Sensationalism may be defined as a theoretical concept that encompasses those features of journalistic products that are capable of attracting the attention of the audience. Since the early days of newspapers, complaints about sensationalism have recurrently emerged in public discussions about the quality of journalistic products. In a nutshell, these complaints pictured sensationalist news as a journalistic device being designed merely to attract the attention of large audiences at the expense of informing them properly about socially significant events. In its defense, it has been argued that sensationalist news is an appropriate response to the evolutionarily developed human habit of attending to information that increases the chances of survival and reproduction (→ Evolutionary Theory).

Traditionally, sensationalism in the news has been conceived of mainly in terms of story content. Stories about topics such as crime, violence, natural disasters, accidents, and fires were considered as sensational. However, this definition of sensationalism provided no theoretical basis to explain why sensationalism would attract the attention. It

also provided no theoretical basis for the negative effects sensationalism is often accused of. Against this background, the concept of sensationalism gradually evolved in the late 1990s. Notably, Grabe et al. (2001) and Hendriks Vettehen et al. (2005) provided a foundation of the concept in psychological theories of information processing, more specifically in the notion that certain types of stimuli elicit automatic attentive processes. In the context of news processing, these stimuli are referred to as *sensationalist features*.

Three categories of sensationalist features may be distinguished: basic needs content, tabloid packaging, and vivid storytelling (cf. Hendriks Vettehen et al. 2005). *Basic needs content* includes audio, visual, and verbal news content that may be considered as important to every person because of its reference to basic human needs; e.g., stories about sex, violence, criminality, disasters, or famines. *Tabloid packaging* refers to formal features in news reports that represent unexpected or changing information. In television news, it includes transitions between scenes or camera shots as the most obvious examples, but also camera movements, uncommon editing techniques, and decorative techniques such as the insertion of music. In newspapers, extraordinarily large headlines or pictures may be considered as examples. *Vivid storytelling* refers to the inclusion in news stories of information that is either concrete or proximate to the audience. Well-known examples of vivid storytelling are the insertion of brief comments by lay persons on an issue in news reports, or the insertion of a report on an individual case history (→ Exemplification and Exemplars, Effects of).

In journalistic as well as scientific discourse, sensationalism has been theoretically linked to the mechanisms of market-driven journalism. The central hypothesis concerning sensationalism holds that an increasing competition puts pressure on news producers and owners to capture the attention of the audience. Sensationalism in the news is considered a successful way of achieving this (→ Commercialization: Impact on Media Content). In line with this view, several studies have provided indications of trends toward more sensationalist television news, both in the U.S. (e.g., Slattery et al. 2001) and in Europe (e.g., Hendriks Vettehen et al. 2005). However, the evidence is correlative, implying that increases in sensationalism may be attributed to developments that coincide with increasing competition, e.g., technological innovations, or trends in journalists' role perceptions (→ News Production and Technology).

Because the concept of sensationalism is based on theories of information processing, predictions about cognitive processing of more or less sensationalist news could be tested. Notably, some studies have shown that the use of sensationalist features in news stories increases attentiveness during the viewing process, but that an unrestricted use of sensationalist devices (e.g., the tabloid packaging of a news topic with basic needs content) will induce cognitive overload, which will harm the storage of the news messages (e.g., Lang et al. 1999; Grabe et al. 2003). Moreover, other studies have shown that a vivid way of storytelling differentially draws attention to the vivid parts of the informational content, which can lead to distorted comprehension and judgments (for an overview, Zillmann & Brosius 2000).

Although knowledge concerning the antecedents of sensationalism and the cognitive processing of sensationalism is accumulating, less is known about audience preferences for sensationalism. Future studies might focus on the relation between the presence of sensationalism in journalism and audience preferences for sensationalism. In addition, it

might focus on audience variables that may relate to preferences for sensationalism, notably the → sensation seeking personality trait.

## **Sense-Making**

*Patrice Buzzanell*

*Purdue University*

Sense-making is an intersubjective process of making meaning for individuals, groups, organizations, and societies. Weick's theorizing about organizing and sense-making (1979; 1995; 2006) has been particularly influential in considerations of sense-making and is oriented toward understanding how people identify and work through puzzling, plausible, or equivocal experiences and how organizing emerges through micro-level and collective communicative practices and improvisations. Weick (1995) characterizes sense-making as a process grounded in identity construction that is retrospective, enactive of environments, social, ongoing, and driven by plausibility rather than accuracy. Although much organizational communication research uses sense-making to depict individual meaning-making

of work, identities, and complex situations, sense-making processes actually link micro-through macro-processes such that → organizational culture, structure, and knowledge are made more resilient (→ Organizational Structure; Knowledge Management).

Weick (1979) acknowledges the importance of communication in enacting, selecting, and retaining multiple → meanings through the use of both rules (i.e., past insights, procedures, scripts, and routines) and cycles (i.e., development of possible novel actions and interpretations) that are validated consensually. Organizational members constantly shape the collective → memory so that they act not only in accordance with expectations but also in response to current circumstances.

Sense-making occasions arise when *gaps between the present and desired future are confused, or difficult to close* (Weick 1995). Sense-making starts with the individual: “First, someone notices something, in an ongoing flow of events, something in the form of a surprise, a discrepant set of cues” (p. 2). Over time, the individual and the collective are intermingled as sense-making, a social process, involves others in actively structuring events and developing accounts to explain surprises. In sense-making, members attempt to fill in gaps by complicating or enriching the ways they and other members represent their organizational realities. Over time, more people join in persuading others about the viability of certain interpretations and actions. Thus organizing and sense-making processes have political consequences because whoever makes sense of confusing experiences, frames the meanings of these experiences for others, and encourages others to join in this collective and iterative framing gains much power and control.

Second, initial sense-making phases focus on *certain extracted cues in situations with multiple possibilities*. The cues, details, or moments that are focused upon and noted as confusing or memorable are extracted from an ongoing stream of human activity and surroundings and then pondered for plausibilities. How organization members determine where, when, and how to focus their → attention has implications for the ways cases, such as accusations of sexual harassment or determinations about courses of action in wildland firefighting, unfold and how scenarios for different stakeholders are constructed (Buzanell 2004; Dougherty & Smythe 2004; Weick 1993).

Next, in the *identification and framing of understandings*, sense-making involves “language work . . . to refine and enrich the representations that people impose on territories to make sense of them” (Weick 1992, 173). To accomplish this framing, members use specific interactional contexts as well as past experiences as resources for meaning creation. For example, Murphy (2001) describes the flight attendant’s dilemma as “knowing when to reproduce their dominant everyday routines and when to break these routines, risking possible organizational and/or interpersonal sanctions” (p. 31). Relating the past with present assessments and future organizational and relational possibilities demands inventive individual and collective sense-making. Flight attendants not only operate within improvisation and constraint in their work – especially during emergency situations but also in their relationships with pilots who operate as authority figures with power.

Fourth, sense-making involves the *crafting of narratives* (→ Storytelling and Narration). These narratives are stories of conviction and integration insofar as sense-making involves challenges to people’s known identities, courage to withstand assaults on credibility (because sense-making centers on possibilities that upset the taken-for-granted ordering of sense-makers’ worlds), and facility with storytelling to pull others into identity craftings and

sense-making processes. As such, organization members create preferred identities and meanings of work through humor (Tracy et al. 2006) as well as discursive strategies of comparison, logic, and support for identity reformulations (Larson & Pepper 2003). It is through the telling of new stories and new frameworks for encountering crisis situations that resilient organizing processes can emerge (Sellnow et al. 2002; → Crisis Communication).

Finally, sense-making mandates the *construction of collective knowledge*. Weick and Roberts (1993) write that communication processes are essential in creating reminders for members to heed or attend to their environments and learn from previous actions. Collective knowledge is (re)constructed every time insiders teach newcomers the ropes and relearn know-how. Collective knowledge construction is enhanced through narrators' candor about failures as well as successes, their narrative skills, and newcomers' attentiveness to sense-making stories. When members share experiences in rich, detailed, and memorable ways, their capacities to recall knowledge through scripts and other means are enhanced.

# Separation of News and Comments

*Donald L. Shaw*

*University of North Carolina at Chapel Hill*

*Thomas C. Terry*

*University of North Carolina at Chapel Hill*

News and comment cannot coexist independently in a social system. Factual news and comment become twisted together like two strands of a rope. What is → news? What is → commentary? When we think of news, we often think of facts that refer to specific objects or events in the world. By contrast, commentary usually refers to a larger context. Commentary frames news (→ Framing of the News). News and commentary are constructed of words, pictures, sounds, or other symbols of social → meaning, but the communicator's intent is different in each case (→ Constructivism). News reports aim to reconstruct events, to create pictures in the minds of audiences. Commentary aims to shape how audiences construct these events. Commentary has intent. While news media usually are careful to separate news from commentary, audiences naturally blend them together. We can obtain a picture of events from news stories alone, as all news stories contain some evaluative descriptions beyond the facts, and one can learn events from commentaries alone, and still will learn some facts.

The separation of news from comment can be studied in all communication systems – in some there is more separation at times than in others, more in some periods of history, less in others (societies under stress) – but news and comment cannot be easily separated and must be evaluated in terms of how they interact within a particular social system. Even if media strictly separate news from editorials and columns, audiences necessarily put the two together as part of the construction of social reality.

One can make an *analogy with agenda-setting theory* (→ Agenda-Setting Effects). Agenda setting, level 1, proposes that the connection between media and audiences at the level of news topics is close. Agenda setting, level 2, argues that the connection between the details in news stories and audience attention is likewise close. Within agenda-setting theory one can argue that news stories contain a heavy focus on facts with some details about events, while news commentary focuses on interpretive detail linked with the same facts. McCombs (2004) has called major news event topics “objects” and details about events “attributes.” In this sense, news stories could be described as objects-over-attributes messages, while commentary can be visualized as attributes-over-objects messages. No message is purely news and no message is purely commentary. There is always a mixture.

Attributes contextualize objects, as the comments of editorial writers, columnists, letters to the editor, photographs (→ Photography), and audio and video contextualize the facts of news events on the front page. If we lived in the controlled environments in which behavioral psychologist B. F. Skinner limited behavior and provided rewards for correct behavior, we might expect the relationships between news (objects) and comment (attributes), demonstrated by correlations between news and audiences, to be close to 1.00. That is, audiences given proper rewards for attending to messages would reflect

messages in exactly the proportions in which they are presented, in terms of objects and attributes, and audiences therefore would be quite able to keep separate in their heads information learned from news and that learned from commentary. Of course, no one does that, even if the media carefully separate news and commentary.

Professional journalists constantly wrestle with balancing fact and comment statements. Journalists construct their social roles relative to the way they gather, organize, and present messages, nearly always with reference to some larger professional duty, such as fairness or objectivity (→ Objectivity in Reporting; Journalists' Role Perception). Clarity in dividing news and comment is often determined by culture. France's *Le Monde* and Germany's *Der Spiegel* contextualize news. In Britain, the *Daily Telegraph* and the *Guardian* are newspapers to which audiences turn for a dependable selection and presentation of news and commentary consistent with their own views. The separation of news and commentary cannot really be addressed without reference to political and cultural systems. The Chinese government tolerates a wide range of news, and even some comment, about purely economic issues, but requires political news to exist within a particular, tightly controlled range (→ China: Media System; Censorship). US journalists pride themselves on their objectivity about news, defined as presenting political messages that provide equal, or at least fair, attention to all aspects of political issues, while directing commentary to editorial pages or personal columns. The free market system exerts influence. Many countries, from Russia to Syria to China, have government-controlled television networks. Britain's → BBC is government-funded, but editorially independent. Al Jazeera represents still another model that is consistently non-objective, while being ostensibly independent of government authority. In fact, all systems find a natural balance between news and comment, however defined for a given national system and culture (→ Arab Satellite TV News).

Political leaders, journalists, social scientists, and others are interested in media systems that help citizens function responsibly. There are many ways to examine the performance of information systems in presenting news and comment. There are basically two *empirical measures to examine the separation of news and commentary*. The first looks at the use of language in the news. What topics are covered? The second compares the valence of items in the news or commentary. To this latter approach belong "*synchronization studies*." They assess the degree to which news and commentary are separated in a news system or in individual news outlets. By means of content analyses one can compare how the valence of the news items correlates with the valence of commentaries on the same issue. One study found that newspapers in the United States reported the number of participants in anti-war demonstrations that were consistent with the newspapers' position on the Vietnam War, as expressed in their editorials and opinion columns. Similar results were found for German reports about the Berlin conflict in the 1970s (Schönbach 1977) and several other political issues (Kepplinger et al. 1991; Hagen 1992).

The balance between news and commentary varies from country to country, culture to culture. Agenda-setting studies in Germany, Britain, Taiwan, Korea, Japan, Australia, and various countries in Africa and South America suggest audiences everywhere are likely to reflect → attention to news and commentary in predictable patterns. If we used the same heuristic as Sir Isaac Newton – the attraction of forces, not objects – we might conclude that while news and comment may appear adverse to each other within any particular

national or cultural setting, audiences meld news and comment into a social construction that fits their own lives, reflecting, perhaps, a law of social gravity that we have not yet discovered.

## **Sesame Street**

*J. Alison Bryant*

*Nickelodeon/MTV Networks*

Sesame Street is an educational children's television series for preschoolers that teaches a broad range of curricula, from letter and numbers to socio-emotional and coping skills (→ Educational Media; Educational Media Content). The series is the longest running US children's television show, having first aired in 1969, and has won over 100 Emmys, more than any other television program. It is often heralded as the hallmark of → entertainment education programming because of its broad spectrum popularity, its stringent research process, and its international impact.

### **THE CONCEPT**

*Sesame Street* was created by Joan Ganz Cooney and Lloyd Morrisett in response to a perceived need to improve basic cognitive, social, and emotional skills in preschool children, particularly minority and inner-city youth (→ Developmental Communication). Through this television program, preschoolers could begin to learn the alphabet, numbers, and positive social skills in their homes. The show's early success paved the way for other

educational programming, especially on the → Public Broadcasting System, where it was aired (→ Public Broadcasting, History of).

A combination of live action, animation, and puppetry, the show is produced in magazine format, a series of short vignettes with a narrative storyline set on the Street with the live-action and puppet characters woven throughout. Although the format has changed slightly, so that the narrative storyline is shown with fewer interruptions, the use of short-form scenes that have inherent educational value has remained constant. The live-action scenes include the diverse set of cast members, the Muppets (the puppets created by Jim Henson and his company), and real children.

The addition of the Muppets to the cast early on was critical to the show's long-term success. Segments with Big Bird, Ernie, Bert, Oscar the Grouch, Grover, and others (including Elmo in later years) had strong appeal with both kids and parents. Although the original funding for creating the series came from federal agencies and philanthropic organizations such as the Ford and Carnegie Foundations, the licensing income from the Muppet-related products sustained the show from the mid-1970s. Since then, the *licensing revenue* has been a major source of income for the show's parent production company, Sesame Workshop (originally called the Children's Television Workshop). In recent years, approximately 40 percent of the Workshop's revenue has come from licensed products. This financially successful model of children's educational television character licensing, and the impact of particular success cases such as the Tickle-Me Elmo doll that was produced by Fisher-Price/Mattel in 1996, has had a strong impact on the licensing models for children's educational programs, such as *Barney* and *Blue's Clues* (Morrow 2006; Bryant 2007).

Another reason for the success of the show is that it appeals to both children and their parents. Guest appearances by prominent personalities and adult-targeted cultural references throughout the show make the program appealing to parents, and therefore help *foster co-viewing between parents and children*. In addition, because of the longevity of the show, many parents today have themselves watched the show as children, and therefore the show has a nostalgic value for them as well.

## RESEARCH AND OUTREACH

One of the hallmarks of the show is the research behind it. Each episode has a specific curriculum, and each vignette or storyline within the episode ties back into the overall curriculum for the show. The show has a research team and curriculum content specialists who work hand in hand with the creative producers to create each episode. Through formative research during the production process, they make sure that children are learning the lessons outlined in the curriculum. Via summative research, conducted after the series airs, they can assess the actual impact of the program on its viewers. This intertwined research–production–content model has come to be called “the Sesame Workshop Model.” *Sesame Street* is the most heavily researched television program ever, with over 1,000 studies conducted about it globally (Fisch & Truglio 2001).

In addition, since one of the main goals of the program is to reach low-income and minority children, outreach has also been a consistent part of the *Sesame Street* project. Outreach materials for the show are available through local PBS stations and distributed through community and national organization partnerships.

## INTERNATIONAL IMPACT

Soon after the early success of *Sesame Street* in the US, Sesame Workshop began to co-produce international variations of the series with partner production companies in countries across the world. The first co-productions, *Plaza Sésamo* in Mexico and *Vila Sésamo* in Brazil, went on air in 1972. One year later *Sesamstrasse* was aired in Germany. Since then, the Workshop has partnered to create over 30 co-productions, from India to Turkey to Brazil to Japan. These co-productions, along with airings of the US version (either in English or dubbed in the native language) of the series, have reached children and parents in 120 countries.

Each of the co-productions is based on the process of the Sesame Workshop Model and fashioned after the original US show, but is overhauled so that it reflects the local culture as well as the specific needs of children in that region. For example, *Takalani Sesame* is a South African co-production which, in addition to the basic cognitive and social curricula, also deals with the HIV/AIDS epidemic in the region through a Muppet called Kami, who is HIV-positive. In Egypt, *Alam Simsim* has a strong focus on empowering girls in order to address the problem of female literacy. In the Middle East, a group of Jordanian, Israeli, and Palestinian co-production partners created *Sippuray Sumsum* which promotes cross-cultural respect through three separate versions of the show that have both unique and shared elements (Cole et al. 2001).

## OTHER MEDIA AND EVENTS

In addition to the television show, *Sesame Street* can now be found on other media platforms, including DVDs, computer games, and on the web. In keeping with its hallmark research-intensive model, these products for children are also created through internal partnerships with researchers, content specialists, and producers. In addition, the website for Sesame Workshop ([www.sesameworkshop.org](http://www.sesameworkshop.org)) has extensive information for parents, including extension activities and caregiving advice. The curricula for each episode can be found on the Public Broadcasting Service's children's programming website <http://pbskids.org/sesame/>.

There is also a number of parks and live shows based on the show. For example, in Japan there is Tokyo Sesame Place and there is a Sesame Place in Pennsylvania (US). In addition, the Sesame Street Live franchise produces live shows that are on tour both in the US and internationally.

## **Sex and Pornography as Media Content, Effects of**

*Neil M. Malamuth*

*University of California, Los Angeles*

*Mark Huppin*

*University of California, Los Angeles*

Research on sex media has often been divided into two categories, depending on whether the sexual stimuli are embedded within a larger context or not. The first type, illustrated by a TV soap opera in which some of the scenes, although typically not a majority, include references to or actual portrayals of sexual interactions, depicted in varying degrees of sexual explicitness. The second category, typically referred to as “pornography,” is primarily intended to sexually arouse the consumer and contains mostly explicitly sexual content.

The most influential theory guiding research in this area has been social learning theory (→ Observational Learning), with emphasis on the concept of “reciprocal determinism,” referring to a continuous reciprocal interaction between the person and the social environment. Thus, people seek out certain types of media that reflect their personalities, interests, attitudes, social interactions, and so forth, and such media experiences in turn may influence these personal characteristics, both directly, and indirectly via influences on peers and others in their social environment. In contrast to people who voluntarily seek out sexual media, there are also those who report unwanted

exposure, particularly on the Internet. Surveys reveal that 25 percent of young Internet users per year are exposed to unwanted sexual pictures and about 20 percent receive unwanted sexual solicitations, with about a quarter of these unwanted exposures described by users as distressing or upsetting (Mitchell et al. 2003).

### EMBEDDED SEXUAL CONTENT

Content analyses have generally shown dramatic increases in sexual content in the past two decades in media such as television and movies (→ Sexualization in the Media). Moreover, only a small fraction emphasizes any risks or advantages of birth control or abstinence (Kunkel et al. 2003).

Surveys of teens generally indicate that they rank entertainment media as a very powerful source of influence for *shaping their knowledge and views* about sexuality and sexual health, and they believe that such media do exert much pressure on them to become sexually active. Systematic studies of whether such effects occur have shown media experiences as one of the complex interacting factors that do have significant influences for many, albeit not all, people (Ward 2003). The data have primarily derived from (1) correlational research in naturalistic settings (→ Correlation Analysis), and (2) experimental research designs, usually limited to laboratory settings (→ Experiment, Laboratory). When the findings have converged from both types of methodologies, the ability to infer causation in naturalistic settings has improved, although caution is certainly needed in inferring causation based on correlational data alone. There have also been some longitudinal data, particularly useful for ascertaining long-term media effects (→ Longitudinal Analysis; Media Effects Duration).

For example, in one study investigators used a national telephone survey in the US in 2001 and 2002 that surveyed 1792 adolescents twice, 1 year apart. Important associations were found between amount of sexual content viewed at Time 1 and sexual behavior at Time 2. For example, the likelihood that adolescents would have sexual intercourse over the year in question doubled for those adolescents residing in the 90th percentile in their exposure to sexual TV content as against those in the 10th percentile (Collins et al. 2004). Another large longitudinal study that surveyed white and black adolescents from the southeastern US found media effects for the former but not the latter. After controlling for factors such as parental disapproval of teenage sex and peer sexual norms, the subsequent sexual behaviors of black adolescents was unaffected by baseline *sexual media diet* (SMD). In contrast, for white teens, even after controlling for other factors, those who had reported the largest SMD at baseline (i.e., those in the top quintile) were 2.2 times more likely than those in the bottom quintile to have had sexual intercourse two years later (Brown et al. 2006).

Results from nonlongitudinal research have also pointed to some significant associations that need to take other factors into account as well. A 2006 study assessing effects of SMD in relation to other contextual factors found that SMD accounted for more of the variance in adolescent *intentions to have sexual intercourse* than religious and school factors, but less than peer, parent, and demographic factors. After controlling for these other factors, SMD added a small but significant contribution to the prediction of adolescent sexual intentions (L'Engle et al. 2006).

Relatively reliable effects of media on attitudinal variables have been found regarding exposure to highly sexual media genres, e.g., soap operas and music videos. These studies also suggest that *individual difference factors* such as viewer involvement may be influential in determining outcome behaviors. Correlational research has found that greater exposure to or involvement with soap operas and music videos can result in more stereotypical sexual attitudes, greater endorsement of dysfunctional relationship models, and greater acceptance of sexual harassment (Ward 2003; Pardun et al. 2005).

In laboratory experiments (i.e., one group is exposed to sexual content, another to neutral content, with the two groups then compared on outcome measures), too, evidence suggests that participants exposed to highly sexual media genres become more accepting of casual and stereotypical attitudes about sex and relationships, and that their real-world perceptions come to reflect their media exposure. For example, students exposed to stereotypic music videos are subsequently more *accepting of sexual harassment* than are students exposed to neutral media content (Ward 2003). Although many experimentally induced attitudinal changes are likely temporary, to the extent that experimental conditions are habitually replicated in real-world environments, enduring attitudinal changes can be expected.

Total media exposure (e.g., total television viewing) has not been linked with behavioral changes, but specific genres such as music videos and soap operas have yielded stronger results (Ward 2003). Frequent viewing of music videos is associated with more sexual experience and more sexual partners for young women. For men, frequent viewing of soap operas has shown similar associations. Lastly, longitudinal studies demonstrate predictive relationships between sexual media exposure and early initiation of sexual behaviors, although associations may vary by demographic variables such as race and age (Brown et al. 2006).

## PORNOGRAPHY

People who seek out sexual images in one type of media often also seek it in other media. For example, among 745 Dutch adolescents, a very high correlation was found between frequency of exposure to sexually explicit content on the Internet and to R- and X-rated TV, movies, and magazines (Peter & Valkenburg 2006).

Although both genders show considerable pornography use in many cultures, research has shown that males are much more likely to be the consumers and to use it, particularly as *masturbatory stimuli*, across all cultures (Malamuth 1996).

Although experimental and correlational studies have provided most of the data, there have also been a few aggregate studies that examine larger populations rather than individuals. Some research has extended the findings with “embedded sexual media.” For instance, in a recent survey of 2,001 *Taiwanese adolescents*, 38 percent of whom indicated that they had accessed pornographic websites, significant correlations were found between Internet pornography exposure and permissive sexual attitudes and behavior, even with demographic variables, general media use, and exposure to traditional pornography controlled for statistically (Lo & Wei 2005). Exposure to → *Internet pornography* showed even stronger associations with sexual attitudes and behavior than did exposure to traditional pornography (→ Sex and Pornography Online).

The focus of many of the other pornography research studies has addressed concerns about *aggression against women*. It has been asserted that certain types of pornography, particularly those presenting nonconsenting or violent images, might cause changes in sexual arousal patterns, fantasies, attitudes, or behaviors, increasing such aggression (→ Sexual Violence in the Media). Some other research has also focused on potential adverse effects of nonviolent pornography use on family values (Zillmann 1994).

The research has been integrated in various → meta-analyses and reviews. These have generally reported that greater exposure to pornography (both violent and nonviolent) may be associated with increased acceptance of violence against women and aggression toward women, and other research also suggests negative changes in family values. The type of pornography people are exposed to does seem to make a difference. For example, depictions of nudity only actually reduce rather than increase aggressive tendencies in laboratory studies, while exposure to violent pornography appears to increase aggressive tendencies (Allen et al. 1995). In correlational studies focusing on consumption in naturalistic settings, however, it has been more difficult to separate consumption of different types of pornography, since consumers typically consume various types, and it has been concluded that higher levels of consumption of even some forms of nonaggressive pornography may be associated with increased *risk for sexual aggression*. Any causal interpretation of such correlational data must, of course, consider the possibility that pornography may be spurious and a “marker” for other risk factors. For example, more generally hostile, antisocial individuals may be more likely to use aggression in sexual interactions and may also be drawn to pornography due to its impersonal opportunity to exert control over a member of the opposite sex.

The third type of research has examined in various cultures how much pornography is being consumed in society at large or in a particular region of the country at large, and changes in such *consumption over time*. Such changes have then been correlated with other changes in the society, such as changes in sexual crimes (Wongsurawat 2006). In contrast to the conclusions emerging from the studies described above, these types of population-level studies actually suggest that increased pornography consumption may be associated with decreases in sexual crimes in society. Although such research has provided an interesting window regarding varied cultures, one problem is that it is difficult to relate changes at the larger societal level to individual behavior. Also, there are typically many other changes that have occurred in a society at the same time as changes in pornography consumption have been happening. Nevertheless, these studies do raise important cautions about any sweeping generalizations about pornography’s effects on varying individuals and in differing cultural environments.

Although the meta-analyses described above indicated that there is generally some association between consumption of pornography and aggression against women and that the associations are typically stronger for nonconsenting adult pornography than for other types of pornography, some earlier studies and particularly more recent ones conducted since these meta-analyses have particularly focused on individual differences among consumers. In the area of aggression against women, research suggests that if a man already has relatively strong tendencies to be aggressive, then heavy pornography consumption may “add fuel to the fire” and increase his aggressive tendencies. This seems to be particularly likely if the type of pornography he is sexually aroused by includes

nonconsenting content. On the other hand, if a man has little risk for being aggressive toward women as defined by researchers (i.e., the majority of the male population) then whether or not he consumes much pornography does not significantly affect his risk for being aggressive toward women (Vega & Malamuth 2007).

# **Sex and Pornography as Media Content: Feminist Perspectives**

*Jane Arthurs*

*University of the West of England*

The ubiquity of sexualized images and narratives across all media forms signals the importance of this topic for research and analysis. In mainstream communications research in the US it has been located in the → “media effects” tradition, where the emphasis has been on the moral risks of explicit sexual content to “family values” (Gunter 2002). This research uses content analysis, which relies on attaching predefined codings of → meaning to large datasets of, mainly, television content, to measure the number of sexual incidents portrayed, and the kind of values they promote (→ Content Analysis, Quantitative). Often funded by pressure groups such as the Kaiser Family Foundation, the aim of this research is to influence media policy on censorship and controls over children’s access to sexual content. The worry is that young people will be influenced to engage in premature sexual activity outside of marriage without heed to the attendant risks. In feminist scholarship, on the other hand, there has been a different agenda. Here the initial emphasis was on the ideological reproduction of patriarchal power relations through the cultural preoccupation with women’s sexuality. Most feminist research uses qualitative analysis of a few exemplary texts, to reveal the ideological work that they perform, such as the degree to which textual pleasure is predicated on women’s subjection to male control (→ Content Analysis, Qualitative).

The impact of globalization and new technologies of production and distribution such as the → Internet (→ Globalization Theories), coupled with a decline in the power of regulators to limit what is available, has enabled a greater diversity in the forms of sexual discourse circulated in the media (→ Pornography, Media Law on). This has brought questions of taste to the forefront of feminist debate in ways that often challenge the assumptions about sexual representation that defined the “second wave” era (→ Morality and Taste in Media Content). Patriarchy is no longer seen as the only determining force, not least because of the influence of feminist critical discourses (→ Cultural Studies: Feminist Popular Culture). Ethnographic studies have also complicated assumptions about textual meaning by revealing the very different interpretations made by audiences embedded in divergent taste cultures. Foucauldian methods of → discourse analysis have been used to map these multiple perspectives alongside theories of hegemony that trace how they compete in a hegemonic struggle to establish or maintain the legitimacy of certain sexual ideologies at the expense of others (→ Ethnography of Communication). For example, feminist scholars have drawn attention to the importance of journalistic reporting that brings sexual issues out of the private and into the → public sphere, where they can be subjected to scrutiny and public debate (→ Scandalization in the News). Infotainment formats circulate these issues more widely, in the responses to celebrity sex scandals, for example, or confessional talk shows where ordinary people expose their sexual problems or transgressive sexual behavior to expert and public commentary (Shattuc 1997; → Infotainment).

## **CRITIQUE OF PATRIARCHAL TEXTUAL/SEXUAL CONVENTIONS**

The critique of mainstream cinema by feminist film theorists, and the call for women to develop new filmmaking practices, has been particularly influential, drawing attention to the sexual politics of recurring narrative structures, visual conventions, and discursive framing, which position the spectator as masculine and foreground male desire. These approaches also cross over into the debates about pornography and to the analysis of the gender politics of television, which came to prominence in the early 1980s. Analytic techniques derived from → semiotics and psychoanalysis have been used in feminist film criticism to show how patriarchal ideologies are reproduced through the eroticization of unequal power relations via the sexual objectification of women's bodies mediated through the male gaze. This also reveals a history of racial subordination and segregation. Marginalized and abjected, in contrast to the idealization of the white female star's sexual allure, women of color have been commonly cast as sexually promiscuous, and lacking the sexual virtue and restraint expected of "civilized" white women. This binary structure of idealization and sexual denigration has been understood psychoanalytically as a complex mixture of fear and desire in men's sexual relationship to women arising from Oedipal guilt. Social prohibitions relegate the unacceptable aspects of sexual desire to the unconscious, which then return in obsessional fantasies that can be traced across the mediascape. The relation that exists between the expression of these unconscious desires and everyday conscious behavior, which has emerged in debates about censorship and pornography, is a matter of dispute. Pro-censorship feminists see it as a harmful legitimization of men's power over women, while others highlight the futility of legislating against the expression of transgressive desires that are themselves the product of societal prohibitions (Krzywinska 2006).

While liberal regimes draw a distinction between mainstream media and a potentially harmful pornography whose circulation must be carefully restricted, feminist analysis points to the continuities across this regulatory boundary in diverse genres, such as → advertising or → Hollywood films, which share with pornography a perspective where women are the object of men's sexual desire. The inherent violence in these textual relations is made explicit in the ubiquity of rape imagery and narratives that constitutes "a cumulative set of discourses that saturate the cultural landscape" (Projansky 2001, 17) and which, it is argued, play a role in maintaining women's subordination through fear. This creates a real difficulty for any program of → censorship, however. Regulatory bodies in the UK, for example, have responded to feminist critique by replacing restrictions on sexual explicitness with a more focused concern with the portrayal of sexual violence. Yet this will not have much impact on the sexual power relations that saturate the media environment. For example, feminist scholars have noted the pleasure women gain from fantasy scenarios of unequal power in "romance" genres, which are as ideologically potent as the more obviously sadistic genres addressed to men. Accusing women of complicity in their own oppression highlights the gap that opened up between feminist critics and the tastes of the majority, which led in the 1990s both to a backlash against "political correctness" and the development of postfeminist popular culture.

### DIVERSIFICATION AND DISTINCTIONS IN TASTE

Other post-war social movements in western democratic societies have also had a substantial impact on the debates about sexual content in the media. A more diverse culture of sexual expression was advocated by the bohemian challenge to bourgeois sexual propriety in the “permissive era” of the sixties. This was followed by a challenge to *heteronormative media cultures*, which, linked to extensive campaigning for political and cultural rights for gays and lesbians, has produced a growing acceptance of “queer” sexual portrayals in the western media. These developments have been further enabled by the niche markets opened up by new digital technologies of production and distribution, and the challenge to top-down regulation of “taste and decency” in a consumer-led market. In television, for example, the development of multiple channel televisions has enabled explicitly sexual programs addressed to a gay and lesbian audience to be developed and sold worldwide. Drama serials such as *Queer as folk*, about a group of gay friends, or the *L word*, about a community of lesbians, have been welcomed for moving away from the “homosexuality as a social problem” approach that previously characterized their treatment in the media (→ Gay, Lesbian, Bisexual, and Transgender Media Studies).

The positive role of fantasy in sexual portrayals is emphasized by libertarian theorists, who welcome the expression of repressed and transgressive erotic desires that limit women’s sexual expression as much as men’s. In this view, “unruly” impulses which are denied expression in everyday life are enjoyed in the “safe” space provided by the popular media, acting as an outlet for sexual drives that exceed the moral and political disciplinary boundaries of the patriarchal order or, indeed, the “politically correct” discourses of feminist critique. Cultural theories emphasize the political ambivalence of these temporary transgressions and their openness to hegemonic appropriations that diminish their political power. For example, there are doubts about the radical value of the “*raunch culture*” that has developed out of the utopian visions of sexual emancipation originally linked to the “second wave” women’s movement, given that it has led to a more intensive commercial exploitation of women’s sexuality alongside a decline in women’s allegiance to feminist politics (Levy 2005). More positively, it has encouraged the address to women as an audience for sexual content in the mainstream media, enabling guilt-free access to sexually explicit media that, it has been argued, is a more significant development for women’s “right to sexual pleasure” than the transgressive pornography valorized by libertarian feminists in that it can be more easily integrated with women’s everyday lives (Juffer 1998).

The globally successful TV series *Sex and the city* on the US pay channel HBO offers a dramatization of this new sensibility in contemporary western cultures, in which women’s desire to achieve sexual satisfaction is a central motif alongside an ironic recognition of the contradictory expectations of contemporary femininity (Arthurs 2004). This ironic response to the continuing power of traditional gender power relations in a postfeminist society is also exemplified by the rise in the 1990s of the knowingly sexist “lads mags” such as *FHM*, which carry sexually explicit pictures of women alongside humorous features and commentary.

## GLOBAL ISSUES

Sexual freedom may be seen as “empowering” in a context where women have won widespread economic and political citizenship in their own right, but is easily appropriated to more exploitative purposes where economically vulnerable women have little choice to refuse the terms on which their “liberated” performances are bought. Marxist feminists point to how capitalist cultures exploit women’s sexuality for profit and women are rarely the ones who control the process. Glamorous images of sexual freedom in the western media have been identified as one of the lures to migration for impoverished and disempowered women in the poorer regions of the world, who, in the worst cases, find themselves trapped into sexual servitude of various kinds. Charitable agencies seek to counteract the dangers via media campaigns about sexual exploitation. MTV Europe Foundation, for example, targeted male customers in a multimedia global campaign in 2005 alerting men to their complicity in trafficking.

The global flows of sexualized imagery via the Internet and → satellite television also generate controversy and censorship where they encounter divergent cultural contexts and regulatory regimes, as has been seen in China’s response to their entry into the international market. The public display of sexualized women’s bodies has also been central to the perceived corruption of values in western consumer cultures that traditional Islamic societies are seeking to resist. Another concern has been the proliferation of pedophile sites on the Internet, which has brought calls for international cooperation to prosecute the producers and consumers.

Cross-cultural exchanges also produce processes of hybridization and syncretization. For example, the impact of the South Asian diaspora on changing sexual cultures and marriage rituals is evident in mainstream Bollywood films and the cosmopolitan bricolage that characterizes the wedding magazines consumed by the new transnational urban middle class in India. Indeed, in this new taste culture “sexuality is most often the site marking and negotiating these class interests” (Desai 2003), while the power relationships involved are explored more critically in low-budget independent films such as *Monsoon wedding* and *Bombay boys*.

## **Sex and Pornography Online**

*Divina Frau-Meigs*

*University of Paris III*

Pornography online, sometimes called “cybersex,” has been assimilated to the discourse on sexuality as a mode of liberation for humankind through the exploration of sexual and political alternatives (Hunt 1993). The question is whether cybersex offers new constructions of pornographic exchanges.

The definition of pornography has not changed much over the centuries (→ Pornography, Feminist Debates on). It is the deliberate representation of obscene material about the body in order to create sexual arousal. Three *conditions to create pornographic desire* are necessary: anonymity, an intimate and yet alien relation to the other’s body, and the possibility of replacing one body with another (*American Journal of Semiotics* 1989). Computer technology meets these three conditions of erotic arousal: it offers secrecy, interaction with strangers, and repeatable substitution.

Seen within this framework, cybersex is traditional pornography disseminated through another medium. The → Internet carries *erotica*, the description of detailed aspects of sexual relations, and *exotica*, representing perversions and deviations like sado-masochism, zoophilia, and necrophilia. They appear on “free” bulletin board systems like alt-sex-bestiality or alt-sex-bondage, on the tacit understanding that the user trades his or her words or images for access. They are mostly, however, to be found on pay systems like Laura’s Lair or Pleasure Dome.

Cybersex holds the promise of total sensitization that the machine provides for users in its virtual reality format (→ Sex and Pornography as Media Content: Feminist Perspectives). Artificially simulated intimacy is present, in the form of three-dimensional

images (→ Body Images in the Media) like Virtual Valerie (the creation of Mike Senz), the first articulated doll to participate in erotic games on a computer; or in the form of exoskeletons with goggles, data-gloves, and sensors that allow the client to meet partners in virtual space. From a human rights perspective, they are presented as less exploitative of the real body, often the female body, and women are quite active in Internet pornographic discourse, as can be seen in magazines like *Mondo 2000* or *Future Sex*.

The changes in pornography mediated by the Internet are with respect to the relation to the other's body. Sexual exchanges on the Internet have accelerated a tendency of pornography to *annihilate the body* in the name of desire and to *intellectualize sex* (→ Sex and Pornography as Media Content, Effects of). This was already the case in the writings of the Marquis de Sade in the eighteenth century. New technology annihilates the body because it replaces the other's body with the computer, as a low tech sexual aid like a dildo replaced the other's body in earlier times. It intellectualizes sex because the computer interface and the use of (hyper)text substitute the language of negotiation for advancing, accepting, or resisting flesh, thus releasing the sensation of pleasure as a drug for the brain, not for the sexual parts of the body.

The screen as an interface for sexual exchange allows these two tendencies to develop fully. It is central to high tech pornographic sex, as it fulfills the conditions of anonymity and distanced intimacy, and it does so because it gives extensions to the body while forbidding the other to have complete access to it. The screen interface renders the body invisible, thanks to a technology of simulation that fosters *dissimulation*. Interaction does not take place with the body of the other but with computer data, through which desire itself is digitalized. The interface redefines the body and its discourse as part of the cybernetics package of information processing (Stone 1995; Green 2001; → Information Processing: Self-Concept).

To counter the risk and fear of physical contact, the computer offers the possibility of substitution by digitalized contact. The interface, by images and through aliases, avatars (→ Avatars and Agents), and hypertextual journals, diaries, and other writings, allows the expansion of this new form of expression. It plays on the fuzzy lines of hypertext as a new means of contact-discourse. The openness of this writing process offers liberating, even libertarian possibilities that Theodor Holm Nelson (1993), the inventor of hypertext, extols as the essence of computer innovation. He considered that "teledildonics" (giving oneself sexual pleasure with technology, especially via computers) was the first outcome of the computer technology (Rheingold 1991, 345).

The Internet offers a multiplicity of imaginable sexual relations – a catalogue of pornographic styles. This follows the typical Sade-like practice of excess and subversion by saturation that builds up the paraphernalia of virtual sex, the third order of sex: after sex as nature and sex as discourse, sex as an unproductive state, without secretion and seduction, that would be characteristic of the postmodern condition (Kroker et al. 1989, 182; Cooper 2000).

Cybersex also offers a third order of evolution in the construction of sexual exchanges by technology, as new communication devices push the historical limits of pornography, testing the confines of what is socially permissible. In the *first order*, before print technologies, pornographic transgression was organized around forbidden objects of desire (religious taboos) that could not be imagined at a distance. Sensitization with the other's body was necessary for arousal. In the *second order*, with the arrival of print and

audiovisual technologies, transgression became organized around fantasy, as the objects of desire could be imagined at a distance. Sensitization became possible by projecting desire onto the other's body. In the *third order*, with the advent of the Internet, the objects of desire no longer have to be socially acceptable, as they can belong to imaginary realms and constructions. Transgression takes the shape of substitution. Sensitization of contact is possible by simulation, as the pornographic exchange consists of interfacing with the data of a virtual body (Frau-Meigs 1996).

Questioning reality follows from the traditional justification of pornography. It functions according to an authenticity code that denounces the artifice of normal relationships and social taboos. With cybersex, the relation to signs and to representation has been reversed such that only what is imagined, dreamed, fantasized has real value. More than a criticism of the world in political terms, cybersex tends to eliminate the external reality of politics and social life, to take refuge more completely in a temporary utopian zone, a site where politics and society can be redefined in individual, fictitious, and abstract codes.

## **Sex Role Stereotypes in the Media**

Joy L. Hart

*University of Louisville*

Sex role stereotypes represent women and men in highly generalized, often unrealistic, ways. Such media → stereotypes are important because representation plays a key role in

shaping what becomes social reality (→ Information Processing: Stereotypes; Media and Perceptions of Reality). Mediated messages influence knowledge as well as what is deemed significant and interesting (Brooks & Hébert 2006).

Repeated media images shape → attitudes, beliefs, and values. The media communicate to audiences the contours of current social reality while simultaneously helping to create it. Within television studies, for example, it has been argued that heavy viewers are most likely to accept stereotypical assumptions about certain groups in society (→ Gerbner 1998; → Cultivation Theory; Cultivation Effects).

Considerable research addresses the media's role in perpetuating stereotypes, including sex role stereotypes (→ Stereotyping and the Media). Scholars have examined a variety of media types – e.g., movies (→ Cinema), → television, → radio, advertisements (→ Advertising), → newspapers, → Internet – and highlighted the potential negative social influence of repeated exposure to stereotypical presentations of sex roles. Sex role stereotypes convey messages about expected appearance and behavior of women and men, shaping both our ideas and expectations of women and men. Moreover, sex role stereotyping in the media creates and perpetuates a reality that oppresses less powerful social groups.

## OVERVIEW OF RESEARCH

Researchers around the world have examined sex role stereotypes in the media. In general, findings tend to be quite consistent, showing that, despite some improvements over the years toward more divergent and realistic portrayals, stereotyping continues. For example, although there are more female characters on television and women are playing increasingly varied parts, they are still underrepresented in relation to men and to their actual numbers in society. Most women who do appear are young (Eschholz et al. 2002). Older women characters tend not to be positively portrayed. Older male characters tend to be depicted as being wise and independent, whereas older women are often represented as irrational and dependent.

Across most media types, women are more often presented as emotional and sensitive and men as serious, dominant, and prone to committing violence. Men act as workforce role models, and women as domestic role models appearing more often in household situations. Various studies indicated that in the late 1990s, male television characters were more likely to be shown at work and to talk about work than female characters, who were repeatedly shown in the private sphere and tended to talk about relationships (for an overview see Ross & Byerly 2004).

## EXAMPLES OF SEX ROLE STEREOTYPES

Over time, a number of common sex role stereotypes have been discussed in the literature. These include general depictions of women and men as well as more specific stereotypes based on a number of factors (e.g., gender, race, sexual orientation, context, age).

Griffin (1998) has highlighted the fact that in the US media, there are several common images of women that tend to *reinforce ideas of sex difference*, including hetero-sexy beauty queens, wholesome girls next door, cute pixies, and wives and mothers. According to Nelson & Paek (2005), in spite of social and economic advances US women have made in

recent years, the media continue to portray them primarily as sex objects, reinforcing the “sex kitten” stereotype (→ Sexualization in the Media). They find this depiction occurs even when the target media audience is women. In assessing US advertising media, some recent findings have shown an increase in the amount of sexism, sexuality, and objectification of women. For example, approximately 50 percent of → magazine ads depict women in sexualized ways. In Japanese television ads, women are significantly more often used as “attention getters” than men (Nelson & Paek 2005). Contemporary media around the world now show an abundance of images of women wearing sexy clothes posing in decorative ways. Repeated audience exposure to such images may over time cultivate the perspective that women are to be defined primarily by and valued for their sexual attractiveness to men (Lavine et al. 1999).

*Stereotypical images of men* are also commonly presented by the media (→ Masculinity and the Media). One avenue of research inquiry has been the examination of male heroes. Across the media, male heroes abound, ranging from traditional types (e.g., heroes in war films and Westerns; → Film Genres) to newer forms of the warrior (e.g., Teenage Mutant Ninja Turtles; Donald 1992). Through these portrayals of warriors, males demonstrate aggression in ways that often receive societal validation. According to Donald (1992), the cowboy, a rugged, resilient figure, and the first hero of many men in the US, is also evident in war films, which are essentially Westerns set in other locales. Recent portrayals of masculinity include the hypermuscular male body with its sculpted shape. Like idealized female body images, this body type is nearly impossible to attain (Hatoum & Belle 2004).

Several studies have examined how women and men of different races tend to be portrayed in the media and numerous sex role stereotypes have been discussed in this work. For example, there has been considerable criticism of the mediated sex role stereotypes of African American women. Brooks & Hébert (2006) discuss several such common stereotypes, including “mammies,” “matriarchs,” “jezebels,” and “welfare mothers.” African American women’s bodies are often portrayed as “hypersexed,” leading some to assert that African American women are seen primarily as sexual, rather than romantic, characters (Brooks & Hébert 2006). Older African American women often appear in roles based on the “mammy archetype,” while younger African American women are more frequently depicted as “welfare queens” and “baby machines,” emphasizing promiscuity and greed (→ Black Feminist Media Studies).

*African American men* are also stereotyped in the media. According to Brooks & Hébert (2006), common stereotypes include “the shuffling Uncle Tom,” “the savage,” and the “childlike Sambo.” Other mediated stereotypes of African American men include “Uncle Remus” and “the magical negro.” Some US programs (e.g., *Frank’s Place*) have challenged traditional conceptualizations of black masculinity. However, Orbe’s (1998) assessment of black masculinity on *The Real World* showed that black men were portrayed as angry and aggressive. Orbe (1998) points out that such images reinforce fear of black men and that the show fails to represent black masculinity in positive ways.

*Far Eastern women and Latinas* are portrayed as exotic and sexual. Women from the Far East tend to be stereotyped as lotus blossoms, who are passive and the love interests of white men, or as dragon ladies, who act as partners in crime of men from their own cultures (Brooks & Hébert 2006). Latinas tend to be depicted as highly emotive, possessing hypersexual toughness, and exotic temptresses (→ Latina Feminist Media Studies).

According to Brooks & Hébert (2006), Far Eastern men are often depicted as menacing foreigners, laborers, corrupt businessmen, and martial artists. In general, they are not shown to have dominant male characteristics. This desexualization, especially combined with portrayals of the hyperfemininity of Far Eastern women playing the love interests of white men, reinforces white male dominance and emasculates Far Eastern males. Media coverage underrepresents and misrepresents Latinos who tend to be represented in problematic work roles (e.g., drug dealers, criminals) and as prone to violence. Frequent stereotypes include the bandito and the Latin lover (Wilson & Gutiérrez 2003).

Research on depictions of *Native American women and men* is scant. In examining images of Native American women, Portman & Herring (2001) explore the “Pocahontas paradox,” which is responsible for the continued romanticization and vilification of Native American women. According to these authors, the US media tend to portray Native American women as having power and strength or beauty and lust, such depictions merging into the Pocahontas stereotype. The mythology surrounding Pocahontas is damaging to Native American women, in part because media discourse foregrounds Pocahontas’s love relationship with a white man, John Smith (Portman & Herring 2001; Brooks & Hébert 2006). Sex role stereotypes of Native American men include the savage, the sidekick, and the underling. Few recent studies exist on the portrayal of Native American men. One exception is analysis of the novel and film *The Indian in the Cupboard*, although scholars disagree on whether the book and film reinforced or combated existing stereotypes (Brooks & Hébert 2006).

*Sex role stereotypes in sports* coverage tend to trivialize women or exclude them altogether. Such mediated messages reinforce the stereotype that sport is a male domain and downplay the appropriateness of female competitiveness. In addition, coverage of women athletes gives more focus to attractiveness and appearance than characteristics linked to sports success for men (e.g., strength, endurance). In spite of increasing participation, women in sports have long been “underrepresented and misrepresented” in media coverage (Hardin et al. 2005). These biases in coverage bolster notions that women are less suitable for sports. Differences in media coverage also exist in sport type. For example, women’s performance in sports regarded as aesthetically pleasing (e.g., figure skating) is highlighted and women tend to show up most frequently in individualized sports (e.g., golf, tennis). Women are more often depicted in passive poses, while men are shown in action. Women engaging in male-dominated team sports, such as ice hockey or basketball, are often ignored or portrayed as masculine. In addition, the physical appearance of women is emphasized much more often than their athletic ability (Hardin et al. 2005; → Sports as Popular Communication).

### CHANGES OVER TIME

Studies on sex role stereotypes in the media in different parts of the world appear to suggest that some types of stereotyping have decreased, but that other forms have taken hold, such as a greater incidence of the sexualization of violence in popular Hindi films (Ramasubramanian & Oliver 2004). Research on how women have been depicted in advertising over time indicates that obvious stereotypical images are less commonly employed but that use of subtle messages about sex roles and the power hierarchy remains frequent (Lindner 2004). In advertisements, for instance, women and girls are objectified,

subordinated, and mentally withdrawn from the situation (Lindner 2004), as extremely thin, physically weak, and childlike (Kilbourne 2003), or, as in the case of US advertising images of Indian women, as exoticized (Ghosh 2003).

Thus, the reality crafted by repetition of such mediated stereotypes is one of restricted representations of women and men – representations that counteract or diminish strides made by women and minorities. Through their subtle unity, sex role stereotypes in the media reinforce patriarchy and hegemonic masculinity (Dyer 2002; Eschholz et al. 2002; → Sexism in the Media). Overall, study results are mixed – suggesting some, little, or no progress in ending sex role stereotypes in the media. Whatever the case, it is clear that much work needs to be done to achieve fairness and equality. Sex role stereotyping continues – as do admonitions from scholars, researchers, and activists that it perpetuates sexism and makes it less likely for social and economic equality between women and men to be imagined and made real.

## Sexism in the Media

Carolyn M. Byerly

Howard University

Sexism in the media relates to concerns about a range of gender inequalities – in content, employment, policy, decision-making, and ownership – that have been a major focus of women's liberation movements throughout the world since the 1970s. Mass media matter to women everywhere. They play a central role in the formulation and dissemination of ideas and the shaping of → public opinion, whether their format is news, entertainment, or → advertising. In fact, the media's influence is even greater today than ever, with 24/7 news channels, and hundreds of satellite and digital services offering everything from natural history to hardcore pornography and picture messaging via mobile phones.

Popular media such as film (→ Cinema), → television, → newspapers, and → magazines have universally tended to frame women (in every sense of the word) within what many have found to be a narrow repertoire of types which bear little or no relation to how real women live their real lives (Byerly & Ross 2006). Since the 1960s and 1970s, with the rise of women's liberation movements – also called feminism – within all nations of the world, women began to recognize and analyze these problems. For example, they saw the numerous ways in which historically they had been ignored or misrepresented by the news, as well as stereotyped in television programs, film, advertising, and magazines (→ Sex Role Stereotypes in the Media). Women also understood that having respectful, accurate, and progressive images and messages about themselves in news and other media was essential if they were to have a louder public voice and more fully participate in public life. The solution would not be a straightforward one, as sexism in the media springs, in large part, from women's larger structural marginalization in society, as well as the more specific lack of control over hiring and content decision-making within media industries. While women's particular relationships to mass media have varied somewhat from nation to nation, women have found a certain consensus in their concerns, which together comprise a feminist critique of mass media and a range of strategies for change.

## FEMINIST CRITIQUE OF MEDIA

*Symbolic annihilation of women:* the first point of the feminist media critique identifies women's absence and trivialization in the news and other "serious" media forms. Such treatment has been called the "symbolic annihilation of women," a concept originated by international media scholar George Gerbner (1978) and then applied to the specific situation of women by US sociologist Gaye Tuchman (1978; → Symbolic Annihilation). In her introduction to the foundational edited book *Hearth and home*, Tuchman said women are symbolically annihilated when they are made invisible, trivial, or otherwise misrepresented in television content. She included representations of women that "make them into ornaments" or needing men's protection in this definition.

*The hyper-sexualized woman:* the second point of the critique revolves around the sexual exploitation of women, which occurs across all media forms, including advertising. The problem manifests itself in several ways. One is the undue emphasis placed on women's sexual attributes over other qualities (e.g., intelligence, competence, achievement). A second relates to patriarchal (i.e., male superior) messages contained in the media content, such as advertisements for women's products that say, in essence, you must use this product to achieve the right look if you want a man to notice or love you. A third way the problem occurs is in the implied or overt use of violence against women by men, including gratuitous depictions of women being harmed, or in humiliating positions. Women have argued that all of these instances affirm men's social, economic, and political dominance, while reinforcing women's marginalization.

*Structural marginalization in the industries:* the third point of the feminist critique of media sexism has focused on women's exclusion from employment and decision-making in, and ownership of, media enterprises. The major issue here has been systematic discrimination that prevents women from being hired, promoted, and retained in news and other media industries. These levels of participation have been understood to hold central importance if women are to exert greater authority over messages and images, and be able to replace sexist content with that which more fairly represents women's range of roles, concerns, aspirations and contributions in and to society. Feminist political economists have placed particular emphasis on women's severe marginalization at the ownership and policy-setting levels and, by contrast, men's overwhelming dominance in media ownership. This pattern, which has accelerated markedly since the 1980s through conglomeration and globalization trends in media industries, has tended to concentrate control of the industries (and the wealth that flows from it) in the hands of a few wealthy men (→ Globalization of the Media; Media Conglomerates; Ownership in the Media; Political Economy of the Media). This gendered structural imbalance in media industries illustrates the material ways in which sexism manifests itself at the macro levels within and across nations.

## RESPONSES TO SEXISM IN MEDIA

Women have moved on a number of fronts throughout the world to redress and reverse sexism in the media. Some of these initiatives have been individual efforts, and others have been undertaken collectively in more organized ways. Together, these efforts constitute women's media activism, something that has been central to women's

liberation movements throughout the world. Byerly and Ross (2006), who have studied that activism, found that women have followed several paths, or approaches, in trying to reform mainstream media, change media policies, and establish women-owned enterprises. For example, some trained as media professionals have used their insider advantage to bring feminist-oriented content into news and other media (→ Feminist Media), or to advocate for women's advancement within media enterprises. South African journalist Crystal Oderson, for instance, has worked to encourage the hiring and retention of black women at her own broadcast station, while French journalists Virginie Barré and Natacha Henry have promoted women's status in news fields through the Association des Femmes Journalistes (Byerly & Ross 2006). Other feminist media activists have formed advocacy groups that monitor the media's performance and/or wage campaigns targeted at some specific problem. For example, Seeta Pena Gangadharan and Aliza Dichter co-founded the Center for International Media Action, in San Francisco, a US-based group that advocates for ownership limits in media through reformed federal policy that would expand women's ownership, particularly in broadcast media. Women's media action has also included the establishment of women-owned media – book publishing houses like Kali for Women, in India; syndicated radio programs, such as Women's International Newsgathering Service (WINGS), Vancouver, Canada; and the online international Women's eNews, based in New York, among others.

### **CONSIDERING PROGRESS**

With any social struggle, change occurs simultaneously alongside resistance to change, in a dialectical process. Thus, women have had some important successes in overcoming sexism in the media, while at the same time they remain vigilant of the persistent sexist patterns described earlier. Some success can be measured quantitatively. For instance, since the 1970s, women have established hundreds of women-owned media companies throughout the world, including feminist-oriented book publishing houses, magazines and newsletters, radio programs, film and video companies, film distribution centers, and, more recently, websites and weblogs (blogs). The last of these, accomplished through new technologies, enable women with computer access to transcend national boundaries, as well as traditional boundaries of private and public spheres. Media scholar Gillian Youngs (2004) has called cyberspace the “new feminist frontier” because it enables women to engage in multiple forms of networking, information sharing, political analysis, collaboration, and agenda building (→ Cyberfeminism).

In terms of women's representation in the traditional media, there are some signs of change. For example, there are stronger and more plentiful roles for women today in both film and television programming in many nations, and women of varied races and of lesbian identity have found a place (though still limited) in many films and television dramas. There are, of course, also the enduring sexist stereotypes, as well as women's graphic victimization as forms of entertainment (→ Sex and Pornography as Media Content, Effects of; Sexual Violence in the Media). In terms of news coverage, many of the issues that women have agitated for (e.g., rape law reform, an end to domestic violence, AIDS prevention) are being covered with greater regularity and sensitivity by many news organizations (Byerly & Ross 2006).

However, the 70-plus-nation Global Media Monitoring Project (GMMP), which has been conducted every five years since 1995, found in its 2005 round that women are truly at the periphery of most news. Very little news around the world – only 10 percent of all stories – focuses specifically on women, with Canada (23 percent) and the US (20 percent) leading. In addition, women are rarely central in stories that comprise the bulk of the news agenda – politics (8 percent) and the economy (3 percent). Reporting on gender inequality (which exists everywhere) is almost nonexistent – only 4 percent of all stories highlighted equality issues. In 2005, 53 percent of those stories were reported by men – something welcomed and encouraged. However, because such a small percentage of the stories do discuss gender equality, the news agenda, overall, can be understood as still dominated by male priorities and perspectives (Gallagher 2006, 19–20).

Some of women's progress in overcoming sexism in the media can be seen in the creation of large-scale strategies with long-range goals. Central here are the more than two dozen media monitoring and advocacy groups functioning in nearly as many nations. Margaret Gallagher, who coordinates the largest of these, the GMMP, places considerable importance on the role of monitoring as a change agent. Monitoring produces data that can be used to advocate for changes within the news media, she says, but also to build on in important ways (Gallagher 2001; → *Activist Media*). For example, the 2005 round of the GMMP utilized its findings to, first, develop an "advocacy toolkit," containing training materials that local advocacy groups use to work more productively with media professionals to improve coverage of women and to bring about other social change. Second, eight regional training workshops were held to teach local community organizers how to use these toolkits. Third, GMMP sponsored "global weeks of action" (February 8–March 8, 2006), something endorsed by → UNESCO and other international groups, to focus attention on women and news. And, finally, a GMMP website on media monitoring and advocacy was established to provide resources and specific "how to" procedures ([www.whomakesthenews.org](http://www.whomakesthenews.org)).

Gender Links, a monitoring, advocacy, and training organization headquartered in Johannesburg, South Africa, is an example of a regional organization that established a network in 2004, called GEMSA – Gender and Media Southern Africa. GEMSA's action program brings media professionals together with women's activists in order to develop best practices for integrating gender into news and other media. The first international effort of its kind, GEMSA conducts research on media policy, media coverage and representation of women, training of both male and female media professionals, and a range of other advocacy organizations (Morna 2004).

