value of the matrices of transition probabilities of each decision-maker, thus the group property is implied in the individual properties.

Therefore, the Chapman-Kolmogorov Equations, Equation (28) can be used to get $\pi^{(n+1)}$ at “time”t_{n+1} from $\pi^{(n)}$ at “time” t_n.

ABSTRACT

This chapter introduces spatial dimensions and measures as a means of enhancing decision support systems with spatial capabilities. By some way or other, spatial related data has been used for a long time; however, spatial dimensions have not been fully exploited. It is presented a data model that tightly integrates data warehouse and geographical information systems — so characterizing a spatial data warehouse (SDW) — ; more precisely, the focus is on a formalization of SDW concepts, on a spatial-aware data cube using object-relational technology, and on issues underlying a SDW — specially regarding spatial data aggregation operations. Finally, the MapWarehouse prototype is presented aiming to validate the ideas proposed. The authors believe that SDW allows for the efficient processing of queries that use, jointly, spatial and numerical temporal data (e.g., temporal series from summarized spatial and numerical measures).

INTRODUCTION

Decision support systems aim to identify historical and localizable tendencies, behaviors and information patterns, which help the decision support process. The technologies that underpin this process, using time and space dimensions as decisive factors, are: data warehouse (DW) — with online analytical processing (OLAP) interface — and geographical information systems (GIS). DW/OLAP systems are responsible for both data extraction from several operational sources and data organization according to a historical, thematic and consolidated multi-dimensional model (Malinowski & Zimányi, 2004), composed by facts (numerical measurements related to business processes) and dimensions (descriptive aggregated information, often hierarchically disposed, which is arranged to define the facts). Conceptually, a DW is a multi-dimensional array, or simply a data cube. OLAP queries over a DW provide data exploration and analysis operations by means of aggregate navigation through dimension hierarchies — drill-down, roll-up. Other typical OLAP operations are data cube slicing, dicing and pivoting. Materialized data cubes aim to guarantee high performance of OLAP operations. On the other side, GIS provide manipulation, storage and visualization of spatial data, so that decision-makers may enhance the quality of their analysis using the spatial dimension.

The main objective of this chapter is to present a spatial data warehouse (SDW) (Rivest, Bédard, & Marchand, 2001; Pourabbas, 2003) conceptual model which tightly integrates DW and GIS. Also, we rigorously define a logical model suitable for implementing decision-making processes using spatial data. The other two main contributions of the chapter are: (1) the proposal of a query language for the logical model with query optimization techniques, and (2) the presentation of a prototype developed in order to validate our ideas.

The advantages separately provided by GIS and DW technologies have motivated research on their integration. Existent integration approaches do not fulfill the requirements for a *stricto sensu* integration, which are: (1) to summarize spatial data (e.g., map-overlay, region merge) through spatial dimensions — spatial roll-up and its counterpart, spatial drill-down —, and (2) to synchronize spatial and numerical historical summarized data.

A case study on agricultural crops in Brazil is discussed throughout the chapter. In order to have an efficient seed distribution policy to Brazilian farmers, several issues ought to be taken into account including soil type, rainfall and type of seed. Hence, a SDW may help authorities in finding the best policy for a particular situation, based on dynamic maps, tables, graphics, reports, and so on. As it can be noticed, this application encompasses space, time and analytical dimensions. Query examples exploiting these dimensions in this particular application domain include:

- Which cultivation better adapts to each municipality, region or state following the plantation conditions of last year (semester or month, etc.)?
- What are the favorable pattern conditions to the corn (mango or coffee, etc.) cultivation for a particular geographical region?
- Where is the best place to plant a particular crop?
- When is the best season for planting a given crop?

The remainder of this chapter is organized as follows. A background with discussion of related work is presented in the following section. Then our spatial multidimensional model is addressed, followed by the proposal of an object-relational spatial data cube. Query optimization techniques and a description of a prototype which aims to validate the proposed ideas — the MapWarehouse Project — are presented. Finally, the conclusion and further research to be undertaken are highlighted.

BACKGROUND

The research on spatial data warehouse is very incipient. Many of the research proposals are based on either federated or integrated architectures. In federated architecture, numerical and spatial data are linked through some common properties without affecting their original sources. Moreover, the responsibility for information capture and translation among different sources is limited to some components. This usually originates lost of transparency and some semantic problems (Kouba et al., 2000; Rivest et al., 2001; Pourabbas, 2003). One of the prominent research project based on this federated architecture is GOLAP (Kouba et al., 2000).

In the GOLAP project, the main component is a mediator — an integration module — which is responsible for the correspondence between a GIS and a DW/OLAP system, by using metadata. Although the system aims to be a generic solution, there is no interaction between the functions of the GIS tool and those of the DW/OLAP. The integration between these systems is restricted to the isolated use of GIS capabilities and related dimensions of the DW. The main drawbacks of this approach are the low performance, as there is no way to perform query optimization jointly on GIS and DW; and the loss of transparency, since for every new GIS and OLAP application, the mediator must be reconfigured.

On the other hand, the integrated architecture uses a singular and adapted environment in which queries involving both spatial and numerical data may be posed. This results in high flexibility and expression power of OLAP operations. Two proposals are highlighted: GeoMiner (Han et al., 1997) and Map Cube (Shekhar et al., 2001).

GeoMiner is a project of spatial data mining that includes three modules for complete numerical-spatial data integration: spatial data cube construction, analytical-spatial query processing, and spatial data mining. To reduce the query processing costs of queries, some algorithms are proposed to selective data materialization, considering the object access frequency. Nevertheless, the Spatial OLAP query module is very incipient: operations like roll-up and drill-down, fundamental in decision support interfaces, are not provided. Hence, GeoMiner cannot be considered a truly SDW.

MapCube is defined by an operator that has a base map parameter, together with data tables and some cartographic preferences, to produce an album of maps, arranged through aggregation hierarchies. It is based on conventional data cube, but it enables the visualization of the results as data tables and maps. Despite of allowing spatial observation (through maps) of summarized data, MapCube does not support spatial roll-up/drill-down OLAP operations. Therefore, MapCube, as GeoMiner, cannot be considered a truly SDW.

As it can be inferred from the previous classification and from the Introduction, our MapWarehouse project is based on an integrated architecture. This architecture is based on well-established standards: Open Geospatial Consortium (OGC, 2005) and Common Warehouse Model (CWM, 2005). The use of such standards aims to achieve interoperability through the integration of heterogeneous data sources.

Heterogeneity in information systems has been classified as semantic, schematic and syntactic (Bishr, 1998). Currently our approach encompasses schematic and syntactic levels. However, as there is a strong interest in semantic heterogeneity, especially with the advent of the semantic Web, SDW may be modeled as ontological commitments which enable interoperability at semantic level. Such ontologies should be used in the extraction, transformation and loading process from heterogeneous spatial and OLAP data sources (Vassiliadis, Simitsis, & Skiadopoulos, 2002). Hence, semantic translations would be employed in order to transform the original data model into OGC and CWM standards used in our approach.

There are several works which address semantic interoperability. Mackey (1999) focuses on the issue of semantic integration of environmental models, in which both GIS and decision support systems play an important role. Fonseca, Davis, and Camara (2003) propose an ontology-driven GIS which aims to integrate heterogeneous GIS without demanding the use of a unique standard. Reitsma and Albrecht (2005) claim the use of ontologies to model earth systems which may provide interoperability among models and simulators. They argue that in the occurrence of natural disasters, the use of the semantic Web enables the integration of models with spatial decision-support systems, providing quick response to the emergency rescue teams.

Nonetheless, none of these works have addressed the integration of GIS with spatial DW in order to obtain an enhanced decision support system which may provide OLAP and spatial capabilities to better retrieve the underlying information.

A SPATIAL MULTIDIMENSIONAL MODEL

Our spatial multidimensional conceptual model integrates completely the common warehouse model (CWM) for DW with the OGC geometry object model (OGC, 2005). Moreover, extensions of traditional OLAP operations (especially drill-down, roll-up) to deal with spatial objects are proposed. For spatial queries, the use of spatial operations such as contains, meets, covers, intersection, union, buffer and so on, is considered. Finally, query results may be presented as maps and tables.

A CWM Schema is a logical container of elements of an OLAP model. It consists of Cube classes, which contain Dimension classes. Dimension classes contain Hierarchy classes, which are level-based (LevelBasedHierarchy classes). A Dimension class generalizes specific dimension classes, such as TimeDimension.

In order to support spatial elements, we extended the CWM model with a new dimension class, SpatialDimension, which extends the Dimension class. A spatial dimension may contain SpatialLevel objects inside Hierarchy classes — SpatialHierarchies. A SpatialLevel object can be shared by several spatial hierarchies. Moreover, we introduce a SpatialMeasure class that is part of the Cube class.

The Geometry class from the OGC specification contains a class hierarchy which may represent vector spatial data as points, lines, areas and collections of these elements. The details of that class are outside the scope of the chapter; the interested reader could refer to OGC (OGC, 2005). Concerning our integration model, the OGC Geometry class is part of both the SpatialLevel and SpatialMeasure classes.

Spatial Model Semantics

Now, we discuss in more details the semantics of the following spatial elements of the model: spatial hierarchy, spatial dimension, spatial fact, and spatial cube. In the discussion, dimension classes apart from the SpatialDimension class are sometimes named NonSpatialDimension classes.

A SpatialLevel class is composed of geometric classes for which the application needs to keep its geometry. SpatialLevel classes can relate to each other through topological relationships such as contains, intersects, overlaps, and so forth. A SpatialHierarchy class contains one or more SpatialLevel classes. Formally:

Definition 1. Spatial hierarchy.

Let $<$ be a symbol for the inside topological relationship between classes. A SpatialHierarchy class SH is a four-tuple $(SL, <_{SL}, \top_{SL}, \perp_{SL})$, where $SL = \{ SL_j, j = 1, \ldots, n\}$ are the SpatialLevel classes of SH with $n \geq 1$, $<_{SL}$ is the inside topological operator on the SL_j´s, with $\top_{SL} \in SL$ and $\perp_{SL} \in SL$ being the top and the bottom element of the ordering, respectively.

Figure 1 is an example of a SpatialHierarchy object, composed of three SpatialLevel objects partially related to each other through the contains topological relationship.

A NonSpatialDimension class is an aggregation criterion for NumericalMeasure classes, all along its NonSpatialHierarchy classes. The unique difference between a SpatialDimension class and a NonSpatialDimension one is that the former includes at least a SpatialHierarchy class. Formally:

Definition 2. Spatial dimension.

A SpatialDimension class D is a three-tuple (SH, ~SH, OT), where SH is a set of SpatialHierarchy classes, ~SH is a set of NonSpatialHierarchy classes, and OT is a set of other classes (that is, different from SpatialHierarchy classes and from NonSpatialHierarchy classes).

An example of a SpatialDimension class called Location would be:

SH = {municipality_geometry < microregion_geometry < region_geometry < state_geometry}
~SH = {municipality_name < microregion_name < region_name < state_name}
OT = {municipality_area, estimated_population}

A SpatialMeasure class is composed of a (set of) Geometry class(es), and it can be aggregated according to either SpatialDimension or NonSpatialDimension classes. Figure 2 shows a CropArea — a SpatialMeasure class — object, which is a set of geometric objects (areas) associated with at least a Location — a SpatialDimension class — object, and a Plantation — a NonSpatialDimension class — object (bean). Figure 3 shows the map overlay of two CropArea objects.

A *SpatialMeasure* class can be formalized as follows:

Definition 3. Spatial measure.

Let SpatialDimension classes SD and NonSpatialDimension classes ~SD. A SpatialMeasure class SM is a tuple (G, R), where G is a non-empty set of geometric classes, and R is a geometric-dimension relation $\{(g_i, d_j), i = 1,\ldots m;\ j = 1, \ldots, n\}$, where $g_i \in G$ and $d_j \in (SD \cup {\sim}SD)$.

A SpatialDataCube class represents an n-dimensional array, in which each cell of the array is either a SpatialMeasure or a NumericalMeasure class, while the dimensions of the array are both SpatialDimension and NonSpatialDimension classes. We may now define formally SpatialDataCube classes.

Definition 4. Spatial data cube.

A SpatialDataCube class SDC is a tuple $(SD \cup {\sim}SD, SM \cup NM, GR, {\sim}GR)$, where SD is a set of SpatialDimension classes, ~SD is a set of NonSpatialDimension classes, SM is a set of SpatialMeasure classes, NM is a set of NumericalMeasure classes, GR is a set of Geometric-Dimension relations and ~GR is a set of NonGeometric-Dimension relations.

In the following section, we precise how one can implement SpatialDataCube classes and their extents.

Figure 1. A spatial hierarchy

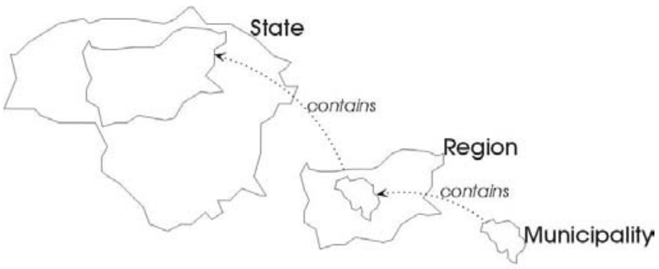

Figure 2. Spatial measures and their location

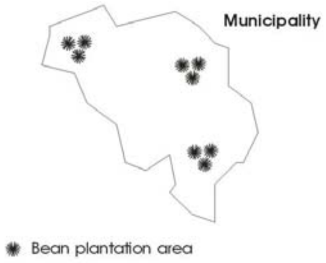

Figure 3. Geometric union of spatial measures

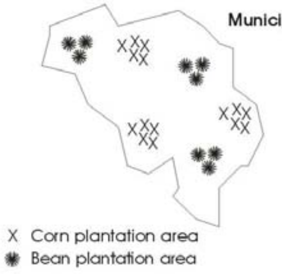


TOWARDS AN OBJECT-RELATIONAL SPATIAL DATA CUBE

A SpatialDataCube class can be implemented as an object-relational (O-R) type, in the following manner. Each Spatial(NonSpatial)Dimension class is mapped to a distinct O-R type — an O-RDimension type. The set of SpatialMeasure classes, together with the set of NumericalMeasure classes, and together with the set of Geometric(NonGeometric)-Dimension relations are mapped to another O-R type — the O-RFact type. The O-RDimension(Fact) type extents are respectively typed tables. We denote O-R spatial data cube this O-R simulation of a spatial data cube. An O-R spatial data cube is formally defined as follows:

Definition 5. O-R spatial data cube.
An *O-R Spatial Data Cube* is constructed from a SpatialDataCube class SDC as follows:

$\forall$ Spatial(NonSpatial)Dimension class $D_i \in$ SDC,
$f_{\text{D-mapping}}$: $D_i \rightarrow$ O-RD_i, where O-RD_i is an O-RDimension type;
$\forall$ SpatialMeasure class SM $\in$ SDC, NumericalMeasure class NM $\in$ SDC, Geometric-Dimension relation GR $\in$ SDC, NonGeometric-Dimension relation ~GR $\in$ SDC
$f_{\text{F-mapping}}$: (SM $\cup$ NM $\cup$ GR $\cup$ ~GR) $\rightarrow$ (O-RSM $\cup$ O-RNM $\cup$ O-RGR $\cup$ O-R~GR) = O-RFact, where O-RFact is an O-R type;
$\forall$ O-RD_i, $f_{\text{Dtable-mapping}}$: O-$RD_i$ $\rightarrow$ O-$RDTable_i$, where O-$RDTable_i$ is a typed table of O-RD_i;
For the O-RFact, $f_{\text{Ftable-mapping}}$: O-RFact $\rightarrow$ O-RFactT, where O-RFacT is a typed table of O-RFact.
Figure 4 illustrates an O-R spatial data cube.

We can clearly visualize here something like the Kimball's Relational Star Schema (Kimball & Ross, 2002). That is only similar, not equal. Notice that the AgroDistribution fact table is not in 1^{ST} normal form, because of the non-atomic spatial measure crop_area and the non-atomic non-spatial measure crop-quantity. Shortly, our *O-R Spatial Data Cube Schema* — or *O-R Spatial Star Schema* to pay homage to Kimball — is not 1NF-normalized. Also, we emphasize the REF types in the AgroDistribution table, so eliminating foreign keys, which are truly artificial columns.

As for relational star schemata, by embedding spatial or non-spatial hierarchies, dimension tables may not be 3NF-normalized; for instance, the dimension tables Location and Time in Figure 4 are not 3NF-normalized, in view of their embedded hierarchies.

In order to avoid redundancies of large geometry objects in non-3FN-normalized dimension tables, these objects may be only referenced in the dimension tables (see the Location table, Figure 4) — this elegant solution is not directly supported by relational star schemata.

Like relational star schemata, O-R star schemata obliterate spatial (non-spatial) hierarchies. Observe in table Location, Figure 4, that the spatial hierarchy municipality_geometry ← micro-region_geometry ← region_geometry ← state_geometry, as well as the non-spatial hierarchy farm_name ← municipality_name ← micro-region_name ← region_name ← state_name, are obliterated, due to the still poor semantics of the O-R model, when compared with our conceptual model, in which hierarchies are explicitly defined.

Spatial OLAP Operations

Spatial or geometric aggregate functions for operating through spatial or non-spatial hierarchies are mandatory for O-R spatial star schemata with spatial OLAP interfaces. In particular, we remark the *spatial roll-up* and *drill-down* operations. The action of *spatial roll-up* is straightforward: it creates geometric aggregate values that roll up from the most detailed level to the least detailed level, following a spatial or non-spatial hierarchy. *Spatial drill-down* is the reverse operation of roll-up. Using the UML-Object Constraint Language formalism (Warmer & Kleppe, 1998), we may define these operators as specified in Rule 1.

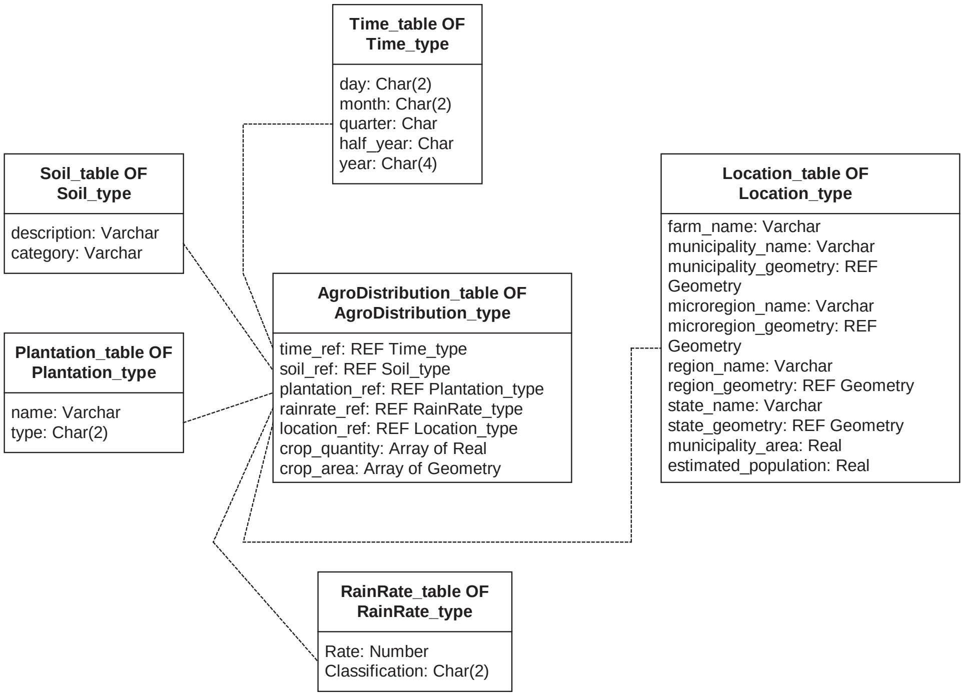
The formalism for the spatial drill-down operation is similar to the roll-up one as specified in Rule 2.

An example of a *spatial roll-up* operation is given in next section.

Querying the O-R Spatial Star Schema

Although there is no SQL implementation for spatial OLAP, we have proposed an O-R SQL query language suitable for O-R spatial star schemata. In order to show the expression power of the language, we give an example that uses a spatial roll-up operation. This query, over the spatial star schema in Figure 4, is “Retrieve the corn crop areas for each micro-region and for each region of the state of Paraíba, during May 2003”.

Figure 4. A spatial data cube example



Rule 1. Spatial roll-up

```
   Parameters:
    d      imRLUP: set of dimensions which rolls up n levels according to the set nLevels
    n      Levels: bag of integer which indicates how many levels to rollup in the hierarchy
         m: set of measures to be aggregated
    a      ggFunc: set of aggregation functions
   Returns:  a new data cube

   context Cube:: spatial_rollup(dimRLUP: Set(Dimension), nLevels:Bag(Integer), m:
Set(Measure), aggFunc:
                     Set(String)): Cube
   pre:      -- verify whether all rollup dimensions are in the current Cube
             self.containsDimensions-> includeAll(dimRULP) and
             -- verify whether all  measures to be aggregated are in the current Cube
             self.containsMeasures-> includeAll(m)  and
             -- make sure that all rollup dimensions are not in the last level
             dimRLUP-> forAll(d1 | d1.currentLevel.hierarchyOwn.childOf <> null) and
             -- make sure that exists at least a spatial dimension or spatial measure
             (dimRLUP-> exists(d2 | d2.isSpatial = true) or m-> exists(m1 | m1.isSpatial = true))
  and
             -- verify whether the dimension set size is equals to the levels of rollup set size
             dimRLUP-> size()  =  nLevels -> size()
             -- verify whether the measure set size is equals to the aggregation function set size
             m-> size()  =  aggFunc -> size()
   inv:    -- update dimension levels
            let dimNewLevels: Set(Dimension) = dimRLUP -> iterate(d:Dimension; resultSetD:
  Set(Dimension)
                   = Set{} | resultSetD.including(d| upLevel(nLevels -> at (dimRLUP ->
  indexOf(d)))))
             in  createNewCube(m->iterate(i:Measure; resultSetM: Set(Cube) = Set{} |
             if m.isSpatial then
             resultSetM->including(self.aggregateSpatialFunction(aggFunc->at(m-> indexOf(i), i,
  dimNewLevels)
              endif   ))

   post:
         result.oclNew()
```

```
Select rl.region_geometry, rl.microregion_geometry,
rl.crop_area
From Location_table l, Plantation_table p, Time_table
t, AgroDistribution_table a, Roll-up(l.region_geometry,
l.microregion_geometry, Geometric_Union(a.crop_area))
rl
Where l.municipality_name = a.location_ref.municipal-
ity_name
And t.month = a.time_ref.month And t.year = a.time_ref.
year And p.name = a.plantation_ref.name And t.year
= '2003' And t.month = '05' And p.name = 'corn' And
l.state_name = 'Paraíba'
```

The main important new feature of the language is its FROM clause. The new interpretation of this clause is as follows: in it, we define single scan variables, each one associated to its collection — typed table, function returning an object-collection type value, etc. —; more precisely, the state of a scan variable, at any time, is

Rule 2. Spatial drill-down

```
    Parameters:
     d   imDROWN: set of dimensions which drills down n levels according to the set nLevels
        nLevels: bag of integer which indicates how many levels to drill down in the hierarchy
         m: set of measures to be aggregated
        detFunc: set of detailed functions
    Returns:  a new data cube

    context Cube:: spatial_drilldown(dimDROWN: Set(Dimension), nLevels:Bag(Integer), m:
Set(Measure),
            detFunc: Set(String)): Cube
 p    re:    -- verify whether all drilldown dimensions are in the current Cube
             self.containsDimensions-> includeAll(dimDROWN) and

```

one and only one of the objects of its associated collection. Formally, the FROM clause is a set of pairs <collection> <scan_variable>. In the example-query, l (p) (t) (a) scans Location_table (Plantation_table) (Time_table) (AgroDistribution_table), while rl scans the collection returned by the function roll-up.

The roll-up function arguments are, in this order: (1) the virtual top element in the spatial hierarchy, (2) the virtual bottom element, and (3) the geometric aggregation function. This function returns a collection, more precisely a table from which the columns are respectively <tableScan_variable>.<top_element>, <tableScan_variable>.<bottom_element>, and <tableScan_variable>.<aggregationFunction_argument>. In the query example, the returned table is scanned by the variable rl, and this table is the result of the query itself.

Figures 5 and 6 are the visualization of the query outputs at the micro-region and region levels for the state of Paraíba, respectively. In these figures, crop areas are represented by geometric points, while that micro-regions and regions are represented by polygons. Gray areas in the maps indicate those municipalities inside their micro-regions (regions) with corn plantations, while that blank areas indicate absence of corn plantations.

QUERY OPTIMIZATION

In this section, we consider the problem of guaranteeing the good performance of the OLAP spatial queries submitted to MapWarehouse, through its GUI. First, we characterize what we call *the spatial optimization problem*.

The Spatial Optimization Problem

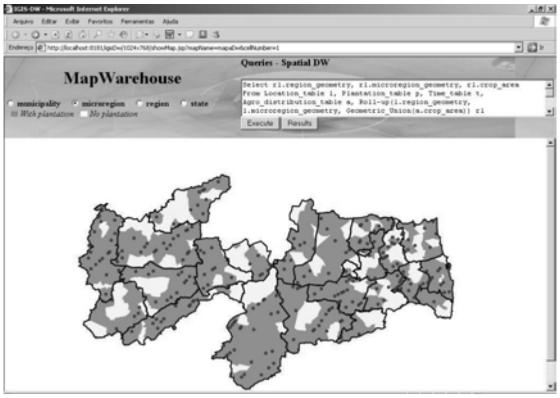
The spatial optimization problem may so be characterized. Consider, for example, only the geography of Brazilian State of Paraíba. Its political division is depicted in Figure 7.

Suppose that only the base-level data and its dimension data are pre-stored. We have thousands of plantations (corn, bean, rice, etc.). Regarding uniquely the example-query (corn plantations in the state of Paraíba — section *Querying the O-R Spatial Star Schema*), and supposing there exists in average 50 plantations by municipality, this gives approximately 11,150 geometries, so distributed:

11,150 crop areas;
223 municipality geometries;
23 micro-region geometries;
4 region geometries;
1 state geometry;
Total: 11,401 geometries, approximately.

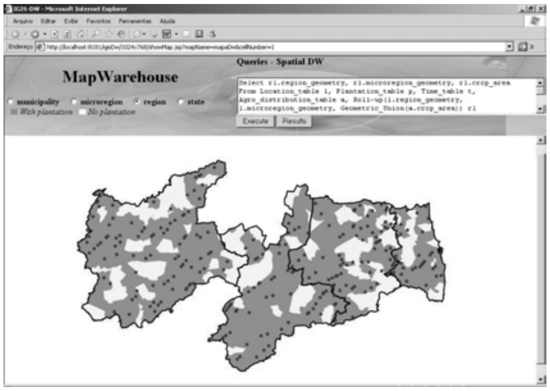
In addition to this, new maps must be dynamically generated, resulting from unions of crop areas and municipality geometries, from unions of

Figure 5. Roll-up operation plantation ← micro-region



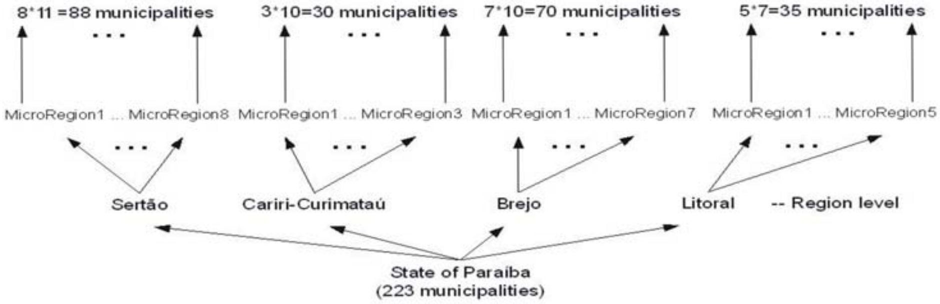
```
Select rl.region_geometry, rl.microregion_geometry, rl.crop_area
From Location_table l, Plantation_table p, Time_table t,
Agro_distribution_table a, Roll-up(l.region_geometry,
l.microregion_geometry, Geometric_Union(a.crop_area)) rl
```

Figure 6. Roll-up operation micro-region ← region



```
Select rl.region_geometry, rl.microregion_geometry, rl.crop_area
From Location_table l, Plantation_table p, Time_table t,
Agro_distribution_table a, Roll-up(l.region_geometry,
l.microregion_geometry, Geometric_Union(a.crop_area)) rl
```

Figure 7. Instantiation of the example´s spatial hierarchy



municipality and micro-region geometries, and from micro-region and region geometries. The question that should be answered is: how many spatial union operations are necessary for the query in section *Querying the O-R Spatial Star Schema*? For this, we have:

223 * 50 = 11,150 union operations crop-municipality;
8*11 + 3*10 + 7*10 + 5*7 = 223 union operations (crop-municipality) - micro-region;
1*8 + 1*3 + 1*7 + 1*5 = 23 union operations (crop-municipality-micro-region) – region;
Total: 11,396 union operations, approximately.

The next step consists in calculating the cost of these 11,396 union operations.

The spatial optimization problem may be generically stated as follows: *given a spatial query, how many concerned spatial aggregation operations must be previously computed, in order to accomplish the query response time requirement?*

Very importantly, the database administrator (DBA) must assume the query performance control, or the DBA must not fight the DBMS optimizer. These considerations lead to an optimization logical model.

The Spatial Logical Optimization

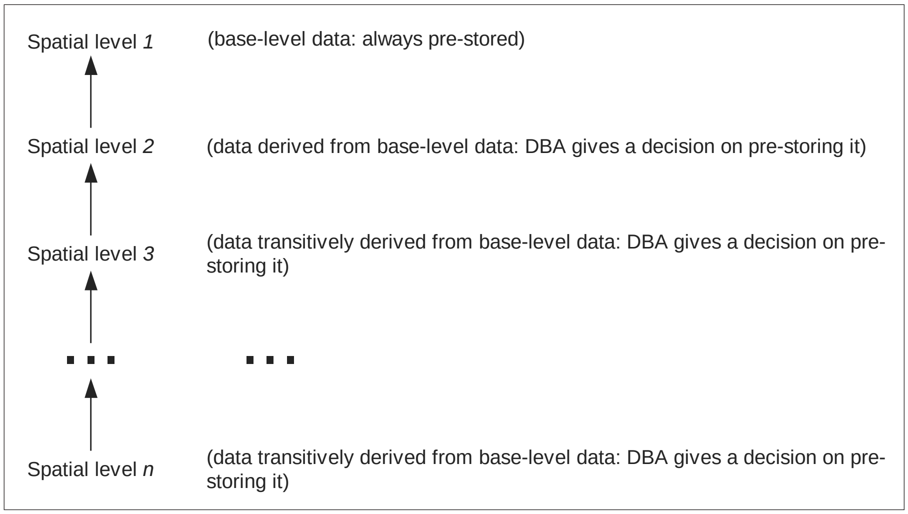
Our spatial optimization logical model is based on the mechanism of pre-storing spatial aggregates — pre-stored spatial aggregates — an extension of the notion of Kimball's pre-stored summary aggregates (Kimball & Ross, 2002). According to Kimball, an aggregate is a fact table record representing a summarization of base-level fact table records; an aggregate fact table record is always associated with one or more aggregate dimension table records.

The extension of this definition, suitable to the SDW context, is such as: a spatial aggregate is a spatial measure of an object in a base-level typed table representing a summarization of spatial measures of objects of the base-level typed table; a spatial aggregate is always associated with one or more aggregate objects in aggregate dimension typed tables. For example, referring to Figure 4, we can imagine the following spatial aggregates:

- Municipality-level crop area aggregates by plantation by day (a one-way spatial aggregate)
- Micro-region-level crop area aggregates by day (a one-way aggregate)
- Region-level crop area aggregates by micro-region (a two-way aggregate)
- Region-level crop area aggregates by micro-region by month (a three-way aggregate)

A pre-stored spatial aggregate is a spatial aggregate computed and stored before query executions which may use it. Pre-stored spatial aggregates are tightly related to spatial hierarchies — Figure 8.

Figure 8. Spatial hierarchy and pre-stored spatial aggregates

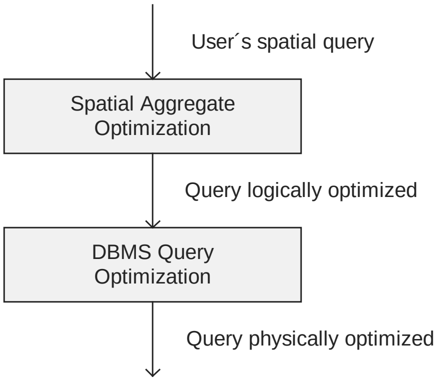


The rationale for our spatial optimization logical model makes the best of a good situation of using pre-stored spatial aggregates in order to ameliorate the performance of the spatial queries; in fact, queries are re-written for accessing the chosen pre-stored spatial aggregates. Once conveniently re-written, queries are still submitted to the specific DBMS's query optimizer — physical optimization — Figure 9.

Returning to our example, the critical factor for the performance of the query in section *Querying the O-R Spatial Star Schema* is the computation of the 11,150 spatial aggregates (here, union operations) at the level 2 — municipality-geometry – of the spatial hierarchy crop_area ← municipality-geometry ← micro-region-geometry ← region-geometry ← state-geometry. Supposing that all corn spatial aggregates at the municipality level — typed table **MunicipalityAgroDistribution_table** (a new fact table) linked to the typed table **Municipality_table** (a new dimension table) and the dimension tables in Figure 4 except Location_table, a one-way spatial aggregate transparent to the user — have been pre-stored, the query is so automatically rewritten:

```
Select rl.region_geometry, rl.microregion_geometry, rl.crop_area
From Municipality_table l, Plantation_table p, Time_table t, MunicipalityAgroDistribution_table a, Roll-up(l.region_geometry, l.microregion_geometry, Geometric_Union(a.crop_area)) rl
Where l.municipality_name = a.location_ref.municipality_name
And t.month = a.time_ref.month And t.year = a.time_ref.year And p.name = a.plantation_ref.name And t.year = '2003' And t.month = '05' And p.name = 'corn' And l.state_name = 'Paraíba'
```

Figure 9. Types of optimization supported by MapWarehouse



Notice that the two boldface items in the previous query are the items that are different between the base-level query and the municipality-aggregate-level query. Upon close inspection, we see that all the logical optimizer has done is to substitute the Location_table dimension table by the Municipality_table dimension table, and the AgroDistribution_table fact table by the MunicipalityAgroDistribution_table fact table.

THE MAP WAREHOUSE PROTOTYPE

In order to validate the previous ideas we have implemented a prototype called *MapWarehouse,* which implements O-R spatial star schemata in an object-relational DBMS, and with a logical query optimizer according to the discussion in the previous section. Particularly in this prototype, we have chosen the Oracle Object-Relational DBMS due to its support to spatial data, including the OGC Standard and the provision of OLAP infra-structure, by implementing CWM (Oracle, 2005).

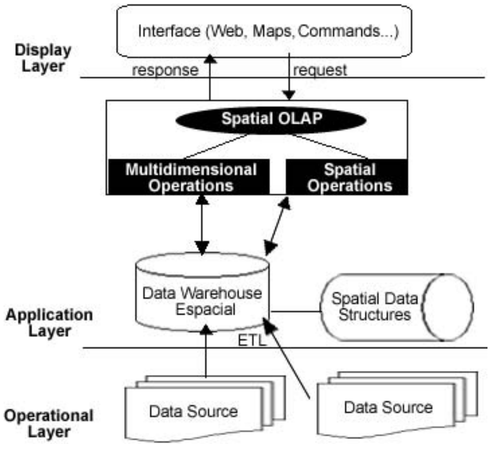
The Oracle spatial capabilities are implemented by the Oracle Spatial Cartridge, which uses the MDSYS schema; CWM is implemented via the CWMLITE metadata packages, the OLAPSYS schema and OLAP API.

The MapWarehouse project implements a new Java-based package known as CWM_OLAP_SPATIAL, which extends the CWNLITE package with spatial measures, dimensions, topological operations and spatial roll-up and spatial drill-down. Spatial data is indexed using R-tree.

The MapWarehouse architecture, as shown in Figure 10, is based on three layers:

- **Operational layer:** composed of the conventional and spatial data sources to model the Spatial DW through the extraction, transformation and loading process (ETL)

Figure 10. The MapWarehouse architecture

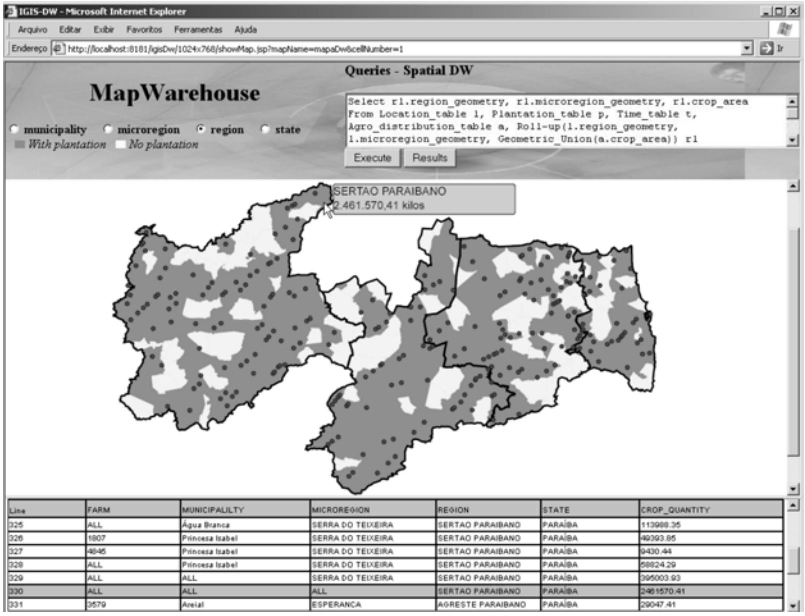


- **Application layer:** responsible for the Spatial OLAP user request processing. It accesses the CWM/OpenGIS metadata and datasources
- **Display layer:** defines the user interface, according to the previous mentioned requirements

The user interface (GUI) enables to visualize the query results through maps and tables. The maps are rendered using SVG format (SVG, 2005) and they are dynamically produced using the iGIS map server (Baptista, Leite Jr., Silva, & Paiva, 2004). iGIS is a framework for rapid application development of GIS applications on the Web. It may use different datasources, such as Oracle, Postgresql, IBM DB2 and GML. Also, iGIS may use different map rendering including SVG, SGV Tiny and JPEG. User interaction on maps includes zooming, panning, information, and tooltip. This user interface is presented in Figure 11. In this figure, the radio buttons indicate the spatial level (state, region, micro-region or municipality), so that user may execute spatial roll-up or spatial drill-down. In the text box, users may pose their queries using the proposed query language.