Thus, feminist-led efforts to end sexism in the media occur at many levels, simultaneously. Latin American sociologist Pilar Riaño (1991) emphasizes the importance of such, particularly at the local level, as something that constitutes women's participation in grassroots public arenas through communicative practice (Riaño 1994, 122) (→ *Community Media*; *Grassroots Media*). At the same time, large-scale regional and international efforts, such as those carried on by GMMP and Gender Links, illustrate how women are making institutional reforms at policy and production levels. The optimistic view of these efforts, taken together, is that change is coming and will continue to come, and that an important role for communication researchers is to follow and evaluate their results.

## **Sexual Violence in the Media**

*Jenny Kitzinger*

*Cardiff University*

The representation of sexual violence has been subject to critical inquiry in two main ways. One strand of research explores whether scenes of sexual violence (in films, computer games, and pornography magazines) might trigger sexual aggression. This sort of research is often pursued under the umbrella of psychology and criminology (→ Violence as Media Content, Effects of). A second strand, more often pursued by communication scholars, focuses more on how the media frame sexual violence as an

issue. The aim of this body of work is to explore how the media present the causes of, and solutions to, sexual violence, and examine how this might help to shape public and policy responses. This approach also includes an interest in the everyday representations of sexuality that infuse popular culture and how these might reinforce gender inequalities or romanticize sexual aggression (Ramasubramanian & Oliver 2006).

## **BACKGROUND**

Research into sexual violence in the media blossomed from the 1970s onwards in the UK and the US alongside the emergence of the women's liberation movement (WLM). WLM activists fought for recognition of the extent and seriousness of all forms of violence. Although rape is the "signature assault" usually used to represent sexual violence, feminists highlighted a continuum of abuses, including sexual harassment in the workplace, forced sex in marriage, domestic violence, and the sexual exploitation of children within the family. Throughout the 1970s and 1980s, the WLM fought to challenge the idea that rape was just "a bit of fun," worked to reform the unsympathetic way in which police treated rape complainants (e.g., the assumption that they must be lying), and questioned the routine use of victims' sexual histories to discredit them in court. The WLM also campaigned for new legislation in many countries, for example that a man could be charged with raping his wife.

Alongside such efforts, feminist campaigning also had a profound impact on media representations: countering the salacious reporting of attacks as titillation and the promotion of the idea that women enjoy rape (→ *Gender: Representation in the Media; Pornography, Feminist Debates on; Sex and Pornography as Media Content: Feminist Perspectives*). Particular TV programs were also instrumental in raising the profile of incest, for example, as well as prompting debate about the legal status of rape in marriage or the abusive nature of police investigations in rape cases (Cuklanz 1996; Kitzinger 2004a).

## **KEY FINDINGS AND ISSUES**

Although there have been major changes in the media representation of sexual violence in many countries since the 1970s and 1980s, more recent research still highlights problems. For example, communication researchers note an element of "moral panic" around the reporting of some forms of violence (such as ritual child sexual abuse). This is combined with a media "fatigue" and a declining interest in the most commonplace forms of sexual assault. Although someone familiar to the victim perpetrates most sexual violence, this is not the impression promoted by the bulk of media reporting (Kitzinger 2004a). In addition, when victims know perpetrators, the perpetrator may be excused or their violence minimized and the victim subtly implicated in her (or his) own victimization (Benedict 1992; Moorti 2002). Indeed, alleged assaults by boyfriends, family members, or others in a position of trust often only seem to attract major headlines through the lens of disbelief. This allows for a new discourse of skepticism to be promulgated. Peak coverage in the UK and the US has focused, for example, on controversies around contested "date rapes" and scandals around allegedly false allegations of child sexual abuse (e.g.,

intervention “scandals” or “false memory syndrome”; Kitzinger 2004a; → Scandalization in the News).

Journalists also often position abusers as “outsiders” via a variety of rhetorical devices. They may portray an assailant as a “beast” or “animal” or use racist stereotypes (tapping into a long history of fear of black men and justification for racist attacks such as lynching; Moorti 2002). Although a white-dominated western feminist movement has often prioritized gender as a category of analysis, critics highlight the inadequacy of a “color-blind” approach, citing the complexity of controversies surrounding sexual harassment/violence accusations against black men such as US boxer Mike Tyson or Clarence Thomas, the nominee for the US Supreme Court (Morrison 1992; → Black Feminist Media Studies). It is also important to examine how media reporting may promote homophobic assumptions (e.g., journalists sometimes conflate gay men and pedophiles; → Gay, Lesbian, Bisexual, and Transgender Media Studies; Heterosexism and the Media). Even apparently neutral or expert concepts, such as the word “pedophile,” are potentially problematic. The very fact that there is a special noun for those who sexually abuse children implies that they constitute a breed apart. It also singles out the sexual abuse of children, as if there were no connection between abuse perpetrated against boys and girls and that perpetrated against adults (Kitzinger 2004a). This effort to isolate the sex offender from society fails to address the continuum of abuse or to confront the widespread nature of “mundane,” everyday, sexual violence and the cultural attitudes that support it (Carter 1998; Kitzinger 2004b).

When journalists *do* connect sexual violence to endemic cultural attitudes, it is usually in considering “sub-” or “foreign” cultures. Coverage of one notorious gang rape in the US, for example, suggested that only the Portuguese-American community held the sort of attitudes that led to such assaults (Moorti 2002). Similarly, reporting about the rape of the Central Park jogger by a group of young black men in 1989 treated “inner-city youth culture” as the problem (Cuklanz 1996). These types of cultural explanations are even more evident in western reporting of sexual violence in “foreign” countries. US news media accounts of the 1991 mass rape case in a Kenyan school, for example, associated the abuse of women with “tribal tradition” and collapsed all Kenyan women into the one-dimensional category of “the oppressed” (Hirsch 1994). Sometimes the western media seem happiest focusing on “exotic” violence against women. “Dowry burning,” “honor rapes,” “female genital mutilation,” or the mistreatment of women under “alien” fundamentalist regimes are then treated as evidence of those countries’ backwardness.

How the media frame the problem of sexual violence is vitally important because such framings help to promote certain types of solutions (→ Framing Effects). The tendencies outlined above allow for individualist, law-and-order, and colonialist solutions to be proposed as the only way forward. Concern about the abuse of women can be used to help justify a disproportionate application of the law to certain populations (such as black inner-city youth) or, indeed, intervention against foreign regimes (e.g., in Afghanistan). Framing the problem of sexual violence in the ways outlined above also leads to the responsibility for prevention being often laid at the door of potential victims. Children, we are told, should be closely supervised; young women should be assertive to forestall “misunderstandings” with their boyfriends; and all potential victims should avoid going out alone at night or being sexually provocative. A key theme running through much of

this analysis is that media reporting often ignores radical and self-reflective social strategies. Journalists sometimes seem to prefer to sensationalize the details of an individual attack, than reflect on the real patterns of sexual violence. Newspapers seem sometimes to orchestrate outrage about sentencing, or the release of individual convicted sex offenders, rather than looking at the social changes within the dominant culture that are needed to make rape and sexual abuse a thing of the past (Kitzinger 2004a).

Some of the most interesting work in this field (becoming widely accessible via the Internet) is emerging from parts of the world such as Asia. Media research initiatives in diverse countries confirm that many of the characteristics of media representation in the west are echoed across other parts of the world (→ Feminist Media Studies, Transnational). Such work also brings new perspectives to western approaches. Alongside particular forms of domestic violence (including “honor killings”), other forms of institutionalized violence are highlighted. Issues such as the use of sexual violence in ethnic cleansing and genocide have increasingly gained recognition, as has military sexual slavery and the increasing trade in sex trafficking. Commentators stress the importance of including a gender-sensitive perspective in thinking about disarmament, demobilization, and reintegration, and the importance of linking issues such as trafficking to the breakdown in social structure. The bridge between academic analysis and activism is often very strong. Media monitoring groups challenge bad reporting, as well as providing support and advice to journalists to improve their practices (see [www.icescolombo.org/vaw](http://www.icescolombo.org/vaw); Lloyd & Howard 2005). Such work also records the key role the media can play in helping support social justice. This might include the role of a local newspaper in challenging the punishment gang rape meted out to a young woman in Pakistan, the role of radio programming in supporting the reintegration of women stigmatized by their sexual exploitation during a war, or the importance of the national media as a route through which to put the issue of “comfort women”/“military sex slaves” on the national agenda and push for restitution.

## NEW DIRECTIONS

There is a need for more work that goes beyond textual analysis to examine, and engage with, how media accounts are produced, and how they impact on the survivors of sexual violence as well as on society as a whole (→ Audiences, Female; Critical Theory). Studies of progressive examples of mass media reporting could provide insight into the role of the media in social transformation. Important work could also be pursued by examining specific campaigns designed to transform dominant social norms about sexual assault: initiatives ranging from “community caravans” in Trinidad and Tobago to a CD “virtual conference” for judges in India (Drenzin 2006; → Community Media).

Technological changes also present new sites of research. The ways in which sexual violence can be facilitated by the Internet (including “Internet pedophilia” and trafficking) is gaining attention from some communication researchers (→ Internet: International Regulation; Internet Law and Regulation; Internet, Technology of). Such changes also raise questions about how the Internet might help to challenge sexual violence, creating an avenue for alternative discourses and challenges to the status quo. The Internet also can support international dialogue – a dialogue which helps create new alliances and also

raises questions about the cross-cultural representation and definition of sexual violence. Such debates can provide productive new directions for research in a field of inquiry that is constantly evolving in response to social, political, and technological changes.

# Sexualization in the Media

*Kaitlynn Mendes*

*Cardiff University*

Sexualization is a concept used in communication research, primarily by feminist and gender studies researchers, to describe an increasingly close link between media images of men, women, and inanimate objects and human sexuality (→ Feminist and Gender Studies). Historical portrayals of sexuality tended to focus on psychological characteristics such as passivity and domesticity for women, and aggression and work for men. In recent years, representations of sexuality have centered on the eroticized body (Gill 2007; → Women in the Media, Images of). This is an important cultural shift, demonstrating an increase in the use of bodies and physicality to sell consumer products. The commoditization of sexuality increases as value and sexual appeal are linked. Additionally, developments in media production and technology, including satellite television and the Internet, have helped provide a cheap and easy forum for consumption, marketing, and distribution of sexualized images (Arthurs 2004).

It is no longer enough to be masculine or feminine to achieve one's desires. Instead, media messages appear to suggest that one must be openly "sexual," which in turn means having a young, beautiful body and a luxurious lifestyle. In tandem with this change, Gill (2007) has argued that there have been cultural shifts in the media around the world from portraying women as objects of (male) desire to women (described by the notion of objectification) who sexualize themselves to seek out their own (consumer oriented) desires. One of the most visible changes in recent years is the increase in the erotic codification of men's bodies, emphasizing, as Laura Mulvey (1975) stated in relation to women, their "to-be-looked-at-ness."

Feminist communication scholars have been at the forefront in conceptualizing and researching media sexualization. While some have applauded the shift from media images of women in traditional (passive) feminine roles, others question whether the increased sexualization of women's (and men's) bodies is "liberating."

## THEORETICAL CONCEPTS

Studies focusing on media stereotypes or representations preceded contemporary research on media sexualization. Research examining stereotypical media images has paid close attention to the broad mental images that are presumed to result, and their supposed effects on human attitudes and behavior toward women (→ Stereotypes; Stereotyping and the Media). Studies of gender representation, on the other hand, are grounded in the assumption that the mass media contribute to systems of representation that structure ideological processes in society. Image and representation studies have been used mostly to explore two themes: *sex roles* and *gender roles*.

Some feminists' concern with sexism led its proponents to seek to better understand "sex roles" – or the false belief that women and men are innately different, and that men are "naturally" dominant and aggressive, whereas women are "naturally" subordinate,

passive, nurturing, and compassionate (→ Sex Role Stereotypes in the Media). The difference between sex and gender is that “sex” is based on assumptions about biological sex differences that are widely regarded as “natural,” whereas the notion of gender is based on the idea that sexuality (femininity and masculinity) is socially constructed and maintained through the presence of a structural ideology of hierarchical sexual difference. Sex-role studies have typically criticized media images of women (and men) and deemed many “negative.” As a result, there has long been a demand for more “positive” and “realistic” portrayals. *Representation studies* have attempted to identify underlying gender ideologies and to encourage wider social/structural change in order to challenge the hierarchical binaries of masculinity and femininity. While scholars have identified that women have tended to be portrayed in a narrow range of sex-role stereotypes, there was not always something innately sexual about these roles. Therefore, some scholars argue that it is not sensible to apply the same framework for describing media images in the 1970s to today’s media (→ Media and Perceptions of Reality). This can be attributed to two main factors: first, the feminization of the media, and second, the growing sexualization of social life in many parts of the world.

Patricia Holland (1998) has argued that media sexualization does not mean the same thing, nor necessarily always lead to increasing media feminization (→ Feminization of Media Content). In some western countries, the feminization of news began as early as the 1880s with the introduction of → soft news features. Feminization describes both an increase in the numbers of female journalists and producers, and an increase in human interest, entertainment, and photography. While not everyone agrees on why feminization occurred, there are two main schools of thought. The first includes changing definitions of what is “newsworthy” (→ News Values). The second has to do with the economics of newspapers, targeting female audiences as an important consumer group (van Zoonen 1998).

Michel Foucault (1981) suggested that it is untrue that sex only recently emerged into public discourse. The widely held idea that until recently it was difficult to discuss sexuality is not backed up by historical evidence. The Victorian era, perceived to be a time of sexual repression, was actually one in which sexuality was constituted as a central feature of western social identity, and produced a proliferation of discourses. There are numerous records of public discussions around sex and sexuality in the early 1900s, and from the 1940s onward, research from sexologists such as Kinsey (1948) and Hite (1976) became widely deliberated. With the rise of new social movements in the 1960s, such as those of women’s and gay rights, media discussions about sex increased in frequency and frankness. The media tapped into such social changes – during this time, for example, US magazines such as *Playboy* and *Cosmopolitan* first appeared. In other parts of the world, however, such as India, the media are often the only public spaces today where sex and sexuality are openly discussed (Ramasubramanian & Oliver 2003).

One of the most concrete examples of media sexualization is in the UK tabloid newspaper the *Sun*. In 1970, one year after Rupert Murdoch bought what was then a politically left of center broadsheet newspaper, editor Larry Lamb introduced the first topless model – the “page three girl.” The feature proved to be extremely popular with readers, and contributed to an impressive rise in circulation for the paper. This success prompted other newspapers to adopt similar formats not only in the UK, but also in the

US, Canada, Australia, and elsewhere (although few went as far as the *Sun*, by featuring topless models). While the *Sun*'s editors said that the page three girl sent a message to women that they were free to be sexual subjects, scholars such as Holland (1998) have argued that the page was really designed for men and their sexual pleasure, not women's. Others have argued that page three has a positive influence in encouraging women to be proud of their bodies. Researchers have also noted that some newspapers now feature images of semi-naked men, and that women have helped create and produce these sexualized images.

### OPERATIONALIZING SEXUALIZATION

Research on media sexualization has taken many forms, focusing on different media institutions, forms, and practices around the world. Studies have examined, for example, sexualized representations of women in sport, television drama, the → news, advertisements, → cinema (including genres such as film noir and → Bollywood), female rock stars, women in → cartoons, minority women, men's magazines, and so forth. In addition, the rise in sexualized images of men has prompted research that explores portrayals of men across a range of media genres. The sexualization of children (mainly young girls) is also a new and growing area of inquiry, particularly with regard to their use in advertising (Hartley 1998).

*Magazines* have always been a popular medium for sex- and gender-role inquiries, and therefore it is unsurprising to find media sexualization researchers have also examined these publications (→ Magazine). British studies have documented an increasing media focus on sexual representation in the past 30 years that has contributed to greater complexity around the construction of sexual identities (McRobbie 1996). In recent years, men's lifestyle magazines (such as *Loaded* and *FHM*) have appeared replete with images of scantily clad women. Some suggest that the sexual objectification of women in these publications ("lad" magazines) can be tied to a "backlash" against women's social and political gains as well as to the supposed rise of the "new man" of the 1990s, who was supposed to be more caring, sensitive, and supportive (Benwell 2003).

In the 1980s and 1990s, the sexual performance from female characters became more explicit and central in Hollywood films such as *Basic Instinct* (1992), *Body of Evidence* (1993), and *Sliver* (1993). In India, Bollywood films featured highly eroticized images of women, as women's bodies became increasingly associated with sexual fantasy, a standard feature of these films (Rai 2006). In the US, filmic images of African-American and Latina women have long stereotyped them as sexual, and whose purpose is to pique the male sexual appetite (Bobo 1988; Valdivia 2000).

Though most studies on media sexualization appear to have been conducted in western countries, there has also been research on this issue in the Middle East, India, China, and central and eastern Europe, to name only a few. Sexualization is culturally specific, and the boundaries are not all drawn the same. For example, a study of *Jordanian cartoons* found that women tend to be portrayed as submissive and sexualized, particularly "liberated women" – a negative feature equated with moral "looseness" (Al-Mahadin 2003). Ramasubramanian and Oliver's (2003) study of contemporary Hindi films demonstrates that the sexualization of women in these films tends to portray sexual and

social submission to men – to both heroes and villains who sexually harass or assault them. The frequency and social acceptability of sexual harassment and assault in many of these films, the authors argue, contributes to a normalization of such behavior both in the films and in society more generally as an inevitable part of romantic relationships.

Research on advertising has found that many of the sexualized images of men portray those whose looks are “Latin” (the “Latin lover”; → Latina Feminist Media Studies). Black men, when represented, are usually associated with sporting products, once again tied to the stereotype of their “natural” physical prowess and sexuality. Asian men are rarely portrayed in a sexual way in advertisements (a typical stereotype used is the martial artist; Wilson and Gutiérrez 2003). Recently, there has been an increased presence of gays and lesbians in advertising, although it has been noted that more of these images portray women in a highly sexualized manner (kissing or embracing other women) primarily for (straight) male consumers. Gay men, when represented, are rarely, if ever, touching or kissing (Fejes 2003).

*Audience studies* have focused on how people tend to negotiate women’s representation on television, concluding that it tends to be oversexualized, stereotyped, and predisposes minority women to ethnic subordination and disempowerment (Rojas 2004). There is very little audience research on media sexualization. What has been done is limited in its scope and claims because it is difficult to prove direct or even indirect correlation between consumption of sexualized imagery and people’s actions, behaviors, and thoughts about gender.

It is also useful to note that while not all studies use the label “sexualization” to refer to the phenomenon addressed here, many researchers nevertheless interrogate its concepts and theoretical implications in their work. Regardless of the term used, media sexualization studies have been conducted across a wide range of media forms and focus on an array of different groups portrayed, including women, children, men, ethnic and sexual minorities, and older people.

## Sibling Interaction

Alan C. Mikkelson

Whitworth University

Sibling relationships can be important and influential throughout the lifespan. During childhood, siblings can influence both personality development and behavior. In adulthood, siblings can be an important source of friendship, support, and information. In old age, siblings are often an important source of both emotional and tangible support. Although much is known about the effects of birth order, family size, and sex differences on intellectual and personality characteristics (Cicerilli 1995), less is known about sibling communication and interaction patterns. Sibling interaction is guided by a set of characteristics that, as a whole, are unique to the sibling relationship.

### CHARACTERISTICS OF SIBLING RELATIONSHIPS

There are six different characteristics that together make the sibling relationship unique. It is pervasive, involuntary and permanent, relatively egalitarian, typically includes a long shared history, is often filled with paradox, and comes in a number of different forms based on family makeup.

First, the sibling relationship is *pervasive* in both its longevity and the number of people who have siblings. A 1998 general social survey reported that 96 percent of American adults have at least one sibling (National Opinion Research Center 1998). The sibling relationship is the longest-lasting relationship in many people's lives, as siblings often stay connected with one another throughout childhood, adulthood, and old age. Further, researchers have estimated that around 80 percent of the population spends at least one third of their lives with their siblings (Fitzpatrick & Badzinski 1994).

Second, the sibling relationship is both *involuntary and permanent*. It is involuntary because it is not a relationship of choice like a friendship. It is permanent because even though siblings might choose to disengage from an active relationship, their relationship status as siblings cannot be dissolved (Cicirelli 1995).

Third, the sibling relationship is relatively *egalitarian* in nature. It is more egalitarian than other family relationships, such as the parent-child relationship (Cicirelli 1995), and becomes still more so as the siblings move out of childhood and adolescence. One reason that siblings, especially in adulthood, can interact as equals is that they typically have similar feelings of acceptance for one another.

Fourth, siblings share a long *family history*. Siblings' shared history is different than a shared history with friends because it includes management of sibling rivalry and conflict, parents' equal or differential treatment of siblings, and specific parent-child relationships.

Fifth, the sibling relationship can be filled with *paradoxical feelings and interactions*. In many sibling relationships competition, conflict, and rivalry may exist alongside feelings of love, care, and support (Mikkelson 2005).

Finally, one of the most distinctive characteristics of the sibling relationship is that it exists in a *number of different forms*, based on common biological origin and legal relationships. Siblings that have both parents in common can be identical twins, with 100 percent genetic relatedness; fraternal twins, with approximately 50 percent genetic relatedness; or full siblings, again with approximately 50 percent genetic relatedness. Siblings that have one parent in common are half siblings, with approximately 25 percent genetic relatedness. Other, legally defined sibling relationships are stepsiblings and adopted siblings. Stepsiblings share neither parent in common, whereas adopted siblings may be related (as in the case of parents adopting a niece or nephew) or may not.

Most sibling research has examined full biological siblings. Thus, less is known about relationships such as adopted siblings, stepsiblings, and half siblings. This is unfortunate, as the Stepfamily Association of America (2006) estimated that at some point, 30 percent of children will live in a stepfamily (this estimate included children who live with a cohabiting parent). Further, in European nations, researchers have estimated that stepfamily rates are as low as 4 percent in some countries and as high as 38 percent in others (Prskawetz et al. 2003). In addition, the 2000 US Census reported that 2.5 percent of children under the age of 18 were adopted (Kreider 2003). Although stepsiblings, adopted siblings, and half siblings are quite frequent in their occurrence, less is known about the communication patterns of these relationships (→ Family Communication Patterns).

## **SIBLING INTERACTION**

### **Contact**

Researchers have studied three aspects of sibling interaction in particular: sibling contact, sibling conflict and rivalry, and sibling support. Because siblings live together during the childhood and adolescent years, sibling contact is relatively high. However, as siblings move out of the household to attend college or to live on their own, the frequency of contact between siblings is greatly reduced because they do not share a living space (Leigh 1982). Not sharing a living space can also reduce contact between siblings because interaction with a sibling becomes more of a personal choice. Contact between siblings often tends to decline as siblings move into middle adulthood, as they become preoccupied with their own marriages and families. However, Leigh (1982) found that as siblings move into the later stages in the lifespan, sibling contact increases. Generally, the contact patterns between siblings can be represented by an hourglass figure, with contact patterns being the highest in youth and old age and the lowest during the middle stages of adulthood.

Researchers have examined the factors that predict the extent to which siblings remain in contact with one another. Lee et al. (1990) found that siblings who were emotionally close, felt responsibility for one another, had an expectation of contact, and were geographically close to one another were most likely to stay in frequent contact. The most important of these variables appears to be emotional closeness, as contact patterns between siblings are highly related to feelings of closeness between them (Cicirelli 1995).

Contact patterns between siblings are also influenced by the type of relationship they share. White and Riedmann (1992) found that contact was greater among full biological siblings than it was between half siblings and stepsiblings. Mikkelson (2006) found that, comparing types of sibling relationships, contact was more frequent between twins and full siblings than between half siblings and stepsiblings. Further, adopted siblings' contact patterns were similar to those of full siblings.

### **Rivalry and Conflict**

Although rivalry between siblings starts in childhood and adolescence, there are conflicting research findings with respect to whether rivalry decreases with age or stays relatively stable. Cicirelli (1995) noted that rivalry decreases as siblings age, so that when siblings reach late adulthood, rivalry is minimal. However, other studies have found that that feelings of rivalry often persist even into old age. Cicirelli (1995) argued that these inconsistent findings might be due to the fact that when older siblings still have feelings of rivalry, they often do not express these feelings overtly. Thus, feelings of rivalry between siblings may exist well into adulthood; however, expressed rivalry may decrease as siblings have developed ways of interacting in which the rivalry and conflict do not become explicit.

Rivalry often begins in sibling relationships when siblings compete for such resources as love, affection, admiration, and money from their parents. Although all siblings probably experience some feelings of rivalry, these feelings can be intensified or diminished depending on whether the siblings are treated relatively equally and how much they are

vying for the same resources. When siblings express feelings of rivalry and jealousy, they tend to express them in a distributive way (arguing, yelling, or making hurtful comments) instead of an integrative way (disclosing feelings, discussion; Bevan 2004). Siblings are more likely to express rivalry or any other type of conflict in a negative way, due to the permanent nature of the relationship (→ Interpersonal Conflict).

Among the different types of sibling relationships, while feelings of rivalry may or may not be higher among half siblings and stepsiblings than among full siblings, half and stepsiblings did report a higher percentage of actual conflict than did full siblings (White & Riedmann 1992).

### Support

Siblings can be an important source of support for each other throughout the lifespan. Goetting (1986) argued that the primary developmental task of siblings during early adulthood is to provide companionship, emotional support, and direct aid to one another. During middle adulthood siblings are relied upon for support, particularly in times of crisis. Siblings' support might be most frequent and important in old age. Cicirelli (1995) found in a study of hospitalized elders that sibling support was second in importance only to support from spouses.

Sibling support is predicted primarily by the amount of contact siblings share and their feelings of closeness to one another (Cicerilli 1995). Similarly, Mikkelson (2006) found that the amount of all five types of social support given (emotional, esteem, informational, network, and tangible) was positively related to the amount of closeness siblings felt (→ Social Support in Interpersonal Communication). Further, Mikkelson (2006) found that the amount of social support siblings gave to one another was related to their relationship type. Specifically, identical twins gave the most social support, followed by fraternal twins and full siblings, followed by half siblings, with adopted siblings and stepsiblings giving the least.

## Sign

*Clay Steinman*

*Macalester College*

The sign, in terms first articulated by Ferdinand de Saussure (1857–1913), the Swiss linguist, has come to serve as the basic unit of approaches to communication that focus on meaning-making relations rather than on the effectiveness of senders' communication of intended messages to designated receivers (→ Linguistics; Meaning). Semiotic approaches have been taken up by general communication studies, → cultural studies, post-1960s literary studies, and other fields. For Saussure and for those who analyze culture in his wake, communication involves not messages but signs, material forms that when articulated and then encountered engender meanings bounded by cultural schemata (→ Culture: Definitions and Concepts). The study of signs, then, is at its core social: What conventions determine how signs are made? What conventions determine their readings?

### THE SOCIAL SIGNIFICANCE OF SIGNS

We communicate about the world indirectly through mediating sign languages – gestures, images, sounds, and words but also through such vehicles as decor, design, and dress (→ Code; Gestures and Kinesics). Signs may be studied as a matter of dispassionate interest, as instruments of persuasion, or as objects of social criticism. In the latter case researchers would ask: if communication is mediated by signification, what forms of economic, political, and social power determine the mediations? This question applies with force whenever labels (such as ability, age, class, ethnicity, gender, nation, race, religion, or sexuality) are attached to people like Post-it® notes, legitimating resource inequalities, whatever the intentions of those who apply them.

Because it does not privilege the intentions of senders as does the sender–receiver model, semiotics finds interest in whatever meanings a communication happens to produce. While those engaged in → persuasion judge communication in terms of their goals, semiotic critics scan more broadly. Advertisers, for example, who know the power of signs and are able to catch just the right wave, might well generate unplanned meanings and effects. They invest fortunes to persuade, intending to endow commodities with meanings to increase their value, structurally uninterested in other effects, but in so doing they occasionally shape constellations of mental life (→ Media Effects; Socialization by the Media). Think of the oft-told tale of advertising for Marlboro, the bestselling brand in the world (Schlach 2002). Like many advertisers, cigarette companies have long enhanced the value of their product by fastening its consumption to images of personal style and sexual allure (→ Advertisement, Visual Characteristics of).

Think how Philip Morris and its advertising agencies appropriated musical and visual motifs from Westerns to assemble a masculinist sign, Marlboro Country (→ Rhetoric and Visuality; Masculinity and the Media). Originally a British brand – note the royal → iconography on the traditional Philip Morris logo – Marlboro had in the first half of the twentieth century been marketed as an unusually mild product for women. As if they were semiotic plastic surgeons, Philip Morris’s marketing specialists successfully removed the brand’s feminine connotations and replaced them with masculine ones (→ Branding). In redefining Marlboro as a quintessentially US product in the 1950s, they created the myth of Marlboro Country and added billions of dollars of value to a delivery system that dispenses toxic wastes, first- and second-hand, regardless of gender or nation. But the Marlboro ads have been able to do their work, become signs for consumers, only to the extent consumers have had compatible templates of meaning-making already in mind.

Not explicitly political in his own scholarship, Saussure was concerned less with questions of power than he was with those of disciplinary definition. He consistently contested commonsense notions about natural labeling, arguing against philosophical accounts of language that he likened to “our first ancestor Adam calling unto him the various animals and giving each one its name” (2006, 162). Such natural naming becomes unthinkable if there is no “prior external basis for the sign,” as for Saussure there was not (→ Sign Systems). Just as language divides undifferentiated territories according to cultural maps, he argued in effect, so objects come into existence as meaningful entities only in the moment they are identified.

## THE DUAL ESSENCE OF LANGUAGE

Those who believe that objects in some sense possess inherent meanings, whether religious or traditionalist, disagree with Saussure, and some linguists remain troubled that Saussure’s theories cannot pass an empirical test. Within the humanities, however, Saussure’s ideas, while contested and revised, have been productive for cultural analysis. Saussure himself saw his linguistic research as but one part of what he hoped would become semiology, or what might now be called the interdisciplinary study of signs (→ Semiotics). Its root, he wrote, was in the “dual essence of language,” the inseparability of form and meaning. “A linguistic sign,” he was quoted as saying by his students, “is not a link between a thing and a name, but between a concept and a sound pattern” (1983, 66).

The meaning a culture assigns to a particular material articulation he called a *signifié* assigned to a “significant.” This is now most often translated in English as a “signified” assigned to a “signifier” (Sd/Sr) but occasionally as a “signification” assigned to a “signal.” Not that there is only one meaning for each Sr, or that the meaning is a positive term. Rather, Saussure saw each sign as embedded in a complex chain of differentiations, its meanings comparative and multiple, depending upon its semiotic surroundings. “Morphologically there are neither *signs* nor *meanings*, but *differences in signs* and *differences in meanings*, (1) each of which exist solely in their relations to others, hence inseparable, but (2) never come into direct contact with each other” (2006, 46; emphasis in original). For Saussure’s theory, “context is everything” (Jameson 1972, 17; → Text and Intertextuality).

The relationship between *concept and sound pattern*, between the idea of a cat, for example, and the understood articulation of the spoken or written word “cat,” is “conventional, and thus arbitrary, wholly lacking in any natural link with the object, completely free of and unregulated by it” (Saussure 2006, 140). The object need not exist; “unicorn” can be a sign no less than “cat.” Similarly there is no territory called “Marlboro Country,” yet it no doubt has a place in cultural maps as real for many people as Oklahoma. Herein lies the axiomatic ground for communication and cultural studies oriented toward change. If the relation between, say, what a culture deems “feminine” and human bodies identified as “female” is conventional and arbitrary, then it can be challenged, and it can change. Given notions of “femininity” and “female” may be maintained by powerful institutions, and by interpersonal relations governed by institutional pressures, but they can also be overthrown (→ Heterosexism and the Media; Gender and Discourse; Gender: Representation in the Media). Signs in this way share the state of being Marx and Engels found characteristic of capitalist modernity: “All that is solid melts into air.”

### TOWARD A SCIENCE OF SIGNS

Roland Barthes (1915–1980) focused on Saussure’s call for a “science of signs” and argued that the “very history of the modern world,” with its abundant sights and sounds, demanded the development of semiology (Barthes 1970, 9; → Barthes, Roland). Thinking of Sd/Sr “in the fashion of the recto and verso of a sheet of paper,” he urged, might help forestall the temptation to think of the sign as only the Sr, “which Saussure wanted at all costs to avoid” (1970, 38). Thinking this way might also help avoid the temptation to think of the Sd as a meaningful object in itself; instead, the Sd is the concept, as understood through the sign. “The signified of the word *ox* is not the animal *ox*, but its mental image” (1970, 43). Indeed, although the Sd/Sr relation is commonly represented in fraction-like form, Barthes proposed thinking of the Sd as “behind” rather than above or below the Sr, since it “can only be reached through it” (1970, 49).

Barthes parted from Saussure over the arbitrariness of signification, preferring “unmotivated” to “arbitrary” for the Sd/Sr relation. He maintained that lack of motivation in signs may be complete or be partial, as in fire/smoke or footprints/past presence, a semiotic category of effect/cause that Charles Sanders Peirce (1839–1914) categorized as an “index” (for Peirce, an “icon” had a likeness and a “symbol” was an entirely arbitrary/unmotivated sign [Peirce 1940, 102]). Barthes also questioned the description “arbitrary” because no individual is “free to modify it” (Barthes 1970, 50), at least under ordinary

circumstances of language use. He called the Sd/Sr relation “contractual in its principle, but this contract is collective, inscribed in a long temporality (Saussure says ‘a language is always a legacy’), and that consequently it is, as it were, *naturalized*” (Barthes 1970, 51; emphasis in original). As a consequence, for post-Saussurean semiology, meaning is never inherent in a Sr. Despite → caricatures to the contrary, this is not an argument that anything can mean anything. Communication here is culturally and historically grounded. People might well decode signs according to schema outside the dominant, heteronormative semiotic system, for example taking the Marlboro Man as a gay icon (Landman 2000).

The complexities do not end there. The bar (/) that separates Sd and Sr itself reappears inside each Sd and Sr, endlessly relating and dividing. Saussure, for example, according to his students’ account of his lectures, insisted that the “sound pattern” was “not actually a sound,” but rather “the hearer’s psychological impression of a sound,” “material” only as a “representation of our sensory impressions” (Saussure 1983, 66). No articulation, no perception, no concept exists in separation from the web of connotations that criss-crosses each encounter, bounded by cultural and historical location.

As Barthes argued, the process of signification does not stop with the recognition of a cultural meaning of a performance, picture, piece of writing, or sound. The consequent sign (the third term that comes into being once Sr and Sd align) connects itself through signification to other cultural meanings, in a “second system” (Barthes 1970, 89), perhaps making “Marlboro Country” a connotative signifier of freedom in the outdoors for its fans, or indeed for anyone who knows the code. For its critics, however, the brand’s image can also be a connotative signifier of a marketing campaign that willingly does harm. This second meaning would not only be against the intention of commercial advertising, it would be a reading of that intention, yet still within this culture’s codes (→ Structuralism; Structuralism in Visual Communication).

## ENCODING/DECODING

For a semiology without guarantees, without fixed meanings, denotation might most usefully be conceptualized as the most common connotation, rather than as a foundational meaning on which connotation trades. Thinking of connotation as a location for changeable flickers of meaning highlights its ideological quality. This can be seen in Stuart Hall’s (2006) discussion of encoding/decoding television. Hall offers three general categories to describe the movement from Sr to Sd in this second, connotative system: “dominant-hegemonic,” “negotiated,” and “oppositional” (2006, 169–173; → Discourse). The following account is based on Hall.

In the first category, the sign is decoded “in terms of the reference code in which it has been encoded,” and meaning is made “within the dominant code” (Hall 2006, 171). Hardly ideal for those who believe in democratic communication, this is the sender-centered “telephone game” come to life. For mainstream journalists, this way of seeing might not seem a way of seeing at all, but a fair and balanced way of reporting the events of the world. Yet as media critics have noted for decades, this form of journalism tends to favor sources and hence viewpoints drawn from public and private elites (Gans 2004; → News as Discourse). (For example, presenting as fact arguments by pro-business economists against a rising minimum wage while marginalizing economists who disagree.)

In cases in which the movement from Sr to Sd has been “negotiated,” general meaning-making along dominant-hegemonic lines is supplemented by “particular or situated logics.” One can read the news and find it sensible overall but not applicable to one’s own situation (e.g., someone earning the minimum wage might accept arguments in the media against a general raise but at the same time believe they do not justify her own boss’s refusal to pay more). In this situation, the telephone game hides the matter of interest when it shows the passage of a whispered text altered as it moves through a chain; different, conflicted understandings in life, motivated by conflicting interests, become misunderstandings in the game, providing examples of what elites might consider a failure of communication.

For Hall, oppositional readings see the Sr in terms hostile to the dominant code, and so understand the sign in terms of a Sd that objects to the dominant project with which it is associated (e.g., taking an argument against the minimum wage as a defense of wealth and an assault on the poor). Listeners in the telephone game can drop out in protest against a whisper just heard, breaking the chain. Yet dropping out from semiosis deemed offensive or even from its excess presence is infrequently an option in life. Future research might well explore how these processes have changed over media, space, and time since Saussure first articulated them nearly a century ago and extend the study of signification to the new experience of unending signs on parade.

Louis Althusser (1971) argued that whenever we make sense of our contemporary world according to dominant codes, our very construction as subjects of that world occurs yet again. For him, ideology was not an organized body of ideas but the way the world is “lived” in meaningful terms (Althusser 1971, 217). Yet the sense that, yes, this is the world, is not a recognition of reality – here Althusser followed Jacques Lacan – but a “misrecognition” (1971, 219) that forgets that signs are always maps, always representational, and never territories themselves (→ Realism in Film and Photography).

Ideology, then, thrives in the space between Sr and Sd. It does its work most effectively for dominant codes when it goes unseen, as if the Sd could be reached without going through the Sr, as if even for those who know they are looking at an ad, in some realm there could be a Marlboro Man, just as there could be a natural and obvious masculinity, thriving in a Marlboro Country that resonates as a familiar if fictional space. Yet Marlboro Man, the sign, might also be read in opposition, as an image using models hired to profit their employers by making smoking attractive, two of them smokers, both of whom lung cancer would kill.

## Sign Systems

*Paul J. Thibault*

*University of Agder*

Sign systems mediate the interactions between agents and their worlds. In Peirce’s (1992, 1998) terms, an agent is a first. The principle of “firstness” refers to the property of existing in the world independently of other entities. Firstness entails relative autonomy: a first always encounters and interacts with something else that enables its autonomy to be achieved. This is what Peirce defined as “secondness.” A first is, in reality, always defined in terms of its interactions with a second. Finally, the interaction between a first and a second is always mediated by a system of relations that makes possible the encounter between a first and a second. This is “thirdness.” Thirdness refers to some principle of systematicity and organization in terms of which encounters between first and seconds are seen as not random but able to be interpreted. Thirdness provides the resources and the principles of organization whereby the interaction between a first and a second can be successfully coordinated and appropriately interpreted.

### SAUSSUREAN PREMISES

A sign system has typically been conceptualized as a system of correlations of forms with meanings that exist in ordered hierarchies of relations. A sign system in this view makes possible the signs that people create in particular circumstances (→ Sign). Sign systems thus conceived have been conceptualized as networks of terms defined *relationally*. The terms are defined negatively by their position within the overall system of relations, rather than by something positive that is intrinsic to them. In other words, a sign system is a network of semiotically salient differences that potentially make a difference for the members of a given culture (→ Semiotics). The early twentieth-century prototype for this way of conceptualizing sign systems was Saussure's (1993) semiological theory of the language system (*la langue*) as a system of potential signs (→ Linguistics).

For Saussure, linguistic value is founded on two essential principles. First, the starting point is the totality of the language system and the relations of coexistence between the terms that constitute the system at a given moment in time (→ Code; Systems Theory). Second, the link between the two orders of linguistic facts – phonic and conceptual terms – is relational and arbitrary. It is therefore relative rather than absolute; value is not based on extra-linguistic physical things (Saussure 1993, 329). Value is based purely on the relations between the terms in the language system (→ Structuralism). Linguistic values are therefore arbitrary in this sense (Saussure 1993, 330).

*La langue* is a normative semiological institution in the sense that its values constrain and regiment the linguistic behavior of individuals. Sign systems therefore entail the typification of the means – the resources – and the situations – the conditions – for creating meanings. Sign systems are based on general categories that can be applied to many different individual cases. If we had to invent a new category for each new case we encountered, our finite brains would not be able to handle it and we would in all likelihood go crazy. The intensional definition of a given class of objects is the least general predication that applies to them all, according to Ryle's (1963) notion of categories.

### SIGN SYSTEMS ARE CONVENTIONALIZED RESOURCES

Take the noun *governor* in the nominal group *the late former Republican governor of Minnesota*. The noun *governor* specifies (symbolizes) a general category – a semantic class of Thing – that can be applied to many different individual cases (→ Symbolism). In Ryle's terms, the noun *governor* is the general predication that applies to a large number of individual cases as their intensional definition. However, the individual, Elmer Andersen, referred to by Al Gore in his book *The Assault on Reason* (2007, 113) by the nominal group in question does not necessitate the making of an entirely new category of Thing to refer to him. Instead, the systemic resources of the nominal group (i.e., deixis: *the*; qualification: *late, former*; classification: *Republican*; post-qualification: *of Minnesota*) combine and interact with the noun in this nominal group to produce a specific referent without Al Gore having to invent an entirely new nominal category. Thus, the noun *governor* is a type category of Thing that can be multiplied and instantiated in different times and places by different persons.

Similarly, the expressions *Can I help you?* and *Are you being served?* are conventionalized resources – typifications – that can be abstracted from many different occasions and seen as typical strategies notwithstanding their different wordings for initiating a sales transaction between customer and client. Now, sales transactions are themselves conventionalized forms of social interaction. In this case, we also see that the conventionalized mode of interaction (discourse genre, activity-type) qua institutionalized convention gives rise to typified forms of interaction, as exemplified in the initiating moves and their functions mentioned above, together with conventionalized speaking and action roles for participants (Halliday 1978, 63; → Language and Social Interaction; Discourse).

Furthermore, the presentation of the self as the bearer of a particular institutionalized role (e.g., salesperson) also puts into play a whole range of skills and competences and bodily and sartorial displays and performances that have the potential to elicit normative judgments as to the appropriateness or the capacity of the individual as a skilful or otherwise bearer of the designated role (Goffman 1971). Similarly, only certain kinds of physical settings will typically be recognized as being of the appropriate or right kind for invoking the conventional institution of sales transaction (→ Social Interaction Structure). Sign systems therefore have the power to evoke context-sensitive social and cultural conventions and norms in ways that are also sensitive to the history of prior such evocations. Sign systems are intertextually sensitive to the possible equivalence classes of these prior evocations and how they might contribute to the construction and understanding of the current situation and its anticipated future development.

The values of a sign system stabilize and regiment the range of possible meanings – the meaning potential – by digitalizing the topological-continuous variation of the underlying biophysical substrate (e.g., the articulatory space of the vocal tract) as discrete digital categories in the phonology and lexico-grammar of natural spoken languages. This process enables persons in interaction to direct the attention of others to specific objects and to coordinate this attention with others even when the object in question is not available to online perception. In other words, linguistic and other signs are not merely physical entities or processes to which structure or meaning is then added by psychological processes of inference and so on (Reed 1996, 17). Instead, signs bring about changes in the organism's relation to its internal and external environment in ways that enable it to organize and to anticipate possible future responses to the environment.

### **SIGN SYSTEMS, BIO-CULTURAL DYNAMICS, AND THE EMERGENCE OF COMPLEXITY**

Sign systems do not have an autonomous social-cultural-semiotic dynamics that is separate from the physical-material-biological processes that embody them (see also Lemke 2000; Thibault 2004). Sign systems are totally dependent on and are always tied to the physical-chemical-biological systems of material processes in which the former are embedded as part of a larger-scale ecosocial semiotic system (Salthe 1993, 45–46; Lemke 2000; Thibault 2004). Therefore, semiotic practices and the sign systems embedded in them are always both semiotic and material processes: on the one hand, they constrain and enable acts of meaning and their associated evaluative stances; on the other, they participate in and entrain physical-material couplings, both somatic and extra-somatic.

Sign systems are often talked about in reductionist terms as being composed of bottom-up assemblages of small-scale elements that are seen as basic, rather like the bricks that are assembled to build a house. In much of twentieth-century linguistics, for example, small elements such as phonemes and morphemes were thus seen as the compositional building blocks of larger structures such as sentences. Consequently, all levels in the hierarchy were viewed in essentially the same way – building blocks all the way up (and down). Sentences were no more than compositions of lower-level elements. In this view, there were no true higher-order levels and attractors (Salthe 1993, 36). In this conception there is no way of explaining how novel properties and processes emerge from the interactions between components on different levels because all levels are treated in the same way.

A further tool for rethinking sign systems, then, is the *three-level scalar hierarchy* view developed by Salthe (1993, 36–52). The three-level scalar hierarchy provides a way of breaking a complex phenomenon down into a triad of constituent levels of organization that enable us to contextualize the relations between levels. Thus, lower levels can be understood in terms of the way they are contextually integrated to higher levels in the hierarchy. Higher levels have emergent properties and processes that are not reducible to lower ones. Thus, meanings qua attractors in a possibility space – a sign system – manipulate and entrain lower-scalar physical-biological processes to their own ends so that new configurations and arrangements of lower-scalar processes and entities arise. These new arrangements are more highly structured and more highly specified with respect to the lower-scalar processes such that the higher-scalar system is able to interpret lower-scalar processes. The reverse is not, generally speaking, the case because lower-scalar entities are not sufficiently structured to do so. Sign systems are therefore global meta-semiotic phenomena that range over and constrain local phenomena.

In terms of three-level hierarchy thinking, newly emergent levels of organization do not come from nowhere. Instead, they emerge between previously existing levels. Semiosis is distributed in a number of different, yet closely related, ways across a hierarchy of interconnected levels, as follows: (1) semiotic-informational (systemic) constraints distributed over higher-scalar levels of an ecosocial semiotic system in historical-cultural time (L+1); (2) semiosis/sign-making distributed between brain, body, and world in the real-time inter-individual activity of social agents (L); (3) micro-temporal neuro-anatomical processes and capacities of human brain and body (L–1).

The interaction between an interpreting agent and a sign is an encounter between a first and a second. This is the intermediate (focal) level (L) in the proposed hierarchy. The higher level (L+1) is where the sign system qua thirdness is located. The level constitutes the higher-scalar environment where sign systems persist on longer time scales than individuals. Sign systems are not housed in individual brains, but are distributed across an entire cultural system. Level L–1 refers to the affordances – the biological and other enabling conditions – that make semiosis possible. Level L, on the other hand, is the level of the intentional social agents-in-activity-in-their-world. Agents are not simply constrained by top-down causation emanating from level L+1; they also have the capacity to modulate and therefore affect the flow of the activities they participate in across diverse space-time scales through their sign-making activity. Level L+1 consists of semiotic constraints that mediate and make possible the semiotic–material couplings and

interpretations that are created in the activity of agents on level L. Level L+1 provides the system of interpretation and therefore the categories and forms of action in and through which agents make sense of and orient to their worlds.

Our interactions with others often involve a great deal of uncertainty that cannot be explained in terms of systemic regularities alone, seen as rule-bound behavioral templates to which participants conform. Sign systems qua conventional resources are not, then, reducible to rule-following templates founded on predictable behavioral regularities and/or inventories of form–meaning correlations. Instead, they are meta-semiotic and cognitive resources that enable participants to find solutions in real time to problems of understanding, interpretation, and social coordination that may be completely unique, one-off occurrences. Sign systems are resources for both participating in and monitoring the complex meaning-making trajectories that we co-construct with others across diverse time and place scales in the process of operating on and transforming the social situations and events we create along these trajectories.

# Simulation

*Peter Ohler*

*Chemnitz University of Technology*

Simulations are imitations of some “real-world” phenomena, especially the states of affairs of (real) natural or social systems or the processes of the systems (processes are defined as temporal sequences of system states). Simulations are used in numerous domains: physics, chemistry, biology, economy, social sciences, and computer and engineering sciences. The general purpose of simulations is to attain insight into the functioning of these systems and to predict their future states.

The main meaning of simulation in the social sciences, communication, cognitive science, and artificial intelligence is computer simulation (CS). Simulations in this sense should always be defined with reference to a “real-world” phenomenon and to an abstract (theoretical) model. If a researcher is interested in a phenomenon (the target) he or she often tries to create an abstract model that is less complex than the target itself. In the social sciences the target usually is a dynamic entity. It changes over time and reacts to its environment. Therefore the model must capture the dynamics of the target. The model can be specified, for example, via a logical calculus or a mathematical equation connecting relevant variables. The development of the model over time can then be explored by the inspection of the development of its relevant variables. In the case of complex models, especially with nonlinear relations (e.g., nonlinear ordinary differential equations) and/or many interacting subsystems this can only be done with the aid of CS.

Simulation now means running the specified model forward through time and inspecting future states of the relevant variables. CS can be helpful if analytical methods are also available. Visualizing simulation results on a computer screen often increases the understanding of a system’s dynamics compared to complicated formulae and their results written down on paper. To summarize: scientific simulations are experiments with an abstract model to gain a better understanding about the dynamic system selectively represented in this model. Famous early examples of simulations are the world models of the Club of Rome based on the method of system dynamics developed by Forrester (1971).

Simulations as scientific tools serve *various functions* (Hartmann 1996). As a technique they allow the investigation of the dynamics of systems. But simulations can also serve an important function as a heuristic tool in the process of the formulation of → hypotheses

and new theories. The analysis of huge sets of runs with systematically or randomly varied parameters may yield unexpected regularities that would not have been inferred from the underlying abstract model. Furthermore, simulations can substitute and extend experiments. If the performance of an experiment is impossible because the real system is withdrawn from human access (e.g., in astronomy), or because an experiment would cause unreasonable modifications of the system or is morally not permissible (e.g., children's long-term viewing of aggressive contents), the only possibility of testing abstract models remains in simulations (→ Experiment, Laboratory; Research Ethics). Simulations are extensions of experiments, because not only can the effect of a specific experimental design be measured but the entire universe of possible condition variations can be inspected. Therefore simulations can be used as generators of ideas for condition variations in laboratory experiments.

One special form is *simulations with multi-agent systems* (MAS), which are used to model the dynamic behavior of populations (Wooldridge 2002). An MAS is a system running on a computer and composed of several agents and their environment. The definition of agents is still controversial, but in MAS an agent mostly represents a life-like artificial unit. Agent-based simulations are suited to models and explain the emergence of higher-level phenomena caused by the interaction of single agents. The interaction of many agents on a microscopic level will sometimes result in stable systems on a macroscopic level (e.g., the emergence of communication systems) that show novel and sometimes unexpected properties. Compared to traditional simulation techniques, MAS have the advantage that global behaviors as well as each agent's individual behavior, including its causes and consequences, can be observed. Examples of social phenomena simulated with MAS are the emergence of social intelligence, the emergence of intergroup cooperation, the spreading of gossip, and the evolution of communication, to mention just a few.

One special case of simulations is *interactive or human-in-the-loop simulations* (HILS). These differ from other simulations in that human operators or users are included in the simulation process. Examples of HILS are medical simulators, flight simulators, and driving simulators. In most cases the goal of HILS is not simply the prediction of future states of dynamic systems. HILS are often used as experimental settings in human-computer interaction research to measure user behavior patterns (→ Experimental Design). The results of the simulations can be used to improve the usability of interfaces (of cars or airplanes). Another function of HILS is the training of personnel. If it is too dangerous or too expensive to permit trainees the use of real equipment, learning in a safe virtual environment is a preferable alternative. To test the fitness of pilots, flight simulators can be used to simulate extremely hazardous scenarios.

Almost all HILS are realized not only as training devices but also as video and computer games (→ Video Games). *City simulators* are tools for urban planners to gain a better understanding of the evolution of a city, but they are also the game engines for computer games. Simulations form a category of their own in the domain of video games. This category can be further subdivided into *sensorimotor simulations* (e.g., flight and racing simulations) and simulations that can be used by the player to organize a dynamic system like a family, an organization, an economic system, or the evolution of a species. *Massively multi-player online role-playing games* (MMORPGs) are very complex simulations of alternative virtual worlds that have no counterparts in the domain of scientific

simulations. Virtual environments like *Second Life* are also simulations with comparable complexity, but they are not games because they do not have a pre-defined goal that the user is expected to reach.

## **Singapore: Media System**

*Kokkeong Wong*

*St. Norbert College*

Singapore, an island nation at the southern tip of mainland Southeast Asia, has a population of about 3.6 million made up of 77 percent Chinese, 14 percent Malays, 7 percent Indians, and 2 percent classified as others. A former British colony, the republic adopts the Westminster parliamentary system, and the government has been controlled by the People's Action Party (PAP) since 1959. The three corporations that provide for the various media in the country are largely owned by the government's investment arm, Temasek.

Singapore Press Holdings (SPH) dominates the *print media*, publishing 14 → newspapers and 80 periodicals. It also operates two → radio stations and → Internet portal services. SPH offers management and ordinary shares, with one management share equaling 200 ordinary shares. Transference of management shares must be approved by the government. MediaCorp dominates the broadcast media, operating five terrestrial TV channels, an outdoor digital TV channel, a TV production company, the channel News Asia providing round-the-clock satellite TV news (→ Television), and 14 radio stations. It also publishes a free-circulation newspaper and 13 periodicals. At the end of 2004, MediaCorp and SPH merged to become MediaCorp TV Holdings, which is now owned 80 percent by the former and 20 percent by the latter. The third corporation, StarHub, is the sole provider of cable TV and a major Internet service provider. Temasek wholly owns MediaCorp and is a major shareholder of SPH and StarHub.

Singapore media come in *four languages*: English, Mandarin, Malay, and Tamil. Media in English and Mandarin command the largest readership or viewership. Newspapers like the English-language *Straits Times* and Mandarin *Lianhe ZaoBao* are known for their

comprehensive coverage of foreign news. US TV programs are highly popular, but Singapore TV has increasingly aired programs produced domestically, with some programs in Mandarin (especially drama serials) and English (especially situation comedies) exported to countries like Malaysia. Singapore is quick to adopt the latest media technology. Digital TV began in 2001 in the form of mobile TV on buses. Internet penetration was at 68 percent of the population in 2005.

Besides the Official Secrets Act, the Sedition Act, the Defamation Act, and the Internal Security Act, which regulate the media, there are: the Undesirable Publications Act, which prevents importation, distribution, or reproduction of undesirable media material of all kinds; the Newspaper and Printing Presses Act, which requires *licensing of all print media*; the Films Act, which regulates possession, importation, production, distribution, and exhibition of films; the Broadcasting Act, which regulates ownership and operation of radio and TV broadcasting; and the Broadcasting Class License Act, which requires licensing of Internet service providers and Internet content providers. The laws empower the government to define topics as out of bounds, such as those that promote communism, contravene moral norms (→ Morality and Taste in Media Content), show excessive or gratuitous sex and violence (→ Pornography, Media Law on), glamorize drug use, or incite racial, religious, or linguistic animosities among the three major ethnic groups in the country. Critics argue the PAP also uses the laws to restrict political opposition and criticism. The government is known to defend itself vigorously against what it considers as personal attacks on public officials. Journalists are believed to exercise a good deal of self-censorship when covering such issues as alleged governmental corruption, nepotism, or a compliant judiciary. The government considers criticisms of domestic politics in the media and cyberspace as out of bounds because they are made outside of the formal political system. Commentators are often exhorted to declare their political affiliations or enter politics. The problem for critics is that the views of the political opposition are marginalized or ignored by the media.

Since the 1980s, the government has planned to make Singapore into a regional media hub. It has attracted global corporations like *HBO*, *MTV*, and *Disney Channel* to set up regional headquarters. But *foreign journalists* reporting on Singapore have to register with the government, submit a security deposit of US\$200,000, and name a person in the country to accept legal service (→ Licensing of Journalists). The government may fine and/or curtail the circulation of foreign publications deemed to have interfered in domestic politics. Audiovisual entertainment programs are also monitored through a citizen advisory panel using guidelines established by the government. The PAP government defends its restriction of media in the name of securing economic development for resource-poor Singapore and maintaining peace and stability among the three ethnic groups in the country. This has led to the view of Singapore media as operating under the developmental media model (→ Development Communication: Asia).

Others see Singapore media as operating under the *authoritarian model*: the strict media restriction is made largely to serve PAP interests and power. When French-based Reporters Without Borders ranked the country's press freedom in 2005 at 144th position out of 166 countries, the government rejected the measurement, claiming it was biased toward the western model of press criticism and opposition, whereas Singapore press followed a different model of contributing to nation-building (→ Political Communication Systems).

Another view of Singapore's media is that of "*controlled commodification*." It argues that the government has the determining influence over the media through its managerial role for capital in order to secure capitalist economic development for the country. Although Singapore is known for its free trade policy, the government restricts the flow of media commodities like films in the name of securing the country's political and cultural sovereignty against foreign, especially western, political or cultural encroachment.

## **Situation Comedies**

*Richard F. Taflinger*

*Washington State University*

The situation comedy, or sitcom, has been a staple of entertainment media for decades. More than 900 have been on the air since 1947. Starting on → radio, it quickly became popular with audiences. With the advent of → television in the late 1940s, sitcoms migrated to the small screen, and it is these sitcoms with which most people today around the world are familiar. Content and neo-Aristotelian analyses of from 1 to 100 episodes each of approximately 800 situation comedies has led to the following understanding of situation comedies and how they work (Taflinger 1996).

### **DEFINITION OF SITUATION COMEDIES**

A definition of situation comedy should look at each word of the name, starting with "situation." There is a continuation from episode to episode of *the same elements*: (1) a

regular group of characters who appear in all or almost all episodes and who maintain a continuing relationship to each other (e.g., husband and wife and perhaps children, siblings, co-workers, neighbors; (2) a group of settings used in all or almost all episodes in which most of the actions take place – for instance homes, workplaces, schools – and in which (3) the premise of the show is established (Taflinger 1996). For example, the situation could be parents teaching their children how to live and behave in the world, or how doctors and nurses cope with being in a war zone, or how a man's reach exceeds his grasp, or how friends try to get and succeed in relationships. The premise is the basis of every episode's story.

However, the above criteria appear to be the basis of other types of episodic fiction TV series, such as lawyer shows, cop shows, medical dramas, and Westerns (→ Drama in Media Content). Separating TV series from other dramatic art forms such as movies and plays, what distinguishes situation comedies from other types of TV shows is that dramas attempt to evoke emotion from their viewers: love, hate, pity, sympathy, excitement – drama aims at the heart. Sitcoms, on the other hand, use humor rather than emotion: they aim at the head rather than the heart. Thus, the second word in situation comedy: “comedy.”

### CRITERIA FOR HUMOR

Six criteria are required for comedy, for an event to elicit laughter from a person (Taflinger 1996). First, it must be *mechanical* (Bergson 1956). In this criterion, the laughable element consists of a mechanical inelasticity, just where one would expect adaptability and flexibility. It is humorous when a person acts in a manner that is inappropriate to a stimulus or situation, as in any slapstick comedy routine. It is funny when a chair is pulled out from under someone who is sitting down, because he or she does not adapt to the change in situation and continues to sit in a mechanical fashion. A character is funny because he or she mechanically reacts to events without thinking about how events have changed the situation.

Second, it must be *inherently human*, or with the capability of reminding us of humanity. Something is funny only insofar as it is or reminds the audience of humanity. This is clear when the participants in the joke are people, even cartoon people. However, the audience may also laugh at the antics of animals, such as chimpanzees or horses or bears, but only in direct proportion to the animal's capability of reminding the audience of something human. Thus, animals such as chimps and orangutans are often dressed in human clothing to heighten the reminder, and horses and mules can talk and think better than the people they are around. It becomes apparent when one examines comedy that it is based on incongruity: the unexpected with the expected, the unusual with the usual, the misfit in what has been established as a societal norm. For there to be incongruity there must be something to be incongruous to. Therefore, for a comedy to work there must be an established set of cultural, human, and societal norms, mores, idioms, idiosyncrasies, and terminologies against which incongruities may be found.

This leads to the next two criteria for humor. Third, there must be a *set of established societal or human norms* with which the observer is familiar; and fourth, the situation and its component parts (the actions performed and the dialogue spoken) must be

*inconsistent or unsuitable to the surrounding* or associations (i.e., the societal or human norms). These latter two criteria explain why some people do not get a joke: they do not know or understand the norms being violated in the joke. Think of a joke you share with your friends. You may only need to say a single word or a phrase, and you all break up laughing. However, others with you will look confused and not laugh. That is because they do not know the situation to which you are referring, which is a norm for you and your friends, but not for them. Thus, the intellectual element really comes to the fore: to get a joke, you must not only understand the situation, but understand how the situation is being violated. This requires mental processing, not just an emotional reaction. Thus, there is the fifth criterion: it must *appeal to the intellect* rather than the emotions.

Finally, there is criterion number six: it must be perceived by the observer as *harmless or painless to the participants*. The comic action is perceived by the audience as causing the participants no actual harm: their physical, mental, psychological, and/or emotional well-being may be stretched, distorted, or crushed, but they recover quickly and by the end of the performance they are once again in their original state. It is funny when someone slips on the ice and falls: people laugh; people expect the person to stand up and look embarrassed – until they realize that the person broke his leg. At that moment the event is no longer humorous. This also applies to ethnic, racial, or social group humor: those in that group find the joke insulting and thus harmful to their self-esteem and the way they wish others to perceive their group. They do not find it funny. A key word in this criterion is “perceived”: the attempt at humor does not have to actually be harmless, it just has to be perceived as harmless by the audience.

### SITUATION COMEDIES AND SOCIETY

When all these criteria have been met, people will usually laugh. If any one of the criteria is absent or violated, then the attempt at humor will fail. Situation comedies use the above criteria in telling their stories. The stories themselves are the same as would be found in dramas (police stories, doctor stories, detective stories, love stories), but the stories aim at people’s cognition, not emotions, and are incongruous to real life, not examples of it. Because of the third and fourth criteria, situation comedies, more than any other mediated communication, reflect the actual beliefs their audiences hold about what their society is and the way people within that society should be. Situation comedies, unlike other forms of communication, must be grounded in the society of their times and audience for that audience to understand the jokes. Therefore, if the rules of society change, the jokes do not work.

Dramatic stories (both dramas and comedies) are constructed following some basic rules: there is a universe in which the stories take place (e.g., unmarried friends looking for love, a war zone, an office); a problem arises in that universe; the characters do things to solve that problem, making the problem worse; and finally, they do the right thing and the problem is solved. Because of the way stories are constructed, there are *three basic types of situation comedies*: the action comedy, the character comedy, and the dramatic comedy (Taflinger 1996).

In an *action comedy*, the characters simply do things, they perform actions, until they finally do the right thing to solve the problem. The characters are often clever, but not too

bright, inventing schemes that they immediately try rather than thinking things through, weighing options, and developing a good plan. The humor comes from watching the characters flounder around until, often apparently by accident, they solve the problem. This type of sitcom is the most common, since it is the easiest to do. More than 86 percent of American sitcoms have been action comedies (Taflinger 1996).

The *character comedy* requires that a character undergo a fundamental change in who he or she is to solve the problem. The problem arises because a character is doing or believing something wrong: that looks are everything, that social status is more important than being true to oneself, that selfishness is the way to behave. In the early part of the story the character seems to be right, but then the negative consequences start to impact the character's life, and they come to the realization that they were wrong and need to change what they believe. This change solves the problem. The character sitcom is rare because it is more difficult to do than just have the characters perform actions to solve the problem, and it requires a greater effort on the part of and concentration by the audience to understand the characters' personal problems and solutions. The character comedy is much rarer than the action comedy, about 13 percent of American sitcoms.

The third and rarest type of sitcom (about 1 percent of the total) is the *dramatic comedy*, or "dramedy." In this type of sitcom, the solution to the problem presented in the show is often unsatisfactory or poor, leaving it up to the audience to think about the problem and decide how they would solve it. For example, two characters may hold diametrically opposed extreme points of view. They present their extreme views on the issue in the episode, but never arrive at a good compromise, consensus, or solution. This leaves it up to the audience to arrive at their own conclusion, a middle ground between the two extremes. Another type of dramedy puts the characters in a difficult, almost impossible, situation and has them try to figure out how to cope with that situation. For example, doctors and nurses, who are dedicated to the saving of life, are living and working in a war zone, which is dedicated to the taking of life. The characters' physical, ethical, moral, and psychological battles are played out, and the audience is left to consider how they would solve the dilemmas and live in the situation presented.

From its inception as a form of episodic entertainment, the situation comedy has been a major element of mass media. Reflecting the mores of its audience and the times in which they live, and poking fun at them, it has provided amusement, and occasionally edification, for its viewers. Although it has had its ups and downs, and even had its obituary published more than once, it has always been and will continue to be a favorite with audiences looking for a laugh.

## Sleeper Effect

*Michael Schenk*

*University of Hohenheim*

“Sleeper effect” describes a phenomenon in which messages from sources with originally low credibility cause opinion change over time. The credibility of a source as perceived by receivers of its message constitutes a central issue in the theory of persuasion, in particular with regard to its impact on attitude change (→ Attitudes). A highly credible communicator (e.g., by virtue of trust, expertise, or reliability) commands an increased probability that the receivers of a message will accept and absorb the persuasive intent of the communication (→ Persuasion). However, the effect of credibility varies during the course of persuasive effects over time. In general, the impact of a persuasive message peaks immediately after exposition and declines over time (→ Credibility Effects). The sleeper effect describes a contrary phenomenon for messages from low-credibility sources. Here, the immediate effect is overruled by the long-term effect: The sleeper effect is thus defined as the absolute increase in attitude change over time for receivers of a low-credibility message (Hovland et al. 1949).

Increase in agreement for low-credibility communication in the long term might be due to the diminishing of initial skepticism over time. Generally, arguments and other content supporting a communicator’s conclusion are subject to being forgotten over time. For a credible communicator, receivers of a message will show a fairly high agreement immediately after exposure, but this will gradually decline over time. For a non-credible communicator, on the other hand, skepticism or antipathy will lead the receivers of the message to show little initial agreement with the communicator’s position. Over time, however, the effects of low-credibility communication take a different course: “If then the discounted source is forgotten more quickly than the content (or ‘dissociated’ from the content) agreement with the recommended opinion should increase with time” (Hovland et al. 1953, 254; → Hovland, Carl I.).

Hovland & Weiss (1951) tested the sleeper effect in an experiment by using identical communications for four different topics. These stimuli were then presented to half each of the test persons by sources considered trustworthy and untrustworthy respectively. Opinion questionnaires were presented to the subjects before the communication, immediately after the communication, and four weeks afterward (→ Experimental Design). The results show that initially the communications presented by the untrustworthy

source were “discounted” by the audience and had less effect on opinion than those presented by the trustworthy sources. With the passing of time, the initial differences attributable to the source disappeared. After a period of four weeks, the amount of opinion change retained from the two sources was approximately equal: “Thus there was a forgetting effect when the presentation was by a trustworthy communicator and a sleeper effect when the communication was presented by a negative communicator” (Hovland et al. 1953, 255; → Media Effects Duration). Hovland and Weiss’s results indicate that there is a decreased tendency over time to reject the communication by an untrustworthy communicator. “This may or may not require that the individual must be less likely with the passage of time to *associate spontaneously* the content with the source” (Hovland & Weiss 1953, 648). Some evidence for this was provided by Kelman and Hovland (1953), who reinstated the source at the time of the delayed opinion test by repeating the introduction of the communicator before passing out the questionnaire. As soon as the source was reactivated in the recipient’s memory by the playback, the original effects were reproduced: the highly credible source yielded a greater impact on attitude change than the less credible source (→ Order of Presentation).

Even today, the sleeper effect remains *controversial*. From a methodological point of view, the experimental design has been criticized (Capon & Hulbert 1973; Gillig & Greenwald 1974), since the original studies included no control groups, which – given that measurement took place at three points in time – would have been necessary to control for a measurement contamination. Still, Praktkanis et al. (1988) found supporting evidence for the sleeper effect given the following presuppositions: subjects have to (1) be aware of the central arguments of a message, (2) receive the disrating stimulus (i.e., the low trustworthiness of a source of opposing arguments) *after* the reception of the message, and (3) evaluate the credibility of the communicator after having received the disrating stimulus. Such a procedure facilitates the message and the disrating stimulus being central to the effects of the communication. Here, the sleeper effect occurs only if the effect of the disrating stimulus fades sooner than the effect of the message. This interpretation of a different course of effects depending on source credibility opposes the dissociation hypothesis elaborated in the original and in subsequent studies. A further explanation is provided on the basis of the *effect of forgetting* (forgetting model). Here, immediately after reception, the message of a trustworthy source is assumed to be more readily remembered than that of an untrustworthy source. Over time, as both kinds of messages are forgotten, the difference in the persuasive effects of messages presented by high- and low-credibility sources diminishes. Differences in the effects of high- and low-credibility sources can be observed only temporarily.

Given the findings of the studies discussed, the sleeper effect has to be summarized as a *relative effect*. Over time, the advantage of high-credibility sources diminishes. The sleeper effect suggests only a temporary impact of credibility. Highly credible message sources do indeed create additional attitude change, but this is leveled out over time as either (1) dissociation or (2) forgetting occur. In the long term, a convergence of the effects of the low- and the high-credibility sources is found.

## **Small Talk and Gossip**

*Justine Coupland*

*Cardiff University*

The need for the companionship of others is one of the fundamental features of human social nature, and talk is a primary form of human communion. “Small” talk is a type of talk through which we mark co-presence, e.g., the mutual recognition provided by threat-reducing talk to strangers in a lift or neighboring airline seat. This need to commune through speech is also enacted across distances (intimacy-confirming phone calls, texts, emails to significant others, friends, family). Within small talk, what is talked *about* may matter less to participants than the interpersonal significance of talking at all – in a range of social contexts – from intimate, playful encounters (e.g. “pillow” talk) to formal, hierarchical gatherings (e.g., in breaking the ice at the beginning of a job interview).

Hence the recent emphasis within research on social interaction on the *social functioning* of small talk (Coupland 2000). Small talk constructs social cohesion, reduces the inherent threat value of social encounters, and helps to structure social interaction. As humans, we have significant emotional investment in the impressions others gain of us (Goffman 1972), so our social competence, as displayed through our use of small talk, is crucial to our well-being (→ Impression Management). Some of the more formulaic

aspects of small talk, as often used in service encounters, e.g., enable servers and customers to define a generally positive relationship while they talk (Coulmas 1981). Such transitional moments of communication are often marked by conventional or ritualized language (“phatic communion”), with participants sharing predictable, “safe” topics, such as enquiries about well-being, comments about the local environment, “purposeless expressions of preference or aversions, accounts of irrelevant happenings, comments on what is perfectly obvious” (Malinowski 1923, 150). This is the type of talk that affords connection to colleagues while they gather for formal meetings at work, for example (→ Rituals in Popular Communication).

Small talk may thus function as avoidance of, retreat from, or delay of talk which is more serious, challenging, or power-ridden. In sociable small talk, people pay (sometimes sustained) topical attention to the safe, the superficial, with attention to detail and displayed preference for agreement, verbal play, and humor, as in “banter.” Eggins and Slade (1997) claim that the fact that “nothing happens” is the central paradox of “casual conversation.” Of course, *all* talk carries social and affective meaning, along with its representational or task-focused aspects. And participants in talk are likely to orient to relational or “face” issues, alongside more instrumental or task-related issues, in a more or less sustained and strategic way, across a wide range of social contexts and activity types. In medical consultations, e.g., conventionalized formulae such as “nice to see you,” comments about the weather, even an opening “how are you?” may be oriented to as polite, humanizing ways of broaching the medical business. And when small talk is used by the paramedic to stop the casualty drifting into unconsciousness, it is being used to serve a very serious, task-related function.

But small talk is a broad and differentiated generic category, which can also incorporate potentially *unsafe* and threatening themes, as in *gossip*. In many definitions, gossip is linked with newsworthy, critical talk about others (usually absent third parties), and (traditionally, though not more recently) with “women’s” language. Unlike small talk more generally, but like rumor, gossip is seen as a form of talk that is essentially information giving. Here, what is talked about does “matter.” Gossip is often but not exclusively realized through storytelling, with much of the disclosed information being confidential or personal. The ambivalent nature of gossip is that it may create nervousness and anxiousness, but also fascination (cf. the relish of being filled in with all the “latest gossip”): we may be doubtful about how honorable it is to talk behind someone’s back, but enjoy it nevertheless.

The related notion of *backstage talk* captures the privacy or secrecy associated with gossip, since, crucially, gossip involves pejorative evaluation of social behaviors, appearance, or other aspects of the protagonist/s. Due to the face-threatening themes, participants in gossip talk are likely to monitor their interlocutors carefully – and to include only “safe” recipients, or those who signal willingness to partake; friends, family members, close colleagues, and intimates. In gossip, people tell stories or anecdotes about others and thus attend to what people *should* or *should not* be doing (Eggins and Slade 1997). Thus, gossip is said to function as a sanctioning mechanism, by a kind of “moral policing,” whereby conversationalists can construct and assert collective values and thus establish normative boundaries. This allows participants to negotiate aspects of group membership, and the inclusion and exclusion of others (Goodwin 1990).

## **Soap Operas**

*Sonia Livingstone*

*London School of Economics and Political Science*

Initially named after the soap manufacturers who advertised in the program breaks, the soap opera has long attracted among the largest audiences of any broadcast genres while being also widely reviled for its supposedly cheap, trashy, and repetitive content. The soap opera audience has, in consequence, received similar criticism, for being mindless, stereotyped, and vulnerable to mass persuasion. Since the 1970s, however, academic commentary, led significantly by the feminist revalorization of “women’s genres,” though drawing also on the rise in active audience studies (or audience reception studies) during the 1980s and 1990s, has resulted in a rethinking of the genre (→ Audiences, Female; Genre; Women’s Media Genres). This has permitted recognition of the genre’s narrative complexity and depth of characterization, its treatment of the moral dilemmas of daily life, and the many satisfactions that audiences obtain from the soap opera.

The soap opera began on radio during the 1930s in the USA, but quickly became a staple of daytime television broadcasting, filling the schedules between midday and early prime time, and providing continuity and predictability for audiences and broadcasters alike. The daytime serials, as they were also known, differed from series insofar as they were, it seemed, never-ending, with episodes running daily or at least several times per week over years, even decades, building up loyal audiences of fans for whom watching the soap opera became a habitual part of their own lives.

As a genre, the soap opera is clearly distinguished from sitcoms, series, and other forms of drama by its narrative structure, comprised of multiple intersecting plots and sub-plots, each stretching out the “endless middle” of the narrative, with cliff-hanger endings to episodes rather than narrative closure. It is also distinctive for lacking a focal hero or heroine but rather encompassing a sizable set of interrelated characters (connected by familial relationships, friendship networks or, most commonly, a shared neighborhood and/or workplace), all roughly equivalent in prominence, whose activities center on the private and emotional – love, sex, jealousy, betrayal, reconciliation. The settings are typically interiors, often simply staged as dyadic shot–reaction-shot sequences, with storylines concerning secrets overheard, love triangles, lost and found relatives, unwanted pregnancies, babies with contested parentage, romantic rivalry, and many more. These permit not only strong emotions but also polarized moral dilemmas, in which multiple characters become entangled.

Different cultures provide different inflections to these themes. Liebes and Katz (1993) identify a series of primordial themes in both prime-time and daytime versions of the genre, centering on inheritance, lineage, paternity, and family. In the north European tradition, the mundane rather than glamorized settings of ordinary life are prioritized in the early evening shows, portraying the frustrations and hardship of working-class life and the strong bonds of social support among women, following in the social realist tradition established by public service broadcasting (O’Donnell 1999). The Latin American telenovela, sometimes argued to be a distinct but parallel genre since it consists of long but finite series rather than serials, tells a rags-to-riches story of social mobility and romance for its heroine (see Rogers & Antona 1985). As Allen (1995) shows, the genre has been very successfully exported often by one country to its geographic, linguistic, or cultural neighbors, being then amended or appropriated by different cultures around the world. The common themes of romantic and familial relationships, the trials and dilemmas of the private sphere, and the complex social relations that anchor people in their community remain prominent in all forms of the genre.

Partly because of its daytime scheduling and explicit address to the housewife, and partly because of its focus on personal relationships, the soap opera has been dubbed a “women’s genre”; undoubtedly, it attracts more women viewers, though ratings often reveal a sizable proportion of the audience to be male. The genre has attracted a body of content analysis concerned with the messages that may influence women (e.g., gender stereotyping, promiscuity, pro- or anti-marriage views, support or not for women’s employment; Frenzt 1992) and, more recently, a body of feminist audience research concerned to understand the nature of the genre’s appeal for women (Geraghty 1990; → Sex Role Stereotypes in the Media).

Reception studies have established that the mode of audience response to the soap opera is less identification with specific characters than parasocial interaction (an imaginative engagement with the community of characters as a whole; → Parasocial Interactions and Relationships) and emotional → realism (as the structure of feeling portrayed, if not the exact scenarios, rings true for many in the audience). Audiences enjoy being critical viewers of the soap opera: far from accepting the messages presented, viewers argue back with the characters, critique the plots, identify inconsistencies or continuity errors (often drawing on knowledge of the soap opera going back for years), and discuss with each other during and after viewing the rights and wrongs of the storylines portrayed. In terms of mass communication theory, research on the soap opera audience has provided convincing evidence for the interpretive activity of viewers in co-constructing the meaning of the text, with evidence of diversity in reception that draws on the cultural resources viewers derive from their life-worlds (→ Interactivity in Reception; Semiotics).

With the growing success of talk shows and reality shows (→ Reality TV) through the 1990s and thereafter, the soap opera has lost some of its prominence as popular culture, and broadcasters have sought to diversify the genre itself in search of audience ratings – producing soap operas for younger audiences and spin-off mini-series, publicizing major cliff-hangers, developing linked websites, and so forth. They have also sought ever-more controversial storylines as competition among channels has grown, risking the emotional realism of the genre and the loyalty of longstanding audiences, but also generating, at times, national debates over pressing moral issues, for example through their treatment of such issues as abortion, incest, homosexuality, and crime.

Notwithstanding the economic drivers behind such storylines, or the melodramatic nature of their treatment, the hallmark of the soap opera continues to be the focus on the emotional responses of characters over time, the portrayal of diverse responses across the community of characters, and the tendency of all apparent resolutions to unravel, opening up new permutations of character and plot for future episodes. The openness of the genre to alternative readings has, in the age of online and interactive media, resulted in ever-greater involvement from its keenest fans, using online forums to rewrite episodes, provide inventive back-stories or fantasy projections, and chat or argue with each other in new communities of fandom, thus extending and perhaps deepening the engagement of viewers in the genre.

## **Social Behavior, Media Effects on**

*Alan M. Rubin*

*Kent State University*

Surveillance, correlation, and transmission functions are basic to the role of mass media in society. *Surveillance* means locating and disseminating → news and → information. *Correlation* deals with interpreting and editorializing about this information (→ Commentary). *Transmission* is the socialization of norms, → attitudes, and values between groups and generations (Lasswell 1948). Socialization research, for example, has compared the effectiveness of different agencies of socialization, such as the family, peers, teachers, and the media, for fostering information gain or molding attitudes about groups and society (→ Socialization by the Media).

When performing their several functions, media can have positive or negative consequences. For example, reporting about societal threats can provide instrumental information and needed warnings for a society, but also may induce panic and anxiety (→ Fear Induction through Media Content). Watching more news- and public-affairs-type programs may be instrumental for gaining information about societal and political structures, but watching greater amounts of → television, in general, may be dysfunctional for acquiring such specific information (Rubin 1978).

In their analysis of coverage of the September 11, 2001, terrorist attacks in the US, Li and Izard confirmed the functions of the media during a crisis to “inform, explain and interpret the news event” (2003, 215), and observed that newspapers and television framed the event differently (→ Framing of the News). The media also help set the political agenda for the public (→ Agenda-Setting Effects). Such an agenda, of course, may or may not reflect societal needs and priorities. In addition, television has altered the conduct of electoral politics, including party functions and structures, campaigns, conventions, and voting, sometimes for the better, and sometimes not (Patterson 1994; → Election Campaign Communication; Political Communication).

In an early study of how television coverage can structure and distort perceptions of public events, Lang and Lang (1953) compared reactions of spectators to the arrival of General Douglas MacArthur in Chicago, Illinois, with those watching the event on television. They observed that, owing to the media build-up, those at the event expected to see a spectacle. Many in the spectator sample were disappointed by the sparse and subdued crowds at the event. The television viewers, though, watched with others, and were not disappointed, as the telecast was produced to conform to their expectations. The telecast gave a distorted image of the event, but provided a perspective not available to the

spectators at the scene. The selectivity of the camera shots and the television commentary added excitement and a personal nature to the event for the television viewers, who could see MacArthur better than the spectators. The study is still applicable to coverage of news events such as public rallies and political campaigns, and to the presentation of sports and other media fare (→ Reality and Media Reality; Media and Perceptions of Reality).

## EFFECTS OF THE MEDIA

For many years, → media effects research has been guided by models that emphasize individual, group, and societal characteristics. These characteristics may discourage or attenuate media effects when performing surveillance, correlation, transmission, or other functions, such as entertaining audiences and promoting or selling products and services. In other words, when performing these functions, the media do not operate in a vacuum. Instead, they operate amid a host of individual differences and group and societal structures.

Researchers have considered such factors that might impede or encourage cognitive, affective, and behavioral effects of the media performing these social functions. Among *cognitive effects* are acquiring information, creating or reducing awareness and ambiguity, producing knowledge gaps (→ Knowledge Gap Effects), defining societal needs and issues, agenda setting, and socialization. Among *affective effects* are promoting attitudes, values, and beliefs such as political support and trust (→ Attitudes, Values, and Beliefs, Media Effects on), efficacy or apathy (→ Political Efficacy), cynicism and alienation, promulgating positive or negative → stereotypes of ethnic groups, cultivating beliefs, → desensitization, and promoting fear and anxiety. *Behavioral effects* consist of a variety of influences including activation or deactivation, engagement or disengagement, cooperation or aggression, violence, conducting campaigns, voting behavior, government operations, and social and power imbalances in society.

The media contribute to these effects for individuals, groups, and society. Media coverage and entertainment programs offer occasions to talk to people and provide information to support one's own opinions (Kepplinger & Martin 1986). Talk radio and the → Internet provide communication outlets for those who feel face-to-face interactants do not value their opinions (Papacharissi & Rubin 2000; → Broadcast Talk). The news media help frame and construct emotional meaning about sub-groups in society (Rodgers et al. 2007). Television portrayals can affect people's impressions of other races, especially when direct information is restricted (Fujioka 1999; → Stereotyping and the Media). The media may trigger violence against minorities and terrorist acts (Brosius & Esser 1995; Weimann & Winn 1994; → Mediated Terrorism). The media stimulate the purchase of new products and enable political participation. Newer and nontraditional media, such as the Internet and television talk shows, play expanded roles in voter learning and involving the citizenry in politics and elections (Drew & Weaver 2006). The media also can mobilize people, as television, radio, and cable networks did in a US\$117 million collaborative fundraising effort for victims and families of the September 11, 2001, US terrorist attacks (Gilbert 2002).

Such effects, though, may not be that direct. Individual, group, and societal characteristics function to deter or to enhance these effects. For example, Kim and Rubin

(1997) examined several individual characteristics that might impede or encourage three media effects: satisfaction, parasocial interaction, and cultivation (→ Parasocial Interactions and Relationships; Cultivation Effects). Specifically, they expected (1) instrumental media motivation, selectivity, → attention, and involvement to enhance these effects, and (2) avoidance, distraction, and skepticism to deter these effects (→ Selective Exposure; Selective Attention; Selective Perception and Selective Retention). Mostly supporting these expectations, they suggested such individual differences help explain why people respond differently to media messages.

## **MODELS OF INDIRECT MEDIA EFFECTS**

### **Media Influence and Personal Influence**

Incorporating psychological and sociological models in media research was initially a response to views that depicted the media as direct causes of mechanistic and uniform effects among isolated audience members. When examining the influence of media in the 1940 US presidential election, for example, → Lazarsfeld et al. (1944) identified several factors affecting people's responses to the campaign: social indicators that affected interest in the campaign, attitudinal predispositions to behave or vote in a certain manner, and opinion leadership within a two-step or multi-step flow of communication (→ Opinion Leader; Two-Step Flow of Communication). On the basis of these factors, election materials were more likely to activate and reinforce certain predispositions rather than to change people's minds or actions. Lazarsfeld and his colleagues observed that not all people have direct links to media messages, but influence often follows a path from the media to opinion leaders and then to less active segments of the population.

Consequently, media messages and influence are often disseminated interpersonally, within and across social groups in which people share certain interests, beliefs, and norms (→ Media Effects: Direct and Indirect Effects; Interpersonal Communication). These groups serve as a means of social support for existing attitudes and opinions. In addition, opinion leaders within diffusion networks spread information and exert influence within a social system over time. Messages can be amplified, distorted, or otherwise altered as they pass along the interpersonal networks.

Studies of opinion leadership and the diffusion of innovation also found that such sociometric and gatekeeping patterns of communication influence operate in many realms, such as marketing, fashion, public issues, entertainment, health, agriculture, and politics (→ Diffusion of Information and Innovation; Katz & Lazarsfeld 1955). Katz & Lazarsfeld found that personal influence was more frequent and more effective than mass media influence in political, → marketing, → fashion, and movie-going decisions.

Group and interpersonal influences were also apparent when Coleman et al. (1957) found that profession-oriented physicians and those better integrated within the medical community of local physicians were more likely than their counterparts to prescribe a new drug sooner for their patients (→ Health Communication). These researchers suggested the better-integrated physicians were more in touch and up to date and felt more secure when facing the risks of innovation. By somewhat of a contrast, when looking

at the diffusion of news, Deutschmann and Danielson (1960) observed the interpersonal relay function of opinion leaders was less operative for salient news stories of important events, except for subsequent discussions of those stories. In other words, the electronic media were the first sources of information for salient news stories. Similarly, Kanhian and Gale (2003) found that 97 percent of their sample were aware of the event within 3 hours of the September 11, 2001, terrorist attacks in New York. Television and radio were the primary sources for those who learned of the attacks early in the diffusion process, but interpersonal channels were important for those who learned later.

### **Sociological and Psychological Models**

The *sociological model* challenges the notion of a uniform, mass audience and emphasizes the role of selective influences in the media effects process, in which effects are mediated (1) by the social categories in which people live, as evidenced by such indicators as age, gender, ethnicity, religion, and socioeconomic status, and (2) by the social relations people maintain, as evidenced by homophily, social networks, interpersonal dissemination of messages, and interpersonal mediation by opinion leaders. As noted in several interpersonal mediation and diffusion studies, opinion leaders are very much like the people they influence. DeFleur and Ball-Rokeach (1989) concluded the redefinition of the media–audience relationship emphasizes that people typically encounter media not as passive, isolated, and disconnected beings, but rather as groupings of people connected in social contexts. Those who share a social category might be expected to select similar communication content and to respond to it in a consistent manner. Social relations place an emphasis on the interpersonal dissemination of messages within social networks.

The *psychological model* adds the important role of individual differences to the media–audience relationship (DeFleur & Ball-Rokeach 1989). A psychological perspective focuses on the individual, and on perception and information processing. Differences in individual characteristics and predispositions lead to variations in media choice and selectivity (i.e., selective exposure, perception, attention, and retention). These individual characteristics include personality traits (e.g., locus of control, neuroticism), motivation (e.g., → information seeking, arousal, diversion), attitudes (e.g., perceived realism, affinity, skepticism), beliefs and values (e.g., honesty, respect), learning ability, and environment (e.g., family, rural vs urban living). The variations in media choice and selectivity lead to differences in interpreting and reacting to media content.

Beside micro-level media effects studies focusing on media influences on individuals, *macro-level effects studies* consider media influences on groups, communities, organizations, and social structures. For example, according to Lazarsfeld and Merton (1948), media perform certain social functions: (1) conferring status by bringing prestige to those who are informed, and (2) enforcing social norms by calling public attention to deviant behavior. The media also have a narcotizing dysfunction when people spend too much time with them, so that they fail to take action themselves. Lazarsfeld and Merton argued that, in performing such social functions and dysfunctions, the structure and ownership of the media work toward maintaining rather than changing existing social and cultural structures. But that is not always the case.

### Examples of Media Effects on Social Behavior

An early example of the application of psychological and sociological models to media effects is a study of why some people panicked when listening to the *War of the Worlds* → radio broadcast in 1938. Cantril (1940) concluded that several conditions created suggestibility to fear and panic from listening: (1) a perception of realism from the program's dramatic excellence; (2) a perception of expert testimony by some characters; (3) reliance of some audience members on radio instead of print for news, especially lower-income and less-educated listeners; (4) feelings of resignation and hopelessness, especially owing to some listeners' levels of religiosity and fear; (5) selective attention and selective perception, leading to a sense of personal involvement with the program by some listeners; and (6) the insecurity of the times due to economic unrest from the Depression and from turmoil in the world. These factors illustrate the mediating role of individual characteristics (e.g., attitudinal predispositions) and social indicators. The realistic media content, the turbulent environment, and differences in fear, control, and perceived veracity contributed to the fear and panic experienced by some in the radio audience. The study illustrates that people differ in their personality, attitudes, and social makeup and these differences influence their perceptions of and responses to media messages.

Social uses of media are important in various communication settings. Katz and Foulkes (1962) observed that media can be used to strengthen one's position in a social relationship. They found that children who are attached to their parents use television to draw themselves closer to their family. Like more contemporary studies of talk radio and of the Internet, they also observed that media can be used to compensate for ineffective social relationships (e.g., Papacharissi & Rubin 2000). Lull (1980) also suggested several social uses of television. Besides using television for structural purposes (e.g., as background noise or to punctuate the time), people use television (1) to facilitate communication (e.g., entering conversations or reducing anxiety), (2) to affiliate with or avoid others (e.g., reducing conflict or maintaining relationships), (3) for social learning (e.g., problem-solving or information dissemination), and (4) to demonstrate competence or dominance (e.g., gatekeeping or exercising authority). Different social uses contribute to different media effects.

# **Social Capital and Communication in Health**

*Susan Koch-Weser*

*Harvard School of Public Health*

*Kavita Karan*

*Nanyang Technological University*

*K. Viswanath*

*Harvard School of Public Health*

The concept of social capital dates back more than 100 years and has intrigued academics, policymakers, and activists interested in understanding intergroup relations and social change in a variety of fields including communication, public health, sociology, and political science (Portes 1998). It has been seen as a promising way to examine how interaction and association among people and groups could influence public health, politics, economics, and overall comity and cohesion among disparate social groups. Despite substantive disagreements about the definition, utility, and appropriate measurement of social capital, there is broad agreement that social capital grows out of relationships between and among individuals and organizations and facilitates social action. Dimensions of social capital are generally understood to include norms of reciprocity, interpersonal trust, solidarity, and cooperation that seem to depend on social networks and civic engagement. Social capital is usually regarded as a positive phenomenon, although it can have negative effects when ties hinder positive action or serve to exclude segments of the population from key resources.

## **DEFINITION OF SOCIAL CAPITAL**

Coleman (1988) defined social capital by its function, as a “variety of entities” that facilitate actions by social actors. Social capital helps in explaining different outcomes of actions of individuals as well as connecting them to larger structural changes. Thus, according to Coleman, social capital, although a property of the social structure, is fungible and used by individuals to accomplish goals.

In contrast, Putnam (1993, 35–36) put a more collective spin on the concept and defined social capital not by its function, but rather as the “features of social organizations, such as networks, norms, and trust, that facilitate action and cooperation for mutual benefit.” Thus the benefits of social capital accrue more markedly at the community, rather than individual, level. Certainly social capital benefits individuals, because individuals form connections that benefit their own interests. However, the connections themselves affect the wider community, so that not all the benefits of social connections will belong to the individual, but rather can contribute to well-being at the group level.

In public health, definitions of social capital that favor the communitarian approach seem to have prevailed. The utility of social capital in examining group-level differences

in health, above and beyond the well-established benefits of social support for individuals, is the novel contribution of social capital to understanding public health (Kawachi et al. 2004). Groups enjoying higher levels of social capital have demonstrated lower levels of stressful conditions, risky behaviors, poor health, and mortality.

Putnam (2000) elaborated two key forms of social capital, “bridging” and “bonding,” to which Szreter and Woolcock (2004) added “linking.” Briefly, *bonding* social capital tends to reinforce homogeneous groups; developing reciprocity and mobilizing solidarity. Bonding social capital often occurs in the context of dense networks such as families, churches, and ethnic enclaves (→ Social Networks). *Bridging* social capital, in contrast, tends to be more inclusive, connecting people of greater diversity, and can generate broader identities and reciprocity. Finally, *linking* social capital is a particular form of bridging social capital, and links people across power or authority gradients in society.

### COMMUNICATION AND SOCIAL CAPITAL

An understanding of the relationship between social capital and communication requires careful attention to both the appropriate level and cross-level analyses (Viswanath in press). For example, a widely viewed → television program mass communication may lead to discussions among co-workers, → interpersonal communication, cementing relationships with a potential for trust and reciprocity, two dimensions of social capital. Accordingly, communication at both interpersonal and mass levels may lead to an increase (or in some cases a decrease) in social capital.

Communication may also be a key to understanding how different variants of social capital – bonding, bridging, and linking – are related to each other. From the point of view of *health*, communication facilitates diffusion of new information (→ Diffusion of Information and Innovation), reinforces → social norms, mobilizes people for collective action (→ Social Movements and Communication), and creates social support, thus providing the base for understanding how social capital may impact public health (→ Social Support in Health Communication). For *individuals*, communication plays a role in integrating people into cohesive communities by helping to support and maintain social ties and in promoting interpersonal trust (→ Community Integration). Interpersonal communication within social networks sustains trust, reciprocity, expectations, and information exchange, all critical dimensions of social capital. In addition, social capital, through interpersonal communications, may reinforce, moderate, and contradict → information people are exposed to in mass media.

*Mass media* communications also play a role in community integration and cohesion, critical elements of social capital (Viswanath in press). A dimension of social capital membership in local organizations and institutions is related to local and national media use (Rothenbuhler et al. 1996; Stamm & Weis 1986; Viswanath et al. 1990). This well-established finding of local media use and community ties is important in understanding exposure to information of all kinds, including health information in the local media. “Media effects” on audience awareness, knowledge, opinions, attitude about health, and health behaviors assume exposure to media content, which is a necessary antecedent to effects (→ Media Effects; Attitudes, Values, and Beliefs, Media Effects on; Agenda-Setting Effects). Community ties may enhance the opportunities for such exposure. Another way

community ties may influence media exposure is through social priming (Demers 1996; → Priming Theory; Exposure to Communication Content). Interaction with interpersonal networks and with members of local associations may “prime” audiences to attend to health information and act as a source of information.

The way media are *used* may also influence the formation of social capital. Media used for information are much more likely to contribute to social capital than media used for entertainment (Shah et al. 2001). News media may provide greater opportunity for exposure to mobilizing information as well as arguments, opinions, and frames that could promote engagements with civic affairs (→ News; Exposure to News; Framing of the News).

It is well documented that mass media are agents of both change and social control (Tichenor et al. 1980). The *agendas of organized social groups* may be amplified, potentially contributing to bridging and linking social capital. Organized efforts to promote public health, such as public health communication campaigns (→ Health Campaigns, Communication in), often use mass media as powerful advocates. Conversely, when the media are not amplifying the agenda of organized social groups, which is more likely to occur when the groups desire changes that threaten fundamental power structure in the social system, groups may engage in media advocacy (→ Media Advocacy in Health Communication). Media advocacy may be more likely to occur in communities with high levels of social capital where members are able to work together and benefit from collective action (Kawachi & Berkman 2000).

The *structure of a community* – its size, economic base, ethnic, racial, and social class diversity, and centralization or decentralization of power among others – also influences the availability of information, how media cover information, diversity of media choices, and how people use the mass media. Heterogeneous networks facilitate the distribution and dissemination of new information (bridging social capital) and collective mobilization (linking social capital) compared to more closely aligned networks of family and friends (bonding social capital). Thus, social capital may also provide a way to examine → communication inequalities that potentially contribute to social disparities (Viswanath 2006). *Communication inequality* – i.e., differences among social classes in the generation, manipulation, and distribution of information at the group level, and differences in access to and ability to take advantage of information at the individual level – may spring in part from differences among communities in social capital. People who participate in voluntary associations are, in general, from a higher socio-economic position than those who do not, and participation in such associations both contributes to social capital and may potentially provide an opportunity for individuals to access and act on information. In short, it is intriguing to explore whether the nature of social capital may influence what people may learn or do not learn from communications and whether that varies by social class, exacerbating inequalities.

## **MEASUREMENT OF SOCIAL CAPITAL**

Measuring social capital is challenging for three reasons (Woolcock & Narayan 2000): (1) the multidimensional nature of most definitions of social capital include different levels and units of analysis; (2) social capital can change over time as the relative importance of informal organizations and formal institutions shifts; and (3) in the initial

development of the concept no standard approach for measurement was developed, and no longstanding surveys have been implemented to measure social capital across time and place (→ Measurement Theory).

In most studies researchers have used data from a variety of sources to compile indices of social capital. Indices generally include items related to structural and cultural aspects of social capital and are constructed either from aggregated micro-level data (such as social → survey items assessing trust) or macro-level data (such as number of voluntary organizations or crime rates). Large-scale studies examining social capital and health at the national or state level have tended to use a few items to assess social capital (often unavoidable because few items may be available given the data sources), while smaller-scale studies have been able to measure social capital with more comprehensive measures (Harpham et al. 2002). Examples of larger-scale studies include work by Kawachi et al. (1999) based on secondary data from general social surveys, using indices that included per capita membership in voluntary groups, interpersonal trust aggregated, and perceived norms of reciprocity. Other examples include work in Australia by Bullen and Onyx (1998), the Social Capital Community Benchmark Survey directed by Putnam (Saguaro Seminar 2001), and work for use in developing countries by the World Bank (Krishna & Shrader 1999).

### **FUTURE RESEARCH**

A more rigorous, systematic, and through understanding of the relationship between health communication and social capital could be valuable in improving public health and reducing inequities among different social classes.

While communication is clearly essential to the formation and maintenance of social capital of all types, the relationships between each form of social capital and *health* communication should be considered. Health communications to inform people or to persuade or motivate them to change behaviors to improve their health often result in differential levels of knowledge across groups. Knowledge gaps are a perennial problem (→ Knowledge Gap Effects), and lower levels of health knowledge have often been found among the same groups that suffer from health disparities (Institute of Medicine 2002; → Health Disparities, Communication in). Understanding aspects of social structure that are likely to shape how information flows through populations is critical to advancing health communication. Social capital theory, which facilitates analyses of micro-to-macro transitions, has potentially great utility for the study of social factors affecting health communication. Social capital, in each of its forms, is likely to structure the communications that reach the individual by influencing the key components of communication.

In the area of interpersonal communications, social capital, and health, it is too early to predict the impact of the → Internet and the world wide web. Nonetheless, their unique characteristics are likely to heavily impact the nature of social interactions and, consequently, trust, reciprocity, and dimensions of health communication (→ Health Communication and the Internet).

## **Social Capital, Media Effects on**

*Dhavan V. Shah*

*University of Wisconsin-Madison*

The term “social capital” has become a popular way for academics, activists, politicians, and the public to describe how an individual’s location in a structure of relationships, and the sense of trust and reciprocity that accompanies this social position, can provide the means for citizens to cooperate on problems requiring collective effort (Coleman 1990). It is defined as the resources of information, shared norms, and social relations embedded in communities that enable people to learn and to coordinate action. As such, social capital concerns contextual, relational, and individual factors that are not overtly political yet have implications for the health of civil society. Of particular relevance to communication research focused on civic and political participation is the considerable attention paid to the mass media’s role in the production and destruction of social capital.

Robert Putnam (2000), who has led the examination of the roots of the decline in Americans’ community engagement and its implications for democratic functioning, sees the answer in the connection between television use and the erosion of social capital (→ Exposure to Television). Available evidence indicates that while contributions to charitable groups are at all-time highs, face-to-face encounters with other community members and involvement in political activities have slid dramatically over the last 50 years, the same period that witnessed the rise of television. And although attendance at public events has remained high, or even increased, it cannot match the sharp rise in privatized entertainment in the form of in-home media use (→ Enjoyment/Entertainment Seeking; Political Communication; Political Media Use).

These downward trends appear to be based on generational differences and individual changes; that is, members of generation X are not only less participatory and trusting than their baby-boomer parents, but they are less connected, engaged, and involved than the boomers were when they were young adults. Likewise, baby-boomers have typically

been less connected and involved than members of the preceding generation. Changes in patterns of media use over time – i.e., rising rate of television usage and decline in newspaper readership – have been identified as some of the main causes of the decline of civic culture (→ Media Use across the Life-Span; Political Socialization through the Media).

Work by Jack McLeod and his colleagues (1996) has found that newspapers, with their informative content and focus on → news and community events, produce pro-civic consequences; newspaper readers, especially those who pay close attention to local news content, are more politically knowledgeable and participatory than nonreaders. Conversely, television has been blamed for civic disengagement. The issue of whether television viewing actually erodes social capital and reduces civic participation has spurred a lively debate on the relationships between media use and civic life (see Shah 1998).

### **MEDIA AND CIVIC ENGAGEMENT**

Many of the factors found to enhance community participation – age and education, employment, church attendance, psychological ties to the community, and general sociability – arguably represent the unmeasured concepts of social trust, civic skills, and social networks that come with social standing and community belonging. Conversely, media use, typically defined as hours of TV use, is viewed as a barrier to civic participation.

The arguments offered for the *expectation of adverse media effects* are intuitively appealing. Time spent with media supposedly privatizes leisure time and therefore displaces other activities that build the community. Further, the depiction of social reality in mass media, particularly television, is thought to cultivate a perception of the world as a mean place, leading to social withdrawal (→ Media and Perceptions of Reality). Thus, television's inaccurate portrayal of society distorts social reality judgments such that television's frequent presentation of violence is thought to lead heavy television viewers to believe that the real world is a more dangerous place than it actually is (Eveland 2002). Consequently, overall television viewing is criticized, often with scant evidence, as the main culprit in the erosion of social capital by fostering anti-civic sentiments (→ Political Cynicism).

Research formally testing time displacement and cultivation effects of mass media on social trust and civic engagement has found only *limited support* for the view that television use undercuts social capital (→ Cultivation Theory; Cultivation Effects). Nonetheless, these arguments, initially advanced for television, have recently been extended to → Internet use, with research relating time spent online with the erosion of psychological well-being, declines in social trust, the loss of real-world ties, and community disengagement (Nie 2001; Kraut et al. 1998; → Exposure to the Internet).

Although these perspectives are provocative, communication scholars have questioned their merits, arguing that these critiques of the media are grounded on the assumption that media use is one-dimensional and that there is only one type of audience when in fact media consumption is a product of varied motives and different types of users (→ Audience; Audience Segmentation). Thus, research on the topic of media use and civic engagement has taken the position that scholars must be attentive to patterns of use, not simply hours of use (Shah et al. 2001). This is critical when considering the effects of the Internet, a medium that many have argued contains the potential to increase knowledge, tighten relations, and ease coordination and cooperation.

## USING MEDIA FOR INFORMATION AND SURVEILLANCE

Information and surveillance motives for media use have received considerable scholarly attention because they promise increased political knowledge and awareness of civic opportunities and objectives. The general conclusion of this work: *informational uses of mass media* – i.e., reading newspapers, watching news programs, and gathering and exchanging information over the Internet – have pro-civic consequences, such as increase in levels of campaign and community participation (Shah et al. 2007). News media, then, do more than educate; they provide the basis for political discussion and deliberation that can lead to civic action (→ Political Knowledge).

*Non-news content* also has the potential to provide information and foster increased reflection about civic life. In particular, social dramas that depict contemporary controversies, often ones that are “ripped from the headlines,” allow for unique representations of various sides of socio-political issues. These programs are emotionally engaging, base claims on experiential rather than factual knowledge, and treat the audience as being physically present within the program, as opposed to the detached and objective approach of most news reports. These programs not only allow viewers to understand community problems in more complex and personal terms, but suggest avenues for involvement that are modeled by fictional characters. Indeed, news programs have increasingly capitalized on the storylines of programs such as *ER* and *NYPD Blue* by developing reports linking community events to the fictional narratives.

Research also suggests that *informational and communicative uses of the Internet* encourage community involvement and foster civic participation, that is, individuals who use the Internet to explore interests, gather data, and send and receive email have been found to be more socially and politically engaged (Wellman et al. 2001). The Internet may promote civic engagement because it allows users to gain knowledge, reinforce social linkages, and coordinate their actions to address joint concerns. The associative features of email may amplify the effects of more traditional forms of social interaction since email allows individuals to coordinate their actions with great efficiency and permits the politically active to present opportunities for civic participation to likely prospects in their social circle (Shah et al. 2007).

This suggests that media use and social networks work together to produce civic engagement, reinforcing the need to be attentive to the social context in which traditional and new media are used. In particular, scholars have theorized a communication mediation model in which socio-economic factors, particularly income and education, work through news consumption and interpersonal communication to shape civic engagement. News media use is thought to encourage citizen engagement through its effects on political discussion. Through these communicative actions, people become better informed, develop more complex conceptions of community issues, acquire psychological resources, and build social trust. Thus, informational media use works with conventional and online citizen communication to mediate the effects of background factors on public-mindedness and civic participation.

## USING MEDIA FOR ENTERTAINMENT AND DIVERSION

The relationship between entertainment/diversion uses of media and involvement in community life has been of increasing research interest. Situation comedies and reality

programs have been of particular interest, both because of their prevalence and their expected connections to trust and participation. There is evidence that upbeat sitcoms such as *Friends* run counter to Putnam's expectations about television, yielding positive relationships with interpersonal trust. Watching programs that depict social reality in a light-hearted manner may be related to a more hopeful worldview of which interpersonal trust is one component (→ Entertainment Content and Reality Perception; Entertainment, Effects of).

*Reality programs* such as *Cops*, *Survivor*, and *Apprentice* present a very different social world, one that is full of deception, betrayal, and finger-pointing. If there is any merit to arguments about "mean-world effects" of media consumption, reality program viewing should be related to social mistrust and civic disengagement. The conventional wisdom concerning this genre asserts that it fosters fear and a more dangerous view of societal interaction, encouraging withdrawal from community life. There is some support for this perspective.

Like sitcoms and reality programs, the use of the Internet for entertainment and escape may also have adverse civic consequences (→ Situation Comedies). Research indicates that individuals who use the Internet for recreation and anonymous socialization may not experience many civic benefits. Such uses of the Internet privatize social recreation; chatrooms and other means of interacting anonymously in online environments provide the illusion of face-to-face social belonging without the benefits. As such, recreational uses of the Internet may erode the individual-level production of social capital since these activities weaken social networks. Of course, the nature of this relationship is at least partly a function of the content of the exchange.

## GENERAL DIFFERENCES IN MEDIA EFFECTS

In addition to conclusions concerning the connection between Internet use and civic life, past research by Shah and colleagues has found substantial generational differences in the relationship between Internet use and civic engagement. The positive and negative associations observed between patterns of Internet use and trust and participation were concentrated among the youngest American adults. Indeed, across the generational groups examined, the predictive power of Internet use became weaker as analysis moved from younger to older groups. These findings, along with findings on generational differences in newspaper use, clearly suggest a generational difference in levels of media use and patterns of media effects.

However, the differential influence of media across generational groups may not simply reflect variation in levels in use; rather, generational contrasts may be a function of an *affinity toward certain types of media*. Research on media reliance has found that effects of media consumption tend to be concentrated among individuals who have learned to depend on a given medium, whether that medium is newspapers, television, or the Internet. In contrast to the Internet, research suggests that older people are more reliant on print media, the medium they developed a connection with in their youth. These generational differences may also provide important clues about how media may be used to build social capital.

## **Social Cognitive Theory**

*Albert Bandura*

*Stanford University*

Theories of human behavior differ in their conceptions of human nature and what they regard as the basic determinants and mechanisms governing self-development, adaptation, and change. Social cognitive theory is rooted in an agentic perspective (→ Bandura 1986, 2006a). To be an agent is to influence one's own functioning and events that affect one's life. In this view people are contributors to their life circumstances, not just products of them.

## CONCEPTIONS OF HUMAN BEHAVIOR

Human behavior has often been explained in terms of unidirectional causation. In the environmental deterministic view, behavior is shaped and controlled by environmental forces. In the dispositional deterministic view, behavior is driven by internal drives and dispositions. Social cognitive theory explains human functioning in terms of triadic reciprocal determination. In this transactional view of self and society, personal factors in the form of cognitive, emotional, and biological processes, the way one behaves, and environmental forces all operate as interacting determinants that influence each other. Individuals are characterized within this theoretical perspective in terms of a number of basic capabilities, which are reviewed next (→ Cognition; Emotion).

Humans are endowed with an extraordinary *capacity for symbolization* that provides them with a powerful tool for comprehending their environment and altering it in ways that touch virtually every aspect of their lives. Most environmental influences operate through cognitive processes. Cognitive factors partly determine which environmental events will be observed, what meaning will be conferred on them, whether they leave any lasting effects, what emotional impact and motivating power they will have, and how the information they convey will be organized for future use. The remarkable flexibility of symbolization enables people to create ideas that transcend their sensory experiences. Through the medium of symbols they can communicate with others at any distance in time and space. With the aid of symbols, people give structure, meaning, and continuity to their lives (→ Symbolism).

## LEARNING FROM MODELS

There are *two basic modes of learning*. People learn by experiencing the effects of their actions, and through the power of social modeling (→ Observational Learning). Direct experience is a tough teacher. Trial-and-error learning is not only an exceedingly tedious process, but a hazardous one when mistakes have costly or injurious consequences. Moreover, the constraints of time, resources, and mobility impose severe limits on the situations and activities that can be directly explored for the acquisition of new knowledge. Fortunately, this process can be cut short by social modeling. Humans have an advanced capacity for observational learning that enables them to expand their knowledge and competencies rapidly through the information conveyed by a rich variety of models (Bandura 1986; Rosenthal & Zimmerman 1978).

Modeling is not just response mimicry as commonly believed. Social modeling operates at a higher level of learning. Modeled judgments and actions may differ in specific content while embodying the same principle. For example, modeled speech may vary in content but have the same underlying structure, as in the passive voice, e.g., “The dog *was* petted,” “The window *was* opened.” Once observers extract the guiding principle underlying the modeled examples, they can use it to generate a variety of sentences in the passive voice that go beyond those they have heard. Abstract modeling provides the means for generative and innovative behavior.

Much of the vicarious learning is based on the models in one’s immediate environment. However, in contemporary society, ideas, values, belief systems, and lifestyles are

socially transmitted via the *extensive modeling in the symbolic environment*. This enables people to transcend the confines of their lived environment. With the revolutionary advances in communications technology, lifestyles are now being modeled and rapidly diffused worldwide. A major importance of symbolic modeling lies in its tremendous reach, speed, and multiplicative power. Unlike learning by doing, which requires shaping the actions of each individual through repeated consequences, in vicarious learning a single model can transmit new ways of thinking and behaving simultaneously to vast populations in widely dispersed locales.

The models upon whom people pattern their behavior come in *diverse forms and sources*. Some involve behavioral modeling in informal everyday activities or formally structured social arrangements. The salient symbolic modeling through the electronic media pervades people's daily lives. Verbal modeling is another source of instructive and inspirational exemplars. In this mode of symbolic modeling, values, lifestyles, and guides for daily living are personalized in the biographies of idealized exemplars.

Social modeling serves diverse functions in promoting personal and social change. With regard to its instructive function, models serve as transmitters of knowledge, competencies, values, cognitive skills, and new styles of behavior. In addition to cultivating new competencies, modeling influences can alter motivation, emotional dispositions, and value systems. Seeing others achieve desired outcomes by their efforts can instill motivating outcome expectations in observers that they can secure similar benefits for comparable performances; seeing others punished for engaging in certain activities can instill negative outcome expectations that serve as disincentives for similar activities. Observers can also acquire lasting attitudes and emotional dispositions toward persons, places, or things that have been associated with modeled fears, likes, and dislikes.

The actions of models can also serve as social prompts that activate, channel, and support previously learned behavior. Thus, the types of models that prevail within a social milieu partly determine which human qualities, from among many alternatives, are selectively encouraged. Finally, people's images of social reality and the structure and ideological orientations of societies are heavily influenced by the symbolic modeling in the mass media (Gerbner et al. 2002).

Symbolic modeling usually serves as the principal conveyer of innovations to widely dispersed areas, especially in early phases of diffusion. Modeling instructs people in new ideas and social practices and designates their functional value (Bandura 1986). People are linked, not only directly by personal relationships. Because acquaintanceships overlap different network clusters, people become linked to each other indirectly by interconnected ties. These multilinked social networks provide diffusion paths for the spread of new ideas, lifestyle patterns, and social practices (Rogers & Kincaid 1981; Granovetter 1983; Bandura 2006b).

### **ANTICIPATING CONSEQUENCES OF BEHAVIORS**

Through forethought people set themselves goals and anticipate likely outcomes of prospective actions to guide and motivate their efforts. Behavior patterns that produce positive outcomes are readily adopted and used, whereas those that bring unrewarding or punishing outcomes are generally discarded. But external consequences are not the only

kind of outcomes that influence human behavior. As previously noted, people profit from the successes and mistakes of others as well as from their own experiences. Because outcomes exert their influence through forethought, they have little or no impact until people discover how outcomes are linked to actions in one's environment. The ability to bring anticipated outcomes to bear on current activities promotes purposeful and foresightful behavior. When projected over a long time course on matters of value, a forethoughtful perspective provides direction, coherence, and meaning to one's life.

People are not only planners and forethinkers. They are also *self-regulators*. They construct standards of merit and ethical conduct and regulate their motivation and behavior by the consequences they apply to themselves. They do things that give them satisfaction and a sense of self-worth, and they refrain from behaving in ways that violate their standards because such conduct gives rise to self-criticism.

Human behavior is governed by the *interplay of extrinsic and self-evaluative consequences*. External outcomes are most likely to wield influence when they are compatible with self-evaluative ones. Under conditions in which the external support and reward for given activities are minimal or lacking, individuals have to sustain their efforts largely through self-encouragement. People experience conflicts of outcomes when they are socially punished for activities they value highly. Principled dissenters and nonconformists often find themselves in such predicaments. The relative strength of self-approval and external censure determine whether the courses of action will be pursued or abandoned. There are individuals, however, whose sense of self-worth is so strongly invested in certain convictions that they will submit to prolonged maltreatment rather than accede to what they regard as unjust or immoral.

People commonly experience conflicts in which they gain material and social benefits for activities that violate their standards. These are conditions under which people may engage in the personally devalued activities but preserve their sense of self-worth. They do so by selective disengagement of moral self-sanctions from their conduct (Bandura 1999). They use worthy ends to justify detrimental means. They sanitize the practices with euphemistic language that makes them personally and socially acceptable. They absolve themselves of accountability by displacement and diffusion of responsibility. They disregard, minimize, or dispute the adverse effects of their conduct. And they devalue and blame those who suffer the adverse effects for bringing the misery on themselves.

### **BELIEF IN EFFICACY**

People are not only agents of action. They are self-examiners of their own functioning. They reflect on their personal efficacy, the soundness of their thoughts and actions, the meaning of their pursuits, and make corrective adjustments if necessary. The meta-cognitive capability to reflect upon oneself and the adequacy of one's thoughts and actions is the most distinctly human core property of agency.

Among the types of thoughts that affect human self-development, adaptation, and change, none is more central or pervasive than people's beliefs in their ability to influence events that affect their lives. This core *belief in one's efficacy* is the foundation of human motivation, performance accomplishments, and emotional well-being. Unless people believe they can produce desired effects by their actions, they have little incentive to

undertake activities, or to persevere in the face of difficulties. Whatever other factors serve as guides, and motivators, they are rooted in the core belief that one has the power to effect changes by one's actions.

Efficacy beliefs operate through their impact on cognitive, motivational, affective, and decisional processes. Such beliefs affect whether individuals think optimistically or pessimistically, in self-enhancing or self-debilitating ways. They affect people's goals and aspirations, how well they motivate themselves, and their perseverance in the face of difficulties and adversity. Efficacy beliefs also shape people's outcome expectations – whether they expect their efforts to produce favorable outcomes or adverse ones (→ Goals, Cognitive Aspects of).

In addition, efficacy beliefs determine how opportunities and impediments are viewed. People of low efficacy are easily convinced of the futility of effort in the face of difficulties. They quickly give up trying. Those of high efficacy view impediments as surmountable by improvement of self-regulatory skills and perseverant effort. They stay the course in the face of difficulties and remain resilient to adversity. Moreover, efficacy beliefs affect the quality of emotional life and vulnerability to stress and depression. And last, but not least, efficacy beliefs determine the choices people make at important decisional points. A factor that influences choice behavior can profoundly affect the courses lives take. This is because the social influences operating in the selected environments continue to promote certain competencies, values, and lifestyles. By choosing their environments people can have a hand in what they become.

Social cognitive theory distinguishes among *three modes of agency*: individual, proxy, and collective. They are rooted in belief in one's efficacy to effect changes by one's actions. In personal agency exercised individually, people bring their influence to bear on their own functioning and on environmental events over which they can wield some influence. However, in many spheres of functioning, people do not have direct control over conditions that affect their lives. They exercise proxy agency by influencing others who have the resources, knowledge, and means to act on their behalf to secure the outcomes they desire. Children turn to their parents to get what they want, marital partners to their spouses, employees to their unions, and the general public to their legislative representatives. People do not live their lives in individual autonomy. Many of the things they seek are achievable only by working together through interdependent effort. In the exercise of collective agency, they pool their knowledge, skills, and resources, and act in concert to shape their future. The effective management of everyday life requires an agentic blend of these three different forms of agency.

## Social Comparison Theory

Marie-Louise Mares

University of Wisconsin-Madison

The central idea of social comparison theory is that individuals often assess how well they are doing by comparing themselves with others around them. When → Festinger (1954) originally developed the theory, he argued that individuals want an accurate assessment of their opinions and performance, and that in the absence of objective standards, they look to others (preferably those who are similar in a relevant dimension) for → information about their relative standing. Individuals, he argued, seek to be right in their opinions, and have a unidirectional drive upward for their abilities.

Much of Festinger's early work focused on individuals comparing their opinions with those of others. In a series of studies, he examined the conditions under which individuals tended to conform or dissent with other people's judgments (e.g., about the length of a line). In the face of consistent opposition, most people conformed; in the presence of at least one other dissenting opinion, most people were willing to express their own dissenting viewpoint. Other early work confirmed the notion that individuals' self-evaluations change depending on the types of comparisons available. In a classic study by Morse and Gergen (1970), university students competed for a job with another applicant who was either organized and well groomed (Mr. Clean) or unkempt and disorganized (Mr. Dirty). Those competing against Mr. Dirty were more positive about their own performance than those competing against Mr. Clean.

### EXPANSION OF THE THEORY

The theory has subsequently expanded in multiple directions. One such direction is in the investigation of various *additional domains of comparison*, including personal values (e.g., "Do other people think this is as important as I do?") and the appropriateness of

emotional responses (e.g., “Are others as scared as I am?”). Some researchers have also pointed out that the drive for self-evaluation and comparison is not always present: Individuals sometimes want to avoid closure on a particular topic and suspend judgment about themselves.

Another direction in which the theory has expanded is in studying *additional motives for comparison*. Despite Festinger’s initial emphasis on accurate self-evaluations, research suggests that there may be several other common motives.

One alternative motive is *self-enhancement*. That is, individuals may sometimes seek out comparisons that make them feel good about themselves (rather than focusing on accurate information). Wills (1981) argued that when individuals want to engage in self-enhancement they make downward social comparisons – that is, they look for others who are doing less well on a relevant dimension in order to feel relatively successful. For those seeking self-enhancement, upward comparisons with those performing better were predicted to be ego-threatening and stressful. Psychologists such as Wood (2000) and Taylor (1991; Taylor et al. 1990) have studied individuals experiencing threat or stress (such as breast cancer, rheumatoid arthritis, or negative feedback about test performance). Numerous studies have reported on the tendency to seek out ego-enhancing, reassuring information about others who were less fortunate or coping less well.