The map is presented according to the executed query and a table which contains numeric information about the query is presented. In Figure 11,

Figure 11. The MapWarehouse GUI



```
Select rl.region_geometry, rl.microregion_geometry, rl.crop_area
From Location_table l, Plantation_table p, Time_table t,
Agro_distribution_table a, Roll-up(l.region_geometry,
l.microregion_geometry, Geometric_Union(a.crop_area)) rl
```

Line	FARM	MUNICIPALILTY	MICROREGION	REGION	STATE	CROP_QUANTITY
325	ALL	Água Branca	SERRA DO TEIXEIRA	SERTAO PARAIBANO	PARAÍBA	113988.35
326	1807	Princesa Isabel	SERRA DO TEIXEIRA	SERTAO PARAIBANO	PARAÍBA	49393.85
327	4846	Princesa Isabel	SERRA DO TEIXEIRA	SERTAO PARAIBANO	PARAÍBA	9430.44
328	ALL	Princesa Isabel	SERRA DO TEIXEIRA	SERTAO PARAIBANO	PARAÍBA	58824.29
329	ALL	ALL	SERRA DO TEIXEIRA	SERTAO PARAIBANO	PARAÍBA	395003.93
330	ALL	ALL	ALL	SERTAO PARAIBANO	PARAÍBA	2461570.41
331	3579	Areial	ESPERANCA	AGRESTE PARAIBANO	PARAÍBA	29047.41

the user has pointed to the *Sertão* region and the tooltip is activated. Then, the equivalent tabular data is highlighted in the underlying table.

During the experiments, spatial data related to the Brazilian State of Paraiba was used. This state is divided into regions, micro-regions and municipalities. Beside the spatial location, this dataset is temporal, from 2002 to 2003 in which day is the minimum granularity, and it contains plantation type, soil type, and rain rate. The whole size of the database is approximately 250,000 tuples.

The server computer used during the experiments was an Athlon XP 2.5 GHz processor with 1024 MB RAM. The Web browser was the Microsoft Internet Explorer 6.0 with the Adobe SVG Viewer 3.0. The Apache Tomcat/5.0.16 was used as Application Server. We used Java technology (JSP and Servlets) to implement MapWarehouse business logic.

In the experiments we run several queries with and without query optimization. In the following the query: "retrieve the total of all crops (rice, bean, corn, etc) produced in June 2003 by municipality, micro-region, region and state" is detailed. This query can be posed using our extended SQL as:

```
Select rl.state_geometry, rl.region_geometry, rl.microregion_geometry, rl.municipality_geometry, rl.crop_area
From Location_table l, Plantation_table p, Time_table t, AgroDistribution_table a, Roll-up(l.state_geometry, l.municipality_geometry, Geometric_Union(a.crop_area)) rl
Where l.municipality_name = a.location_ref.municipality_name And t.month = a.time_ref.month And t.year = a.time_ref.year And t.year = '2003' And t.month = '06' And l.state_name = 'Paraíba'
```

Table 1 shows the costs of the previous query with and without query optimization. Notice that by using the query optimization the query is rewritten according to the technique explained in the section *Query Optimization*.

During the tests, we have noticed that by using query optimization based on pre-stored spatial aggregates the overall response time is reduced in

Table 1. Performance evaluation

Costs	Without Query Optimization	With Query Optimization
Cost of pre-storing spatial aggregates	25 sec.	0 sec.
Cost of map generation	25 sec.	25 sec.
Cost of map loading	10 sec.	10 sec.
Total cost	60 sec.	35 sec.

almost 50%. This performance gain is improved for large datasets.

CONCLUSION

Although data warehouse and geographical information system technologies are very useful in the decision making process, usually they are used separately. Research on integrating these two technologies is in its infancy. This integration coins new terms: spatial datawarehouse (SDW) and spatial OLAP (SOLAP). By using SOLAP, users may enhance their capacity to explore the underlying dataset once spatial methods incorporated into OLAP ones may be used.

In this chapter we have proposed an integrated architecture for a SDW. The main contributions of our proposal include: a formalized data model for SDW; a SQL extension query language which enables spatial roll-up and drill-down; optimization techniques which improve performance of complex spatial queries by pre-storing spatial aggregates; and a prototype, *MapWarehouse*, which validates the ideas proposed.

In order to achieve interoperability, we have chosen to use well-known standards such as OGC for dealing with spatial data and CWM for OLAP. This approach aims to facilitate the integration of *MapWarehouse* with other systems. However, we recognize that the interoperability provided is at schematic and syntactic level. Hence, it is important to mention that a new layer based on semantic Web concepts ought to be developed so that semantic interoperability may be achieved.

As further work, we plan to improve usability as currently user needs to know the query language syntax and the underlying schema in order to pose their queries. We plan to develop a visual query language for SOLAP to facilitate user interaction.

Also, the provision of ad-hoc dimensions, which are defined on-the-fly, is another important issue to be addressed. Nowadays, the spatial interaction is done via predefined hierarchies (e.g., State, Region, Micro-region and Municipality); however, sometimes user may choose an arbitrary area via a bounding box and he demands for aggregation on that specific area. In that case, the aggregation is done on-the-fly and new indexing mechanisms need to be investigated.

Finally, another interesting work is to extend the *MapWarehouse* architecture to Web services. Thus, distributed SDW may be provided and SOLAP becomes a service which may be automatically discovered and invoked.

Chapter 8.9

A Multi-Agent Decision Support Architecture for Knowledge Representation and Exchange

Rahul Singh
University of North Carolina at Greensboro, USA

ABSTRACT

Organizations rely on knowledge-driven systems for delivering problem-specific knowledge over Internet-based distributed platforms to decision-makers. Recent advances in systems support for problem solving have seen increased use of artificial intelligence (AI) techniques for knowledge representation in multiple forms. This article presents an Intelligent Knowledge-based Multi-agent Decision Support Architecture" (IKMDSA) to illustrate how to represent and exchange domain-specific knowledge in XML-format through intelligent agents to create, exchange and use knowledge in decision support. IKMDSA integrates knowledge discovery and machine learning techniques for the creation of knowledge from organizational data; and knowledge repositories (KR) for its storage management and use by intelligent software agents in providing effective knowledge-driven decision support. Implementation details of the architecture, its business implications and directions for further research are discussed.

INTRODUCTION

The importance of knowledge as an organizational asset that enables sustainable competitive advantage explains the increasing interest of organizations in KM. Many organizations are developing knowledge management systems (KMS) that are specifically designed to facilitate the sharing and integration of knowledge, as opposed to data or information, in decision support activities (Bolloju, Khalifa, & Turban, 2002). Decision support systems (DSS) are computer technology solutions used to support complex decision-making and problem solving (Shim, Warkentin, Courtney, Power, Sharda, & Carlsson, 2002). Organizations are becoming increasingly complex with emphasis on decentralized decision-making. Such changes create the need for DSS that focus on supporting problem solving activities on distributed platforms by providing problem specific data and knowledge to a decision maker anywhere, using Internet-based technologies. This trend necessitates enterprise DSS for effective decision-making with processes and facilities to support the use of knowledge management (KM).

Recent advances in systems support for problem solving and decision-making witness the increased use of artificial intelligence (AI) based techniques for knowledge representation (Goul, 2005; Whinston, 1997). Knowledge representation takes multiple forms including the incorporation of business rules, decision analytical models and models generated from the application of machine learning algorithms. Intelligent decision support systems (IDSS) incorporate intelligence in the form of knowledge about the problem domain, with knowledge representation to inform the decision process, facilitate problem solving and reduce the cognitive load of the decision maker. Weber and Aha (2003) identified requirements for organizational KMS where the central unit is a repository of knowledge artifacts collected from internal or external organizational sources. These KMS can vary based on the type of knowledge artifact stored, the scope and nature of the topic described and the orientation (Weber & Aha, 2003). Ba, Lang and Whinston (1997) enumerate the KM principles necessary to achieve intra-organizational knowledge bases as: (1) the use of corporate data to derive and create higher-level information and knowledge, (2) provision of tools to transform scattered data into meaningful business information. Knowledge repositories play a central and critical role in the storage, distribution and management of knowledge in an organization. Interestingly, Bolloju et. al. (2002) proposed an approach for integrating decision support and KM that facilitates knowledge conversion through suitable automated techniques to:

1. apply knowledge discovery techniques (KDT) for knowledge externalization,
2. employ repositories for storing externalized knowledge, and
3. extend KDT for supporting various types of knowledge conversions.

This article is motivated by these principles and attempts to develop and present an intelligent knowledge-based multi-agent architecture for knowledge-based decision support using eXtensible Markup Language (XML) related technologies for knowledge representation and knowledge exchange over distributed and heterogeneous platforms. The proposed architecture integrates DSS and KMS using XML as the medium for the representation and exchange of domain specific knowledge, and intelligent agents to facilitate the creation, exchanges and use of the knowledge in decision support activities. This is the primary contribution of this research to the existing body of knowledge in DSS, KMS and multi-agent research.

This research builds on existing bodies of knowledge in intelligent agents, KM, DSS and XML technology standards. Our research focuses on achieving a transparent translation between XML and Decision Trees through software agents. This creates the foundation for knowledge representation and exchange, through intelligent agents, to support decision-making activity for users of the system. We use a knowledge repository to store knowledge, captured in XML documents, that can used and shared by software agents within the multi-agent architecture. We call this architecture an *Intelligent Knowledge-based Multi-agent Decision Support Architecture* (IKMDSA). IKMDSA integrates KDT and knowledge repositories for storing externalized knowledge. It utilizes an intelligent multi-agent system with explanation facility to provide distributed decision support using Internet-based technologies. The implementation incorporates, and is built upon XML and its related technologies to achieve knowledge representation, storage and knowledge exchange among participating intelligent agents to deliver decision support to the user. The proposed IKMDSA incorporates mechanisms whereby agents can provide distributed intelligent decision support by exchanging their knowledge using XML and its related set of standards. Implementation details of the implementation of the architecture and their implications for further research in this area by academics and practitioners are provided.

In the second section, we review relevant literature in intelligent agents and the role of decision trees in inductive learning and knowledge representation in terms of decision rules. In the third section, we discuss the role of XML in representing and facilitating knowledge exchange for intelligent agents. The fourth section provides a detailed description of the various components of the IKMDSA architecture and their interrelationships in facilitating the creation, representation, exchange and use of domain specific knowledge for decision support tasks. In the fifth section, we provide a detailed description of the implementation of the architecture through the use of an illustrative example. The sixth section 6 includes a discussion of the implications of integrating KMS and DSS support in business, and the role of the proposed IKMDSA architecture. The seventh section concludes with limitations and future research directions.

LITERATURE REVIEW

Software Agents and Intelligent Decision Support Systems (IDSS)

An intelligent agent is "a computer system situated in some environment and that is capable of flexible autonomous action in this environment in order to meet its design objectives" (Jennings & Wooldridge, 1998). While the terms agents, software agents and intelligent agents are often used interchangeably in the literature, all agents do not necessarily have to be intelligent. Jennings and Wooldridge (1998) observe that agent-based systems are not necessarily intelligent, and require that an agent be flexible to be considered intelligent. Such flexibility in intelligent agent based systems requires that the agents should be: (Bradshaw, 1997; Jennings & Wooldridge, 1998)

- cognizant of their environment and be *responsive* to changes therein;
- reactive and proactive to opportunities in their environment;
- autonomous in goal-directed behavior;
- collaborative in their ability to interact with other agents in exhibiting the goal-oriented behavior; and
- adaptive in their ability to learn with experience.

Agent-based systems may consist of a single agent engaged in autonomous goal-oriented behavior, or multiple agents that work together to exhibit granular as well as overall goal directed behavior. The general multi-agent system is one in which the interoperation of separately developed and self-interested agents provide a service beyond the capability of any single agent model. Such mutli-agent systems provide a powerful abstraction that can be used to model systems where multiple entities, exhibiting self directed behaviors must coexist in a environment and achieve the system wide objective of the environment.

Intelligent agents are action-oriented abstractions in electronic systems entrusted to carry out various generic and specific goal-oriented actions on behalf of users. The agent abstraction manifests itself in the system as a representation of the user and performs necessary tasks on behalf of the user. This role may involve taking directions from the user on a need basis and advising and informing the user of alternatives and consequences (Whinston, 1997). The agent paradigm can support a range of decision making activity including information retrieval, generation of alternatives, preference order ranking of options and alternatives and supporting analysis of the alternative-goal relationships. In this respect, intelligent agents have come a long way from being digital scourers and static filters of information to active partners in information processing tasks. Such a shift has significant design implications on the abstractions used to model information systems, objects or agents, and on the architecture of information resources that are available to entities involved in the electronic system. Another implication is that knowledge must be available in formats that are conducive to its representation and manipulation by software applications, including software agents.

Decision Trees and IDSS

Models of decision problems provide analytical support to the decision maker by facilitating a greater understanding of the problem domain and allowing the decision maker to assess the utility of alternative decision paths with respect to achieving the objective of the decision task. Decision trees are a popular modeling technique with wide applicability to a variety of business problems (Sung, Chang, & Lee, 1999). The performance of a particular method in modeling human decisions is dependent on the conformance of the method with the decision makers' mental model of the decision problem (Kim, Chung, & Paradice, 1997). Simplicity of model representation is particularly relevant if the discovered explicit models are to be internalized by decision makers (Bolloju et al., 2002). Decision Trees represent a natural choice for IDSS whose goal is to generate decision paths that are easy to understand, to explain and to convert to natural language (Sung et al., 1999). The choice of decision trees as the modeling methodology affords the ability to incorporate inductive learning in the IDSS. Decision trees are among the most commonly used inductive learning techniques used to learn patterns from data (Kudoh, Haraguchi, & Okubo, 2003; Takimoto & Maruoka, 2003). The ID3, C4.5, and SEE5 algorithms provide a formal method to create and model decision rules from categorical and continuous data (Quinlan, 1996; Sung et al., 1999) compared multiple machine learning techniques in predicting bankruptcies and found that the decision tree technique had the most interpretive power. In this research, the C4.5 (ID3) method is used due to the popularity of the algorithm (Kiang, 2003).

Additionally, decision trees solutions lend themselves to automatic generation of structured queries to extract pertinent data from organizational data repositories (Adriaans & Zantinge, 1996). This makes them particularly useful in providing insights and explanations for the non-technical user (Apte & Weiss, 1997). Decision trees are especially suitable for decision problems that require the generation of human understandable decision rules based on a mix of classification of categorical and continuous data (Quinlan, 1996; Sung et al., 1999). They provide clear indication of the importance of individual data fields to the decision problem and are therefore useful in reducing the cognitive burden of the decision maker. It is clear that decision trees represent a powerful and easily interpretable technique for modeling business decisions that can be reduced to a rule-based form. The benefits of the technique highlighted above provide a strong basis for choosing decision trees as a component for intelligent DSS.

USING XML AND DECISION TREES FOR KNOWLEDGE REPRESENTATION AND EXCHANGE

XML and Document Type Definitions (DTDs)

Since the advent of the Internet, the World Wide Web has become very popular because of the simplicity provided by HTML for its usage and content presentation. HTML provides a fixed set of tags that are used to markup content (information) primarily for consumption by human beings. Despite its efficiency for presenting information in human readable format, HTML is very limited in extensibility and customization of markup tags and description of the data contained in those tags. This constraint limits the use of HTML by application software for information sharing in a distributed computing environment where application programs, including intelligent agents are expected to work with available data, rules and knowledge without human intervention.

The use of XML and its related set of standards, developed by the World Wide Web Consortium, (W3C http://www.w3c.org), have helped overcome some of these limitations. XML allows for the creation of custom tags that contain data from specific domains. XML is a meta-language that allows for the creation of languages that can be represented by customized XML tags. For example, a company in the furniture industry may develop customized tags for the representation of content to serve its business domain. By creating custom tags, the company can represent the data in a more meaningful and flexible way than it could using HTML. The company may also develop documents that represent business-rules using XML that can shared either with human agents or with software agents. Unambiguous understanding of the content of customized XML tags by interested parties requires description of both the content and structure of XML documents. This description of structures in XML documents is provided by the XML schema which can be written following the set of standards called XML Schema and/or the Document Type Definition (DTD) language as adopted and standardized by the W3C. XML schema describes specific elements, their relationships and specific types of data that can be stored in each tag. XML documents can be validated and parsed by application software provided either the DTD or the XML Schema of the corresponding document is made available. XML parsers written in C, C++ or Java can process and validate XML documents (containing business rules and data) based on XML schemas written based on either the DTD or the XML Schema specification. Application software appropriate parser utilities are able to read and/or write to XML documents following the W3C standards and specification. This provides the foundation technology, built upon an agreed and accepted standard from W3C, for the capture, representation, exchange and storage of knowledge represented by business rules and related data in XML format that can be potentially used and shared by software agents.

Recent initiatives to develop technologies for the "Semantic Web" (Berners–Lee, Hendler, & Lassila, 2001) make the content of the Web unambiguously computer-interpretable, thus making it amenable to agent interoperability and automatic reasoning techniques (McIllraith, Son, & Zeng, 2001). Two important technologies for developing Semantic Web are already in place — XML and the resource description framework (RDF). The W3C developed the RDF as a standard for metadata to add a formal semantics to the Web, defined on top of XML, to provide a data model and syntax convention for representing the semantics of data in standardized interoperable manner (McIllraith, et al., 2001). The RDF working group also developed RDF Schema (RDFS), an object-oriented type system that can be effectively thought of as a minimal ontology modeling language. Recently, there have been several efforts to build on RDF and RDFS with more AI-inspired knowledge representation languages such as SHOE, DAML-ONT, OIL and DAML+OIL (Fensel, 1997). While these initiatives are extremely promising for agent interoperability and reasoning, they are at their early stages of development. In this article, we focus on the use of more mature and widely used and available standardized technologies such as XML and DTDs to represent knowledge. This approach, along with other initiatives, should allow researchers to develop intelligent agent-based systems that are both practical and viable for providing intelligent decision support to users in a business environment.

XML and Decision Trees for Knowledge Representation

The W3C XML specification allows for the creation of customized tags for content modeling. Customized tags are used to create data-centric content models and rule-based content models. Data-centric content models imply XML documents that have XML tags that contain data, for example from a database, and can be parsed by application software for processing in distributed computing environments. XML documents containing rule-based content models can be used for knowledge representation. XML tags can be created to represent rules and corresponding parameters. Software agents can then parse and read the rules in these XML documents for use in making intelligent decisions. Before making intelligent decisions, the software agents should be able to codify or represent their knowledge. Decision Trees and inductive learning algorithms such as ID3, C4.5 can be used by agents to develop the rule-based decision tree. This learned decision tree can be converted into an XML document with the corresponding use of a DTD. This XML document, containing the learned decision tree, forms the basis for knowledge representation and sharing with other software agents in the community. We demonstrate architecture for agent-based intelligent information systems to accomplish this.

XML and Decision Trees for Knowledge Representation and Exchange

Software agents for knowledge exchange and sharing in the agent community can exchange decision trees represented in XML documents. For example, a new agent can learn from the knowledge of the existing agents in the community by using the decision tree available in XML format in a knowledge repository. The existence of this knowledge repository allows knowledge to be stored and retrieved as needed basis by the agents and updated to reflect the new knowledge from various agents in the community. The explanatory power of decision trees from their ability to generate understandable rules and the provide clear indication of important fields for classification allows the incorporation of explanation facility, similar to expert systems, among the agents in this type of architecture (Sung et al., 1999). Moreover, explanation is essential to the interaction between users and knowledge-based systems (KBS), describing what a system does, how it works, and why its actions are appropriate (Mao & Benbasat, 2000). Among 87 KBS shell capabilities, users rated explanation facilities and the capability to customize explanations as the fourth and fifth most important factors, respectively (Stylianou, Madey, & Smith, 1992). Explanation can make KBS conclusions more acceptable (Ye & Johnson, 1995) and builds trust in a system. The ability of the agents to explain the decision rules used in the decision making process makes agents powerful tools to aid human agents in complex decision tasks. Such intelligent agent architecture, built around well-grounded and well-researched decision models along with standards-based widely available technologies (such as XML, DTDs), is a significant contribution to furthering research on agent-based distributed computing and DSS. In the following section, we present the details of IKMDSA and discuss its knowledge externalization, knowledge representation, knowledge management and knowledge delivery mechanism for decision support.

Integrated Intelligent Knowledge-Based Decision Support Architecture (IKMDSA)

A KMS has facilities to create, exchange, store and retrieve knowledge in an exchangeable and usable format for decision-making activity. IKMDSA utilizes ID3 algorithms to create knowledge from raw data to a decision tree representational form. A domain knowledge object represents information about a specific problem domain in IKMDSA. The domain knowledge object contains information about the characteristics of the various domain attributes important to the problem domain. The domain knowledge object describes the problem context and provides rules for making decisions in the problem context. The domain knowledge object represents the abstraction used for creating, exchanging and using modular knowledge objects in IKMDSA. IKMDSA uses intelligent software agents as the mechanism for encapsulation and exchange of knowledge between agents at the site of knowledge creation and the site of knowledge storage. Intelligent agents deliver knowledge to the user interface to support intelligent decision-making activity. The agent abstraction is built upon basic objects that take on additional behaviors, as required by its function (Shoham, 1993). Knowledge exchange and delivery in IKMDSA is facilitated through the exchange of the domain knowledge objects among intelligent agents. Figure 1 illustrates this basic building block of IKMDSA, where an agent has a composition relationship with the domain knowledge object, and thereby has access to knowledge in the form of standard XML document object model (DOM) objects.

Every agent can share its knowledge through the domain knowledge component by invoking its share knowledge behavior. The domain knowledge object contains behaviors to inform agents of the name of the problem domain, share information about the various domain attributes that are pertinent to the specific knowledge context, and share rules about making decisions for their specific problem domain. We use these core components to develop the functionality of IKMDSA to learn rules and domain attributes from raw data, create domain specific knowledge, share it with other agents and apply this knowledge in solving domain specific problems with a user. Once the attributes and domain rules are captured in the domain knowledge object, using standard XML DOM format, they can be exchanged between agents. Figure 2 provides a schematic of this activity sequence where knowledge is created from raw data and ultimately delivered in usable form to the decision maker.

Learning agents interact with a raw data repository and extract raw data used to generate domain specific knowledge. Our model does not specify the storage representation and the data contained in the repository may be of multiple representation formats including flat files, data stored as relational tables that can be extracted using multiple queries into a recordset, or raw data represented using XML documents. The learning agent extracts the raw data and applies machine learning algorithms to generate decision rules

Figure 1. Agents have access to domain knowledge objects that abstract domain specific knowledge

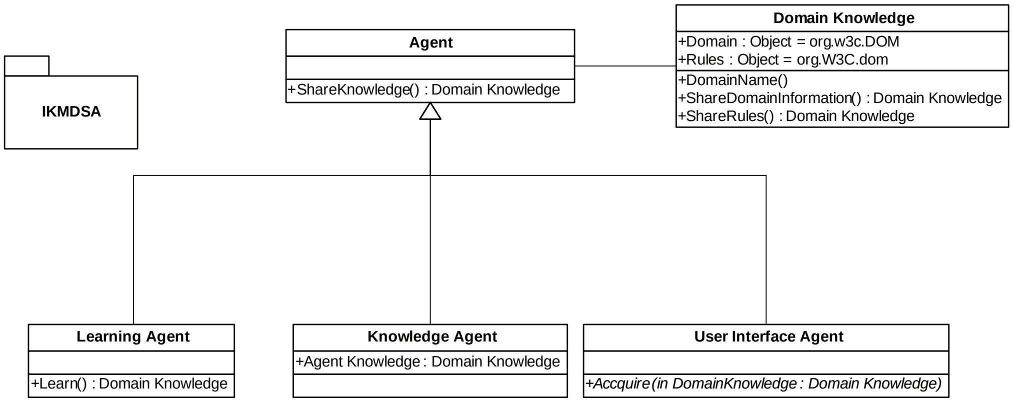

Figure 2. A schematic showing the generation, exchange, storage, retrieval and use of knowledge in IKMDSA

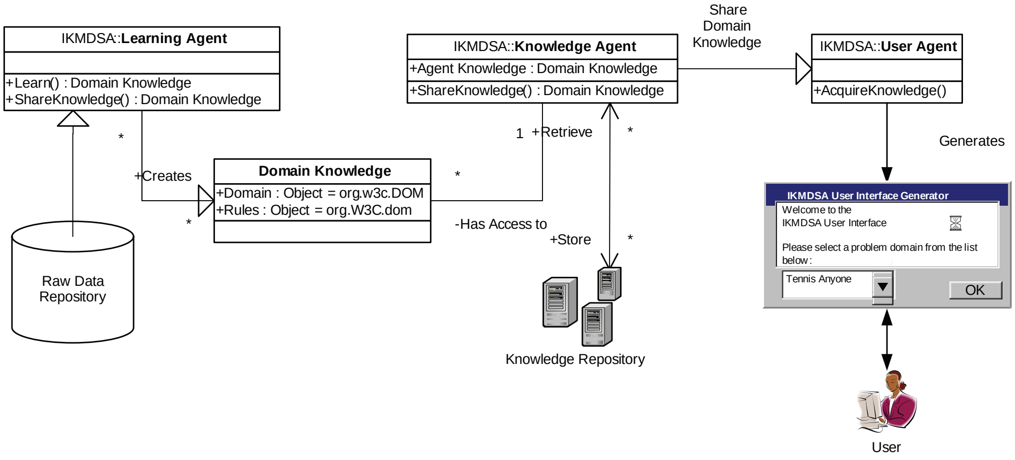


for the problem domain. The repository contains information about the context and syntactical representation of the information. This information provides the domain attributes pertinent to the decision problem. This generates domain specific knowledge in the form of domain attribute information and rules for making decisions in the specific problem context. The system ensures that this knowledge is generated in a format conducive for sharing and use of the information across a distributed and heterogonous platform.

We use the domain knowledge object as the modular abstraction for knowledge representation and knowledge exchange facilitation in IKMDSA. Domain knowledge objects are made available to agents by the learning agent sharing the object with the knowledge agent. The knowledge agent manages the knowledge available in IKMDSA and allows for other agents in the system to know of, request and receive the domain knowledge in the system. The system utilizes the domain knowledge object as the modular knowledge abstraction for communication of knowledge across the multiple agents of the system. Therefore, when the domain knowledge object is shared with an agent of the system, the agent becomes aware of the problem context descriptions, in addition to the rules that govern decision-making in the specific problem context. The knowledge agent is also responsible for the maintaining the collection of domain knowledge available in the system through interactions with a knowledge repository. The Knowledge Agent contains methods to generate rules to support ad-hoc queries by the user agent. This is supported through the interactions of the Knowledge Agent with the knowledge repository of the system that is implemented as a set of XML documents that can be stored in a repository that is capable of storing XML documents such as the Oracle 9i family of information management products. This knowledge repository allows for the easy storage and retrieval of the knowledge contained in a domain knowledge object. Thus, the knowledge is available to all the agents in the system through the activities of the KM behaviors of the knowledge agent object. In this respect, the interactions among the agents in this system are modeled as collaborative interactions, where the agents in the multi-agent community work together to provide decision support and knowledge-based explanations of the decision problem domain to the user.

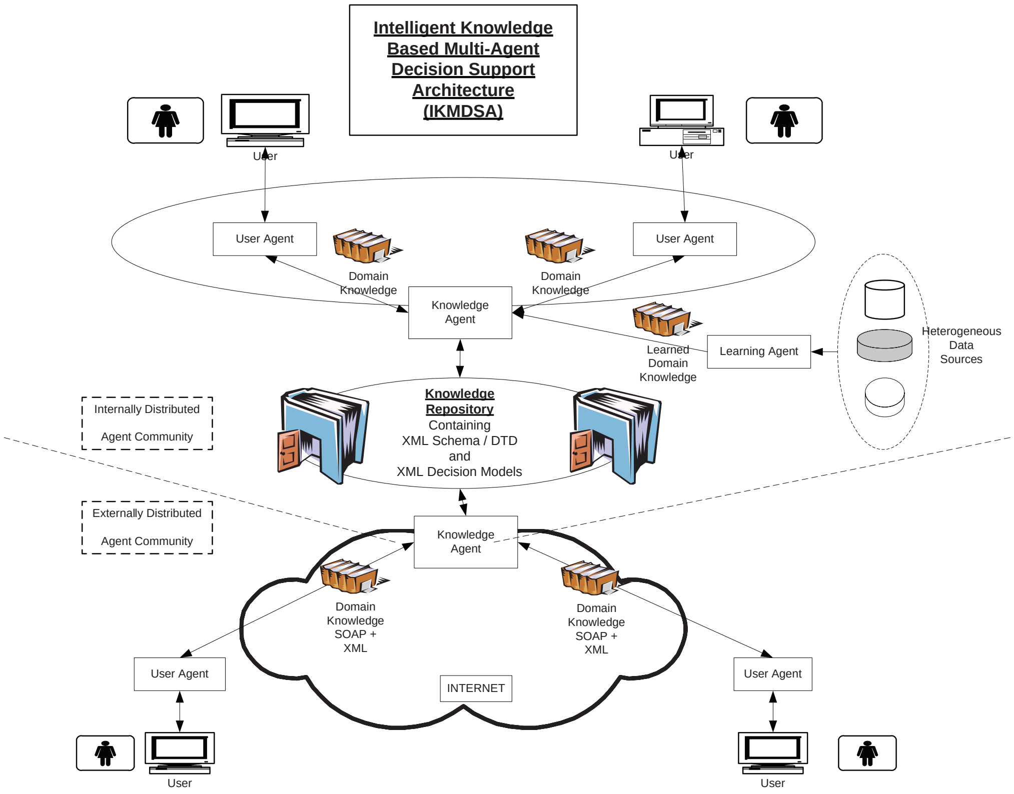
As shown in Figure 2, users of IKMDSA interact with the system through User Agents that are constantly aware of all domain knowledge contexts available to the system, through a list of names of the domain knowledge objects that is published and managed by the knowledge agent. This allows every user agent, and hence every user, to be aware of the entire problem space covered by the system. The user agent requests and receives the knowledge available for a specific problem domain by making a request to the knowledge agent, at the behest of the user. The knowledge agent, upon receiving this request, shares a domain knowledge object with the user agent, thereby making problem domain information and decision rules available to the user agent. The knowledge agents also serve as the means to service any ad-hoc queries that cannot be answered by the user interface agents, such as queries regarding knowledge parameters that are not available to the user interface agents. In such cases, the Knowledge agent, with direct access to the knowledge repository can provide such knowledge to the user agents, for the benefit of the user. This information is shared in the form of two W3C compliant XML document object model (DOM) objects, Domain and Rules, which represent an enumeration and explanation of the domain attributes that are pertinent to the problem context and the rules for making decisions in the specified problem context. Once the domain knowledge object is available to the user agent, the user agent becomes problem domain aware and is ready to assist the user through a decision making process in the specific problem domain.

The user agent contains methods to generate a user-friendly interface to inform the user about problem domain attributes that are pertinent to the decision problem under consideration. The user interface offers explanations about each domain attribute and provides the user with contextual information on the different values that each domain attribute may take. This serves the purpose of informing the user and increasing their knowledge about the various factors that affect a decision in the problem domain under consideration. The user agent also contains methods to generate a decision making interface that allows a decision maker to consider and choose values for pertinent attributes. This selection process creates an instance of an observation that can be compared against the rules available to the user agent through the domain knowledge. The user interacts with the User Interface agent by asking question about the decision problem and receives responses containing decision alternatives and explanation of the choices made by the agent. This is achieved through parsing the decision rules based on the parameters supplied by the user. The agent compares the users' selections with the known rules and decides on the rule(s) that are fired for the given instance. These rules are formatted in a user-friendly format and made available to the user. This provides the user with a decision, given their selection of domain attributes and provides the user with explanations of the decisions made, given the selections made by the users.

The above sections provide a complete description of the process of knowledge creation, knowledge representation, knowledge exchange, KM and the use of the knowledge for decision making employed by IKMDSA. Figure 3 provides a schematic of this overall process. As shown in Figure 3, IKMDSA is designed for a distributed platform where the knowledge available to the agents in the system can be made available on an intranet and an Internet based platform by enclosing the domain knowledge objects in SOAP wrappers that enables the knowledge broker functions of the knowledge agent by making its knowledge available as a Web service.

IKMDSA consists of intelligent agents as discussed above that are able to provide intelligent decision support to the end-users. All of the agents in the architecture are FIPA compliant in terms of their requirements and behavior. The learning agents create knowledge from the raw data in a data repository, knowledge agents primarily acquire this knowledge from learning agents and manage this knowledge through a knowledge repository,

Figure 3.The intelligent knowledge-based multi-agent decision support architecture (IKMDSA)



while user agents help the users make decisions on specific problems using the knowledge contained in the decision trees. The exchange of knowledge between agents and between users and agents is achieved through sharing of content information using XML. The agents work on a distributed platform and enable the transfer of knowledge by exposing their public methods as Web Services using SOAP and XML. The rule-based modular knowledge can be used and shared by agents. Capturing the modular knowledge in XML format also facilitates their storage in a knowledge repository - a repository that enables storage and retrieval of XML documents. The architecture allows for multiple knowledge repositories depending upon the problem domain. The benefits of such knowledge repositories are the historical capture of knowledge modules that are then shared among agents in the agent community. This minimizes the learning curve of newly created agents who are instantiated with the current knowledge that is available to the entire system. This is achieved in IKMDSA since agents have captured rule-based knowledge modules and have stored such knowledge modules in XML format in the knowledge repository for the benefit of the entire agent community and the system.

IKMDSA also provides a decision explanation facility to the end-users where agents are able to explain how they arrived at a particular decision. This has three important benefits:

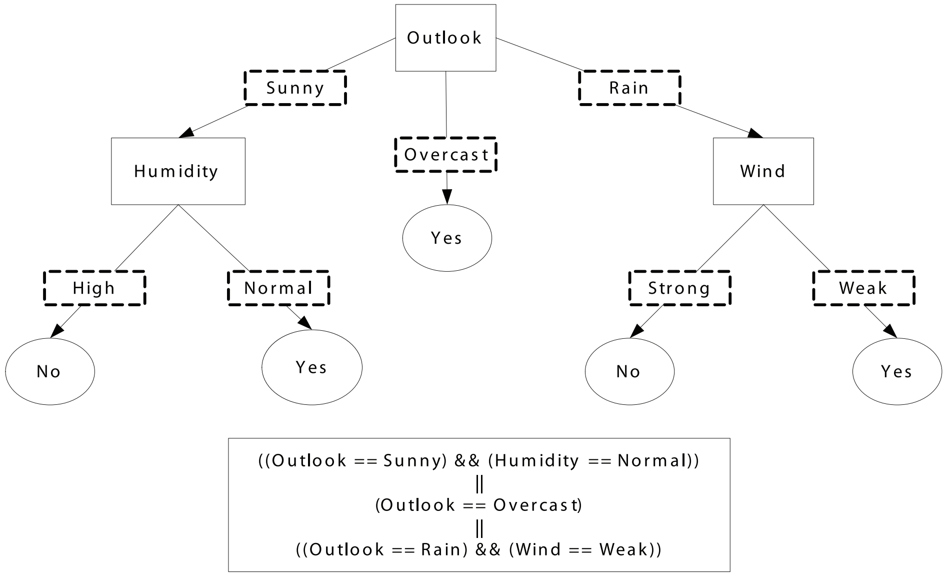
- the end-user can understand how the decision was made by the software agent,
- the end-user can make a clear assessment of the viability of the decision, and
- the end-user can learn about the problem domain by studying the decision paths used by the agent.

Agents are able to explain the rules and parameters that were used by the agent in arriving at the stated decision. This explanation facility is a natural extension of using decision trees in general for solving rule-based decision problems. Non-technical end-users are able to easily understand how a problem was solved using decision trees compared to other existing problem-solving methods such as neural networks, statistical and fuzzy logic-based systems (Sung et al., 1999). The IKMDSA architecture can provide intelligent distributed decision support that may be internal to the company and the other focusing on providing intelligent distributed decision support that may be external to the company. In the second case, the proposed architecture incorporates the W3C Web Services architecture that uses the simple object access protocol (SOAP) and XML. The incorporation of this architecture creates a flexible means of exposing the services of the agents using the Web Services architecture by a company to its potential or existing global population of customers and suppliers.

Implementation of the IKMDSA Architecture and Illustrative Example

The problem domain selected for the initial proof of concept is the play tennis decision problem (Mitchell, 1997) using the ID3 decision tree method. The selection of the problem domain was due to it being widely adopted (Mitchell, 1997) to represent decision problems in the ID3 decision tree research and also for its simplicity in illustrating the proposed architecture. The decision problem for this problem domain is to decide whether, or not, to play tennis on a particular day based on climatic conditions such as the day's weather outlook, the level of humidity, the temperature, and the wind conditions. Figure 4 shows a schematic of the decision solutions under consideration. The leaf nodes of the decision tree represent the final outcome of the decision of whether to play tennis on a certain day, based on what the weather is like. The problem is simple to understand; yet it illustrates the fundamental requirements of the system and provides an elegant way to test the various features of the agents and the architecture.

Figure 4. Decision Tree representation of the play tennis problem (adapted from Mitchell, 1997)



The end-user provides the existing weather condition to the user agent as input and the agent makes a decision and presents the decision to the end-user whether or not tennis can be played that particular day given the conditions entered by the user. The user is given information about each of the atmospheric conditions and their categories. These atmospheric conditions form the domain attributes for the play tennis problem and define the context specific information that is pertinent to this decision problem. The agent provides information on each domain attribute thereby informing the user through the process of selection of the attributes that are pertinent on any given day. The representation of the domain attributes generated by the agents shows the DTD and the XML files (see Figures 5 and 6) for the representation of information about the context of the problem domain. The XML representation of the domain attributes is dynamically parsed by the user agent to generate a context specific user interface (as shown in Figure 7). This allows the user to make a decision about each pertinent domain attribute. After the user makes a selection from all the domain attributes, the user agent has enough information to make a decision about the problem domain. This is accomplished by parsing the set of domain rules that specify a final decision based on observations of domain attributes. As mentioned earlier, the user agent has access to an XML representation of domain rules about a given problem context, through the XML DOM object contained in the Domain Knowledge object for a decision problem. The structure for this set of rules is shown as a DTD in Figure 8, while Figure 9 shows the XML representation of the rules used by IKMDSA for the play tennis problem. The user agent parses these rules and identifies the rules that are fired for the given set of observations. These rules are then presented to the user in user-friendly format as explanation from the decision made by the user agent.

In the prototype implementation of the proposed IKMDSA architecture, we use the Java programming language to implement the agents as extensions of objects. The choice of Java was based upon the widely accepted advantage of Java providing portable code and XML providing portable data. In addition, we use Oracle 9i Database and Application Server platforms (http://www.oracle.com) to implement the knowledge repository and use the Sun Microsystems Java XML API toolkit to interface the agents with the XML repository. The decision tree implementation consists of tree nodes with branches for every category of the node variable. Each traversal from the root node of the decision tree to a leaf node leads to a separate decision path as illustrated in Figure 4. The agents contain methods to traverse the decision tree and obtain a decision path that can then be translated into an XML object and an XML document using a DTD file. These form the basis for the generation of decision alternatives and for the explanations of decisions by the agents. The agents are implemented as java beans and their explanations are available to the user through calls made to their public methods that are exposed as services, and presented to the user as dynamically generated web content by using Java Server Pages technology (http://java.sun.com/products/jsp/index.html).

BUSINESS APPLICATION

Organizations are taking advantage of "data mining" techniques to leverage the vast amount of data to make better business decisions (Fan, Lu, Madnick, & Cheung, 2002; Padmanabhan & Tuzhilin, 1999). For example, data mining has been used for customer profiling in CRM and customer service support (Hui & Jha, 2000), credit card application approval, fraud detection, telecommunications network monitoring, market-based analysis (Fayyad, Piatetsky-Shapiro, & Smyth, 1996), healthcare quality assurance (Tsechansky, Pliskin, Rabinowitz, & Porath, 1999) and many other decision-making areas (Brachman, Khabaza, Kloesgen, Piatetsky-Shapiro, & Simoudis,

1996). There is a growing need to not only mine data for decision support, but also to externalize knowledge from enterprise data warehouses and data marts, to share such knowledge among end users through automated knowledge discovery and distribution system for effective decision support. In other words, there is an increasing need for the integration of KMS and DSS systems to meet the needs of the complex business decision situations. According to Bolloju et al. (2002) "Such integration is expected to enhance the quality of support provided by the system to decision makers and also to help in building up organizational memory and knowledge bases. The integration will result in decision support environments for the next generation" (p. 164). The proposed IKMDSA architecture illustrates such a next generation integrated KMS and DSS system. The detailed presentation of the implementation of the architecture is intended to further the research that combines multiple but related set of research streams such as data mining, automated knowledge discovery, knowledge representation and storage using XML, knowledge exchange among participating intelligent agents using knowledge context, and explanation facility (from expert systems research). The authors are currently extending the architecture in various business domains such as credit approval processing, bankruptcy prediction, electronic commerce and consumer behavior and Web mining.

Emergent Internet technologies have significant impact on business processes of organizations operating in the digital economy. Realizing the potential benefits of emergent technologies is dependent on the effective sharing and use of business intelligence and process knowledge among business partners to provide accurate, relevant and timely information and knowledge. This requires system models to support and enable information integration, knowledge exchange and improved collaboration among business partners. Such systems must provide collaborating partners with intelligent knowledge management (KM) capabilities for seamless and transparent exchange of dynamic supply and demand information. Implementing and managing such integration over distributed and heterogeneous information platforms, such as the Internet, is a challenging task; yet, realizing this task can have significant benefits for organizations embracing such collaborations. An application of the IKMDSA for Collaborative Commerce to enable collaborative work in B2B e-Marketplaces would have significant benefits in developing information partnerships by creating the foundation for knowledge representation and exchange by intelligent agents that support collaborative work between business partners.

CONCLUSION, LIMITATIONS AND FUTURE DIRECTION FOR RESEARCH

In this research we have presented a methodology to represent modular, rule-based knowledge using the eXtensible Markup Language (XML) and the Document Type Definition (DTD) standards from the World Wide Web Consortium (W3C). Using this methodology, we have shown how such an approach can be used to create problem-specific knowledge modules that can easily be distributed over the Internet to support distributed IDSS design. Such an approach will facilitate intelligent decision support by providing the required knowledge representation and the decision analytical support. We had presented the conceptual architecture of such a distributed IDSS, and have provided details of the components of the architecture, including the agents involved and their interactions, the details of the knowledge representation and implementation of knowledge exchange through a distributed interface. We also provided indication of how such architecture might be used to support the user and how it might assume the role of an expert and provide explanations to the user, while retaining the benefits of an active DSS through extensible knowledge generation by incorporating machine learning algorithms. The example used in this article is simple, intuitive, and elegantly achieves its purpose of illustrating the use of the architecture while minimizing complications inherent to a more complex problem domain. We continue to do research on elaborating this architecture for a variety of problems that lend themselves to rule-based, inductive decision making with a need for user interactions and which benefit from greater understanding of the problem domain by the user.

The limitations of this research derive from the use of decision trees and inductive learning algorithms and techniques. The limitations inherent to decision trees and such techniques are also the limitation of this architecture. Therefore, further research needs to be conducted to understand how this architecture can be expanded to incorporate other types of learning and rule induction or rule creation to be shared and used by software agents. Despite this limitation, this research contributes significantly to the advancement of our understanding of how emerging technologies can be incorporated into intelligent agent-based architecture to enhance the value of such systems in distributed intelligent DSS that incorporates knowledge.

Chapter 8.10

The Future of Supply Chain Management:

Shifting from Logistics Driven to a Customer Driven Model

Ketan Vanjara
Microsoft, India

ABSTRACT

This chapter initiates the concept of a customer-centric model in supply chain systems. It discusses various constraints of present-day supply chain systems resulting from their roots being in logistics management and suggests an alternative next-level paradigm of a customer-centric matrix model. This chapter further demonstrates how this model would add value to the customer by taking the example of a healthcare information management system. The chapter also delves into the limitations of and anticipated issues and challenges in implementing the suggested model. Finally, the chapter hints at some broad directions for future research and action in the field. Emergent behavior is what happens when an interconnected system of relatively simple elements begins to self-organize to form a more intelligent and more adaptive higher-level system (Johnson, 2001).

INTRODUCTION

Supply chain systems have come a long way from their initial days when their sole purpose was to support the inventory management function in terms of controlling inventory carrying and fulfillment costs, while making inventory management more efficient and effective. However, as the roots of Supply Chain Management (SCM) lie in managing supplies or inputs to a process or an enterprise, most of the developments (solutions, tools, and technologies) in this field obviously have been around effective management of supply chain toward better, faster, and more cost-effective fulfillment of customer demand.

While this focus on logistics and inventory management has certainly helped business, it still falls short of making the best use of the current tools and technologies for businesses. In order to provide this SCM advantage to businesses, the next level of evolution for the concept of supply chain would be to focus on the needs of the ultimate consumer in contrast to the needs of interim customers (i.e., manufacturers) that are the present-day focus. This chapter seeks to explore the possibilities of elevating the focus of SCM from a logistics-driven model to the next level of customer-driven model, thereby enhancing the value delivered to the end customer. The issues and challenges expected in the process also are delved into.

The chapter reviews some of the latest literature available on SCM, describes various models of supply chain since its origin, enumerates the limitations of the existing supply chain model, and suggests a customer-centric model. Furthermore, it goes on to discuss the challenges in the implementation of this model and the constraints of this model that will have to be addressed. Supply and procurement of healthcare services as well as a health care information management software developed by the author for the creation and management of virtual healthcare communities in line with the suggested customer-centric model is used as an illustration throughout the chapter.

ORIGINS

As per one definition, SCM is the coordination of the demand and supply of products and services between a supplier's supplier and a customer's customer. It involves the flow of products, information, and money between the trading partners of a company's supply chain. The proactive improvement in the efficiency and effectiveness of the flow of goods, services, and knowledge across all stakeholders achieves the goal of reducing total costs and obtaining a competitive advantage for all parties.

Supply chain is the network of facilities (warehouses, factories, terminals, ports, stores, and homes), vehicles (trucks, trains, planes, and ocean vessels), and logistics information systems connected by an enterprise's suppliers' suppliers and its customers' customers. Supply chain flow is optimized when material, information, and money flow simultaneously in real time and without paper.[5]

SCM revolves around efficient integration of suppliers, manufacturers, warehouses, and stores. Other definitions are more comprehensive and detailed:

> *The challenge in supply chain integration is to co-ordinate activities across the supply chain encompassing these various players, whose systems are bound to be disparate right from the beginning. It is only with such integration that the enterprises can improve performance, reduce costs and increase their service levels to the end-user, the customer. These integration challenges are met not only by coordinating production, transportation, and inventory decisions but more generally by integrating the front-end of the supply chain, customer demand, to the back-end of the supply chain, the production and manufacturing portion of the supply chain.* (Simchi-Levi et al., 2003)

As it can be seen from our discussion thus far and from the voluminous literature on supply chain, the focus is constantly on the network of facilities, logistics, supplies, and suppliers. This is due to two main reasons: (1) the origins of the concept of supply chain lie in logistics and in inventory. and (2) the supply chain is related mostly to manufacturing or tangible goods, and thereby, the developments in the services sector and in the knowledge economy are overlooked.

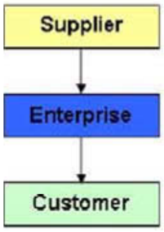
Some thoughts are emanating gradually on the use of supply chains for customer satisfaction. For instance, "efficient integration of suppliers, manufacturers, … so that enterprise can increase service level" (Simchi-Levi et al., 2003) and "maximize customer service and minimize cost of the same" (Frazelle, 2002). The closest one gets to customer focus is in the following statement:

> *[A] supply chain consists of all parties involved, directly or indirectly, in fulfilling a customer*

request. The supply chain not only includes the manufacturer and suppliers, but also transporters, warehouses, retailers and customers themselves … the customer is an integral part of the supply chain. The primary purpose for the existence of any supply chain is to satisfy customer needs. (Chopra & Meindl, 2004)

However, most of the integration referred to in most SCM literature is the vertical integration of suppliers, manufacturers, distributors and other business partners for the ultimate purpose of customer consumption and satisfaction. Thus, essentially, SCM has focused on vertical flow of goods and services toward order fulfillment, as described in Models A, B, and C in Figures 1, 2, and 3, respectively. But, as the delivery models of products and services become more complex (Model D), as shown in Figure 4, with the objective of fulfilling end-to-end requirements of a customer, supply chain systems will have to focus on integrating processes laterally, as well. The spread of such lateral processes across heterogeneous enterprises and geographical boundaries is becoming almost mandatory with the rapid globalization of enterprises, consequently adding to the challenge of managing supply chains.

Figure 1. Simple vertical model (1-1-1 relationship)



MODEL A: Simple Vertical Model (1-1-1 Relationship)

This model is based on an enterprise with a single product, single supplier, and single customer. Such a scenario exists in the case of contractual outsourcing or certain niche industries, products, or markets. Here, an enterprise fulfills the demands of its customer by adding value to the inputs from its supplier. The only contribution made by SCM in this model is the control of inventory-carrying

Figure 2. MODEL B: Simple vertical model (many-1-many relationships)

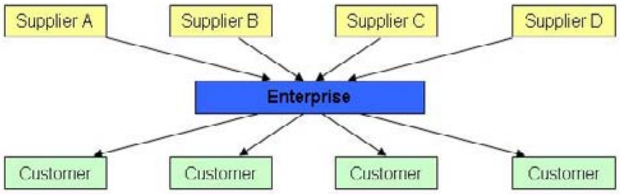


Figure 3. MODEL C: Complex vertical model (many-many-many relationships)

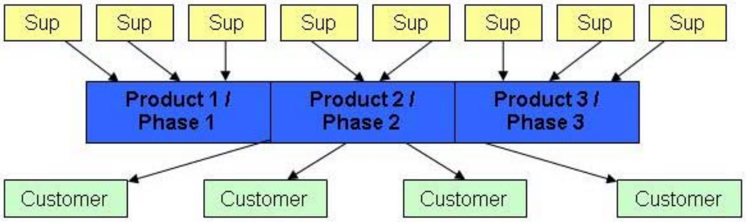

Figure 4. Healthcare services procurement by a patient

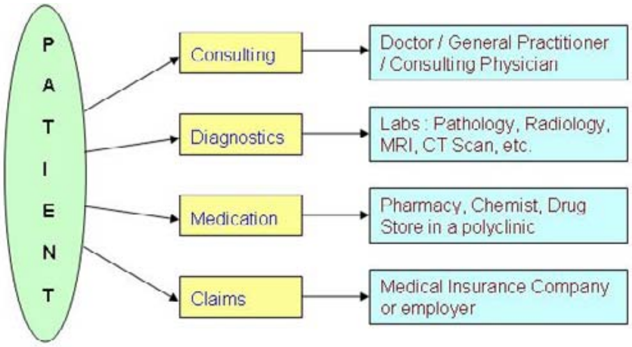


costs, if at all. This is only a marginal improvisation over JIT (just-in-time) inventory systems.

MODEL B: Simple Vertical Model (Many-1-Many Relationships)

In this model, the enterprise still has a single product and phase of production but has many suppliers and customers. Many of the enterprises that are creating and/or providing goods and services (e.g., component manufacturers for automobiles or home appliances, PCB fabs, etc.) would fall under this category. Here, an enterprise fulfills the requirements of its (many) customers by adding value to the inputs from its (many) suppliers. The contributions made by SCM in this model are more than just control of inventory carrying costs. SCM contributes to the overall inventory management of an enterprise, depending on the level of integration among the systems of the suppliers and the enterprise.

MODEL C: Complex Vertical Model (Many-Many-Many Relationships)

In this model, the enterprise has multiple products and phases of production and also has many suppliers and customers. A large number of enterprises that are creating and/or providing goods and services would fall under this category. This would include enterprises offering relatively complex products and services like white goods, home appliances, automobiles, IT and telecom equipment, real estate, banking, healthcare, and so forth.

Here, an enterprise either offers a variety of goods and/or services or has multiple phases of a complex production cycle that produces products to fulfill the requirements of its (many) customers by adding value to the inputs from its (many) suppliers. The contributions made by SCM in this model are enormous. A supply chain system in such a model is normally well-integrated with the inventory as well as with production planning and control systems of an enterprise and, thus, facilitates all the suppliers under the ambit of the SCM to support the inventory and PPC functions of the enterprise. Apart from controlling inventory-carrying and fulfillment costs, such an integrated approach also addresses issues related to timely deliveries (at different phases), quality of deliveries, exception handling, real-time changes in requirements, and so forth.

THE PROBLEM

While all the models mentioned earlier (A-C) contribute to customer satisfaction through reduced costs and faster deliveries, they add little direct value to the customer in terms of increased convenience, choice, or higher value for money.

This is further compounded by the trends of globalization, restructuring of various industries, fragmentation of supply chain ownership, and the nature and structure of new industries evolving in the knowledge economy.

For a moment, let us step back to the physical world of goods and services as it existed a few decades ago. Taking the example of various services offered by governments to their citizens, a citizen had to go from pillar to post filling out various forms and documents for obtaining some service, and, after a few days if not weeks or months and a lot of agony, the citizen would get out of the bureaucratic maze with some positive result. This is quite akin to Model C with one major exception: the various stages of the process were not so efficiently integrated in case of a typical government organization.

To add to the convenience of their citizens, to introduce transparency into their work processes, and also to deliver faster positive results, many government organizations introduced the single-window system, whereby the end customer—the citizen—had to submit a set of documents only once at a window and collect deliverables in the form of some document, certificate, or money on a predetermined date or, sometimes, even instantaneously. As a result, the end customer could receive faster service with a lot of convenience. At the same time, the efficiency and effectiveness of various processes manned by specialist or expert bureaucrats was not compromised. It was either replaced with technology solutions or carried out in the back office without affecting the consumer.

Similar scenarios and examples exist today in services like travel and healthcare. The domain of healthcare services is replete with many of the issues and problems discussed earlier. For example, if a patient needs attention and requires the services of any of the healthcare service providers, at the very least, patients have to visit a doctor and a pharmacist. However, and more often than not, a number of visits to multiple service providers is required, especially if lab tests and diagnostic results are required. The prevailing bureaucratic governmental restrictions and the rigid health service practices add to the misery and suffering of patients by delaying their treatment. Typical stages of healthcare service procurement of a patient are shown in Figure 4.

As shown in Figure 4, the patient has to approach numerous service providers to get treated. Typically, the steps required are as follows:

- Patient visits the doctor.
- The doctor may suggest further diagnostic tests (the probability of this increases with the advancement of medical science).
- Patient goes to the respective laboratory for getting the diagnostic tests done.
- Patient visits the laboratory again to collect the diagnostic reports.
- Patient visits the doctor again with the diagnostic reports.
- The doctor prescribes medication to the patient.
- Patient visits the pharmacy to buy the medication.
- Patient approaches the insurance company or concerned agency for reimbursement of medical expenses. Alternatively, the medical agencies (like the physician) approach the insurance company for reimbursement.

It is clear from this example that it is quite an exercise to move people and documents all over the place, sometimes in circles, to access one important and critical service most people require continuously. This is true for most of the service sector industries.

The ERPs, CRMs, and SCMs of today's world need to integrate and elevate to provide a single-window solution to the end customer in various areas, especially the service sector. One way of doing this is to offer all the products and services related to a solution through a single enterprise—creating a Web-based single window.

The government services department example can be extended here. One also can think of travel service firms offering all related services, like hotel bookings, car bookings, and so forth, or hospitals and healthcare polyclinics providing all the healthcare services in one place.

However, there are some significant limitations to this approach:

- Such an integration of services may not be possible in all domains.
- Integrated offering of all services may result in a loss of focus for an enterprise and thereby inhibit the enterprise from developing expertise in any field. As a result, the end customer may not get the best possible service, may get it at a premium, or both.
- The end customer does not get multiple options—if customers want to avail of the single-window convenience, they will have to hire a car through the same travel agent who books their tickets, although there could be better options elsewhere.
- Such a solution also creates a constraint of physical proximity, especially with respect to services like banking and healthcare. The consumer always has to visit or transact with a particular single-window service provider (e.g., a hospital). Thus, after procuring a product or service from a vendor, if consumers move to some other location, they will have no or limited access to the products and services of that particular vendor. For instance, after getting treated at a hospital or polyclinic, when a patient moves to another place, the patient not only will be unable to avail of the services provided by that hospital but also will not have his or her medical history to get faster and better treatment from a hospital at the new location.

THE SOLUTION

As seen in the example of healthcare services, solutions and services in today's world are offered by a chain of multiple enterprises within an industry, and customers personally have to navigate through a mesh of network to procure an end-to-end solution to their requirements, which is obviously not very convenient. Since the mesh of network is the cause of the problem, a corresponding solution ought to be network-based.

MODEL D: Matrix Model (Many-Many-Many Relationships Spread Across Different Enterprises/ Geographical Locations)

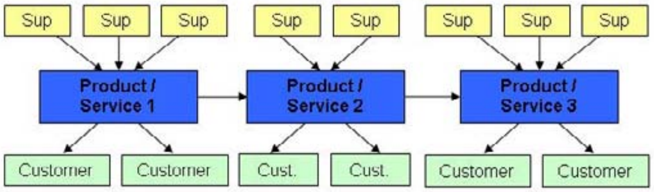
One way of offering the single-window solution to the end customer is by creating virtual communities (mesh of network) of service providers on the Web. These communities can share and exchange data on a need-to-know basis and provide the single-window advantage to the consumer without any of the limitations discussed earlier.

The introduction of a horizontal flow of supply chain in addition to a vertical flow is of major significance in the matrix model. This assumes greater importance when subset products or services of the same set are offered either by different business units of the same enterprise spread across different geographies or by different enterprises all together.

Before getting into more details of the solution, let us also harp upon why such a solution is required. The reasons for such a shift are as follows:

- The changing method of product or service provisioning is one reason. With the globalization of almost every industry and the increasing quality-consciousness of the consumer, it is critically important to any industry to respond appropriately. One major

Figure 5. MODEL D: Matrix model (Many-many-many vertical and horizontal relationships spread across different enterprises or geographical locations)



response of many industries has been their focus on specialization and customization of customer requirements and needs. With this, the end-to-end solution is provided to the consumer by multiple enterprises—physical and virtual. In the absence of a comprehensive solution, consumers have to approach more than one enterprise to fulfill their requirements. This is also known as multiple funnel delivery.

- With the fragmentation of supply chain ownership, it is becoming increasingly difficult for the consumer to get the best value for money in a convenient manner. If at all, the consumer is required to put in considerable effort to get good value.
- Intangibles occupy a prominent position in the consumption and commerce that happens worldwide today. The dynamics of commerce and the consumption of intangibles are quite different from those of tangibles. So are the supply chains. This, too, necessitates a different solution.
- With the growth of the Internet and other facilitating infrastructures, the customer expects 24/7 service based on a direct delivery model wherein services are delivered directly from the manufacturer or provider of services.
- Flexible pricing, product portfolio, promotions, and discrimination on service make the selection and procurement of a product or service a very complex decision for the consumer in the absence of an integrated solution.
- General expanse in the domain knowledge and increasing complexity in most domains of products and services add to the woes of the customer.
- An increasing number of alternatives in every sphere of products and services also compounds the problem.

All these and the primary requirement of providing the best value for money to the customer with utmost convenience create the need for a customer-centric SCM.

Virtual Communities

As mentioned earlier, the solution has to be network-based. A software solution created by the author for the formation and management of virtual communities for provisioning end-to-end healthcare services will be used as an example.

There are two potential solutions: (1) as mentioned earlier, hospitals and polyclinics (remember the single-window example); and (2) the creation of virtual communities of healthcare service providers, even globally.

While hospitals and polyclinics offer a viable solution, they are fraught with the limitations discussed earlier. Quite often, they also happen to be quite expensive. This necessitates the creation of a solution that would provide best services from distributed supply chains to the customer (here, the patient) with increased convenience.

The most compatible solution in such a scenario can be the creation of virtual communities of all the agencies involved in healthcare services provisioning. A virtual community is a collection of related individuals or organizations that connect with one another with the help of various communication media (e.g., the Internet) to fulfill a common objective or achieve a common goal. All are aware of different types of virtual communities like portals, newsgroups, chat groups, and so forth. However, most of them do not provide for transaction facility (if at all, it is permitted only within a closed user group), and most of them also are moderated or owned by an individual or an organization.

The virtual community proposed here is different on these two parameters. One, its primary function will be to facilitate transactions, and two; it will have shared moderation and ownership.

How will a virtual community help the customer?

- It becomes a one-stop shop for all the products and services in a particular segment.
- The customer can receive faster service.
- It is independent of location and, therefore, creates no physical proximity constraint. As the medical history of a patient is stored in the virtual space, a patient can obtain services from almost any part of the world.
- It reduces unnecessary physical movement of the customer (here, the patient).
- Customers can avail of the best services from the service provider of their choice.
- It can be integrated with various data-capturing tools, including equipment like those used for self-diagnostics.

Applying the matrix model to healthcare services provisioning, the flow would look like Figure 6.

This model certainly will enhance the convenience of the patient, since now, the various service providers also are interconnected. A meshed solution as follows (Figure 7) will create the maximum impact.

The networked model interconnects all the service providers who, in turn, can interact with one another on a need-to-know basis. For instance, after a patient has gone through the diagnostic tests, they do not have to revisit the laboratories to collect the reports; these can be collected by the patient as well as the doctor over the Web. Similarly, the medication also can be delivered to a patient's home by the nearest pharmacy, based on the prescription posted by the doctor on the Web and subsequently collected or received by the pharmacist.

This substantially reduces the number of steps that a patient has to go through to get treated. In most of the cases, only two steps are required:

Figure 6. Application of matrix model in healthcare services provisioning

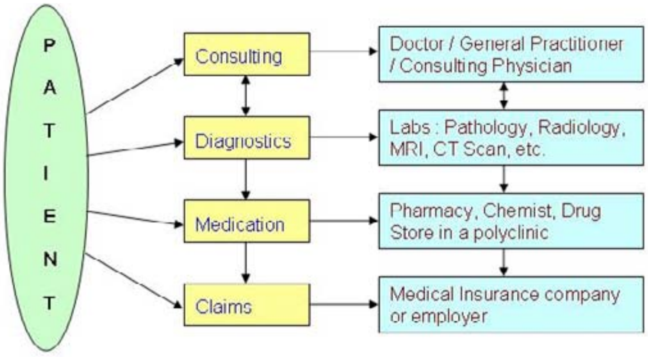


Figure 7. Networked model in health care services provisioning

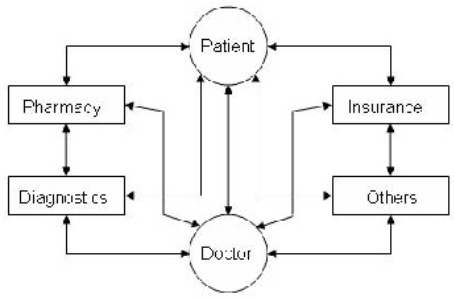


1. Patient visits the doctor for consultation.
2. Patient visits diagnostic labs for tests.

HOW DOES THE SOLUTION WORK?

In a virtual community, as the suppliers of all the interrelated products and services are interconnected logically, in spite of being separate geographically (in the form of different locations of the same enterprise) or legally (in the form of different enterprises), they are able to provide an end-to-end solution to the consumer faster and with enhanced convenience.

In the example of healthcare services, the core engine of virtual communities takes care of most of the steps. Here is how it works:

- Patient visits the doctor for consultation.
- If diagnostics are required, the doctor submits a prescription of tests to be conducted to the intelligent engine and database of the virtual community, where it is picked up by the diagnostic lab chosen by the patient. If diagnostic tests are not required, a prescription of medicines is submitted.
- Patient visits the diagnostic lab of its choice for conducting the tests.
- The lab pulls the test prescription from the database of the virtual community to conduct tests. Patients are not required to worry about the prescription.
- Diagnostic labs submit test reports to the same engine and database of the virtual community; where it is picked up by the doctor. The patient is spared a second visit to the lab.
- On receipt of test reports, the doctor submits a prescription of medicine. In most cases, patient will not have to visit the doctor again to obtain the prescription.
- The pharmacy of the patient's choice gets the prescription of the patient and manages to deliver the necessary medicines at the patient's doorstep. Again, this step does not require any movement on the part of the patient.
- Depending on the insurance plan, the doctor and/or patient can submit necessary documents electronically for claims processing and get paid by the insurance company directly into their bank account.

As all these steps happen over fiber (communication or Internet), the pace of transactions is much faster than physical movements of people and paper.

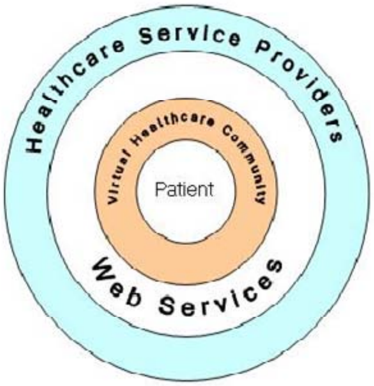
The availability of technologies like Web services and wireless networks not only make the solution feasible but make it even more capable.

The high-level architecture of such customer-centric model, wherein all the healthcare service providers can serve the patient by using the virtual healthcare community infrastructure through Web services, is shown in Figure 8.

BENEFITS OF A CUSTOMER-CENTRIC MODEL

A customer-centric model creates a win-win situation for all the stakeholders in the model. While it certainly benefits the customers and the suppliers involved in the model, it also creates some benefits

Figure 8. High-level architecture of customer-centric model for supply of healthcare services



at a higher level for the entire community. Some of the benefits generated by this model for various stakeholders are specified hereafter.

Generic Benefits

Greater value-add in the form of best price performance, procurement of end-to-end products and/or services, and greater customer convenience through provisioning of ease in the procurement of end-to-end products and services is the primary objective of the customer-driven model.

Be it supply of healthcare services or other services like travel, finance, and so forth, this enhanced supply chain model has certain inherent benefits for the customer as well as suppliers.

Benefits to Customers

- The community becomes a one-stop shop for all the interrelated products and services in a particular domain.
- The customer gets the best of both worlds—better and specialized services without the associated overheads of an integrated physical model.
- The customer also has the luxury of making choices among various service providers.
- There is no constraint of physical proximity. The customer can procure a product or service virtually anytime, anywhere.

Benefits to Suppliers

- Suppliers now can focus on their areas of specialization and yet offer their products and services at competitive prices to their customers.
- Depending on the nature of their product or service offering, suppliers need not be constrained by geographical proximity.
- In cases like pharmacies, suppliers can do away with physical stores altogether. Drugs can be shipped straight from their warehouse, based on prescriptions received.
- As participants of virtual community, suppliers can gain from mutual coordination and exchange of aggregated information

Benefits to Community

- The virtual community also creates quite a few extra benefits that can be shared by individual suppliers as well as customers. Such benefits are in the form of:
  - Creation of aggregated information and knowledge related to the industry.
  - Making the processes and workflows more efficient and effective, resulting into cost savings at individual entity levels.
  - Providing a platform to conduct industry-related research. For instance, medical schools and colleges as well as pharmaceutical companies can use the virtual healthcare community to conduct industry-specific research on aggregated data.

Thus, a customer-centric SCM would be beneficial to all the stakeholders in the supply chain. As mentioned earlier, the supplies, especially information supplies, in this model would flow vertically as well as horizontally. In the example of healthcare services, for instance, the diagnosis reports would flow vertically to the patient as well as horizontally to the doctor. Similarly, a prescription would flow vertically to the patient and horizontally to the pharmacy.

In addition to forward integration with ERPs, the existing supply chain systems need to incorporate the horizontal flow of information in order to facilitate the creation of such virtual communities and thereby enable enhanced customer satisfaction.

LIMITATIONS OF THE MODEL

Like any good solution, this one also comes with a set of its own limitations. Some of the limitations of this solution are as follows:

- As the model is heavily dependent on information and communication technologies, any interruption in the availability of these in the form of communication media like the Internet and so forth can cause disruption in providing basic services like healthcare. Many people on the east coast of the US experienced such an inconvenience due to major power outages during late 2003. This happened due to people's heavy reliance on electricity as the major source of energy.
- While the model would deliver better products and services to the customer faster and at a reasonable price, on the downside, it can have a sociological impact on persons for whom a personal visit to any product or service provider also creates an opportunity for social interaction. For instance, many of the older people in Australia have been objecting to the installation of ATMs that lead to closure of several bank branches. Though ATMs provide better and faster service 24/7, a personal visit to the bank for cash withdrawals or deposits is a far more important opportunity, especially for the retired and elderly, from a social interaction standpoint.
- In services like healthcare, such a heavily automated model also can lead to the creation of some information gaps. Repeated interactions with the patient provide the doctor with quite a bit of relevant information that cannot be obtained through a structured approach.
- Also, in services like healthcare, a relationship of mutual trust and faith between the patient and the doctor is of vital importance. As repeated interactions have a bearing on the depth and expanse of such a relationship, the technology-based solution certainly would hamper that.

ISSUES AND CHALLENGES

Coordination among various partners in a supply chain is a huge challenge even today in the present state of SCM solutions. With the increased complexity of the solution, more issues and challenges are expected to arise.

According to Chopra et al. (2004), over the past several decades, most firms have become less vertically integrated. As companies have shed non-core functions, they have been able to take advantage of supplier customer competencies that they did not have. This new ownership structure also has made managing the supply chain more difficult. With the chain broken into many owners and each having its own policies and interests, the chain is more difficult to coordinate. In their book, Chopra and Meindl (2004) go on to list the causes of difficulties in coordination as well as the impact of lack of coordination in integrated supply chain models.

The following are two points to be noted: (1) reducing vertical integration with the new ownership structure and (2) increased difficulty in coordination.

The customer-centric model proposes horizontal integration of broken supply chain ownerships at a much higher level and spread across geographies, potentially making it a global solution.

Some of the challenges that can be anticipated for the customer-centric supply chain management system are listed hereafter. Wherever possible, potential solutions to challenges also are mentioned, together with the issues.

- **Diversity:** The model is an attempt to provide a universal solution that is independent of geographical constraints. In other words, it seeks to provide a uniform solution to diverse environments. The diversity could be in the form of the following:
  - **Standards:** Different countries follow different standards and codes pertaining to various industries like healthcare. Addressing all of these in a single solution could be a major challenge. Some ways of making this happen can be through the adoption of standards like HIPAA (Health Insurance Portability and Accountability Act) of the US by various countries or cooperative creation and implementation of global standards under the aegis of a UN body like WHO (World Health Organization), and so forth.
  - **Laws:** Laws related to the conduct of various industries like healthcare are widely different in various countries. These also need to be aligned at a broad level in order for a universal solution to work. While this is very difficult and far-fetched, if all the countries in the world can sign charters and conventions on pollution control, IPRs and many such issues, and create a common legal framework at a higher level for the benefit of mankind (e.g., in the area of healthcare) this certainly can be made possible in the long term.
  - **Language:** A global solution also has to address the need of multiplicity of languages. This, though, is the least of problems, as quite a few solutions (from Microsoft Windows to small accounting packages like Quickbooks and MYOB) already have addressed this issue. Unicode-based solutions also can be considered to address this issue.
- **Creation of a Common Framework:** Given the diversity of laws, standards, and many other practices related to an industry, creation of a universal solution or a framework in itself would pose an enormous challenge. However, good news is that common global XML standards are emerging in most of the industries, from news to banking to healthcare to entertainment. In the healthcare sector, for instance, HL7 is almost a universally accepted standard, and most of the software solutions created for healthcare industry (no matter who creates them where) are HL7 compliant. In fact, the author and his team have created a common software framework of reusable components that can be used to construct a global solution for the healthcare industry.
- **Ownership and Control of Virtual Communities:** While the components of a supply chain have a broken ownership, the solution that ties them up needs to have some command and control structure. This, too, would be a challenge to reckon with. To address this, one either can fall back upon the proven model of managing the Internet and assigning IP addresses and domain names (Internet Corporation for Assigned Names and Numbers [ICANN]) or attempt to create a new model, based on the paradigm of ant colonies. An emergent system is smarter than the sum of its parts. There is no master planner or executive branch—the overall group creates the intelligence and adaptability. Randomness is a key component. Almost all emergent systems are networks or grids. They tend to be flatter and more

horizontal. Experimentation is another key component (Exact Software, 2004).

- **Data Trusteeship and Use:** Needless to say, a software solution that facilitates and manages such virtual communities in any industry will also create large databases of immense value to the industry. However, as the aggregated data would belong to the community as a whole and not to any individual participant in the community, it has to be held and maintained under trusteeship in order to prevent any leakage or misuse. This responsibility also can be undertaken by the same body that owns and controls the virtual communities on a distributed or centralized basis.
- **Data Sharing:** Another challenge pertaining to data would be sharing it among different entities of the community on authorization by the owner of the data. An interesting paradigm shift that happens here is the split between the owner and the possessor of data. Taking the example of healthcare, a patient's data in the form of medical history are currently possessed as well as owned by the doctor. Therefore, whenever a patient moves from one place to another, there is a rare chance that the patient or the doctor at the new place will have access to historical medical records of the patient. However, the customer-centric model can shift the ownership of data to patients, who then can provide access to the doctor or medical institution of their choice.
- **Security and Privacy:** Since the solution depends on information and communication technology, it also is prone to the security and privacy threats faced by such networks. The threat is all the more perceptible, given the sensitivity of certain types of data, like financial data, medical records, and so forth. However, this is a manageable challenge, given the number of high-quality encryption solutions available now.