A related line of research associated with Taylor and her colleagues (Taylor 1991) has focused on the *benefits of positive illusions*. Positive (though unrealistic) beliefs that one is doing better than most other people in the same situation have been correlated with prospective psychological adjustment and lowered physiological indicators of stress. The absence of such illusions has been associated with negative → emotions and even depression. A contrasting view is that not all positive illusions are beneficial and that self-enhancement can be detrimental. In some studies, individuals who rated themselves much more positively than others rated them generally showed long-term negative outcomes. A recent suggestion is that one way to resolve this seeming inconsistency is to distinguish between self-enhancement as social comparison (rating oneself more positively than one rates other people) and self-enhancement as poor self-insight (rating oneself more positively than other people rate one). Self-enhancement via social comparison may be linked to positive results, while poor self-insight may be linked to negative results (Kwan et al. 2004).

Other motives for social comparison include *self-improvement* and *inspiration*. That is, at times individuals may seek out information about those performing brilliantly. Such comparisons may provide hope for the individual’s possible future, information about how to perform similarly, and motivation to work hard.

## TARGETS FOR SOCIAL COMPARISONS

In an extended critique of the theory, Kruglanski and Mayseless (1990) argued that a central weakness of social comparison theory lies in the difficulty of predicting who would be a relevant or similar target for comparison, even when an individual’s motives are given. For example, even if a female runner were seeking an accurate self-evaluation, it is unclear whether she would compare herself to another runner of similar age, or another runner of similar experience, or another woman runner, or a runner with similar racing style.

Moreover, the variety of motives for social comparison suggests that similarity of target is not always the primary concern. Taylor et al. (1990) pointed out that Festinger's description of a unidirectional drive upward for abilities is ambiguous and has been interpreted in various ways in the empirical literature. Some researchers interpret this to mean that (for example) the hypothetical runner would try to improve her performance by comparing herself with slightly better runners; others have focused on her motivation to compare herself with less talented runners.

The traditional view is that people who want accurate information for self-evaluation of opinions or abilities would choose a similar or slightly better target; those seeking self-enhancement would choose downward comparisons to provide a sense of relative well-being; and those seeking self-improvement would look to more successful others (upward comparison) for relevant information and inspiration. More recently, however, researchers have argued that comparison choices may be even more complicated. For example, individuals seeking reassurance and self-enhancement may not want to make downward comparisons if such comparisons raise the possibility of similar bad outcomes occurring to them. Instead, these individuals may look for successful role models to provide the needed reassurance ("If they can do it, so can I"). Conversely, individuals seeking self-improvement may sometimes look to unsuccessful others to provide information about what to avoid or to create fear as motivation to work hard.

Some researchers have also argued that at times individuals may compare themselves not to others in their social environment, but to past selves ("At least I'm not as bad as I was") or imagined others ("I'm sure I'm doing better than most other women").

### **FACTORS AFFECTING THE OUTCOMES OF SOCIAL COMPARISONS**

Pelham and Wachsmuth (1995) pointed out that most social comparison research has focused on contrast effects (feeling better than the target of a downward comparison; feeling inferior to the target of an upward comparison). They argued that assimilation effects (overestimating the similarity between oneself and a target) also take place and may even be more common. In their description, individuals sometimes adopt the belief that "birds of a feather flock together" and exaggeratedly assign to themselves the qualities of those around them, rather than perceiving and responding to the differences. Thus a runner who trains with a pack of faster runners may not focus on the ego-damaging difference between her time and the others' but rather consider herself a fast runner to be part of such a speedy group.

Researchers have studied the factors that affect whether individuals will engage in contrast or assimilation. In various studies, *assimilation* has been observed to occur when individuals do not explicitly evaluate the comparison target; when they share a close bond, common attributes, or group membership with the comparison target; and when they are very confident in their self-image and so do not tend to engage in explicit self-evaluations and comparisons. Conversely, *contrast effects* have been observed to occur when individuals explicitly evaluate the comparison target and use it as a reference point for evaluating the self, and when they are less confident of their self-image and hence more interested in making self-evaluations.

Another relevant factor is whether individuals think they can change on the relevant dimension, and in what direction. When individuals believe they can improve, an upward comparison can be inspiring. When improvement is not seen as possible, upward comparisons can be demoralizing. When individuals fear they may decline, downward comparisons may be frightening, but when they are sure they will not decline, downward comparisons may be ego-enhancing. In a series of studies by Lockwood and her colleagues (e.g., Lockwood & Kunda 1997), individuals who were first asked to think about their most successful moments and subsequently read about a highly superior superstar appeared to be struck by the contrast between their best and the superstar's best, and were accordingly demoralized. Those who were not asked to recall their best performance appeared to engage in affiliation with the superstar and gave more positive self-evaluations.

Yet another important variable affecting the outcome of comparisons appears to be whether they relate to an ability or trait that is central to one's self-definition. The runner may feel proud (rather than demoralized) that her father can sing better than she can, but feel humiliated if he beats her in a race.

Thus, the people individuals select for comparison, and whether they engage in upward or downward comparison, assimilation, or contrast, seems to vary greatly depending on a number of factors. Moreover, Wood (2000) pointed out that researchers have varied substantially in their measures of social comparison and its effects and that this variation has led to numerous instances of inconsistent findings.

### **USE OF SOCIAL COMPARISON THEORY IN COMMUNICATIONS RESEARCH**

Despite these complications, the central tenet of social comparison theory (that individuals compare themselves to others and alter their self-evaluations accordingly) is at the heart of many accounts of → media effects, even when it is not explicitly acknowledged. For example, much of the criticism of unrealistic media portrayals of body images (→ Body Images in the Media) rests on the assumption that viewers (particularly young teens) will compare their bodies to those media images and engage in destructive behaviors as a result. The outcomes of studies of media use and eating disorders reflect the joint processes of assimilation (e.g., thin women feeling better after watching images of thin, attractive models) and contrast (e.g., women feeling worse about themselves after seeing images of thin, attractive models). Social comparison theory is also related to notions of wishful → identification with media characters (both fictional and nonfictional; → Fiction).

Other media scholars have used the notion of *relevant similarity* to explain viewers' preferences for media characters that are same-sex or same-age. Researchers who address the possible effects of media content on self-categorization and social identity (e.g., among older viewers) are also making use of social comparison theory.

Social comparison theory has been used to predict patterns of → selective exposure to positively or negatively valenced media content (→ Mood Management). Examples include individuals' choice of health-related content on the → Internet, or their choice of whether to listen to sad or happy songs about love. In a series of studies, Knobloch and Zillmann (e.g., 2003) found that students who were romantically dissatisfied preferred to listen to sad songs, presumably to avoid the pain of upward comparison.

## **Social Conflict and Communication**

*Douglas Blanks Hindman*

*Washington State University*

In a world of finite resources, growing populations, expanding democracy among weak nations, and expanding opportunities for communication across geographic boundaries, disagreements are inevitable. Disagreements might be about the distribution or conservation of resources, about status, power, or differences among various groups within the population, about the history of past interactions, or about a myriad of other issues, both

real and imagined. These struggles are indications of social conflict, or public clashes among groups over competing claims (Coser 1956).

Communication is crucial to social conflict because through it, social conflict can escalate into violence or de-escalate into resolution and reconciliation, and can lead to clearer definitions of opposing positions (Gilboa 2006). Conflict is a ubiquitous form of social interaction that can have positive or negative consequences for the groups involved, can have implications for both social change and social stability, and can be understood as both a product of the social setting and a purely symbolic act that has no relationship to what are imagined as real conditions.

Social conflicts, as intense forms of human interaction, tend to draw crowds of bystanders wherever they occur. News media, perhaps relying on the idea of “what the public wants,” include a disproportionate amount of social conflict, occasionally framing as conflict situations that are not viewed that way by the participants (→ Conflict as Media Content; Framing of the News). In most cases, however, the parties involved in conflict are often quite eager to make their position known to a wider audience. Hence, social conflict is a frequent theme of news coverage, particularly → television news about international politics (→ Foreign Policy and the Media).

## **SOCIAL CONFLICT AND COMMUNICATION RESEARCH**

The emphasis among conflict scholars has changed in tandem with broader social changes. In the nineteenth and early twentieth centuries, social conflict was understood in the context of industrialization, urbanization, and bureaucratization. The failure of socialist revolts and the rise of fascist regimes in the early middle of the twentieth century coincided with scholarship that critiqued scientific approaches to communication research and that focused on the role of ideology and coercion in stemming revolution. The relatively stable US social environment of the late middle of the twentieth century was paralleled by studies of the integrative aspects of social conflict. The civil rights, antiwar, and environmental protests of the latter half of the twentieth century focused attention on communication and social conflict as symbolic struggles over ideology, with potential for individual emancipation and radical social change (→ Civil Rights Movement and the Media).

The study of communication and social conflict has advanced along a number of divergent paths, owing mainly to the philosophical worldviews and methodological preferences of the researchers. Scholars committed to understanding the world as it is tend to view social conflict and communication as components of a highly integrated and gradually changing world. Radical scholars committed to understanding the world as it might become tend to be interested in the use of communication to suppress revolutionary conflict and to maintain the dominance of oppressive groups (Burrell and Morgan 1979).

### **Conflict, Communication, and Radical Change**

As a social reformer and political activist, *Karl Marx* (1818–1883) viewed social conflict, and class conflict in particular, as a driving force behind social change. Antagonisms

between the owners of the means of production and the exploited laborers, in combination with widening economic crises, would eventually lead to revolutionary change. Private property and capitalist-supporting institutions such as the government and religion would be abolished, and the working class would become the ruling class, finally able to enjoy the fruits of their labor. Although history has proven Marx incorrect regarding the inevitability of revolutionary change, many of his ideas continue to stimulate research about the relationships between social conflict and change, about the connections among the legal, political, and economic systems, and about social institutions' support of dominant groups.

Scholars who are influenced by the economic aspects of Marxian scholarship focus on the concentration of ownership and interlocking directorships of media industries, and the accompanying concentration of the means of cultural production (→ Concentration in Media Systems). C. Wright Mills's focus was on the "power elite": an alliance of leaders within business, military, and governmental bureaucracies. These highly interlinked groups of leaders work together to insure their own position at the seats of power, and to ensure that the war-making economy is perpetuated. Mills argued that mass media play an important role in legitimizing and perpetuating the power of elites and by distancing elites from citizens. Mills's conclusion was that the media serve primarily to hand down decisions to the public, which can only react, and not influence them (→ Political Socialization through the Media).

Cultural critical studies emerged as an attempt to explain why the revolution that Marx predicted never came to be, and to emphasize processes by which dominant ideology becomes integrated into common sense so that citizens become the instruments of their own oppression. Critical cultural scholars find opportunities for both emancipation and coercion in → popular culture and mass media. Todd Gitlin's (1980) analysis of media roles in the social construction and demise of a radical student movement in the 1960s illustrates how potent challenges to the status quo can be absorbed without resulting in substantive social change (→ Critical Theory; Cultural Studies).

### **Communication and the Regulation of Conflict**

Marx's concern with social conflict was based primarily on his analysis of capitalism and his observation of the excesses of the industrial revolution. *Max Weber* (1864–1917), on the other hand, was more broadly interested in conflict that was not solely reducible to economic differences. Weber defined conflict as simply action that is intended to carry out an actor's own will against the resistance of others (Weber 1994, 13). Power is distributed on the basis of class, status, and political parties – not exclusively according to economic classes. Authority derives from claims to legitimacy based on rationality, bureaucracy, rules, and laws. Legitimacy derives from claims based on tradition, as in hereditary power. Authority derives from claims based on the charisma or heroism of the individual (Weber 1994, 108). Conflict parties with greater power and authority are more likely to prevail.

*Ralf Dahrendorf's* (b. 1929) theory of social conflict builds upon revisions of Marx's and Weber's concepts of conflict and power. Rejecting Marx's claim that the only force for change in society was revolutionary class conflict, Dahrendorf saw instead that conflict

was a fundamental and ubiquitous force behind the gradual forms of social change that characterize society. In Dahrendorf's definition, conflict comprises relations between two groups each of which wants to attain something available to only one group. Dahrendorf's revision of Marxism was to reject property ownership as the only basis for class formation. Instead, he argued that the main determinants of conflict are power and authority, both of which are more fundamental than class or property ownership. Conflict groups, then, typically represent a group with authority that wants to preserve the status quo versus another group lacking in authority and intent on challenging the status quo.

Weber described a number of features of rationality-based authority that are pertinent to questions of communication and social conflict. Ultimately, bureaucracy can be understood as a means of limiting communication and controlling conflict both within an organization and between an organization and the outside world. Conflicts are channeled to specially trained employees according to formally defined procedures and rules. The hierarchical nature of the bureaucracy insures that the organization's leaders are not bothered by each dispute that occurs at lower levels of the organization. This is because subordinates are restricted in their ability to communicate beyond a level or two above their own position. The organization can continue to function even as various levels of the bureaucracy are engaged in conflict control. Although bureaucratic control of conflict may lead to unsatisfactory resolutions for one or more participants in the conflict, the principle of equality before the law is in most circumstances preferred over conflict resolution according to privilege and favor.

Just as bureaucracies can be viewed as mechanisms for limiting and controlling conflict, the division of labor, or specialization of occupations and tasks, can be viewed not only as a means of increasing productivity but also as a means of limiting conflict and competition among organizations. *Emile Durkheim* (1858–1917) considered the interdependencies created by the division of labor to be the main unifying force of modern society.

In keeping with Durkheim's emphasis on questions of social order, a line of conflict sociologists developed propositions that stress the integrative aspects of social conflict. *Georg Simmel* (1858–1918) argued, in direct contradiction of Marx, that conflict is merely an intense but pervasive aspect of social interaction that can have positive or negative effects on society.

*Robert Park* (1864–1944) was a former journalist, and a student of Charles Dewey and Georg Simmel, who spent the majority of his academic career as a sociologist at the University of Chicago. Park's notion of conflict was also heavily influenced by Weber. He argued that conflict, and its less intense forms of struggle, namely competition and rivalry, are intrinsic to the formation and maintenance of social groups. Building on one of Simmel's propositions, Park claimed that the most intense, emotionally involving conflicts are over ideals in which the individuals fight not for themselves but instead for an abstract ideal. He coined the term "urban ecology" to explain the distribution of various groups of people throughout the city, and the succession of ethnic groups from the core of the city to the outer edges. For Park and his colleagues at the University of Chicago, ethnic media played an important role in maintaining the cultures and social control of ethnic neighborhoods, substituting publicity for the gossip and ostracism that were used to control deviant members of the community in the old world.

Another University of Chicago sociologist, *Herbert Blumer* (1900–1987), shared Park's interest in community formation through public discussion. The public is a group of people who are confronted with an issue, are divided in their view of how to solve the issue, and discuss the issue. Through discussion, the various factions come into conflict and thus intensify their critical powers in order to advance better arguments and to stake out their respective positions. This becomes the basis of public opinion: sharpened differences that emerge among conflicting groups engaged in public discussion (Blumer 1954). Social conflict in combination with public discussion can clarify the positions of the conflicting groups, and can lead to the search for additional information and solutions to the problem.

*Lewis Coser* (1913–2003) organized and formalized many of Simmel's propositions about the relationship between conflict and the integration of social groups. For example, conflict with outgroups is expected to increase the solidarity within the group, leads to rallying behind the leader, leads to the search for allies, and leads to an interest in maintaining the enemy in order to maintain solidarity within the group. Within large and complex groups, internal conflict increases cohesion as conflicting groups become more loyal to their own group and because formal procedures are used to give each group a fair hearing.

A program of mass communication research that combines Coser's integrative view of social conflict with Dahrendorf's interest in the division between authorities and those without authority was developed and applied to the analysis of news media in Minnesota communities. *Phillip Tichenor, George Donohue, and Clarice Olien* developed the community structural pluralism model over 30 years of research on the relationship between mass communication and its social and institutional environment. In this perspective, local mass media are best understood in terms of their dependence upon powerful local and non-local institutions. The general principle is that the media can report whatever their sources are willing to tell them. In the end, media reports of social conflict serve both social control and social change functions. Their "guard dog" metaphor suggests that mass media tend to be particularly vigorous in reporting conflict when elites are divided over an issue. At the national level, news media cover international events from the perspective of the home country's political and economic elites (→ Community Structure Model).

## **FUTURE DIRECTIONS IN COMMUNICATION AND CONFLICT RESEARCH**

Just as the communication and social conflict research of the previous generation was responsive to the social and cultural climate of the day, current and future research acknowledges significant trends in the nature of conflict itself. The historic shift since World War II has been from conflict among industrial-age, professional military forces to the civil wars, ethnic violence, and other forms of what Charles Tilly (2003) calls contentious politics.

Incessant and critical media coverage of the humanitarian crises resulting from modern social conflicts is thought in some cases to stimulate western military intervention. On closer examination, Robinson (2002) showed that the so-called "CNN effect" was limited to cases in which a western country has no existing policy regarding the issues related to the crisis, and its elites are undecided on how to deal with the crisis (→ CNN).

As global climate change produces increasing environmental catastrophes, media coverage of the aftermath can be expected to amplify the jurisdictional disputes that arise among relief agencies, and are expected to prime viewers to judge political leaders on the basis of their presence and performance during the disaster.

As communities become more diverse, with more potential centers for organized social power, contentious politics have replaced a previous generation's bowling leagues and fraternal clubs as the primary method of social participation. Scholars and community organizers are developing *new methods of conflict mediation* to manage racial, ethnic, and environmental disputes. The idea is that conflict is primarily a communication-based act that can be channeled, via communications, into positive outcomes (Gilboa 2006; Warfield 2006). Through this process, social conflict and communication can activate citizens to participate in their community's civic life, even as more benign forms of social participation such as bowling leagues and civic club membership continue to decline. Civic journalism projects were designed to use local media to stimulate civic involvement by first creating forums to air citizen concerns, then using media resources to explore the scope of the problems and to create forums in which elected officials and the public discuss policies to address the problems (→ Community Integration; Community Media; Conflict Resolution).

Mass media do not create social conflict or social movements, yet media coverage is one of the key resources that conflict groups mobilize to achieve political goals (→ Instrumental Actualization). New information technologies are proving to be valuable tools for coalition formation and message dissemination, both among protest groups and between protest groups and the public. Mainstream media reporters covering large-scale social protests such as demonstrations during World Trade Organization meetings can turn to the websites of the various groups involved in the protest in order to learn about the substantive goals of each (Owens & Palmer 2003). Social movement scholars focusing on the strategic mobilization of the resources among protest groups understand that new communication technologies are among the many resources available for organizing against authorities.

Social conflict theorists tend to view all of history as result of various groups struggling to control scarce resources. As long as humans continue to interact, communication, as the primary expression of social conflict, will continue to be an important field of study.

# Social Desirability

*Roland Mangold*

*Stuttgart Media University*

The social desirability bias is a major → response set that is possibly active when data are collected in empirical social studies with → interviews, psychometric tests, or questionnaires in particular. This tendency interferes with the “true values” of the subjects’ traits or states that are to be assessed and puts a systematic bias onto the measured values (→ Scales; Measurement Theory; Validity). People react in a socially desirable way if they do not answer in a way or choose the alternative that best reflects the intensity or strength of the state or trait that is to be measured. Instead, subjects answer in a way that they assume to be expected by their peer group or the interviewer/experimenter or approved by the general public (→ Climate of Opinion; Public Opinion). For example, a person who sympathizes with a radical (right-wing) political party and is asked in a questionnaire to state his or her beliefs concerning migration or foreign persons will probably give moderate answers despite holding a more radical view. By that, the person intends not to stand out from other subjects or to the experimenter as being deviant or radical.

A stronger bias toward social desirability is to be expected if the questions are closely related to → social norms and value systems and if the subject is aware of that relationship. The amount to which a data collection method is subject to a social desirability bias can be estimated by assessing data for one group of subjects under normal conditions, and comparing with data from another group, where the subjects are additionally instructed to present themselves as much as possible in a socially desirable way.

In early social research the assumption prevailed that the tendency to appear in a good light to others is a general one and applies to all humans in the same way. It has since been found, however, that the social desirability tendency is influenced by factors like the age, gender, and social stratum of the subjects participating in the studies. Furthermore, there are correlations between the social desirability tendency and characteristics of the test situation as well as the topic of the questionnaire (→ Test Theory). In addition, regional- and time-dependent influences on the social desirability tendency can also be observed.

Thorough item construction as well as carefully planned instructions can reduce the effects of social desirability. Questions and answering alternatives should be formulated in a way that reveals as little as possible about test intentions and keeps the personal state or trait to be measured hidden from the subject. Furthermore, groups of alternative answers can be composed that all have a similar low or high social desirability. In that way, subjects are constrained to choose an alternative independently of social desirability (i.e., forced choice). In order to assess the strength of socially desirable responding, scales have been developed that can help to either control the social desirability tendency or even correct test scores (e.g., the Marlowe–Crowne Social Desirability Scale, MCSDS). To do so, a number of items are put together where an honest answer and an answer oriented toward social desirability diverge. For example, if a subject is negating questions like

“Have you ever been dishonest?” more frequently than other persons, this indicates a reaction tendency toward social desirability. The subjects’ answers can indicate whether they have filled out the questionnaire in an honest and true manner or whether they have been dishonest, which could account for biased test scores.

Finally, a tendency toward social desirability can also be reduced by providing appropriate instructions. Subjects should explicitly be asked to give honest answers and not to answer in a way that is biased with respect to social norms. During the test procedure a relaxed atmosphere is of advantage, where subjects do not feel themselves provoked to present themselves in a socially desirable way and to leave a good impression. Subjects should be convinced that it is in their interest to present themselves as accurately as possible and not in terms of what they assume to be considered preferable.

A laborious but effective method for controlling social desirability is the bogus pipeline procedure. Subjects are confronted with a set-up for the measurement of physiological indicators (such as skin conductance or heart rate). They are informed that this procedure allows a person’s attitudes to be recorded with great → reliability and validity. Filling out the questionnaire only serves to give an idea of how precisely a person knows his or her own attitudes and is able to communicate them. This method has been demonstrated to be relatively resistant against faking, social desirability, and other response sets.

## **Social Exchange**

*Michael E. Roloff*

*Northwestern University*

Human survival is based on the ability to exchange resources, and as a result of evolution, the human brain has adapted so as to facilitate exchange (Cosmides & Tooby 2005).

Communication is a tool by which individuals can negotiate an exchange (→ Negotiation and Bargaining) as well as provide resources (Roloff 1981). Appropriately, communication scholars have used social exchange theories to guide their research. Interpersonal researchers have applied these frameworks to a variety of relational processes (→ Disclosure in Interpersonal Communication; Interpersonal Conflict; Relationship Development; Relational Maintenance). Organizational researchers have found the frameworks useful for investigating → supervisor–subordinate relationships, as well as other aspects of the workplace (Cropanzano & Mitchell 2005).

### THEORETICAL CONCEPTS

Although different in some respects, social exchange theories assume that individuals are self-interested and that they will act in ways that meet their resource needs. People repeat rewarded behavior largely because they anticipate that those actions will be rewarded relative to other behaviors. Acting in a purely self-interested fashion could create exploitation that threatens social cohesion. To prevent exploitation, norms have emerged that guide social exchange. For example, the norm of reciprocity dictates that after receiving a resource, the receiver must act in a supportive way toward the giver until the debt is repaid. When norms are violated, individuals become upset and violators may be punished.

A variety of *exchange patterns* exist. Social exchanges are more informal than are economic exchanges. Instead of following an explicit contract, social exchanges are guided by understandings about what will be exchanged, and when and where the exchange will take place. Some exchanges involve giving resources whereas others involve taking away or denying resources. Individuals may communicate respect by exchanging compliments, but they can deny respect by expressing insults. *Restricted exchanges* occur when individuals provide each other with resources, whereas *generalized exchanges* occur when individuals receive resources from another but must repay the debt by giving a resource to someone other than the giver.

Restricted exchanges such as those between a buyer and seller are thought to be individualistic since each party is concerned about receiving resources that are better than the ones given away. Generalized exchanges are thought to have a collectivistic element. Parents may invest considerable resources in their children's future not because they expect their children to care for them but because they hope the children will use the resources to build a better life for grandchildren. Some exchanges are "tit for tat," in which one resource is returned in repayment for having received a specific resource, whereas other exchanges work on a "bank account model," in which resources are invested in a relationship and can be withdrawn when needed. Finally, some exchanges are trades in which two individuals agree to transfer specific resources to each other, whereas others are distributions wherein an allocator decides how much resource each individual in a group should receive from a supply. Buyers and sellers trade money for goods and services. In contrast, a supervisor allocates money from a budget designated for raises among a group of employees.

Individuals have *resource categories* that are used to interpret behaviors. Some resources are thought to be highly symbolic, such as love and respect, whereas others are more

concrete, such as money and goods. A behavior might be placed into multiple categories, and individuals may disagree as to which category is correct. Resource value can also be difficult to determine. In some cases, the value of a resource is based on supply and demand, but in others, it could be based upon how recently a resource has been received, norms, or its physical qualities. Possessing scarce and needed resources increases a person's power. The key principle of power is to make others dependent upon one's resources while maintaining one's own independence. When individuals become dependent on a person's resources, they have little choice but to grant his or her demands.

Finally, individuals use justice norms to *evaluate the fairness* of a social exchange. *Distributive justice* is focused on whether individuals have received resources that they deserved. One pervasive norm is equity, which dictates that each person should receive resources in proportion to what he or she contributes. An employee who has been more productive than a co-worker expects to receive more valuable resources, and the co-worker expects to receive less. Individuals vary in the degree to which they are sensitive to equity, and other distributive norms dictate that resources should be given on the basis of need, status, and equality. *Procedural justice* is focused on the decision process that produced the exchange.

Generally parties to an exchange should have voice in the decision-making (→ Participative Processes in Organizations). Voice means that they could directly express their desires, but expression can also occur when their representatives or decision-makers similar to them can communicate their wishes. Voice also requires that decision-makers actually listen to the points of view rather than simply letting parties express them. In part, voice is important because it implies respect for an individual. However, voice is of greatest concern when distributive justice is violated, and individuals are more upset when their own voice is denied than when other people have been denied voice. *Interaction justice* focuses on how the conditions of the social exchange are communicated. Fair interactions occur when justifications are provided for how the resources were distributed and the announcement is expressed in a sensitive manner. Communicating sensitively can overcome the negative reactions to violations of procedural justice.

Although the social exchange theories are useful, a number of *controversies* have surrounded them. Some critics question the degree to which human behavior is really self-interested and point to altruistic actions. Indeed, some types of relationships may be guided by a communal orientation aimed at meeting another's needs rather than an exchange orientation aimed at gaining resources for self. Other critics have argued that many of the exchange concepts are fuzzy. Resource value is especially problematic, given that so many factors influence perceived value and often the value of a resource is not clear until after exchange. The notion of contribution is a key feature of equity-based approaches, yet the notion of what constitutes a contribution is subjective. Also, the social exchange theories portray human behavior as being strategic. Individuals consider positive and negative consequences prior to doing something, which may not always be true. Finally, some critics have questioned the degree to which social exchange concepts provide insight into the various processes occurring during communication. The precise manner in which linguistic cues and nonverbal behaviors are used to express or infer resources is unclear.

## MEASURES AND FINDINGS

Because many of the concepts in the social exchange theories are focused on perceptions, they are measured through self-reports. For example, individuals are asked whether they received resources they deserved, what type of resources were exchanged, how valuable they were, whether they had voice in the exchange, and whether they felt adequate justifications were provided. In some cases, researchers study how individuals differ with regard to their feelings about exchange. Hence, scales assess desire to be in an exchange relationship, the tendency to feel indebted to another, and expectations for reciprocity.

Few attempts have been made to create less subjective measures of exchange. Formulae have been created to assess equity by mathematically combining contributions and benefits. Schemes for identifying resources being exchanged during an interaction have been developed. Statistical techniques have been used to determine whether individuals reciprocate information disclosures. However, these methods are rarely used.

Rusbult's (1980) Investment Model has guided research on close relationships as well as jobs. It posits that investments, satisfaction with current outcomes, and alternative sources for rewards determine the degree to which a person is committed to remaining in a relationship or a job. Commitment, in turn, increases the likelihood that a person will try to maintain their relationship or employment. Maintenance includes devaluing alternatives and responding to a partner's or employer's provocative actions in a constructive fashion. Commitment increases relational stability (Le & Agnew 2003; → Research Methods).

## FUTURE DIRECTIONS

Given increased access arising from information technologies and the blurring of work and family boundaries, communication may be a commodity whose supply can be quickly depleted by growing demands (→ Information Overload). If so, future research will focus on the commoditization of communication. How do individuals decide with whom to interact and for how long? Do individuals create barriers to communication when overwhelmed by contacts? How do individuals replenish their ability to communicate? Do individuals value face-to-face contact more than other, mediated forms of communication?

## Social Identity Theory

*Scott A. Reid*

*University of California, Santa Barbara*

*Howard Giles*

*University of California, Santa Barbara*

Social identity theory (Tajfel & Turner 1979) was originally developed to explain prejudice and discrimination, and the circumstances under which societies would move from relatively cooperative and harmonious arrangements to overt conflict. The theory has since expanded enormously, and has become the basis for a general social identity approach to social psychological and communicative phenomena. This includes, but is not limited to, ethnolinguistic identity theory (Giles & Johnson 1981), → communication accommodation theory (Giles & Coupland 1991), and self-categorization theory (Turner 1987). This expansion has occurred through empirical and theoretical advances that have elaborated the core idea of the theory to explain a wide range of other phenomena. Notable examples include the use of the social identity approach as a basis for understanding language expansion and language death, bilingualism and multilingualism, communicative shifts in accent and language along micro- and macro-social dimensions, language attitudes, social influence and → persuasion, stereotyping, and most recently, media selection and perception.

It is rare for a social scientific theory to become so developed. In the case of social identity theory, Tajfel's critical insight followed from a critique of early approaches to understanding prejudice and discrimination (→ Prejudiced and Discriminatory Communication). Tajfel observed, as did others, that the common approach to understanding these phenomena rested solely on the psychology of the individual, typically motivations or putative biological needs. By focusing on the individual to the exclusion of social context, these approaches were unable to explain when groups of people would simultaneously develop prejudices, and when these prejudices might be amplified or ameliorated. Because of this, such approaches were unable to account for the critical process of social change.

According to social identity theory, people are motivated to maintain or enhance a positive sense of social identity, but the way in which this occurs is directed and

constrained by beliefs about the legitimacy and stability of ingroup status vis-à-vis relevant outgroups, the degree to which boundaries between groups are thought to be permeable, and the individuals' degree of identification with their ingroup. Combinations of these beliefs, driven by a desire for positive social identity, lead to the crystallization of *three different social belief structures*, namely social mobility, social competition, and social creativity. In each case, these belief structures are best understood as resulting from an intergroup struggle for power, prestige, and status. Those groups that fare well in the intergroup context are those that emerge with relatively high status, and by extension group members achieve positive social identity (→ Intergroup Contact and Communication).

When people consider their group to have stable and legitimate low status, believe it possible to join a high-status group, and have little commitment to their ingroup, then they are likely to have *social mobility beliefs*. In other words, the problem of striving for positive social identity is solved by adopting an ideology based on individual movement between groups. On the other hand, people might perceive their group's status to be low, but consider the circumstances that produce that low status to be illegitimate and unstable. If this is combined with a sense that it is not possible to shift into another group, and strong ingroup identification, such a person is likely to solve the problem of positive social identity by engaging in *social competition*. In other words, people with these beliefs are likely to have hostile attitudes about members of the higher-status outgroup, and may engage in social action designed to change the situation. Examples would include engaging in language revival movements, engaging in social protest, or developing prejudicial attitudes toward members of the advantaged group.

Finally, someone who believes that it is not possible to individually join another group, but who also believe that the status of their group is stable (i.e., cannot be easily changed through some form of social action), is likely to value their ingroup but avoid confrontation with an outgroup. *Social, creative responses* to this problem of resolving positive social identity include finding a lower-status group to make comparison with, rejecting the basis for social comparison (e.g., the slogan "black is beautiful"), or ignoring the basis for status (e.g., intelligence, competence, wealth), and focusing instead on an alternative solidarity-based dimension for defining the ingroup (e.g., integrity, benevolence, or decency).

More recent research has considered the *role of the mass media* in particular as affecting group vitality and the likelihood of collective action (Reid et al. 2004; → Collective Action and Communication). Indigenous groups such as Native Americans and Hawaiians typically receive short shrift on mainstream television, and such a lack of exposure will likely have a negative impact upon subjective group vitality (→ Symbolic Annihilation). Similarly, there is much evidence that minority groups, such as women and older adults, have received relatively little exposure on mainstream television. Further to the lack of media representation, the depictions that are presented are often negative and stereotypic. It is likely that such portrayals negatively impact the subjective vitality of members of such groups, both within the minority group and in the minds of non-minority group members (→ Media and Group Representations).

There is, however, evidence that people engage with the media in ways designed to gratify social identities. In other words, people actively search for media content that provides information about the ingroup, and there is evidence that consuming such

material can have a positive impact on social identity (→ Exposure to Communication Content). Despite the presence of negative depictions of groups, it is possible that individuals' active attempts to find positive ingroup images can override the effect of more mainstream depictions. Other lines of more recent research include application of this approach to under-studied groups such as those defined by disability, age, civilian–police encounters, homosexual–heterosexual interactions, and the presence and effect of intergroup relations on the Internet (see Harwood & Giles 2005).

## **Social Interaction Structure**

*Edward A. Mabry*

*University of Wisconsin-Milwaukee*

How someone behaves verbally, physically, or through their presence in a social context influences the behavior of other people in that context. This is a logical and practical assumption about any form of shared human activity (→ Interactivity, Concept of). The variety of ways that behavior takes shape and is repeated over time and situations is referred to as “social interaction structure.” The concept of structure also implies that observable patterns of behavior give individual acts, messages, and other behaviors a frame of reference that can be used in their interpretation. The study of social interaction structures also encompasses analyses of natural language in multi-speaker conversations

(→ Conversation Analysis). Scholars who explore language-based approaches to social interaction often focus on how *rules* of language use and norms governing social behavior influence communication practices (McLaughlin 1984). The study of social interaction structure is also closely aligned with the study of communication as a dynamic *process* (→ Models of Communication) and is often used as the basis for empirically representing *communication systems*. Social interaction structures are studied in a number of sub-fields including group, intercultural, interpersonal, and organizational communication.

## IDENTIFYING AND INTERPRETING SOCIAL INTERACTION STRUCTURES

Interpreting social interaction structure involves applying theories about how social interaction is, or should be, organized to the results of observations and measurements of social activity. The content of social interaction structures can range from ordinary social behaviors, like words and physical movements, to the inclusion of graphical or melodic representations of ideas, thoughts, and emotions. Researchers may use very literal representations of actual messages (e.g., questions, statistics, etc.) or more generally descriptive terms reflecting broader categories of message themes (e.g., assertive, passive, etc.). Researchers also combine verbal and nonverbal messages together in making inferences about message content (e.g., expressions of sarcasm or irony).

An important variable used in defining the organization of communication processes is *time*. Time may account for the *duration* of events observed during social interaction as well as their *rate* of occurrence (the number of instances a behavior occurs in a given time unit). A related concept is *cyclicity*. Cycles represent structures based on the repetition of behaviors. Greeting rituals are examples of cycles that are an almost taken-for-granted part of ordinary social interaction. Cycles can also define the intervals between separate occurrences of social interaction. The intensity of emotional involvement displayed by people in a dispute, for example, can be judged by how little time elapses between messages or turns at talk.

Theoretical guidance is used in identifying message content and procedures for determining how messages are linked and interpreted. Social interaction structures can be classified into one or more of *four identifiable patterns*: distributional, sequential, temporal, and relational (Mabry 1999). These patterns represent increasingly complex explanations of the underlying social interaction.

## DISTRIBUTIONAL STRUCTURE

Distributional structures reveal variability in the frequency or rates of occurrence of social interaction. Classification measures of messages and/or speakers are designed to indicate the extent to which behavior is equally or unevenly distributed according to a method for defining the behavior. The examination of distributional structure is a basic result obtained from analyses of communication content (→ Coding; Measurement Theory; Content Analysis, Qualitative; Content Analysis, Quantitative).

Bales's interaction process analysis (IPA) observation system, for example, classifies message acts uttered in group discussions according to whether they represent *questions* or *attempted answers* regarding information, opinion, or suggested action, or are *positive*

or *negative social-emotional* expressions; overall, 12 types of messages expressed by group members are measured (e.g., agrees, gives suggestions, asks for information, disagrees, etc.). In his research using IPA, Bales found that a typical group problem-solving session produced about five times as many attempted answers as it did questions and roughly twice as many positive acts as negative acts; individual message category distributions showed that giving information accounted for the largest amount of interaction, about 30 percent, compared with positive or negative expressions of friendliness, which each accounted for about 3 percent of group interaction. Distributional structures were quite different in groups where members were satisfied or dissatisfied, experienced protracted conflicts, or worked under intense time pressure (see Bales 1999 for a thorough summary of his research and its implications). Distributional structures are used when communication research goals emphasize the types of messages shared during social interaction (→ Classroom Student–Teacher Interaction; Marital Typologies; Mediated Social Interaction; Online Relationships; Relationship Development).

### SEQUENTIAL STRUCTURE

Sequential structures reflect the event order of messages involved in communication episodes or streams of conversation such as greetings, agreements, disagreements, or attempts at invoking or acceding to power displays. Norms of social interaction lead us to expect that a message exchange where, for example, person A says, “I agree” is likely to stimulate a different set of message responses from person B (or other parties) than if person A said “I disagree” (→ Social Conflict and Communication). Sequential structures are also instrumental in revealing how conversations are organized. The fact that speakers take turns helps make conversations predictable. Conversational organization also helps to explain speakers’ intentions and goals as communicators. How certain types of messages precede or follow each other is important for understanding whether speakers are being argumentative, dominating, playful, or sarcastic (→ Language and Social Interaction).

Rogers and Farace’s (1975) transactional method for analyzing relational communication identifies sequential structures based on influence control behaviors (→ Relational Control). These researchers analyzed records of conversations between relational partners to reveal successive pairs of sequentially occurring interpersonal control messages. Three sequential patterns of influence control structures emerged: *symmetrical*, *complementary*, or *transitory*. Symmetrical structures involved message sequences where both parties enacted the same type of control message. Complementary structure involved message sequences where one person’s message attempted to gain control and the other person was signaling a willingness to yield control. A transitory sequence occurred when a message either attempting to gain or yield control was paired with a message that appeared to neutralize control. Rogers and Farace (1975) also reported that transitory interactions comprised 60 percent of observed exchanges in their sample of couples’ interactions, symmetrical structures were the second most frequent sequence with 28 percent of the exchanges, and complementary exchanges accounted for only 12 percent of the interactions. Such findings suggest that couples spend a substantial amount of time attempting to neutralize their partners’ attempts at relational control instead of either challenging or acceding to the attempted influence. Assessments of sequential structure are often the

basis for theories advanced to explain how interpersonal relationships function and why they change.

### TEMPORAL STRUCTURE

Temporal structures integrate time-related factors into the organization of social interaction. Temporal structure is also judged by *event order* cycles based on changes in distributional or sequential structures. For instance, people in meetings may be somewhat more agreeable at the beginning of the meeting and toward the point in time when they want to end the meeting. But agreement may decrease, and disagreements increase, during the middle part of the meeting (Bales 1999). How groups and organizations pursue goals and react to external conditions can be tracked by observing changing patterns of communication that define specific phases or transitional stages (→ Organizational Change Processes).

Temporal structure is also implied in studies of how interpersonal relationships form, evolve, and dissolve. Berger and Calabrese (1975), for example, proposed that initial interaction between strangers passed through three phases motivated by needs for reducing uncertainty (→ Uncertainty Management). An “entry” phase draws on prior participants’ social information and norms of conduct assumed to be appropriate for that situation. Communication is more structured and oriented toward exchanging descriptive information. A second, “personal” phase may follow the entry phase, when people begin revealing information connected to core beliefs and values and how they perceive the other person(s) in the encounter. An “exit” phase marks the termination of the conversation and the encounter. Messages may revert back to normative expectations about ending social encounters or extend positive impressions made in the personal phase and solicit commitments to future contact. Although a linear trajectory is often implied in studies of temporal structure there is little agreement about the validity of this assumption. There is substantial agreement that studying transitional stages provides important insights about how communication functions in all social contexts.

### RELATIONAL STRUCTURE

Relational structures reflect the extent of *connectivity* between interacting parties (individuals, groups, and/or organizations). They resemble *network* configurations displaying how communicating units are connected by the amount of messages they exchange or time spent interacting (→ Social Networks). In romantic relationships, for example, Parks and Adelman (1983) demonstrated that couples were less likely to break up when they increased interaction with their partners and their partners’ network of family and friends. They attributed the results to a decline in uncertainty about the partner caused by increased social information and support generated from becoming more embedded in the romantic partner’s social network.

In his study of organizational networks, Danowski (1980) found network members in production- and innovation-oriented networks had similar beliefs and attitudes that reinforced network affiliations, whereas social maintenance (support) networks drew on more immediate, perceived problem issues. Relational structures are assessed through

direct observation of social interaction or by self-reported information obtained from participants (→ Network Analysis). All social contexts contain communication networks; however, people vary greatly regarding how densely connected (embedded) they are in their networks or the strength of their connections, on the basis of how much they interact with others with whom they are connected.

## RESEARCH IMPLICATIONS

Theories of social interaction structure are often linked to classes or specific types of mathematical analysis (e.g., distributional structure and log-linear models; sequential structure and Markov models). The merging of theory and analysis in the assessment of social interaction structure is often referred to as *modeling* (→ Linear and Nonlinear Models of Causal Analysis). Models represent mathematical expressions of how measured variables, like messages, are related to other variables (either messages or other social variables like attitudes or demographic attributes).

Mathematical modeling is uniquely suited to the complexity of analysis required for studying social interaction structures. Models provide relatively straightforward operational maps that can account for the persistence or changeability of a communication structure. The methodological options available for model development also have been demonstrated to provide increasing clarity and validity with more complex structures like sequential, temporal, and relational social interaction structures (VanLear 1996).

## Social Judgment Theory

*Charles K. Atkin*

*Michigan State University*

*Sandi W. Smith*

*Michigan State University*

Social judgment theory (SJT; Sherif & Hovland 1961; Sherif et al. 1965) is based on the premise that the effect of a persuasive message on a particular issue depends on the way that the receiver evaluates the position that the message puts forth (O’Keefe 1990; → Persuasion). Sherif et al. (1965) claimed that an individual’s attitude toward a particular issue or behavior is not adequately reflected by a single alternative or position among those available. Research in the SJT tradition determines the limits of the position of the receiver “relative to the bounds of possible alternatives defined by the extreme positions on the issue” (Sherif et al. 1965, 3) in terms of the → latitudes of acceptance, noncommitment, and rejection.

In SJT, each receiver judges the range of alternatives individually, and then these judgments can be combined “to reflect the consensus, defined by social norms, prevailing among given people” (Sherif et al. 1965, 10). Thus, SJT allows for delineating group patterns that emerge from perceptions of individuals (→ Social Norms). Additionally, SJT claims that the members of the population in question are affected by these patterns, in that they “develop and adopt a variety of practices, customs, traditions, and definitions that mark off latitudes for acceptable attitudes and behavior and for objectionable attitudes and behavior among members in various matters of consequence to the group . . . These shared practices and definitions with their highly evaluative aspects, are the norms of the group” (Sherif et al. 1965).

### THEORETICAL CONCEPTS

The following are some basic concepts of social judgment theory. When an issue has intrinsic importance or significant consequences for the life of the receiver, he or she is said to be highly ego involved. As *ego involvement* goes up, the trend is for the latitude of rejection to increase while the latitude of noncommitment decreases. An *ordered alternatives questionnaire* is a continuum of beliefs that form the complete range of alternative positions on an issue. It is bounded by the most extreme and opposite

positions possible, with a neutral position in the center, and there are usually between 7 and 11 beliefs listed. Granberg (1983) suggested that some of these statements should be ambiguous in order to facilitate detection of assimilation and contrast effects.

An *own categories questionnaire* is a subjective procedure whereby respondents sort the statements into categories that are meaningful to them. They are then asked which pile comes closest to their own position, which are acceptable, and which are objectionable. The *anchor point* is the position on the ordered alternatives that the receiver holds initially; the *latitude of acceptance* specifies the positions that he or she finds acceptable; the *latitude of noncommitment* represents the positions that he or she finds neither acceptable nor unacceptable; and the *latitude of rejection* represents the positions that he or she finds unacceptable. The *assimilation effect* is the judgmental distortion where one sees the persuasive message as falling closer to the anchor point than it really does. Little or no persuasion occurs because the receiver believes that he or she already holds a similar position on the topic. The *contrast effect* is the judgmental distortion where one sees the persuasive message as falling further from the anchor point than it really does. No persuasion is likely because the receiver believes that this message represents a view that he or she rejects outright. *Persuasion* is an attitude change toward or away from the position advocated by the persuader, which is affected by the receiver's initial judgment within the possible continuum of beliefs (→ Attitudes, Values, and Beliefs, Media Effects on).

## MEASUREMENT AND FINDINGS

In order to measure individual and group positions on a particular issue, SJT involves the construction of an ordered alternatives questionnaire or the own categories procedure, which presents the gamut of possible positions on the issue. Respondents are asked to indicate the positions they find acceptable, unacceptable, or neither acceptable nor unacceptable. The size of the latitude of rejection provides a measure of ego involvement. From these individual responses, group responses can be calculated that reflect the audience's latitudes of acceptance, rejection, and noncommitment.

Persuasive messages for a particular audience should be aimed at the far reaches of their latitude of acceptance, or into their latitude of noncommitment. Messages that fall into the latitude of acceptance are likely to cause an assimilation effect, whereby they are seen as being closer to the audience's position than they really are. Messages that fall into the latitude of rejection are seen as being further away from the audience's position than they really are due to a contrast effect. An audience with less involvement is more likely to be persuaded with a discrepant message than is an audience with high involvement in the issue because the latitude of rejection of the former should be smaller (O'Keefe 1990), thus the latitudes of acceptance and noncommitment should be relatively larger (→ News Processing and Retention; Scales; Test Theory).

Although SJT has been employed in a wide variety of contexts within the field of communication such as → political communication, → health communication, group communication, advertising research, public relations, and legal communication, this review will focus on the first two.

### Political Communication

There is a long history of the application of SJT principles to political communication and attempted attitude change (→ Political Persuasion). O’Keefe (1990) notes that while political campaigns are quite clear in their persuasive messages to get the voters to engage in the overt behavior of voting for their candidate, they are usually more ambiguous in their messages about campaign issues. That is because candidates hope that voters will assume that the candidate’s view and the voters’ views are closer than they actually are. In this case, then, an assimilation effect is desired. Granberg (1983) provides some fascinating examples of the use of ambiguity in political communication, citing examples ranging from General Douglas MacArthur to Robert Kennedy. He noted that McGovern, Stevenson, and Goldwater tried to be too specific when communicating their stances on political issues, while the Nixon, Carter, and Bush, Sr. campaigns benefited from a lack of clarity. He claimed that, “experience has taught politicians that it is unwise to sharpen the issues too much . . . Our system puts a premium on ambiguity” (Granberg 1983; → Election Campaign Communication; Strategic Framing).

Granberg (1983) also provided an overview of findings relevant to political persuasion using SJT (→ Third-Person Effects). He claimed that people tend to assimilate the stands of a preferred candidate, that the degree of assimilation is related to the importance of that issue, that the tendency to contrast the stands of a nonpreferred politician is not as strong as the tendency to assimilate the stands of a preferred politician, and that while ambiguity facilitates assimilation of a preferred candidate, lack of ambiguity facilitates contrast effects in a nonpreferred candidate.

More recently, researchers have studied the *third-person effect* (TPE) in political attack ads via the lens of SJT. Paek et al. (2005) investigated whether people estimated the effects of political attack ads to be stronger on others than on themselves. They predicted, consistent with SJT, that lack of credible evidence and social distance between the respondent and the third person would enhance the third-person effect with regard to political ads. They claimed that SJT offers theoretical potential for understanding the underlying mechanisms of the TPE and seeing it as a cognitive fallacy that can be corrected through presentation of credible and relevant information. They found that “credible information on overall message ineffectiveness leads to the reduction of estimated effects on both self and various others and in self–other perceptual gaps when the other is more distant from self.”

### Health Communication

One recent study applies SJT to health communication campaigns (→ Health Campaigns, Communication in). Smith et al. (2006) merged the social norms approach (SNA) with SJT. The SNA predicts that campaign messages providing true normative information about widely misperceived health behaviors will reduce the gap between inaccurate perceptions and actual practices, and consequently reduce behaviors originally based on exaggerated norms. At the formative evaluation stage of designing messages informed by SJT, the researcher should measure the boundaries of the latitudes of acceptance, noncommitment, and rejection for true normative information to be conveyed to an audience (→ Message Design Logics). This study focused on norms for moderate

consumption of alcohol on a college campus, discovering that the three latitudes were significantly different from one another in believability. SJT predicts that a campaign based on a norm falling in the latitude of noncommitment is most likely to be effective.

A series of messages using the true norm, which fell within the latitude of noncommitment, were part of a year-long media-based health persuasion campaign (→ Cumulative Media Effects). Subsequent → survey data showed significant reductions in the gap in perceived versus actual percentage of alcohol consumption and actual versus perceived number of drinks; moreover, self-reports of consumption of five or fewer drinks increased significantly (→ Risk Communication). Therefore, using SJT as a guiding force in the message testing stage of the campaign was effective. SJT can also explain the effects of failed campaigns using persuasive messages that fell into the audience's latitude of rejection.

SJT can be assessed in terms of the criteria for a strong scientific theory (Granberg 1983). It synthesizes the known body of facts well and is grounded in findings generated from empirical studies. Not all studies have findings that are readily explained by the tenets of SJT, so it has established disconfirmation. The theory is unique in its focus on assessment of the full gamut of possible positions on a persuasive topic and its delineation of the latitudes of acceptance, noncommitment, and rejection, along with the subsequent possible assimilation and contrast effects from messages aimed at these latitudes. SJT is relatively parsimonious: "It does not contain excess baggage" (Granberg 1983). It has not had the heuristic value of other classic persuasion theories, however. Perhaps a resurgence of SJT principles might occur as researchers such as Smith et al. (2006) pair it with other theories, models, and approaches.

# Social Marketing

*Timothy Edgar*

*Emerson College*

Social marketing is a tool or framework that “relies on multiple scientific disciplines to create programs designed to influence human behavior on a large scale” (Smith 2006, 138). It traces its roots to an article written in the 1950s by the sociologist G. D. Wiebe, who “expressed concern that marketing was not being applied to such problems as ‘selling brotherhood like soap’” (Andreasen 2003, 294). The idea did not grow, however, until the 1960s and 1970s, when scholars such as Philip Kotler, Sidney Levy, Gerald Zaltman, and Alan Andreasen began to write about its core principles and gave it a name (Andreasen 2003).

Although social marketing has been used to address a variety of social concerns, it has been most consistently used in health promotion and disease prevention (Andreasen 2002), which has made it an area of special interest to scholars in health communication. Successful social marketing initiatives focused on health outcomes have included the *truth*<sup>®</sup> anti-smoking campaign aimed at teenagers; the Swiss *Stop AIDS* program, which sought to increase condom use among casual sex partners; the *VERB*<sup>™</sup> campaign, which promoted activity among 9–13 year olds; and the *PREMI* initiative, which increased immunization coverage in Ecuador (for more detailed examples, see Lefebvre & Flora 1988; Grier & Bryant 2005; Smith 2006; → Health Communication; Marketing).

Social marketing is characterized by *six defining criteria* (Andreasen 2002). (1) Behavior change is the benchmark used to design and evaluate interventions. (2) Projects consistently use audience research to (a) understand target audiences at the outset of the interventions (i.e., formative research), (b) routinely pre-test intervention elements before they are implemented, and (c) monitor interventions as they are rolled out. (3) There is careful segmentation of the target audiences to ensure maximum efficiency and effectiveness in the use of scarce resources. (4) The central element of any influence strategy is creating attractive motivational exchanges with target audiences. (5). The strategy attempts to use all four Ps (i.e., product, price, place, and promotion) of the traditional marketing mix. (6) Careful attention is paid to the competition faced by the desired behavior.

## THEORETICAL FOUNDATION

Although social marketers have turned to a variety of theoretical perspectives for insight into individual initiatives, *exchange theory* serves as social marketing’s primary conceptual foundation. Exchange theory, which is derived from psychological and economic principles, “assumes that we are need-directed beings with a natural inclination to try and improve our lot” (Hastings & Saren 2003, 309). In order for a successful exchange to occur, both parties act primarily to fulfill their own interests. In the case of a health-related initiative, an effective marketing organization assesses and meets the needs of a target audience, and the organization benefits in return when members of the audience change their behavior (Maibach 2002). According to Smith (2000), the emphasis on

exchange theory differentiates social marketing from other approaches to behavior change such as education, which assumes that knowledge in and of itself leads to change, and a regulatory approach, which highlights enforcement as the most effective path to change.

## THE MARKETING MIX

One of the important features of social marketing is the marketing mix, which is borrowed from commercial marketing and is commonly referred to as the 4 Ps. A social marketing initiative carefully integrates all four elements.

The first of the four Ps is *product*, which is the “bundle of benefits being offered to members of the target audience” (Maibach 2002, 11). Although it is possible for the product to be a physical object such as a condom, more commonly social marketers attempt to “sell” an intangible product such as an idea, a social cause, or, most frequently, a change of behavior (e.g., eating more fruits and vegetables or using seat belts). When the product is not something one can easily hold or touch, the social marketer has the challenge of making “these ‘intangibles’ tangible in a way that appeals to the target audience” (Lefebvre & Flora 1988, 306).

In commercial marketing, *price* usually refers to the monetary value placed on a product. In social marketing, money also can figure into the price an audience member must pay in order to change behavior, but price also refers, at least in part, to the collective barriers that an individual must overcome to adopt the proposed action (Smith 2000). Non-monetary barriers can be “social, behavioral, psychological, temporal, structural, geographic, and physical” (Lefebvre & Flora 1988, 307). Price, however, is not simply about the downside of change. Part of conducting a price analysis for social marketers is also identifying the incentives a member of the target group can enjoy as a result of adopting a new behavior (e.g., an increased sense of self-esteem after losing weight).

*Place*, which also can be called the distribution channel, refers to “the process by which the product is made available to members of the target market at the time and place when it will be of most value to them” (Maibach 2002, 11). In order for social marketers to take advantage of the most ideal places, they have to identify what Grier and Bryant (2005) called “path points,” which are locations people regularly visit; times of the day, week, or year of their visits; and points in the life cycle where people are likely to act.

*Promotion*, which is the most visible component of the marketing mix (Grier & Bryant 2005), is the social marketing element most directly linked to communication. The communication options available to a social marketer are many and varied. One can, for instance, promote a product through → advertising, → public relations, consumer promotions, education, counseling, community organizations, interpersonal networks (→ Social Networks), point-of-purchase materials, direct mail, signage, special events and displays, printed materials, entertainment media, and the web (Grier & Bryant 2005; Maibach 2002; Smith 2000). Social marketing scholars posit that too often individuals not familiar with the complex relationship of all four Ps to one another reduce social marketing to promotion only (Maibach 2002). For an initiative to be labeled accurately as social marketing, the process must include the entire mix and not just the creation and communication of a message.

## CRITICISMS AND DIRECTIONS

### Use of Theory

One area of criticism frequently associated with social marketing is the application of theory. These criticisms have come in two forms. First, many social marketing initiatives either forego a direct reference to a theoretical base altogether, or, at the very least, reflect an application of theory that lacks formality. Walsh et al. (1993, 115) noted that professional social marketers often approach their task as “intuitive tinkerers” who are “impatient with the proposition that their craft warrants or can fruitfully be subjected to formal theory testing.”

Second, some scholars, such as Lefebvre, have argued that social marketing should go beyond exchange theory and called for theoretical eclecticism that will make social marketing a stronger, more vibrant approach to behavior change (Bryant 2004). Grier and Bryant (2005) also argued for eclecticism by suggesting that social marketers incorporate standard health behavior theories and models (e.g., theory of reasoned action, social learning theory, transtheoretical model) when appropriate, as well as frameworks less familiar to social marketers such as the emotional contagion model, political risk compensation theory, risk homeostasis theory, and social capital.

### Research and Evaluation

Another major challenge social marketers face is to incorporate rigorous research into their campaigns. This is difficult for two reasons. First, quality research at any level requires resources in the form of money, people, and time. Many organizations and groups (e.g., government offices and nonprofits) that wish to create campaigns often sacrifice needed research in order to dedicate what resources are available to the promotion portion of the marketing mix (i.e., communicating the message).

For instance, at the formative stage of campaign development, some social marketers forego data collection altogether, or the *information they gather provides limited insights*. Grier and Bryant (2005) argued, for example, that social marketers rely too heavily on focus groups, which often can be completed more quickly and with less expense, to make strategic decisions (→ Qualitative Methodology). Although focus groups conducted properly can provide very meaningful knowledge, Grier and Bryant believed that (1) disproportionate use of focus groups can be misleading because issues that people discuss do not always have the greatest impact on behavioral decisions; and (2) focus group data cannot provide needed insight into audience segmentation in the way that quantitative data can, which often are more resource intensive to gather (→ Health Campaigns, Communication in; Communication and Social Change: Research Methods; Research Methods).

Second, social marketing initiatives often *lack sufficient outcome data* to provide persuasive evidence that a campaign actually worked. Again, lack of resources accounts for much of the problem, but a larger issue relates to measurement and evaluation design. Commercial marketers typically have clearly defined objectives against which success can be measured, such as sales or market share, but outcome evaluation for social marketers

requires greater creativity to detect change. Grier and Bryant (2005) contended that there are innovative methods available to social marketers for providing convincing evidence for change, but results will only be taken seriously when they avoid the common mistakes made in outcome evaluation, such as measuring outcomes too early, before change can occur, failing to measure exposure to the promotion and expecting too much from a limited intervention “dose,” measuring the wrong outcomes, and using the wrong units of analysis when measuring effects (e.g., individuals instead of communities).

Although there have been criticisms directed at social marketing as a framework for behavior change and there are continued challenges that social marketers face, consistent evidence suggests that when applied with rigor social marketing has great potential as a tool for positive effect.

# Social Mobilization

Andrew Calabrese

*University of Colorado at Boulder*

Social mobilizations are concrete evidence of commitment and activism aimed at some form of social transformation, whether in the formal sense of changing laws or by influencing informal social norms. Mobilizations are episodic and shorter-lived than movements, and are often key milestones in the history of movements, providing observable evidence of solidarity, progress, and public awareness built around a particular cause or set of related causes (→ Social Movements and Communication). Mobilizations may receive the conferral of legitimacy through the support of political institutions such as local and national governments, or intergovernmental organizations such as UN agencies. But mobilizations also may challenge and serve to undermine the moral authority and/or political legitimacy of such institutions. They can be understood as means to the ends sought by social movements, and although no single mobilization is sufficient evidence of the existence and scope of a social movement, no movement can be said to exist without one or more forms of observable mobilization.

*Mobilization repertoires* may vary according to legality/illegality, scale, size, cost, intensity, and purpose. Practices may include mass street demonstrations; protest marches; sit-ins and blockades; occupations of land or buildings; street theatre and performance; temporary public art installations; “culture jamming,” often involving spoofs played with brand icons or other familiar corporate or government symbols; boycotts; petitions and lobbying activities; and “electronic civil disobedience” (also known as → “hacktivism”), typically to interrupt service or access to corporate or government websites.

Some forms of social mobilization entail acts of violence, which often are committed to “send a message.” For example, activists may not only break minor laws through such acts as trespassing, which is often the case with nonviolent civil disobedience, but they may also be involved in the theft or destruction of property, kidnapping, hostage-taking, torture, and killing. In modern parlance, non-state actors who use violent means, regardless of their cause, are often labeled “terrorists” by governments to which they are opposed. Whether and when violence is justified as a response to injustice is disputed widely, but the use of violence as a means of social mobilization against extreme injustice by non-state actors has been defended by many political writers, including Thomas Jefferson, Hannah Arendt, Frantz Fanon, Jean-Paul Sartre, and John Rawls. But if the definition of “social mobilization” is to be restricted only to political action through nonviolent means, it would deny the legitimacy of all past and future armed struggles for national independence, regardless of how barbaric the colonial conditions may have been.

Social historians date “modern” social movements as far back as the early and mid-nineteenth-century transatlantic (British and North American) movement against slavery. Research on the abolitionist movement reveals a well-developed set of communicative practices that not only were successful in drawing public outrage toward the barbarism of slavery, but also were an early manifestation of *transnational* social mobilization (→ Social Movement Media, Transnational; Transnational Civil Society). Records of speeches, written

texts, and other forms of public expression indicate a rhetorical strategy, sustained over the course of many decades, which provided eyewitness accounts of the inhumanity of slavery and the slave trade, and which aimed to bring shame to those responsible while bringing public pressure to abolish the institution of slavery itself. Today, the practices of bearing witness, shaming, and other forms of public pressure remain time-tested mobilization strategies.

In late nineteenth- and early twentieth-century Europe, *trade unions and socialist political parties* were the seedbeds of important debates about class struggle, and for generations they have defined the image and substance of the most influential social mobilization under capitalism. In Rosa Luxemburg's 1908 pamphlet "Social reform or revolution?" she argued that reform must be understood as a *means* to the end of socialist revolution. Luxemburg rejected the view advanced by her contemporaries within the German Social Democratic Party (SPD) who argued that parliamentary reform was a more realistic goal, and instead she argued for more aggressive tactics, including the general strike, as clear demonstrations of the power of the working class to bring about radical social transformation. Naturally, "revolutionary" mobilization strategies came to be seen as quite distinct from "reformist" strategies, and as definitely more threatening to capitalist class power.

In most countries, radical social agendas are less likely to gain favorable attention from and access to dominant media institutions, and consequently, media used for radical mobilization are likely to be smaller scale and/or less costly to operate (→ Access to the Media). Today's low-cost digital audio and video recording technology, laptop computers, and increasingly global → Internet coverage have come to supplement and even replace the working-class press and made it possible for social mobilization to take place at an unprecedented scale and speed. Mobilizations since the late 1990s, targeted against global trade and investment liberalization – for example, protesting the Multilateral Agreement on Investment, the policies of the World Trade Organization, and the "structural adjustment" policies of the International Monetary Fund – have demonstrated political will and imaginative efforts to pursue "global justice" on a global scale (→ Technology and Globalization). At the same time, parallel efforts have emerged to articulate a broad range of "communication rights" in multilateral forums, summits, and declarations, which is not surprising, given how central the means of communication are to large-scale mobilization efforts at national and transnational levels.

As in previous generations, movement organizers face the risk of repression by governments seeking to prevent, control, disrupt, infiltrate, co-opt, or otherwise undermine social mobilizations through covert and overt means. Some methods used by states are generally recognized as reasonable, such as the uniform application of limits on the time, place, and manner in which demonstrations and marches may take place. However, other techniques used by states can be in violation not only of rights elaborated in the United Nations Universal Declaration of Human Rights, but also of a country's own laws. Various forms of government surveillance, infiltration, and disruption of lawful political activity; unlawful searches and seizures of the property of movement actors; the denial of due legal process (e.g., lack of probable cause for arrest, and unlawful detention); physical abuse, torture, and even killing of activists; as well as ongoing harassment and intimidation, are all ways in which democratically elected governments sometimes violate their own constitutional principles in order to limit or prevent the potential of social mobilizations to draw public attention to actual or alleged injustice.

## **Social Movement Media, Transnational**

*Karin Gwinn Wilkins*

*University of Texas at Austin*

Transnational social movements engage in communication processes as well as the creation of media products in their strategic work toward social change. Media attention to these efforts as well becomes part of the ongoing struggle to promote social justice, political opportunities, and economic equality. The bridging of social movement interests across national boundaries signals the importance of issues beyond narrowly defined territories along with the coordinated efforts of actors across political boundaries (→ Transnational Civil Society; Social Movements and Communication).

Social movements offer a critical vehicle for engaging in strategic change across a variety of circumstances and for promoting varied goals and processes. The wide variation across these collectives and organizations that exists is worth noting, given the impact this has on constructing generalizable analyses from the particular historical and structural conditions of any given group (→ Generalizability). Some of the potential distinctions to consider might include the degree to which the social movement's agenda resonates with dominant or competing ideological tendencies, the potential to mobilize financial as well as social and cultural resources toward political gain, and other elements of the context within which the movement is attempting to achieve critical change. At issue here are those movements united by transnational interests, coordinating and acting across politically defined nation-states.

### **COMMUNICATION PROCESSES**

Given the transnational character of these social movements, the strategic efforts of these groups demand coordination across communities of participants who are not directly

known to one another. Communication technologies help these processes through *facilitating the mobilization and coordination* of plans as well as actions. Many anti-globalization movements, such as protests against the G8 meeting in Genoa in July 2001 and the planning of the European Social Forum in Florence in November 2002, relied on email as well as web-based communications to organize protests, coordinate transportation, and offer accommodation to engaged activists (→ Technology and Communication; Network Organizations through Communication Technology).

The use of communication technologies also provides a *vehicle for discussion and networking*, beyond the functional aspect of planning, thereby promoting a sense of shared purpose and identity. Development Alternatives with Women for a New Era (DAWN), a group based on principles of global feminism, was able to promote this spirit of collectivity through a combination of communication processes based in email and web systems as well as fax machines.

In addition to promoting the internal functioning and identity of the transnational social movement, communications also represents a *text* (→ Text and Intertextuality), recognizing the potential for asserting claims on interpretations of social struggles. As a product, → activist media offer distinct visions of social problems and possible solutions not typically present in the mainstream media. When dominant interpretations of communities and events in the media are deemed limited or problematic, the importance of creating alternative texts is imperative (→ Arab Satellite TV News; Kurdish International Broadcasting; Le Monde Diplomatique; TeleSur). IndyMedia groups, for example, employed a variety of video and textually based formats to counter dominant trivializations of groups protesting in Seattle in 1999. Similarly, the World Social Forum offers a virtual information sphere in order to publicize and legitimize alternative visions of crises and justice.

While some social movements focus on producing their own mediated texts, such as radio programs, video installations, and web-based sites of information, other groups engage in *media advocacy*, attempting to inspire media attention as well as legitimize their efforts in mainstream media industries. Transnational social movements advocating better conditions for workers in sweatshops were able to gain media attention through disseminating information on devastating conditions through the → Internet.

The Zapatista community was also able to leverage broad public support for resistance to injustices suffered in the Chiapas region in Mexico. Gaining legitimacy outside of the local territory was possible through the electronic networking of several groups, such as Global Exchange, Mexico Solidarity Network, and others. Attention to clear human rights violations and military coercion gained traction as first-hand accounts traveled through web-based systems toward other media.

## CASE STUDIES

The following → case studies illustrate some of the ways in which transnational social movements have integrated media into their internal communication processes, as well as creating or attracting media as texts signifying the struggles of these groups. Specific illustrations remind us of the importance of contextual factors in understanding the nature of social change and the potential for active engagement, rather than positing social movements or processes as somehow universal.

### **Global Social Justice Movement**

As a first case, paramount were the historical conditions giving rise to the mobilization against the World Trade Organization (WTO) meetings in 1999, as well as the particular communication technologies available toward promoting the process and vision of these groups. Diverse groups, mostly but not entirely based in the US, coordinated efforts in these protests through the use of the Internet and web-based systems. In addition, digital media were used to document the activities and intentions of the groups, in order to offer subsequent media texts countering a dominant vision of protestors as trivial or marginal. These texts included video, audio, and print in a variety of formats, distributed through the web, radio, magazines, newspapers, and other forms of communication. IndyMedia, as one organization devoted to the principles of resisting neo-liberal capitalism embodied by the WTO, offered a media outlet for different groups of participants to organize and chronicle their work in this broader effort (→ Independent Media Centers Network).

Subsequent protests against the G8 summit in July 2001, along with the advent of the European Social Forum the following year, exemplified similar applications of media systems, as representing both functional value in facilitating internal communication toward planning strategies, and critical value in composing a site for political engagement. Participants heavily relied upon computer-based technologies for email, online dialogues, and web-sites to engage in networking and publicize their interests, positioned against opposing views presented in mainstream media. For example, IndyMedia offered a vision of peaceful, ordinary citizens engaging in protests countering a mainstream version emphasizing violent, chaotic mobs.

### **Transnational Feminist Movements**

Just as resistance to global agencies promoting neo-liberal capitalism necessitates mobilization across national boundaries, so feminist movements engage in transnational action in response to patriarchal policies and actions (→ Feminist Media Studies, Transnational). Although the particular conditions circumscribing the role of gender in power dynamics are recognized as integral to experiences of oppression, connecting gender with issues of ethnicity, class, sexuality, and other circumstances, these groups are united in their interest in promoting social justice and equality. Some of these social movements, including DAWN, Network Women in Development Europe (WIDE), and Women Living Under Muslim Laws (WLUML), have used a variety of communications technologies, including fax as well as email and websites, to promote women's rights in the region they refer to as the global south.

Constituted through the work of participants based mostly in Asia, Africa, and Latin America, DAWN works with nongovernmental organizations (NGOs) in supporting feminist analyses of globalization, sustainability, and sexual and reproductive health and rights, among other issues. WIDE includes a policy component in its work, attempting to influence European and other international policies on issues of gender equity, building from a network of NGOs based in European Union countries. WLUML attempts to foster a sense of community among women living in Muslim countries, coordinated through regional offices in Pakistan and Nigeria, such that experiences can be shared and

strategies invoked to resist patriarchal control. These feminist groups share an interest in reinforcing transnational communities of feminist activists, through their use of communications technologies to share experiences and permit dialogue. Each of these organizations offers documents and news of their work through its website. Some also incorporate subscription-based services toward supplemental types of information exchange.

### **Sarvodaya Shramadana Movement**

Another social movement demonstrates how one local effort grew into more broadly based global groups through connecting activities and information through media. The Sarvodaya Shramadana Movement, initially enacted through local leadership and participation in Sri Lanka, has since evolved into a network of global participants (across Asian, African, American, and European regions) interested in creating “eco-villages” or communities creating practices alternative to usual approaches to modernity.

Internet systems have offered networked participants the opportunity to share information on past practices and organize conferences, while those with access to these technologies are able to view projected information on selected projects and ideals.

### **CONCERNS AND LIMITATIONS**

Although communications offer important processes as well as products critical to the struggles articulated through the work of transnational social movements, some concerns and limitations remain. Computer-based technologies appear to be integral to the coordination of transnational collectives, yet many other formats and technologies, encompassing attention to → popular culture, news and community radio and newspapers (→ Community Media), and electronic listservs, remain central to the broader context of social change.

Concerns about the → digital divide in access to computer technologies remind us of the limitations of access not only to computers and to the infrastructure supporting them (such as reliable systems of electricity), but also to the languages and literacies of practice and to cultural capital supporting use. Newer technologies presuppose a structural basis of social, financial, and other forms of capital that privilege elite participants, yet the agenda of social change needs to include those participants without access to such resources. Thus the conditions that underscore the very problems engaged by transnational social movements may be inadvertently reinforced by practices of resistance. The careful strategic use of media and communications must be engaged with in order to address global concerns with inequality and injustice.

## **Social Movements and Communication**

*James K. Hertog*

*University of Kentucky*

In all societies, social critics challenge unequal distributions of wealth, power, and privilege, effects of social policy, and cultural change or transgression. Aggrieved groups may organize to pursue their shared beliefs and interests. If they are unable to obtain satisfaction by petitioning legitimized political, economic, and cultural institutions they may take to the streets. Social movements are sustained collective actions occurring outside legitimated institutions of social power in pursuit of social goals (→ Collective Action and Communication).

Social movements historically have championed the interests of disadvantaged groups such as industrial workers, racial minorities, and women. Unable to command the economic or political resources available to interest groups and political parties, movements must generate a large and dedicated membership as their power base. Widespread support for movement goals will not guarantee a large or committed membership, however.

### **RECRUITMENT AND MOBILIZATION**

Olson (1965) noted that activists pay a price for their activism but they rarely are materially compensated for all their costs. To explain the widespread existence of social movements and the sometimes extreme sacrifice members make on their behalf, scholars point to subjective rewards of movement membership.

Interpersonal communication and interaction among activists are intrinsically satisfying, generating affective bonds and increased mutual respect (→ Interpersonal Communication). Blumer (1955) stated that activists, through interpersonal interaction in

intimate settings, develop feelings of “mutual sympathy and responsiveness” and a sense of belonging. Melucci (1989) argues that the development of a collective identity is a necessary precondition for movement effectiveness. The existence of an intellectually and emotionally supportive community reassures each activist that she or he is engaging in a worthwhile and noble cause. Membership in a revered group enhances self-esteem and provides meaning to one’s own life. For extremists the group acts as a haven from criticism and isolation.

Personal attachments often precede movement membership as existing interpersonal networks and local organizations are mined for recruits (→ Social Networks). Black churches in the southern United States and interpersonal networks among activists in the north were important for recruitment to the US civil rights movement in the 1960s (McAdam et al. 2001; → Civil Rights Movement and the Media). To promote the development of interpersonal networks and emotional ties, movement organizations sponsor picnics, hunting trips, and music festivals and set aside time at formal meetings and official gatherings for interaction. Collective actions promote interpersonal ties and collective identity. When facing riot police or organized opposition, activists are forced to count on one another, deepening bonds and developing trust and esteem. Shared hardship and confrontation starkly demarcate friend from foe, “we” from “they,” and serve to cement the adoption of a collective identity by activists. Subsequent encounters with fellow activists, bystanders, and members of the opposition are colored by their collective identities. Public protest, especially when it generates physical hardship, is a form of ritual sacrifice by the community and its members in the name of the larger utopian vision of the movement.

Incorporating and reinterpreting portions of the host culture, and innovating with new symbols and meanings, movements construct their own unique culture complete with myths and narratives, styles of dress, language, hairstyles, songs, heroes, and villains (→ Culture: Definitions and Concepts). Shared culture strengthens the sense of community and serves to demarcate the boundary between member and nonmember. Wearing movement clothes and singing movement songs serves to display publicly the activists’ identification with the movement, proudly proclaiming membership and accepting alienation from the opposition. Movement culture may become popular among a wider audience, potentially serving as a recruitment tool as reggae music has done for the Rastafari movement.

## **IDEOLOGY AND RHETORIC**

Social movements do ideological work. They frame social conditions as social problems, explain how those problems arose and how they operate in society, and propose and promote corrective social action. Certain *framing strategies* allow leaders to deepen activist commitment or to form coalitions with other activist groups (→ Framing Effects; Strategic Framing). Powerful frames incorporate widely held beliefs and values, present member interests as widely shared, and resonate with the everyday experience of activists.

Compelling frames emphasize injustice, identifying a group that is unfairly victimized, specifying an identifiable villain, and presenting a call to action to end the injustice (Gamson 1992). Such frames appeal to emotion as well as reason. Movement organizations

promote their frames for social problems to the media. The media are more likely to adopt frames that are reformist rather than revolutionary, and that are promoted by legitimated groups. Media framing influences public opinion on issues, and can impact the legitimacy and effectiveness of social movement organizations (→ Framing of the News).

## ORGANIZATION OF SOCIAL MOVEMENTS

### Movement Propaganda

To provide movement continuity, coordinate movement actions at regional, national, and international levels, and provide leadership that can represent movements to major social institutions, activists develop organizations of varying formality and permanence. The conditions that social movement leaders face require them to be exceptional rhetors (Simons and Mechling 1981). They must satisfy fractious volunteer memberships that often prefer radical rhetoric and at the same time avoid alienating potential allies among the elite and wider public, usually by reassuring them privately that the movement seeks moderate goals through peaceful means. Should the discrepancy be made public, leaders must explain themselves, as American civil rights leader Reverend Martin Luther King, Jr., adeptly did by appealing to higher values and purposes.

The predominant means for resource-starved social movements to reach their goals is to convince officials or the wider public to adopt supportive beliefs and opinions. Social movements employ a wide range of → *propaganda tactics*, but are especially known for public protest, including demonstrations, sit-ins, marches, and picketing. Public protest draws attention to an existing social condition and defines it as contested or problematic, demonstrates that a group of citizens are willing to sacrifice time and effort and to risk incarceration or injury to address the problem, provides an opportunity to recruit sympathizers and to influence → public opinion, and challenges institutional authorities to respond.

### Getting News Coverage

Movements *seek out news coverage* by engaging in dramatic public protest actions, making leaders available for interviews, holding → press conferences, and sending out press releases. Television coverage of US civil rights protests during the early 1960s has been credited with generating emotional and monetary support for the movement, pressuring the federal government to provide protection for activists, and positively influencing the passage of movement-sponsored legislation. Other movements have found coverage to be less valuable, or even to be harmful. The Black Panther Party, also seeking the expansion of African-American rights and welfare, was portrayed as extreme and dangerous, making state repression more palatable to the public.

Content analyses of protest coverage show that even large demonstrations, strikes, or rallies may be ignored if the movement is especially disfavored, as, for example, neo-fascist movements, or if the action does not seem newsworthy to journalists (→ News Values; Content Analysis, Quantitative). News organizations value the odd and the sensational and highlight them in protest coverage, at times to the detriment of coverage

of protesters' message. Violence, especially, is likely to be highlighted where present and even its absence noted or discussed (→ News Factors; Sensationalism). Activists must choose between adopting confrontational or sensational tactics to draw attention, knowing that the tone will likely be negative and the focus on the actions rather than the movement message, and eschewing sensation and disruption, with the knowledge that the movement's struggle may be ignored. At anti-globalization protests in Seattle, Quebec City, Genoa, Cancun, and Hong Kong from 1999 to 2005, activists attempted to gain attention without appearing dangerous or unbalanced by engaging in innovative, dramatic, and symbolically pregnant expression such as street theatre, skydiving into demonstrations, hanging massive signs from buildings or overpasses, dressing up as sea turtles, undressing, dancing, singing and chanting, burning flags, and even committing suicide.

Media preference for the sensational may affect movement organizations themselves. Gitlin (1980) described how press preference for the more radical and flamboyant members of the Students for a Democratic Society (SDS) during the 1960s generated a public perception that the organization was a militant extreme leftist organization. Those whose politics reflected that perception were more likely to join the organization than were moderates, so that the organization was radicalized. Public perception of the organization as radical decreased mainstream support for the SDS, encouraging government repression and organizational decline.

Sustained movement activity may draw more diverse coverage, including a more complete discussion of movement ideology and social critique. Attention in the news confers social legitimacy, increasing movement spokespersons' access to editorial media, such as news magazines and television or radio talk shows. Feminist, environmentalist, and peace movements in many countries have been ignored, or faced dismissive or delegitimizing coverage, during their early development. As these and other movements have evolved, media coverage has come to portray them as legitimate social critics and their rhetoric as reasonable and even compelling. On some occasions, movement frames have come to dominate media discourse. For example, a frame that asserts that citizens should have equal rights regardless of race or sex now predominates in many countries.

### **Use of Alternative and Popular Media**

Movements propagandize through any readily available media. Intellectuals and agitators produce → books for scholarly and more popular audiences. Documentary film portrays movement beliefs and values in an emotionally compelling manner (→ Documentary Film). With some notable exceptions these materials tend to cater to small audiences predisposed to support movement beliefs. To reach larger audiences, activists have favored → popular music as a vehicle for movement rhetoric. Movement music demonstrating economic potential has been prone to appropriation by commercial music producers, draining it of its critical potential. Popular media have been the target of movement protest as well as its vehicle. Movements seeking to construct and promote a positive identity for social groups that have been traditionally seen as inferior, deviant, or just different have targeted cultural production organizations and artists with demonstrations

and criticism, as well as with awards and incentives to influence portrayals of ethnic, racial, gender, and sexual preference groups. Conservative religious groups have lobbied advertisers and engaged in letter-writing campaigns to authorities in attempts to reduce the incidence and explicitness of sex and violence on television (→ Popular Communication).

Mainstream media rarely provide access to radical movements, and political authorities will not help them gain a larger audience. Radical movements have historically turned to alternative media in the form of underground books, magazines, and newsletters. More recently, cable and → satellite television networks and, especially, websites have been used to carry movement ideology (→ Cable Television; Television Networks). A massive amount of material produced by movements from extreme left to extreme right can be accessed through the world wide web. Alternative media provide access to movement ideology for potential recruits and current activists, construct a space for debate among activists, and reassure and reinvigorate radicals by demonstrating the existence and vitality of an ideologically supportive community.

Despite their limited resources, movements regularly attempt to *influence political and economic elites directly*. Social movement organizations lobby law-makers, protest at speeches and meetings, conduct letter-writing campaigns, and sue opponents in court. In some instances, activists have extensive technical expertise that they use to gain entry into decision-making processes. With resources donated by wealthy sponsors, activists have set up think tanks where ideologically dedicated experts produce policy treatises that are disseminated to the public and to political decision-makers.

### CONSEQUENCES OF SOCIAL MOVEMENTS

Opposition to movements often leads to the formation of counter-movements, especially among those who would suffer materially or emotionally should the movements be successful. An example is the ongoing conflict between “pro-life” and “pro-choice” forces over abortion policy. Counter-movements may ultimately be more successful than the social movements that originally inspired them.

Though they face long odds, social movements do sometimes succeed in attaining their goals. More often, they achieve partial success or induce unexpected cultural, political, or economic change. Multiple waves of activism characterize social movements promoting feminism, anti-colonialism, Aryan nationalism, democratization, the end to poverty, and many others. Each wave inherits tactical knowledge, issue frames, movement culture, and sometimes surviving organizational structure from earlier waves. New movements emerge within a new political, economic, and cultural context that bears the imprint of earlier waves of contention.

## **Social Networks**

*Thomas W. Valente*

*University of Southern California*

Social networks are the interpersonal relationships people have with friends, family, colleagues, acquaintances, and others they may come into contact with directly or via media communications. Social → network analysis is used to understand these social relationships and how they help explain individual and social behavior (Scott 2000; Wasserman & Faust 1994). Social networks are studied at multiple levels of analysis including dyadic, group, and system. There are three primary types of network data collection technique: local, partial, and complete (Morris 2004).

## NETWORK DATA COLLECTION TECHNIQUES

*Local or egocentric* techniques are used to measure a person's local social network. For example, a researcher can record the first names of respondents' closest friends, and then record data about the friends' socio-demographic characteristics and other attributes. Local networks are amenable to random sampling approaches (→ Sampling, Random) and can provide data generalizable to larger populations. For example, egocentric network data can be collected to investigate how interpersonal communications about a media campaign might influence its reception. Local or egocentric data are analyzed primarily using standard statistical software (SAS, SPSS, STATA). *Partial or snowball* techniques start with a set of respondents who provide the names of their social networks, who are in turn enrolled as participants (either all or some sample of the network ties). Partial networks can be used to study the spread of rumors or for subject recruitment.

*Complete or socio-metric* techniques provide a measure of the entire social network by interviewing all members of a bounded community. Socio-metric techniques are most often used in small communities, schools, and organizations where the boundary of the network can be defined. They provide a global view of network relations and thus also provide indicators for individual positions in that network. Socio-metric techniques require the use of specialty social network software, such as UCINET, Pajek, or R (visit [www.insna.org](http://www.insna.org) for links to these programs), or specific mathematical programming to calculate network indicators. The ability to generate a complete social network map of social relations provides considerable explanatory power.

## PRESENTATION AND ANALYSIS

Social network analysis has developed along two related fronts: visualization and mathematical analytics (Freeman 2004). Visualization software enables researchers to display the set of connections in networks (Fig. 1) and understand the social structure by use of colors or shapes, or with variations in the lines connecting nodes, rotation of the graph, and other visual aids. Analytic techniques include the growth and sophistication of algorithms used to measure network characteristics (Newman et al. 2006).

Figure 1 provides a network graph or sociogram indicating who is friends with whom in one sixth-grade classroom (Valente et al. 2003). Each node is labeled with the ID number of the student, and the lines connecting them indicate who chose whom as a friend. Although this network is small (37 people), network analysis can be conducted on large networks (e.g., thousands of nodes) and some researchers study very large networks such as the Internet.

## SOCIAL NETWORK MEASURES

Social network measures are generated primarily at three ecological levels: the individual, dyadic, and network. There are hundreds of *individual measures* that can be generated from one social network question (Borgatti et al. 2005). For example, asking students for the names of their friends at school can generate hundreds of indicators measuring their relative centrality in the friendship network, their membership in groups, reciprocity of

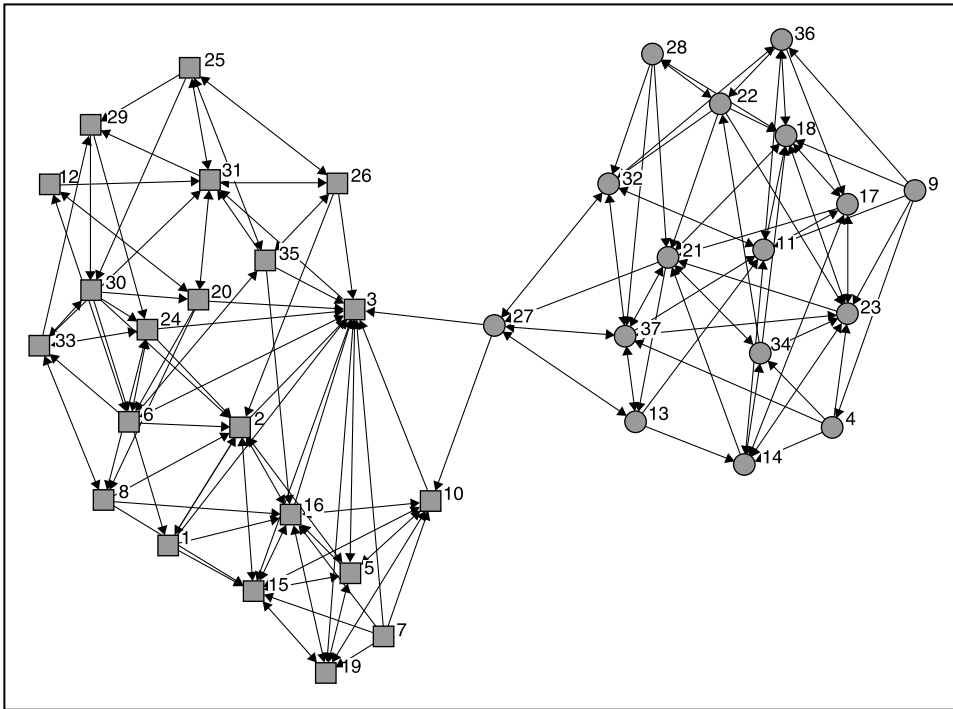

Figure 1 A friendship network among students in a sixth-grade classroom (boys shown by squares and girls by circles)

ties, and so on. The same data can be used to generate network-level indicators such as the degree to which the network is dense or sparse, its centralization, the number of cliques, their overlap, and so on.

One individual social network measure is *centrality*, which measures the degree to which a person occupies a prominent position in the network. For example, in Figure 1 persons 2, 3, and 21 are central nodes in the network, as indicated by how many friendship nominations they received. There are over a dozen measures of centrality (Borgatti et al. 2005). Another individual measure is a *bridge* or *liaison*: nodes 3, 10, and 27 are bridge nodes and the link from 27 to 3 constitutes a bridge. Other individual measures include being a group member or being an isolate. These individual measures can be related to individual behaviors. For example, researchers have shown that students who are central in friendship networks are more likely to become smokers in schools with a high smoking prevalence (Valente et al. 2005).

*Dyadic measures* can also be derived from the network in Figure 1. For example, one can calculate whether specific links are reciprocated, and the degree to which a person's links are reciprocated. Another dyadic measure is homophily, which measures the degree to which a person's ties are to others who have characteristics similar to ego. Homophily in networks creates pockets of interconnectivity (e.g., in Figure 1, boys overwhelmingly choose boys as friends while girls choose girls). Researchers also calculate network exposure to behaviors. For example, researchers have shown that adolescents with

friendship networks comprised of smokers are more likely to smoke themselves (Valente et al. 2005).

*Network-level measures* characterize the overall structure of the network. Some measures are simple, such as network *size* and *density*, which indicate the number of people and links in a network. Other measures require some calculation, such as the *average path length* (APL), which indicates how many steps, on average, it takes to connect different people in the network (Watts 1999). It is easier to transmit messages in a network with a short APL than in one with a longer APL because there are fewer steps separating everyone in the network. Stanley Milgram's early experiment showed that it took on average six steps for a message to reach a randomly selected person in Nebraska, and a Boston stockbroker created the "six degrees of separation" phenomenon (Watts 1999). APL is also used as a measure of network cohesion, since a shorter APL indicates a dense and closely connected network whereas a longer APL indicates a network characterized by long distances between people. Centralization measures the degree to which the network ties are concentrated toward one or a few nodes. Many scholars have discovered that networks are often centralized, characterized by few nodes having many ties, and many nodes having few (Newman et al. 2006).

## RESEARCH FINDINGS, DEVELOPMENT, AND CHALLENGES

Social network measures at the individual, dyadic, and network levels have been associated with behaviors in intuitive and counterintuitive ways. For example, bridges act as conduits for information flow across disconnected sub-groups in the network (Granovetter 1973) even as they can be bottlenecks which restrict the flow of resources. For a second example, studies have shown that as one's network fills with others who hold certain opinions or beliefs, one is more likely to embrace those opinions or beliefs. Conversely, however, studies have uncovered network thresholds that indicate that some people are willing to adopt a new idea or practice even though none or few of their network partners do (Valente 1995). In another example, studies showed that dense networks accelerate diffusion of ideas and practices (→ Diffusion of Information and Innovation) because there are more paths for information and influence to flow through. A recent study, however, documented that too much density inhibits adoption of new ideas (Valente et al. 2007).

Social network analysis was originally applied mainly to the study of communication and interaction within small groups (→ Group Communication; Group Communication and Social Influence; Interpersonal Communication). Researchers investigated how the structure and patterns of their interactions reflected and affected individual outcomes such as depression, satisfaction, and success. Researchers were also interested in how network structural indicators might affect the overall success and performance of the group, community, or organization (→ Group Communication and Problem-Solving). The predominance of inferential statistical approaches in the social sciences (→ Statistics, Explanatory) meant that the more contextual approach and methods of social networks were eclipsed in favor of random independent sampling approaches.

By the mid-1990s, however, the growth in multilevel modeling and the → Internet brought increased attention to connectedness and explicit data on interpersonal connections

via computer communications. Social networks of online communities and patterns of communication via email could be studied. More powerful computer programs were developed to handle the analysis of large social networks. Thus social network analysis has emerged as a strong intellectual tradition interfacing with many different disciplines across the social, physical, and natural sciences (Monge & Contractor 2005).

There are many broad areas of emphasis currently being investigated in the network analysis field. The development of better and faster algorithms for calculating network indices at the individual and network levels continues. In addition, there is continued improvement in computer programs for the management, analysis, and display of social network data. Many researchers have also been investigating how social network data can be used to accelerate the spread of ideas and practices, or for disease control and/or security threats, in addition to using network data to reduce the spread of disease or increase the capacity for collective action.

One of the central challenges facing social network research has been the difficulty of applying inferential statistics and methodology to the analysis of social network data. Network data violate the independence assumption of inferential statistics and so need to be analyzed and interpreted with caution. Scholars have now begun to develop programs which can analyze network dynamics and behavior and study their co-evolution. Although it is in its infancy, the ability to understand the factors that affect the formation and dissolution of network ties, while studying how attributes of nodes affect, and are affected by, the network dynamics, promises to have a profound effect on science.

## Social Norms

*Rajiv N. Rimal*

*Johns Hopkins Bloomberg School of Public Health*

*Maria Knight Lapinski*

*Michigan State University*

What people choose to do, the behaviors they enact or refrain from enacting, is guided by a number of factors, including their own dispositions, the situational context in which they find themselves, the social roles they take on, and their interpersonal relationships. The study of how people's behaviors are guided, in part, by social norms has been the focus of considerable research in recent years.

Although the influence of norms on human behavior occurs across many domains, a great deal of research has focused on understanding normative influences in health-related behaviors, likely because of the inclusion of the subjective norm concept in the theory of reasoned action (TRA; Ajzen & Fishbein 1980); the TRA has been widely used to predict health behaviors (→ Reasoned Action, Theory of).

Norms have been conceptualized in several ways, but terms identified in the literature that deal implicitly or explicitly with the influence of referent others' attitudes or behaviors on people's own behaviors include: subjective norms (Ajzen & Fishbein 1980), social norms (Perkins & Berkowitz 1986), normative influences (Cialdini et al. 1990), or simply norms (Bendor & Swistak 2001). Cialdini et al. (1990) make a conceptual distinction between two different types of norms: descriptive and injunctive. *Descriptive norms* are conceptualized as perceptions about the prevalence of a behavior; they refer to what people perceive others actually do. *Injunctive norms* are social pressures that people experience from members of a referent group to enact or refrain from enacting a particular behavior (Cialdini et al. 1990; → Climate of Opinion; Social Perception; Interpersonal Communication). Both "descriptive norms" and "injunctive norms" are used in the literature to signify people's perceptions, which may or may not conform to reality.

## THEORY OF PLANNED BEHAVIOR AS THEORETICAL PERSPECTIVES ON NORMS

### Conceptualization

In both the TRA and theory of planned behavior (TPB; Ajzen 1985; → Planned Behavior, Theory of), subjective norms are conceptualized as comprising two factors: individuals' perceptions about others' beliefs about a behavior, and their motivations to comply with those beliefs (Ajzen and Fishbein 1980). Operationally, these two factors are thought to act in a multiplicative way such that a small increase in either can result in a large increase in the overall value of norms. Ajzen and Fishbein (1980, 57) intentionally conceptualized subjective norms in a "much more restricted" fashion than the broad definitions of norms found in much of the social psychological literature; they proffer the view that persons make decisions about whether or not to engage in a behavior based, in part, on what referent others (e.g., family, friends, and relational partners) think they should do, and on how much they are motivated to comply with those referent others.

Another distinction made in the literature is that between collective and perceived norms. *Collective norms*, operating at the level of the social system, represent codes of conduct that impinge on individuals within the system (Lapinski & Rimal 2005). From a sociological perspective, collective norms are closely related to Durkheim's (1947) notion of social control, which refers to the mechanisms that societies use to maintain the social order. These mechanisms can be either formal (e.g., laws and regulations) or informal (e.g., traditions and customs), but they serve to prevent chaos or anomie in society; Durkheim refers to this process of control as regulation. In contrast, *perceived norms* are individuals' understanding of the prevailing collective norm, and they operate at the individual, psychological level.

These distinctions are important because, among other things, they can differentially affect behaviors. It is often the case that descriptive and injunctive norms are congruent – for example, when a majority of people engage in a behavior, it is likely that individuals feel social pressures to conform to that behavior. Similarly, collective and perceived norms are often congruent, as when individuals correctly perceive the prevalence of a behavior in their environment. Interesting outcomes can occur, however, when there is a divergence between the two corresponding norms – as when individuals incorrectly believe that they will incur social sanctions if they do not conform, or when they harbor exaggerated perceptions about the prevalence of a behavior in their social midst.

### Evidence

There is a great deal of evidence, for example, that American college students believe that their peers drink much more alcohol than they actually do; these perceptions, in turn, are associated with students' own alcohol consumption (Perkins & Berkowitz 1986). Similarly, the literature on → pluralistic ignorance (O'Gorman 1988) shows that, on important social issues, the public often believes that the prevailing public opinion is more conservative than it actually is. This in turn makes them more resistant to change. The point here is that different types of norms exert influence in different ways and it is

important to specify which norm is being invoked in any given situation (→ Perceived Reality: Meta-Analyses; Third-Person Effects).

The TRA provides a description not only of how norms are operationalized (the product of others' beliefs and motivation to comply with those beliefs), but also of the role of norms in affecting behavioral intentions. Together with attitudes, TRA posits that subjective norms exert a direct influence on behavioral intentions. The TRA has been used as a basis for understanding the role of subjective norms in health-related behaviors and as part of a larger theoretical framework for predicting behaviors. Several scholars have provided meta-analytical reviews of the TRA research (e.g., Albarracin et al. 2001).

### **OTHER THEORETICAL PERSPECTIVES**

Several other theoretical perspectives deal explicitly with normative influence on behaviors, including the model of spontaneous processing (Fazio 1990), focus theory of normative conduct (Cialdini et al. 1990), and the theory of normative social behavior (Rimal & Real 2005). Central to the thinking about norms is the concept of referent – that is, to whom do people look for normative information? The theoretical perspectives on norms generally consider referent others as ranging from the relationally close (family, partner; Ajzen & Fishbein 1980) to the distant (any person in a social situation; Cialdini et al. 1990). Other theoretical perspectives suggest that the influence of referents is dependent on whether or not referent others have access to information about one's behaviors.

#### **Model of Spontaneous Processing**

The model of spontaneous processing (Fazio 1990) focuses on the informational nature of norms and addresses how they serve to help persons define situations (termed “informational dependence”). Fazio states that the influence of normative information is dependent, in part, on whether people believe their behaviors will be known by others. People may look to their referents to determine the prevailing norms surrounding a particular behavior, but they can also choose to defy the norms if they believe that their behaviors will not become known to referent others. For example, individuals may perceive that referent others do not approve of smoking, but they themselves may choose to do so in a private setting because enactment of this behavior will not be known to others. In public settings, informational dependence may be coupled with a perceived threat of social sanctions for defying the norm.

#### **Focus Theory of Normative Conduct**

The focus theory of normative conduct (Cialdini et al. 1990) suggests that the salience of norms is an essential part of understanding the relationship between social norms and behaviors. The theory was developed on the basis of a series of experiments on littering behavior that indicated that norms will not influence behaviors unless a particular norm is focal. In other words, norms are more likely to exert their influence if they are made salient at the time of action.

In this research, focus on normative information was enhanced by manipulating characteristics of the situation or by priming (see Cialdini et al. 1990; Kallgren et al. 2000). These studies suggest that focusing on injunctive norms predicts behavior across situations but that the findings for descriptive norms are less robust. Further, it is believed that activation of injunctive norms may motivate socially desirable behavior in situations where the descriptive norm is socially undesirable. That is, if attention is focused on socially desirable injunctive norms, attention will shift away from undesirable descriptive norms and motivate action toward the desirable injunctive norm.

### **Theory of Normative Social Behavior**

The theory of normative social behavior (TNSB; Rimal & Real 2005) also makes the distinction between descriptive and injunctive norms, and it focuses on the underlying cognitive mechanisms – the moderators – that explain how descriptive norms affect behaviors. According to the TNSB, these moderators include injunctive norms, outcome expectations, group identity, and behavioral involvement. Specifically, the TNSB posits that the influence of descriptive norms on behavior is heightened if individuals also perceive strong injunctive norms to enact the behavior, if the behavior is thought to be beneficial, if there is a strong social connection with others enacting the behavior, and if individuals' own personal connection with the behavior is strong.

### **AREAS OF FURTHER INQUIRY**

There is ample empirical evidence in the literature to support the theoretical expectation that human behavior is guided, in part, by perceptions about how others evaluate, and whether they engage in, the same behavior themselves. *Uncovering the conditions under which this influence occurs* will continue to produce meaningful research findings. These conditions (or moderating factors) are likely a function not only of individuals' perceptions (their belief, for example, that they will get socially rewarded or punished for engaging in the behavior), but also of environmental conditions under which the behavior is enacted (for example, whether the behavior takes place in private or under public scrutiny) as well as the specific attributes that define the behavior in question (for example, the extent to which anonymity is a defining feature of the behavior, as is the case in HIV testing, or whether the behavior is habitual and familiar or episodic and novel). Hence, we envision a comprehensive model of normative influence that takes into account all three factors – individual perceptions, environmental conditions, and behavioral attributes.

A second area of future study pertains to gaining a better understanding of the *reciprocal relationships that exist between communication processes and normative influences*. To date, much of the research on the intersection between communication and norms has investigated how communication influences norms (the idea being that normative influences are social in nature, and hence interpersonal and mediated communication serve to perpetuate information about norms) or how they jointly affect behaviors. Less research has focused, however, on understanding how normative processes affect communication. Early work on the → spiral of silence (Noelle-Neumann 1974) focused on individuals' propensity to refrain from expressing unpopular opinions, but there has been

less systematic research recently on understanding the underlying processes that govern how communication is affected by norms.

It is possible, for example, that the nature of the communication that occurs among individuals who are correctly aware of the widespread support for their point of view in a group will be different from the communication that occurs when there is a great deal of uncertainty surrounding a particular point of view in a group. Research designed to understand how normative processes affect communication can ask questions not only about the nature of the communication that ensues, but also about the type of norms in question (for example, whether it is descriptive, injunctive, subjective, objective, or perceived), the characteristics of the social environment (free and open versus controlled, for example) in which the communication occurs, and the characteristics of the individuals engaged in the communication.

Research on normative influences has helped us understand a great deal about human communication processes, beliefs, and behaviors. Many areas of communication scholarship – particularly those that deal with some aspect of persuasion – are also concerned with changing human behaviors. Health communication scholars, for example, typically use principles of communication to implement interventions designed to persuade people to engage in healthy behaviors (→ Health Communication). Findings from the vast research on normative influences are likely to continue to make significant contributions toward this and other efforts that seek to persuade people to change their attitudes, perceptions, or behaviors.

## Social Perception

*Jakub Samochowiec*

*University of Basel*

*Michaela Wänke*

*University of Basel*

The term “social perception” might seem a misnomer, as it refers less to how people perceive their social environment through their senses than to how they make a judgment. Unlike the color of a car or the loudness of a piece of music, both of which can be more or less directly perceived by the respective sensory systems, the trustworthiness of a person or the aggressiveness of a social exchange can only be inferred or construed from various indirect cues. People have to go beyond the information given in order to arrive at a social judgment. In this sense, social perception is an *active and constructive process* of the perceiver. Not surprisingly, then, the same social situation or the same person may be “perceived” quite differently by different perceivers, or by the same perceiver in different situational contexts.

Nevertheless, a theoretical framework that was originally suggested for visual perception, Brunswick’s *lens model* (1947), provides a quite suitable approach to social perception. This model suggests that objects have certain “real” properties (distal stimuli; e.g., shyness), which translate into certain cues (proximal stimuli; e.g., little eye contact). Only the cues, not the “real” thing, can be directly perceived by an observer. Cues are retranslated and inferences from different cues are then put together to form a picture.

### THE NATURE OF CUES

Proximal cues can differ dramatically in their abstractness and in the information they imply. A cue might be simple and concrete, such as a behavior (e.g., avoiding eye contact)

or the physical appearance of a person. Cues also may be abstract, such as biographical data, group membership (the person is a librarian), or others. In all cases, however, the cue as such is meaningless. It is only meaningful to a particular perceiver, who has stored an association of the cue with the concept to be judged (e.g., shyness). Such associations may have been established in different ways.

One source of cue significance is that people have learned over time and over many observations that the proximal stimulus co-varies with a particular distal stimulus (eye contact and shyness). Other associations may have originated from single observations (“I know one other person who comes from Portugal, and this person is very shy”). Whether on the basis of multiple or single observations, people form individual and subjective lay theories about the associations of particular behaviors, appearance, biographical data, etc. with personality traits. Yet other associations may not be based on individual theories about the significance of cues but on shared cultural knowledge (e.g., stereotypes: librarians tend to be shy).

### THE VALIDITY OF THE SOCIAL CONSTRUCTION

Obviously, errors may occur at different steps in the construction process, and the lens model offers a nice framework for understanding where errors may happen. First, perceivers – or, better, judges – can never fully observe all possible cues but only a subset. Perceivers may miss some important cues and focus on the wrong ones. Moreover, some distal stimuli have clearer cues than others. For example, there are many easily observable diagnostic cues of intelligence (e.g., performance on intellectually difficult tasks), but it is harder to judge trustworthiness. The latter example also illustrates the further problem that people, the object of social judgments, may try to influence the judgment and deceive the perceiver (appearing more trustworthy than they are). Finally, cues may vary in their validity. For example, “hitting another person” is probably more strongly related to aggressiveness than being a Libra is. Still, even cues with generally high validity may not hold for a particular person or a particular instance. Hitting another person in self-defense is different from hitting someone who jumps the queue.

In this latter regard, Heider (1958) proposed that what people need to do in order to find out what a person is like (e.g., whether aggressive or not) is to correct for the situational influence in the observed behavior. For Heider a person’s trait was a stable concept, which could be extracted despite steadily changing observations in different situations. Although there is no act without both an actor and a situation, one can at least attempt to disentangle the two factors, and determine which influence is a stronger cause, by using the *principle of covariance*: in order to be attributed as a cause of an effect, the factor should be present when the effect occurs but be absent when the effect does not occur.

By this logic Heider (1958), Kelley (1967), and other authors proposed one can identify dispositions by comparing the behavior of a person over many situations and also comparing the behavior of other persons in such situations. If a person behaves aggressively in one situation, one may conclude neither dispositional or situational causes. But if the person behaves aggressively in many different situations, it becomes more justifiable to assume dispositional aggressiveness. If other people behave aggressively in the same situation, it is assumed that the situation brings out aggressiveness in people. Some

situations allow a large variance of behavior, where different people can act differently and therefore show their individual differences, while other situations force people to act in one specific way. When someone pulls her hand away when touching a hot plate, one does not infer that this person is special because she does not like her hand being burned, or that she pulled her hand away because of her personality. In fact, in this situation, one would expect everybody to act in the same manner, and therefore the behavior is not very illuminating regarding the person's dispositions but merely reflects the situation.

### PROCESSES AND MODERATORS

What the social perceiver *should do* is assess the situation to determine whether it allows a broad range of behaviors. Only if the situation allows different responses should one infer personality traits from the observed behavior. However, what the social perceiver really *does* instead is often something very different. Initially, people automatically infer personality traits from observed behavior. This tendency to think that people are the way they act and to explain behavior with underlying personality traits is often called the *correspondence bias* or *fundamental attribution error*. This dispositional attribution does not require much mental effort and may occur automatically. It is only as a second step that perceivers may consider the situational influence, and this may result in a correction of the initial automatic impression. Most of the time this second step, however, does not happen. Considering the power of a situation and thinking about its influence on other people is laborious and does not work as automatically as the inference of personality traits (see Gilbert 1989). To engage in this effortful processing one needs cognitive resources, which may be constrained when one is tired or distracted. Besides, people are often quite satisfied with attributing actions to dispositions, since this makes their social world simpler and more predictable. Only when an accurate judgment is very important would people be motivated to spend more effort on the processing of information and on making correct attributions.

Even in those cases where people are motivated to find out about the real causes of a behavior, they may not succeed. The problem for social situations is that it is not always possible to compare different people and different situations. People often do not know how the person acts at other times, or may not have observed many other people in exactly the same situation. What they can do, however, is to imagine themselves in that situation and consider how they would behave. This method is of course far from being perfect, since it is difficult to correctly construe the situation the way it is subjectively experienced by the other person. Thus, the impact of the situation is often underestimated.

### PUTTING IT ALL TOGETHER

Inferences do not occur piece by piece or independently. Rather, the different pieces of information mutually influence each other's interpretation. Expectations and activated stereotypes may influence which cues a perceiver focuses on and how they are interpreted. For example, a shove might be interpreted as hostile behavior when performed by an African-American and as playing around or dramatizing when performed by a Caucasian (→ Communication Modes, African; Communication Modes, Western; Nonverbal

Communication and Culture). Even the mere sequence in which the information is acquired influences the impression people eventually form. Apparently the first information colors the interpretation of subsequent information.

From this one may conclude that social perception is hard work. Cues have to be identified and interpreted, the importance of the perceived cues has to be weighed, new information has to be inferred from activated schemas, and all the gathered information has to be integrated into one single, coherent impression. All that must happen in a very short time. Despite this apparent complexity, perceiving somebody's shyness *does* feel like perceiving the color of a car. People think they *see* that somebody is shy and often do not consciously monitor their inference processes. Indeed, people can extract an almost incredible amount of information from very short episodes (thin slices) of behavior (see Ambady et al. 2000 for a review), and the construction process may even happen without people being aware of it. Often people do not even know which cues influence their impressions. For example, smiling faces are judged as happier when their eye muscles contract, but judges seem to be unable to report why they judge these faces as happier than those with mere lip-smiles.

At the beginning of this entry, social perception was compared to the perception of inanimate objects, but clearly people differ from inanimate objects. Several factors make social perception a more *complex and difficult task* than simply perceiving the color of a car or the size of a building (see Bless et al. 2004). First, people may try to influence the impression others have of them. Usually, they will present themselves in a favorable way, and perceivers have to sort out diagnostic from less diagnostic cues. Whether on purpose or inadvertently, people also may behave differently when they know they are being observed. Second, people may change and perceivers may need to update their impressions accordingly. A person who seemed shy at the beginning of a conversation may appear more extraverted after a while. And third, as outlined in this entry, although social perception may feel as easy as perceiving inanimate objects, there is much more construction going on in the case of social perception. It is not passive observation; the larger part of what we call social perception is being constructed in our brains. Even if we do not always realize it, the construction site of social reality is a very busy place.

## Social Perception: Impersonal Impact

Patricia Moy

University of Washington

According to the impersonal impact hypothesis, the mass media influence individuals' perceptions of risk to others (societal-level risk), but not perceptions of risk to themselves (personal risk; → Risk Perceptions). Implicit in this hypothesis is the notion that individuals can compartmentalize various perceptions of risk, differentiating between societal-level judgments, or beliefs about the larger community with respect to a given risk, and personal-level judgments, or estimations of their own vulnerability to that risk (Tyler & Cook 1984).

Although the disjuncture between first and third persons in impersonal impact also is seen in the → *third-person effect*, two key points are noteworthy. Not only is the perceived risk in the third-person effect the media message itself, but also, unlike the impersonal impact hypothesis, the third-person effect does not require consumption of the media message. Indeed, the third-person effect posits that people believe media to have greater effects on others than on themselves (Davison 1983). Impersonal impact also is conceptually distinct from *impersonal influence*, a term Mutz (1998) used to describe how anonymous others and individuals outside one's immediate life-space can influence one's attitudes, cognitions, and behaviors. Within this domain of research, the media's role is as a conduit of information regarding others' attitudes, behaviors, and cognitions (→ Bandwagon Effect; Social Perception).

Studies of impersonal impact are quite robust, illustrating that exposure to media messages shapes individuals' perceptions that a problem will occur in general; however, these same individuals will not perceive themselves to be afflicted by this problem. This trend has emerged across numerous contexts including social risks such as crime, drunk driving, firearms; environmental risks including fires, tornadoes, floods, and radioactive waste; and health risks such as AIDS and skin cancer. Methodologically, survey research and experimental design are the two most common tools used to test this hypothesis.

Some scholars believe that media messages may not have any "personal" impact because individuals tend to see themselves as less susceptible to risk than others. This unrealistic optimism exists regardless of exposure to media coverage of risk: individuals think negative events are much less likely to happen to them, and positive events much more likely to occur. Also, individuals are unwilling to acknowledge the risk unless they are aware of behaviors that might reduce the risk at hand, and media coverage of risk

tends to provide different types of information. Given journalistic practices, news stories are more likely to report on events rather than the likelihood of those events occurring (→ News Routines; News Factors). Reporters also appeal to human interest by including exemplars (e.g., interviews with individuals, anecdotes) that may or may not accurately represent reality or base-rate information (Fiegeonson & Bailis 2001; → Exemplification and Exemplars, Effects of). Even if the story reports risks, individuals tend to process messages consistent with existing cognitions and attitudes.

In contrast to media messages, → *interpersonal communication* concerning a particular risk can influence personal-level judgments. After all, interpersonal communication often is with like-minded others who have similar life experiences and can be more persuasive than the media in getting one to take action (→ Diffusion of Information and Innovation). This similarity between the individual and a like-minded source of communication may enhance the processing of messages. Also, because certain information, such as that derived from personal experience with a given risk, is deemed more relevant than media reports of that risk, it is processed and assimilated into one's schema more easily. Not surprisingly then, assessments of personal risk would be based on the calling forth of direct experience (Shrum & Bischak 2001).

Despite the prevalence of support for the impersonal impact hypothesis, more recent research has generated evidence of media impact on personal-level judgments. Collectively, these studies support the *differential impact hypothesis*, which posits that under some conditions, the media will influence perceptions of risk to oneself. For instance, in line with media system dependency theory, media effects are stronger when other information sources (e.g., interpersonal communication) are insufficient (→ Media System Dependency Theory). Consistent with previous findings, one study showed that exposure to newspaper stories about skin cancer increased estimates of societal risk, and that interpersonal talk about skin cancer increased perceptions of risk to oneself. However, newspaper exposure increased perceptions of personal risk of skin cancer only among those who depended heavily on newspapers for health information (Morton & Duck 2001).

Another factor that might facilitate the personal impact of media messages involves the *vividness of the message*. Vivid information is emotionally interesting and dramatic, and typically includes numerous images. The nature of vivid information therefore makes the story (and the risk) more likely to be recalled when individuals are asked for estimates of risk. Also, the dramatic fashion in which this type of information is conveyed may encourage the media consumer to identify with the portrayed victim, and perceived similarity tends to reduce the gap between perceptions of societal- and personal-level risk. In support of this theorizing is evidence that exposure to entertainment media and communication with peers, professionals, and parents – not exposure to news media – influenced undergraduates' perceptions of personal risk of AIDS (Snyder & Rouse 1995).

Findings that support the impersonal impact hypothesis and the differential impact hypothesis have great theoretical and practical implications. On the theoretical front, this body of research suggests that the mass media/interpersonal communication divide can indeed be bridged, and the two can and do work in tandem to influence perceptions. Moreover, individual-level characteristics need to be factored into the study of effects.

Although media impact on risk perceptions provides scholars with a theoretically interesting area of research, the more significant question revolves around how media and

perceptions of risk influence risk-related behaviors. Research on the impersonal impact hypothesis has profound implications for the construction of health campaign messages. Campaign planners will need to decide how to format their messages – for example, determine whether to use dramatically presented information, and whether a particular celebrity sponsor will be effective. These considerations, among others, will go into crafting specific messages for specific audiences the campaign is trying to target. Planners also will need to ascertain which media messages will generate interpersonal discussion, and which will likely lead to perceptions of personal risk and, ultimately, to behaviors that will reduce the risk at hand.

## **Social Perception: Unrealistic Optimism**

*Ronald E. Ostman*

*Cornell University*

Unrealistic optimism, suggested by LeJeune and Alex in 1973, was described as the “illusion of unique invulnerability.” It was further developed by Weinstein (1980) in an article on individual perceptions of future life events. This illusion refers to an individual’s tendency to believe oneself invulnerable or at very low risk of suffering misfortune and victimization. It does not refer to the perceptions of individuals who have been victims of a particular misfortune (→ Victimization, Secondary). However, victim experience with one misfortune does not negate unrealistic optimism regarding other misfortunes.

Unrealistically optimistic persons believe others may be more susceptible to such victimization (a pessimistic bias regarding others). The optimism is considered “unrealistic” because, except in extremely skewed distributions, a vast majority of a population cannot be less vulnerable than average. Most unrealistic optimism research has focused on *health risk perceptions*. Other risk topics have explored the potential of being an earthquake victim or suffering a divorce. Weinstein argued that unrealistically optimistic judgments regarding one’s future life could be risky, dangerous, and potentially harmful (Weinstein et al. 2005; → Risk Perceptions; Health Communication). The unrealistic optimism bias also applies to positive events; for example, that one is more likely than others to benefit in the future, such as enjoying success in marriage or financial rewards.

A *comparison of self to others* is at the perception’s core. One’s own perceived chances of future misfortune are evaluated against others’ perceived chances, and a biased discrepancy results in the direction of optimism for self (Gunther & Mundy 1993) and pessimism for others (Culbertson & Stempel 1985). This tendency is similar to perceptions of mass media effects, where individuals are apt to see others as more influenced by media messages than themselves (→ *Third-Person Effects*).

However, these perceptual judgments are *affected by the degree of personal involvement* (→ Social Perception: Impersonal Impact). It is important to differentiate between judgments concerning personal risk susceptibility (often based on personal experience and interpersonal communications) and judgments involving increased susceptibilities of generalized others in society (notably as influenced by mass media; Glynn et al. 1995). In addition to being conceptualized as predictors of vulnerability and risk perceptions, unrealistic optimism and impersonal impact contribute to third-person effect outcomes (Brosius & Engel 1996).

Sears (1983) argued that “*person-positivity bias*” might be a factor in unrealistic optimism. The person-positivity bias posits that an individual typically values individual members of a group more than the group as a collective entity. When the individual is asked to compare perceptions of personal future risk with that of others, it may make a difference to whom the self is being compared. Accordingly, investigators have collected data using referent others who vary in proximity, familiarity, similarity, and importance to the self. Comparisons range from same-sex best friend, to a randomly selected known other, to “average,” “typical,” “most others known,” or a collective societal mass. At least one study found no person-positivity bias; however, the possible influence of proximity, familiarity, similarity, and importance with the compared other requires further research with varied subject pools, respondent samples, different risk contexts, etc.

Unrealistic optimism’s roles in theory building range from independent to moderator to dependent variable. Schemas that conceive of unrealistic optimism as a dependent variable, for example, argue its dependence upon influences such as cultural socialization (Heine & Lehman 1995), gender differentials regarding perceived personal risk (Lin & Raghbir 2005), age, locus of control, and degree of familiarity with the other to whom self is compared (→ Schemas).

## Social Stereotyping and Communication

Mary Lee Hummert

University of Kansas

The journalist → Walter Lippmann introduced the notion of → stereotypes in 1922 and described them as “pictures in our heads”. Current psychological theory conceptualizes those “pictures” as cognitive structures or → schemas that represent widely shared beliefs about the defining characteristics of social groups (Operario & Fiske 2004). Any group might be subject to stereotypes, but the most commonly studied stereotypes are those based on race or ethnicity, nationality, religion, sex, and age. The beliefs that compose stereotypes may include physical characteristics, personality traits, behavioral tendencies, etc. Although stereotypes have traditionally been associated with exclusively negative beliefs about social groups, they generally include positive beliefs as well. For example, stereotypes of older people include not only such negative traits as forgetful and sad, but also positive traits such as wise and family-oriented (Hummert et al. 2004).

As cognitive structures, stereotypes serve as resources that help individuals to organize and respond to new people and situations (Ashmore & Del Boca 1981). *Social stereotyping*

refers to this use or application of stereotypes in person perception and social interaction, including communication (Leyens et al. 1994). Just as stereotypes are not exclusively negative in content, they are not exclusively negative in their application. Nevertheless, because stereotypes are often applied without conscious awareness of their influence (Greenwald & Banaji 1995), and because their negative aspects tend to outweigh the positive, they have the potential to lead to judgment bias and prejudiced behaviors (Operario & Fiske 2004).

### THE ROLE OF SOCIAL STEREOTYPING IN COMMUNICATION

One major communication theory, → *Communication Accommodation Theory* (CAT; Giles et al. 1991), has included stereotyping in its model of the communication process. In the initial conception of CAT (labeled at that time *Speech Accommodation Theory*), Giles et al. showed how group identity processes can influence communication behavior, outlining the conditions under which an individual (e.g., a Welshman) might choose to converge to or diverge from the linguistic style or accent of an outgroup member (e.g., standard British speaker) in interpersonal communication, as well as the consequences of that convergence or divergence.