CONCLUSION

This chapter has initiated the concept of a customer-centric model in supply chain systems. The chapter also has discussed how the model can work and how it addresses various constraints of the existing, essentially vertical supply chain systems by putting forward a matrix model. Apart from the global trends in various industries and supply chain that necessitate such a paradigm shift, the chapter seeks to ascertain the high value addition of the customer-centric model and how it will enhance the present-day supply chains to the next level. It further has enumerated the limitations of the new model and the issues and challenges that are anticipated in implementing the customer-centric supply chain model. While discussing the issues and challenges, the author has attempted to suggest some potential solutions to the challenges. Finally, the chapter has provided some directions for future research and action.

THE FUTURE

As discussed earlier in this chapter and also noted in the literature surveyed, there is a definite shift from vertical integration to matrix relationships among various partners in the supply chain. This, in conjunction with globalization, specialization, and broken ownerships of various components of the supply chain, certainly creates a need for a paradigm shift in the models and solutions of supply chain management conceived and practiced so far. In the opinion of the author, whether this paradigm shift will happen in the future probably is not a question; when it will happen is worth speculating and preparing for.

In the years to come, one can expect more aggressive initiatives toward this paradigm shift. This also throws up multiple business and research opportunities in a completely new direction. Such opportunities will be created in both areas—the respective domains of various industries as well as the domain of information and communication technology. Given the wide scope of the suggested solution, there could be opportunities in the areas of international relations and creation of global standards, as well.

Some specific opportunities for the immediate future are the following:

- Creation of globally acceptable standards related to operations, transactions, workflow, and information flow in various industries, especially in those belonging to the knowledge economy.
- Creation of software components, frameworks, and libraries that can facilitate the implementation of a customer-centric supply chain management system.
- Innovating new concepts to address the challenges around data management and sharing.
- Conceptualization of management models for ownership and control of virtual communities.
- Creation of a legal framework that would govern the working virtual communities.

Finally, I believe that mankind has all the necessary knowledge, tools, and technologies to make this happen. Does it have the will in the larger interest of mankind? Will we do it? Let time answer these questions.

Chapter 8.11

Strategic Decisions for Green Electricity Marketing:

Learning from Past Experiences

Marta Pérez-Plaza
Universidad Pontificia Comillas, Spain

Pedro Linares
Universidad Pontificia Comillas, Spain

ABSTRACT

Green electricity (GE) has emerged as one of the most interesting instruments for promoting renewable electricity in liberalized markets, at least in theory. Indeed, some experiences have already been carried out, mostly in the U.S. and Europe. However, most of them have been largely unsuccessful. In this chapter, we look at previous surveys and studies carried out on customer response, and provide a review of the most relevant results achieved by GE experiences, in order to learn from them. As a result, we provide what we believe are the key strategic recommendations for green electricity retailers to launch a successful GE program. Although the green electricity market remains a difficult one, several improvements can be achieved by learning from past mistakes and carefully analysing the alternatives and the boundary conditions.

INTRODUCTION

Now that the risks of the current energy mix are being recognized and awareness of the benefits of electricity production from renewable energy sources has become widely extended, there is a general consensus on the need to stimulate technical progress and development of renewable electricity sources. However, there is still controversy about which should be the instrument chosen to achieve these objectives. Indeed, a wide array of support schemes and policies have been introduced with the aim of stimulating competition with conventional technologies, the most used of which are feed-in tariffs, subsidies, or renewable energy quotas (see e.g., Del Río & Gual, 2004).

One of these instruments, which in principle is well suited to liberalized markets, is green electricity. This consists basically of the possibility for electricity retailers to offer a differentiated product, electricity produced from "green" sources, charge a premium for it in order to account for the extra cost of these green sources, and let the customer decide whether to accept the offer and pay this extra amount or to not accept it. It is a voluntary mechanism based on product differentiation and relying exclusively on market forces.

Green electricity may take the form of "green pricing" (Moskovitz, 1993) in regulated markets, whereby consumers may pay a premium to their electric utility in order to be supplied with electricity from renewable energy sources or increase the contribution of renewable energy into the system. In competitive markets, this is also known as "green power marketing," the difference being that customers may have a choice of different suppliers and products, and therefore switch between them. However, the concept is essentially the same, and hence we will consider both under the same "green electricity" name.

On first inspection, it seems that green electricity programs are then a quite straightforward and market-based approach to promoting renewables. The problem is, this is not as easy as it may seem.

A first problem is how to define "green." Usually, green means renewable electricity: hydro (large and small), wind, biomass, solar, and other minor ones such as geothermal, wave, or tidal energy. Of course, it would be arguable that some renewables are "green" in the sense that they do have large impacts on the environment. In fact, some programs exclude large hydro due to this reason. In addition, sometimes other nonrenewable electricity is also included in "green" programs: co-generation is sometimes included because of the environmental benefits it provides to the system (due to its higher efficiency in energy conversion). The fact is that there may be differences in customer response depending on the type of energy included in the program, but in the end, most of the analysis applies to all types described. So, for practical purposes, we will consider "green" equivalent to "renewable."

But the major problem is that, although many experiences have been carried out with green electricity retailing in different countries, none of these experiences has been truly successful, due to the complex issues lied to this option: green energy definition and certification, customer response, specificities of the electricity markets, and compatibility with other renewable electricity support policies.

Let us put as an example the green electricity programs launched in Spain during 2004. The major Spanish utilities offered their customers the possibility of consuming electricity only from renewable sources, mostly hydro and wind, at a quite small premium (around 15%). Each of them devised large publicity campaigns and built customer service centers specially devoted to this issue. Given that Spain is one of the European countries with the largest contribution of renewable electricity, and that the electricity retail market was just being liberalized, it seemed a good business opportunity. However, after some months, the real participation in the program was less than 1%, and in fact all programs were discontinued after less than 1 year. It seems that many elements in this strategy were mistaken, as has happened with many other programs around the world.

In this chapter, we aim to learn from these experiences in order to provide recommendations on how to successfully market green electricity. We first look at the most salient of the considerable number of surveys and studies carried out regarding green electricity and consumer willingness to pay for it. Second, we provide a review of the results achieved in the most relevant real green electricity programs. By looking at these programs in the U.S. and the European Union, concrete examples of how these instruments were designed, how successful green electricity as a product was, and how much new renewable capacity was installed as a result of these markets are analyzed. The final part of the chapter provides some strategic recommendations for green electricity retailers in liberalized markets. Although the green electricity market remains a difficult one, several improvements can be achieved by learning from past mistakes and carefully analyzing the alternatives and the boundary conditions.

BACKGROUND

In principle, there are many reasons for the attractiveness of green electricity programs: they may provide benefits for utilities, for companies, and, possibly, for individual customers.

Utilities find green electricity programs interesting in that they help them improve their environmental performance and corporate image (especially interesting for those with environmental management systems or under regulatory constraints); differentiate from the competition and provide niche markets; retain or gain environmentally-minded customers; and also may be thought as a defensive strategy against critical stakeholders (usually from the environmental community) (Kotchen, Moore, & Clark, 2001; Wüstenhagen, Markard, & Truffer, 2003). They also have the potential to encourage learning processes, which are certainly welcome given the recent liberalization context.

For companies, buying green electricity is a way of signaling their concern for the environment, of reinforcing their corporate image (Fouquet, 1998). They can also help meet corporate and institutional goals related to corporate social responsibility.

Incentives for individual customers to participate, however, are less understood. Green electricity is an impure public good, in that it provides both private (electricity consumption) and public benefits (the improvement of the environment compared to the use of conventional energy). But because the latter is the essential characteristic of green electricity, it should be expected that individuals will have little incentive to provide such a public good and instead free-ride (Clark, Kotchen, & Moore, 2003). In fact, RE advocates have opposed the concept (Swezey & Bird, 2001): since this is a public good, all consumers should share the cost of RE development. A survey by Wiser (2007) reinforces this idea by showing that collective payment methods are generally preferred by consumers, that is, that consumers prefer all to pay for this good.

But then, environmental concerns, altruistic attitudes, or even egoistic reasons may exist that explain why, as will be shown in the following section, individual customers are willing to engage in these programs. Some authors (e.g., Ek, 2005) have pointed out that when people deal with public issues, they may adopt public rather than private preferences. In addition, these programs provide an opportunity for individuals to express personal preferences and thus are beneficial to them. Indeed, they may also help them form preferences, attitudes, and consumer behavior (Markard & Truffer, 2006). Green electricity programs also integrate consumers into the RE support process.

Several studies have analyzed both the willingness to pay (WTP) of individual consumers for increased renewable energy contribution in the system, and also the success of the different green electricity programs implemented. A good review of WTP estimates may be found in Menger (2003), whereas Swezey and Bird (2001), Bird, Swezey, and Aabakken (2004), Bird, Wustenhagen, and Aabakken (2004), Bird and Kaiser (2007) and Wiser, Olson, Bird, and Swezey (2004) provide good overviews of green electricity programs. In this section, we bring these two issues together, and we update them with the most recent results and findings, in order to draw meaningful recommendations for the green electricity marketer.

The Willingness to Pay for Green Electricity

As mentioned before, green electricity, although having public good characteristics, shows a certain attractiveness to consumers, which are hypothetically willing to pay a premium over normal electricity prices. In fact, empirically observed levels of provision of public goods such as green electricity usually exceed levels predicted by rational-choice theories. This is usually explained by some kind of pro-environmental behavior, derived from a combination of egoistic, social altruistic, and biocentric value orientations (Kotchen et al., 2001).

Therefore, most studies show positive WTP values. Fouquet (1998) cites a survey indicating that 5% of residential customers in the UK would pay a 20% premium for environmentally friendly electricity. In Switzerland, Truffer, Markard, and Wustenhagen (2001) state that 20% of the households are willing to pay a 10-20% premium. Farhar (1999), in a market survey, found that there is a consistent pattern for the U.S. in that 70% of residential customers would pay $5/month, 40% would pay $10/month, and 20% would pay $15/month. Wüstenhagen et al. (2003), based on results from Germany, Sweden, the UK, and Switzerland, estimates that 20% of consumers would pay a 20% premium, whereas almost none would pay a 40% premium.

These WTP estimates are averages. However, they will depend on many parameters (including those related to pro-environmental behavior mentioned above). Roe, Teisl, Levy, and Russell (2001) identified several differences in WTP across regions in the U.S. They also found that a higher income, a higher education level, and affiliation with an environmental organization would increase the hypothetical premium. These results are consistent with those obtained by Rowlands, Scott, and Parker (2003), which identified as the major drivers for WTP the following: ecological concerns, altruism, education, perceived effectiveness, age (younger people have higher WTP), income, and involvement in community services or environmental organizations.

WTP estimates may also be conditioned by the type of renewable energy offered. Borchers, Duke, and Parsons (2007) found a positive WTP for green electricity in the U.S., but also found that the energy source affects this WTP. Thus, they found that solar is better, wind is similar to a generic offer, and that biomass and biogas achieve lower WTP estimates.

Finally, most of the estimates correspond to residential customers, because no studies have been found on the WTP of firms or institutions to buy green electricity. This is unfortunate, because these clients may be powerful drivers for the green electricity market.

So, to summarize: there is a positive willingness to pay for green electricity, and this WTP will depend on some issues which should be contemplated carefully by green electricity retailers, such as the client profile, the type of renewable offered, and the premium at which the green electricity is sold.

Green Electricity Programs Across the World

As has been shown, there are a large number of households and firms willing to pay a premium for green electricity. However, when it comes to actually signing in for green electricity programs, participation rates plummet: Market penetration rates for green electricity programs around the world are generally 1% (Bird et al., 2004). Although some programs have been more successful (up to 15% in some cases), this is much lower than the rates expected from the WTP studies. Some factors which may explain this are:

- Failure in marketing research
- Overestimation of WTP due to its hypothetical nature

- Free-riding
- Education or communication failure

It should also be kept in mind that the personal attitude toward environmental or energy policy is not necessarily the same as the perception about the personal responsibility to fulfill environmental goals. This should not be considered free-riding, but rather a view on how public goods should be provided. This may also explain the different consumer response across countries with different public-private cultures. For example, in Europe, consumers usually consider the environmental impact of electricity generation as the responsibility of the regulator and utilities (Fuchs & Arentsen, 2002).

We will now review the major green electricity experiences across the world, briefly reflecting on their major characteristics. The basic data for these are summarized in Table 1.

As may be observed, most of the programs have achieved very small penetration rates. However, it may also be noticed that some of them have achieved significant rates, such as the Netherlands, Sweden, or Switzerland. We will briefly review these cases below.

The Dutch case is the most noticeable: Here market penetration rates were very large. This can be explained by a number of reasons: first, green electricity was offered at or below conventional electricity rates, due to an exemption from the common energy tax (in fact, this exemption was the major RE support mechanism); second, green electricity was liberalized well before the rest of electricity sources, that is, the Dutch government decided that, during the first stage of the liberalization process, green electricity was the only option for those customers who wanted to switch suppliers; finally, large-hydro power imported from France was in a first stage considered as green electricity by the Dutch government, and that allowed for a large supply of RE. However, the Dutch example is not usually considered a success story: most of the green electricity was imported and already existing, and therefore the growth in RE production was almost insignificant (Reijnders, 2002). In fact, partly as a result of this lack of delivery and the realization by the Dutch government that the real bottleneck was in domestic supply, not in demand, the tax exemption and the possibility to use imported hydro power were terminated in 2005, and replaced by a feed-in tariff only for domestic sources (Van Damme & Zwart, 2003; Van Rooijen & Van Wees, 2006). This also ended with the growth in green electricity share.

Sweden also features a large penetration of green electricity (9%). In this case, the major reason is the use of existing cheap hydro power, and also the large involvement of government and public companies, which signed up to a large extent for these programs (Ek, 2005). But again, in spite of the large market share, there was not a significant growth of renewable energy, because most of it was already existing power.

Finally, we should also look at the Swiss case. Here, penetration rates have not been very large (between 0 and 4.4% depending on the program), but the interesting point is that most of it is due to photovoltaic electricity, with its associated large premiums (prices 4 to 7 times higher than ordinary electricity). This case shows the possibility of using green electricity for small niches of price-insensitive, environmentally-concerned, customers (Wüstenhagen et al., 2003).

So we see that there are large differences between the different green electricity programs. Even in countries with low market shares, there are very successful programs (in the U.S., for example, there are programs which have achieved almost 5% penetration rates). It seems then that it is not only the market environment, but also how the program is designed, that really drives its success. In the next section, we review the major aspects to be considered in order to design a successful green electricity program.

Table 1. Green electricity programs in the world

	Electricity Market					Green Electricity Market							
	Total customers (mill)	Residential customers (mill)	Total consumption (Bill.kWh)	Residential consumption (Bill kWh)	Cost (c€/ kWh)	Generation Capacity (GW)	Number of green suppliers	Green customers	Green retail customers (%)	Price premium (%)	Market share (%)	New capacity installed (aprox.)	
AUSTRALIA	8.7	7.5	205.25	46.5	12.8	37.9	20	68000	0.9	31.25	0.3	200 MW	Due to certification systems, a great amount of new capacity installed
CANADA	14.9	11.9	572.99	129.5	6	109.8	<10	6500	1	40 to 100	0.03	80 MW	Only some states offer green products
GERMANY	43.5	38.4	566.89	130.5	15.9	107.8	140	325000	0.8	4 to 50	0.2	54 MW	Lack of regulation (free access to grid). Many regional small players.
FINLAND	2.9	2.3	81.6	31	9.1	16.1	>30	8000	0.4	0 to 10	0.2	n/a	
HOLLAND	7.2	5.8	92.7	20.8	13.2	14.2	15	775000	10.8	-3 to 10	3	50 MW	Favorable fiscal system
JAPAN	71	56.8	974.4	251.8	21.2	226.4	>10	38000	0.3	30 to 40	0.003	12 MW	Limited eligibility
SWEDEN	5.2	n/a	157.6	n/a	11.2	n/a	75	n/a	n/a	0-5	10.3	n/a	Existing hydro
SWITZERLAND	3.8	3	61.97	15.1	13.1	14.6	135	48000	1.3	10(hydro) to 500 (new solar)	0.3	10 MW	Environmentally conscious retail clients
U.K.	27.3	21.8	363.17	109.6	11.7	69.9	10	45000	0.21	10 to 60	0.04	30 MW	Limited success
USA	126	101.4	3979.04	1193.4	6.64	785.9	>100	375000	1	8 to 200	0.1	650 MW

STRATEGIC DECISIONS

As mentioned before, a careful program design and marketing can increase largely its success in customer response (Swezey & Bird, 2001): Market penetration rates beyond 10% (Bird et al., 2002) or even up to 20% (Ethier, Poe, Schulze, & Clark, 2000) are achievable under favorable conditions.

In this section, we detail a number of issues which should be carefully considered by green electricity retailers when designing their products. Basically, these issues should help counteract the little knowledge existing among consumers about green electricity, and also its additional costs due to generation, administration, and certification.

Basic Design of the Program

There are basically two types of basic green-electricity program designs, contribution-based programs (also known as voluntary contribution mechanisms or VCM), and green tariff programs (GTM).

Contribution-based programs are those whereby households donate money to finance new renewable electricity capacity. Payments are independent of electricity consumption. In contrast, GTM programs link payments for green electricity with household consumption, by setting up a specific tariff per kWh. In some cases, this tariff may apply only to a fraction of the total household consumption.

Generally, it has been shown (Kotchen & Moore, 2007) that GTMs will generate lower demand levels than VCMs. But this is only if consumers are allowed to choose the fraction of demand to be supplied by green electricity. All-or-nothing GTMs (when demand is covered 100% by green electricity) can generate either lower or higher demand levels, depending on other issues. The comparison between them will depend on the green tariff: sufficiently low or high tariffs continue to favor the VCM, whereas for mid-range tariffs the all-or-nothing GTM may be preferred (Kotchen & Moore, 2007). Some surveys (Swezey & Bird, 2001) argue that contribution programs have resulted in only small amounts of new RE capacity, except for photovoltaics.

The type of program will also have an influence on the target client: VCM contribution is affected by environmental concerns, altruistic attitudes, household income, gender, and household size. However, GTM participation is not affected by household income, but essentially by the effective price of participation (Kotchen & Moore, 2007)

In addition to these basic program features, there may also be some elements which may contribute to a greater participation rate. For example, provision point mechanisms have been shown to improve participation rates. These mechanisms consist of providing a minimum threshold of participants in the program, so that the program will only be effectively started if this threshold is attained. The major effect of this mechanism is the reduction of free-riding, and so it has been shown to better reflect actual preferences, and to increase participation rates in real programs (Ethier et al., 2000; Rose, Clark, Poe, Rondeau, & Schulze, 2002). This mechanism also increases the perceived program effectiveness, which has also been shown as a driving factor for increased participation (Rowlands et al., 2003).

Other programs have also proposed money-back guarantees: if the project is not undertaken, then money will be returned to customers. This mechanism has been strongly favored in surveys, but seems not to be significant for joining into the program (Rose et al., 2002).

Finally, a last issue is the continuity of the program: Older programs tend to achieve higher levels of success, because they are able to increase their market share with time (Wiser et al., 2004). This may have to do with different issues, such as credibility, program effectiveness, or consumer awareness.

Renewable Electricity Types

Much of the green power sold has been supplied from existing sources, both in the U.S. (Bird et al., 2002) and Europe (Chappaz, 2003), in some cases even from either amortized or supported by long-term purchase contracts. This certainly allows for lower premiums, which are in principle desirable. However, it seems that consumers are eager to pay more for newly created generation, even if its total amount is not significant (Roe et al., 2001).

In addition, if we consider the amount of new RE capacity as a measure of the success of green electricity programs, then newly created generation should be a must. In some cases, this may be mandatory, as in Australia (ICON, 2004), whereas in other countries it relies entirely on the firm's decisions.

As for the type of RE source, a study by Borchers et al. (2007) found that solar energy was able to generate larger premiums from consumers than wind energy, and that biomass and biogas were the less valued energy sources for green electricity. No data have been found for large hydro or cogeneration.

The use of biomass, cogeneration, or large hydro is worth citing: Although some clients may have problems with them, because of their "impure" renewable characteristic (which can be avoided by using eco-labeling, as mentioned below), they are required if the retailer wants to provide real-time renewable energy to the customer (i.e., to follow his or her demand curve), because they are the only technologies able to regulate their production.

The case of large hydro is also relevant because of its large volume, and because it does not usually require a premium. Therefore, many utilities are considering it for their green electricity programs. However, in most countries this is a depleted technology (i.e., with no further expansion capacity), and introducing it into green electricity programs would merely displace it from some customers to others without creating additional environmental benefits (see the section on additionality). And then there is the question of the price at which this electricity should be offered: Because most of the large hydro plants are competitive, and in addition have been almost paid off, in principle the price should be low; on the other hand, hydro should be priced at the opportunity cost of the alternative electricity, which is the marginal electricity price, but that may be difficult to explain to customers.

It is obvious that the percentage of renewable included, the type of technologies used, and whether there are new plants or not will determine the final price of the product, as well as the possibility to balance generation and demand in real time. In most cases, retailers may offer different possibilities, adapting mixes to the price sensitivity and needs of the customer.

Customer Demand Coverage

At least in principle, the type of contract that leaves more purchase flexibility to the retailer, and minimizes the need of demand forecasting, is covering with renewables the aggregate of total annual consumption (or a percentage of it), because this method removes the need for real time generation-consumption balance. Therefore, the retailer can purchase cheaper electricity by avoiding buying electricity in peak hours. The only commitment would be to acquire a quantity of renewable energy equal to that consumed by the client at the end of the year, without taking into account when it was generated or acquired.

Nonetheless, there is a fundamental drawback: A well informed client could argue that there is an excessive dependency on nonrenewable generation to follow her demand in real time. The retailers that choose this option focus on the fact that the renewable generation is intrinsically very unpredictable, and that nowadays the installed capacity is insufficient to cover demand fluctuations in real time.

Coverage in real time with renewables is a more complicated option. Previous experiences in some countries confirm that this coverage would need a suitable method of forecasting demand as well as major flexibility in the mix of technologies (e.g., the use of cogeneration or biomass, which allows dispatch). The relative weight of each technology in the mix should fluctuate according to the needs, although it is possible to establish required margins of values.

The option not to cover the total consumption with a green tariff, but, for example, to cover only 20% and the 80% remaining with a normal tariff, might be translated in a significant final price reduction. This would have economic sense in case the client was more interested in enhancing its brand image than in the environmental benefit. This might be the case of the small industry and commercial sector.

Energy Purchases

Depending on the country, the green electricity retailer may choose among different alternatives when buying renewable electricity from producers. In most cases, the most interesting option will be a combination of them.

Wholesale Market

This is the more flexible but riskier alternative. It will be advantageous if the contract specifies that total green energy generated will equal total retail supply of green electricity on an annual basis. The retailer may then obtain better prices, provided it has the flexibility to choose when to buy the green electricity (avoiding peak hours).

However, not many green electricity producers sell their output on the wholesale market. The vast majority of them prefer bilateral contract agreements or alternatively, they are owned directly by the utility or retailer.

Consumers must have confidence that those products offer genuine environmental benefits. Wholesale market electricity has no way of identification, so green labels and certificates are crucial to guarantee the greenness of the electricity purchased (see below).

The main drawback of this option is the consumer perception of this scheme as excessively dependent on nonrenewable generation, and also the need to guarantee in a credible way the origin of the electricity.

Bilateral Contracts

These contracts make it easier to guarantee the green origin of the energy supplied. Nevertheless, it would be desirable for an independent third party to certify that the generation facilities comply with the necessary requirements to be considered “green.”

It is a less risky option, given that price is fixed in advance, but potential savings from buying during off-peak hours are not available. On the other hand, the reduced risk due to the long-term contract may help lower the price of this electricity.

However, given the lack of flexibility and predictability associated with renewable generation, it might be difficult to use this option to follow hourly demand if cogeneration, large hydro, or biomass is not included. Therefore, a certain trade in the wholesale market may be required.

Vertical Integration

In case the retailer does not only devote itself to green marketing, but also to generation (with any type of facilities, renewable or not) and distribution, this option would have a certain advantage when considering to acquire or to build green generation facilities, as opposed to a nonvertically integrated retailer. This initial advantage would come from the experience and the know-how in the generating business, as well as from the previous availability of the necessary means to operate the facilities. If this option is chosen, the retailer would have green energy at generating price, and it would know exactly the cost of generation. There would be no need for intermediate steps and negotiations, although risks of own capital investment must be taken into account.

Investing the profits obtained in new renewable generation to integrate vertically looks like a particularly attractive option for a green retailer, because this strategy allows putting this money at work and at the same time makes it easier to justify that clients' contribution is being used to improve the environment.

Tradable Green Certificate (TGC) Systems

There is another possibility, although only feasible in some countries: the establishment of a TGC system would allow the retailer to acquire the physical energy separately from the green certificate. The retailer should possess at the end of the year a number of TGCs equivalent to the quantity of energy consumed by clients (and to have acquired, though separately, the corresponding energy). This concept could be applied to any of the purchase options cited previously: to wholesale markets purchases (where it seems to be especially necessary), and to bilateral contracts (theoretically, it would be possible to have a bilateral contract with a nonrenewable facility, and purchase the number of equivalent certificates from another facility).

The major advantage of this system is the flexibility it provides for the retailer.

Target Clients

Different target clients may be identified, depending on the type of product to be supplied. A good analysis of the general client segments to be targeted may be found in Fuchs and Arentsen (2002).

The first customer segment to be targeted seems to be those clients more prone to pay high premiums. These are households with pro-environmental and altruistic attitudes, high income, few members, and high education levels. It has been shown that these aspects reliably predict participation in a green electricity program, according to several studies (Clark et al., 2003, Kotchen & Moore, 2007; Wiser, 2007).

Household income is important, but this depends on the type of program: For example, income does not affect participation in GTM programs, whereas for VCM programs it is the only factor influencing the amount contributed (Kotchen & Moore, 2007). Therefore, these authors propose to target households with higher income when using a VCM program, and to target households with lower electricity consumption (to lower effective prices) when using a GTM program.

Although some authors (Rowlands et al., 2003) argue that gender is not important, others (Kotchen & Moore, 2007; Wiser, 2007) have found that females tend to make larger contributions than males.

In addition to this major target group, it might also be interesting to direct efforts at the large group of "conventional" customers, because a small premium in this large group will be very significant overall. This group is usually very responsive to information, but also very sensitive to prices, although this can be modified when they are made to reflect on the low share of electricity consumption in their budget (see section on premiums).

Social and economic elites may also be interesting target groups, because of their high consumption level and their capacity to influence other groups. In addition, they are easy to target because of their small size.

Finally, private firms, governments, and institutions should also be target clients for green electricity programs. As already mentioned, they are increasingly recognizing the interest of this type of electricity for meeting their institutional goals, and can help much in the success of the program, by providing an example to residential customers, and also free advertising. In fact, nonresidential customers already represent about 25% of the total green power sold in the U.S. (Swezey & Bird, 2001).

Another important issue regarding the target client is its origin: Those more prone to enter into these programs are those already buying electricity from the same utility. In fact, most green electricity clients have purchased it without switching suppliers. This is easy to explain, because, given the very low switching rates experienced in most liberalized markets, requiring the customer to switch supplier will certainly decrease her participation rate in a green electricity program.

It has to be reminded that consumers are used to receiving their electricity from monopolies, with no room or need for making choices. Many find supplier choice, and the related information analysis demand, too encumbering, and prefer to stay with the original supplier (Salmela & Varho, 2006).

Premiums

In this point, evidence looks contradictory: Whereas some studies point to the significant influence of price in customer response (Bird et al., 2002), others (Swezey & Bird, 2001; Wiser et al., 2004) argue that there is no definitive relationship between the amount of the premium and participation rates. This may also be observed by looking at the Swiss case described in the section analyzing green electricity programs across the world, where a market share similar to other countries was achieved in spite of much higher premiums. Indeed, electricity purchases represent a very small percentage of household budgets, so one should not expect a large elasticity of demand here.

However, the success of green products when offered at prices below or similar to conventional electricity cannot be denied. All in all, it seems that premiums should range from 0 to 30%. A premium of more than 30% has been considered as too high in some surveys (Truffer et al., 2001; Salmela & Varho, 2006), although again the Swiss case shows that some customers are ready to pay much more.

Here the intelligent approach seems to rely on market segmentation: If a firm only offers a single program, it could be neglecting segments of customers willing to pay more. To this extent, posted prices seem not to be desirable, because they do not allow households to select the amount which better represents their preferences. A range of products with different prices helps meet the varying WTP.

An additional, but important concern expressed by consumers regarding premiums is that they should not be dominated by administrative and marketing costs (Swezey & Bird, 2001).

Finally, it should also be considered the possibility of offering green electricity at no premium, with the utility bearing the additional costs. This might be considered as a tool for retaining customers or as a way to improve its environmental profile.

Value Creation

Green electricity is not only about pricing, it is also about providing customers with values or private benefits which will drive them to pay more for it. These values may be monetary or not. Monetary ones may be tax deductibility or protection from fuel price increases. Nonmonetary ones include personal recognition, civic pride, promoting sustainability, or educational benefits. The important thing is to make these values visible to customers.

A critical issue then is to know which are the values more prized by green electricity program participants. The major reasons cited by Kotchen et al. (2001) in their study of a program in Michigan were: health of natural ecosystems, local pollution benefits, then personal health, global warming, and finally, warm glow. Altruism toward the environment is more important than toward regional residents or health-based egoism. Local environment is also more important to them than global environment.

Therefore, marketing campaigns should highlight the positive environmental impact of buying green electricity. And these benefits should be made as personal as possible, appealing to personal health rather than to a general improvement in the environment (Rowlands et al., 2003).

The most common methods of providing non-monetary values are program updates in periodic newsletters and window decals. In addition, programs may recognize businesses through program advertisements in media, or provide customers with plaques or other recognitions (Bird et al., 2004). A large visibility of the RE projects promoted by green electricity programs is also useful for creating value (Swezey & Bird, 2001).

Being precise about objectives may also increase the value creation of the program, by providing enhanced visibility of its benefits. According to Rowlands et al. (2003), several utilities have found that programs focusing on a well-defined RE project tend to be more successful in attracting customers than those promoting RE in general.

Information to Customers

Lack of knowledge of green electricity is widespread, and this may explain to a large extent the low participation rates. In fact, consumers are frequently uninformed even of their own electricity consumption and of the related costs and environmental impacts (Fuchs & Arentsen, 2002). This is not surprising in liberalized markets, given the multiplicity of products and technologies. Therefore, any effort to increase consumer awareness will certainly improve these rates.

For example, participation rates in a New York state program were 20%, when sufficient information was provided (Ethier et al., 2000). As another example, 15% of the Australian customers provided with the right information did sign up (ICON, 2004).

An important issue is that the information provided has to be credible, and true. The information provided might be misleading when, even being true, it is not complete or sufficient, so that the advertising might be deceitful not only for what it says, but also for what it does not. Misinforming the customer may backlash against the program, as shown in some experiences (CNE, 2004).

A very interesting way of raising awareness while enhancing credibility is by teaming with environmental or community organizations in order to reinforce messages.

As for the vehicle to provide this information, most utilities perceive telemarketing as the most useful way (Bird et al., 2004). However, most of them use cheaper, but less efficient ones, such as bill inserts and media advertisements. An important point is to keep it as simple as possible, not to overburden customers with excessive information which may deter them from analyzing it.

Credibility

In order to buy green electricity, consumers must have confidence in that the product offered features genuine environmental benefits, and value for money. This requires usually a certification or legitimating process.

Sometimes utilities may not be viewed as legitimate providers of environmental benefits, and therefore the credibility of the program may be greatly enhanced by engaging in partnerships with environmental organizations. Also, green electricity purchases by government or public firms may contribute to improve credibility, as well as to the overall success of the program. These same partnerships may also provide an additional benefit, free advertising.

In the U.S., Wiser (2007) found that private providers were able to elicit higher WTP than public ones because of their higher credibility. However, this may probably vary depending on the country, and in Europe the contrary might be expected.

Legitimacy may also be provided by eco-labeling, which can reduce the transaction costs associated to credibility issues (Truffer et al., 2001). The recognition of the eco-label will be enhanced if it is accepted as a standard not only by consumers but also by competitors, so a broadly accepted label should be sought after by green electricity programs. There are several labels applicable to renewable electricity, such as the Eugene label developed by the European Commission, which not only certify the renewable origin of electricity but also ask for additional environmental benefits, which is certainly relevant for RE sources such as hydro.

Relationship with Other RE Support Schemes

The existence of other support mechanisms for renewable electricity may have either positive or negative impacts on green electricity. For example, some authors (e.g., Markard & Truffer, 2006) argue that the existence of feed-in tariffs in Germany or Spain may be an explanation for the almost negligible role of green electricity in these markets. On the other hand, Menger (2003) argues that the amount that customers are willing to pay to prevent environmental damage is independent of the amount of damage prevented, and therefore, that there is a potential for voluntary demand in addition to mandatory support schemes.

What everybody agrees on (e.g., Menger, 2003) is that all green electricity programs should be additional: The funds collected from these programs should be clearly earmarked for new RE investments, additional to those which would have taken place anyway under the other RE support mechanisms.

This does not necessarily mean that green electricity and other RE support schemes should be incompatible. In fact, some argue (e.g., Swezey & Bird, 2001) that other support schemes should be sought by retailers in order to lower the premiums. The key point here is that this is done only to effectively lower the premium and not to increase artificially the profits of the retailer (e.g., by charging a premium for electricity which is already competitive and therefore does not need the premium to operate).

Although those plants which are economical under other support schemes might be sold without a premium, they would not comply with the requirement of being additional, because they would have been installed anyway. One possibility might be for these plants to decline to participate in the mandatory support scheme, and try to get the premium instead. That would certainly comply then with the additionality criterion. However, this should be handled with care, because such a combination of support mechanisms creates confusion among consumers, and burdens the administration of the system (Dinica & Arentsen, 2002).

Therefore, only those RE plants uneconomical under other RE support schemes, or those which decline to enter into them, should be allowed to be included in green electricity programs (e.g., by only certifying as renewable energy this type of plants). The premium in both cases should be carefully monitored so that it reflects the additional cost of the technology (plus the administrative and certification expenses required) and not undue profits for the retailer. Some countries (e.g., Spain) have already regulated these aspects for green electricity retailers, by requiring separate accounts and a specific use of premiums.

Another way of thinking of additionality is to use the premium to reduce the environmental impact of existing RE plants beyond the current regulations (e.g., helping windmills integrate in the landscape, providing additional fish stairs for small hydro). However, it is arguable whether consumers will respond equally favorably to this additionality concept, because they might argue that these measures should have been taken anyway.

SUMMARY AND CONCLUSION

Based on our review, we can conclude that there seems to be a considerable gap between being environmentally conscious and acting upon these convictions, which has hindered the success of past green electricity schemes, together with some strategic errors on the part of retailers.

Therefore, major improvements on retailing strategies are still required in order to achieve a larger penetration of green electricity, both by maximizing customer participation and also new RE development. As mentioned before, rates up to 20% may be achieved for selected market segments, when all recommendations are met. Below we summarize our major recommendations:

- Green tariff programs (GCM) are more effective, at the usual tariff levels, in providing new RE development, so they should be generally chosen to contribution-based ones (VCM).
- A provision point mechanism reduces free-riding, and can therefore increase participation rates.
- Persistence pays: Long-term programs see steady increases in customers.
- Whereas solar and wind seem to attract higher participation and premiums, they are not able to provide real-time coverage of demand. If this is the goal, biomass and cogeneration should be included. Hydro presents several problems which should be addressed carefully.
- Premiums should range between 0% and 30%. Variable premiums (based on different products) help account for the differences in WTP among clients.
- Bilateral contracts help lower costs, by reducing risks, and increase the credibility of the green origin of the electricity.
- It appears that the greater success will be obtained by targeting young-age, highly-educated households with greater concerns for the environment or stronger altruistic values.
- Teaming up with environmental and charitable NGOs may prove really useful, because that will also provide greater credibility for the program, help provide information and raise awareness, and may even provide free advertising.
- Relying on the existing utility client base enhances participation, by eliminating the switching barrier problem.
- The retailer must be able to define clearly, simply, and visibly the environmental advantages of the product, to offer something tangible that has added value and to provide arguments supporting the legitimacy of its right to receive a premium. Focusing on specific RE projects increase visibility and credibility. A local focus seems also to be more effective than broadly-based programs.
- Complete information on the characteristics and advantages of the program must be provided in a simple and effective way (e.g., via telemarketing) to consumers.

Of course, most of our conclusions are general, and therefore specific analysis should be carried out for different market conditions, because, as mentioned along this chapter, both cultural differences, energy policy, and electricity market design may influence to a large extent the issues to be considered (e.g., an analysis for the Spanish electricity market may be found in Pérez-Plaza, 2004). However, we consider them to be a necessary first step if successful green electricity programs are to be devised, and an analysis which had not been undertaken before.

FUTURE RESEARCH DIRECTIONS

There are several areas in which future research may improve significantly our knowledge of this issue, and therefore the effectiveness of green electricity programs.

First of all, an extension of the market surveys and WTP studies to other countries where green electricity programs might be implemented would be a very welcome future line of research. Most WTP studies have been carried out in the U.S., UK and northern Europe. However, many other countries show good potential for these programs, and estimations of WTP values would be the first input for the definition of marketing strategies in these countries.

Second, there is no data on the willingness to pay of firms and institutions for green electricity, in spite of the seemingly larger interest that this type of consumers may have on these programs. An extension of WTP studies to firms or institutions would therefore be very interesting.

Finally, it should be pointed out that most of the work done on the analysis of green electricity programs has been carried out from the energy policy or environmental economics fields, whereas it is clearly an issue to be studied within the marketing community, which have specific tools and methods to address this issue. Again, this research might prove critical for the success of green electricity programs.

ACKNOWLEDGMENT

Chapter 8.12

Information Technology Service Management and Opportunities for Information Systems Curricula

Sue Conger
University of Dallas, USA

ABSTRACT

Historically, information systems (IS) programs have taught two of the three areas of information technology (IT) management: strategy and management, and applications development. Academic programs have ignored the third area, IT operations. IT operations management is becoming increasingly important as it is recognized as consuming as much as 90% of the IT budget and as acquisition of software becomes more prevalent than development of custom applications. Along with the shift of management focus to IT operations, standards such as the IT infrastructure library (ITIL) have been adopted by businesses to guide the development of processes for IT operations that facilitate evolution to IT service management. This shift to servitizing IT management, creates an opportunity for IS programs to align with business practices by innovating in the teaching of IT service management. Several methods of incorporating ITSM material into educational programs are explored. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

With increasing frequency, disruptive technology-related innovations cause a paradigm shift in IT practice and management. In the 1950s and 1960s, methodologies codified best practices in application development for analyzing and computerizing complex processes (De Marco, 1979; Yourdon, 1988). Subsequent generations of methodologies evolved to include data orientation, then object orientation, and most recently, event orientation. Relational database technology, introduced by Codd and Date, similarly disrupted data management in the 1970s (Codd, 1970; Date, 1999). The development of personal computers disrupted both industry and academia in the 1980s. Object orientation changed methods of teaching application development and programming in the 1990s (Jacobson et al., 1998). The Internet changed business conduct beginning with its privatization in 1993 but accelerating with technology maturity in the late 1990s and early 2000s. This decade is witnessing two disruptions relating to the servitizing of IT organizations, one technical in the form of service-oriented architecture (SOA) (Durvasula et al., 2008), and one process and management oriented in the form of IT Service Management (ITSM) (itSMF, 2007).

This article addresses the changes in the conduct of IT in business and the related need for academic programs to address those changes. Alternative approaches for developing academic programs are presented and discussed.

THE CONDUCT OF IT IN BUSINESS

In the last century, Information Technology (IT) and the Chief Information Office (CIO) often were separated from the business strategy-development team. Business strategy was developed and possibly discussed with the CIO, who developed an IT strategy, to the extent possible, that fit the business strategy. Enlightened organizations might allow the CIO to sit in the meetings so the later discussion was circumvented. Enlightened organizations might also conduct their critical decision making to prioritize and select projects for development or acquisition through an IT steering committee comprised of the CIO plus other executives who represented critical stakeholders to the decision process (cf. King, 1985). The outcome of a successful matching exercise should align the business and the IT strategy.

IT in Business: The Academic View

More recently, the need for more seamless integration of business and IT strategies has been described (Weill & Ross, 2004). Under the newer scheme, IT moves away from responding to single requests in a never-ending queue toward architecture-driven IT decisions that ensure improved organizational support and, eventually, improved organizational response to changing environmental conditions (Ross et al., 2006; Broadbent & Kitzis, 2005; Ross et al., 2006). Under these more recent schemes, the responsibility for alignment is shared between the C-level executives and the CIO, with successful organizations being those that most closely align IT with business strategy. However, alignment activities apply to matching applications to strategy and does not extend to operations, help desk, or other types of services.

One key issue in these writings and others like them is that the prescriptions give little guidance on how to actually conduct business within the IT department that mirrors and fulfills the alignment objectives decided. Frameworks, such as the IT Infrastructure Library (ITIL), Control Objectives for Information and related Technology (CobiT) or the Capability Maturity Model - Integrated (CMMI) might be alluded to with an implicit assumption that their application will provide the needed IT discipline for IT organizations to act as desired (SEI, 2006; ITGI, 2007; OGC, 2008).

These ways of thinking, rather than avoiding the issues of IT management, either assume that the important actions take place in the decision process or that day to day operation of the IT organization is not relevant to discussions of strategy. Further, books and academic programs that *do* address daily functioning of IT focus on applications development, such as object orientation, or technology, such as telecommunications with little regard to how they are configured and managed in a production environment.

IT in Business: Business Practice

Business organizations, whether public, private, profit, or non-profit, have realized that undisciplined, non-repeatable work can undermine the best governance architecture. To develop a process discipline along with a culture of service, organizations of all types are rapidly servitizing the IT organization and its offerings. Adoption of the IT Infrastructure Library (ITIL) has spread to about 70% of non-US organizations and about 60% of US organizations (Dubie, 2008). In the U.S., 87% of companies with more than 10,000 employees have adopted ITIL (All, 2008). ITIL is chosen over or in concert with Cobit, CMMI, and Six Sigma because as Evelyn Huber of Forrester Research says, “there is nothing else” (Anthes, 2008, pg 2.)

The adoption of service management tenets is idiosyncratic to each organization with significant contextualization of each adopted process and function (Conger & Schultze, 2008). In addition to the high global adoption rate for ITSM tenets and ITIL, in particular, the adopting companies generate a significant number of new jobs requiring service management and process understanding. One U.S. study of itSMF-USA (a practitioner organization) member companies found that about 15,000 jobs requiring ITIL knowledge and skills are created annually (Conger et al., 2008).

The combination of adoption rate and job growth has not gone completely unnoticed with about 15 programs in Australia, Europe, Africa, Mexico, and New Zealand (Cater-Steel & Toleman, 2007). By contrast there are two undergraduate and one graduate ITSM program in the U.S. These adopting universities are bucking established programs and courses to bridge the gap between business and academia. However, the gap is firmly institutionalized in academic program guidelines that hinder broad adoption. The divide between business practice and academic practice is an important one for it permeates IT education. The nature of the divide is explored in the next section.

IT IN EDUCATION

The Model Curriculum guidelines for undergraduate IS/IT education in the U.S. exemplify the business-IS/IT curriculum divide. U.S. curriculum is developed by the Joint Task Force on Computing Curricula, comprised of mostly academics through the Association for Computing Machinery (ACM), Association for Information Systems (AIS), and Institute for Electrical and Electronics Engineers (IEEE). While the 2005, currently official, version is discussed here, an update for 2008 was let for review recently. This discussion applies equally to the 2008 update which only uses the term ‘service’ in terms of student *service* projects, not mentioning IT management, IT operations, process, or service in any pedagogical discussion (The Joint Task Force, 2008).

The computing curriculum guidelines are summarized with weights applied to knowledge areas as shown in Table 1. Degree types and abbreviations include Computer Engineering (CE), Computer Science (CS), Information Systems (IS), Information Technology (IT), and Software Engineering (SE). The numbers ranges from zero to five and represent the relative emphasis at which program coverage is recommended (The Joint Task Force, 2005). Figure 1 shows the “organization” emphasis for information systems. These figures imply that there should be a preponderance of organizational information in IS programs. In fact, the Joint Task Force report says:

“The meaningful question is: ‘Has an IS program broadened its scope to include an integrated view of the enterprise with complex information needs and high-level dependency on IT-enabled business processes?’ ... IS students must learn how to assess and evaluate organizational information

Table 1. Comparative weights of program components

needs, specify information requirements, and design practical systems to satisfy these requirements" (ACM/AIS/IEEE The Joint Task Force on Computing Curricula, 2005, p. 32).

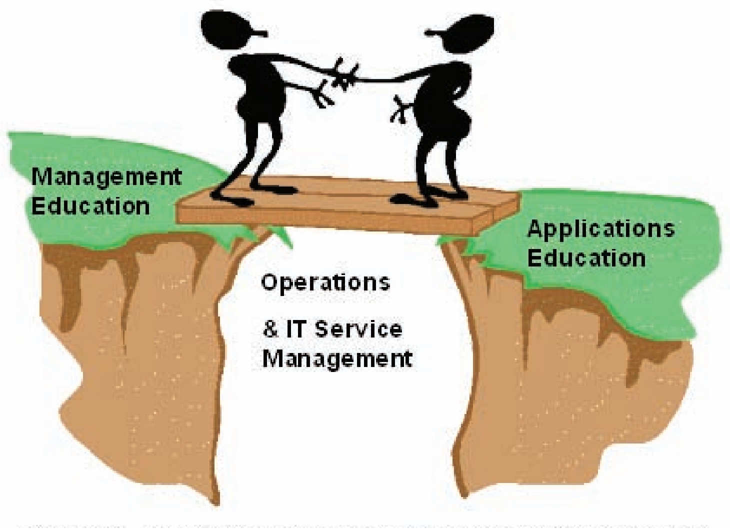
The lower half of Table 1 lists 'business' knowledge to be included in undergraduate curricula, including organization models, theory, structures, and functions along with system concepts and theories, skills in benchmarking, value chain analysis, quality concepts, valuation concepts, and evaluation of investment performance (ACM/AIS/AITP Joint Task Force on Computing Curricula, 2002, p. 14; The Joint Task Force, 2005). For graduate students, recommended 'business' knowledge includes financial accounting, organizational behavior, and marketing (ACM/IEEE The Joint Task Force on Computing Curricula, 2000, p. 18) in courses with no ties to or even discussion of information technology or its relationship to the topic area. That is, the emphasis, even in programs with a focus on organizational issues does not actually attend to the daily operation of an IT organization.

Neither undergraduates nor graduates in IS programs are required to learn basic information such as how to define, recognize, or analyze a process, let alone how to determine whether or not a process can be improved through automation. Process modeling is confined to creation of data flow diagrams, not process maps that include non-automated activities. Further, the specific management processes applied to the management of IS/IT organizations are missing.

There is nothing in IS/IT curricula about IT Operations or how this function delivers IT resources to organizational customers. This gap is depicted in Figure 2 in which the three key aspects of IT academic program gaps are depicted. On the one hand, IT management, discussing topics recommended in the curriculum guidelines, describes business functions (e.g., Marketing), information levels, and how information is used in organizations. From a service perspective, this discussion is lacking in discussion of the non-functional requirements that must come from business users, for instance, criticality of an application to the organization, and requirements for security, privacy, and recoverability. On the other side of the divide is the application development function for which academic programs discuss programming, requirements modeling, and use case development.

In the gap are Operations, which manages the organization's IT infrastructure and IT Service

Figure 2. IT in education with operations and ITSM as the missing links



Management, the discipline that provides process maturity to the entire IT organization. Scant infrastructure organization knowledge or its tasks are recommended in any programs (see Table 1). Further, what infrastructure topics are discussed tend to be 'silo' technology topics such as telecommunications or operating systems. There is no discussion of how the product an applications group delivers actually is placed into production or how it is managed in a production environment. There is no discussion of how to size an application, let alone capacity modeling or planning for a data center. There is no discussion of any of the processes involved in running a data center such as availability management, finance management, incident management, change management, continuity management, and so on. These areas of knowledge are the focus for IT Service Management, the emerging, disruptive IT-related set of management best practices that promises to bridge the gaps between applications and management. ITSM is the first step to servitizing an IT organization and thus, facilitating alignment of IT with its related business strategy.

IT SERVICE MANAGEMENT EDUCATION OPPORTUNITIES

Since infrastructure represents a significant gap in all computing education programs, and since management of IT is articulated within the IS academic discipline, IS curricula are the most likely place for ITSM programs. In this section, ITSM is briefly explained and linked to IT strategy. Then, three options for incorporating ITSM concepts into IS curricula are described.

IT Service Management

IT Service Management is generally used to refer to the management of processes within IT Operations so that, through efficient and effective execution of the processes, value accrues to the organization. Thus, companies can create value through application of best practices to IT Operations (Nieves & Iqbal, 2007). IT operations are critical to organizational effectiveness since as much as 90% of IT budgets is used to manage operations (Fleming, 2005).

The term "service" has no single definition and ranges from a change in condition or state of an entity caused by another to a set of deeds, processes, and resulting performances (Zeithaml & Bitner, 1996). From the ITIL perspective, a service is "a means of delivering value to customers by facilitating outcomes customers want to achieve without the ownership of specific costs and risks" (TSO, 2007, p. 45).

IT service management begins with business strategy, which when new or changed, causes reflection on the existing IT service offerings in the form of applications, computing resources and user services. The heart of service management is a series of processes and functions (e.g., service/help desk) where a "process is the set of activities (repeated steps or tasks) that accomplishes some business function" (Conger & Schultze, 2008, pg. 4). Thus, students of ITSM need to understand how business strategy is reciprocally created with IT strategy, and how the development of strategy can cause changes in any IT resources – human, financial, or capital (e.g., hardware), and how the changes are embodied in processes that ensure repeatability and quality.

The processes in ITIL relate to keeping an operations organization functional. The main ITIL processes relate to management of incidents, problems, changes, releases, configuration, availability, capacity planning, financial planning, continuity, and service levels. While the processes apply to any size organization, the benefits of scale are best attained in global organizations, such as Unilever or Proctor and Gamble. One important body of knowledge relates to the scaling of process management from small to large organizations.

ITIL tends to be implemented in the infrastructure organization first. However, many ITIL processes, for instance, incident and change management, though initiated within operations, are actually remedied or executed within another organization usually within IT, such as applications maintenance. Thus, service management processes have tendrils that permeate other organizational processes and coordination of activities throughout an organization is needed to ensure successful and encompassing ITIL implementation. This integration of operations with all other IT organizational activities includes a need for operational process understanding for applications, database, security, and all technology areas.

While ITIL is the only best practice framework that principally addresses IT Operations, there are many valuable alternatives to ITIL that a company might adopt. For instance, the Control Objectives for Information and Technology (CobiT©), the framework most closely related to financial reporting compliance (e.g., Sarbanes-Oxley in the U.S.), was initiated in the auditing world but has crossed over to management of the IT organization (ITGI, 2007). Another often-used framework is the Capability Maturity Model – Integrated (CMMI©), which was originally developed to support application development management has crossed over to use by operations organizations for such areas as project management (SEI, 2006).

Similarly, there are customized versions of ITIL by Microsoft – the Microsoft Operations Framework (MOF©), Hewlett-Packard, IBM, and others. These frameworks adopt ITIL as their base and build on them by customizing for a suite of support software that imbeds the process within the operational framework of software for help desk, network monitoring and the like.

For all of these frameworks, and for service management in general, the goal is creation of value to the organization through its IT operations function. A secondary goal and outcome of successful service management implementation is alignment with the strategy of the business since strategy is the starting point for the development of all service offerings.

Curricular Alternatives Incorporating IT Service Management

The three alternatives for incorporating ITSM into IS academic programs include the following:

- Part of an existing course(s)
- A single course
- A concentration or major set of courses (Beachboard et al., 2007).

Each of these alternatives is briefly discussed.

ITSM as Part of Existing Course(s)

If ITSM were incorporated into a single existing course, one likely course would be an IS Foundations course because it serves the broadest audience. A module on ITSM could discuss concepts of process and service, providing definitions and examples of each. In addition, a brief overview of IT Operations and its criticality to organizational functioning could be provided. Finally, a high level discussion defining various operational processes, such as capacity management, and describing their relationship to other operational processes could be included.

Other existing courses into which ITSM concepts could be interjected include any applications development, database, or telecommunications courses. For instance, during systems analysis and design (SAD), risk analysis and related security mitigations should be discussed. Also in an SAD class, the need for early capacity planning to ensure adequacy of testing and production facilities for hardware, data storage, and telecommunications could be included. A partial list of non-functional requirements and the need for their articulation and sharing with IT Operations would include, for example, transaction volumes and peaks, number of users and locations, security and privacy, compliance requirements, data integrity, organizational criticality, recoverability, help desk, and access requirements (Conger, 2008). Also in SAD, change management, both for users in terms of using a new application and for the developers in terms of moving the application from testing into a production environment and the work that such a move entails could be included.

Single Course in ITSM

A single course could address Fundamentals of ITSM. This course could discuss alignment of business strategy and IT strategy with the need for demand management driving the creation and presentation of services to the organization. If ITIL were the basis for the course, the five main areas of the framework, relating to strategy, planning, transition, operations, and continuous improvement could be structured into one to three sessions each with case studies and practical exercises for students to apply the concepts.

Concentration or Major in ITSM

A concentration in ITSM requires decisions on content and purpose of the major. If the goal of the program is to obtain the highest possible certifications for students, then alignment with ISO/IEC 20000 would allow students to obtain master's level certification (EXIN, 2008). The ITIL v3 certification scheme now requires over 10 courses and takes more than five years to obtain and is thus beyond the scope of most academic programs (Taylor, 2007). Under the EXIN scheme, the courses relate to ITIL version 2 (the basis for the international standard ISO/IEC 20000) and include Foundations of Service Management, Advanced Services Support and Advanced Service Delivery. One or two other courses could be electives, for instance, Systems Analysis and Design, Process Management, and/or Managing the IT Function.

One issue with a program based on the ITIL framework is that ITIL, per se, does not guarantee 'service management' (Conger & Schultze, 2008). Ultimately, servitizing requires proactive demand management. As in manufacturing operations, IT demand management is used to plan and deploy resources (i.e., applications, computing resources and user services). Once deployed, demand management concentrates on delivering a product that meets a contracted level of service. Under this more 'service management' approach, courses might include some combination of Foundations of Service Management, IT Service Management, Process and Service Design, Service Delivery, Demand Management, and IT Governance.

CONCLUSION

This article argues that IS academic programs are incomplete because of the absence of any content dealing with servitizing the IT function. This absence has caused a widening gap between business conduct and IT academic programs. Servitization includes not only the management of IT Operations but also courses on the processes required to actually manage an IT function. IT Service Management, in the form of ITIL, has become a significant activity in many organizations, and its body of knowledge directly addresses both the gap between IT academic programs and business practice and provides the 'how' to aligning business strategy with IT service delivery. Therefore, ITSM provides an opportunity to move toward explaining *how* to align IT with business strategy, provide students with an understanding of process and service orientations, and move toward developing courseware that comprehends the servitizing of IT.

ABSTRACT

Environmental issues are rapidly emerging as one of the most important topics in strategic manufacturing decisions. Perusal of the literature has shown many models to support executives in the assessment of a company's environmental performance. Unfortunately, none of these identifies operating guidelines on how the systems should be adapted to support the deployment of different types of green supply-chain strategies. This chapter seeks to investigate how system dynamics modeling can be supportive for management of feasible green supply-chain strategies. Besides conceptual considerations, we base our arguments on the development of efficient performance measurement systems for remanufacturing facilities in reverse supply chains, taking into account not only economic but also environmental issues. The behavior of the green supply-chain management under study is analyzed through a simulation model based on the principles of the system dynamics methodology. The simulation model can be helpful for green strategic management as an experimental tool, which can be used to evaluate alternative long-term strategies ("what-if" analysis) using total supply chain profit as measure of strategy effectiveness. Validation and numerical

experimentation further illustrate the applicability of the developed methodology, while providing additional intuitively sound insights.

INTRODUCTION

Environmental issues are rapidly emerging as one of the most important topics for strategic manufacturing decisions. The scarcity of natural resources and the growing concern in the market for "green" issues have forced executives to manage operations within an environmental perspective (Dimitrios Vlachos, Georgiadis, & Iakovou, 2007). Growing public awareness and increasing government interest in the environment have induced many Chinese manufacturing enterprises to adopt programs aimed at improving the environmental performance of their operations (Vincent, 2006; Zhu & Sarkis, 2004).

In the light of the strategic importance of environmental issues and of their effects on the corporate management system, a growing body of literature is focused on how companies should manage environmental issues. Two major lines of research are evident:

- Studies which analyze feasible green supply-chain strategies available to operations managers and describe how growing environmental concern impacts on the process of strategy formation; and
- General approaches aimed at supporting managers in the assessment of a company's environmental performance, such as life-cycle assessment methods, or models reporting physical indicators, environmental costs, contingent liabilities, and so forth.

Despite the availability of the various approaches to develop performance measurement systems (PMSs) in respect of distinct green supply-chain strategies, none of them attempted to quantify the effects of various environmentally friendly activities pursued by the manufacturing function. Such a shortcoming is, in our opinion, critical, since environmental behavior results from specific environment-related objectives and has its own managerial and financial implications on the corporate system.

In response to the issues identified in the above paragraphs this chapter presents a quantitative framework to:

- Define the basic green supply-chain strategies a company can implement and identify factors affecting environmental performance and their relationships for operations management
- Structure environmental performance measures hierarchically
  Quantify the effectiveness of a planned environmental strategy on environmental performance
- "What if" analysis on environmental performance and green supply-chain strategy selection

By bringing together existing contributions on strategic environmental management and performance measurement systems, the chapter aims to develop quantitative models for environmental performance measurement systems (QMEPMS) using supermatrix, cause and effect diagrams, tree diagrams, and the analytical network process. It describes how different green supply-chain strategies can be deployed and presents the technique that can be used to identify factors affecting environmental performance and their relationships, structure them hierarchically, quantify the effect of the factors on environmental performance, and express them quantitatively.

The chapter is divided into six major sections. First, we give a taxonomy of green supply-chain management (GSCM) and highlight the problem existing in a company's strategic management, describe research objectives and methodology to quantify the effect of the factors on an EPMS, and specify a quantitative model on how to structure critical factors hierarchically to support managers in the implementation for an EPMS. Then, we analyse how the suggested QMEPMS can be implemented in practice. Finally, we draw some conclusions from the suggested approach and indicate future directions for further environment-related research.

LITERATURE REVIEW

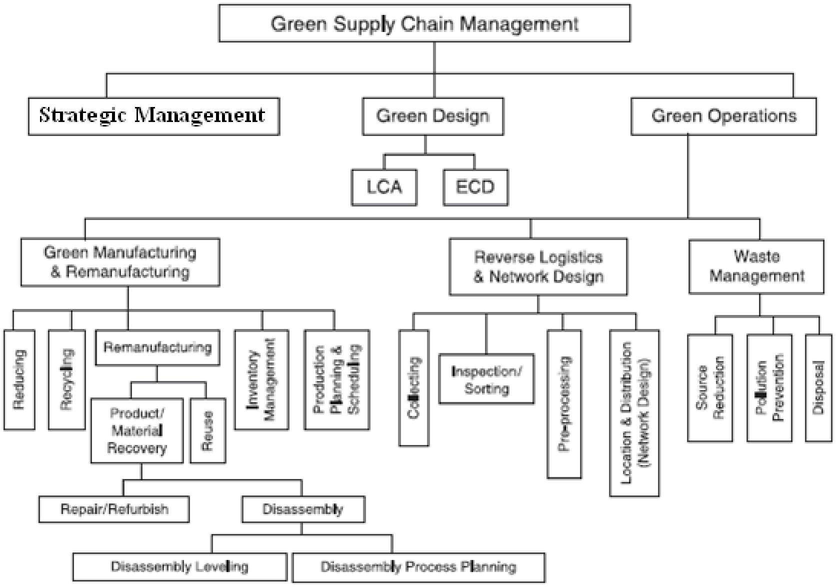
Sufficient literature exists about various aspects and facets of GSCM. Comprehensive reviews on green design (Zhang, Kuo, Lu, & Huang, 1997), repairable inventory (Guide, Jayaraman, & Srivastava, 1997, 1999), production planning and control for remanufacturing (Bras & McIntosh, 1999; Guide, 1997; Guide, Jr., 2000; Guide, Spencer, & Srivastava, 1997), issues in green manufacturing and product recovery (Guide, Spencer, & Srivastava, 1996; Gungor & Gupta, 1999), reverse logistics (RL) (Carter & Ellram, 1998; Fleischmann et al., 1997), logistics network design (Fleischmann, Beullens, Bloemhof-Ruwaard, & van Wassenhove, 2001; Fleischmann, Krikke, Dekker, & Flapper, 2000; Jayaraman, Patterson, & Rolland, 2003), and green product databases (Nimse, Vijayan, Kumar, & Varadarajan, 2007)have been published.

Earlier works and reviews have a limited focus and narrow perspective. They do not cover adequately all the aspects and facets of GSCM. Much of the work is empirical and does not focus adequately on strategic management, mathematical modeling, and network design-related issues and practices. The objective of this section is to present a comprehensive integrated view of the published literature on all the aspects and facets of GSCM, taking a "reverse logistics angle" so as to facilitate further study, practice, and research. To meet this objective, we define GSCM as "integrating environmental thinking into supply-chain management, including product design, material sourcing and selection, manufacturing processes, delivery of the final product to the consumers as well as end-of-life management of the product after its useful life." We specifically focus on strategic management, reverse logistics (RL) and mathematical modeling aspects in order to facilitate further study and research. Qualitative analysis was applied to classify the existing literature on the basis of problem context and the methodology/approach adopted. We also map the tools/techniques vis-à-vis the problem context classification.

Classification Based on Problem Context

We classify the existing GSCM literature into three broad categories based on the problem context in supply chain design: literature highlighting the strategic management; literature on green design; and literature on green operations, as shown in Figure 1, which was adapted from Srivastava (2007). Green design may be looked into from the viewpoint of environment conscious design taking lifecycle assessment of the product/process into account. Similarly, green operations involve all operational aspects related to RL and network design (collection; inspection/sorting; preprocessing; network design), green manufacturing and remanufacturing (reduce; recycle; production planning and scheduling; inventory management; remanufacturing: re-use, product and material recovery), and waste management(source reduction; pollution prevention; disposal).We purposely do not consider literature and practices related to green logistics, as we feel that the issues are more operational than strategic in nature and may not be significant in the supply chain design per se. We also do not focus in detail on empirical studies on GSCM and literature on green purchasing,

Figure 1. Classification based on problem context in supply chain design



industrial ecology and industrial ecosystems, as it is delimited by our research design. We focus more on RL as the establishment of efficient and effective RL networks as a prerequisite for efficient and profitable recycling and remanufacturing. We also focus more on mathematical modeling aspects. Both of these have received less attention in the GSCM literature so far.

The classification is for the purpose of easier understanding of different problem contexts of GSCM—their interactions and relationships—in order to present a well defined and clear picture for further study and research. It is not rigid, and there may be many overlaps (e.g., reduce gets attention not only in green manufacturing and remanufacturing, but also elsewhere as in reverse logistics and waste management; green design, too, emphasizes reduced use of virgin material and other resources). Similarly, green design should take into account the whole product life-cycle cost, including those during manufacturing and remanufacturing, reverse logistics, and disposal. Figure 1 does not take account of all these complex relationships and interactions but presents a simplistic view. Further, we do not show some other relevant aspects and areas such as green purchasing, industrial ecology, and industrial ecosystems, as they are delimited by our research design.

Strategic Management

As in any emerging research area, the early literature focuses on the necessity and strategic management, defines the meaning and scope of various terms and suggests approaches to explore the area further. Fundamentals of greening as a competitive initiative are explained by Porter and van der Linde. Their basic reasoning is that investments in greening can be resource saving, waste eliminating, and productivity improving (Porter & van der Linde, 1995a, 1995b). Three approaches in GSCM, namely reactive, proactive, and value-seeking, are suggested (Hoek, 1999). In the reactive approach, companies commit minimal resources to environmental management, start labeling products that are recyclable and use “end of pipeline” initiatives to lower the environmental impact of production. In the proactive approach, they start to preempt new environmental laws by realizing a modest resource commitment to initiate the recycling of products and designing green products. In the value-seeking approach, companies integrate environmental activities such as green purchasing and ISO implementation as strategic initiatives into their business strategy.

The perspective then changes from greening as a burden to greening as a potential source of competitive advantage (Hoek, 1999). Owen (1993) discusses environmentally conscious manufacturing. Friedman (1992), Guide, Jr., and Van Wassenhove (2002), and Gupta and Sharma (1996) discuss the changing role of the environmental manager. Interactions among various stakeholders on integrated GSCM and advantages that may accrue to them have been described by Gungor and Gupta (1999). At the end of the 1990s, integrating these issues into the mainstream was identified as the future research agenda (Angell & Klassen, 1999). In a study linking GSCM elements and performance measurement, Beamon (1999) advocates for the establishment and implementation of new performance measurement systems. He suggests that the traditional performance measurement structure of the supply chain must be extended to include mechanisms for product recovery (RL) (Beamon, 1999).

During the present decade, related and emergent issues such as consideration of stages of the product life cycle during material selection (Kaiser, Eagan, & Shaner, 2001), impact of green purchasing on a firm’s supplier selection (Zhu, Geng, & Spring, 2002), waste management (Theyel, 2001), packaging and regulatory compliance (Min & Galle, 2001), greener manufacturing and operations (Sarkis, 2001), study of the environmental management system (EMS) implementation practices (Hui, Chan, & Pun, 2001), selection of environmental performance indicators (Scherpereel, van Koppen, & Heering, 2001), relationship between environmental and economic performance of firms (Wagner, Schaltegger, & Wehrmeyer, 2001), focus on third-party logistics providers (Krumwiede & Sheu, 2002; Meade & Sarkis, 2002), overview of management challenges and environmental consequences in reverse manufacturing (White, Masanet, Rosen, & Beckman, 2003) and extended producer responsibility (Spicer & Johnson, 2004), including OEM, pooled and third-party take-back, have been taken up by researchers.

Zhu and Sarkis (2004) describe empirical findings on relationships between operational practices and performance among early adopters of green supply-chain management(Zhu & Sarkis, 2004), while Bowen, Cousins, Lamming, and Faruk (2001) seek to resolve the apparent paradox between the desirability and the actual slow implementation of GSCM in practice (Bowen, Cousins, Lamming, & Faruk, 2001). Chouinard et al. (2005) deal with problems related to the integration of RL activities within a supply chain information system (Chouinard, D'Amours, & Aït-Kadi, 2005). Nagurney and Toyasaki (2005) develop a multi-tiered network equilibrium framework for e-cycling (Nagurney & Toyasaki, 2005), while Sheu et al. (2005) present an optimization based integrated logistics operational model for GSCM (Sheu, Chou, & Hu, 2005). Ravi et al. (2005) analyze alternatives in RL (Ravi, Shankar, & Tiwari, 2005), Mukhopadhyay and Setoputro (2005) derive a number of managerial guidelines for return policies of build-to-order products, while Srivastava and Srivastava (2006) suggest ways to manage end-of-life product returns. Kainuma and Tawara (2006) extend the range of supply chain to include re-use and recycling throughout the life cycle of product and services and propose a “lean and green” multiple utility theory approach to evaluate green supply chain performance from an environmental performance point of view (Kainuma & Tawara, 2006).

Green Design

The literature emphasizes both environmentally conscious design (ECD) and life-cycle assessment/analysis (LCA) of the product. The aim is to develop an understanding of how design decisions affect a product's environmental compatibility (Glantschnig, 1994; Navinchandra, 1991). Madu et al. (2002) present a very useful hierarchic framework for environmentally conscious design (Madu, Kuei, & Madu, 2002).

Sufficient literature exists on design for material and product recovery (Barros, Dekker, & Scholten, 1998; Ferrer, 1997a, 1997b; Ferrer & Whybark, 2001; Gatenby & Foo, 1990; Guide, Jr., & Van Wassenhove, 2001; Krikke, van Harten, & Schuur, 1999a, 1999b; Louwers, Kip, Peters, Souren, & Flapper, 1999; Melissen & de Ron, 1999; Seliger, Zussman, & Kriwet, 1994). Boothroyd and Alting (1992), Krikke, Bloemhof-Ruwaard, and Van Wassenhove (2003), Kroll, Beardsley, and Parulian (1996), Laperiere and ElMaraghy (1992), Lee, O'Callaghan, and Allen (1995), Moore, Gungor, and Gupta (2001), Scheuring, Bras, and Lee (1994), Seliger et al. (1994), and Taleb and Gupta (1997) discuss design for disassembly, whereas Gupta and Sharma (1996), He, Gao, Yang, and Edwards (2004), Jahre (1995), Jayaraman, Guide, and Srivastava (1999), Johnson (1998), and Sarkis and Cordeiro (2001) deal with design for waste minimization.

A common approach is to replace a potentially hazardous material or process by one that appears less problematic. This seemingly reasonable action can sometimes be undesirable if it results in the rapid depletion of a potentially scarce resource or increased extraction of other environmentally problematic materials. Several examples of such equivocal proposals are presented by Graedel (2002).

Green Operations

Some of the key challenges of GSCM such as integrating remanufacturing with internal operations (Ferrer & Whybark, 2001), understanding the effects of competition among remanufacturers (Majumder, Groenevelt, & Summer, 2001), integrating product design, product take-back, and supply chain incentives (Guide, Jr., & Van Wassenhove, 2001; Guide & van Wassenhove, 2002), and integrating remanufacturing and RL with supply chain design (Chouinard et al., 2005; Fleischmann et al., 2001; Goggin & Browne, 2000; Savaskan, Bhattacharya, & Van Wassenhove, 2004) are posed in this area.

In recent years, a lot of work related to quantitative approaches in RL has been published. Shih (2001) discusses in detail the RL system planning for recycling electrical appliances and computers in Taiwan. Hu, Sheu, and Huang (2002) present a cost-minimization model for a multi-time-step, multi-type hazardous-waste RL system. They present application cases to demonstrate the feasibility of their proposed approach. Nagurney and Toyasaki (2005) develop an integrated framework for modeling the electronic waste RL network which includes recycling, while the framework of Srivastava and Srivastava (2005) incorporates three types of rework facilities. Ravi et al. (2005) use analytical network process (ANP) and balanced score card for analysing RL alternatives for end-of-life computers. Listes and Dekker (2005) present a stochastic programming-based approach by which a deterministic location model for product recovery network design may be extended to account explicitly for uncertainties. They apply it to a representative real case study on recycling sand from demolition waste in The Netherlands. Their interpretation of the results gives useful insights into decision-making under uncertainty in a RL context. Pochampally and Gupta (2005) propose a three-phase mathematical programming approach, taking the above uncertainties into account, for strategic planning of a reverse supply chain network. Mostard and Teunter (2006) carry out a case study to derive a simple closed-form equation. They determine the optimal order quantity given the demand distribution, the probability that a sold product is returned, and all relevant revenues and costs for a single period model. Min, Ko, and Ko (2006) determine the number and location of centralized return centres using a nonlinear mixed-integer programming model and a genetic algorithm that solves the RL problem involving product returns.

Classification Based on Approach

The literature on GSCM may also be classified on the basis of methodology and approach used into: thought papers and perspectives; frameworks and approaches; empirical studies; mathematical modeling approaches; and reviews. This helps us to understand GSCM from a different perspective from the problem context described earlier. Thought papers and perspectives as well as frameworks- and approaches-related articles have been sufficiently covered in "Strategic management." Similarly, review papers have been covered in the introduction, and are not covered further. Therefore, empirical studies and mathematical modeling approaches are covered here.

Empirical Studies

Empirical research studies include case research, field surveys and interviews, field experiments, mail surveys, laboratory experiments, and game simulations. Several empirical studies in the area of GSCM have been published. They consist mainly of case studies and surveys. Most case studies deal with green design (product and logistics) and green operations (remanufacturing, recycling, RL, etc.). Goldsby and Closs (2000) describe the case study of a Michigan beverage distributor and retailer who collects empty beverage containers for recycling purposes. They discuss the reengineering of supply chain-wide processes using activity-based costing (ABC). Duhaime, Riopel, and Langevin (2000) describe value analysis and optimization of reusable containers at Canada Post. Ritchie, Burnes, Whittle, and Hey (2000) discuss the RL supply chain of a UK pharmacy. Warren, Rhodes, and Carter (2001) describe a total product system concept for a highly customized build-to-order product system. Scherpereel et al. (2001) use a case study to establish the relevance of selecting environmental performance indicators, while Khoo, Spedding, Bainbridge, and Taplin (2001) present a case study of a supply chain concerned with the distribution of aluminum. They use simulation to create a green supply chain. Tan, Yu, and Kumar (2002) take on a computer company in the Asia-Pacific region. De Koster, de Brito, and van de Vendel (2002) carry out an exploratory study with nine retailer warehouses regarding returns handling. Review of a number of case studies in RL is provided by de Brito, Flapper, and Dekker (2003). Flapper, van Nunen, and van Wassenhove (2005) address a number of case studies on closed-loop supply chains covering pharmaceuticals, electronics, breweries, containers, mail orders, tyres, photocopiers, cars, computers, cosmetics, and consumer durables.

Mathematical Modeling

A variety of tools and techniques have been used for problem formulation. A variety of the above tools and techniques have been used for problem formulation, solution, and analysis in papers published in edited books such as Dekker, Fleischmann, Inderfurth, and Van Wassenhove (2004), Dyckhoff, Lackes, and Reese (2003), and Fleishmann and Klose (2005). We map various mathematical tools/techniques vis-à-vis the contexts of GSCM. This depends much on the methodology used and also helps us to gauge their applicability/suitability. This is shown in Table 1.