In explaining certain kinds of divergences and convergences, Giles et al. drew on → *Social Identity Theory* (SIT; Tajfel & Turner 1986), which posits that individuals' identification of themselves as members of social groups is important to maintaining self-esteem. As a result, according to SIT, they are motivated not only to see the social world in terms of ingroups (groups of which they are members) and outgroups (groups of which they are not members), but also to maintain the status of their ingroups relative to outgroups as a way to preserve their self-esteem (→ *Power in Intergroup Settings*). As CAT has evolved, it has expanded its focus beyond group linguistic style to include other aspects of group identity and representations as influences on communication behavior more generally. In particular, CAT has incorporated stereotypes of outgroups into its model of the communication process, accounting for how individuals may choose to accommodate or not to the stereotypes in their interpersonal communication with outgroup members (→ *Intercultural and Intergroup Communication*).

The *Communication Predicament of Aging Model* (CPA; Ryan et al. 1986) illustrates how *age stereotypes* may affect the communication accommodation process (→ *Intergenerational Communication*). This model describes what can occur when a younger individual meets an older person. According to the model, the recognition of age cues such as grey hair, wrinkles, etc. can trigger negative age stereotypes in the younger person. Negative age stereotypes include beliefs about age-related deficiencies such as poor hearing and memory that are associated with beliefs about appropriate or necessary communication accommodations to address those deficiencies (e.g., speak more loudly, use short and simple statements, be repetitive). The younger person who adapts his or her communication to the older person in line with these beliefs, rather than with attention to the unique abilities of that individual, is *overaccommodating* to the age stereotype (→ *Intergroup Accommodative Processes*).

As CAT has continued to evolve, its models have incorporated the individual characteristics of communicators as predictors of both their reliance on negative as

opposed to positive stereotypes of outgroup members, and their proclivity to approach the interaction as intergroup rather than interpersonal (Williams & Harwood 2004). One example of this evolution is the *Age Stereotypes in Interactions Model* (ASI; Hummert et al. 2004), which extended the CPA model to interactions between older people and middle-aged individuals, as well as to those between older people and their peers. It also included such factors as the age salience of the situation and the role of the characteristics of the older person in triggering positive or negative age stereotypes and subsequent communication accommodations to negative age stereotypes. In brief, research has supported the predictions of this model, showing that negative age stereotyping and communicative overaccommodations to those stereotypes are most likely to occur with younger perceivers, in situations which increase the salience of age differences, and with individuals whose physical appearance suggests advanced age and whose personal characteristics are consistent with traits associated with age-related declines (Hummert et al. 2004).

### **CONSEQUENCES OF SOCIAL STEREOTYPING IN COMMUNICATION**

According to CAT (Giles et al. 1991), overaccommodations to stereotypes in communication can have negative consequences for the individuals involved, whether they are the targets or perpetrators of stereotyping. As presented in the CPA model (Ryan et al. 1986), those consequences for the target of the overaccommodation include lowered self-esteem, low satisfaction with the interaction, and the reinforcement of stereotypic behaviors. Together these consequences can contribute to a negative feedback loop that leads to greater age-related decline for the older individual. For the person who produced the overaccommodative talk, likewise, consequences include the reinforcement of negative age stereotypes and low satisfaction with the interaction. To the extent that the individuals associate their low satisfaction with the intergenerational (i.e., outgroup) nature of the interaction, they might be expected to avoid such interactions in the future, further reinforcing their stereotypical beliefs. Empirical research has supported these consequences of overaccommodation to stereotypes in intergenerational interactions (Hummert et al. 2004).

The predictions of CAT for social stereotyping have been most widely tested in the context of age stereotypes. However, Hummert & Ryan (2001) have shown that overaccommodation of the type documented toward older individuals occurs in interaction with members of other groups that are similarly stereotyped: women, persons with physical or developmental disabilities, and those with mental illness. Other social psychological research has demonstrated that stereotypes about gender, age, race, and ethnicity emerge in communication in similar ways, resulting in bias and prejudice (Ruscher 2001; → Prejudiced and Discriminatory Communication).

### **LANGUAGE AND THE MAINTENANCE OF STEREOTYPES THROUGH COMMUNICATION**

As discussed, communicating in ways consistent with stereotypical beliefs serves to reinforce the validity of the stereotypes, increasing the likelihood that they will be

maintained and influence future interactions. To this point, the focus has been on how communicative styles such as overaccommodation may reveal social stereotyping in communication. However, social stereotyping can also be reflected in the language used to describe the behaviors of those in stereotyped groups in comparison to that used to describe the behaviors of members of ingroups (Fiedler & Schmid 2004).

In their linguistic category model, Semin and Fiedler (1991) identified four levels of abstraction, ranging from the most concrete to the most abstract: (1) descriptive action verbs, “John *threw* the ball”; (2) interpretive action verbs, “John *got rid of* the ball”; (3) state verbs, “John *enjoys* playing ball”; and (4) adjectives, “John *is athletic*.” According to Semin and Fiedler, perceptions of the stability of traits increases as language becomes more abstract. As a result, saying that “John threw the ball” tells the listener only about John’s behavior in this unique instance, whereas stating that he is “athletic” tells the listener not only how he behaves now, but also how he will behave in the future – the abstract term is therefore viewed as more diagnostic of John’s abilities than the concrete descriptor.

These characteristics of language in the context of social stereotyping are reflected in a phenomenon termed the *linguistic intergroup bias* (Maass et al. 1989). That is, individuals tend to use more abstract language in describing negative characteristics of outgroups and positive characteristics of their ingroups, whereas they tend to use more concrete language to describe positive behaviors of outgroups and negative behaviors of ingroups. The linguistic intergroup bias, then, is a communicative mechanism that reinforces negative components of outgroup stereotypes and positive aspects of ingroup stereotypes. This bias in communication may help to explain why the negative components of group stereotypes seem more robust, influential in behavior, and resistant to change than positive ones (Fiedler & Schmid 2004; Hummert et al. 2004; Operario & Fiske 2004).

### **SELF-STEREOTYPING IN COMMUNICATION**

Recently interest has developed in the phenomenon of self-stereotyping, i.e., behaving in ways consistent with negative stereotypes of one’s group (Levy 2003). Some self-stereotyping behavior may result from reactions to the overaccommodative or biased communication behaviors of others, as predicated in the CPA model (Ryan et al. 1986). However, other self-stereotyping in communication can occur as individuals describe their own actions in stereotypic terms (Hummert et al. 2004). For instance, older people may talk about having “senior moments” or not having the energy that they used to, echoing age stereotypes in their self-descriptions. A woman might describe herself as “a typical blonde” in a humorous excuse for an error, bringing a common sub-category of the female stereotype into the conversation. From a CAT perspective, the danger in such seemingly innocent remarks, even when made in jest, is that they reinforce stereotypical beliefs and emphasize the speaker’s category membership for both the speaker and listeners. Practically, they encourage listeners to think of the speaker as a member of a stereotyped group, with all of the characteristics associated with that group, rather than as an individual. For the speaker, they carry the danger of implicitly promoting stereotype-consistent behaviors in daily interaction.

## REDUCING SOCIAL STEREOTYPING IN COMMUNICATION

Several characteristics of social stereotyping create a *challenge for reducing its influence* in the communication process. First, from a cognitive perspective, stereotypes are useful heuristics that enable communicators to reduce their uncertainty when they encounter new people (Operario & Fiske 2004). Second, from a CAT perspective, communicators rely on stereotypes not because they wish to engage in biased and prejudiced communication, but because they wish to be effective communicators and adapt their communication to the needs of the other person (Hummert et al. 2004). Third, stereotyping in communication occurs most often at an implicit or unconscious level, so that communicators are unaware that they are basing their communication choices on stereotypical information (Greenwald & Banaji 1995; Hummert et al. 2004). Fourth, the ways in which stereotyping emerges in communication can be very subtle, occurring even at the level of word choice (Maass et al. 1989), and serve to reinforce the underlying stereotypical beliefs.

Psychological research on stereotyping shows that making individuals aware of their application of stereotypes, encouraging them to take the perspective of the other person, and providing them with individuating information on the other person can help them to control the tendency to rely on the stereotype as a heuristic (Hummert et al. 2004; Hummert & Ryan 2001). Awareness can help to reduce self-stereotyping as well. The linguistic intergroup bias (Maass et al. 1989) suggests that working on using more concrete language to describe the behavior of both ingroup and outgroup members would be another strategy to reduce not only the application of stereotypes in conversation, but also the strength of stereotypical cognitive representations.

Whether communication with members of stereotyped groups can change underlying attitudes and stereotypes of those groups has long been a question in intergroup research. Intergroup contact theory, as originally proposed, predicted that frequent contact with stereotyped group members would change attitudes (→ Intergroup Contact and Communication). However, Brown and Hewstone (2005) argue that simple contact is not sufficient. Rather, their revision of intergroup contact theory predicts that communication will effect positive change in attitudes and stereotypes only when (1) group membership is salient during the interaction, (2) the communicator views the outgroup member as typical of the stereotyped group, (3) interaction with the outgroup member is sufficiently frequent, and (4) interaction with the outgroup member is assessed positively by the communicator. Harwood et al. (2005) have found support for this revision of intergroup contact theory in their study of age stereotypes in the context of grandparent–grandchild relationships. Harwood et al. also point out that focus on a family identity offers a way for grandparents and grandchildren to transcend ingroup/outgroup identities based on age groups.

Clearly, not all relationships with members of stereotyped groups can use the family as a transcendent, common identity. However, Wohl et al. (2006) review research demonstrating ways that prejudice toward outgroup members can be reduced, even among members of groups with a long history of conflictual relationships such as Israelis and Palestinians. They identify two strategies with communicative implications. One strategy shifts the group categorization level to a more inclusive level, such as the human family, or another joint identity shared by the two groups (e.g., African-Americans and White

Americans can be jointly categorized as Americans). Another strategy increases the ingroup's recognition of their responsibility (collective guilt) for harmful acts perpetrated against outgroup members. This can be accomplished in a variety of ways, such as emphasizing the illegitimacy or immorality of those harmful acts or asking members of the more powerful group to consider the advantages they experience due to their group membership.

As societies worldwide become more diverse, communication opportunities with members of outgroups should become more frequent. Strategies to insure that those opportunities result in positive interactions can serve to reduce stereotyping in communication. The research and theories reviewed here offer some suggestions for such strategies.

## Social Support in Health Communication

Neeraj K. Arora

US National Cancer Institute

Interest in social support as an important determinant of people's health stemmed from a number of influential papers published in the 1970s (e.g., Cobb 1976). These early writings suggested that people's interpersonal relationships with members of their → social network can reduce the negative impact of stress on their health. The specific mechanisms by which these relationships buffer the impact of stress were collectively termed "social support" (Wortman 1984).

Four *types of supportive behaviors* have been commonly described as dimensions of social support (House 1981): *Emotional support* involves demonstration of empathy, reassurance, love, and caring. *Informational support* involves provision of information that individuals may find helpful in dealing with stressful situations; this typically refers to information that is useful for problem-solving. *Appraisal support* refers to provision of information that is more relevant for self-appraisal, including provision of constructive feedback and affirmation about the appropriateness of beliefs or acts of another individual facing a stressful situation. *Instrumental support* involves provision of tangible goods and services to aid individuals in need. While a majority of the literature focuses on behaviors such as helping with daily chores or assisting with transportation, instrumental support can also include assistance with problem-solving tasks such as making important decisions.

Social support is likely to have a positive impact on people's health in a variety of situations; however, it takes on even greater significance when the stressor is a life-threatening illness such as cancer. A diagnosis of cancer often results in significant emotional trauma to the individual. Feelings of loss of control over and uncertainty about one's future are common. Individuals in such situations have to often deal with complex medical

information and make difficult treatment decisions that might have long-term implications for their quality of life (QOL). Supportive social relationships have been shown to minimize the negative impact of cancer and its treatment on patients' QOL.

While family and friends have the potential to provide support in most stressful situations, the supportive role of formal social network members such as health-care professionals becomes important within the context of an illness like cancer. Several studies show that patients rely on clinicians for informational, decision-making, appraisal, and even emotional support at various stages of their cancer journey (Arora 2003). Thus, the clinician–patient interaction becomes a key vehicle for social support in such situations.

The field of *clinician–patient communication* (→ Patient–Provider Communication) has a rich history of more than four decades of empirical research. Studies have ranged from micro-level assessments, focusing on the actual dialogue between clinicians and patients during a single visit, to more macro-level assessments of the patient's perception of clinicians' communication behavior over a defined period of time. Several studies have shown significant associations between clinician–patient communication and patient outcomes including patient satisfaction, adherence to recommendations, and QOL (Arora 2003). Unfortunately, empirical work in clinician–patient communication has often been criticized as largely exploratory in nature and lacking conceptual clarity.

Conceptualizing clinician–patient communication in terms of provision of social support is likely to provide much-needed conceptual refinement to the field. Perhaps in recognition of the supportive function of communication, the term “clinician–patient communication” is evolving into “patient-centered communication” (PCC), i.e., communication that is aimed at supporting patient needs as well as possible. Epstein and Street (2007) recently conceptualized PCC as including *six key functions*: fostering healing relationships, exchanging information, responding to emotions, managing uncertainty, making decisions, and enabling patient self-management. While this was perhaps not intended by the authors, these functions significantly overlap with the four-dimension framework of social support: fostering healing relationships and responding to emotions parallel emotional support; exchanging information parallels informational support; managing uncertainty requires appraisal support; making decisions is a component of instrumental support; and enabling patient self-management requires both appraisal and instrumental support.

The social support framework and the related conceptualization by Epstein and Street (2007) thus provide an important conceptual model for *future communication research* (→ Health Communication). However, to maximize the impact of future studies on health-care delivery, researchers may need to follow the following recommendations. First, rigorous efforts should be made to develop psychometrically sound measures of the six functions of PCC. Second, instead of the typical cross-sectional approach to studying communication, researchers should employ longitudinal study designs that would facilitate the monitoring of PCC over time. Third, researchers should study the interactions between the health-care delivery team or teams and the patient and family team, instead of the dyad of a single doctor and a patient. Fourth, researchers should explore how advances in information technology may be leveraged to develop data-collection systems to efficiently collect PCC data in busy health-care delivery settings (→ Consumer Informatics; Health Communication and the Internet). Specifically, the way that real-

time data-collection methods and electronic medical record and patient health record systems might be utilized to collect PCC data should be explored. Fifth, to truly understand and demonstrate the salience of PCC, researchers need to empirically identify specific mechanisms (mediators) by which PCC impacts patient health outcomes, as well as to identify factors that might facilitate or undermine (moderators) the association between PCC and patient outcomes. Finally, future studies will need to evaluate the advantages and disadvantages of provision of support to patients by clinicians in face-to-face settings versus more mediated communication channels such as email.

Supportive clinician–patient interactions are vital to the delivery of patient-centered care, a key indicator of health-care quality. However, as suggested, to make the delivery of patient-centered communication a reality in routine health-care, a new approach to research will be needed.

## **Social Support in Interpersonal Communication**

*Daena J. Goldsmith*

*Lewis and Clark College*

Social support is a diverse, multidisciplinary area of study that addresses the question: why do people who are involved in relationships tend to be mentally and physically healthier than those who are not? One approach to answering this question focuses on what people say and do to help one another cope with stress (enacted support or supportive communication). Alternatively, scholars have examined how cognitive schemas and beliefs about relationships influence one's coping and outlook on life (perceived available support). A third way of studying social support focuses on how integration in social networks shapes opportunities, information, immunity, and the flow of resources (social networks and social integration). Within each of these traditions, scholars have recognized that relationships are sometimes harmful rather than beneficial, and have

sought to identify circumstances in which and processes through which social support has positive outcomes.

The term “social support” emerged in the mid-1970s from several influential lectures, essays, and books that synthesized research showing how the social environment contributed to individual well-being. Over the next decade, considerable evidence accumulated to show that social support had beneficial effects, some of which came about through the ways social support buffers individuals from the otherwise detrimental effects of stress, and some through other processes independent of stress (e.g., by providing coherence or regulating behavior). By the 1980s, reviewers of this rapidly growing body of research expressed concern that diverse conceptualizations hindered theoretical explanation for how, why, and when social support had beneficial effects. There are various ways of parsing the literature, but it is common to differentiate among “enacted social support,” “perceived available social support,” and “social network/integration approaches.”

### ENACTED SOCIAL SUPPORT

The enacted social support tradition has been most prominent among interpersonal communication researchers because of its focus on messages and conversations that are intended to assist others in need (for reviews see Burleson & MacGeorge 2002; Goldsmith 2004). Some studies have described what types of actions are intended or interpreted as “supportive.” For example, it is common to differentiate providing information or tangible aid (problem-solving support) from attempting to comfort, bolster self-esteem, or convey caring or belonging (emotional support). Central research problems include explaining what makes some messages more effective and appropriate than others and identifying processes that account for the link between message or conversation features and beneficial outcomes. Recently, scholars have focused not only on the individual benefits of social support but also on its significance for relational functioning and satisfaction.

Albrecht and Adelman (1987) brought social support to the attention of interpersonal communication scholars in their book *Communicating social support*. They proposed that social support involved symbolic processes through which individuals managed uncertainty to gain a sense of personal control (→ Uncertainty Management). Stressful events may create uncertainty about outcomes, one’s individual identity and capabilities, and relationships. To the extent that interactions with one’s social network assist in managing this uncertainty, social support can bring about improved coping and adjustment. Managing uncertainty can entail reducing, sustaining, or increasing uncertainty, and challenges may arise as relational partners coordinate their preferred approaches.

Burleson and his colleagues’ studies of comforting shed light on the processes of emotional support (→ Comforting Communication). Messages intended to comfort vary in person-centeredness, i.e., the degree to which the distressed person’s feelings are acknowledged, legitimated, and elaborated. Persons high in cognitive complexity are more likely to produce person-centered messages, and both men and women find person-centered messages comforting when facing a loss or disappointment. Nonverbal immediacy cues combine with person-centered content to produce the most comforting responses. Person-centered messages are part of a larger process of encouraging talk about feelings. Such talk may bring about emotional relief by assisting in re-appraising a distressing situation.

Well-intended efforts at support can also entail risks and costs, including threats to competence, invasion of privacy, negative impressions, obligation, emotional contagion, and burden. Goldsmith and her colleagues propose that many of these risks and costs involve threats to identities and relational definitions; hence, conversations are helpful to the degree that they not only facilitate coping but also enact valued identities and relationships (Goldsmith 2004). Acts such as advice-giving may be intended as supportive but can also threaten the recipient's autonomy and competence, imply criticism of coping efforts, and convey status or solidarity. Consequently, features of conversations that save face, enact valued identities, or negotiate power and closeness may explain why some attempts at giving support succeed whereas others fail (→ Identities and Discourse; Politeness Theory; Relational Control).

Researchers have also begun to turn attention to the processes through which supportive communication is coordinated. Participants in a supportive conversation need to coordinate their view of the problem and the type of help it requires as well as their desires to approach or avoid problems. Offering practical information to someone who wants sympathy or trying to distract someone who wants to talk is likely to be perceived as unsupportive. Coordination may be particularly challenging when both members of a couple or multiple members of a group or community are affected by the same stressor. The term “communal coping” refers to the blurring of “provider” and “recipient” roles that may occur when individuals recognize a common stressor, communicate about it, and cooperate in their coping efforts.

### **PERCEIVED AVAILABLE SUPPORT**

Perceived available support is one's perception of being valued by others who will provide support if needed. The belief that others are there to help enhances coping with a variety of stressors in personal and professional life and also contributes to relationship satisfaction. Perceptions of available support are not strongly correlated with reports of enacted support, suggesting that perceived available support is based on more than just a past history of supportive actions. Instead, perceived available support appears to be linked to individual cognitive schemas for relationships (e.g., attachment models) and to more global properties of relationships such as responsiveness, interdependence, commitment, and sentiment.

Although perceptions of available support are not strongly tied to support received for specific stressors, there is evidence that ongoing patterns of communication that demonstrate trustworthiness and care contribute to the perceived supportiveness of a relationship. Perceived available support is also relevant to interpersonal communication because an individual's global sense that support is available, and his or her beliefs about the supportiveness of a particular relationship, create a perceptual lens that colors how specific supportive actions and conversations are evaluated.

### **SOCIAL NETWORKS AND SOCIAL INTEGRATION**

The term → “social network” refers to the ties that connect individuals. Structural features of networks have been examined for their relationship to positive outcomes. For

example, networks with dense interconnections are helpful for validating social identities and for making support needs known and then coordinating provision of tangible aid. In contrast, loose interconnections aid in enacting a new identity or connecting with previously unknown information or resources. Network size is a poor predictor of outcomes, perhaps because conflictual ties offset the benefits of supportive relationships. An appreciation of the influence of social structures beyond the individual and his or her immediate contacts is a distinctive feature of social network research. For the interpersonal communication scholar, this tradition helps to embed particular interactions and relationships within a broader social milieu.

Social integration reflects involvement in a diverse range of relationships, including family, friends, neighbors, co-workers, and community and religious organizations. Those who are socially integrated live longer and healthier lives than those who are isolated. Diversity of social contacts, rather than sheer number, confers a health advantage. Social integration may promote health through enhancing personal control, meaning, self-concept, affect, and healthful behavior. Interpersonal communication scholars could contribute to our understanding of how to develop a diverse network and manage the potential communication challenges of sustaining multiple different types of relationships (→ Relationship Development; Relational Maintenance; Relational Dialectics).

### **ISSUES IN MEASUREMENT AND METHODOLOGY**

Several widely used measures of social support exist (see Cohen et al. 2000 for a review); however, most focus on perceived available support, sources of support, integration, or frequency of enacted support. Interpersonal communication scholars have developed ways to measure the quality of social support (i.e., not just how much is received but also whether it is seen as helpful, supportive, and sensitive). Common methods involve asking participants to rate hypothetical messages, recalled conversations, or brief interactions with a stranger or confederate. Although powerful, these methodologies often divorce messages from conversational context, either because the messages are presented or coded apart from surrounding dialogue or because participants do not recall potentially important details of conversational structure. Observational studies usually occur between strangers, despite evidence that most support is sought and received in personal relationships. Even when researchers have obtained participants' ratings of a particular conversation between close partners, it is challenging to determine to what extent ratings reflect observable conversational features or broader relational patterns and perceptions that exist beyond the conversation under examination. Qualitative methods are increasingly used to address the meaning and context of social support and are a useful complement to the dominant quantitative approach (→ Qualitative Methodology).

### **SOCIAL SUPPORT INTERVENTIONS**

Social support research provides a basis for interventions, including programs designed to provide new supportive relationships (e.g., buddy programs, support groups, mentors) and programs that attempt to make existing relationships more supportive (e.g., developing skills in identifying and seeking support, educating support providers).

Perhaps not surprisingly, the success of support interventions depends upon adaptation to the social environment and personal characteristics of participants. Many programs lack systematic and rigorous evaluation and few have a basis in theories of communication processes. This is an area ripe for the application of theories of relationship development, group communication, and communication skill development (→ Interpersonal Communication Competence and Social Skills).

Support groups and self-help groups, both face-to-face and through the Internet (→ P2P Networking), are an increasingly popular form of social support intervention. Participation in a support group can improve individual coping and mental and physical health. However, the willingness and ability to participate is greater in some socio-cultural groups than in others and for some conditions than for others. Some evidence suggests optimal group functioning occurs when participants include both those who are coping well and those who are struggling; yet while those who were previously lacking in personal and social resources benefit from the group, those who were coping well to start with may be at greater risk of psychological distress and reduced satisfaction with their support system. Many support group interventions have not been adequately assessed. Studies that have assessed such interventions often find participants report high levels of satisfaction, but input from individuals who declined to participate or dropped out is less often available, and links to outcomes such as coping or well-being are less often measured and less consistently demonstrated. Theories of group and interpersonal communication could bring a needed perspective on how the outcomes of support groups may be contingent upon communication processes.

# Socialization by the Media

Amy I. Nathanson

Ohio State University

The mass media can play a significant role in shaping the social attitudes and social behaviors of children and adolescents. These effects are distinct from more general media effects that do not involve attitudes toward or behaviors with others, such as purchasing behaviors or learning educational content (→ Advertising as Persuasion; Educational Television, Children's Responses to; Sesame Street). Although parents exert the most influence on children, the mass media can be considered secondary agents of socialization. Research has found that mass media use, especially exposure to television, can affect the development of children's self-image, attitudes toward others, and interpersonal behaviors. Researchers also have studied the role of media in youth's development of political attitudes and behaviors.

## EFFECTS ON CHILDREN'S SELF-IMAGE

When children view television, they compare themselves to characters and situations and form assessments of themselves. Usually, the effect on children's self-image is negative. For example, viewing of advertisements is related to lower self-esteem and depression among children who come from low-income families. It is likely that children feel bad about themselves because they cannot have the products that are advertised on television.

The link between television exposure and self-image also is evident among adolescents (→ Exposure to Television). Research on body image shows that adolescent girls who view a lot of television feel worse about their bodies and are more likely to have symptoms of eating disorders than do adolescent girls who watch less television (→ Body Images in the Media). Scholars speculate that this effect is due to the comparisons the viewers make between themselves and the people they see on television. In this case, consistent viewing of very thin female bodies leads adolescent girls to believe that this body type is normal and desirable, thereby leading to feelings of inadequacy if their bodies do not compare favorably.

At times, the effect of television viewing on self-image and self-esteem can be positive. Among African-American children, for instance, viewing of television featuring African-American actors is related to higher self-esteem scores. Although televised depictions of African-Americans tend to be stereotyped, it seems that the sheer presence of members of their own racial group improves African-American children's self-esteem. In addition, when children or adolescents compare themselves to characters who seem to be worse off than themselves, either physically or socially, television can bolster self-esteem.

## EFFECTS ON CHILDREN'S ATTITUDES ABOUT OTHERS

Television viewing also can influence *children's attitudes about others*. Numerous analyses of the content of television have shown that televised depictions of women are stereotypical (→ Sex Role Stereotypes in the Media; Stereotyping and the Media).

Research has found that women appear less often on television (with → soap operas as the exception); and, when they do appear, they are typically young, attractive, involved in romantic relationships, and either without employment or holding very stereotypical types of jobs. Research suggests that exposure to these images helps children develop or maintain stereotypes about women. For example, children who are heavy television viewers are more likely to believe that women should engage in a very narrow and stereotypical range of behaviors and hold certain types of jobs, such as teachers and nurses. Moreover, television can influence young girls' career aspirations, as heavy viewers tend to desire more stereotypical jobs than do lighter viewers.

In addition, portrayals of minorities are stereotypical. For example, African-American actors are seen less often on television. When they do appear, they are typically cast in a very narrow range of minor roles. The presence and portrayal of African-Americans also differ by the genre of the program. African-Americans are most plentiful in comedies, where they assume less serious roles. When they appear in dramas, the storylines surrounding African-American characters often focus on race issues. Finally, news programs often over-represent African-Americans as law breakers, providing viewers with a skewed perception of their role in crime.

Television viewing also can shape children's – and adults' – *wariness about other people and situations*. Heavy viewers, for example, are more likely to believe that the world is a mean and dangerous place (→ Cultivation Effects). These individuals are more prone to overestimating both the likelihood that they will be victims of crime and the crime rate in general. Some scholars believe that television cultivates us to accept that the world we see on television is reflective of the world outside of our own windows. Because television is filled with violence and stereotypes, heavy viewers develop skewed beliefs about people and the world. Communication scholar → George Gerbner developed this → “cultivation theory,” and he and his colleagues have found some support for it. On the other hand, cultivation theory also has been the subject of much criticism. Among other things, critics charge that the theory's underlying assumption – that any type of television content carries the same message – is flawed (Gerbner et al. 1994).

## EFFECTS ON CHILDREN'S INTERPERSONAL BEHAVIORS

A lot of research has studied the effects of television viewing on children's interpersonal behaviors, including how children handle conflict and other social situations. The research suggests that heavy viewing is associated with more aggression among children. This effect is strongest among elementary-school children, perhaps because they are most impressionable and are still actively seeking role models for behavior. In addition, the effect is usually stronger among boys than among girls. This could be because, in general, aggression is a more tolerable form of behavior among males than females (Paik & Comstock 1994).

Certain televised portrayals increase the likelihood that children will *imitate television aggression* (→ Violence as Media Content, Effects on Children of). Aggressors who are physically attractive and have a sympathetic reason for violence (that is, those who engage in justified violence) are more likely to be imitated than are unattractive characters who engage in senseless aggressive acts. In addition, children are more likely to copy violence

that is rewarded or paired with humor. Classic cartoons typically contain many of these elements. As a result, classic cartoons are considered to be the most problematic type of content for children's learning of aggressive attitudes and behaviors.

There is a growing body of research that has found a relationship between video game use and increased aggressive behaviors among children (→ Video Games; Computer Games and Child Development). Video games are seen as a particularly worrisome form of entertainment because players are active participants, assuming the roles of perpetrators of violence and actually committing the virtual violence.

Although not as plentiful as the work on media violence, there is some work on the effects of viewing *pro-social or positive portrayals* on children's interpersonal behaviors. This work shows that viewing of pro-social content, including programs that teach sharing or helping behaviors or emphasize being generous, is related to pro-social outcomes in children. In fact, the effect of viewing pro-social television is twice as strong as the effect of viewing antisocial television. This could be because pro-social behaviors are condoned and encouraged by society and therefore are more likely to be imitated.

Research also has studied the relationship between television viewing and youngsters' *attitudes toward and initiation of intimate relationships*. Most of this work has focused on adolescents. Research in this area has found that heavy television viewing is associated with more permissive attitudes about sex, including the belief that premarital sex is acceptable, normal, and desirable. In addition, adolescents who view more television are more likely to engage in sexual activity than are adolescents who view less television.

In the case of *sexual attitudes and behaviors*, television has the potential to have a very strong effect on adolescents. In fact, television could become a primary agent of socialization for teenagers. Because of the subject matter and the embarrassment that surrounds it, parents often are reluctant to discuss sex with their children; and because of the central role that intimacy and sexual relations play during adolescence, teenagers actively seek whatever information they can about the subject. The mass media, and television in particular, are readily available and full of strong messages about sex. As a result, teenagers can easily acquire information about sex from television, and in the absence of parental communication about sex, they are apt to grant a lot of credibility to that information. In addition, the → Internet is a popular source of information about sex for teenagers. Given that the Internet is becoming more accessible to teenagers, it too can have a very strong influence on their attitudes and behaviors.

### **EFFECTS ON CHILDREN'S POLITICAL SOCIALIZATION**

Finally, media use can play an important role in children's or adolescents' political socialization (→ Political Socialization through the Media). That is, exposure to media can shape youngsters' knowledge about politics and the likelihood that they have an opinion about political issues and will participate in political processes. The political socialization research focuses on a variety of media as potential influences, including television, newspapers, and the Internet. In this sense, it is distinct from the other lines of research that have studied children's socialization by media. Adolescents are particularly prone to the political socializing effect of media because, cognitively, they are advanced enough to think about abstract ideas like politics. Research has shown that teenagers who

are exposed to news media are more likely to be knowledgeable about politics and have a stronger motivation to participate in political activities.

Future research on the socialization by media should expand to include a focus on the role of newer technologies, such as the Internet (→ Internet Use across the Life-Span). To date, the majority of research in this area has studied television. Although television is still the most frequently used medium among children, the Internet is quickly becoming a popular alternative. Children and adolescents are spending more and more time with the Internet, using it to learn about a range of topics and sometimes relying on it as a means of communicating with friends and family, and yet we know very little about the effect of Internet use on this vulnerable population. Research on the socializing effect of the Internet will continue to be an important topic for communication scholars in the years to come.

# Soft News

*Hyun Ban*

*University of Incheon*

The nature of news content has changed during the past decades due to the changes in media environment. As new media such as cable television, satellite television, and the Internet have appeared, the news media market has become more competitive than ever and news contents have tended to be more audience-oriented and softer. The problem is that soft news is not only “weakening the foundation of democracy by diminishing the public’s information about public affairs and its interest in politics” but also “has increased dramatically as a proportion of news coverage” (Patterson 2000, 2).

The definition of soft news varies, but one of its common characterizations is “all the news that is not hard news” (Davis 1996, 108–109). Hard news may then be defined by coverage of breaking events involving top leaders, major issues, or significant disruptions in the routines of daily life, such as an earthquake or airline disaster (Smith 1985).

One difference between hard and soft news is the tone of presentation. While a hard news story tells its audience the facts regarding what happens and leaves it up to the audience to decide what to do with the information, a soft news story tries instead to entertain or advise the reader. For instance, newspaper or TV stories may promise “news you can use.” Examples might be tips on how to stretch properly before exercising, or what to look for when buying a new computer. Soft news has also been identified by certain characteristics. It has been described, e.g., as news that is typically more sensational, more personality oriented, less time-bound, more practical, and more incident-based than other news (Spragens 1995). Knowing the difference between hard and soft news helps the audience develop a sense of how news is covered and what sorts of stories different news media tend to publish or broadcast.

The examples of soft news abound in the real media world. These include tabloid, syndicated, US-based programs like *Hard Copy*, and nightly network newscast features on personal finance, consumer affairs, and health. The regular features of network news magazines – *Dateline NBC*, *ABC Primetime Live*, *CBS 48 Hours*, and the made-for-soft-news spin-off *ABC 20/20 Downtown* – are “notorious” for their soft news formats.

Major print media outlets rate only marginally better than television at providing hard news over soft news coverage. The leading example of newspaper soft news journalism is *USA Today*, which from its inception has adopted an editorial direction that seeks a “television in print” style, with a heavy emphasis on color, photos, flashy graphics, brief articles, and coverage of lifestyle, entertainment, and “news you can use.” Many newspapers around the world have copied the model. Elite newspapers like the *New York Times* and the *Washington Post* in the US, the *Frankfurter Allgemeine Zeitung* in Germany, or *Le Monde* in France have avoided the *USA Today* approach, making purposive editorial decisions to build readership through in-depth journalism focused on public affairs. Other newspapers, however, like the *Atlanta Journal-Constitution* in the US or the *Independent* in the United Kingdom, have weakened their strong journalistic traditions by

attempting to compete with television on television's terms, and by combining business with editorial departments (Underwood 2001).

In the magazine industry, many publications have taken a soft news approach to public affairs. *Newsweek* and *Time* routinely feature soft journalism cover stories. For example, across the eight issues released in March and April 2001, *Time* ran cover stories on phobias, yoga, Jesus (an annual Easter rite), how to raise a "superkid," and the death of race car driver, Dale Earnhardt, Sr.

In another perspective, Patterson (2000) found that soft news has increased while hard news has decreased. He proposed that soft news has been defined as more personal and familiar in its form of presentation and less distant and institutional. He found a dramatic change in the vocabulary, consistent with the soft news thesis: *collectives* and *self-references*. That is, during the past two decades, reporters' use of collective words (crowd, army, congress, country, etc.), which are part of the vocabulary of hard news, has declined substantially, while their use of the self-references category (I, me, myself, etc.), from the vocabulary of soft news, has increased substantially.

The growth of soft news is rooted in marketing studies that indicate entertainment-based news can attract and hold audiences. According to Patterson (2000), Americans tend to believe the news has declined in quality. People who think the news has gone "soft" are more likely to say its quality has deteriorated.

Then do people prefer soft news to hard news in general? Some have insisted that the increase of soft news has occurred because it can attract more audience attention. The play theory and the uses and gratification model explain that the consumption of soft news can be viewed as a vehicle by which such enjoyment is obtained, and therefore audiences prefer soft news (Palmgreen & Rayburn 1985; Rayburn et al. 1984; Stephenson 1988). The results of Patterson's survey, however, suggest otherwise. The report indicated that "hard news is more appealing than soft news to most people" (Patterson 2000, 7). This suggests that hard news consumers are the foundation of the news audience and those who prefer hard news devote a lot more time to news.

Thus, although soft news has been the industry's answer to the problem of shrinking audiences, it may be diminishing the overall level of interest in news. Furthermore, it may be causing, ironically, the decrease in the news audience, with serious implications for democracy. Soft news distorts the public's perception of what the journalist Walter Lippmann called "the world outside." As Patterson (2000, 15) pointed out, "the irony is that, in the long run, these distortions also make that world a less attractive and inviting one. Interest in public affairs declines and so, too, does interest in news."

## Sony Corporation

*Mara Einstein*

*City University of New York*

Sony is a leading global producer of consumer electronic equipment. Principal products include, among many others, home and portable audio, video cameras, digital cameras, Aiwa products, and home and portable gaming systems. Sony also is a producer of media content including recorded music, motion pictures (→ Cinema), → television programs and → video games. The company also has a fledgling financial services division, which offers insurance as well as → Internet banking.

Sony had revenues of approximately US\$63.5 billion for the fiscal year ended March 2006, an increase of 4.4 percent over the previous year, and the company had operations in 150 countries worldwide. Sony's five business divisions were electronics, games, pictures, financial services, and other, with almost 64 percent of revenues generated by the electronics division (*Datamonitor* 2006).

Sony was established in Tokyo, Japan, in May 1946 as an electronics company, making its reputation for innovation starting with the first all-transistor radio in 1954. Over the decades, Sony became an international company, establishing divisions around the world including in the United States, Britain, and Germany. The company continued to innovate, with the Trinitron television introduced in 1968 and the Betamax VCR in 1975 (→ Video), the Sony Walkman in 1979, the first CD player in 1982, and the first consumer camcorder in 1983.

Moving beyond its machine-based roots, the company began acquiring content providers in the late 1980s. The first acquisition was CBS Records, which was purchased in 1988. The following year, Sony acquired the long-running → Hollywood film studio Columbia Pictures Entertainment, occasioning at the time an upsurge of anti-Japanese anxiety in some quarters in the US. In 1991, these two companies were renamed Sony Music Entertainment Inc. and Sony Pictures Entertainment Inc., respectively. In 1991, Sony Pictures Entertainment purchased the company's remaining interest in RCA/

Columbia Home Video, now known as Columbia TriStar Home Video Inc. Sony sold its 50 percent stake in the Game Show Network to Liberty Digital, Inc., and in 2002 sold off its stake in Telemundo Communications Group Inc., a 24-hour Spanish-language network, to NBC. In 2003, Sony Music entered a joint venture agreement with Bertelsmann's BMG combining the two music companies with each owning a 50 percent stake in the joint venture (→ Bertelsmann Corporation).

In the 1990s, Sony made its entry into the video game industry through a collaboration with Nintendo. That partnership was unsuccessful, however, and Sony began developing its own gaming system, which would become the first Playstation, launched in 1995.

Sony Corporation develops, designs, manufactures, and sells electronic equipment and consumer entertainment in seven main areas: electronics, video and online games, music, movies, television, robots, and internet services and applications. These products are produced through five business segments: electronics, games, pictures (film and TV), financial services, and "all other."

The electronics segment includes audio (home, portable, car, and navigation systems), video (cameras, decks, and DVD players), televisions, information and communication devices (including professional equipment), and semiconductors, among many others. Mobile communications operate through a joint venture with Ericsson – Sony Ericsson Mobile. The subsidiary produces mobile phones. Product names produced by Sony include Vaio, Trinitron, Bravia, and Handicam,

Sony Computer Entertainment was the home of Playstation 2, the dominant leader in the game console category. This product continued to sell well, due to deep price cutting, even after the introduction of the Playstation 3 in 2007. The PSP – the company's hand-held device – also has continued strong sales, though in 2007 Nintendo remained the leader in this segment. Station.com, a separate unit, produced online games including EverQuest and the Matrix Online.

Sony Pictures Entertainment (SPE) produces and distributes motion pictures as well as television programming. The *Spider Man* franchise was a major success for this division. This area of the company has also had a number of television programming hits, particularly for cable outlets, including *Rescue Me*, *Strong Medicine*, and *The Shield*. In addition, they produced daytime programming such as soap operas, *The Young and the Restless*, and *Days of Our Lives*, as well as syndicated programming like *Judge Hatchett* and *Judge Maria Lopez*. This division housed home video acquisition and studio facilities operations, developed new entertainment technologies, and included AXN, an action and adventure television production company.

The "other" category for Sony included its financial services and the company's music business. Sony Life Insurance Co., Sony Assurance, Sony Bank, and Sony Finance International made up the financial services segment of the company. In addition to insurance products, this division offered Internet banking and credit card and leasing services. Sony Music Entertainment Inc. and Sony Music Entertainment (Japan) Inc., which included the Columbia, Epic, Legacy, Sony Classic, and Sony Nashville labels, sell recorded music and videos. In addition, the company has begun a monthly subscription service for music downloads.

## **Sound Bites**

*Tim P. Vos*

*Seton Hall University*

A sound bite is a portion of recorded human speech that is presented as part of a broadcast news report. Referred to by a variety of names, including actuality, sound clip, and sound-on-tape, the sound bite is characteristically the distillation of a person's message, usually in one or two well-turned phrases or sentences. The overwhelming body of research on sound bites has focused on their brevity and subsequent effect on political discourse. Modest attempts are being made to expand the research agenda on sound bites to include issues of journalistic mediation and effects on learning information.

Most of the research on sound bites has examined their characteristics and use in television news reports of US national election campaigns (→ Television News; Political News). Content analyses (Hallin 1992; Lowry & Shidler 1998) have produced a consistent description: while the average sound bite in national campaigns was nearly 43 seconds in 1968, by 1988 the length had shrunk to under 10 seconds. As a comparison, a similar content analysis in Germany showed that candidates' sound bites on German television news average around 20 seconds (Donsbach & Jandura 2003). Broadcast practitioners took note of the findings, leading some networks to announce policies in 1992 for longer sound bites. Nevertheless, average sound bites have remained under 10 seconds. The brevity of sound bites has in turn affected → political discourse. Political consultants have steered candidates into speech behaviors that are suited to sound bites; i.e., main ideas expressed in concise or simple terms and compelling enough to make it past journalistic gatekeepers (→ Political Consultant). Through a change in behavior to suit broadcast news, all political speech has been affected, whether that speech is broadcast or not.

This research has been met with normative concerns that political speech is stripped of complexity and nuance, feeding voters simple solutions to complicated problems (Slayden & Whillock 1999). Hence, sound bites weaken democratic or republican governance by diluting discourse among voters and between voters and representatives. Some fear that sound bites, at their worst, are a means of creating false consciousness among the electorate, thereby aiding in manufacturing public consent. Others have argued that such fears are unfounded and rooted in deterministic assumptions. While news stories rely on sound bites, candidates also have access to more long-form interview programs than in the past. In the end, broadcast journalists are doing what print journalists have done for decades: crafting news for clarity and conciseness.

The shrinking sound bite has become symbolic of the increasingly active, mediating role of broadcast journalists (→ Broadcast Journalism). As studies have shown, the shorter a candidate's sound bite, the longer the reporter's narration. Research has documented that even though the number of sound bites in a news report has increased and reports have gotten shorter, the percentage of time devoted to journalists' narration has increased (Steele & Barnhurst 1996). This marks a change in political reporting from a relatively passive role to a more mediated form of news. News reports in the US in the 1960s typically relied on lengthy sound bites to carry the narrative thread of the story. By the 1980s, reporters' narration created the narrative unity of the news story. This increase in editorial control increases journalists' power in the delivery of political communication (→ Media as Political Actors).

The concern for some is that this more mediated approach to news leads to a narrative line stressing the campaign as a horse race rather than stressing a candidate's policy platform. Increased mediation also opens up the possibility for more bias on the part of reporters or news organizations (→ Bias in the News). In fact, some have argued that the shrinking sound bite has created a structural bias in favor of conservative policies. However, US studies of sound bite bias have detected a modest tilting toward Democratic candidates (Lowry & Shidler 1998), and have found that sound bites were slightly longer for Democrats than Republicans. Nevertheless, the length of sound bites did not prove to be related to how favorably a candidate was viewed by voters (Russomanno & Everett 1995).

Whether sound bites alter political discourse or contribute to bias, these effects are generally understood as unintended consequences. The shrinking sound bite and greater editorial control by broadcast journalists are typically explained in economic terms (Hallin 1992). The tightly edited pace of stories with short sound bites is believed to be preferred by audiences. News consultants have sold shorter sound bites to broadcasters as a means of maximizing ratings, which in turn maximizes profits. Other explanations have noted the technological development of broadcasting, which allowed for easier editing to create more complex or mediated news reports. Still other explanations have noted the broader shift in journalism, particularly following Watergate in the US, from a disseminating to an interpretive role (→ Journalists' Role Perception). The interpretive role is consistent with the more mediated style, which uses shorter sound bites and more reporter narration.

A new area of research on sound bites has explored how audience members learn from news that is driven by sound bites (→ News Processing and Retention). Some evidence suggests that viewers learn more information from a montage of sound bites and images than they do strictly from reporters' narration.

## Source Protection

*Anthony L. Fargo*

*Indiana University*

Journalists sometimes get information from sources who, for various reasons, wish to keep their identities secret. The use of confidential sources raises a number of complex ethical and legal issues (→ Ethics in Journalism). To begin with, the idea of keeping information secret seems anathema to the basic purpose of journalism, which is to disseminate information to an audience. Also, some sources wish to remain confidential to hide their participation in questionable behavior, putting journalists in the awkward position of helping people escape social, political, or legal responsibility for their actions. If the identity of the source becomes a central question in a criminal investigation or civil trial, the journalist may have to choose between identifying the source and facing imprisonment or fines for refusing to do so. A journalist who voluntarily reveals a confidential source's identity can face serious professional and legal repercussions (→ Journalism: Legal Situation).

### THE JOURNALIST'S CONFLICT

Often, however, confidential sources who want to remain anonymous to protect their jobs, families, or safety have helped journalists expose substantial government or corporate wrongdoing. Perhaps the most famous example is “Deep Throat,” the source who helped guide *Washington Post* reporters Carl Bernstein and Bob Woodward as they uncovered the → *Watergate scandal* in the early 1970s that led to Richard Nixon's resignation from the American presidency. Deep Throat's identity remained secret until 2005, when a former Federal Bureau of Investigation official revealed that he was the source. There are countless other examples of journalists breaking important stories with the assistance of confidential sources.

Journalists across the globe fear that if they identify a confidential source, that source and other potential sources will be afraid to provide useful information in the future. Studies of journalists worldwide have found broad agreement that it is unacceptable to

identify a confidential source, even when there is little agreement across borders about other ethical practices and principles (Weaver 1998). Professional ethics codes generally agree that journalists should be cautious about promising confidentiality to sources but should keep such promises when given (→ Professionalization of Journalism).

Keeping the promise is often easier said than done because of the potential *legal complications*. In nations that adhere to the rule of law, controversies over criminal violations and civil law disputes between persons or corporations end up in courts of justice. Courts attempting to determine guilt or innocence or balancing the rights of civil litigants generally require that all persons with relevant evidence provide that evidence to the litigants or investigators. Rules, often called privileges, that allow some persons to escape the obligation to provide relevant evidence are often narrowly construed and are only acceptable when they protect a societal interest that is deemed more important than the value of the evidence lost. To varying degrees, courts in many countries allow attorneys, mental health counselors, medical doctors, priests and other clergy, and spouses of accused criminals to escape the obligation to testify or turn over documents to courts or investigatory bodies. Additionally, courts in many countries have rules that allow potential witnesses to escape the obligation to testify if doing so would be unusually burdensome or would reveal irrelevant information. Persons who are not covered by such a specific privilege or general rule run the risk of being punished with fines or imprisonment if they do not cooperate with authorities.

Journalists have often sought legal protection that would allow them to conceal the identities of confidential sources without the pressure of being threatened with imprisonment or fines. Journalists have succeeded in many countries in winning limited protection, but one problem they face is that, unlike attorneys, mental health counselors, and medical doctors, among others, journalists usually do not have licenses or other credentials that would make it easy to define clearly and to limit the number of privileged people. Therefore, courts and other governmental bodies are sometimes reluctant to provide a privilege to an uncertainly defined group.

## COUNTRY-SPECIFIC REGULATIONS

In countries that recognize a qualified (limited) privilege for journalists, the privilege usually allows journalists to avoid testifying to investigative bodies or in courts of law unless the information they possess is critical to the case and unavailable from another source. The privilege in nations or geographic regions of nations is created in various ways: constitutional provisions, general statutory evidence or procedure codes, specific shield statutes for journalists, or through court decisions interpreting constitutional or common law.

For example, constitutions in *Argentina, Mozambique, and Sweden* specifically protect journalists' rights to keep sources confidential. Not surprisingly, there is little case law about the journalist's privilege in those countries. General codes of evidence or procedure have provisions protecting journalists from being forced to disclose sources in *Australia, Austria, El Salvador, France, Germany, Japan, and Norway*. For example, the Supreme Court of Japan in 2006 found that a general procedural rule protecting "professional secrets" from forced disclosure applied to the identities of journalists' sources.

Russia has a specific federal law on the mass media that provides for source confidentiality, and many of the now-independent states of the *former Soviet Union* have adopted similar legislation, including Kazakhstan, Kyrgyzstan, Moldova, Tajikistan, Ukraine, and Uzbekistan. However, the mass media law's protection of the journalistic right to conceal sources is subordinate to general procedure codes and other important interests.

In *Canada, New Zealand, Nigeria, the United Kingdom, and the United States*, among others, journalists' rights to conceal source identities rely to a great extent on judicial interpretations of general press freedom statements in constitutions or statutes. Nigerian courts handed down several decisions in the early 1980s recognizing a right of journalists to conceal sources under the constitution's press freedom provisions, but a series of disruptions in the government has left the value of those decisions uncertain. Courts in Canada have been reluctant to tie the journalist's privilege to the constitution's free-press guarantee, instead requiring journalists to meet a high burden of proof that the source's unmasking would interfere severely with legitimate media privacy concerns. In both New Zealand and the United Kingdom, a so-called "newspaper rule" allows the media to avoid disclosure of a confidential source during the discovery phase of a defamation case. New Zealand courts have used that rule as the basis for creating a broader common-law privilege for journalists, while courts in the UK have been unwilling to do so.

In the UK, international law may do what national law does not. In 1996, the → European Court of Human Rights (ECHR) overturned British appellate courts and recognized a privilege under Article 10 of the European Convention on Human Rights, which protects freedom of expression. A few years later the same court held, in a case out of Luxembourg, that the use of search warrants against journalists was even more invasive of free-expression rights than the use of a subpoena to compel testimony. Decisions of the ECHR are binding on all member nations of the European Union. Shortly after the ECHR ruling in 1996, the Supreme Court of the Netherlands agreed with the ECHR that Article 10 required protection of confidential source identities.

In another case involving a court with multinational jurisdiction, the International Criminal Tribunal for the Former Yugoslavia (ICTY) ruled in 2002, and affirmed in 2005, that *war correspondents* have a qualified privilege. A former *Washington Post* reporter, Jonathan Randal, was called to testify about his interview, through an interpreter, with a man accused of taking part in the "ethnic cleansing" of Bosnia-Herzegovina in the 1990s. The ICTY's Appeals Chamber eventually agreed with Randal that war correspondents faced particular dangers if forced to reveal sources. Routinely requiring reporters to reveal sources would undermine trust in reporters and could put them in greater physical danger from suspicious sources than they already faced in war zones. The ICTY declined, however, to extend the privilege to all reporters.

## THE LEGAL SITUATION IN THE US

The United States is often noted for its "exceptionalism" on freedom of speech and the press, and the first amendment to its constitution was one of the first such official recognitions of the right to free expression (→ Freedom of Communication; Freedom of the Press, Concept of). However, journalists in the United States are often less sure of being able to protect their sources than journalists in other countries. The highest court

in the United States, the Supreme Court, has only considered once whether the free-press guarantee in the first amendment gives reporters the right to conceal source identities from investigators. In 1972, the court in *Branzburg v. Hayes* said journalists had no right to refuse to testify before criminal investigation bodies called grand juries. The court ruled that in such a circumstance the public's need to bring criminals to justice outweighed the need to protect journalists' sources.

The decision was sharply divided, however, and lower federal courts in the United States have said, for the most part, that journalists do have the right to conceal sources in criminal and civil cases under the conditions proposed by Justice Potter Stewart in a dissenting opinion in *Branzburg*. This means that journalists' attempts to conceal sources are judged on a case-by-case basis and that the party seeking the journalist's testimony, notes, or source names must show that the information is highly relevant and important to a case and unavailable elsewhere. In addition to this common law protection in federal courts, 34 of the 50 American states, plus the District of Columbia, have shield laws that protect journalists to varying degrees in those jurisdictions. Most of the other states have court rulings recognizing a qualified common law privilege. There was no nationwide shield law at this writing, although proposals for such a law appeared in Congress, the national legislature, whenever journalists were jailed or fined for refusing to cooperate with federal investigations.

The uncertainty caused by differing jurisdictional rules on privileges raises the question of whether, and to what extent, the legal status of a privilege affects journalist-source relationships. Several American courts, including the Supreme Court in the *Branzburg* case, have lamented the lack of strong empirical data on the effects of privileges on sources and journalists. Such a study could be fertile ground for further research. Still unanswered with any certainty is the question of how to define "journalist" so as to grant protection to people gathering and reporting news without making the definition too broad. The problem is even more acute today with the existence of the → Internet, which allows many more persons to publish their opinions and the results of their own investigations for a wide audience without being employed by a commonly recognized medium of mass communication. The Internet also allows for the easy flow of information internationally, and the increased globalization of information industries, including the news media, raises questions about the comparative rights of journalists in various countries, including the right to conceal sources. More research is needed into how various nations recognize and protect the news-gathering rights of journalists.

## South Africa: Media System

*Guy Berger*

*Rhodes University*

South Africa had an estimated population of 47 million people in 2005. Eight in ten people were classified as African; among the rest, whites were the largest minority. Since 1994, there has been a constitutional democracy with an executive president elected by parliament, which recognizes 11 official languages (although these are still far from equitable representation in the media). The former liberation movement, the African National Congress (ANC), is the ruling party, having won overwhelming electoral mandates since 1994. Under its policies, some 85 percent of homes had electricity by 2005, enabling increased TV penetration. There is a growing black middle class. The government practices a “black economic empowerment” policy, which gives preference to formerly disadvantaged South Africans in terms of contracts and broadcast licensing.

### HISTORICAL STAGES AND DETERMINANTS

The country was infamous for its apartheid policies (1948–1994), which built upon the white domination and segregation that evolved after Dutch settlers began arriving in the mid-seventeenth century. British colonialism in the nineteenth century saw 100 years of wars of conquest and resistance, ending with African South Africans retaining only 13 percent of the land. An indigenous middle class had developed its own press in the late nineteenth century, but this media died when its class basis was destroyed as white hegemony consolidated. Waves of resistance → newspapers developed in the twentieth century, closely linked to the fortunes of political movements such as the Industrial and Commercial Workers Union (1920s), the Congress movement (1950s), communists (1930s–1940s),

Black Consciousness (1970s), and the United Democratic Front (1980s). State repression of these political movements saw a range of tactics being used to silence the media associated with them (→ Censorship). The banned ANC put out underground publications (→ Underground Press) and ran a shortwave → radio station from the 1960s.

The English-language white colonial press successfully campaigned for press freedom from early on (→ Freedom of the Press, Concept of), and secured this in 1828. In its mainstream form, this media sector came to be owned by the mining industry for most of the twentieth century, from which base it was mildly critical of apartheid.

The Afrikaans-language press emerged as part of the Afrikaner nationalist movement in the twentieth century, financed by Afrikaner finance capital, and completely intertwined with the ruling National Party during most of the apartheid era. Radio broadcasting as a state monopoly easily fell under government domination after the advent of apartheid. Its subsequent services were geared to uniting whites, and – when additional stations were launched in the 1950s and 1960s – fragmenting black identities along ethnic or tribal lines. The → television arm of the South African broadcasting Corporation (SABC) was started only in 1976, aimed mainly at a white audience, and it had three channels – all commercialized – in operation at the time of the transition to democracy in 1994. The newspaper industry owned a subscription entertainment channel, M-Net.

After apartheid, substantial broadcast pluralism emerged, as well as a degree of black ownership of both print and electronic media (→ Ownership in the Media). However, of the major print groups in 2006, Independent Newspapers was a foreign investor with no local shareholder (having bought the Argus group from the mining industry in 1993), while Naspers (commonly known as Media24) had only minor ownership among people other than Afrikaners.

## **NORMATIVE AND LEGAL FRAMEWORK**

The 1996 constitution included a Bill of Rights that provides for rights to freedom of speech, freedom of the media, and access to information (→ Freedom of Communication). As part of freedom of speech, journalists are not required to register. However, freedom of speech does not extend to hate speech, and it has to be balanced with rights to dignity and privacy (→ Hate Speech and Ethnophobias). Since 1999, the Film and Publications Act has provided for pre-publication restrictions on content relating to age and distribution. It covers both child pornography and hate speech, and is applied to print media that are not members of the industry body (which operates a self-regulatory press ombudsman). The Act has not applied to licensed broadcasters, who are governed by the statutory Independent Communications Authority of South Africa, as well as the self-regulatory Broadcasting Complaints Commission of South Africa. Those that are subject (e.g., cinemas) may not screen any film classified XX or “which, judged within context, amounts to propaganda for war, incites imminent violence, or advocates hatred that is based on race, ethnicity, gender or religion and which constitutes incitement to cause harm” (South African Government 1999). A parliamentary bill in September 2006 elicited major condemnation when it sought to scrap the exemption of the mass media bodies that operate under recognized self-regulatory mechanisms.

Another law dealing with hate speech is the Promotion of Equality and Prevention of Unfair Discrimination Act (2000), which bans publication of “anything that could reasonably be construed to demonstrate a clear intention to be hurtful, cause harm or promote hatred on the basis of race, gender, sex, pregnancy, marital status, ethnic or social origin, colour, sexual orientation, age disability, religion, conscience, belief, culture, language or birth” (South African Government 2000). No media have been prosecuted for hate speech during the democratic era, and new legal precedents have meant fewer convictions for infringements of “dignity” (i.e., defamation) than previously.

One of the constitutional rights has been developed into the Promotion of Access to Information Act (2002), although this law is little used by the media (→ Right to Know). There remain some security laws as well as restrictions on reporting courts, but these have also been mainly moribund during the democratic era.

In 1993, a year before the democratic elections, political negotiations led to the passage of the Independent Broadcasting Authority Act, the autonomous status of which was maintained in the 1996 constitution. The Independent Broadcasting Authority later became the Independent Communications Authority of South Africa (Icasa) after expanding to include telecommunications and (later) postal regulation. The authority’s councilors are appointed by the minister of communications from a list supplied by parliament after a public nominations process. After a decade of forward-and-back lobbying, by 1996 ministerial powers over Icasa excluded intervention in specific licensing, and were mostly limited to broad policymaking that also has to be open to public comment.

Under the 1993 founding Act, the regulator may only license broadcasters within certain boundaries relating to degrees of → cross-ownership by newspaper groups, concentration of ownership of stations, and foreign ownership percentage. The regulator imposes degrees of public service commitments (e.g., → news, local content; → Local News) depending on whether licensees are classed as “public,” “commercial,” or “community.” Community licenses are for local, nonprofit radio stations, which must demonstrate ownership and participation by community groups.

A law passed in 2006, the Electronic Communications Act, tackles convergence and requires a license for “unidirectional” audio and audiovisual content, irrespective of technology used. However, “content services” are exempted from the category of “electronic communications” licenses, which implies that (most) websites can continue to be freely published, although ambiguity may lead to contention.

The Broadcasting Act of 1999 formalized a system whereby board members of the SABC are appointed by the president on the advice of parliament. The 2002 Amendment Act retained the 1999 inclusion of a charter enshrining the corporation’s political independence, but also requiring it to operate in both the public and the “national interest.” The SABC is also accountable to Icasa, which has imposed detailed public service license conditions on the broadcaster’s many stations (→ Public Broadcasting Systems).

In 2002, the Media Development and Diversity Agency Act was passed, creating an institution mandated (despite a small budget) to promote new small-scale media (→ Development Communication: Africa). The SA Advertising Research Foundation, financed by the media industry, conducts market research (the source of statistics below).

## OVERVIEW OF THE MEDIA

### Printed Press

The country's approximately 45 daily, weekly, and biweekly newspapers are owned by four media groups: Naspers, Johncom, Caxton, and Independent. They are complemented by more than 50 free sheets. Total circulation of daily newspapers was 1.57 million in 2006. Most newspapers are declining in circulation, but there is strong growth in tabloid newspapers, and to a lesser extent in African-language publishing. In 2005, 41 percent of the adult population read a newspaper. The magazine sector is growing. About 20 million audited magazines, including targeted customer publications, are circulated every month.