Very few models have been used for strategic management of GSCM. AHP/ANP, Regression, DEA, and descriptive statistics (based on surveys/interviews) have been tried. Linear programming, nonlinear programming (NLP), and MILP have also been suggested in books but have not been

Table 1. Mapping of mathematical tools/techniques used vis-à-vis the contexts of GSCM

Mathematical tools/techniques	Strategic Management	Green Design	Green Operations

Heuristics		(Richter & Sombrutzki, 2000; Richter & Weber, 2001)	(Barros et al., 1998; Bloemhof-Ruwaard, Solomon, & Van Wassenhove, 1996; Jayaraman et al., 2003; Mourao & Amado, 2005)
I/O Model	(Ferrer & Ayres, 2000)		(Ferrer & Ayres, 2000)
LP and MILP	(Sarkis, 2001)	(Barros et al., 1998; Bloemhof-Ruwaard, Solomon et al., 1996; Bloemhof-Ruwaard, van Wassenhove, Gabel, & Weaver, 1996)	(Fleischmann et al., 2001; Haas & Murphy, 2002; Hu et al., 2002; Kroon & Vrijens, 1995) (Jayaraman & Srivastava, 1995; Louwers et al., 1999; Marin & Pelegrin, 1998) (Jayaraman et al., 1999; Jayaraman, Srivastava, & Benton, 1998; Ritchie et al., 2000; Srivastava & Srivastava, 2005)
Markov chain/queuing		(Van der Laan, Dekker, & Salomon, 1996; Van der Laan, Dekker, Salomon, & Ridder, 1996)	(Fleischmann, Kuik, & Dekker, 2002; Gupta, 1993; Kiesmuller & van der Laan, 2001; van der Laan & Salomon, 1997)
Metaheuristics			(Min et al., 2006; Minner, 2001)
Nonlinear programming	(Sarkis, 2001)		(Jayaraman et al., 1998; Richter & Dobos, 1999; Sarkis, 2001)
Petri net			(Moore, Gungor, & Gupta, 1998; Moore et al., 2001)
Regression	(Klassen, 2001; Sarkis, 2001; Zhu & Sarkis, 2004)	(Minner, 2001)	(Ferrer, 1997a; Haas & Murphy, 2002; Sarkis & Cordeiro, 2001; Zhu & Sarkis, 2004)
Scenario/sensitivity analysis			(Klausner & Hendrickson, 2000; Linton & Johnston, 2000; van der Laan, Salomon, & Dekker, 1999; van der Laan, Salomon, Dekker, & van Wassenhove, 1999)
Simulation			(Ashayeri et al., 1996; Khoo et al., 2001; Marx-Gomez et al., 2002; Vlachos & Tagaras, 2001)
Software and spreadsheets	(Nagel & Meyer, 1999)		(Krikke, Harten, & Schuur, 1998; Louwers et al., 1999)

used to a great extent. Green design has seen very little application in terms of mathematical tools, techniques, and methodologies. Lately, LP, MILP formulations, and software packages and spreadsheets for solution have been used. Green operations have used mathematical models, tools, and techniques to a much larger extent. MILP, simulation, computer programming, software packages, spreadsheets, and dynamic programming have been used extensively. Other traditional tools and techniques such as simulation, Markov chains, algebraic equations, ANOVA, heuristics, metaheuristics, and regression have also been used. Fuzzy reasoning, neuro-fuzzy, and game theory too have been tried.

One of the biggest challenges facing the field of GSCM is the developing of strategic and tactical tools. The inherent complexity of environmental issues—their multiple stakeholders, uncertain implications for competitiveness, and international importance—present significant challenges to researchers. Much research is needed to support the evolution in business strategy towards greening along the entire supply chain. Effective approaches for data sharing across the supply chain need to be developed. Researchers might take advantage of the emergent ICT for more effective collaboration and cooperation.

Although the current development in GSCM research is encouraging, a few studies link GSC strategy and performance measurement. Beamon (1999) suggests the traditional performance measurement structure of the supply chain must be extended and include mechanisms for product recovery (reverse logistics) and the establishment and implementation of new performance measurement systems. Yet, overall environmental performance measurement and supporting systems, across supply chains has not been as extensively studied (Hervani, Helms, & Sarkis, 2005).

RESEARCH OBJECTIVES AND METHODOLOGY

The objective of the research adopted under the heading of quantitative models for environmental performance measurement systems (QMEPMS) was to identify tools and techniques that would facilitate:

- Identification of factors affecting environmental performance
- Identification of the relationship between factors affecting environmental performance
- Quantification of these relationships on one another, and on the overall performance of the production processes
- Establishment of "What if" analysis on process performance and strategy selection

The introduction of a green supply-chain strategy is a very complex issue, since it presents a multidimensional impact on performance and often induces a significant modification in management procedures. In the light of these issues, it is important to analyze feasible patterns of strategic environmental behavior, under which conditions these are a sustainable option and the implications on operations management.

The introduction of factors describing a company's strategic attitude towards the environment, that is, how executives consider "green" issues, and of external variables describing the stakeholders' environment-related pressures, allows us:

- To highlight in which context(s) a specific green supply-chain strategy may be considered a sustainable option; and
- To identify the key elements of an efficient EPMS.

A company's strategic attitude heavily depends on managers' environmental awareness. For example, managers:

- Could have an ethical objective: in this case, the reduction of the company's impact on the natural environment is a more important task than the improvement of economic performance;
- May consider the environment as a means of achieving a competitive advantage: the introduction of new "green" product development procedures or the definition of a unique blend of "green" competencies identifying would be appropriate managerial solutions;
- Might concentrate on ensuring compliance with current environmental regulations or leading "green" movements/customers by developing products which are consistent with their requirements;
- May take no initiative to improve environmental performance; this behavior essentially reflects short-term vision and a resistant management.

Many authors (DePass, 2006; Rentmeester, 2005; Srivastava, 2007) have tried to identify the drivers of environmental pressures. It has been claimed that cost control, total quality management, communities, investors, and environmental regulations are the main pressures faced by companies.

Such environmental drivers do not affect a company's pattern of environmental behavior in equal measure. Their influence depends on industry- and country-specific factors. In our opinion, the major external influences concern:

- "Green" movements or regulators: specifically, the binding pressure of regulations and the importance of "green" movements are significant variables that could explain the adoption of a green supply-chain strategy; and
- The company's relationships with the other supply value chain partners (Dickinson, Draper, Saminathan, Sohn, & Williams, 1995; Hervani et al., 2005).

In the light of the above issues, we distinguish between (see Table 2).

This framework reflects the extensive literature on environmental strategies. Nevertheless, it differs from other state of the art approaches, as it introduces a more detailed taxonomy of strategic patterns of environmental behavior. The reasons for this choice are to identify precisely the operat-

Table 2. Main characteristics of the green supply-chain strategies

Strategy	Context	Characteristic
"evangelist" strategy	ethical objective and radical approach to environmental issues	Futurity
Pro-active green strategy	"systemic" initiatives affecting the whole value chain and relationships with suppliers	High bargaining power of the company Strategic perspective
Responsive strategy	bargaining power vs. suppliers/shredders is low the regulators' pressures are low	High/low bargaining power of the company Technical perspective
Reactive strategy	comply with environmental regulations or customers' environmental requirements	External oriented: High pressures from regulators and Technical perspective Market driven: High pressures of "green" customers and Technical perspective
Unresponsive strategy	limited financial resources, passive pattern of environmental behaviour and delay "green" programmes	High importance of cost based strategy

ing objectives associated with the implemented environment-related initiatives and to define the key requirements that an effective EPMS might respect in order to assess these.

Effective operating EPMSs to support the implementation of the above green supply-chain strategies and assess the resulting environmental performance might respect two general requirements:

- Measurability of the output, in order to have measures that can be used in identifying both to assess the company's "green" efficiency and to reward effective EPMSs employees;
- Long-term orientation, such a requirement is particularly important if the EPMS is adopted to support the implementation of "evangelist," pro-active, and responsive strategies.

Completeness, timeliness, and cost of the analysis are significant elements of an effective operating EPMS, but their importance varies with the different green supply-chain strategies. Completeness means the extent to which the model can take account of all the relevant performance factors in the environmental field; timeliness aims to describe how long the EPMS takes to analyze the collected data; while cost refers to the amount of time and human resources needed to implement the EPMS.

In the light of these issues, it is clear that the development of a complete and timely model represents the best solution, but this implies great computational costs. Hence, on the basis of the main characteristics of the identified green supply-chain strategies, we attempt to define EPMSs that, within each context, ensure the best trade-off between completeness, timeliness, and cost.

The six steps of the approach were developed as a result of the QMEPMS methodology implementation as depicted in Figure 2. The details of this approach have been explained through a case study.

The QMEPMS methodology, which is adopted in this research, is a modeling and simulation technique specifically designed for long-term, chronic, dynamic management problems. It focuses on understanding how the physical processes, information flows, and managerial policies interact so as to create the dynamics of the variables of

Describe the Green SCM using event driven process chains.

Using system dynamics model to define the strategic objectives and critical factors.

Linkage of QMEPMS to MIS enables timely collecting data and tracking of performance.

Using simulation technology to forecast Environmental Performance and adjust strategy proactively interest. The totality of the relationships between these components defines the "structure" of the system. Hence, it is said that the "structure" of the system, operating over time, generates its "dynamic behavior patterns." It is most crucial in QMEPMS that the model structure provides a valid description of the real processes. The typical purpose of a QMEPMS study is to understand how and why the dynamics of concern are generated and then search for policies to further improve the system performance. Policies refer to the long-term, macrolevel decision rules used by upper management.

In order to achieve the green supply chain, manufacturing organizations must follow the basic principles established by ISO 14000. In particular, organizations must develop procedures that focus on operations analysis, continuous improvement, measurement, and objectives. An implementation procedure for implementing the green supply chain strategy includes the following tasks:

- **Establishing strategic perspectives:** For each product within the supply chain, identify all inputs, outputs, by-products, and resources.
- **Identifying environmental performance measures:** Defining green objectives in multiple views, including measures, indicators, targets, initiatives, and tasks. Environmental performance indicators are core requirements of a GSCM/PMS when evaluating the environmental performance of activities, processes, hardware, and services. Environmental performance indicators are described in ISO 14031 (environmental management-environmental performance evaluation of the ISO 14001 accreditation guidelines). Environmental performance indicators are needed when evaluating the environmental performance of activities, processes, hardware, and services. Given the complexity of most supply chains, a single performance measure will likely be inadequate in assessing the true performance of the supply chain. Thus, a system of performance measures will be necessary. Such a performance measurement system must include measures for the three environmental categories given above, as well as existing operational measures.
- **Describing green supply chain:** Describe the Green SCM using event driven process chains (EPCs). EPCs are directed graphs, which visualize the control flow and consist of events, functions and connectors. Each EPC starts with at least one event and ends with at least one event. An event triggers a function, which leads to a new event. Three types of connectors (AND, Exclusive OR, OR) can be used to model splits and joins.
- **Establishing cause-effect diagram:** Using system dynamics model to define the strategic objectives and critical factors (Figure 4). Calculate the actual composite performance at each step in the supply chain process for each product. The composite performance, as calculated at each supply chain process step, will be a function of the performance measures developed above. The composite performance, therefore, may be a single numerical value, or (more likely) a vector of numerical values.
- **Linkage to data model and MIS:** Linkage of QMEPMS to MIS enables timely collecting, measuring of data, and tracking of performance. After all processes for all products have been measured, prioritize the process steps in order of increasing composite performance, as calculated above.
- **Development of control model:** Develop alternative simulation models for performance improvement (targeting first those process steps exhibiting the worst composite performance, based on prioritization above), and select a preferred approach. Establish

schedules and procedures for auditing and continuous improvement, including emergency and noncompliance procedures.

QUANTITATIVE MODEL FOR ENVIRONMENTAL PMS

Performance measurement systems usually involve a number of multidimensional performance measures. Neely pointed out that a problem, which arises from that situation is the integration of those several measures expressed in heterogeneous units into a single unit (Neely et al., 2000).

The key techniques of the QMEPMSs are a set of models of business object, coupling operation and system dynamics. These models are proposed based on the object-oriented approach, and are shown in Figure 3.

Business Object Models (BOMs)

Our BOMs are divided from three views and their relationships are also shown in Figure 3.

Organization View

The organizational model is a typical form of representing organizational structures. Person Type (PT) objects can be defined as a 3-tuple:

$$PT = \{(personID, roleName, prsType)\} \quad (1)$$

Where *personID* is the identifier of a human resource; *roleName* is defined as the role of a person in the business process; *prsType* is the type of a person when he processes information resources, such as listener, processor, and dispatcher.

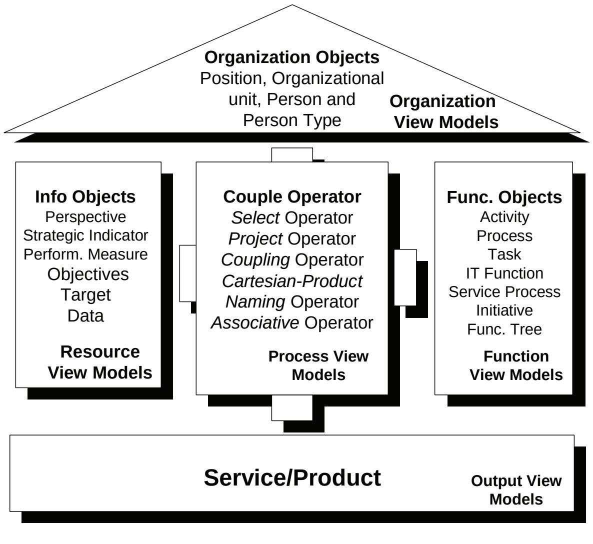
Function View

An enterprise activity (EA) is defined as a 9-tuple:

$$EA = \{(activityID, actFunction, \\ , orgBelongTo) actType \} \quad (2)$$

Where activityID is the identifier of an EA; actFunction is defined as the function of EA; orgBelongTo defines the organization to which activity belongs; actType refers to the type of

Figure 3. Relationship views of the QMEPMS model



activity which can be cataloged as a structured activity and a nonstructured activity.

Info View

An info view model includes a description of the semantic data model of the field which is to be examined. An information resource (IR) can be defined as a 5-tuple:

$$IR = \{(inforResID, content, generationTime, periodOfValidity\ inforType)\} \quad (3)$$

Where inforResID is the identifier of IR; content includes three components: clear definition or meaning of data, correct value(s), and understandable presentation (the format represented to PTs); generationTime refers to the time when the IR comes into being; periodOfValidity refers to the age of the IR remaining valid; inforType is the type of the IR which can be classified as environmental, inner, and efferent.

Output View

An output view model includes a description of the products or services performed in a company. A product service (PS) can be defined as a 6-tuple:

$$PS = \{(ProdServID, Name, Frequency, Costs, Significance, Price)\} \quad (4)$$

Coupling Operation Models (COMs)

The coupling operation consists of a set of operations that take one or two sets as the input and produce a new set as their result. The fundamental operations in the coupling operation are select, project, Cartesian product, and associative.

The Select Operator

The select operation selects tuples that satisfy a given predicate. We use the lowercase Greek letter sigma (σ) to denote selection. The predicate appears as a subscript to σ. The argument relation is in parentheses after the σ. Thus, to select those tuples of the IR in Equation (2) object where the inforResID is "1," we write: σ inforResID = "1" (IR).

In general, we allow comparisons using =, $\neq$, $<$, $\leqslant$, $>$, $\geqslant$, $\nless$, $\ngtr$ in the selection predicate. Furthermore, we can combine several predicates into a larger predicate by using the connectives and ($\wedge$), or ($\vee$), and not ($\neg$).

The Project Operator

Suppose we want to list all names and values of IR, but do not care about the identifier of IR. The project operation allows us to produce this relation. The project operation is a unary operation that returns its argument relation, with certain attributes left out. Since a relation is a set, any duplicate rows are eliminated. Projection is denoted by the uppercase Greek letter pi (Π). We list those attributes that we wish to appear in the result as a subscript to Π. The argument relation follows in parentheses. Thus, we write the query to list all periodOfValidity of IR as: ΠperiodOfValidity (IR)

Composition of Coupling Operator

The fact that the result of a coupling operation is itself a set is important. Consider the more complicated query "Find periodOfValidity of the IR which inforResID is 1." We write:

$$\Pi_{periodOfVality}(\sigma_{\inf or \operatorname{Re} sID=1}(IR)) \quad (5)$$

The Cartesian-Product Operator

The Cartesian-product operation, denoted by a cross (×), allows us to combine information from any two objects. We write the Cartesian product of object o1 and o2 as o1×o2.

The Naming Operator

However, since the same attribute name may appear in both o1 and o2, we devise a naming operation to distinguish the object from which the attribute originally came. For example, the relation schema for R = IR × RI is shown in Box 1.

With this operation, we can distinguish IR.inforResID from RI.inforResID. For those attributes that appear in only one of the two objects, we shall usually drop the relation-name prefix. This simplification does not lead to any ambiguity. We can then write the relation schema for R as shown in Box 2.

The Associative Operator

It is often desirable to simplify certain operations that require a Cartesian product. Usually, an operation that involves a Cartesian product includes a selection operation on the result of the Cartesian product. Consider the operation "Find the contents of all IRs which come into the object of RI, along with the peridodOfValidity and generationTime." Then, we select those tuples that pertain to only the same inforResID, followed by the projection of the resulting content, generationTime, and peridodOfValidity:

$$\Pi_{\text{content, generationTime, periodOfValidity}} (\sigma_{\text{IR.inforResID=RI.inforResID}} (\text{IR} \times \text{RI})) \qquad (6)$$

The associative operation is a binary operation that allows us to combine certain selections and a Cartesian product into one operation. It is denoted by the "join" symbol "⊠." The associative operation forms a Cartesian product of its two arguments, performs a selection forcing equality on those attributes that appear in both relation objects, and finally removes the duplicate attributes.

Although the definition of an associative operation is complicated, the operation is easy to apply. As an illustration, consider again the example "Find the contents of all IRs which come into the object of RI, along with the peridodOfValidity and generationTime." We express this operation by using the associative operation as following:

$$\Pi_{\text{content, generationTime, periodOfValidity}} (\sigma\, (\text{IR} \boxtimes \text{RI}))$$

System Dynamics Models (SDMs)

This section is a detailed discussion of the system dynamics modeling, which allows for simple representation of complex cause-and-effect re-

Box 1.

$$\text{IR} \times \text{RI} = \{(\text{IR.inforResID, IR.content, IR.generationTime, IR.periodOfValidity, IR.inforType,}$$
$$\text{RI.resInputID,RI.receiveTime, RI.activityID, RI.inforResID, RI.personID, RI.IQMeasure})\}$$

Box 2.

$$\text{IR} \times \text{RI} = \{(\text{IR.inforResID, content, generationTime, periodOfValidity, inforType}$$
$$\text{resInputID, receiveTime, activityID, RI.inforResID, personID, IQMeasure})\}$$

lationships. For the discussion that follows, it is important to understand that it is the levels (or state variables) that define the dynamics of a system. For the mathematically inclined, we can introduce this in a more formal way. The following equations show the basic mathematical form of the QMEPMS.

$$measures[i]_t = \int_0^T levels[j]_t dt; \quad \frac{d}{dt} measures[i]_t = levels[j]_t \tag{7}$$

$$rates_t = \mathrm{g}(levels_t, aux_t, data_t, const) \tag{8}$$

$$aux_t = \mathrm{f}(levels_t, aux_t, data_t, const) \tag{9}$$

$$levels_0 = \mathrm{h}(levels_0, aux_0, data_0, const) \tag{10}$$

In these equations g, h, and f are arbitrary, nonlinear, potentially time varying, vector-valued functions. Equation represents the evolution of the system over time, equation the computation of the rates determining that evolution, equation the intermediate results necessary to compute the rates, and equation the initialization of the system.

QMEPMS differs significantly from a traditional simulation method, such as discrete-event simulation where the most important modeling issue is a point-by-point match between the model behavior and the real behavior, that is, an accurate forecast. Rather, for an EPMS model it is important to produce the major “dynamic patterns” of concern (such as exponential growth, collapse, asymptotic growth, S-shaped growth, damping or expanding oscillations, etc). Therefore, the purpose of our model would not be to predict what the total green supply chain profit level would be each week for the years to come, but to reveal under what conditions and capacity planning policies the total profit would be higher, if and when it would be negative, and if and how it can be controlled.

Model Variables

The flow variables represent the flows in the system (i.e., remanufacturing rate), which result from the decision-making process. Below, we define the model variables (stock, smoothed stock, and flow) converters and constants and cost parameters, their explanation, where necessary, and their units. We chose to keep a nomenclature consistent with the commercial software package that we employed; thus, for the variable names we use terms with underscore since this is the requirement of the software package (it does not accept spaces). The stock variables in order that they appear in the green supply chain processes are the following:

- **Raw_Materials:** Inventory of raw materials [items].
- **Serviceable_Inventory:** On-hand inventory of new and remanufactured products [items].
- **Distributors_Inventory:** On-hand inventory of the distributor [items].
- **Collected_Products:** The inventory of collected reused products [items].
- **Collection_Capacity:** The maximum volume of products handled by the collection and inspection facilities per day [items/day].

The smoothed stock variables are:

- **Expected_Distributors_Orders:** Forecast of distributor’s orders using exponential smoothing with smoothing factor a_DI [items/day].
- **Expected_Demand:** Demand forecast using exponential smoothing with smoothing factor a_D [items/day].
- **Expected_Remanufacturing_Rate:** Forecast of remanufacturer rate using exponential smoothing with smoothing factor a_RR [items/day].

- **Expected_Used_Products:** Forecast of used products obtained using exponential smoothing with smoothing factor a_UP [items/day].
- **Desired_CC:** Estimation of collection capacity obtained by exponential smoothing of Used_Products with smoothing factor a_CC [items/day].
- **Production_Rate:** [items/day].
- **Products_Rejected_for_Reuse:** The flow of used products that have not passed inspection and should be disposed [items/day].
- **Controllable_Disposal:** The flow of surplus stock of reusable products to prevent the costly accumulation if there is not enough remanufacturing capacity to handle them [items/day].
- **RC_Adding_Rate:** Remanufacturing capacity adding rate [items/day/day].

Constants, converters are:

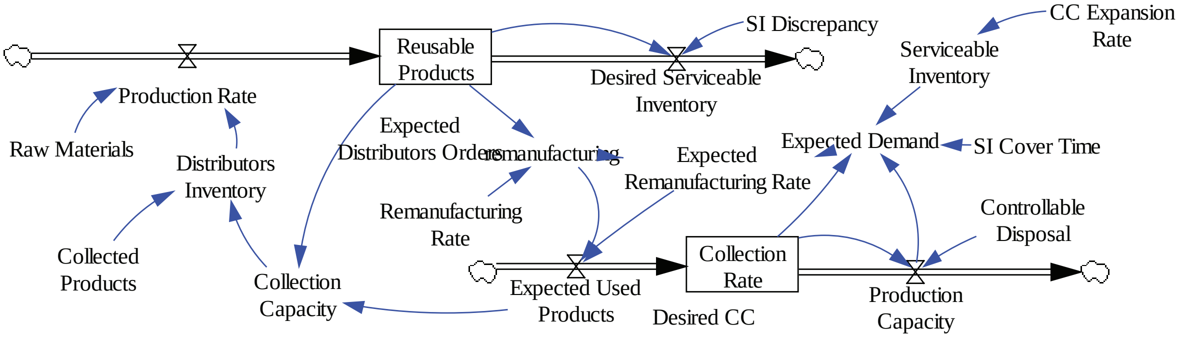
- **CC_Discrepancy:** Discrepancy between desired and actual collection capacity [items/day].
- **CC_Expansion_Rate:** Collection capacity expansion rate [items/day/day].
- **DI_Adj_Time:** Distributor's inventory adjustment time [days].
- **DI_Cover_Time:** Distributor's inventory cover time [days].
- **Pr:** Remanufacturing capacity review period [days].
- **Reuse_Ratio:** The ratio of Expected_Remanufacturing_Capacity to Expected_Used_Products [dimensionless].
- **SI_Adj_Time:** Serviceable inventory adjustment time [days].
- **SI_Cover_Time:** Serviceable inventory cover time [days].

Cause-Effect Diagram

The structure of a system in QMEPMS methodology is captured by cause-effect diagrams. A cause-effect diagram represents the major feedback mechanisms. These mechanisms are either negative feedback (balancing) or positive feedback (reinforcing) loops. A negative feedback loop exhibits goal-seeking behavior: after a disturbance, the system seeks to return to an equilibrium situation. In a positive feedback loop an initial disturbance leads to further change, suggesting the presence of an unstable equilibrium. Cause-effect diagrams play two important roles in QMEPMS methodologies. First, during model development, they serve as preliminary sketches of causal hypotheses and secondly, they can simplify the representation of a model.

The first step of our analysis is to capture the relationships among the system operations in a QMEPMS manner and to construct the appropri-

Figure 4. Cause-effect diagram of the green supply chain



ate cause-effect diagram. Figure 3 depicts the cause-effect diagram of the system under study which includes both the forward and the reverse manufacturing process. To improve appearance and distinction among the variables, we removed underscores from the variable names and changed the letter style according to the variable type. Specifically, stock variables are written in capital letters, the smoothed stock variables are written in small italics and the flow variables are written in small plain letters. These variables may be quantitative, such as levels of inventories and capacities, or qualitative, such as failure mechanisms.

Mathematical Formulation

The next step of QMEPMS methodology includes the development of the mathematical model, also presented as a cause-effect diagram that captures the model structure and the interrelationships among the variables. The cause-effect diagram is easily translated to a system of differential equations, which is then solved via simulation.

The cause-effect diagram is a graphical representation of the mathematical model. The embedded mathematical equations are divided into two main categories: the stock equations, defining the accumulations within the system through the time integrals of the net flow rates, and the rate equations, defining the flows among the stocks as functions of time. In the remaining of this section, we present selected formulations related to important model assumptions.

The equations related to collection green supply chain policy are the following:

$$\mathit{Desired\_CC(t)} = \mathrm{DELAYINF}(\mathit{Used\_Products}, \mathit{a\_CC}, 1, \mathit{Used\_Products}) \quad (11)$$

$$\mathit{Collection\_Capacity}(0) = 0 \quad (12)$$

$$\mathit{Collection\_Capacity}(t + dt) = \mathit{Collection\_Capacity}(t) + dt * \mathit{CC\_Adding\_Rate}, \quad (13)$$

$$\mathit{CC\_Adding\_Rate} = \mathrm{DELAYMTR}(\mathit{CC\_Expansion\_Rate}, 24, 3, 0), \quad (14)$$

$$\mathit{CC\_Discrepancy} = \mathrm{PULSE}(\mathit{Desired\_CC} * \mathit{Collection\_Capacity}, 50, P_c), \quad (15)$$

$$\mathit{CC\_Expansion\_Rate} = \max(K_c * \mathit{CC\_Discrepancy}, 0), \quad (16)$$

Desired_CC is a first order exponential smoothing of Used_Products with smoothing coefficient a_CC. Its initial value is the initial value of Used_Products. Collection_Capacity begins at zero and changes following CC_Adding_Rate, which is a delayed capacity expansion decision (CC_Expansion_Rate) with an average delay time of 24 time units, an order of delay equal to 3 and initial value equal to zero at t = 0. CC_Expansion_Rate is proportional to the CC_Discrepancy between the desired and actual collection capacity, multiplied by Kc. The pulse function determines when the first decision is made (50 time units) and the review period Pc. Similar equations dictate the green supply chain policy.

The total profit per period is given from:

$$\mathit{Total\_Profit\_per\_Period} = \mathit{Total\_Revenue\_per\_Period} - \mathit{Total\_Cost\_per\_Period}, \quad (17)$$

Where

$$\mathit{Total\_Cost\_per\_Period} = \mathit{Investment\_Cost} + \mathit{Operational\_Cost} + \mathit{Penalty\_Cost}, \quad (18)$$

$$\mathit{Total\_Revenue\_per\_Period} = \mathit{Sales} * \mathit{Price}, \quad (19)$$

$$\mathit{Investment\_Cost} = (\mathit{CC\_Expansion\_rate})^{0.6} * \mathit{Col\_Cap\_Construction\_Cost} + (\mathit{RC\_Expansion\_rate})^{0.6} * \mathit{Rem\_Cap\_Construction\_Cost}, \quad (20)$$

$$Operational\_Cost = Collection\_Rate * Collection\_Cost$$

$$\begin{aligned} & Remanufacturing\_Rate * Remanufacturing\_Cost \\ & + Production\_Rate * Production\_Cost \\ & + Reusable\_Products * Holding\_Cost \\ & + Sales * DI\_Transportation\_Cost \\ & + Distributors\_Inventory * DI\_Holding\_Cost \\ & + Shipments\_to\_Distributor \\ & \quad * SI\_Transportation\_Cost \\ & + Serviceable\_Inventory \\ & \quad * SI\_Holding\_Cost, \end{aligned} \tag{21}$$

ILLUSTRATIVE CASE

Owing to the wide set of measures and processes that must often be considered in an EPMS, the implementation of the suggested quantitative models may be complex. To understand the major models of the identified EPMSs, An example that highlights how measures must be structured at the operational level is given. In the following section, the case of FAW Toyota Changchun Engine Co. Ltd. (FTCE) in the automotive industry is analyzed.

First Auto Works (FAW) is the largest Chinese corporation in the automotive industry. It has industrial sites both in Changchun and Tianjin, and over the last few years has adopted a green manufacturing strategy aimed at reducing product costs (through innovative technology) and improving product quality. As a pioneering automobile company, FTCE has initiated multiple dimensions of GSCM practices, including internal environmental management, green purchasing, green marketing, and eco-design.

Since 2000, senior management has been committed to a reduction in the environmental impact resulting from industrial activities, and product usage. In terms of operational policy, such an interest in "green" issues has given rise to two major programmes:

- The F1 program, specifically aimed at improving the environmental performance of the production processes.
- The F2 program, which focuses on the introduction of new environmentally friendly cars. Indeed, in 1999, the group developed a new generation of recyclable cars.

In the light of these issues, it is clear that First Auto has adopted a pro-active pattern of environmental behavior, whereby it has tried to improve its ("green") image.

In the sample application, an EPMS was designed to support operations managers in assessing the results of the Crown model. The car is designed to respect recycling and dismantling techniques, and allows the company to recover all end-of-life components. Materials for engines are recycled into plastics for air ducts in the dashboard, glass is recovered to produce colored bottles; reclining seats are recycled into carpets for furnishing, and so forth. Here, the effectiveness of engine recycling is assessed, since it is the only activity that is implemented internally.

Producing environmentally sound engines is one key dimension FTCE uses to establish their environmental image, and thus gain and keep competitiveness. Within this competitive market, senior managers in the FTCE put forward a call of ‘‘Green plant, environmental engines." They have worked on furthering their environmental image by producing petrol engines with low emissions, low petrol consumption, low noise, as well as high dynamic functions and reliability. To at least maintain and potentially improve its environmental performance, FTCE has invested over 14 million RMB since 2004. The plant purchased equipment for emission purification, noise elimination and wastewater treatment, which greatly improved its internal environmental conditions. In 2006, FTCE initiated a waste water reuse project, and became the first company realizing "zero emissions" for both industrial and municipal waste water in Changchun, which is very important in a municipality that is consistently threatened with water shortages. To complete this program the plant invested 3.26 million RMB for a wastewater treatment project by using flocculation, bio-chemical, ultra-filtration, and reverse osmosis technologies.

Environmental issues are main concerns for FTCE during its product design and development. The Product Development Director in FTCE stated that environmental requirements are quickly becoming primary priorities, even over economic benefits. To help them address this management priority, the plant closely cooperates with our research methodology and models on eco-design projects. As an example of this success, since April 2007, all products produced by the FTCE meet the Europe II emission standards.

The plant has also implemented cleaner production activities in its production stages focusing on source reduction and waste prevention. The plant implements collaborative development efforts with its suppliers, which include environmental considerations, and these efforts and programs are driven by the organization's internal environmental strategy and policy. Customer collaboration is also evident here. For different types of vehicles, road conditions, and consumer characteristics, the plant and its main customer, FAW, jointly develop improved engines that consume less fuel, while maintaining suitable performance standards (including acceleration and cooling systems capabilities).

The significance of outsourcing practiced by FTCE requires them to more closely monitor supplier environmental practices to guarantee both quality and environmental performance requirements. The plant not only collects environmental information related to suppliers, but also establishes a database on environmental situations for main component suppliers. The plant jointly implements research on substitute materials and technologies to improve environmental practices with those partners and even joins in some of these innovation programs with competitors. At the same time, the plant also outsources other nonmanufacturing functions, such as logistics functions to help achieve their goals of just-in-time (JIT) production. This outsourcing requires monitoring of its distribution and transportation environmental and economic performance. JIT provides a managerial challenge since JIT's minimization of waste philosophy is environmentally sound, yet, more frequent delivery requirements weaken transportation energy efficiency, causing environmentally detrimental consequences.

FTCE has improved both environmental and economic performance through GSCM-related practices. It is complying with regulatory and market pressures by offering innovative and environmentally sound products. However, the plant has also faced numerous challenges. Prices for energy and raw materials have continuously increased. Emission standards have become increasingly strict. For example, the federal government recently announced plans to implement Euro III standards on emissions by the end of 2007. These continued pressures and forces will cause not only FTCE to adopt and advance GSCM innovation, but other manufacturers will need to react as well.

In line with the above discussion, the change in the main (physical) environmental performance resulting from the implementation of this program and the main drivers of shareholders' value were calculated.

The implementation of the above initiative results in the modification of design, process efficiency, and volume indices (see Table 3). Specifically, the take-back of engines leads to a reduction in the purchase of plastic raw materials and energy consumption (30% with respect to traditional plants), since the fluff resulting from the grinding of car bodies is cleaner.

From a financial perspective (see Table 4), the program affects expenditure related to the internal efficiency of operations, for example, the reduction of energy, raw materials, and environmental regulations related costs (regarding both waste water and solid wastes), as well as other operating costs associated to the take back and recycling of engines, higher labor costs to implement the recycling process internally, and increased expense for the recycling process itself. In addition, the introduction of new cars produced an increase in volume (50,000 units).

In the light of the above analysis, it can be concluded that the company respected its own targets: indeed, the increase in actual labor costs over standard costs is only marginal and, above all, the result of the growth in production volumes.

The above discussion highlights that there are significant differences in the deployment and assessment of a pro-active or a reactive green supply-chain strategy. In particular, both the design of the EPMS and the gathering of data present different operating problems which depend on the adopted pattern of environmental behavior.

In general terms, the design of an effective EPMS is more complex within pro-active companies than within reactive organizations. It must be noted that the assessment of a pro-active green supply-chain strategy requires identification of physical and economic indicators which well describe a company's potential environment-related sources of competitive advantage. This implies significant changes in the traditional systems adopted to monitor the evolution of environmental performance. Indeed, the latter were

Table 3. Measures expressing a company's impact on the state of natural resources

		Planned value	***Reported measure***
	Time for production	4 hours	3.5 hours
	Time for disassembling	5.8 hours	4.6 hours
	No. of different materials in the product	4	9
Volume index	Quantity of recovered plastics	6.376 tons	8.670 tons
	SOx	523 tons	532 tons
	NOx	412 tons	395 tons
Process efficiency	Electrical energy	445,000 Mwh	430,000 Mwh
	Oil	2,250 tons	2,383 tons
	COD	35,500 tons	33,000 tons
	Sulphates	368,000 tons	369,500 tons

Table 4. The economic items affected by the initiative

	Forecast Value (RMB)	***Reported measure (RMB)***
Revenue		
Total Revenue per Period	2,150,000,000	2,345,000,000
Total Cost per Period		
Total Profit per Period	56,500,000,000	58,450,000,000
Operational Cost	18,250,000,000	17,750,000,000
Energy costs	5,650,000,000	5,537,000,000
Other environmental costs		
Recycling costs	435,720,000	428,780,000
Costs related to environmental regulations	593,500,000	693,000,000

usually designed to verify compliance with existing regulations. A reactive green supply-chain strategy simply demands verification of whether environmental performance of the company's products or processes are consistent with the stakeholders', that is, regulators' or customers', requirements. The implementation of the suggested approach in FA (the reactive firm) did not in fact require the definition of new measures, as the company's EPMS already considered compliance indicators.

It is evident that, apart from managers' skills and the effectiveness of the information system, the deployment of innovation-based green supply-chain strategies (evangelist, pro-active and responsive) is more complex than passive patterns of environmental behavior. A key point in the effective assessment of innovative environmental policies is the identification of measures clarifying how the company positions itself with respect to competitors, and how the adopted programmes affect the company's profitability. In this respect, a growing body of literature highlights that the failure of some ambitious environmental strategies is a direct consequence of an incorrect selection of the indicators to be used in the EPMS.

CONCLUDING REMARKS

The suggested framework is, in our opinion, an effective tool for operations managers wishing to design EPMSs. The operational guidelines on PMS architecture and the appropriate measurement techniques provide support in devising performance indicators that best suit the intended green supply-chain strategy.

The model can be used to analyze various scenarios (i.e., to conduct various "what-if" analyses), thus identifying efficient policies and further to answer questions about the long-term operation of green supply chain using total process profit as the measure of performance. The model could further be adopted and used not only for product recovery, but also for material recycling systems. Thus, it may prove useful to policy-makers/regulators and decision-makers dealing with long-term strategic management issues along with researchers in environmental management. The benefits of the QMEPMS approach may be summarized as follows:

- Factors affecting performance can be identified and then their effects can be quantified
- Effects of multidimensional factors on performance can be aggregated into a single dimensionless unit (priority)
- Help managers to quantify the level of impact of each factor on overall performance and therefore assists in focusing improvement activities
- The relationships between factors can be clearly identified and expressed in quantitative terms
- Models can be easily altered to assists understanding the dynamic behavior of factors affecting performance
- Facilitates the reduction of the number of performance measurement reports

An important benefit gained from the QMEPMS approach is that the interaction of the factors can be clearly identified and expressed in quantitative terms. This identification will bring us one step forward in understanding the dynamic behavior of factors affecting environmental performance.

Moreover, the approach can be used in a "dynamic perspective," that is, to analyze whether to change the adopted pattern of environmental behavior from a passive/re-active to a pro-active strategic attitude. In operational terms, this implies, for example, that a reactive firm has to design an EPMS which includes indicators highlighting how the company's economic value may change with the introduction of innovation-based environmental programmes (i.e., the EPMS suggested for a pro-active manufacturing strategy).

However, the suggested framework does not solve all the problems associated to environmental performance measurement. In this respect, two directions for further research can be identified:

The integration of environmental aspects into the corporate management control system, since, in the above discussion, we considered the control of the implemented environmental programmes as an isolated problem. The design of a comprehensive PMS which includes the environmental dimension as well as the other competitive priorities (i.e., cost, quality, time, flexibility, innovation) may be difficult. A key point for future research is to avoid excessive proliferation of data, since this may hinder the use of PMS to identify how a company performs with respect to the planned objectives.

Decision-making techniques must be developed which allow physical and economical measures to be integrated into a synthetic judgment. The assessment of different "green" options requires the decision maker to identify how each alternative contributes to the reduction of environmental impact and shareholders' value creation. The definition of a synthetic indicator is of fundamental importance if the comparison of the available "green" options shows contrasting results with regards environmental performance and the financial implications of its implementation.

FUTURE DIRECTION

Research in GSCM to date may be considered compartmentalized into content areas drawn from operations strategy. The primary areas of emphasis have been quality, operations strategy, supply-chain management, and product and process technologies, which are collectively beginning to contribute to a more systematic knowledge base. It is reasonable to expect that these research areas will continue to hold the greatest promise for advance in the short term. However, more integrative contributions are needed in the longer term, including green supply chain strategy, intra- and inter-firm diffusion of best practices, green technology transfer, and environmental performance measurement.

One of the biggest challenges facing the field of GSCM is the inherent complexity of environmental issues, such as natural environment limits, multiple stakeholders, uncertain implications for competitiveness, international importance, and so forth. These present significant challenges to researchers, management academicians, and application practitioners. Much research is needed to support the evolution in business practice towards green supply chain strategy. Effective quantitative models for green supply chain need to be developed. Researchers might take advantage of the emergent mathematical modeling technologies for more effective collaboration and cooperation. Although research on intelligent GSCM is still in its infancy, there is no doubt that this will be the hottest topic in the near future. Artificial intelligence techniques, including knowledge-based systems, fuzzy systems, and neural networks, are expected to play a significant role in research and development.

Although many case studies, survey-based empirical methods, and so forth, have been carried out, they have not dealt with strategic management aspect of GSCM. Detailed empirical case studies need to be carried out in such areas as organizational function to GSCM at the firm level, selection of returns and rework facilities in alignment with competitive priorities, the influence of remanufacturing on the supply chain of a particular firm, and how service quality and recovery strategies influence consumer behavior and vice versa. The chance also exists to carry out empirical studies to find how the regulatory environment, economic considerations, and level of function influence the volume of returns. Similarly, studies to find how various uncertainties influence channel relationships within GSCM are also desired.

The product life cycle has been studied in great depth. However, more research is needed in understanding strategic management and its connection to the product life cycle. An important area for investigation would be to see how, in practice, strategic management activities do change over the life of a particular product. More information is needed about returns levels. At a strategic level, there is little published information on product return levels by product type. More study of the impact of marketing on strategies is needed. In general, theory and models need to be developed and consolidated to establish the relationship between new product sales and returns rates. Research is needed into how companies should process, store, and dispose of returned goods. Much more research is needed in understanding secondary markets, and how companies should best sell unwanted products. In addition to traditional brokers, many firms are now selling this material through online and traditional auctions.

Although the current development in GSCM research is encouraging, literature on integrated business strategy (comprising product and process design, manufacturing, marketing, RL and regulatory compliance) in the context of GSCM is at the level of thought papers and frameworks only. More research is needed in determining how companies should best select green strategies for each outlet to maximize returns, while still protecting brand integrity. Further, GSCM deserves special attention in terms of resource function within a firm/ supply chain.

GSCM seems a promising area for trying out new research techniques and for using traditional techniques for overall GSCM Strategy. The problem is complex and challenging, as a very large number of parameters, decision variables, and constraints are involved along with a large number of estimation requirements such as those of expected demands and returns and cost criteria associated with each decision. Perhaps a combination of various tools and techniques may be combined for the purpose of formulation, approximation, analysis, and solution of such complex problems.

Developing and further improving greening strategy concepts means that it will be more beneficial for manufacturing companies to implement recycling, refurbishing, and remanufacturing operations for economic reasons alone besides meeting the consumer pressures and regulatory norms. By determining the factors that most influence a firm's greening strategy undertakings, it can concentrate its limited resources in those areas. Areas and topics such as integrated logistics for network design, under which circumstances should returns be handled, stored, transported, processed jointly with forward flows and when should they be treated separately, comparing cost of remanufacturing with cost of production from virgin materials, potential attractiveness of postponement operations in greening strategy, change in a firm's green strategy for a particular product over the course of the product's life, and modeling for situation when customer returns cannot be cost minimization model may be explored for further research.

ADDITIONAL READING

Flapper, S., Wassenhove, L. V., & Nunen, J. v. (2005). *Managing closed-loop supply chains*. Berlin/Heidelberg: Springer-Verlag. This book provides a framework for analysis and design of closed-loop supply chains including technical, organizational, planning and control, information, environmental and business economic issues, as well as the interactions between them.

Sarkis, J. (2006). *Greening the supply chain*. London: Springer-Verlag. This book is a good introduction for investigating green supply chain management. The chapters of this book include work from a number of international authors from

theoretical and practical backgrounds, sharing their research and experiences in the field to promote a better understanding of the environmental influence of supply chain management.

System dynamics modeling allows researchers to specify stocks and flows of resources, and the relatedness of decisions about those resources (Forrester, 1999). Relatedness may be in the font of direct or indirect feedback loops (with or without time lags) that reinforce or dampen effects from other decisions. The process of modeling strategic decision environments compels researchers to specify assumptions and variables explicitly (Crossland & Smith, 2002).

Dynamic models can be classified as white box and black box (Forrester, 2007b). Black-box models are data driven, and comparing the forecast outcome with actual outcomes can test their validity (Forrester, 2007a). White-box models are descriptive and theory-like in that they try to explain the behavior of a system. System dynamics models, which are of the white-box type, exhibit validity if their internal structure adequately represents the issues relevant to the behavior being described. Further, the internal structure cannot be validated from an entirely objective, formal, and quantitative perspective (Burgelman & McKinney, 2006). Software designed for building system dynamic models assists in clarifying the internal logic of relationships. The responsibility for the accuracy of the description of the system that is being modeled, however, remains with the researcher (Hilmola, Helo, & Ojala, 2003). The availability of system dynamics software facilitates applying concepts, such as the supply chain, to case studies. We chose Vensim® Version 5 software for our study.

Fundamentals of greening as a competitive initiative are explained by Porter and van der Linde (1995). Three strategies in GSCM, namely reactive, proactive, and value-seeking, are suggested by van Hoek (1999) and Johnson (1998). Nasr (1997) and Gungor and Gupta (1999) discuss environmentally conscious manufacturing. Friedman (1992), Guide and Van Wassenhove (2002) and Gupta and Sharma (1996) discuss the changing role of the environmental manager. Interactions among various stakeholders on integrated GSCM and advantages that may accrue to them have been described by Gungor and Gupta (1999).

ABSTRACT

This article presents a system to enable access to those Information Systems at the National Autonomous University of Mexico (UNAM) that are related to Biodiversity and the Environment. The system in question associates existing Geographic Information Systems (GIS's) as well as standard relational databases in a federation, allows the contents of the individual GIS (or relational databases) to be consulted in a manner transparent to the user, and permits the exports of the underlying systems' data under the corresponding set of permissions. Our approach is based upon three principles: compliance with international standards, reliance upon Open Source Software in implementation, and usage of servers of proven reliability and robustness. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

Mexico occupies a very high position in biodiversity, especially for reptiles, mammals, amphibians, vascular plants, and birds. The National University of Mexico (UNAM) and other institutions possess a treasure trove of collections gathered since the 19th century, and these unique collections continue to grow exponentially. Several research centers at UNAM as well as other Mexican institutions, such as the National Commission for Biodiversity (CONABIO), the National Polytechnic Institute, or U. of the Americas, have developed Geographic Information Systems (GIS) concerning biodiversity and spatial information. Because they have been developed independently, the GIS's reflect both the idiosyncrasies of the software used in their implementation as well as the peculiarities of each developing institution. A challenge stems from this multiplicity of origins: To allow transparent access to the information of these dissimilar sources to enable their joint exploitation.

To answer this challenge, there has been research on systems' integration (Levy, 2001; McBrien and Poulovassilis, 2003) and on methods to match ontologies (Aumueller et al., 2005), as well as international standards for specifying:

1. Common schemata for defining the fields for exchanging biodiversity information (Graham et al., 2004).
2. Protocols for accessing, via the Internet, data nodes from a diverse array of biodiversity collections (Graham et al., 2004).
3. Spatial data types and their exchange format (OpenGIS, 1999).
4. Canonical operations for accessing spatial data (Clementini et al., 1993; Worboys, 2004).
5. Catalogs of Spatial Reference Systems (OpenGIS, 1999).
6. Query predicates for spatial features in a Web environment (Clementini et al., 1993).
7. The representation of semi-structured spatial information (Lake et al., 2004) by means of a Geographic Markup Language (GML), a standard developed by the Open Geospatial Consortium.

UNAM has established a University Biodiversity System (UNIBIO) that states as its mission: "the generation of a system that allows the capture, organization and public access to Mexico's biodiversity information". Parallel to UNIBIO, UNAM has established the UNIGEO project to unify its geo-spatial information using the standards of the Open Geospatial Consortium (OGC) (Lake et al., 2004). The Mediator system described in this article has been developed by UNIBIO to unify it with UNIGEO, using international standards to bridge the gaps between the different data sources.

The remaining sections of this document describe related work, explain the system's goals and components, present the architecture of the two main constituents of our project to, finally, give results and enumerate conclusions.

REVIEW OF RELATED SYSTEMS

As mentioned in the introduction, the mediator project involves the integration of two types of information systems: the ones concerning biological collections and those related to geo-spatial information. This section describes work in each of these two fields.

Accessing Biological Collections

Two main XML schemata are used for information exchange and data integration on biological collections, namely, the Darwin Core and the schema of the Task Group on *Access to Biological Collection Data* (ABCD) (Sarkar, 2007; Darwin Core, 2003; ABCD, 2005). These schemata have the following characteristics:

Darwin Core specifies elements that describe the domain of an observation. It has 48 elements, five of them required; the longitude, latitude, geodetic datum and coordinate uncertainty are among the non-required elements. Access to Darwin Core sources is commonly accomplished through a protocol called *Distributed Generic Info Retrieval* or DiGIR (DiGIR, 2001); this protocol obtains data by means of HTTP and XML.

ABCD considers more than 2000 elements and may include, apart from the collection's data proper, information on the metadata and on the providers. The ABCD schema is structured in modules and allows the inclusion of new extensions. The expressivity of this schema is greater than the one attainable by the Darwin Core one; however, this complexity translates in a greater difficulty in adapting it to existing collections, thus reducing its popularity. Access to this schema is provided by the BioCase Access Protocol

A protocol called TAPIR (*TDWG Access Protocol for Information Retrieval*) has been proposed in (TAPIR, 2004). This protocol allows the access of both ABCD and Darwin Core schemata.

The collections of UNIBIO use Darwin Core and are accessed through the DiGIR protocol.

Accessing Geospatial Data

There exist two main methods for integrating information systems: using a Warehouse and using a Mediator.

In the Warehouse approach, all data is transferred to a single information system to be handled in a uniform manner; the Mediator, on the contrary, lets the information reside in their original sources and, when receiving a request, orchestrates a series of queries to the original sources and procedures that mix and integrate the results of these queries.

The advantages and disadvantages of each of these approaches are as follows:

A Warehouse provides these benefits: it simplifies the optimization and processing of queries, since both the data files and its statistics are readily available and the physical structure/indexing of the files can be reconfigured for better performance; it allows the administrator to define cleaning/repair procedures to diminish, for instance, data redundancy or false references; and it enables users to add their own annotations to stored data.

On the other hand, this approach must implement mechanisms for updating the information coming from each of the sources and it may present problems with the ownership of information: old data can still be resident in the warehouse even if one of the sources has denied access to its information.

A Mediator has these advantages: it simplifies the retrieval of fresh data, it is easier to connect to new data sources, and it gives the owners of the data more control on the availability of this information.

In a Mediator, however, the cleaning procedures for data redundancy are more difficult since they have to be executed "on the fly", and the efficiency of query processing is generally lower than that attainable in a Warehouse.

Mediators as well as Warehouses must perform both vertical integration, in which the data of several provenances with similar formats are unified, and horizontal integration, in which the results of the query combine data from difference provenances.

In a Warehouse, these integrations are performed while data is being transferred from a source to the Warehouse. A Mediator, however, performs this integration for each individual query.

For the purpose of data integration, a Mediator needs a method to unify, in a global schema, the schemata of the underlying sources. Two main approaches are available: representing the global schema as views of the local schemata (also known as "Global as a View", GAV) or representing the local schemata as views of the global schema (known as "Local as a View, LAV). The GAV approach, most commonly followed, allows a very simple reformulation of a global query in terms of the local schemata; on the other hand, the global schema is difficult to maintain when a local schema changes. This situation is reversed in a LAV approach, in which a simpler maintainability of a schema is achieved at the cost of a more elaborated query preprocessing.

Finally, a Mediator can obey either a Centralized paradigm, in which the mediation is done in a hub and the data sources must comply with pre-fixed data models and command languages, or a Grid Services paradigm, which relies on a cluster of relative independent nodes that register their services for the description, exchange, replication, and processing of data.

The next subsection gives an example of the Centralized paradigm, followed by two examples that illustrate the Grid Services paradigm.

VirGIS

VirGis (Boucelma et al., 2002) is a mediator for geographic information developed at the University of Provence. This system can combine diverse sources of geospatial information and uses a restricted form of the "Local as a View" method to help in this integration.

The data sources of a VirGIS mediation system are accessed using the Web Feature Service of GML, a protocol used to access information with a spatial component represented in a vector format. VirGIS' users pose their queries against the global schema either by employing Keyword-Valued Pairs (KVPs), or by means of GQuery, a language that extends XQuery by adding spatial operators.

VirGIS is internally comprised of four modules doing these functions:

1. The *Decomposition* Module converts the original query (be it in GQuery or in KVPs) into a sequence of elementary requests expressed in terms of the global schema; these queries form an initial version of the execution plan.
2. The *Rewriting* Module considers both the transformations dictated by the global schema and the sources' capabilities, and uses these considerations to rewrite each of the elementary queries generated by the decomposition module, producing subqueries that can be understood by the data sources.
3. The *Execution* Module sends the rewritten subqueries to the corresponding data source and combines the results.
4. The *Recomposition* Module processes the results of the execution module, removes duplicates (if necessary), and returns the results as a GML stream.

In future versions, VirGIS contemplates the development of further query optimization.

Grid Enabled Mediation Services (GEMS)

GEMS (Zaslavsky et al., 2003) is a collection of grid services developed at the San Diego Supercomputer Center, that supports spatial data mediation, ontology and schema conflict resolution, and composite map assembly.

These grid services have been developed within the Geosciences Network Project (GEON), a network that allows its information to be searched using sets of keywords, descriptions, titles, or by means of ontologies.

GEMS allow users to register their datasets and to formulate queries that the system rewrites to suit the idiosyncrasies of the individual datasets, since geospatial sources follow different and often incompatible schemata. To harmonize dissimilar sources, query reformulation requires that the elements of the database schema be associated to concepts in a domain ontology; this association is done at registration time.

The process of a data source's registration involves providing information about the manner in which the source's metadata is to be indexed using a domain ontology, about the source's schemata and the source's exported functions, about the mechanisms to access the source, e.g., ODBC, Web Services, etc., and about the permissions used to specify control restrictions according to a GEMS role-based authentication mechanism

In GEMS, ontology/based queries go through the following four services.

1. A *Concept Expansion* Service, in which the terms and returns the descendents (hyponyms) of the concepts used in the query. Thus, as mentioned in an example in (Zaslavsky et al., 2003), a query that requests formations in the Tertiary age will return the concepts "Neogene", "Pliocene", "Placenzian", "Miocene", etc., all descendents from the Tertiary.
2. A *Concept Resolution* Service, used to provide all values that reference the terms expanded by the previous service. Thus, in the example cited, the returned values may include "Tertiary", "Quaternary/Tertiary", "Tertiary/Cretaceous", etc. The values provided by these service are used to modify the "WHERE" clause of the original request.
3. A *Mediation* Service that forwards each of the data sources its corresponding fragment of the rewritten query, directing their answer to the assembly service.
4. A *Map Assembly* Service that, taking into account the initial query, retrieves into a local staging area the fragments generated by each data source, performs (if required) the necessary transformations and forms a composite map to be returned to the user.

Global Earth Observation System of Systems (GEOSS)

GEOSS (Khalsa et al, 2007) is a project of the Group on Earth Observations (GEO), providing an infrastructure of analytical tools and data for public information.

The systems that participate in GEOSS, though initially developed to suit their individual needs, must adapt their inputs and outputs to be interoperable with other systems. Presently, GEOSS has the IP3 Project (*Interoperability Process Pilot Project*) that concentrates on the interoperability situations that come to light by trying to interface with other systems affiliated to GEOSS via "interoperability arrangements".

For this, IP3 has implemented a Component Register. If a component is to be included in the Register the corresponding organization must complete a registration form, citing all interfaces of the service to be registered. The registering organization is presented with a list of standards existing in the Standards Register, needing to select the ones that apply to the service. If all interfaces to be registered obey one of those standards, the component's registration can be submitted; otherwise, the process is referred to a forum for further consideration.

In the next three sections, the system's goals and general structure will be presented, to then describe in more detail its principal elements.

SYSTEM'S GOALS

Three goals were set prior to the system's design:

1. To form a federation of GIS' that integrates the rich and growing trove of Geographic, Biologic and Environmental information at UNAM into a uniform information system. This system will allow the access of each member's information as if it resided in a single database, transforming, if needed, between coordinate systems. This federation will allow both the vertical and the horizontal integration of data sources.

2. To provide users with access to this information via a graphic interface. The queries will be able to span simultaneously several sources and to utilize spatial predicates (e.g., “give me all species collected in Cajeme County”). The results of the users’ queries will be rendered in GML (Lake et al., 2004); information requests to individual sources will make use of GML’s services, like the *Web Feature Service* (WFS) and the *Web Map Service* (WMS) (OpenGIS, 2002). The query interface will provide all predicates and functions specified by OGC.
3. To provide the client with capabilities to navigate and analyze the results of a query, giving it the option to export them to another system to perform more detailed analysis (e.g., Data Mining).

It was decided to adopt a Mediator (vs. a Warehouse) solution because it allowed more respect to the rights of the data owners and more flexibility in including data sources. Still, the implementation agreed upon is, in a way, a hybrid of both approaches. This is because the system, though capable of mediating among different sources, can still store in a warehouse (a PostGis database) either data that has been entrusted to it or data that has been periodically mined from some selected DiGIR sources; this warehoused information is seen by the mediator as resident in a special kind of source that can resolve more complex queries.

System’s Components

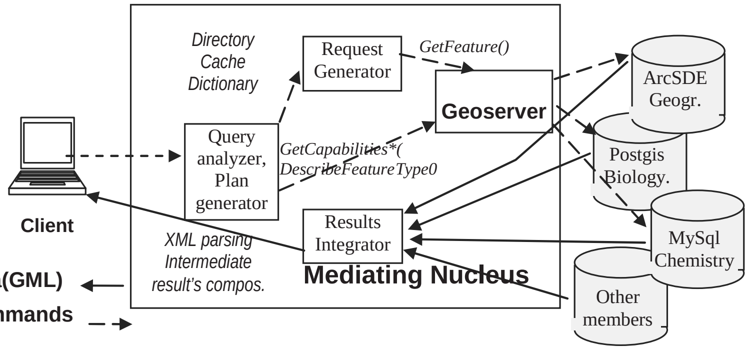
To achieve the three goals above, the system is designed and formed by the three components as shown in Figure 1:

1. A client that produces information requests.
2. A mediating nucleus that receives HTTP commands from the client to then analyze and decompose them into a series of requests to the individual members of the federation. Once the members’ responses arrive, these results are processed and combined, and finally, the response is sent to the client in a GML format.
3. The individual members of the University Biodoversity System (and of UNIGEO). There are two conditions for joining this federation: to permit one or more mediators to access the contents of the potential member’s information contents, and to be capable of rendering these contents by means of a standard service.

Results’ Format and Structure

The client was designed to have the following capabilities: (a) To formulate queries involving

Figure 1. System’s diagram



several sources, using join conditions; (b) to display the spatial component of the results of query and to show, if requested, non-spatial attributes; (c) to store temporarily the results of a query, and to be able define predicates for selecting subsets of the results without resorting to the mediator; (d) to navigate from a selected subset of data elements to a different subset of elements related by the query; and (e) to export using standard formats the results of the execution of a query, so further analysis can be performed on them using specialized tools.

Since the queries posed to the mediator may decree the existence of joins on the information of two or more sources, three alternative format options were considered for returning a query's results to the client:

1. Flatten all results into a relational table.
2. Use a nested representation.
3. Use an ER (Entity/Relationship) model to provide the results in which the relationships are determined by the associations between entities dictated by the join conditions.

The following considerations, related to the types of data sources, were taken into account to decide on one of the previous options: (a) UNIBIO allows information retrieval using DiGIR (DiGIR, 2001) that follows the Darwin Core standard; (b) UNIGEO, in turn, uses two services defined in the GML standard: WMS (Web Map Service) that supplies information in an image format and WFS (*Web Feature Service*) that provides information in a vector format; (c) neither the DiGIR nor the WFS data format allow nesting on any of their non-geometric elements and; both DiGIR and WFS sources provide unique identifiers to each data record (GUIds for DiGIR, Feature Identifiers or FId's for WFS).

The first option was discarded because, in addition to requiring extra data transmission, it would complicate the implementation of the client's ability to navigate between subsets of elements associated by the query. Since the client's design did not prescribe any particular nesting order and since both DiGIR and WFS do not allow nesting, the third option was preferred over the second one and, thus, it was decided to send the entities to the client using a GML format, and the relationships as pairs of FIds/GUIds.

The rest of this article is organized as follows: initially, both the nucleus and the client are described, then some performance results are given and, finally, conclusions and future plans are presented.

DESCRIPTION OF THE MEDIATING NUCLEUS

The mediating nucleus obtains information from three categories of sources:

1. Members that allow the access to their individual servers, either in its native form (e.g., ArcSDE) or using a GML source.
2. Sources that, for performance reasons, deposit their information in a spatial data base server intimately related to the nucleus.
3. Sources that are accessible through DiGIR servers, who, periodically, will have their information migrated to the nucleus' server.

The first category of sources will be accessed by means of a *GeoServer*, an open source platform that uses OGC standards to connect to GIS's in an uniform manner (Geoserver, 2003), while the information of the remaining two categories will be deposited in a PostGIS server.

The nucleus is composed of several environments; these environment are either aimed at supervising the client's connections (the *Connection's* Environment), or at administrating the users' permits (the *Users*' environment), or at handling the DiGIR migrating environment (the *Migrating* environment), or at managing the registration and exposing the contents and metadata of the federation's servers (the *Servers*' environment), or at solving the clients' queries (the *Per-Query* environment).

Figure 2 illustrates the relationships among the nucleus' components.

The next paragraphs will concentrate in the discussion of the per-query environment that optimizes, executes and assembles a user's requests.

The Per Query Environment

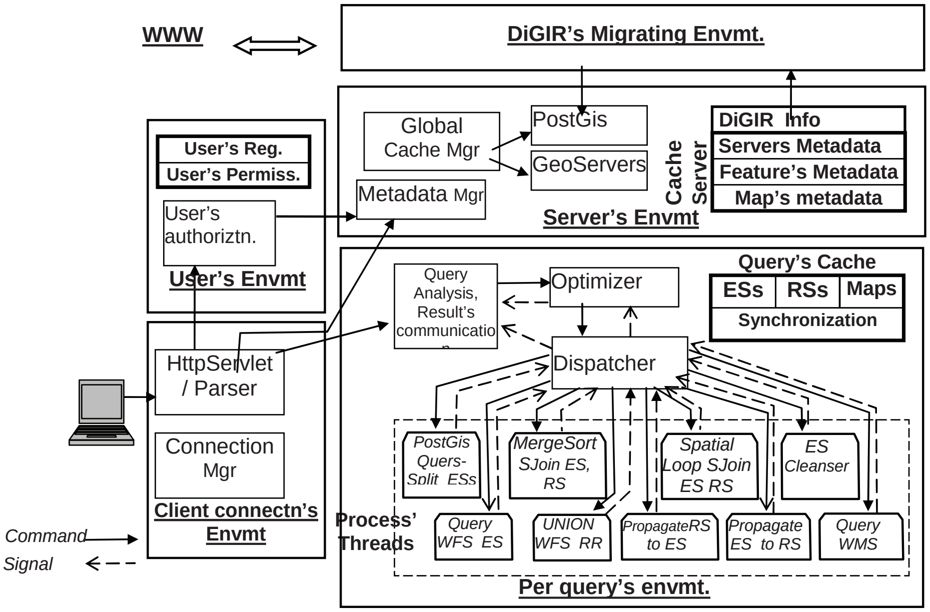
The Per-Query (*PQ*) environment receives two kinds of information requests from the client:

1. Requests asking for background maps using a command of GML that obtains an image of geographic data rendered in a pre-defined style; these requests are merely delegated to a GML server.
2. Requests involving one or more types of spatial features, usually related by join conditions. These requests require a more extensive processing, described in the paragraphs below.

Only the second kind of requests will be discussed here. Inside the nucleus, the PQ environment uses a GML format to handle both the intermediate results and the final solution to these requests. This information is represented by means of two kinds of structures:

1. *Entity Structures* (ES), one for each collection of features involved in the query; according to the GML standard, every component of a feature collection is associated with a FId (Feature Identifier), which is unique within the feature's source.
2. *Relationship Structures* (RS), one for each pair of features involved in a join condition. Each of these structures contains a collection of pairs of FId's that represent the associations created by the join condition involved.

Figure 2. Nucleus' components



In the Per-Query environment, a query is solved in four stages:

1. Parsing and analysis. The client sends, via HTTP, a XML coded request representing a Select-Project-Join-Union query; the format employed reuses WFS's schemas for coding the selects. The request dictates, in addition, the spatial projection in which the results are to be rendered. If the request is correct, query processing continues to the next stage.
2. Optimization. Once the query has been parsed, the set of possible execution alternatives must be explored searching for a good execution plan. To evaluate and generate possible alternatives, several things are needed: (a) methods to formulate sets of equivalent execution plans for the query; (b) formulas to evaluate the performance of candidate plans (these formulas are based on the statistics of the data processed by the query); and (c) methods to retrieve these statistics.
3. Execution of Tasks. The optimizer produces a sequence of operators to be applied to the data; this plan is sent to the Dispatcher for its enforcement. In turn, the Dispatcher launches a sequence of threads, one for each operator whose entry data is ready, starting from the plan's "leaves". When a thread terminates its task, the Dispatcher consults the optimizer's plan and either launches a new operator or sends the results to the client.
4. Submission of results. When the plan completes execution, be it normally or because of an error, the Dispatcher forwards the query's results (or failure notification) to the Query Analyzer. Once this task is completed, the corresponding PQ environment disappears.

The next two entries describe, respectively, optimization and task execution.

Plan Optimization

A good execution plan, specifying both the kind and the sequence of the operators to be applied, is crucial to achieving an adequate performance. Obtaining a proper plan requires quantifying the costs of each alternative. These cost functions, in turn, need numerical and statistical information both on the input and the output data structures. Attaining this information involves, among other issues, obtaining the cardinality and size of the structures and the values (or sets of values) contained in them. In commercial database systems this information is typically acquired by processes that sample the data at idle times.

This statistical information is not available in the kind of servers that integrate our federation (OpenGIS, 2002) that can only provide either full sets of results or the cardinality of them.

As an initial solution, the Mediator dictates the order of the semijoin's plan, giving priority to non-spatial over spatial operations and, when considering semijoins that use the same kind of operators, giving preference to those associated with the structures of least cardinality. Both the propagation and the cleansing operations are delayed until needed.

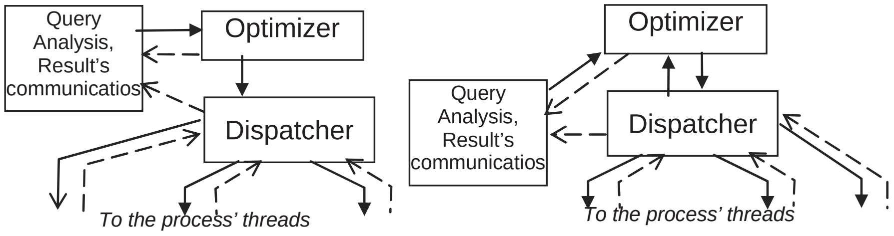
Thus, at present, an architecture in which the optimizer dictates a plan prior to processing is used (Figure 3, Option a).

In line with Deshpande et al., (2007) and lyas et al. (2007), the optimizer and the dispatcher are being redesigned to interact with each other periodically (Figure 3, Option b). In this design, as the operations proceed, the plan is re-examined once certain operations finish; at these points, statistics can be obtained or modified, and a decision made as to whether to continue with the existing plan or to switch to a more promising one.

Task Execution

The threads executed by the dispatcher perform three kinds of tasks:

Figure 3. Two alternatives for the optimizer in the PQ environment



Option a): A-priori plani

Option b): Periodic adaptation

1. Populating the ES's from the data sources.
2. Performing intermediate operators to the ES's and RS's.
3. Cleansing/adapting the results.

In addition to these three tasks, the Dispatcher assigns and manages the memory resources to store the ES and ER structures, orchestrates the synchronization mechanisms needed to coordinate the different threads, and can terminate the execution of a query upon receipt of a client's request. The following paragraphs explore the three kind of tasks cited.

Populating the Entity Structures (ES's)

Presently, the ES's are populated by two methods: (a) by means of a WFS request that retrieves data obeying a certain conditions or (b) as a consequence of the execution of a PostGIS plan. We are planning to include a third method, using DiGIR, a protocol for retrieving structured data from biological collections.

Populating an ES via a WFS command is done by sending a WFS request to the corresponding source; in the case of one accessible by GeoServer, this request includes the "Select" predicates related to the associated Feature.

Populating the structures via PostGIS plan differs from the method above in that the command's execution may fill one or more ES's as well as some RS's. To formulate such a query, the query analyzer processes the query graph, looking for maximal subgraphs that are: (a) connected, and (b) composed entirely of features resident in the Mediator's entrusted data that resides in PostGIS. After these queries are executed, the results are split into the corresponding ES's and RS's, translating them into GML.

Intermediate Operators

Entity Structures are initially populated by sending a request to the corresponding source; the request includes the "Select" predicates associated to the source in question.

The mediating nucleus can perform "Select-Project-Join-Union" queries: Since the "Select" predicates are performed by the data sources, the nucleus implements operators to perform the Union and Join capabilities. The Project functionality will be discussed when describing the cleansing and adaptation of results; the implementation of the Join and the Union capabilities has the following characteristics:

Join Operations. To reduce memory footprint, Joins are implemented as of a program of double semijoins; Suppose, for instance, that two ES's named A and B are semi-joined, perhaps this operation will eliminate some tuples in A and/or in B and also will produce a new RS (R$_{AB}$,) made of pairs of those Fid's of A and B that are associated by the join's condition. If, at a later time, A is needed in a new join with C, the new reductions caused in A will be propagated first from to A to R$_{AB}$ and then from R$_{AB}$ to B. Thus, the nucleus has implemented operators (a) to propagate changes from an ES to an RS and vice versa and (b) to perform semijoins; this latter operator comes in different implementations to consider either spatial or non-spatial predicates.

Union Operations. The version presently implemented by the nucleus requires that all of the ES's involved in it must have the same schema, this being a constraint of DiGIR.

Cleansing and Adaptation of Results

These operations are executed "just in time" by the ES cleaner (Figure 2); this component can concatenate these operations to execute them, if needed, in a single pass. These operations include: (a) Algebraic Projection operators, to remove fields that are no longer included; (b) transformation of spatial coordinates to the cartographic projection desired by the client; and (c) application to individual fields of functions that are required either at the output or to perform some intermediate step, like transformation to upper/lower case, field concatenation, XML type transformations, elimination of accents, etc.

DESCRIPTION OF THE CLIENT

This tool, programmed in C++, has been designed as a semi-light component; this means that, in order to reduce the information flow from/to the mediating nucleus, the Client can maintain state by storing a query's results either to do some exploration on them or to export them to another program.

The Client allows a user to query the members of the federation in graphical form; these queries are sent via *http* to the Mediator. The layout of the client's windows have been inspired by *uDig*, a desktop internet GIS (http://www.refractions.net:8080/confluence/display/UDIG/Home).

The client has four types of windows:

1. *ViewPort*. It is the principal panel that contains both editors and views.
2. *Views*. Their mission is the display of metadata, be it a catalog of the federation members' features, or descriptions of the projects stored in the client, or of the maps generated inside a project, or of the layers that constitute a map. These results in four views: *Catalog*, *Projects*, *Map*, and *Layer*; a layer, in turn, may contain the results of more than one query.
3. *Editors*. They are used to either pose queries or to display data (vs. metadata). There are four of them: (a) *Map* editor. It is used to display the results of queries, represented against background provided by WMS, the map service specified in GML. This editor is the main window of the client and the user may access from it other editors or tools that allow her both to explore the data contents of the results as to navigate through the relationships established by the join conditions; (b) *Query* editor, which poses a request to the mediator, using a graphic interface *a la* Microsoft's Access; (c) *Attribute* editor, which shows the attributes of sets features selected from the map editor; and (d) *Graphic* editor, which allows the definition of polygons, points, lines, etc. in a vector form, to be used in the conditions of Select predicates.
4. *Tools*. They are specialized graphic components, invoked from either views or editors, used to perform certain tasks. Examples of them are: the *Join-predicate* tool, called from the Query editor; the *Map* tool, used by the Map view to prescribe which contents of the map editor are to be shown, as well as their depth order; the *Style* tool, called either from the Layer view or from the Map editor, to select the colors and transparency of the layers within a map, their order of display, and the attribute used to tag a feature; the *Selection and Navigation* tool, to choose subsets of a

certain feature type or to navigate from one subset of features to corresponding subsets in other features related by the query; and a tool used to obtain background maps.

Tables 1 and 2 list the tools, editors and functions accessible from the Map Editor, as well as their icons.

To start a session, the client will connect to a chosen mediator. Once the connection is established, the Catalog view (as well as the icons on shown on the ViewPort) is activated; later clicks on the catalog view will request the metadata of the members of the federation, by issuing to the mediator WFS commands to obtain the data sources available and, for each one of them, metadata describing the source's contents. The system, in turn, will forward these commands to the Geoservers connected to the mediator or to the internal PostGIS database.

To illustrate the usage of the query editor, one can consider a request to localize, within a certain area of interest *A*, the existence of plant species that contain strychnine and are within a certain distance of a river. Suppose that the Institute of Chemistry has a purely relational database (no spatial features) on the contents of plant species (*Compuesto*), that Biology has a spatial table called "*Colectas*" with the collections of plants, and that the Institute of Geography has maps of rivers (*Rios*).

Table 1. Tools/editors accessible from the map editor

Icon	Editor or Tool
🖌	Style tool
✎	Graphic editor
▷	Selection/navigation tool

Table 2. Functions accessible from the map editor

Icon	Function
✖ ↻	Clean/refresh map editor
✥	Adjust to window
⊕ ⊖	Zoom in/out
X	Cancel command's execution

Formulating the query has three steps:

1. Dragging the features involved in the query (Chemical Contents, Collections, and Rivers) from the catalog view to the query editor. Figure 4 illustrates the results of this step.
2. Including into these features the "Select Conditions", e.g., that the collections have to be inside a certain area, or that the plants in the Chemical Contents feature must have strychnine. This step also defines the attributes that are to be retrieved for each feature.
3. Specifying, by means of the Join-predicate tool, conditions to build relationships among the different features of the query.

The client will translate this inquiry to a Query graph, and will send it to the Mediator using a SOAP command.

RESULTS AND PERFORMANCE

The performance of spatial joins in the Mediator, including the Web retrieval from the individual sources, is comparable or superior at times to the one achieved by PostGIS using spatial indices; the performance of non-spatial joins in the Mediator can be three to eight times slower than PostGIS.

Performance, Non-Spatial Joins

Table 3 describes the results of an equijoin between two relations, *cab_mun* that has data about the head cities of the municipalities in Mexico and *marloc95a* that contains information about townships; the table shows the results of queries that return the populations and geometries (the "*the_geometry*" attribute) of the cities and munici-

Figure 4. Adding three features to the query editor

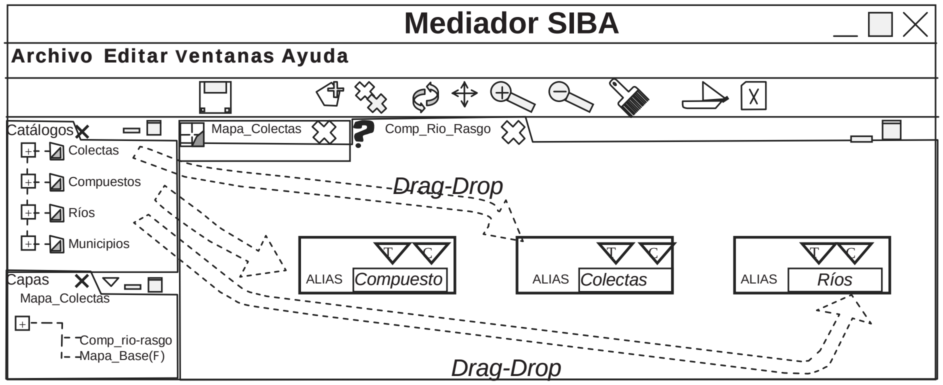


Table 3. Comparison, Mediator vs. PostGIS, non-spatial query

#R1, #R2	# Results	Time, (sec) Mediator Geo-server	Time (sec), PostGIS
2443, 2500	581	1.032	0.172
2443, 5000	1,111	1.328	0.328
2443, 10000	2,340	2.156	0.641
2443, 20000	4,011	3.484	1.094
2443, 30000	6,114	5.172	1.656
2443, 40000	8,123	6.484	2.187
2443, 50000	10,091	8.140	2.703

palities, using different subsets of *marloc95a*; the Mediator used a sort-join algorithm that used an external sort. The PostGis query, in SQL, is:

SELECT R1.gid, R2.gid, R1.total_pop, R2.tot_population,

ASGML(R1.the_geometry), ASGML(R2.the_geometry)

FROM cab_mun R1, marloc95a R2

WHERE R1.tot_population = R2.tot_population

Performance, Spatial Joins

Two example queries are presented to evaluate the performance of spatial joins. Both queries use a mammal's collection extracted from a Darwin Core depository and a weather map of a geographic sub region of Mexico (*clima1mg*); in both data sources, the spatial component is called "*the_geometry*". The first query obtains the rodents that are within the sub region; the second one obtains the rodents that are in an arid climate. The first PostGis query is:

SELECT COUNT (c.gid) FROM clima1mg c, mammals c1

WHERE c.the_geometry && c1.the_geometry

AND CONTAINS (c.the_geometry,c1.the_geometry) AND c1.order='RODENTIA'

The second query adds an extra conjunction (*AND c.clima_llav=23*) to the first one.