### Radio

Radio reaches more than 92 percent of South Africans, and some 88 percent of households have a set. In 2005, there were some 90 community radio stations (though many were struggling; → Community Media), five SABC national footprint stations, and 13 SABC regional stations. The same year, there were 13 privately owned radio stations – mainly regional and held by black ownership groups. However all stations, including SABC's, compete without any license limits for → advertising. Those with elite and urban markets draw the highest revenues. The largest audience is held by the SABC's isiZulu-language station, *Ukhozi FM*, heard by 21 percent of the country's adults in 2005. The same year, the SABC's *Radio Metro*, an English-language urban-music station, had grown to be the second largest with 17 percent. Other African-language stations follow with 16 percent (*isiXhosa*) and 12 percent (*seSotho*). Seven new commercial licenses were issued during 2006.

### Television

In 2005, 7.76 million households (72.1 percent) were estimated to own a television set. Almost 80 percent of South Africans were watching television at least once a week.

The main television service is terrestrial free-to-air. The SABC has three national channels for domestic audiences, and SABC Africa, which targets the remainder of the continent via satellite. The public broadcaster has been licensed to launch two regional channels in indigenous languages, but their launch is pending funding. A company with significant black (union) ownership owns the only private channel, *e.tv*.

All these channels are licensed to take advertising – not more than 10 minutes of advertising an hour; and not more than 12 minutes in a given hour. The SABC's two public service channels, however, have to carry 55 percent local content (versus 35 percent for the broadcaster's commercial service), and had to start reaching 80 percent African-language broadcasting in 2007. *SABC 1* had the highest viewership in 2005 (68 percent), with *e.tv* coming second at 55 percent.

The terrestrial pay service *M-Net* has 10 percent of viewers, while its sister company DSTV reached 6 percent through 60 television and 40 other channels via satellite.

## Internet

Internet access remains very much a minority facility, with just 5 percent of South Africans benefiting in 2005 (→ Digital Divide). Further, access on a daily basis is enjoyed by just 3.3 percent of adults (or slightly over 1 million people). A study in 2004 showed that this represented 1 percent usage by women compared to 4 percent by men (Gender Links 2004). Most access (57 percent) is via workplaces, because the high cost of telephony deters home-based connections (*Goldstuck 2005*). E-commerce is low, with only 13 percent of Internet users reporting having transacted online (OMD 2005; → E-Commerce). Connectivity at multipurpose community centers and schools is fraught with problems.

## GENERAL TRENDS

In a very free environment, South Africa has a media system that escapes being politically controlled. Instead, it is largely driven by commercial logic (although the weak community radio sector is characterized by volunteer rather than waged labor). The effect of dependence on advertising has led to particular controversy around the public broadcaster. Its competitors complain of unfair competition, while civil society and even the ruling party criticize the neglect of public service delivery, especially in indigenous languages. Nevertheless, it is unlikely that government policy will change toward a public funding model for the SABC. The extant policy has not meant, however, a lack of attempts by government to establish greater political control over the SABC. Most of these have been unsuccessful in the face of extensive lobbying, reflecting a strong democratic tradition in the country. Similar battles have been fought over government's aspirations to control Icasa. Notwithstanding government being kept at arm's length from broadcasting, and the need for the SABC to compete with editorially credible alternatives, the public broadcaster still frequently incurs accusations that it is not living up to its mandate of independent public broadcasting. On the other hand, e.tv, along with private radio and print, is generally seen as playing a watchdog role, often to the chagrin of the authorities, who say media should be supportive at this stage of national development. There is increasing choice of media, though not generally in mother-tongues. There is little "serious media" in the overall landscape, but that which exists (the *Mail & Guardian* newspaper, for example) has significant national influence.

## South Korea: Media System

*Jae-won Lee*

*Cleveland State University*

South Korea, in its pan-national homogeneity across many fronts, has been a friendly and profitable market for the mass media industry. All South Koreans speak in just one common language of their own, and they all come from just one identical race. Hence they all share an identical heritage from their common history, ancient and modern. The literacy rate is extremely high at 99 percent. The literate and educated public, armed with affluence from the vibrant economy, handsomely supports a steady consumption of the traditional media as well as ready experimentation with the rapidly advancing new media.

Though the press and other media in South Korea now enjoy a full range of freedom, they nevertheless retain a mixed bag of various legacies from Korea's turbulent modern history (Lee 1982, 2003). During the last 100 years alone, South Korea changed from a five-century-old kingdom (1392–1910) to Japanese colonial rule (1910–1945), to US military government (1945–1948), to the beginning of an independent democratic state (1948), through the Korean War (1950–1953) to a military coup and successive military dictatorships (1961–1992), and to the beginning of civilian governments since 1993.

While the present shape of the South Korean political system is an unmistakable democracy, it often exhibits the characteristics of “formal democracy,” where consolidation of democracy is still to be desired (Halvorsen 1992).

### PRINTED PRESS

South Korea is a country of national dailies dominating the nation's media scene. Eleven general-interest national dailies, all published in the capital city of Seoul, fiercely compete for circulations, often resorting to free distribution with gifts to potential subscribers (→ Newspaper). The Big Three general-interest national dailies – *Chosun Ilbo*, *Dong-a Ilbo*, and *Joong-ang Ilbo* – sell more than two million copies each, with a fourth paper, *Hankook Ilbo*, publishing around 750,000 copies (KPF 2004a, 2004b). The first three

papers are not only the most influential and prestigious dailies but also the ones with mainstream conservative orientations. Contrasting to this set of papers is a group of three other national dailies – *Hankyoreh*, *Seoul Shinmun*, and *Kyunghyang Shinmun* – that are rather progressive and center-left in editorial leaning. The circulations of this second group are much smaller – 200,000 to 400,000 each.

Of the total of 138 dailies being published in South Korea, 79 are local dailies, which are relatively weak in financial base and mostly being published out of local boosterism or for the influence or prestige accruing from owning news media. Among the local dailies, the *Busan Ilbo* and the (Daegu) *Maeil Shinmun* are exceptionally strong and influential in their respective provinces. The total includes eight foreign-language dailies (in English and Chinese), eight business papers, three sports dailies, three children’s papers, and ten others exclusively specializing in a variety of industrial fields. The Korea Audit Bureau of Circulations (KABC) estimated the newspaper readership rate at 338 per 1,000 population unit in 2005 (KABC 2006).

The Big Three national dailies, as of 2006, have been engaging in a continual tug-of-war with the center-left President Roh Moo-hyun (2003–) over his populist government’s “engagement” policy toward North Korea. The Big Three define the Roh administration as communist sympathizers, while the ruling power tries to undercut these powerful media as outdated conservative complainants (→ Political Communication; Journalists’ Role Perception). The Big Three are more than dailies; they are all huge media complexes, each additionally publishing a very popular weekly → news magazine, a monthly → magazine (often over 600 pages in length), a women’s monthly, and also some other periodicals – literary, outdoors, fashion, etc. Dailies print 24 to 52 pages in broadsheet. Only one national news agency, Yonhap, operates in South Korea.

## RADIO AND TELEVISION

In South Korea, → television is assumed to have reached full saturation, with every household owning at least one set. Leading the television sector are three *major networks*: KBS (Korean Broadcasting System, public-service television), MBC (Munhwa Broadcasting Corporation, operating commercially but legally required to be public television), and SBS (Seoul Broadcasting System, commercial television). Also on air is a fourth network, EBS (Educational Broadcasting System), which specializes in instructional programming (→ Television Networks). Additionally, → cable television, with about 120 channels, is available in some 77 percent of the nation’s households, though most of these channels operate on shoestring budgets. Radio is everywhere with its specialized services from traffic to religious groups. The broadcasting sector cultivates the digital television (DTV) and digital multimedia broadcasting (DMB) services, while the new-media sector pursues the WiBro (wireless broadband) services.

The three major television networks are electronic counterparts of the Big Three print press. They are especially influential during election times for their ability to reach millions of people with images and messages critical to setting agendas for public discourse. On occasion, they compete in news reporting, as the MBC network did in 2005 by exposing the globally controversial stem-cell research scandal involving a Korean scientist. But, generally, the television networks compete in serial drama programs,

perhaps the most popular television fare among South Koreans (→ Soap Operas). Such programs, resembling the popular telenovela genre in Latin America, are the key players in the popularity of South Korean pop arts in the adjacent countries, including China, Japan, Taiwan, the Philippines, and other Southeast Asian nations. This trend is referred to as “Hallyu” or the Korean wave (Lee 2005; Ming 2005).

The *KBS network* has been continually controversial for its public service mission, which is often undermined by the ruling regime’s political influence. The president of the country has de facto power to appoint the network’s top managers, who have been invariably the president’s or the ruling party’s cronies. Budget-wise, KBS is bound to be stable since it collects license fees from all television set owners. It draws an additional revenue from airing commercials on its second television channel. The network is equipped with state-of-the-art facilities and manned by some 5,500 employees. KBS is criticized for its perceived indifference to quality programming and for indulging instead in ratings competitions in the domestic market. The network rarely deviates from the ruling power’s policy lines in its news broadcast (→ Public Service Broadcasting: Law and Policy; Television Broadcasting, Regulation of; Communication Law and Policy: Asia).

## NEW MEDIA AND THE INTERNET

South Korea ranks among the top countries in the use of the → Internet-based electronic media of various recent technological advances (→ Exposure to the Internet). Mobile phones are ubiquitous; it is not uncommon for a large family to have one for everyone, from children to grandparents. Especially remarkable is the high rate of broadband access – 77 percents of households, as of 2005 (MIC 2005). Nationally, about 73 percent of the population aged 6 and over use Internet-related services, with personal computers being owned by some 78 percent of all households.

“Information Highway” has been a national capital improvement endeavor ever since the early 1990s. Besides this government initiative, South Korea enjoys another advantage in this field in being the home of the world’s two leading *electronic manufacturers* – → Samsung Corporation and LG Group. These two often use the home base as a test market for their latest innovations. The government also promotes and supports production of software programs and online digital contents as a service-sector industry and a potential trade item for export. In mid-2006, there was a national uproar over the widespread misuse of the very successful computer games programs for gambling by millions of people. Addiction to this habit is increasingly becoming a societal concern.

All the traditional media, like the daily papers and television networks, provide highly elaborate online versions of their services, often in multiple languages beyond their vernacular version. News portals of various orientations are growing in number constantly. Independent online newspapers – numbering around 260 as of mid-2006 – also flourish, sometimes posing competition to the mainstream media’s online service. Especially notable is the emergence and success of several “citizens’ media” that promote “citizen reporters” and interactive journalism. One of them, *Ohmynews* ([www.ohmynews.com](http://www.ohmynews.com), [english.ohmynews.com](http://english.ohmynews.com)), is recognized as a leading model of this genre in the relevant global arena (→ Online Media).

## SYSTEMIC ISSUES

Though the future of the South Korean media industry looks bright, there are several systemic issues that continue to plague the South Korean press, like growing pains in a body that refuses to leave the cradle of tradition. One example is the temptation and practice on the part of the ruling power to indirectly undermine the constitutionally guaranteed freedom of the press (→ Freedom of the Press, Concept of). Since the Press Acts stipulate press responsibility as well as freedom, various government offices, including the presidential Blue House, readily take reports of any critical stance to the Press Arbitration Commission, thus fostering an environment of *chilling effects*. Even some of the powerful national prosecutors often file complaints against the media with the commission, requesting hefty fines for alleged wrongful reporting. President Roh himself has resorted to such measures several times. His press secretary often orders off-limit sanctions against “unfriendly” reporters for their critical reporting.

Roh’s administration manipulated the antitrust provisions in the Press Acts and the Press Arbitration Acts to charge large-circulation papers with monopoly practices, and thus to control the papers, if their circulation tops 30 percent of the subscriber-based market. Leading dailies took the case to the Constitutional Court, which rendered this particular provision unconstitutional in a decision in 2006. Roh’s administration, however, instituted a measure by which the government can financially help weak or failing papers with subsidies. The prospective beneficiaries, the smaller dailies, included several papers well known for their pro-government editorial stance (→ Concentration in Media Systems; Antitrust Regulation).

Another issue endemic in the South Korean press is the relative *ethical lapse in the newsroom*, often involving cash payments for favorable coverage. There is a specific word for this practice, “chonji,” meaning “a small consideration.” This under-the-table transaction remains a cause of shame to most other ethically conscientious practitioners, but the tradition goes on in many different variations: free golf games paid for by affluent news sources, free trips abroad in the name of on-site news coverage, expensive gifts during holiday seasons, quid-pro-quo favors arranged for influential media figures, and so on. Popular television anchors and influential politics editors often jump ship, becoming congressional candidates of certain political parties the next day. But, structurally speaking, South Korea’s system of ethical control should be airtight, as it has not just one but two separate institutional devices: the Korea Press Ethics Commission, run as a voluntary press council, and the Press Arbitration Commission, a statutory organ with the power of sanctions (→ Ethics in Journalism).

Also problematic is the confrontational relationship between *media owners and press unions*. Major dailies are all owned by families, but these owners, relatively speaking, are not well known for their intellectual leadership in editorial integrity and dedication to professionalism in journalism. The family owners of the Big Three press were all convicted of dodging tax at one time or another, though their supporters attribute this to the government’s political use of the magical power of tax auditing. In this climate, press unions raise their voice for “editorial independence in the newsroom” (→ Journalists: Professional Associations).

Finally, it is instructive to note the fact that, in spite of the media-rich setting in South Korea, the mainstream leaders in the influential national dailies are rather underperforming in their editorially enterprising endeavor. Their coverage of daily news is often excessively redundant, lacking long-term projects of investigative in-depth reportage. They have cutting-edge facilities and they hire well-educated personnel in the newsroom, thanks to the prestige of the reporting job. A case in point here is their apparent weakness in reporting on the North Korean concern, one hot global issue in recent years. The South Korean media, though geographically well positioned for exclusive, insightful reporting on the North, continue a “he said, she said” level of news reporting and nothing much more.

# Spain: Media System

*Carlos Barrera*

*University of Navarra*

Spain had in 2005 a population of 44.1 million inhabitants and was twelfth in world ranking in GDP. Just after Greece and Portugal, it became the third Mediterranean country in Europe to re-establish a democratic system in the early 1970s. The new regime after the death of the dictator General Francisco Franco in 1975 brought about the restoration of the monarchy and the creation of a parliamentary system, along with a gradual devolution of power to the 17 regions, which turned Spain into a quasi-federal state. The most important international recognition of the new Spanish democracy came from its admission as a new member of the European Union in 1986. From the media perspective, the transition to democracy had already begun with a new press law in 1966. The press, subjected until then to strong censorship, was granted broader margins of freedom, so that some newspapers and magazines were able to reflect varying degrees of criticism or reticence about the last governments of the dictatorship.

## LEGAL DEVELOPMENT OF MEDIA STRUCTURE

Some legal measures concerning the media accompanied the political transition. In April 1977, a decree suppressed government powers to close and seize newspapers. In October 1977, another decree broke the monopoly of public radio on the broadcasting of home political news. Article 20 of the Constitution, approved in December 1978, established “the right to freely communicate or receive truthful information by any means” and stated that a specific law, “respecting society pluralism and the diverse languages of Spain,” should regulate state-run media and their control by parliament (Barrera 1995). The Statute for Radio and Television (1980) defined these media as “essential public services whose ownership belongs to the State.” The so-called Third Channels Law (1983) permitted each region to create its own public radio and television network. Catalonia and the Basque Country were the first to avail themselves of this law (Maxwell 1995).

In the case of the *printed media*, the legacy of many decades of press control led both politicians and journalists to agree that the best press law is no press law at all. Not even self-regulated rules have been adopted since then, except in the case of Catalonia, where the Audiovisual Council was established to monitor television and radio. State subsidy of the press, in force since the late years of Francoism, was maintained by the first, centrist governments of the transition; later socialist governments regulated them in 1984, and finally decided to discontinue the policy in 1990 in accordance with the requirements of the European Commission (Fernández & Santana 2000; → European Union: Communication Law).

Two new laws in the late 1980s increased state intervention in the Spanish media: the law concerning the Organization of Telecommunications (1987) and the law concerning Private Television (1988). Public radio was favored and some measures restricted the free market in the television sector, where, e.g., one shareholder could own a maximum of only 25 percent of the capital in a private television company. Foreign capital, too, was

limited to 25 percent. These conditions, which were finally suppressed in the late 1990s, required that difficult agreements be reached among at least four partners, and facilitated government involvement to organize the process. In the end, three channels began to broadcast: Antena 3, Tele 5, and Canal +, the last a pay-TV channel which monopolized that new sector.

The pluralism of the Spanish *radio* system grew through the awarding of new FM station licenses during three periods (1981–1982, 1989, and 1999–2000), which allowed the establishment of new radio networks. Political decentralization meant that regional governments became the primary decision-makers in the distribution of licenses, generally granted to media with similar political leanings to the different regional powers; thus, this process has been almost invariably controversial.

The technological development of other *television* formats in the 1990s led to a doubly inadequate response from government, which enacted regulatory laws and provisions either too late or too early. The first situation arose in the case of the regulations approved for local (more than 1,000 local stations were in operation at that time), cable, and satellite television in December 1995. On the other hand, the regulations concerning digital terrestrial television (DTT), approved in 1998 with the two licenses awarded two years later, were enacted before the technological resources which would allow the audience to receive those signals had been provided. It is only since 2006 that DTT has begun to reach TV users in an effective way. A 2006 law for public television definitely established the priority of digital transmission over analog, whose deadline for obsolescence is 2010.

Competition in the pay-per-view satellite television sector had two protagonists: *Canal Satélite Digital* (CSD) and *Vía Digital* (VD), both launched in 1997; the first owned in effect by the pro-socialist Prisa Group and the other by Telefónica with the political support of the then recently elected conservative government. An intense, year-long political and economic war was waged among media and politicians during which both companies suffered significant losses, a situation which ultimately led to their merger in 2003 as the new Digital + (→ Satellite Television).

## PRINTED PRESS

The number of *newspapers* published has increased during the democratic period. For many years, 110–115 newspapers were published. Between 1995 and 2004, this number rose to 139, which leaves Spain second only to Germany among EU countries. However, Spain also has one of the lowest indices of newspaper circulation per inhabitant: 104 in 2004, higher only than Italy, Greece, and Portugal (*Libro Blanco* 2006). One clear conclusion to be drawn is that many Spanish newspapers have low circulation figures: only 10 newspapers have average sales above 100,000 copies. The significant contribution of sports dailies, which account for 20 percent of total newspaper circulation, must be underlined. Monthly *magazines*, especially the so-called *revistas del corazón* based on true-romance news and photo-spreads, have had larger global circulation than weekly magazines since 1997 (Díaz-Nosty 2006).

The sport and financial dailies apart, only four newspapers have national circulation (*El País*, *El Mundo*, *ABC*, and *La Razón*), while the rest may be regarded as basically regional or local. In almost all of the Spanish provinces, the largest newspaper in terms of

circulation and consequently the most influential is regional or local. Many of them belong to larger media holdings; thus, by 2004, the seven largest Spanish media groups controlled 76.1 percent of total circulation. *Free daily newspapers* are the latest challenge to paid newspapers in terms of sales and advertising. Since the appearance of *20 Minutos* and *Metro* in Madrid and Barcelona in 2000 and 2001, this new sector has achieved significant shares of readership; the four free newspapers published in 2006 (*Qué!* and *ADN* had joined the other two) reached more than 3.1 millions readers every day – i.e., one fifth of all newspaper readers.

## BROADCASTING

The *radio* system has evolved toward a greater pluralism in recent years. Despite the favorable deal received by public radio in the assignment of frequencies and power for its stations, four private national networks account for the majority of audience share: *SER*, *COPE*, *Onda Cero*, and *Punto Radio*. In contrast to television, the national public radio network (*Radio Nacional*) survives only through state funding and has no income from advertising. Unlike the case of the television sector, too, none of the radio companies has any foreign shareholders. Although all-music channels account for more than half of listeners, Spanish radio is a very influential medium in the political arena, especially through the news services and the so-called *tertulias*, round-table debates among journalists, experts, and other public figures who analyze day-to-day politics.

There are two sectors of public *television*: the state-run *Televisión Española* (TVE), founded in 1956 and comprising two channels, and the 14 *regional television* bodies, which depend on the respective regional governments. Some of the latter use the language of their region, such as Basque, Catalan, and Galician. The financing of both state and regional television is mixed: public funding and revenue from advertising. This mixed financing arrangement is controversial and the commercial stations regard it as unfair competition. The three private television channels started in 1990 are still in operation, although one of them, *Canal +*, changed from pay-per-view to open-access TV in 2005 under the new brand *Cuatro*. A fourth channel (*La Sexta*) emerged in 2006. The latter two developments, in line with decisions taken by the new socialist government elected in 2004, were quite controversial for both political and business reasons. Public television has suffered the main damage in terms of audience. In 1995, five years after the emergence of private channels, the public sector held 52.3 percent of audience share; 10 years later, that figure had decreased to 43.1 percent; and in 2004 Tele 5 surpassed TVE-1 in terms of audience.

*Satellite TV* developed faster than cable in Spain. At the time of their merger in 2003, the two leading companies had a combined total of approximately 1.4 million subscribers. In 2005 the category “other channels,” which included themed or pay-per-view TV, local stations, etc., already reached 7.4 million in its average share. Fragmentation of audiences is one of the main consequences of the variety of mixed television models available and derives from a number of different patterns: pay/open, terrestrial/satellite/cable, public/private, national/regional/local.

The *Internet* has also had an impact on traditional media through online editions of printed newspapers, new digital newspapers, specialized *confidential* websites that publish

news and rumors, and, finally, the uncontrolled *blogosphere*. Thus, the conventional media has partially lost its authority and credibility in the shaping of public opinion. In only six years, daily use of the Internet increased in Spain from 5.6 percent of population (2000) to 21 percent (2006). It is still far below the average levels of use in central and northern European countries, and low in relation to population percentages for other Spanish media (41.4 for newspapers, 49.0 for magazines, 56.0 for radio, and 88.7 for television), but it continues to grow rapidly, especially among young and urban sectors of the population. In contrast, the average age of newspaper readers has been rising, and reached 43.3 years in 2005 (→ Digital Media, History of).

Concentration of media ownership in Spain is now an established trend, although, in comparison with other developed countries, the most important groups are not especially large. In 2006, the top 10 Spanish holdings controlled the 10 largest newspapers, three of the four national radio networks, three of the four national private TV channels, the two DTT channels, and the only satellite television station. Proof of their strength is reflected in the fact that three television companies and the Prisa Group were listed on the stock exchange between 2000 and 2004. Nevertheless only Prisa has a significant holding in the capital of foreign media, especially in Latin America. By contrast, foreign shareholders own significant interests in important newspapers or television channels in Spain, e.g., the Italian holdings RCS and Mediaset in the case of *El Mundo* and Tele 5 respectively. A number of other multinational groups control the majority of important magazines (→ Concentration in Media Systems).

The Spanish media system basically matches the description that Hallin and Mancini (2004) give of the so-called *polarized pluralist model*, with characteristics such as low press circulation, high degree of politicization, external pluralism, frequent state intervention, and a strong dislike of journalists toward self-regulation for historical reasons.

# Special Effects

Sean Cubitt

University of Melbourne

Special effects are those techniques employed in moving image technologies to provide images other than those recorded by simply opening the camera's shutter and recording. In some cases the entire image may be produced using non-camera techniques. Alternatively, events may be staged or images altered to produce special effects. Special effects (hereafter "effects") may usefully be divided between (1) physical effects produced in front of the camera; (2) effects produced in the camera; (3) effects produced during printing; and (4) effects produced during editing. A fifth, relatively rare category of effects is produced at the point of reception (→ Film Production).

Christian Metz (1974) identified five → codes of → cinema: → photography, music, dialogue, sound effects, and writing. He did not include a graphical code for → *animation*, even for the ubiquitous rostrum camera animation of title sequences. And yet, since animation in its various forms is the earliest of all special effects (in the work of J. Stuart Blackton, Emile Cohl, and Georges Méliès) and ubiquitous in contemporary effects work, it should be understood not only as a code, but perhaps the code of the moving image. The → cartoon employs "cel animation," in which individual drawings are photographed frame by frame. In many studio-produced animations, these drawings are created on transparent cels, which can be laid over and moved in relation to one another. Stop-motion animation places physical models in front of the camera, performing small movements of the model between the exposure of successive frames. Both techniques can be combined with live action (as in the 1933 *King Kong*), as can the many experimental techniques developed over the last century. Manovich (2001) asserts that the very principle of → cinematography – animated photographs – is only a subset of the wider field of animation.

## EFFECTS PRODUCED IN FRONT OF THE CAMERA

Effects produced in front of the camera are not restricted to cels and models. Set design draws on the history of theatrical technique to produce illusionistic effects, such as forced perspective, in which the appearance of depth is increased by making props further from the camera considerably smaller than those close to it (→ Perspective, Pictorial). Even locations are usually dressed before a shoot: props physically removed or added, for example to secure a period look. More clearly "effects" than set construction or dressing, stunts are typically carried out by doubles or extras, and by trained animals, whose wranglers can be major participants in films like *Babe*. Horse-mounted actors have been shot on trailers being pulled through locations from Eisenstein's *Alexander Nevsky* to Jackson's *The Lord of the Rings*. Virtual aviators have flown earthbound mock-ups of planes for more than half a century, and more than one plane crash has been staged by dropping a mocked-up aircraft into a studio tank. Squibs full of blood have exploded on actors' bodies for decades; their weapons have fired powder charges; fisherfolk have

withstood dump tanks full of water, and some have died as their cardboard temples crashed to the ground.

*Pro-filmic devices* (events constructed in order to be filmed) include pyrotechnics and miniatures (and miniature pyrotechnics). Many events (the burning of Atlanta in *Gone with the Wind*, for example, which involved setting fire to the old *King Kong* set) are too expensive to stage more than once, requiring multiple cameras to ensure adequate footage is recorded. Others pose challenges of scale: water notoriously acts very differently at miniature scales, and often requires chemical additives in order to move and reflect light appropriately. Smashable sugar-crystal bottles, fly-away sets and self-dismantling furniture for fight scenes, and the kind of costuming made notorious by Howard Hughes's obsessive construction of a brassière for Jane Russell in *The Outlaw*, indicate the degree to which props, makeup, costume, and hairstyling construct performers as effects for the camera; while we should not forget that acting too is a mode of illusionism that might well be included in the category (→ Realism in Film and Photography). This is the more apparent when we consider motion-capture technologies used to produce virtual actors or “synthespians” like Gollum in *The Lord of the Rings*.

### SPECIAL EFFECTS CAMERAS

Cameras themselves have been developed to shoot underwater, from the air, dangled from ropes, or tied to stampeding cattle. The development of *steadicam* in the 1980s permitted the fluidity of hand-held camerawork with the stability of a tripod. In addition to stop-motion, cameras can also be adjusted to shoot faster or slower than the standard 24 (film) or 25 (television) frames per second to produce, respectively, slowed-down or speeded-up imagery. Film stocks sensitive to nonvisible light (used in motion capture, but also for night-vision sequences) have found a place in a number of action series and films, as have micro-photographic devices capable of recording even the interior of living bodies.

Matte painting, in which elements of a scene, such as the sky, that otherwise might not be photographable are painted onto glass sheets in front of the camera, are used, for example, in the long shots of Tara in *Gone with the Wind*. Unpainted areas are photographed as they are (with the addition of lighting), and the camera adjusted so that both painted glass sheet and the scene beyond it are in focus. Back projection, of the kind used extensively by Hitchcock, involves careful adjustment of projection onto a glass-bead screen, in front of which actors play out, for example, the action of driving, while the rear-projected scenery recedes behind them. Matching actions, color, shadows, and focus in mattes and rear-projection requires extreme precision, even now that they are largely digitized.

### PRINTING AND EDITING OF FILM

*Printing* is one of the stages of film production least discussed in the literature, yet one that has retained its importance during the change to digital. The key device is an optical printer, through which pass one exposed and one unexposed strip simultaneously, transferring the image from one onto the other. Interventions in this process include

grading, the matching of color and tonality from one shot to the next, and superimposition, involving the printing of two images onto a single strip. Variants on superimposition include a variety of editing effects, such as dissolves, fades, wipes, and irises. Especially important is the related technique of masking off segments of the film strip so that different areas of the resulting image, printed during separate passes through the optical printer, appear to occur at the same time and place, as in the climactic steadicam race through the forest in *Star Wars: Return of the Jedi*.

With the move to *digital editing*, many techniques that were the province of the other moments of production have moved to the cutting room. Some new effects have become available, such as the shot transitions afforded by morphing software (Sobchack 2000), and digital grading, which allows changes to parts of images as well as the whole frame (→ Digital Imagery). Specialized and therefore expensive techniques like mattes and rear-projection are combined with in-camera, editing, and printing effects in digital compositing for economic as well as aesthetic reasons. For *The Return of the King*, location stills of mountains were combined to produce a massive range, over which elements from several location shoots of clouds and weather were blended digitally to create a digital cyclorama as backdrop to the final battle. Into this were added live actors, many wearing prosthetics and all equipped with lavishly detailed costumes and props, their stunt doubles, extras, and horses, digitally created 3D animals, and an army of virtual soldiers engineered to exhibit different kinds of behavior. In all, over 40 layers of miscellaneous footage from different sources were combined into the final shots. This process, known as compositing, is today the apogee of the craft hierarchy in moving image production.

### EFFECTS PRODUCED IN RECEPTION

A final category of effects belongs more properly to reception. These include such effects as 3D, which uses either separate red and blue (or red and green) projections or polarized light that, when viewed through the appropriate eyeglasses, produces illusion that objects on the screen project outward into the auditorium. Other effects include the use of tiny electric shocks to selected seats in the auditorium for the eponymous *The Tingler*, and the highly regarded scratch-and-sniff cards provided by John Waters for *Polyester*.

Many projection technologies have presented themselves as special effects, starting with those of the Lumière Brothers themselves (inventors not only of cine projection but of the massive widescreen Domitor system), passing through Cinemascope, to arrive at IMAX and theme-park movie rides. Similarly, advertising for domestic technologies, including home movie theaters, high-definition TV, plasma screens, and digital light programming (DLP) projectors, indicate the persistent persuasive allure of → spectacle and verisimilitude.

### FUTURE TRENDS

Special effects are no longer special. The economic efficiency of digital editing allows film and program makers the option of “fixing it in post,” leaving flaws that would once have been physically removed, or sets that would once have been built or visited, to be painted out or constructed digitally in even the lowest-budget films. Tricks such as Warner’s use

of limited numbers of key lights to hide shoddy sets have become stylistic tropes in films like *Sin City*. As Michelle Pierson (2002) observes, many effects have ceased to be marvelous, and vanished into the fabric of the narrative world. To this extent, as Metz (1977, 657) noted, “to some extent, all cinema is a special effect,” and the same can be said of television (→ Television, Visual Characteristics of).

Even documentary can be seen as “special” when it shows us events that we would otherwise never witness, be they war-torn villages or spectacular wildlife (→ Documentary Film). As domestic footage of the Boxing Day 2004 tsunami evidenced, even amateurs produce footage at which we can only marvel. Simultaneously, however, contemporary audiences are now not only willing dupes but also critical connoisseurs of special effects. Films frequently address this double spectatorship in narratives whose culmination lies in the dispersal of illusion, the end of magic, or the destruction of the marvelous monster (LaValley 1985).

As special effects migrate from science fiction to the mundane world of police procedural TV series, and as the tools for producing digital animations and composites migrate to domestic technologies, it appears that the demands of viewers have moved increasingly toward films and, especially, television programs that promise authenticity (→ Media Events and Pseudo-Events). But with reality TV, perhaps, we witness the effect of this upsurge of interest: the industrial production of authenticity as a system of melodramatic signs. These contradictions indicate that the purpose of special effects, and of the moving image in general, is not, or not only, or no longer, to represent the world aright. Introducing technology as a partner in communication rather than an obstacle to be surmounted, effects techniques and technologies now indicate that the purpose of media is to mediate (→ Media).

# Spectacle

Marita Sturken

New York University

The term “spectacle” refers to an event or image that is particularly striking in its visual display, to the point of inspiring awe in viewers. In its origins, the concept of spectacle was used to describe something impressive and unusual, which thrilled because it looked like things never seen before or which deployed immense scale to dwarf its spectators. The notion of spectacle was applied to high-culture products such as visually impressive dramas or operatic displays as well as religious ceremonies and folk spectacles.

The idea of spectacle is considered today, however, almost entirely within the *framework of modern media*. It is used primarily for cinematic, photographic, or technologically enhanced images and visual displays (from the spectacle of cinema to a fireworks display, for instance; → Visual Communication; Visual Culture). While the term “spectacle” has often been used to convey the idea of unique and thrilling events, beginning with late twentieth-century theory, the idea of spectacle has come to mean an empty, media-obsessed, image-saturated world that numbs viewers with an onslaught of spectacular images (→ Media Events and Pseudo-Events; Sensationalism).

The *key text* that helped to shape this new understanding of the concept of spectacle was Guy Debord’s *The society of the spectacle* (1994, 1st pub. 1967). Debord was a founding member of the radical group Situationist International, in Paris in the late 1960s, who were interested in using guerrilla tactics and innovative publication styles to intervene in the homogenized experience of everyday life. The society of the spectacle, according to Debord and the Situationists, defines contemporary society as an ongoing and constant spectacle that produces an autocratic political context in which the awe of the image creates political acquiescence in increasingly passive citizens. Debord defined *several different kinds of spectacles* (such as the “concentrated spectacle” of fascist and communist societies, the “diffuse spectacle” of advanced capitalism and commodity culture), arriving at the term “integrated spectacle” for recent forms of spectacle that borrow from the concentrated and diffuse and that define the pervasive realization of the spectacle of the liberal democracy.

While Debord and the Situationists were rooted in the social movements of the 1960s, it could be argued that the relevance of their ideas and the world of spectacle have reached new heights in the decades since, in particular in relation to media spectacle and the “empty” spectacle of political events (→ Political Communication). The term “spectacle” is thus used to convey to varying degrees awe-inspiring events that produce a mystification of power and an increasingly passive public (→ Propaganda). The term has thereby come to increasingly *convey a negative context*, in which media events overpower political debate and discourse, and citizens are drawn in and disempowered by their awe of the spectacle (→ Propaganda, Visual Communication of). It has been a foundational idea in the critique of media events that deploy aspects of spectacle and entertainment styles in ways that mask their superficiality. For instance, Daniel Dayan and → Elihu Katz (1992) argue that the immensity of media events such as the Olympics or the Prince Charles–Lady

Diana wedding are forms of spectacle that take on the aura of religious ceremonies. In addition, the concept of the spectacle is key to the concepts of postmodernism, as defined by such theorists as Jean Baudrillard, that critique the world of surface and simulation of contemporary societies. For Baudrillard (1983), the mesmerized public is fascinated by spectacle over meaning, and this gives rise to the embrace of simulations over representations and the loss of a sense of the real (→ Postmodernism and Communication).

The notion of spectacle as a key force in modern society has been reinforced in the past few decades by the dominance of *spectacular images in the global media contexts* of massive live audiences watching riveting events, such as the Persian Gulf War in 1991 and the mass spectacle of the funeral of Princess Diana in 1997 (→ Globalization of the Media; Conflict as Media Content). It reached what appeared to be a particularly powerful manifestation in 9/11, an event that has been defined by many as the quintessential moment of the triumph of spectacle (→ Disasters and Communication). Thus, theorists such as Slavoj Žižek proclaimed that the terrorist attacks of 9/11 intended, above all, to produce spectacular images and the spectacle of terrorism (→ Mediated Terrorism), which was why they reminded so many observers of the spectacle of → Hollywood film (→ Cinema). Thus, even with its negative connotations, “spectacle” is a term that has come to seem increasingly prescient in relation to world events and the role of the media.

## **Spectator Gaze**

*Marita Sturken*

*New York University*

The concept of the spectator gaze was central to the development of theories of → cinema and art history, emerging primarily in the 1970s. Its origins most likely lie in Jean-Paul

Sartre's theory of the look (in French, *le regard*) and the extension of that theory into psychoanalytic theory by Jacques Lacan. This theory postulates the position of an idealized spectator (of cinema, for instance) and the idea that an image (still or moving) is defined by a particular kind of gaze upon it (→ Film Theory).

The concept of this ideal spectator is central to theories of cinema that find their foundation in psychoanalysis and → semiotics, and what have been termed the apparatus theories of early film theory, which focus on the technology of cinema exhibition as a metaphor for viewer consciousness (→ Structuralism in Visual Communication). The spectator designates an abstract subject position of an imagined viewer of cinema, though it might be occupied by particular viewers of cinema in various contexts. Thus, theories of spectatorship are theories of address (how cinema or other image systems are seen to address viewers) rather than a theory of actual reception (what particular viewers do in response to image texts).

The concept of the gaze (→ Gaze in Interaction) emerged in the context of 1970s film theory most obviously in relationship to two texts: Laura Mulvey's canonical essay "Visual pleasure and narrative cinema" (1975) and John Berger's well-known book (which was part of a broader collaboration) *Ways of seeing*. In Mulvey's formulation, → Hollywood cinema creates *several intersecting gazes*: the gaze of the male protagonist upon the female subject in the film, the gaze of the movie camera upon the actors, and the gaze of the spectator upon the screen. Mulvey used psychoanalysis to postulate that this intersection of gazes is defined within classic Hollywood cinema as a "male gaze." This refers not simply to the gaze of actual male spectators upon the screen, but to an overarching male gaze through which all spectators, including female spectators, must look. Mulvey theorized that this created a kind of masochistic subject position for female spectators.

Likewise, Berger argued that throughout the history of art, the *depiction of women* has been one in which the gaze is defined as male, with female figures often turned away from male figures within the picture frame and toward the spectator himself. Berger famously wrote that in the codes of representation throughout the history of art, "men act and women appear" (1972, 47); thus the male gaze defined a look upon a passive female figure (→ Sex Role Stereotypes in the Media). It is central to these concepts of the gaze that the person looking retains power over the person who is looked upon, and the looking is not only powerful and voyeuristic but pleasurable. Mulvey's concepts hinged on the idea that such looking is inherently sadistic in its → voyeurism. It is also central to the theory of the gaze that image texts define the gaze that looks upon them. Thus, in this formulation, an image such as a Hollywood film determines (and limits) the particular kinds of gazes that can look upon it, no matter the identity of the person actually looking.

The model of psychoanalytic-semiotic theory that produced the concept of the gaze has been debated and critiqued over the past two decades, and has been updated and modified by many theorists, including Mulvey herself. In particular, the unitary aspects of the original model of the gaze have been questioned and reconfigured over time. The ahistorical aspects of the psychoanalytic model, its overemphasis on sexual difference, and its dependence on the model of a fixed spectator all limited the extent to which the theory of the spectator might apply to other contexts and media (→ Visual Culture).

This *rethinking of the concept* has given way to a broad range of theories about different kinds of gazes, a pluralism of potential gazes, and different ways of thinking about spectator

identification with images. Thus, many theorists have proposed models of negotiation for understanding what spectators do with particular images, rather than the model of a spectator who is positioned by a film text. Such theorists have proposed not only categories such as black spectatorship and lesbian spectatorship, but also the idea that the study of actual spectators in particular socio-historical contexts could be more useful than the limited notion of an abstract, ideal spectator. The concept of the spectator gaze is thus used today to characterize a diverse range of strategies that viewers use when looking at and identifying with images.

## **Speech Anxiety**

*Chia-Fang Hsu*

*University of Wyoming*

*Michael Hazel*

*Gonzaga University*

*Joe Ayres*

*Washington State University*

Speech anxiety, also known as → stage fright, refers to the feeling of anxiousness or fear associated with delivering a speech. The symptoms of speech anxiety typically involve physiological arousal (e.g., elevated heart rate), negative thoughts (e.g., being negatively evaluated), and behavioral disruptions (e.g., verbal disfluency; Ayres & Hopf 1993). According to Ayres et al. (in press), the study of speech anxiety can be traced back to ancient Greek rhetoricians 2,000 years ago, who viewed speech anxiety as arising from a lack of

confidence or skills. Serious research using scientific methods did not begin until the mid-1930s, when psychologists developed ways to measure stage fright, and examined the causes and effects associated with communication fear. Following Clevenger's (1959) synthesis article on stage fright, many communication scholars began to develop theories, measurement approaches, and interventions in the areas of communication apprehension and reticence, which refer to fear or anxiety across various communication situations.

## THEORY DEVELOPMENT

Spielberger et al. (1970) distinguished between the concepts of *state* and *trait* anxiety. A *state* refers to a transitory condition varying over time and situations, whereas a *trait* is a more stable individual difference or personality characteristic. Accordingly, the causes of speech anxiety can be attributed to trait (enduring) or state (situational) factors (→ Communication Apprehension; McCroskey 1997b). The trait explanations include learned helplessness, modeling, and genetic predisposition. From the "learned helplessness" perspective, people develop speech anxiety because they learn to associate negative outcomes with speaking, such as being ridiculed by peers. According to the "modeling" explanation, people develop speech anxiety when they cannot learn proper speaking skills from others. More recently, some scholars have argued that communication fear, such as speech anxiety, is mostly genetically determined (→ Communibiology). Despite these different explanations, many scholars hold the "interaction" view, i.e., that the interaction between gene and environment results in speech anxiety (Ayes et al. in press).

Regarding state anxiety, there are *seven situational factors*: novelty (new experience), formality (formal situation), conspicuousness (too noticeable), subordinate status (inferior to audience), unfamiliarity (unfamiliar audience), dissimilarity (different from audience), and degree of attention (too little or too much; Ayres et al. in press). McCroskey (1997b) added one more situational factor: degree of evaluation, which refers to whether the speech will be evaluated or graded. Although several situational causes are identified, many scholars believe that trait anxiety predisposes speakers to experience these situational factors in certain ways, which in turn affects their state anxiety level (Ayres et al. in press).

Although most *explanations* of speech anxiety have been based on the trait perspective, a few scholars have developed state anxiety theories from the situational perspective. One major development is → *action assembly theory*, which posits that state anxiety arises because people cannot identify effective strategies or engage in appropriate behaviors to accomplish their goals in a given interaction (Greene & Sparks 1983). Concomitantly, social psychologists developed the self-presentation theory of social anxiety, positing that social anxiety is a function of one's desire to make a particular impression and the perceived probability of making the desired impression on others (→ Communication Apprehension and Social Anxiety; Schlenker & Leary 1982). Thus, one would expect a speaker to experience high levels of speech anxiety when he or she wants to make a specific impression with speech and doubts the possibility of achieving such a goal.

More recently, Ayres et al. (in press) have constructed a *component theory* of state communication apprehension, in which state anxiety can be predicted by the interaction of the speaker's nervous system sensitivity, and self-perception of motivation, negative

evaluation, and communication competence. Specifically, speakers will experience high levels of state anxiety when they are very sensitive to environmental changes, are motivated to accomplish a goal via speech, anticipate being negatively evaluated by others, and perceive themselves as having low levels of speaking ability.

## MEASUREMENT DEVELOPMENT

The three primary approaches to measuring trait and state public speaking anxiety are self-report scales, physiological instruments, and observers' ratings. Self-report scales measure individuals' feeling or thoughts associated with giving a speech; physiological instruments measure the degree of arousal experienced; and observers' ratings assess behavioral disruptions. Self-report scales are the most widely employed approach. The specific measures for each approach are briefly introduced below (→ Research Methods).

Several *self-report measures* of speech anxiety have been developed during the past decades. According to McCroskey (1997a), the earliest developed scale is the Personal Report of Confidence as a Speaker, which has been demonstrated to be highly reliable and valid in numerous research studies. However, this scale is rarely employed today. A more frequently used scale is the Personal Report of Public Speaking Anxiety. This instrument is a 34-item, 5-point Likert scale. Respondents are instructed to indicate their level of agreement with statements such as "My thoughts become confused and jumbled when I am giving a speech." This measure has been demonstrated to be highly reliable and valid. The most widely used scale of trait anxiety today is the public speaking subscale of the Personal Report of Communication Apprehension, which has 20-item and 24-item versions. The 24-item version includes six items for communication in each of four contexts: public, meetings, small groups, and dyads. This scale has been demonstrated to have high reliability and strong validity in numerous studies both nationally and internationally (McCroskey 1997a).

The *state anxiety scale* developed by Spielberger et al. (1970) is the most widely used measure of state anxiety today (→ Scales). This instrument has 20-item and 5-item versions. Both versions use a 5-point Likert scale, in which respondents are asked to indicate how they felt in the speech they have just completed by choosing a category from "strongly agree" to "strongly disagree" for each statement (e.g., "I feel nervous"). Both versions have high reliability and good validity.

Another self-report measure that has been used frequently is the *Communication Anxiety Inventory* developed by Booth-Butterfield and Gould (1986). This inventory has two separate scales for trait and state anxiety. The trait form assesses individuals' predisposition to experience anxiety in three contexts – dyadic encounters, small group, and public speaking – while the state form asks respondents to indicate how they felt during a communication experience they have just completed. The trait form uses a four-point frequency scale ranging from "almost never" to "almost always." The state form also uses a four-point scale, ranging from "not at all" to "very much so." One example of the statements in the trait form is "I enjoy speaking in public," and one example in the state form is "I felt calm when I was talking." Both forms have satisfactory reliability and validity.

In addition to self-report measures, researchers use *physiological measurement* on speech anxiety. According to Beatty and Dobos (1997), the two most commonly used

instruments are measures of heart rate and skin conductivity. For instance, speakers' heart rates were measured continuously during a public speaking performance. Heart rates were recorded at one-minute intervals before, during, and after a speech. The heart rates of speakers generally increased slightly before a speech presentation, elevated dramatically when they began to speak, and then declined until the end of the speech. Several studies have also employed the galvanic skin response (measuring changes in the ability of the skin to conduct electricity during exposure to an emotional stimulus, such as giving a speech) to assess the effects of interventions on apprehension or anxiety, and some studies have recently started to use brain temperature to assess physiological response to public speaking.

In addition to self-report and physiological measurement, researchers have also used *observers' ratings* to measure behavioral aspects of speech anxiety, such as verbal disfluency and tense bodily movement (→ Observation). Mulac and Sherman (1974) developed the Behavioral Assessment of Speech Anxiety. This 18-item instrument requires that trained observers rate the severity of occurrence of each behavior for a given speaker, as compared to the other speakers being rated, using a 10-point scale ranging from "not at all" to "strong." Statistical analysis revealed four dimensions of this instrument: rigidity, inhibition, disfluency, and agitation. This instrument has been demonstrated to have high inter-observer reliability in numerous studies for the rating as a whole and for each dimension. In terms of validity, its ratings were negatively correlated with perceptions of speech skills and credibility. However, only a small relationship was found between observers' ratings and speakers' self-report anxiety level. That is, a speaker may feel quite nervous, but is able to control his or her behaviors so that observers are not able to detect any cue of nervousness. On the other hand, a speaker may feel calm but act in ways that observers perceive as signs of anxiousness, which may reduce his or her credibility.

In sum, these three approaches measure different aspects of speech anxiety: self-perceptions, physiological symptoms, and behavioral disruptions. For objective assessment of anxiety level, one can use all three methods and compare their results. If consistent results are found, one can be certain that the observed anxiety level is accurate. On the other hand, if the results conflict, it is likely that a speaker suffers only one or two sources of anxiety: negative thoughts, nervous feeling, or inadequate skills. Interventions are available to help reduce each source of anxiety (→ Communication Apprehension: Intervention Techniques).

## Speech Codes Theory

Gerry Philipson

University of Washington

Speech codes are historically situated and socially constructed systems of symbols, meanings, premises, and rules about communicative conduct. The “speech” in “speech codes” is a shorthand term, a figure of speech, standing here for all the possible means of communicative conduct that can be encountered in a given time and place. The “code” in “speech codes” refers to a system of symbols, meanings, premises, and rules pertaining to those means. These senses of “speech” and of “code,” when placed together in the term “speech code,” establish a definition of a speech code as a historically situated and socially constructed system of resources that people use to talk about their own and others’ communicative conduct.

A speech code is a construct that an observer-analyst formulates explicitly in order to interpret and explain communicative conduct in a particular speech community. The observer-analyst notices that participants in the discursive life of a speech community use particular resources – acts, practices, patterns of activity, symbols, meanings, premises, and rules – to enact, name, interpret, and judge communicative conduct. And the analyst uses what was noticed to construct a hypothesis as to the existence and nature of a system of resources that these participants use to do that enactment, naming, interpretation, and evaluation. That hypothesis is the observer-analyst’s formulation of a speech code.

Two *examples* help to illustrate the concept of speech code as presented here. Gullestad (1992) formulates such a code as part of a larger Norwegian cultural code. Although she does not use the term “speech code,” she does use the word “code” and her work suggests a historically situated and socially constructed code of communicative conduct. She reports, as part of what she designates as a “code” of “social relations,” the use, in contemporary Norway, of the Norwegian words *fred* (“peace”) and *ro* (“quiet”), the Norwegian expressions *fred for enhver pris* (“peace at any price”), and the expressions, in English, of Norwegian notions of “not involving oneself too much” (in others’ lives), “avoiding open personal conflict,” and the importance of giving and understanding “a little hint,” of keeping oneself “whole, balanced, and safe,” and of “good social relations.” As Gullestad describes the code, such communicative practices as “not involving oneself too much” (in others’ lives), “avoiding open personal conflict,” speaking indirectly (with “a little hint”), and paying close attention to the “little hints” that others might give are linked to the achievement and maintenance of “peace,” which she interprets as being “free from disturbances from others.” “Peace,” in turn, is linked to “quiet,” which Gullestad interprets as the achievement of a desired “state of mind characterized by wholeness and control” (of self). A synthesizing premise of the code is that social distance (peace) creates good social relations as well as a desired state of individual well-being (1992, 137–164).

The cultural code that Gullestad reports for Norway can be contrasted to one found in the contemporary US. Several scholars (Katriel & Philipsen 1981; Carbaugh 1988) report the use, in the US, of such terms as “real communication,” “open communication,” “self,” and “healthy relationship” as terms in an American code. As these scholars formulate the code, “open communication” is linked to the achievement of the culturally desired state of a unique “self” and to the achievement of a “healthy relationship” with a friend, relative, or intimate partner. An important premise in this code is that communication (particularly “open communication”) is necessary for the establishment and sustenance of a (“good” or “satisfactory”) relationship (Katriel & Philipsen 1981, 310).

The Norwegian and American codes mentioned briefly here are but two among many that have been discovered and formulated, either implicitly or explicitly, as speech codes. Such formulations have been made for codes discovered in many societies and in many languages, including multiple codes found in the US, and codes found in Israel, Finland, Colombia, and Mexico (→ *Ethnography of Communication*). A large body of original ethnographic research into speech codes has provided the bulk of the evidence upon which speech codes theory rests (Philipsen 1992, 1997).

There are three broad *purposes to speech codes theory*. The *first* is to provide ways to discern and formulate the presence of a speech code in the communicative conduct of a particular time and place – a particular social world, setting, or milieu. The theory is concerned to specify where to look and listen, in communicative conduct, for elements of speech codes, that is, for indigenous symbols, meanings, premises, and rules pertaining to communicative conduct. This is the subject of one of the principal and longstanding propositions that is part of the theory, which states that the elements of a speech code – its symbols, meanings, premises, and rules – are inextricably woven into speaking itself. This provides an answer to the question of where to look and listen for evidence of culture in communicative conduct, that is, to look and listen for it in communicative conduct itself. The present version of the theory points to three broad types of places where such

elements can be found: in (1) locally prominent and poignant keywords or cultural terms pertaining to, (2) locally recognizable patterns of, and (3) local and particular genres and forms of communicative conduct, as the particular sites in which speech codes elements might appear (→ Storytelling and Narration).

The *second* purpose of speech codes theory is to formulate descriptive generalizations derived from the corpus of empirical research into particular speech codes. The most recent version of the theory presents three such descriptive generalizations.

The first of these *descriptive generalizations* is that everywhere that there is a distinctive cultural code, there is a distinctive speech code. This was illustrated in the brief juxtaposition of (some elements of) Norwegian and American speech codes, with the suggestion that the Norwegian code gives greater endorsement than does the American to communication that is indirect and respectful of personal boundaries, while the American code gives greater endorsement than does the Norwegian to directness of communication and to a more permeable self. Philipsen provides extensive documentation of support for this proposition across a wide range of societies and languages.

The second descriptive generalization is that in the life-world of every individual there are multiple speech codes. For example, although some Norwegians or Americans use the codes reported above, they draw on other codes as well that are used in their social environment. Gullestad (1992) and Philipsen (1992) provide book-length treatments of the societies in which they studied the codes they report, Norwegian and American, and in both cases show evidence of more than one code being used in these societies. The body of evidence on which speech codes theory is built suggests that the presence of multiple speech codes in any given life-world, of an individual or a speech community, is a universal feature of social life.

The third descriptive generalization is that in every speech code, the words, meanings, premises, and rules pertaining to communicative conduct are systematically linked with words, meanings, premises, and rules pertaining to the nature of persons and the nature of social relationships. This was illustrated here, in terms of cultural beliefs, for the Norwegian code in the linkage between (1) indirectness of communication and (2) the preservation of the well-being of a bounded person. And it was illustrated here for the American code in the linkage between (1) openness of communication and (2) the strength of interpersonal relationships. The import of this generalization is that in every speech code the symbols and meanings pertaining to communicative conduct are linked as well to symbols and meanings pertaining to notions of self and/or of interpersonal relations. Carbaugh (1989) and Philipsen (1989a) provide extensive documentation of the wide scope of this generalization across many societies and languages.

*Third*, speech codes theory posits a way to interpret and explain observed communicative conduct, and involves two propositions. One is that the significance of particular communicative acts is contingent upon the speech codes that people use to interpret them. For example, if someone observed a husband refusing to speak up to his mother in defense of the rights of his wife and himself as a couple, the not speaking up would be heard differently if interpreted in the terms of the Norwegian and of the American codes, as these codes were described above (→ Intimate Talk with Family and Friends). The other proposition says that people do not necessarily shape their communicative conduct so as to conform to their idea of what is culturally acceptable

conduct, that is, codes do not strictly determine conduct. Nonetheless, codes have a shaping power in communicative conduct to the extent that people use codes to support their evaluations – praise, criticism, and their appeals to others pertaining to what is acceptable and desirable communicative conduct. The body of empirical research on which the theory is grounded shows that people do appeal to cultural notions of acceptability of communicative conduct in the process of retrospectively framing and evaluating such conduct as they explain it to others. Furthermore, justifications of communicative conduct that are framed in the terms of a socially legitimated speech code are treated as more persuasive, by those who read or hear them, than those that are not so framed. What the extant studies of the force of speech codes have in common is that they explicitly acknowledge the limits of cultural codes to shape conduct, while at the same time showing that such codes nonetheless are deployed strategically in communication about social conduct, and are deployed in ways that have consequences for social interaction.

# Speech Communication, History of

William Keith

University of Wisconsin-Milwaukee

The field of speech emerged out of changing teaching practices in US higher education in the early twentieth century. Between 1880 and 1920, many of the academic fields in the US formed associations and university departments. University education, with the rise of the research university and the land-grant schools, was becoming accessible to a larger and more diverse group of Americans. Higher education was outstripping its traditional function of reproducing an elite class, qualifying them only for the “gentle professions” of the clergyman, the lawyer, and the politician. Speech instruction had traditionally been integrated into the general, liberal education of the private colleges, with students writing and speaking as part of the study of classics and philosophy. But as the nineteenth century came to a close, speech instruction, focused mainly on delivery, became a separate course in the curriculum. Speaking as a performance art, that of the “platform entertainer,” had become lucrative and popular, and college instruction reflected that reality.

The resulting pedagogy, called *elocutionism*, focused almost exclusively on delivery and performance aspects of speaking, and was perhaps more closely related to theatre than to public address. Elocutionism harmonized with a middle-class culture of oral and musical performance, but remained in tension with the civic traditions of public address. In 1890, the National Speech Arts Association (NSAA) was founded, with the intention of bringing together both private and university elocution teachers under the term “speech,” allowing them to include diverse activities involving the voice.

## EVOLUTION OF THE SPEECH DISCIPLINE

In the universities, speech instruction was evolving from traditional patterns. A precursor to the field of speech was “oral English,” which included courses (or sometimes parts of courses) that focused on students reading out loud or interpreting essays, stories, or poetry that had been written; speaking was understood as a complement to writing instruction. This resulted in a kind of second-class status for those who taught speaking; they were paid less than others and typically were not eligible for promotion. Oral English was short-lived, as most of the people who taught these courses moved to speech departments when they were formed. The relationship between speech teachers and English departments was generally unstable, although there were attempts at professional cohesion.

In 1910, the *Eastern Public Speaking Conference* (called until 1914 by the unwieldy name “The Public Speaking Conference of the New England and North Atlantic States”) became the primary organization for college teachers of speech. Paul Pearson officially called the first meeting at his institution, Swarthmore College. The idea of a conference of public speaking teachers in particular came from James Winans of Dartmouth College, later a renowned teacher at Cornell University; Winans was concerned about differences between NSAA teachers and the emerging group of speaking teachers and debate coaches.

The journal of the conference was the *Public Speaking Review*, a curious mix of teaching tips, professional news, and reports from the conference. Yet speaking instruction was flowering all across the country, and at the national level, speaking teachers met as a section of the National Council of Teachers of English (NCTE), an organization which supplemented the research-oriented Modern Language Association by being focused on teaching and including secondary school teachers.

The meetings became increasingly uncomfortable, as the *tensions between speech teachers and their English colleagues* increased. At the 1914 meeting of the public speaking section of the NCTE in Chicago, Illinois, James O'Neill of the University of Wisconsin suggested a post-convention meeting of the speech teachers, and at this meeting they decided to create a new association, the National Association of Academic Teachers of Public Speaking (NAATPS), along with a journal, the *Quarterly Journal of Public Speaking*. O'Neill would be president for the first five years, with Howard Woodward of Western Reserve University in Cleveland as the treasurer. The first years of the NAATPS saw the widespread change in universities from departments of "oratory" and "elocution" to departments of speech; partly this was a change underway already, but the Association also encouraged members to form separate departments when they could.

The new field was more than public speaking. The most common pattern for speech departments, sometimes called the "Midwestern" or "Illinois" model (after Charles Woolbert's design for the department there), included every activity that involved human speech. Courses included public speaking, debate, persuasion, physiology of the voice, diction and vocal expression, theatre, and interpretation (of literature), the new name for what had been called "reading." The early field did not view these as separate areas simply thrown into a department (as had been the case with speech in English departments) but as a unified course of study, beginning with the voice mechanism and proceeding to the various uses of human speech. Sometimes the "psychology" of speech was included as a unifying perspective, while sometimes classical rhetoric was invoked to provide a common thread.

The curriculum also included some *novel areas*. Rhetoric became a standard part of the curriculum due to the many PhDs produced by the program at Cornell University; sometimes the focus was classical, sometimes on the emerging idea of "rhetorical criticism," but most often on a study of British and American public address of the last two hundred years (→ Rhetorical Studies). Speech pathology, devised by Smiley Blanton (who had an MD from Johns Hopkins) at the University of Wisconsin, became a staple of the field until the 1960s and 1970s, and the early journal has a fair number of articles on lisping and stuttering. Consistent with the unified vision of the field, improvement of "speech" by addressing lisping or stuttering was of a piece with improving speech by "normalizing" a student's accent, or improving his or her interpersonal skills. This last function was often glossed as "social hygiene" or "speech hygiene." Teachers by the late 1920s assumed that civil society was organic, and that there was a normal, "healthy" function of individuals in social groups. Rather than a simple-minded conformity, they had in mind a kind of civic humanism inspired by John Dewey, where the democratic functioning of groups large and small required individuals who possessed the skills of both contributing their individual points of view and helping the group to function overall.