The processing times are shown in Table 4:

CONCLUSION AND FUTURE WORK

In its current form, the Mediator does not support cyclic queries or aggregate functions; its implementation of union operators is limited and it only admits conjunctions as join predicates; selection predicates, however, are not restricted. The plan is to allow cyclic queries, using methods similar to those of Kambayashi et al. (1982).

Presently, the Mediator can access information in GML and DiGIR servers. It is planned to

Table 4. Comparison, Mediator vs. PostGIS, spatial query

OPTION	Query 1		Query 2

expand the system to access information in Grid Raster format, to be able to include data like that related to the climate information contained in WorldClim (WorldClim, 2008).

GML servers, in their present stage of development, do not support aggregate or sampling functions necessary for obtaining statistics needed by the optimizer. To solve this, a process of designing and implementing an adaptive query processor has been started (Deshpande et al., 2007); Ilyas et al., 2007).

Finally, users have expressed a need to query the mediator about what information is available on certain topics in predetermined regions so that they can pose queries involving non-familiar origins. It would be advantageous to allow the client to provide, for each of the data sources, richer information about the metadata (other than data types, value ranges, etc.), and to allow accessibility to the ontologies that describe these sources, in the lines of Torres et al., (2005) and Bartolini et al., (2006).

Therefore, the Mediator's future developments will be directed by users' needs as expressed in the focus areas of accessibility and information about contents.

ABSTRACT

Organizations are implementing IT Service Management (ITSM) and creating quality standards to design, deliver, and manage IT services to meet or exceed an agreed level of quality. ITSM uses the best practices of IT Infrastructure Library (ITIL) that informs IT management what needs to be done and how it will get done from the process perspective. However when undertaking an ITSM a project to implement ITIL, ITIL does not provide a method for measuring quality or identifying and completing process improvement projects. By integrating the Six Sigma quality methodology, IT management will have the methodology and tools for measuring quality and improving processes. Adopting Six Sigma principles also helps IT managers focus on their business strategy and customers, manage proactively based on facts, and reinforce collaboration across the enterprise. The framework in our exploratory experience based research has been built upon a deductive study which has been developed through a literature review and synthesis and an exploratory inductive research which has been developed using a qualitative case study methodology in the e-services and mobile applications field. [Article copies are available for purchase from InfoSci-on-Demand.com]

OVERVIEW OF INFORMATION TECHNOLOGY SERVICE MANAGEMENT (ITSM)

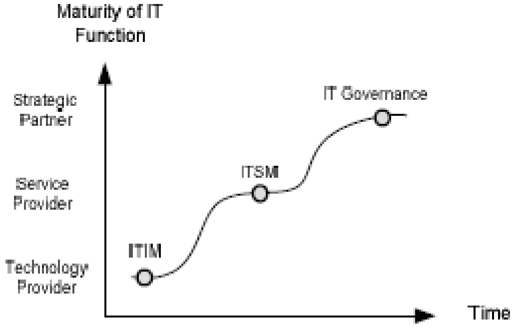
Today's executives are challenged to deliver value to their shareholders in a global market place and to compete, organizations are setting business strategies for the entire organization. This management change presents a significant change for Information Technology (IT) organizations that have historically dealt with individual business units or functional domains. Now IT must support the enterprise's business strategy and the entirety of the enterprise. Technology organizations must deliver interoperation of processes, people and technology to the entire enterprise.

The rise of services oriented architecture, client server computing, virtualization and distributed applications have created a plethora of moving targets in the information technology (IT) organization. IT organizations have had to deal with a business that have historically been siloed by function or department and have been separated from the business. However since organizations have adopted an enterprise approach running their businesses, IT managers can no longer run an IT organization as a technology-based organization. They must be able to migrate to being a value-based service provider and contributor to the enterprise strategy instead of an overhead cost. IT Service Management (ITSM) is a process-based practice intended to align the delivery of IT services with needs of the enterprise, emphasizing benefits to customers. ITSM involves a paradigm shift from managing IT as stacks of individual components to focusing on the delivery of end-to-end services using best practice process models (WhatIs.com, 2008). Information Technology Infrastructure Library (ITIL) is a globally recognized collection of best practices for information technology (IT) service management.

ITSM audits are based on analysis of four key performance indicators in specific ways:

- Growth and value, which involves tracking revenue growth against investment and utilization.
- Budget adherence, which involves optimizing the use of available funds and avoiding unnecessary expenditures.
- Risk impact, which involves identifying and evaluating the consequences of risks taken or avoided.
- Communication effectiveness. IT managers need to adopt a service management approach consisting of well-defined IT processes and a continuous improvement program in order to meet their customer's expectations and contribute to the enterprise's goals.

Figure 1. Evolution of the IT function within organizations (Salle, 2004, p. 1)



ITSM Evolves IT to Achieve Higher Result with Business Focus

To meet the challenge, IT managers in USA are adopting ITSM, a practice that has been used by their European counterparts for over 24 years. According to Salle (2004), the evolution of IT organizations typically mature through three stages: technology provider, service provider and strategic partner.

Continual maturity occurs as the IT organization moves through each stage. In the initial stage the IT organization operates as a technology provider and it is using IT infrastructure management (ITIM). In this stage, the focus is to manage and provide a solid infrastructure to the enterprise by maximizing the return on technical assets and controlling the infrastructure including its hardware and data. As an organization moves to becoming a service provider it will use ITSM which leverages ITIL to identify the "services its customers need and focusing on planning and delivering those services to meet availability, performance, and security requirements. In addition, IT is managing service-level agreements, both internally and externally, to meet agreed-upon quality and cost targets. Ultimately, when IT organizations evolve to IT business value management (IT Governance), they are transformed into true business partners enabling new business opportunities. In that stage, IT processes are fully integrated with the complete lifecycle of business processes improving service quality and business agility." (Salle, 2004, p. 1). Alternatively the Capability Maturity Model Integrative (CMMI) model from the Software Engineering Institute can also be used as the organization evolves in the maturity level of its processes.

This article is structured as follows: the key attributes of ITSM, ITIL and Six Sigma are discussed independently before illustrating some business cases integrating ITSM, ITIL and Six Sigma. This is followed by the discussion of the implications for research and management before the conclusion. The framework in this exploratory experience based research has been built upon a deductive study which has been developed through a literature review and synthesis and an exploratory inductive research which has been developed using a qualitative case study methodology in the e-services and mobile applications field. It makes the case for leveraging ITIL and Six Sigma with ITSM in practice and discusses opportunities for future research and implications for management.

ITIL

What are ITIL and ITIL Service Management Practices?

The U.K. government's Central Computer and Telecommunication Agency created ITIL. It is a framework and does not require a license to practice and it is independent of any commercial solution or platform. In the last 24 years, ITIL has become a de-facto standard and most widely used accepted approach to define processes for IT service-oriented organizations. It aligns IT processes to overall business goals. ITIL is a guide for establishing common processes, roles and activities, with appropriate reference to each other and how communication lines should exist (ITIL, 2007). Although processes dictate how services are delivered, processes are of little interest to customers because they are not visible. ITIL is a public domain set of books that describes comprehensive and consistent best practice guidance in the area of organizing a coherent process for IT Service Management. In the late 1980's when it was originated it consisted of more than 30 books, but the release of ITIL V3 condensed the framework into 5 books.

The latest version is ITIL V3 and it is designed to address the significant shortcomings of ITIL V2. ITIL V3 has a broader scope and contains everything that was included in Version 2. Version 3 pays more attention to the areas of designing services suitable for the business and creating a strategy around this. Version 3 gives more advice on Continual Service Improvement (Damiano & McLauglin, 2005, p. 253). ITIL V3 addresses the life cycle of service management. It embraces a more holistic service management practice that included business and IT at strategic, tactical, and operational layer. While in comparison, ITIL V2 focused just on the operational layer of IT operations. The new version provides best practice guidance to implement a true life cycle of service management in five best practice guides. Version 3 of ITIL library consists of 5 five sets of books (See Table 1).

Benefits of ITIL for Service-Oriented Organizations

ITIL's framework of best practices can be used to assist organizations as their needs and technology evolve around processes. ITIL Service Management Practices offer benefits that demonstrate their value and ROI. Organizations can use ITIL to add more value to their business, be more agile with their responses, define standards, implement new technologies, adopt new trends, regulate compliance, and improve the quality of IT services. Additionally, companies gain higher productivity from both business and IT staff. These best practices for the support and delivery of IT services can help a company document IT processes as required for Sarbanes-Oxley (Worthen, 2005). ITIL is part of the foundation of the COBIT model, which defines control objectives for IT in support of business processes. COBIT was explicitly chosen as the tool of choice for external auditors to use in IT audits for Sarbanes-Oxley. The ITIL process documentation and COBIT control objectives are a powerful combination that can accelerate Sarbox compliance. ITIL allows IT staff to become more innovative in their work. "The results of a recent survey by Axios Systems, show that over one-third of IT professionals have already adopted the ITIL framework, while another one-third plan to roll-out the framework within a year. In the same research, 70% of the Best-in-Class businesses had the ability to measure end-user satisfaction and 60% of the Best-in-Class businesses could compare service delivery standards against SLA provisions" (Brown, 2007, p.5).

Table 1.

Book	Responsibility of Book
Service Strategy	Defines the policies and strategies to implement Service Management in line with the overall business strategy. It focuses on the planning aspect of the policies and strategies.
Service Design	Describes how to use the strategy to create design and specifications for the service. This book has more structure and explains a step-by-step approach to designing services. Much of what was in this book was already addressed by ITIL v2 with the exception of security management.
Service Transition	Covers configuration, change and release management. Change management focuses on how to assess and plan for changes. Configuration management has been extended to include service assets or IT assets, which are important for IT to be aware of. This book also Details how to get the specification into the live environment.
Service Transition	Defines how to best support the support the day- to-day running of the service throughout its life cycle. Provides guidance on running a live production environment.
Service Operation	Provides a framework for Continual Service Improvement. Service performance is measured at each stage ensuring that IT align and continually realign to the needs of the business. This book makes it clear that, for organizations to become more proactive, assessments must be a continual process, rather than one that only happens when a failure occurs.

What Does ITIL not Do?

ITIL does not focus on a specific industry segment or restricted geographically. ITIL does not address who within the organization is going to be in charge of implementing each process. It does not address the how to use the tools that are needed to implement these processes. ITIL does not offer corporate or organization certificates but rather personal certification. Certification does not guarantee service quality and this is a common misconception within IT organizations. Many vendors and consultants offer services in restructuring ITIL, and many customers seek such guidance. However, ITIL does not promote an organizational structure, or require any particular management. Nor does the ITIL mandate any particular workflow design or process. Here is a quote from ITIL: "For each of the processes described in this book, one or more roles are identified for carrying out the functions and activities required. It should be noted that organizations may allocate more than one role to an individual within the organization, or may allocate more than one individual role. The purpose of the role is to lace responsibility rather than to create an organizational structure" (ITIL Organization, 2006)

What you Need to Know before Adopting ITIL?

ITIL's core practice guides are adaptable and applicable within a variety of organizational context. However, every organization is different and should have its own unique requirement. ITIL can be intimidating to understand and organizations should realize that you can not conform to, adopt, comply with or implement ITIL because it is not a set standard and you can not use what ITIL says verbatim.

IT is a service function providing effectiveness, value, and support to the enterprise and its strategy. Organizations should focus on service and business performance improvement first and not processes. An organization should put in place just enough process to answer the question for any given situation to avoid adding processes that don't add value or are not definitive.

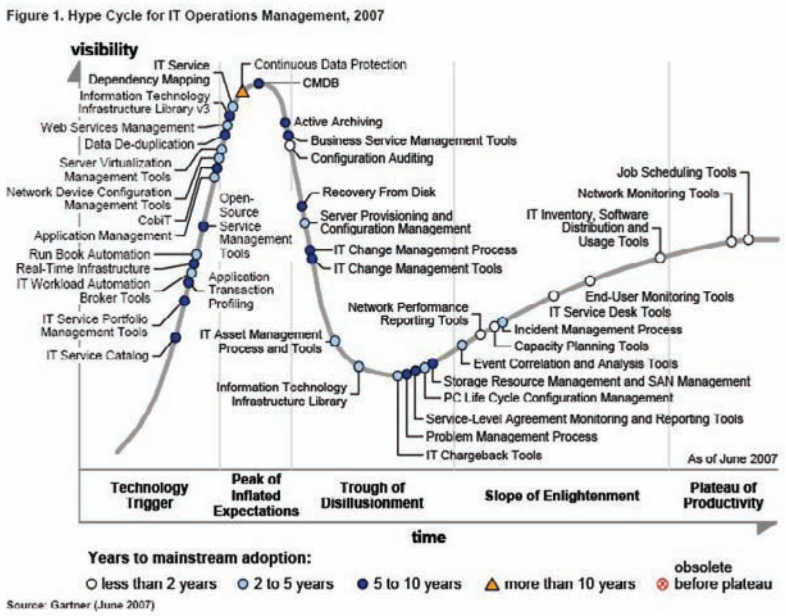
Organizations have been adopting ITIL for approximately 25 years. As illustrated in figure 2, that is consistent with the diffusion theory organizations are moving towards becoming service providers as discussed by Salle in 2004.

SIX SIGMA

Six Sigma was introduced and created by the U.S. based electronics manufacturer Motorola, Inc. In the mid-1980's CEO Bob Galvin established a goal to improve "all products – goods as well as services – by an order of magnitude (e.g. factor of 10) within 5 years" (Klefsjo & Wiklund & Edgeman, 2001, p. 31). During this time, Motorola's field sales force received and reported increased customer complaints about warranty claims. To address the issue, "Bill Smith, a senior engineer and scientist within the Communications Division" invented the new quality method, Six Sigma which standardized the counting defects; by reaching Six Sigma defects would be "near perfect," only 3.4 defects per million. Smith convinced Bob Galvin that this process would be a "key to addressing quality concerns" (McCarty, 2004, p. 1). "Six Sigma clearly focused resources at Motorola, including human effort, on reducing variation in all processes, that is to say manufacturing processes, administrative processes and all other processes. To set a clear measure on the improvement work, the program called Six Sigma was launched in 1988" (Klefsjo et al., 2001).

Antony, (2007) states, "There have been three recognizable generations of six sigma. The first generation of six sigma lasted for a period of 8 years (1987-1994) and the focus was on reduction of defects. Motorola was a great example of a successful first generation company. The second generation of six sigma spanned the period from

Figure 2. Hype cycle for IT operations management, 2007 (Govekar et al., 2007)



1994 to 2000 and the focus was on cost reduction" (p. 17). During this period the methodology was popularized by GE's, CEO Jack Welsh embracing the approach to quality. For example, "AlliedSignal attained savings of $US2 billion during a five-year period while General Electric saved $US1 billion over a two year window" (Klefsjo et al., 2001, Six Sigma origins section). The third generation, according to Antony (2007) started after 2000, and its focus "is on creating value to customers and the enterprise itself. The first companies to embrace third generation of six sigma are foreign. Examples of third generation of six sigma companies include Posco, Samsung, etc." (p. 17).

Six Sigma Themes

Although the beginning of Six Sigma is steeped in quantitative analysis, it is a misperception that Six Sigma is only a statistical measure with a goal of perfection. Pete Pande and Larry Holpp (2002) in the book "What is Six Sigma?" assert Six Sigma is more than a statistical and process methodology and they distribute Six Sigma into Six themes:

- Understand and focus on the customer.
- Be dependent on data- and fact-driven management.
- Master and improve your key processes.
- Manage proactively.
- Collaborate across boundaries within the organization.
- "Drive for perfection, but tolerate failure" (p. 14-16)

Six Sigma Methodologies: DMAIC and DMADV

There are two key Six Sigma methodologies: DMAIC and DMADV. DMAIC is an acronym for Define, Measure, Analyze, Improve, and Control. DMADV is Define, Measure, Analyze, Design, and Verify (DMADV). According to Kerri Simon (2002) in the article, DMAIC versus

DMADV, the DMAIC method is predominant in Six Sigma implementations and "should be used when a product or process is in existence at your company but is not meeting customer specification or is not performing adequately." Practitioners when employing DMAIC, seek to "root out and eliminate the causes of defects" (American Society for Quality). Pande and Holpp (2002) agree that organizations needing to fix broken processes can reap benefits of implementing DMAIC. By using DMAIC organizations will have proven and identified the extent of the problem. By assessing and measuring problems, an organization will be spending time and resources solving high value problems. When the problem is proven and selected for resolution, its root cause is identified using data and facts, not intuition and gut feel. As the DMAIC team works to create a solution, their purpose is to affect real change to the existing problematic process. The resulting solution must be well tested to manage risks to the organization. After the solution is implemented within the enterprise, the organization measures the results validates that the solution is sustaining change (2002, p. 30-31). In the table below, Chieh (2007), outlines in the chart below how DMAIC can be utilized to fix under performing processes….

When designing new processes, the approach used is Design for Sigma Six (DSFF). DSFF uses DMADV not DMAIC in order to design and move to market "new products or services measures by customer-based critical-to quality metrics" (Foster, 2007, p. 463). Simon expands the uses of DMADV beyond the creation of new products or services and advocates using DMADV approach after optimizing an "existing product or process" fails to meet "customer specification or Six Sigma level" (Simon, 2007).

Six Sigma Key Roles

To carry out the work, Six Sigma identifies key roles and responsibilities. The Executives and Champions are responsible for selecting project that will be implemented by the organization. The associates responsible for implementing the projects and process improvements are Master Black Belts, Black Belts, Green Belts, Yellow Belts, and White Belts. It is important to note that successful Six Sigma implementations have a top-down management approach.

Tools of Six Sigma

The teams once formed will use a series of tools, which are employed with the Six Sigma methodology. The expansive toolset, which teams leverage to complete their work, is a primary benefit Six Sigma. Pande and Holpe (2002) recommend teams limit the use of tools to only those that help "get the job done" (p. 67) and categorize the tools as follows (See Table 3).

Criticism of Six Sigma

There is a recent debate of whether Six Sigma has a place in companies embracing the new innovation economy. The argument is that it is difficult for innovation and Six Sigma practices to coexist because by their very nature they are opposite. Six Sigma requires the organization to focus and direct its resources on operational excellence and perfection; it has a very low tolerance for risk because imperfection is increased when risk is introduced. On the other hand, innovation is by its very nature a high risk because it is dealing with new concepts (Rae, 2007). Dr. Thomas Davenport contends that the time for Six Sigma has passed as companies are embracing innovation:

Process management is a good thing. But I think it always has to be leavened a bit with a focus on innovation and [customer relationships]." The discipline was developed as a systematic way to improve quality, but the reason it caught fire was its effectiveness in cutting costs and improving profitability. That makes it a powerful tool—if those are a company's goals. But as innovation becomes the cause du jour, companies are increas-

Table 2. DMAIC in mathematical terms

Steps	Phase	Questions
1. Understand what process is to be improved and set a goal.	Define	> What is the Y or the outcome measure?
2. Measure the current state.	Measure	> What is Y's current performance?
3. Develop cause-and-effect theories of what may be causing the problem. 4. Search for the real causes of the problem and scientifically prove the cause-and-effect linkage.	Analyze	> What are the potential Xs or causes? > What may be causing the problem? > What are the real Xs or causes? > What is really causing the problem?
5. Take action.	Improve	> How can the understanding of the real causes of the problem be exploited to eliminate or reduce the size of the problem? > How can this Y = f(X) understanding be exploited?
6. Measure to verify improvement has taken place. 7. Take actions to sustain the gains.	Control	> Did Y really improve? > How can the Xs be controlled so the gains in Y remain?

(Chieh, 2007, n.p.)

Adapted from Pande and Holpe (2002, p. 51- 67) ingly confronting the side effects of a Six Sigma culture (Grow & Hindo, 2007).

The above opinion is supported by Benner and Tushman's research that suggests that Six Sigma will lead to more incremental innovation at the expense of more blue-sky work. The two professors analyzed the types of patents granted to paint and photography companies over a 20-year period, before and after a quality improvement drive. Their work shows that, after the quality push, patents issued based primarily on prior work made up a dramatically larger share of the total, while those not based on prior work plummeted (Hindo, 2007).

Examples of Six Sigma's fall from extreme favor can be seen at many fortune 100 companies including Home Depot, GE and 3M. The new CEO of Home Depot, Blake Frank has scaled back the strictness of the Six Sigma implementation enacted under the former CEO Robert Nardelli by giving more decision making to store managers. After the departure of James McNerney, 3M's leadership has changed its implementation of Six Sigma. Even GE, who under Jack Welsh popularized Six Sigma within the United States, is working to change how Six Sigma is used. Jack Immelt is attempting to move his team to innovate around a theme of "ecomangination" with mixed results (Grow & Hindo, 2007).

This debate does not mean that Six Sigma cannot provide value to organizations. It does mean that Six Sigma cannot be implemented in a vacuum. Multiple methodologies are needed to support the enterprise strategy. For example, companies that are looking to innovate while supporting and improving processes and products are adopting the "Ambidextrous Organization" proposed by O'Rielly and Tushman's (2004) research that shows that successful companies pursue innovations because "they separate their new, exploratory units from their traditional, exploitative ones, allowing for different processes, structures, and cultures; at the same time" (p. 74). The organizations "maintain tight links across units at the senior executive level. In other words, they manage organizational separation through a tightly integrated senior team" O'Reilly & Tushman, 2004, p. 75). To describe these organizations, O'Reilly and Tushman (2004) have coined the term "ambidextrous organizations" and believe that the organizations have provided a "practical and proven model for forward-looking executives seeking to pioneer radical or disruptive innovations while pursuing incremental gains. A business does not have to escape its past; these cases show how to renew itself for the future. Their study showed that 90% of the ambidextrous organizations achieved their goals (O'Reilly & Tushman, 2004, p. 76).

BUSINESS CASES INTEGRATING ITSM, ITIL AND SIX SIGMA

Combining ITIL® and Six Sigma to Improve Information Technology Service Management at General Electric, Fry and Bolt (2004) outline the process that GE undertook in 2004 to improve internal practices for their IT service management. The IT Solutions Enterprise Planning & Strategy consulting group was engaged to develop a process improvement methodology that combined ITIL and Six Sigma to migrate from the current state to "measurable, ITIL-compatible processes" (p. 3). The group used Six Sigma to assess risk, compare current state and processes to the end goal, and then identified the solution which leveraged Remedy's "ITSM Suite to automate and improve ITSM processes" (Fry & Bolt, 2004, p. 3) The five objectives set by the team included 1) Achieve ISO Compliance for ITSM using ITIL for GE IT standards (ITIL is ISO 9000 compliant), 2) Use ITIL framework to define ITSM best practice standards, 3) Assess the current state of IT service by using the Capability Maturity Model (CMM) and Capability Assessment Tool against the ITIL standard, 4) Constantly improve ITSM processes using Six Sigma and Deming's

Total Quality Management (TQM), and 5) Define measurement using Six Sigma to assure control and improvement (Fry & Bolt, 2004, p. 3)

To implement the methodology and meet the objectives set by the team, the team executed the Six Sigma DMAIC. The chart below outlines the project phase, goal or purpose and deliverable as stated by Fry and Bolt (2004) in the case study (See Table 4).

Table 4.

Phase	Goal or Purpose	Deliverable
Phase 1: Define Opportunities	Align ITSM strategy with the business, organizational, and technological strategies. The desired result is to set a definitive vision, scope, and strategic approach for ITSM operations.	> Team charter that describes the purpose, goals, and resources for the project. > Data collection plan that includes such items as interview schedules and questions. > Critical to Quality (CTQ) outline that identifies the critical success factors. > Current situation analysis that was created using the CAT tool. > Customers/Output—Process—Input/Suppliers (COPIS) "as-is" process map outline that provides an understanding of the current processes to which the solution
Phase 2: Measure performance	Create a current-state assessment of how well the current environment supports the ITSM strategy. The desired result is to determine current processes, issues, and the critical success factors—or Critical To Quality factors (CTQs)—of the desired future state environment.	> An accurate assessment of current process performance. > Detailed "as-is" process maps derived from the COPIS outline created in Phase 1 > Critical Success Factors (CTQ) summary chart
Phase 3: Analyze factors impacting performance	Examines the data collected in the Measure phase to generate a prioritized list of the sources of variation. The Analyze phase focuses improvement efforts by separating the "vital few" variables (those most likely responsible for the variation) from the "trivial many" (those least likely responsible for variation).	> Opportunities Table: Solutions mapped to process gap > Critical Success Factors (CTQs) benchmarked against ITIL best practices to identify opportunities for improvement > Cause and Effect Diagram > Pareto Chart of Opportunities
Phase 4: Improve Performance	Define and refine recommended tactical solutions based on information determined in phases 1-3. The desired result is a documented recommendation based on strategic fit, cost, and benefits.	> Risk Assessment/Failure Modes and Effect Analysis (FMEA)/Contingency Plan. > Prioritized potential solutions > Solution Pilot > "To Be" process maps
Phase 5: Control Performance	Propose a plan for designing and implementing the ITSM process improvement solution. The desired result is a true life cycle ITSM solution that allows for continuous improvement.	> Multi-Generational Product Plan (MGPP) > Process metrics defined > Full solution implemented > Control/Response Plan implemented > Risk mitigation actions complete

Source: Fry & Bolt, 2004, pp. 4-8

GE's project to improve their IT service management demonstrates that ITIL and Six Sigma can be leveraged together to implement and maintain ITSM within an organization. The benefits that GE found included 1) reducing cost by minimizing "potential downtime and the adverse effects of system, network, and application failures and install, move, adds, change and decommission implementations". 2) "Improve decision-making ability by facilitating access to information throughout the organization, and by enabling the enterprise wide use of outputs from an integrated framework of processes and tools through such devices as cross functional IT service dashboards" and 3) "Improve IT service levels by creating operational efficiencies and enabling a linked IT Service Management process loop for defining, measuring, analyzing, improving, and controlling service performance" (Fry & Bolt, 2004, p. 9).

Liberty Mutual, a diversified global insurer and sixth largest property and casualty insurer in the U.S., has introduced Lean Six Sigma and ITIL to dramatically reduce cycle times, improve quality and reduce cost. Although it is still in the early days of introducing Lean Six Sigma to the overall organization, preliminary results have been encouraging. Since 1994, the Boston-based company has almost tripled net revenue, to $23.5 billion, while shedding noncore businesses like financial services and health care. For example, in one of the company's underwriting groups, process reengineering has helped reduce cycle time by as much as 70 percent. Within the IT group, Lean Six Sigma is the foundation for all process-improvement efforts. Stuart McGuigan, CIO and senior VP of Liberty Mutual Group, calls ITIL a "common-sense model" and believes it can empower a large organization like Liberty Mutual by helping the organization break work into meaningful components and achievable goals. He also says that ITIL gives him a common language that was missing during the days when each technology silo had its own terms and conventions. "ITIL," he says, "has given us an end-to-end vocabulary." (Brown, 2008).

In another case study, Integrated Mobile delivers end-to-end life cycle management of an enterprise's entire inventory of wireless assets through a single management interface. With capabilities built on the lean Six Sigma, ITIL and CMM principles, Integrated Mobile eliminates the obstacles, challenges and distractions of managing wireless services resulting in a highly efficient and effective mobile enterprise. The issue was managing mobile services and assets of more than 925 retail outlets across major metropolitan markets in 49 states with more than 76,000 employees. Adding more than 17,000 new employees annually and several new stores, including international outlets, could lead to a mobile environment that is overwhelming. The company needed to find an efficient way to handle the multitude of inquiries, tasks and transactions associated with their mobile communications since there was too much time and money being spent on maintaining wireless devices. In this state of chaos there was no time to identify ways to drive efficiencies and improve the end-user experience.

This specialty retailer turned to Integrated Mobile's iManage solution, a feature-rich, managed service that helped eliminate the chaos and excessive costs often associated with a mobile enterprise (Integrated Mobile, 2007). Integrated Mobile's iManage solution includes:

- A Single Interface for All Wireless Management for All Carriers
- Supply Chain Automation
- Custom Kitting
- Provisioning and Fulfillment
- Standardized Handsets and Catalog Management that Supports Business Rules
- Approval Workflow
- Cost Allocation
- Credit Card Transaction Processing

- 24x7 Bilingual Administrative and Technical Tier 1 Support
- Asset Management
- Comprehensive Reporting, Transactions, Trends, Defects
- Validation of Transactions on the Carrier Bill
- MACD Processing
- Rate Plan Optimization
- Defect Elimination
- Optional iCare and iBill services for application and device support and invoice processing

This is how the specialty apparel retailer in this case study was able to improve satisfaction and productivity while driving down the cost of wireless with capabilities built on the lean Six Sigma, ITIL and CMM principles.

Lessons for IT Managers

It was to be expected that GE, an organization whose culture under the direction of Jack Welsh became entrenched in Six Sigma, leveraged Six Sigma when it implemented a project to use ITIL to improve its IT Service Management. But even organizations that are not Six Sigma implementations can benefit from using Six Sigma principles, methods, and tools. For example, the purpose of ITSM is to align the IT organization with the enterprise. This aligns to Pande and Holppe (2000) contention that within the Six Sigma implementation that there should be an emphasis and focus on the customer. Additionally, Six Sigma recommends collaborations across boundaries within the organization which is important to IT management because they need to determine service many divisions and functions and must provide enterprise level not silo level support and service. Using the DMAIC project management approach provides the IT organization a methodology to establish a vision and strategy for ITSM within the organization, assess the current state and its effectiveness in supporting the ITSM strategy, determine what is most likely for not meeting the defined strategy, identify a solution and propose a plan for implementation ITSM. Alternatively, if ITSM and ITIL are currently in place within the organization, the Six Sigma approach to organizing and getting work done including identifying and selecting problems to be solved could be used. Additionally, the Six Sigma tool kit provides tools that assist IT staff identify problems, determine root causes, and recommend ITIL solutions to fix existing problems. To provide sound IT service management, organizations should use ITIL and Six Sigma combined to ensure strategic alignment with their organization.

IMPLICATIONS FOR RESEARCH

The framework in our exploratory research has been built upon a deductive study which has been developed through a literature review and synthesis and an exploratory inductive research which has been developed using a qualitative case study. It makes the case for leveraging ITIL and Six Sigma with ITSM in practice and opportunities for future research.

IT operations, as the production arm of IT departments, have been mostly ignored by IT research. There is a growing body of research on isolated aspects of operations services; but there is little research that is explicitly ITSM related. Despite the significant growth of ITSM practice in industry, there is no academic work or community of scholars that shares a common mission to understand how to advance it. Services are emerging in separate areas of academic, industry and government but few attempts to integrate them (Conger et al, 2007, p. 50). Since the early versions of ITIL lacked truly quantifiable business values, IT organizations are not interested in and supportive of IT Service Management processes. ITIL faces an uphill battle for acceptance and creditability that needs to be won across the entire organization.

Six Sigma is a measurement-driven approach to continuous process improvement that focuses on reduction of variation, consistency and high product quality. Therefore, in terms of IT service oriented industry, combining Six Sigma with ITIL can migrate current processes toward usable, measurable, ITIL-compatible processes as mentioned above with the case study on GE, however there is no research on version 3 because it is relatively recent, i.e., released in May 2007. Based on this we have shown the Six Sigma tools, which can be used to improve ITSM processes using the DMAIC model.

IMPLICATIONS FOR MANAGEMENT

At this point we have provided background on ITSM, ITIL and Six Sigma individually. But the question is can an organization's ITSM implementation benefit by integrating ITIL and Six Sigma? We conclude that ITIL and Six Sigma should be leveraged in tandem by IT organizations. Together with the ITIL best practices model and Six Sigma continual improvement and measurement, IT will be able to set boundaries and provide control elements for the senior IT management. ITIL is needed to provide the framework and best practices for ITSM. ITIL provide a set of guidelines to specify what an IT organization should do based on industry best practices. ITIL best practices process model is a key item to drive IT to meet the enterprises expectation.

However, ITIL does not define for an organization how it should be accomplished. According to Fry and Bolt (2004) "Six Sigma provides a process improvement approach that is based on statistical measurement, drives quality improvement, and reduces operational costs. It helps in developing detailed work instructions, and it defines a methodology for continually mapping, measuring, and improving the quality process. Six Sigma tells how, but it doesn't tell what to do nor does it specify any best practices specifically for ITSM…ITIL defines the "what" of service management and Six Sigma defines the "how" of quality improvement. Together, they make a great combination for improving the quality of IT service delivery and support" (p.2). ITSM, ITIL and Six Sigma combined can also assist IT govern itself and ensure that it is meeting and sustaining the enterprises strategies and objectives (Colbeck et al., 2005).

CONCLUSION

Over the next decade, executives will continue to be challenged to deliver value to share holders and other stakeholders. To support the organization, IT executives and managers will be challenged to transform their organization from delivering technology to providing service and ultimately becoming a business partner within the organization. To meet the challenge, we encourage the use of ITIL in combination with Six Sigma in IT Organizations with an ITSM implementation. IT managers need to leverage ITSM to develop, deliver and manage IT services to agreed upon quality standard. To have a sound IT management, managers should use ITIL v3 as best practices. Six Sigma DMAIC should be used to make certain that ITSM is aligned with the customer and to provide the mechanism to deliver and monitor all the IT service management processes. The case study at GE shows that ITIL and Six Sigma can be used in tandem to deliver ITSM and meet the organization's business objectives. Nevertheless, delivering ITSM using ITIL and Six Sigma is a one building block for building a world-class company. World-class competitors do not achieve the status because they adopted a "tool or technique." They achieve the status because they are good in "performing the fundamentals "including understanding their customers, products, employees, competitors' landscape, the market they are competing in and the enabling technologies. The world-class competitors succeed because they are creative and know how to make use of operations processes to their best advantages (Foster, 2007, p. 509). ITIL and Six Sigma are just two tools that should be used for the IT organization to deliver world class IT Service Management and meet quality targets. As the IT organization successfully delivers ITSM, it will become a business partner within the organization

APPENDIX A: ROLES WITHIN SIX SIGMA

The hierarchy and the roles within a Six Sigma organization are described by the American Society for Quality (http://www.asq.org) and Thomas Pyzdek as follows:

Roles	Description of Role
Executives/Leadership	Must be lead by the CEO because "Six Sigma involves changing major value streams that cut across organizational barriers (Pyzde, 2000). Provides overall alignment by establishing the strategic focus of the Six Sigma program within the context of the organization's culture (ASQ).
Champions	Champions are the next level within the organization. These are "high-level individuals who understand Six Sigma and are committed to its success." In a Six Sigma implementation there will also be "informal leaders" who are daily practitioners and are communicating the "Six Sigma message" within the organization (Pyzde, 2000). The role of a champion is to "translate the company's vision, mission, goals and metrics to create an organizational deployment plan and identify individual projects." They are also to "identify resources and remove roadblocks" (ASQ).
Sponsors	Sponsors own processes and systems that can be improved using the DAIMC process. They "help initiate and coordinate Six Sigma improvement activities in their areas of responsibilities" (Pyzde, 2000).
Master Black Belts	Within the project hierarchy, the Master Black belt is "highest level of technical and organizational proficiency." The Master Black Belt is responsible for providing technical leadership, including statistical training and assistance to Black Belts, developing key metrics, and strategy within the Six Sigma program. The Black Belt must have the same knowledge as the Black Belt; additionally, they must "understand the statistical mathematical theory on which the methods are based… There is usually about one Master Black Belts for every ten Black Belts, or about 1 Master Black Belt per 1,000 employees" (Pyzde, 2000). They are similar to a Program Manager within the Project Management hierarchy
Black Belts	Black Belts are respected leaders and technically inclined; they "receive 160 hours of classroom instruction, plus one-on-one project coaching from Master Black Belts or consultants." An organization will have on average "about one percent of their work force as Black Belt." A Black Belt, Project Manager, will complete between 5 to 7 projects each year. (Pyzde, 2000). Black Belts are responsible for leading "problem solving projects and the training of and coaching of project teams" (ASQ).
Green Belts	Green Belts are the equivalent of a project lead within the Six Sigma program. They are capable "of forming and facilitating Six Sigma teams and managing Six Sigma projects from concept to completion" (Pyzde, 2000). Green Belts are also responsible for assisting "with data collection and analysis for Black Belt projects" (ASQ).
Yellow Belts	Yellow Belts are project team members. They review "process improvements that support the project" (ASQ).
White Belts	White Belts "can work on local problem-solving teams that support." overall projects, but may not be part of a Six Sigma project team. They understand "basic Six Sigma concepts from an awareness perspective" (ASQ).