The NAATPS changed its name in 1920 to the National Association of Teachers of Speech (NATS), which conserved the pedagogic focus that defined the early field while accommodating the move to teaching the full range of courses involving speech. In 1947, the name was changed to the Speech Association of America, recognizing the growing research component of the field, demonstrated in the *Quarterly Journal of Speech* and *Speech Monographs* (now *Communication Monographs*), established in 1934. The *Speech Teacher* (now *Communication Education*) began in 1952 as a forum for teaching methods, and later published mainly social scientific work on communication pedagogy.

In the *post-World War II era*, the speech discipline began, slowly but steadily, to lose the integrated structure that had characterized its early years, in several ways. First, and most obviously, the “Midwestern” model of the departments began to break up. As speech pathology (or “speech science” or “communication disorders”) became increasingly professionalized, it had less and less in common with speech departments. Their focus was on research in the physiology of speech and hearing and treatment of speech and hearing disorders, and on the production of accredited audiologists and speech pathologists for private practice and schools. Theatre, in many cases, had more in common with other performing arts such as music and dance, sharing the need for performance spaces and having their faculty evaluated for their artistic output rather than publications. In departments with mass media, radio, television, or film components, the level of student interest and the increasing scholarly and professional profile for media scholars and practitioners led in many cases to the formation of a separate department where there wasn’t already one.

But the *loss of the integrated vision* also happened on deeper levels, both methodological and epistemic. To an extent speech scholars in the 1930s and 1940s had seen themselves as answering empirical questions in different forms, sometimes about the historical context of speeches, sometimes about the causes of stuttering or the correlates of effective speaking. Increasingly, especially with the development of sophisticated experimental and statistical techniques, some speech scholars began to emulate researchers in psychology and sociology and adopt a more clearly social scientific approach to communication research. A rift between humanistic and social science research would continue to grow, and by the 1970s debates on the relative merits of each approach were common.

## RHETORICAL STUDIES

At the same time, humanistic scholars in communication increasingly identified themselves as “rhetoricians,” those who study rhetoric, a general theory of persuasion. With their discovery of Kenneth Burke’s writings in the early 1950s, they merged a classical tradition of rhetoric with symbolic interactionism, developing a general approach to the human use of symbols (→ Rhetorics: New Rhetorics; Symbolic Interaction). Through the 1960s, they expanded their notion of public → discourse beyond speeches by politicians to include pictorial and nonverbal rhetoric, protest rhetoric, and the rhetoric of social movements, while in the 1980s and 1990s, literary theory and → cultural studies decisively influenced the course of rhetorical theory and criticism (Rhetoric, Nonverbal; Rhetoric and Social Protest).

Even though the term “rhetoric,” since the eighteenth century, had been a synonym for style instead of content, and in the early twentieth century was associated in the US with

writing courses (the “freshman rhetoric”), a more dignified and intellectually satisfying account of rhetoric has been natural to (speech) communication departments. From Henry Hudson’s “The field of rhetoric” (1923) to Donald Bryant’s “Rhetoric: Its functions and its scope” (1953) and the proceedings of the Wingspread Conference in 1970 (Bitzer & Black 1971), scholars in this tradition sought to illuminate the social, cultural, and intellectual value in the study of persuasion.

The Wingspread conference, held in Racine, Wisconsin, was sponsored by the Speech Communication Association (as part of its National Developmental Project on Rhetoric) and organized by faculty at the University of Wisconsin-Madison. An interdisciplinary group of scholars responded to the question “What is the essential outline of a conception of rhetoric useful in the second half of the twentieth century?” In a superb set of essays and responses, participants outlined an expanded notion of rhetoric, which went far beyond the public address tradition. In light of the political unrest of the time, contributors noted that a starting point must be the inadequacy of traditional conceptions of political discourse as a foundation for rhetorical theory and criticism. In the wake of the Wingspread proceedings, called *The prospect of rhetoric* (Bitzer & Black 1971), some common threads connect rhetorical scholarship. Rhetorical analyses are not empirical studies or theories about the effects of persuasion; these are left to social scientists, marketers, and mass communication researchers (→ Rhetoric and Psychology). Rhetorical theory and criticism must account for common speech as well as the speeches of politicians, lowbrow discourse as well as highbrow, science as well as popular culture (→ Rhetoric of Science; Rhetoric, Vernacular). Rhetoric is never merely technical, never just a set of means to an end; rhetoric is always both style and substance, ornament and argument. The moral dimension of rhetoric cannot be separated from its technical aspects, and rhetoric is not only a conveyer of knowledge but is constitutive of knowledge (→ Rhetoric and Epistemology; Rhetoric and Ethics).

## FROM SPEECH TO COMMUNICATION

On the social science side of the field, the quickly growing body of research on persuasion and influence in psychology and sociology stimulated parallel lines of research for speech communication scholars. Expanding on the Yale studies of → persuasion, communication research in both speech and media departments began to take a variable-centered approach to studying interpersonal and public influence. In the mid-1940s a group of researchers at the Massachusetts Institute of Technology, led by the social psychologist Kurt Lewin, began to study group interaction (“group dynamics”) reflexively, having group members simultaneously participate in and observe groups. These researchers established the National Training Laboratory (NTL) in Bethel, Maine, as a site for intensive summer studies of group process. As the NTL evolved, it began to move away from strictly group process and toward interpersonal communication more generally. This focus on personal relationships was actually somewhat novel. Speech scholars who attended the NTL summer sessions came away with not only a new framework for studying communication but a new ethic for communication. Some of them became part of what was sometimes called the human potential movement, an approach that sought to maximize the possibility of authentic and transparent communication.

This approach represented an extension and transformation of social hygiene, and was typified by textbooks such as Virginia Satir's *Peoplemaking* (1972). In addition, other contexts of communication became standard parts of speech pedagogy and research, including professional communication and → organizational communication (→ Interpersonal Communication; Group Communication).

As more and diverse topics were included in the curriculum, the term "speech" began to seem restrictive, and the more general term "communication" seemed more appropriate, since it easily accommodated nonverbal, written, and mediated communication, as well as the perspective that focused on human relationships generally, rather than the parts of them conducted through speech (→ Communication: Definitions and Concepts). In 1968, a conference in New Orleans, Louisiana, was sponsored by the US Office of Education and the Speech Association of America, resulting in proceedings called *Conceptual frontiers in speech-communication: Report of the New Orleans Conference on Research and Instructional Development* (Kibler & Barker 1969). At this conference, the recommendation was made to change the name of the field to speech-communication, and this name, minus the hyphen, was adopted the next year, resulting in the Speech Communication Association (SCA).

The conference's recommendations were made in recognition of the expanding understanding of the field, so that communication, a more general term that encompassed diverse channels, media, and modes of human interaction, was a more appropriate name for the field than speech, even though the conference adopted "spoken symbolic interaction" as the focus of study. The report acknowledged some old themes: the field as basically interdisciplinary, the importance of speech processes to democratic decision-making, the necessity of speech instruction for people to become functioning members of society. But these themes developed a new urgency due to the recognition of the plight of the underprivileged in society. This conference also marked the emergence of → applied communication research, serving the needs of both society and (later) business.

Speech communication as a field of undergraduate instruction underwent explosive growth in the 1970s (Craig & Carlone 1998). Students wanted to study in the many "new" areas of communication: interpersonal, organizational, group, and others. In fact, the diversity began, gradually, to outgrow the bounds of the term "speech" and the term "communication," as cultural studies and media studies became integrated into the field's teaching and research. So, despite being shared by other departments, including media and speech pathology, "communication" seemed increasingly a better fit. Another name change, based on the results of a vote by the membership, created the current National Communication Association in 1997.

## INTERNATIONAL LINKS

In most ways, the speech communication tradition was a *peculiarly American* one. While speech pathology, linguistics, classical rhetoric, and the social psychology of interpersonal relationships were studied in Europe and Asia, the configuration that brought them all together was found only in the US. Granting that oral communication instruction (in the elocutionist tradition) long survived in Europe, in Asia speech instruction was unknown until recently, and in neither case were there academic units devoted to the study of

speech. Yet by the 1980s, US speech communication scholars were forging links with their European counterparts on several fronts.

In the late 1970s, → conversation analysis, a qualitative methodology from sociology, made its way into communication departments, and with it contact and collaboration with an international group of conversation analysts. In 1985, a group of Dutch scholars, led by Rob Grootendorst and Frans van Eemeren (as well as the German scholar Norbert Gutenberg and, later, Canadian informal logicians such as Anthony Blair and Ralph Johnson), made contact with US scholars of argument, attending a biannual conference in Alta, Utah. In 1987, the US conference on argument was joined in the off year by a large, heavily international conference in Amsterdam, sponsored by the International Society for the Study of Argumentation (ISSA), and later by conferences of the Ontario Society for the Study of Argumentation (OSSA). Contacts with Finnish communication scholars resulted in an international conference in University of Jyväskylä, Finland, in the summer of 2000. All of these conferences represented significant contact among scholars from many countries.

## Speech Fluency and Speech Errors

*Kyle James Tusing*

*University of Arizona*

Speech fluency refers to clear oral communication devoid of speech errors. A speaker who is able to deliver a message that features a continuous flow of information at an appropriate rate, unmarred by any of the multiple speech errors, is said to possess speech fluency, an area of communication mastery. Speech fluency is the product of mental skills, such as recall of procedural and declarative knowledge, and physical motor skills involving correct functioning and use of the vocal cords, tongue, mouth, and lips to produce speech (→ Message Production).

*Situational factors* that facilitate speech fluency include an attentive audience, an absence of distraction, the speaker being able to prepare and practice the message ahead of time, and a monologue rather than a dialogue communication format where there are fewer opportunities for interruptions and no requirement to manage turn-taking. In terms of *individual difference factors*, some speakers are naturally more fluent than others, whereas at the opposite end of the spectrum there are those who are burdened by anxiety with regard to communication. Nearly all speakers have the ability through training and practice to become communication masters whose speech is fluent. There are treatments available to improve speakers' speech fluency. Treatments include physical therapy, coaching, and confidence training. The goal of all treatments is to decrease errors, thereby increasing fluency (→ Speech Anxiety).

*Positive outcomes* associated with speech fluency are multiple. Speech fluency is a component of behaving as a socially skilled individual. Such skilled individuals benefit by making good impressions on others, which result in tangible rewards such as attracting relational partners and achieving professional goals. Speech fluency is also beneficial for engaging in persuasion and deception (→ Deceptive Message Production), as message receivers are not as accurate in detecting deception from fluent speakers.

There are many different *types of speech errors*, which are most often, though not universally, a nonverbal part of speech (→ Nonverbal Signals, Effects of). Among the most common types of speech errors are stuttering, audible pauses such as “uh” or “ah,” excessively long, frequent, or misplaced silent pauses, an unusually slow or accelerated speech rate, and counterfactual utterances.

*Stuttering* is an involuntary speech pattern marked by frequent disfluencies. Stuttering can include stammering, sound repetition, word repetition, hesitation, and elongation of sounds, usually vowels. Approximately 5 percent of children suffer from stuttering though many of them overcome the disorder such that only 1 percent of the adult population stutters, with varying degrees of severity. The cause of stuttering is unknown. There is no cure other than speech therapy techniques aimed to improve fluency.

*Pauses* are negative when they occur frequently, are long in duration, are audible, and occur in the middle of an idea. Such pauses direct attention to the pause itself rather than the speaker's content. Pauses are positive when they are used for emphasis and variation. Typically, these more effective types of pauses occur infrequently, are short in duration, are silent, and occur at the end of an idea.

Speech rates outside of an acceptable range are problematic because they lead to unwanted perceptions. An unusually *slow speech rate* sounds like grief and depression. Furthermore, the human capacity for processing speech is approximately four times greater than the normal speech rate of between 125 and 150 words per minute, so a slow speech rate is especially problematic, as it can cause listeners to become bored due to the low demand of the task. This boredom on the part of the audience can lead to audience distraction, which is a factor that can disturb the speaker, causing additional speech errors. An unusually *fast speech rate* sounds like fear and anger. Even though fast speech rates within an acceptable range are associated with judgments of speaker dynamism and extroversion, they are also thought to indicate less trustworthiness and poise.

*Counterfactual utterances* represent a verbal type of speech error. If a speaker is intending to state accurate information, then any misstatement of fact or omission of data represents a speech error. The cause of counterfactual utterances could be due to poor recall of declarative knowledge brought on by any of the many causes of speech errors.

Some of the *causes of speech errors* include a heavy cognitive load, → communication apprehension and social anxiety, physical deformity, Broca's aphasia (a brain disorder that affects the user's ability to produce fluent speech), mental illness, advancing age (→ Aging and Message Production and Processing), message complexity (→ Information Processing), and a dialogue rather than a monologue communication format, where turn-taking is an additional communication obstacle speakers must successfully negotiate.

*Negative outcomes* associated with speech errors include negative judgments about the speaker on important social dimensions such as competence, social attractiveness, and trustworthiness. An abundance of speech errors is likely to lead to low ratings of speaker credibility and persuasiveness. Ultimately, these negative judgments will translate to an inability for a nonfluent speaker to accomplish social goals and achieve success relative to a fluent speaker. Speech fluency is a fundamental component of successful interpersonal, organizational, public, and mediated oral communication.

## Spin Doctor

Frank Esser

University of Zurich

The term “spin doctor” is an amalgam of “spin,” meaning the interpretation or slant placed on events (which is a sporting metaphor, referring to the spin a pool player puts on a cue ball), and “doctor,” derived from the figurative uses of the word to mean patch up, piece together, and falsify. The “doctor” part also derives from the employment of professionals rather than untrained amateurs to administer the spin.

The term “spin doctor” was coined by American novelist Saul Bellow, who spoke in his 1977 Jefferson Lecture about political actors “capturing the presidency itself with the aid of spin doctors.” The word “spin” first appeared in the press on January 22, 1979, in a *Guardian Weekly* article; the phrase “spin doctor” first appeared in the press on October 21, 1984, in a *New York Times* editorial commenting on the televising of presidential debates. It took another decade until it was picked up by academics: Maltese (1994, 215–216) discussed the significance of spin doctoring for political communication, and Sumpter and Tankard (1994) for public relations. Theoretical concepts most closely related to spin are priming and framing (→ Framing of the News; Priming Theory). Medvic (2001), for example, considers “deliberate priming” as the main responsibility of spin doctors, by which he means producing campaign messages that focus on issues that are to a politician’s advantage and trigger appropriate schemas within targeted voters when evaluating the politician. Other works tied spinning to “strategic framing,” which Bennett (2005) defines as delivering a message with the “right” scripting to lead journalists to pick the preferred category for accentuating the message (→ Election Campaign Communication; Strategic Framing).

It should be pointed out that many scholars do not take spin doctoring too seriously, because it is neither a neutral scientific concept (such as “communication”) nor the

self-labeling of a branch (such as → “public relations”), but rather a biased term used by journalists to discredit, hype, or mystify the work of political public relations (PR) experts (e.g., as powerful manipulators; → Political Consultant). To discuss the term’s relevance for political communication research it seems helpful to distinguish a realist and a constructionist position. The realist position tries to answer the question of what spin doctoring actually means, where spin doctors are active, and what they actually do. The constructionist position doubts the existence of spin doctors as such and considers the use of the term a rhetorical strategy; it tries to answer the question why this term has become such a prominent media phenomenon.

### REALIST APPROACH

Arguing from a realist position, Andrews (2006) distinguishes four stages with regard to how the term “spin doctoring” has been used and how it has changed its meaning in the process. Initially, spin was used as a *technical definition* of a specific US campaign tactic whereby, after a televised presidential debate had ended, campaign operatives emerged to try to massage how reporters interpreted the meaning of the event (→ Televised Debates). “Spinning gave political handlers a chance to explain away and thus repair the damage a candidate had done to himself, or to inflict damage on the opponent that their candidate might not have” (Rosenstiel 1994, 309). The practice of party officials patrolling their media contacts after major campaign events turned out to be of mutual benefit, because reporters were keen to speak to dependable sources capable of giving them an instant interpretation as well as background guidance on the likely consequences (→ News Sources). The 1988 US presidential election was a watershed insofar as for the first time the news media reported extensively on the practice of spin doctoring (Lemert et al. 1991).

In the second phase, the term rapidly spread to other countries and considerably *broadened in meaning*. From a specific post-debate tactic it came to signify anyone or anything included in what were believed to be the black arts of campaigning (Andrews 2006). By using the term in an increasingly arbitrary fashion, journalists themselves were arguably putting a spin on minor stories, presumably to increase readers’ interest. As a result, campaign techniques as varied as briefing journalists, explaining campaign strategy or candidates’ actions to journalists, attacking opponents, rapid rebuttals, speech and → image consulting, media monitoring, → political advertising, or opinion polling (→ Public Opinion Polling) were all attributed to spin doctors, a cross-national content analysis of campaign coverage found (Esser et al. 2001; → Content Analysis, Quantitative).

A contributing factor to a broadening understanding of spin doctoring was the documentary *The War Room*. This showed Clinton advisors James Carville and George Stephanopoulos engaged in a wide range of campaign activities during the 1992 presidential election. The press pictured Carville’s and Stephanopoulos’ personalities as so intriguing that it turned them into celebrities. Both readily admitted to being spin doctors (and even labeled themselves as such) and appeared on news programs, on talk shows, and in people magazines (as did Alastair Campbell or Peter Mandelson a few years later in Great Britain). Journalists and campaigners in other countries were also fascinated by *The War Room* and how it staged the campaign process as a glamorous sort of warfare. In the 1990s, carefully planned backstage access for journalists to observe the process of image

construction became an essential element of campaigns in many modern democracies. This highly managed strategy of meta-imaging (Parry-Giles & Parry-Giles 1999) triggered a new type of campaign coverage called meta-coverage (Esser & D'Angelo 2003).

In the third stage, spin made the progression to an encompassing word for *media operations of political institutions*. Important milestones in this development were John A. Maltese's book *Spin control* (1994), Howard Kurtz's book *Spin cycle* (1998), and Dick Morris's insider account *Behind the Oval Office* (1997). Maltese classified as spin control any measure by the White House Office of Communication – responsible for long-term PR planning – that governments since Richard Nixon used in an effort to influence media coverage of administrations and their policies. Kurtz focused on the White House chief press secretary Mike McCurry, characterized as a master of spin, and described his Press Office Staff as being engaged in a constant spin cycle designed to reactively downplay negative issues and proactively promote positive issues. Clinton adviser Morris emphasized the importance of bypassing the cynical mainstream news media and holding instead what he called a second conversation with the general public, by listening to it through polls and talking to it through ads. The same broadening of meaning signified by the term “spin doctor” could be observed in Great Britain. From there it was only a short way to the fourth and final stage when authors began to equate spin doctoring with any type of commercial PR (see Andrews 2006).

### CONSTRUCTIONIST APPROACH

Against the backdrop of this development, it becomes clear that any attempt to classify this particular circle of consultants precisely is an undertaking doomed to fail. The broad use of the term makes it difficult if not impossible to adequately define spin doctors from a realist position. As a consequence, the constructionist position explicitly steps away from the idea that the term “spin doctor” refers to a specifically defined group of people. This approach turns its attention to the question of why there is suddenly a new expression for a well-known and long-established profile of tasks (i.e., political PR). The constructionist position starts from the observation that newly emerging occupations (such as PR) try to attain greater professional recognition by employing strategies of self-promotion. This strategy involves stage-managing one's own importance by publicly promoting the marketable values of one's activity. In other words, this strategy is based less on the question of whether someone possesses certain professional characteristics or not, and more on the question of whether one is able to act and appear professional.

According to this *strategic approach toward professionalization*, the key resource for political PR experts in managing their professional status focuses on the presentation of their own performance. While the majority of political PR experts does not seem to go this route and prefers to remain invisible to the public, a small media-savvy minority began pursuing this strategy actively in the 1990s. These consultants consciously sought the media limelight and had a strong self-interest in creating and sustaining the myth of powerful, omnipotent “spin doctors.” Nowadays, there is probably nobody who would like to admit to being a spin doctor, but for some time the term appeared new and seemed to help some political PR experts to set themselves apart from existing or related occupations. Due to the media attention they received, this small group was highly visible

but not representative of the occupation of political PR experts as a whole. This mechanism helps explain the professional image of consultants that in some countries has remained distorted to this date (Tenschler 2003).

The second argument of the constructionist position refers to the behavior of journalists: they also had an interest in creating and sustaining the *myth of the spin doctor*. Initially, journalists used the term to hype or mystify political PR because it corresponded to an important journalistic demand: it adds drama and color to otherwise boring, stage-managed events. Stories about spin are enjoyable to write and easy to research because they naturally take place in the journalists' own direct environment. Undoubtedly, one can also assume a fair degree of professional narcissism when journalists report on political PR, because they implicitly write about themselves as the subject of news management. Later, journalists used the term in a more degrading manner in order to discredit the legitimate aims of candidates, parties, and governments to assert themselves against increasingly autonomous and powerful media organizations, which often pursue an agenda of their own and whose motives are not always exclusively oriented toward the public welfare. The *demonization of spin* is to be understood as a counter-strategy of journalists to prove their independence and legitimacy (→ Journalists' Role Perception). Yet the discrediting use of the spin metaphor by journalists oftentimes conceals the fact that political PR experts provide essential information, without which the media could not possibly carry out their task of informing the public about the internal mechanism of the political process.

The third argument of the constructionist position is that the widely noticed increase in news reports about political PR must be seen as an outcome of a new, modernized, and *media-centered approach to policymaking and campaigning* (→ Media Democracy; Media Logic). Just as politicians have become adept at devising strategies geared toward effectively communicating their policy and image messages to the electorate, so, too, have journalists adapted to these changing circumstances by weaving into stories information about the behaviors and roles of political publication experts, as well as about the behaviors and roles of journalists. On this basis, Esser & D'Angelo (2003, 2006) developed a theory of meta-coverage that works from the premise that journalists are compelled to cover political PR in order to accurately describe, interpret, and analyze the media politics environment.

## Spin and Double-Speak

Lisa T. Fall

University of Tennessee

The term “spin” has historically been associated with political and governmental campaigns. Two prominent citations stem from the *Washington Post* and *New York Times*. In 1977, *Washington Post* staff writer Spencer Rich wrote an editorial about Mike Pertschuk, former chief counsel and staff director, Senate Commerce Committee. Rich accused Pertschuk of “being too ardent a consumer advocate, of ‘lobbying’ members of the committee on behalf of things he thinks are good, of putting his own philosophical ‘spin’ on options, of being too close to Ralph Nader, of having excessive influence on Magnuson; in short, of acting like the ‘101st senator.’” In 1984, under the headline “The debates and the spin doctors,” *New York Times* editorial writer Jack Rosenthal predicted that “a bazaar will suddenly materialize in the pressroom” during a presidential debate between Ronald Reagan and Walter Mondale. He explained: “A dozen men in good suits and women in silk dresses will circulate smoothly among the reporters, spouting confident opinions. They won’t be just press agents trying to impart a favorable spin to a routine release. They’ll be the Spin Doctors, senior advisors to the candidates, and they’ll be playing for very high stakes.”

Doublespeak appears to be a “close cousin” to spin. Kinnick stated, “doublespeak represents a language that is strategically chosen to distort or obscure reality. It is often associated with misleading advertising claims, unethical politicians, and public relations

‘spin doctors’ who use language to frame a subject in the most positive light” (2005, 260; → Spin Doctor).

Somewhere between its early beginnings among the political arena and its present-day use, the term “spin” has become associated with the public relations profession. Sumpter and Tankard (1994) identified the *spin model* as an alternative approach being practiced in the public relations industry. Part of the reasons this profession may be connected with spinning behavior is because these practitioners have been – historically – associated with using → propaganda techniques. The term *propaganda* itself has a negative connotation. So we should consider the way we engage in and discuss the concept of strategic → persuasion. The term *motivation* has a much more positive connotation, and people seem more responsive to being *motivated* to do something than being *persuaded* to do it.

With something of the ominous and the conspiracy theory about it, the public relations spin model still prevails today. Evidence lies not only in the profession but also in the plethora of literature written about spin and its relationship to → public relations. The reasons behind this association are open to speculation; however, they may stem from misrepresentation and misinformation.

Public relations activities are very diverse. Some practitioners engage in publicity and promotional activities, and they utilize varying propaganda-type techniques (bandwagon, glittering generalities, etc.) and persuasive methods (→ Bandwagon Effect). Although this paradigm determines how many public relations professionals have been depicted on television, in the newspaper, and in movies, these are *not* the only kinds of activities in which practitioners are involved. Public relations professionals are responsible for much more, including strategic planning and counseling, → fundraising, researching, and developing and maintaining relationships between an organization and its key publics (→ Public Relations Planning; Strategic Framing). This is just a range – not a cumulative list by any means. And public relations is practiced among a variety of disciplines, ranging from health-care, government, entertainment, and travel/tourism to corporate, nonprofit, and financial institutions (→ Health Campaigns, Communication in; Issue Management in Politics; Political Consultant; Political Marketing; Financial Communication).

There are several reasons why the communication profession supports strategic persuasion:

- Every issue has two sides; hence, there are two viewpoints.
- Practitioners are merely utilizing framing and agenda-setting strategies (→ Agenda-Setting Effects) to disseminate their messages.
- Practitioners are responsible for advocating the viewpoint of the organization they represent, on the basis of the fiduciary relationship/commitment between the organization and its stockholders.
- Strategic persuasion has been around for centuries (e.g., James E. Grunig’s [1992] press agency model, Edward Bernays’s [1923] “engineering” of → public opinion).
- Society should be exposed to a “free marketplace of ideas,” which, in turn, supports socially responsible behavior.
- Strategic persuasion supports the absolutist view of the First Amendment to the US Constitution and corresponding provisions in other countries, and of moral judgment: actions are moral provided they yield positive consequences through moral conformity to moral rules.

There are also several reasons why the communication profession denounces spin:

- Spinning is unethical behavior because it misrepresents and distorts truth (→ Public Relations Ethics).
- Spinning is the antithesis of J. E. Grunig's two-way symmetrical model of public relations, which seeks to develop mutually beneficial relationships between an organization and its publics.
- Spinning is a form of propaganda that, when used deceitfully and manipulatively, does not fairly represent the information.
- The spin model suggests that public relations professionals are nothing more than "press agents" whose main goal and obligations are to "earn ink" and to make their organization "look good."
- The word "spin" has a negative connotation, and "perception is reality"; hence, some may view this negative word and its association with the behavior it represents as representative of the behavior of *all* practitioners.
- The spin paradigm does not support socially responsible behavior.

The word "spin" will never completely go away. However, by being kept alive via use in everyday dialogue, the word's existence is perpetuated, thereby giving it power to survive. Communication professionals should strive to diminish its use as a commonplace term among the media and further be committed to practicing ethical communication. Further still, they should never deceitfully manipulate a message to communicate half-truths. And the behavior of those who assert that they practice spin as their "duty" as communication professionals should be discouraged.

Finally, the public relations profession, in particular, should continue to educate people about what it is and its contribution to society. People need to be reminded that, although publicity and promotional strategies are viable components of the communication mix, they are not the sole functions of public relations. Furthermore, instead of advocating *propaganda* as the foundation for these activities, we need to broaden our thinking to that of *motivating* particular behaviors that influence positive changes in our society and of the free marketplace of ideas.

## Spiral of Silence

*Thomas Petersen*

*Allensbach Institute*

Developed by German survey and communication researcher → Elisabeth Noelle-Neumann in the 1960s and 1970s, the spiral of silence theory describes collective opinion formation and societal decision-making in situations where the issue being debated or decided upon is controversial and morally loaded (→ Public Opinion; Conflict as Media Content; Social Conflict and Communication). The theory is one of the most frequently cited and debated to emerge from the field of communication studies during the latter half of the twentieth century.

In the literature in the field, the spiral of silence theory is often reduced to a single premise, i.e., that people who feel their opinion is held by the minority tend to fall silent in public. Although this is a perfectly accurate description of one key aspect of the theory, it is in fact just one element of a far more comprehensive theory of how public opinion functions. This theory rests on the notion that there is such a thing as a “*social nature of humans*,” which causes people to fear social isolation and thus substantially influences their actions in public. The term “*public opinion*” then refers to opinions or behavior that can be displayed or expressed in public without running the risk of social isolation or, in some cases, that even must be displayed to avoid the danger of isolation. The term → “public” is here interpreted in a social psychological perspective as a state of consciousness in which individuals who are subjected to the gaze of those around them consciously realize that their actions are “seen by all” and “heard by all.” People must therefore constantly monitor the reactions of others in their environment (→ Social Perception).

Accordingly, Noelle-Neumann views public opinion as a form of *social control* that ultimately applies to everyone, regardless of social class. She states that this control is apparent in many areas of life, ranging from controversial political issues to → fashion, morals, and values. Noelle-Neumann’s understanding of public opinion stands in contrast

to another conception that views public opinion as the result of rational debate among an educated elite that is of crucial importance for the state (Holcombe 1923; Bourdieu 1979).

### ORIGINS OF THE THEORY

The theory originated from a surprising empirical research finding from the 1965 German federal election campaign. Over the course of 10 months, from December 1964 to shortly before election day, → survey findings on voting intentions remained practically unchanged, with a dead heat between the governing Christian Democratic Party and the opposing Social Democratic Party (→ Election Polls and Forecasts; Election Surveys). In the final few weeks and days prior to the election, however, the situation suddenly changed, with survey findings showing a so-called “last-minute swing” in favor of the Christian Democrats. The election outcome confirmed the final survey findings.

While voting intentions remained unchanged over the course of many months, over the same period of time responses to the following question had shifted dramatically: “Of course, nobody can know for sure, but what do you think: who is going to win the election?” In December 1964, the percentage of respondents who expected the Social Democrats would win the election was about the same as the share who anticipated a Christian Democratic victory. But by July 1965, the Christian Democrats were clearly in the lead; and by August, almost 50 percent anticipated a Christian Democratic victory. The relationship between the two measures – voting intention and expectation of the winner – made the *puzzle, which gave rise to the theory* of the spiral of silence.

Subsequently, especially during the emotionally charged federal election campaign of 1972, the Allensbach Institute gradually gathered survey data pointing to humans’ fear of isolation, to their tendency to speak out or fall silent in controversial, morally loaded debates. The pattern that had been observed during the 1965 campaign was detected again on other occasions – and thus the spiral of silence theory slowly began to take shape.

### KEY ELEMENTS OF THE THEORY

People experience fear of isolation. They have a fear – probably developed over the course of evolution – of being rejected by those around them. For this reason, people constantly *monitor the behavior of others* in their surroundings, attentively noting which opinions and modes of behavior meet with public approval or disapproval. But people do not only observe their environment. They also in part unconsciously issue their own threats of isolation via what they say and do, via behavior such as turning away from someone, knitting their brow, laughing at someone, etc. These are signals that individuals perceive, and that show people which of their opinions meet with their fellow humans’ approval and which do not.

Since most people fear isolation, they tend to refrain from publicly stating their position when they perceive that this would attract enraged objections, laughter, scorn, or similar *threats of isolation*. Conversely, those who sense that their opinion meets with approval tend to voice their convictions fearlessly, freely, gladly, and at times vociferously. Speaking out loudly and gladly enhances the threat of isolation directed at those who think

differently. It reinforces their sense of standing alone with their opinion and thus augments their tendency to conceal their opinion in public. A *spiraling process* begins, whereby the dominant camp becomes ever louder and more self-confident, while the other camp falls increasingly silent.

This process does not occur at all times and in all situations, but only in connection with issues that have a strong *moral component*. The process is not set in motion if there is no underlying moral foundation implying that those who think differently are not merely stupid, but bad. This moral element is what gives public opinion power, allowing it to raise the threat of isolation that sets the spiral of silence in motion. Only controversial issues can trigger a spiral of silence. Topics on which there is social consensus – true consensus and not merely outward agreement – give rise to no disagreement and thus leave no room for a spiral of silence. The actual strength of the different camps of opinion does not necessarily determine which view will predominate in public. An opinion can dominate in public and exert the pressure of isolation even if the majority of the population holds the opposing view, yet does not speak out publicly.

The *mass media* can significantly influence the spiral-of-silence process. If the majority of the media take the same side in a morally charged controversy, they exert a substantial, presumably even decisive influence on the direction that the spiral of silence takes. Thus far, no instances in which a spiral of silence ran contrary to the media tenor have been observed (→ Public Opinion, Media Effects on). As a rule, people are not consciously aware of either the fear or threat of isolation. They observe behavior in their environment that is indicative of self-confidence and strength, and react practically instinctively with fear and silence to threats of isolation raised by their surroundings.

Public opinion is *limited by time and place*. As a rule, a spiral of silence only holds sway over a society for a limited period of time. In this regard, there are both short-lived instances, such as the controversy over the sinking of the Brent Spar oil platform in some European countries in the 1990s, and extremely long-term examples, such as the growing tendency in western societies over the course of the past centuries to attach ever greater importance to the value of equality (→ Attitudes, Values, and Beliefs, Media Effects on). In geographical terms, the area in which a certain → *climate of opinion* predominates can be of varying size. There have even been a few cases of globally valid public opinion in recent history, such as the public opinion that isolated South Africa around the world for decades and ultimately forced the apartheid regime to step down from power. Generally, however, the process of public opinion and thus the spiral of silence tend to be limited by national borders or the borders of a particular cultural group. When viewed with hindsight or from an outsider's perspective, it is hard to comprehend the agitation and emotional fervor that accompany a spiral of silence.

Finally, public opinion serves as an instrument of social control, indirectly insuring *social cohesion*. Whenever there is especially strong integrative pressure in a society, as found in connection with the spiral of silence, this generally indicates that the issue or controversy that triggered the spiral of silence poses a particularly great threat to social cohesion. In extreme cases, the spiral of silence culminates in a situation where certain topics can either only be broached using a specific vocabulary (political correctness) or cannot be mentioned at all (taboo), lest people wish to be the target of extremely harsh signals of social isolation (Noelle-Neumann 1993).

## CRITIQUE OF THE THEORY

The theory of the spiral of silence has always been an object of controversy in communication research since its first publication in the *Journal of Communication* in 1974. Criticism concentrated on *three crucial issues*.

First, the theory was said to fail to consider, to a sufficient degree, the part that *reference groups* play in the formation of the population's opinions. People tend to orient themselves more strongly to their personal environment than to society or the public at large, so some critics hold (cf. Glynn & McLeod 1985). Second, Noelle-Neumann asserts that people are capable of estimating the distribution of opinions in the population. This capability, critics hold, is at odds with the well-documented phenomenon of → "*pluralistic ignorance*" – the majority errs about who is in the majority – and "looking-glass perception" – most humans tend to believe the majority shares their own opinion (Salmon & Kline 1985). Third, the theory of the spiral of silence is thought by some to possibly explain human behavior in societies that put much emphasis on the collective, but *not to apply to individualistic societies* such as the United States or many western European countries (Huang 2005). In addition to these three main points, Noelle-Neumann's thesis that the mass media play a decisive part in the development of the pressure of isolation, which silences those who hold the majority opinion, was criticized mostly in the early years.

Whereas the first critical argument rests on a misunderstanding insofar as Noelle-Neumann has never claimed her theory is the sole explanation of public opinion processes, and has never denied the importance of other influences such as reference groups on individuals' opinion formation, the other two arguments are in need of thorough testing. The theory explicitly holds that the behavior described is to be found in all societies, including decidedly individualistic ones. And the relationship between Noelle-Neumann's "quasi-statistical sense" (see below) and looking-glass perception is unresolved to this day.

## TESTING THE THEORY

On considering the wealth of studies that have attempted to empirically test the spiral of silence theory over the past 20 years, it is obvious that one of the greatest problems with any such endeavor is correctly identifying the type of social situation in which a test of this kind can be completed. This sort of situation cannot be arbitrarily created within the framework of a representative survey. Instead, researchers must wait for an auspicious moment to arise.

One common misapprehension concerns the concept of the "*quasi-statistical sense*," a term that Noelle-Neumann used to describe people's tendency to constantly monitor their environment, thereby assessing which opinions are gaining ground and may be expressed in public, and which views are losing ground and hence subject to the threat of isolation. The concept does not imply that people have a cash-register-like capability to continually estimate and record the percentage of the population that holds one opinion or the other.

Further, a test of the spiral of silence requires an *issue with certain prerequisites*. The issue must have a strong moral dimension, it must be in the public spotlight, and the public must be divided into different opinion camps. Further, a spiral of silence is particularly likely to come into being in situations where the majority of the mass media clearly side

with one of the opinion camps involved in the debate. In addition, the pressure of the climate of opinion that emanates from the issue must be so strong that respondents directly perceive the threat of isolation during the survey interview and do not have to imagine such pressure in a hypothetical situation (→ Public Opinion Polling).

On *analyzing the findings*, the behavior of respondents whose opinion is actually in the majority or gaining ground must be compared with the behavior of those who are in fact in the minority or whose opinion is under pressure from the climate of opinion. Comparing those who say they believe themselves to be in the majority or in the minority would produce misleading results. According to the theory, the threat of isolation is inseparably entwined with concrete issues and opinions. Whether people rationally believe their opinion is shared by the majority is irrelevant. Supporters of a standpoint that is subject to pressure from the climate of opinion tend to fall silent even if they – like most people – claim during the interview to hold the majority view (→ False Consensus).

If a suitable social situation for testing the spiral of silence can be identified, that is, a situation that involves a real struggle for public opinion, the following information must be obtained via surveys and media content analyses (→ Content Analysis, Quantitative) in order to test the spiral of silence:

- 1 the *distribution of opinions* on the issue among the population: which view is held by the majority and which by the minority? This information is needed to identify and compare the supporters and opponents of a particular opinion in the analysis phase of the investigation.
- 2 the *climate of opinion*; in other words, a question measuring the population's general feeling as to which opinion is getting stronger and which opinion is losing ground. This can be ascertained by means of questions such as "How do you think most people feel about this?" With this question one can pinpoint those issues that entail pressure from the climate of opinion. Whenever the percentage of respondents who believe that most people hold a particular opinion is considerably greater than the share who actually take this stance themselves, this is a sure sign that we are dealing with an issue that could ultimately trigger a spiral of silence.
- 3 *willingness to advocate a certain position* or speak out in public. This can, for example, be measured via the "train test," which has in the meantime become a classic question in spiral of silence research: "Suppose you are taking a long train ride and one of the passengers in your compartment starts talking strongly in favor of (or against) opinion X. Would you want to talk with this person so as to get to know his or her point of view better, or wouldn't you want to do that?" In countries such as the United States, where long train trips are unusual, other questions can be used. The most common version is the so-called reporter question: "Suppose a television reporter approached you on the street and asked you on camera about . . ."
- 4 the *degree of emotionalization* surrounding an issue – the strength of its moral component. There are a number of indicator questions that can possibly reveal the degree of emotionalization that a particular issue entails. Using one tried and tested model, respondents are presented with a number of topics and asked: "Which of these are delicate issues that might get you into hot water if you were to talk about them?"
- 5 the *intensity and bias of reporting* on the issue by the opinion-setting mass media.

Another reason why it has proved so difficult to test the spiral of silence theory empirically is the fact that these requirements rarely occur simultaneously and, even when they do, researchers must be able to begin measuring the effects on time. In cases where this has been possible, however, the findings would seem to confirm the validity of the theory. Examples of this are Cheryl Katz and Mark Baldassare's test of the theory completed during the 1992 US presidential elections, or Noelle-Neumann's own test during the 2002 German federal election campaign (Katz and Baldassare 1994; Noelle-Neumann and Petersen 2005).

# Spirituality and Development

*H. Leslie Steeves*

*University of Oregon*

Most approaches to → development communication are grounded in economic frameworks concerned with how material resources are allocated in society. The dominant → modernization philosophy aims to maximize individual opportunities for material gain, while critical perspectives argue for just distributions of resources and against the inequities of capitalist systems. Both literatures usually fail to consider non-material aspects of people's lives, thereby neglecting a vital resource for empowerment and social change (→ Communication Strategies for Empowerment; Planned Social Change through Communication; Secular Social Change).

Modernization is grounded in neo-classical economic theory and Enlightenment philosophy, which privilege the → public sphere of reason, science, technology, economics, and politics, and devalue other areas of human experience. Modernization therefore assumes that development should address material needs, whereas religion speaks primarily to spiritual needs, which may conflict with material gain. Material development goals require a set of communication strategies. In large projects, campaigns usually are planned in a highly rational and systematic manner via → social marketing research. Religion is seldom considered except as a barrier or a resistance point (e.g., to family planning or HIV prevention) that needs to be overcome by research-based strategic planning.

In much of critical or Marxian thought, religion and spirituality likewise are regarded as more problematic than helpful. Religion is the opiate of the masses, blinding people to material inequalities and injustice. While some critical arguments do address non-material concerns of ideological influence and cultural imperialism (→ Cultural Imperialism Theories), these arguments have been largely subordinate to questions of power over capital resources.

Hence, non-material considerations that move development to the realm of the spiritual have seldom been priorities of western development aid. Few writings on development communication in mainstream traditions have addressed the role of religion and spirituality. Most scholars and practitioners make only passing references to religion, as a simple demographic or in a negative sense, as an obstacle to development. Further, just as western development usually ignores non-material realities, much theological writing and practice focuses on religion and spirituality with little or no attention to material injustice.

Yet religion, spiritual practice, communication, and material realities are inseparable in most of the world. In contrast to the secular orientation of western cultures, in many societies religious values are a part of everyday life, providing a foundational framework for behaviors related to everything from clothing styles to childrearing to health-care. Also religious rituals play a central organizational role in marking key life events.

Not all of this is positive, as religion and spirituality often do seriously impede progressive social change. This may be particularly the case for women and minority

ethnic groups (→ Development, Gender, and Communication). Also heinous crimes have been carried out in the name of religion.

Efforts to bridge the intellectual gap between the material and spiritual may be found in the practice of → hermeneutics, which involves the interpretation of sacred texts within historically specific contexts. Hermeneutics therefore assumes that no religious beliefs and practices are fixed and rejects a sharp and inseparable divide between people's spiritual and material needs.

Outcomes of hermeneutics include liberation theologies within every major religion, with leaders who are making arguments for development as a process of liberation from injustice, discrimination, and prejudice wherever they occur, including within their own organizations (Melkote & Steeves 2001). These arguments – plus accompanying faith and spiritual practice – frequently catalyze activism and provide openings for individual and community empowerment and social change.

In applications of liberation theology to development communication and education, the work of Paolo Freire (e.g., 1970) is particularly significant. Although his ideas emerged initially from the Christian liberation theology movement of 1960s Brazil, he drew upon works from other traditions as well, especially that of Ghandi. The impact of his arguments and methodologies has been broad, beginning in Latin America and spreading globally. From liberation theology, Freire's assumptions of what development communication should do are radically different from the assumptions of modernization, which emphasizes message transfer supportive of economic gain. Rather, for Freire, development communication ideally is emancipatory dialogue that leads to expanded individual and communal consciousness and power. Freire assumes that once people name their sources of oppression, as well as their sources of power, they can determine their own collective and individual solutions via a process of action and reflection. For development communication practice, the central focus should be dialogue. The success of the awakening process via dialogue requires spiritual practice, a form of communication seldom examined by western communication specialists.

The assumption is that spiritual practice by individuals and groups taps resources that provide the necessary consciousness, energy, and motivation for change. Other forms of traditional religious communication may additionally be significant in the liberation or empowerment communication process. These forms are unique to each religious tradition and culture (→ Culture: Definitions and Concepts), and may include song, → dance, storytelling (→ Storytelling and Narration), and gatherings of groups with shared interests. Additionally, uses of mass-mediated information and communication technologies are not necessarily inconsistent with the goals of liberation (→ Information and Communication Technology, Development of).

Freire has inspired many scholars and practitioners who remain secular in their assumptions. Additionally, arguments consistent with his approach are made by some branches of feminism and of critical scholarship, and by advocates of communitarian theory (→ Feminist and Gender Studies; Critical Theory); all advocate context-based dialogue as a means of challenging unequal power relations. Yet Freire and other proponents of liberation theologies go further in emphasizing the role of religion and spirituality in dialogic processes of empowerment.

A particularly well-known application of Christian liberation theology is the base ecclesial community movement in much of Latin America. The US Civil Rights movement is another. However, there are many examples in other religious traditions, including Hinduism, Buddhism, and Islam (Melkote & Steeves 2001).

Most development projects do not rise to the level of social movements (→ Social Movements and Communication). Yet their strategies and outcomes can be improved via consultation and active collaboration with religious and spiritual leaders. For examples, see the journal *Media Development*, published by the World Association for Christian Communication, and also the website of the Communication Initiative, and its free online publication, *Drum Beat*.

## **Sports and the Media, History of**

*David Rowe*

*University of Western Sydney*

Sports and the media, from the vantage point of the twenty-first century, are so deeply interconnected as to give the impression of a smooth integration between two powerful socio-cultural institutions. Many – perhaps most – people across the world have a daily encounter with the sports media in some form (→ Sports as Popular Communication), including print, electronic, online, and even branded T-shirts and footwear (Boyle & Haynes 2000; Rowe 2004). But it has not ever been thus, and the history of sports and the media has been marked by competition and conflict as well as cooperation and synergy. Indeed, this history can be adjudged a struggle for power over sports and spectatorship that the media seem largely to have won, although at some organizational and financial cost. This is not just a matter of contending information and service industries, but also of social institutions, the people who engage with them as workers or consumers, and the

wider impact of the media–sport relationship on local, national, and global popular culture (→ Globalization of the Media).

## HISTORY OF THE RELATIONSHIP

Sports and the media can be regarded as a “match made in heaven,” but might also be seen as a relationship prone to degrees of disharmony. Sports as understood today emerged in eighteenth-century Britain as a codification of earlier forms of folk play and physical culture. It displayed both a strong commitment to amateurism (playing the game for the love of it) and a strengthening professional ethos as part of the growth of industrialized leisure, in which spectators would pay to watch sports contests in enclosed spaces, engage in betting and wagering on them, and enjoy an overall social experience that conventionally involved consuming alcohol and vocally supporting one team or individual against another. As sports increasingly mutated into the “sportsbiz,” they became integrated into commercial structures and practices that, while not entirely stripped of their premodern, precapitalist features, became progressively removed from them (Rowe 2004).

Sports developed as significant social and commercial activities, and so, in the first instance, the print news media began to cover them as part of daily life, and also promoted sports events through advertising and sponsorship (Harris 1998). This was the beginning of an exchange relationship between sports and the media – newspapers informed potential consumers of forthcoming events and subsequently reported on them, while at the same time attracting readers and advertising revenue from sports and other nascent and established industries (→ Advertising). It soon became apparent that sports could attract popular attention and enable product endorsement, as effective means of capturing audiences for exposure to commodities given the seal of approval by respected, even revered athletes. In return, sports received a higher profile and greater visibility, so cementing their social importance and commercial viability, and inducing an upward spiral of *print media coverage* and sports prominence. Thus sports journalism developed far beyond mere provision of results and factual description, consuming many pages of → newspapers and → magazines (both general and sport-specific). The discourse of sport, therefore, insinuated itself into the everyday lives not only of sports appreciators (now referred to as fans), but of all those acquainted with a media culture, in the first instance deeply reliant on the written word and the still photograph.

Sports and the media, though, were still substantially constrained by time and space until the early to mid-twentieth century. Sports involved mainly local events, and, even where local “representatives” traveled to sports contests, the limitations of the print and telegraphic media dictated that events could be anticipated and reported only after considerable delay, given the available technologies of print media and physical transport. Sports newsreels were popular, but involved the cumbersome process of transportation to exhibition venues.

But the media became less and less temporally and spatially constrained, by means of first → *radio* and then → *television broadcasting* (Buscombe 1975; Rader 1984). The latter, crucially, offered both unprecedented audiovisual representation and instantaneity

to a majority of citizens in western countries in their homes within two decades of World War II (and with striking vividness following the introduction of color television; → Television as Popular Culture). This technology (→ Television Technology), and the major sports events it covered (such as the Olympic Games and the Association Football World Cup), enhanced the globalization of sports (Miller et al. 2001).

## RESEARCH QUESTIONS

At the moment when the electronic media could give a strong impression of “having been there” to viewers, two key questions were raised: could the media representation of sports create superior experience to that involving physical attendance? Would the institution of the media come to dominate that of sports? Sports organizations were generally concerned about the impact of television on attendances and so their prime source of revenue – gate takings. But the sale of broadcast rights on a competitive basis, with its associated spin-offs of merchandising, marketing, and publicity, facilitated a massive infusion of capital that accelerated the professionalization of sports and created the conditions for a more fluid national and international sports labor market (Miller et al. 2001), and new linkages of sports to other industries, such as fashion, clothing, and tourism.

In countries with strong public service broadcasting systems, such as Britain, much of continental Europe, Canada, Australia, and New Zealand, the heightened commercial desirability of sports through broadcast media had the progressive impact of reducing the role of public service broadcasting in sports (→ Public Broadcasting Systems). In nations with a historically stronger private television sector, notably the USA, commercial television has always dominated sports broadcasting (Chandler 1988). Television sports competition under such circumstances developed as that between advertiser-supported free-to-air networks and subscription or pay-per-view arrangements, the latter constituting an “electronic turnstile” that parallels the cost of physical entry to the sports arena. As more countries have followed cable and satellite televisual sports provision at the expense of public and private free-to-air access, one of the most pressing issues in contemporary media sports has emerged – that of the “cultural citizenship” rights attached to the free and unencumbered broadcast provision of prime sports events conceived as being of major national cultural significance (Rowe 2004). Contentious debates over whether citizens should pay to watch major sports on television that were previously provided free-to-air demonstrate the density and intensity of the media–sports nexus (Boyle & Haynes 2000). As with other cultural forms, these matters revolve around questions of production, text, and reception (Wenner 1998), but in terms not of whether sports and media should interconnect, but of how, and according to which set of power relations.

## POWER OF MEDIA CORPORATIONS

With regard to the production of media sports, the main area of concern involves the growing global power of media corporations, notably News Corporation, over sports (→ Political Economy of the Media). Rupert Murdoch, News Corporation’s current

chairman and manager director, is frequently cited as the most powerful individual in contemporary sports, and regularly asserts the importance of subscription television sports as a “battering ram” in breaking through to viewers with a wide range of interactive media services, ranging from gambling to shopping. The *tendency to monopoly power* in the highly capitalized world of broadcast sports is not just revealed in the development of global media sports networks and the swallowing of smaller “players,” but also extends to the ownership of sports clubs by media companies (→ Consolidation of Media Markets; Concentration in Media Systems). These arrangements open up enormous possibilities for cross-promotion across print and electronic media platforms, but also provoke concerns about conflicts of interest, in which media companies may exert excessive power over sports competitions and organizations (Miller et al. 2001; Rowe 2004).

These issues surrounding media sports production have a direct impact on the second key area of concern – that of the *media sports text*. The → spectacle of sports is a highly salable commodity, but the sports event in real time and space constitutes only the apex of a much larger entity – the mediated audience. For example, in order to maximize television viewership, sports events can be represented in a more dramatic fashion, with the imperative of attracting and holding attention leading to faster, more spectacular audiovisual images (Goldlust 1987) that show little respect for the tactical subtleties and variations of pace savored by more committed sports fans (a minority of the potential audience). Media corporations can also exert considerable power over sports rules and forms, such as tie-breaks in tennis and one-day cricket matches, which are both “telegenic” and more easily contained in predictable temporal frameworks. To accommodate broadcast audiences in key markets, especially the east coast of the USA, Olympic marathons may take place in the heat of the day, swimming races in the early morning, and boxing matches after midnight. Similarly, in the news media, sports are increasingly molded to entertainment coverage, with celebrity scandals and gossip turning sports into a much broader cultural phenomenon (Boyle 2006) that may have little direct dependence on traditional conceptions of it.

## **ROLE OF THE AUDIENCE**

This refashioning and proliferation of media sports texts raises issues of relationships with, and impacts on, audiences. It is misleading to see audiences as simple victims of powerful media sports organizations: individually and collectively they not only have the capacity to protest against developments in media sports, but also hold the ultimate power of veto – to refuse to view or read what is produced. But it is difficult for sports aficionados, who may well have a lifelong attachment to sports, to resist (in both senses) media sports. Thus, while audiences may sometimes be successful in obstructing aspects of the transformation of media sports – for example, lobbying governments to block takeovers of sports clubs by media companies or to introduce stricter protections for broadcast sports access – they conventionally use the media services (especially televisual) made available to them. The qualities, meanings, and uses of these media sports texts and audience interaction with them should, therefore, be subject to close scrutiny. Critical media sports scholars analyze the ways in which these seemingly innocent, pleasurable

texts have embedded within them damaging ideologies, including sexism, homophobia, racism, ethnocentrism, class prejudice, excessive nationalism, and xenophobia (Wenner 1998). Correspondingly, media sport producers are called upon to disseminate “progressive” messages opposing sports’ enlistment as a vehicle of social oppression. Thus, media sports are fertile ground for the testing of socio-cultural theories and concepts linking sports to major structures of societal power, and interrogating the politics of popular culture.

The history of media sports is a dynamic one, and in the contemporary context many new and potential changes are evident, such as the increased availability of media sports texts via flexible, digital, and converged means such as digital television, computers and mobile phones, and new forms of sports journalism (Boyle 2006) made possible by the Internet and the practice of blogging. There is no doubt that the established interdependence of the media and sports will persist, and that new forms of media sports representation will emerge, such as the use of implanted technology that will turn athletes’ experience of sports contests into the virtual reality of spectators. The institutional specificity of the media and sports should be acknowledged, while at the same time it should be recognized that studying them and their links to wider social processes reveals much about the formation and constitution of contemporary societies.

# Sports as Popular Communication

Marie Hardin

Pennsylvania State University

Although they are often framed as “merely” fun and games, sports and the communication that surrounds them influence social norms. Many scholars recognize that the “sports–media complex,” identified as such by Jhally (1989, 77) because of the virtually inseparable relationship between high-profile sports and media, is one that entertains but also reflects and reinforces existing social dynamics. As outlined by media sociologist Robert McChesney (1989), the sports–media complex is a commercial enterprise and has evolved in pace with consumerism and with communication technology.

Since the rise of → television in the mid-twentieth century, sports communication has diminished emphasis on traditional western ideals associated with sports (such as fair play and teamwork, for instance) and moved toward what some scholars call “sportainment” or “confrontainment,” which emphasizes individual stars (e.g., Tiger Woods, David Beckham, Michael Schumacher) and spectacle in mega-events such as the World Cup or American Super Bowl (→ Sports and the Media, History of).

## THE PHENOMENON OF SPORTS COMMUNICATION: SCOPE AND IMPACT

More than perhaps any other single genre of entertainment, sport has the power to draw national and global audiences simultaneously to a single event – to watch, cheer, cajole, and, occasionally, cry. In the case of an international competition (such as a World Cup soccer match or the Olympics), the sports stadium holds just a fragment of its audience. Millions of fans, speaking dozens of different languages and living thousands of miles apart, may also share the experience through mediated coverage. Events smaller in scope, such as an Australian rugby game, also draw significant audiences. Four of the ten most-watched shows in US television history (→ Television: Social History) have been Super Bowls. The audience for the 2004 Olympics in Athens was 3.9 billion, up from 3.6 billion for the 2000 Olympics in Sydney. Audiences for sports can rival those for televised phenomena such as the funeral of Princess Diana or the finale of the top-rated US sitcom *Friends*, which drew more than 50 million viewers in 2004.

Viewers translate into advertising dollars and profit for sports organizations, sponsors, and media partners (→ Advertising, Economics of). For instance, broadcast and cable networks in the US pay billions of dollars per year to broadcast games of the National Football Leagues, and yet they do so in expectation of a profit as they charge advertisers to reach a target audience. The average Super Bowl commercial sold for \$2.4 million in 2005, and the FIFA World Cup media rights value reached \$879 million in 2006 (Bryant & Holt 2006).

There is no reason to believe that such growth in consumption and revenues will not increase as young audiences demand coverage of a wider array of sports and as technologies make it possible to track live events virtually everywhere.

## DEVELOPMENT OF THE SPORTS–MEDIA COMPLEX

The marriage of organized sports and media in Canada, the US, and Europe has followed the same general trajectory, as part of newsheets and magazines in the early-to-mid-1800s, mass-circulation newspapers in the mid-1800s, radio in the early-to-mid-1900s, and then television and the Internet during the past half-century (→ Newspaper, History of; Magazines, History of).

The *sporting press*, which began its rapid expansion during the nineteenth century, communicated on a wide scale the cultural parameters of sports. Mass-circulated media accounts generally did not question the politics of sports or the behavior of athletes but instead used sports as a way to provide escapist fare to draw the largest possible audience and attract advertisers. During the early twentieth century in the US, for instance, top-circulation newspapers allowed the lines between journalists and sports organizations to blur as team owners paid newspapers to cover their teams on the road, which manifested reporting that ignored unethical behavior by athletes and instead took a “gee-whiz” tone and promoted athletes as heroes. At the same time, advertising became central to the consumer-driven economy, and mass media came to depend on advertisers, which sought outlets that were attractive to consumers.

The *rise of radio* in the 1920s, and, more importantly, that of *television*, made the live spectator experience possible for those outside the ballpark or arena. The explosion of televised sports has been facilitated since then by global economic factors: it has provided a readymade vehicle for major transnational corporations to develop brand-name recognition and cultural familiarity (→ Branding) and to push consumption. Technological developments that led to sports coverage via cable or satellite (ESPN was launched in 1979; → Satellite Television; Cable Television), the → Internet, and, now, wireless devices have continued to feed the voracious public appetite for sports coverage and the corporate desire to promote brands and products. For instance, multinational media owner Rupert Murdoch uses sports entertainment as a “battering ram” (lead offering) in → News Corporation’s pay-television operations because, as he announced in the 1990s, sports has more power than any other form of entertainment to draw viewers (cited in Cashmore 2005, 365). Nike, a multinational corporation that started as a sports-and-fitness apparel maker in the 1970s and has since moved into sports entertainment, perhaps best evidences the synergy between commercial sports and consumption. Nike’s marketing of NBA superstar Michael Jordan to sell shoes during the 1990s was a key reason its revenues increased more than eight-fold from the mid-1980s, and enabled it to position the famous swoosh and logo (“Just Do It”) with the pursuit of sports and fitness globally (→ Globalization of the Media).

## THE SPORTS–MEDIA COMPLEX AND SPORTAINMENT

Broadcasters and cable operators rely on the audiences and advertising revenue that sports coverage generates. Sports leagues depend on broadcast rights fees, which can run into the hundreds of millions annually. Both institutions – sports and media – have transformed to accommodate their symbiotic relationship.

An example of this is in the way broadcasters invest and brand themselves by their sports coverage, as in the NBC Network's investment of significant resources in coverage of the Olympics, and the way sporting events have altered themselves to fit the commercial demands of TV (e.g., rule changes in international tennis to speed up the game, compression of cricket tournaments, and "television timeouts" in American football games). Sports must make themselves "televsual" to thrive, and networks and cable operators must be willing to attain the most televisually friendly (thus, popular) sports (→ Television Networks). Further, advertisers' demands for access to target consumers, combined with the technological ability of media producers to reach them, has led to fragmentation and specialization of sports programming. Audiences can be sliced into thinner and thinner segments on the basis of media they seek. For instance, US advertisers who want to reach devoted auto-racing or horse-racing fans who watch cable television in a particular region can speak to them via networks such as the Speed Channel. The Internet has also provided space for advertisers to reach groups of consumers based on narrowly defined interests, including in sports that may receive relatively little television coverage, such as professional weightlifting (→ Audience Segmentation).

To retain audiences to deliver to advertisers, televised (and Internet-streamed) sports must also be entertaining (→ Enjoyment/Entertainment Seeking). This demand has led to increasing pressure on leagues, teams, and athletes to become spectacles. John Gerdy, author of *Sports: The All-American addiction* (2002), argues that this emphasis on sports-as-spectacle has produced "*sportainment*," which is generally devoid of the values traditionally cherished in organized sports, such as character-building, teamwork, and sportsmanship. Instead, athletes have been transformed into entertainers; thus sports for sports' sake have been trivialized. Other critics argue that "*confrontainment*" is a more apt descriptor because of the emphasis on conflict-driven drama in programming. Media and culture critic Michael Real (1998, 25) has compared the presentation of sports mega-events to cockfights because of their emphasis on "death, masculinity, rage."

## REFLECTING SOCIAL NORMS AND CULTURAL IDEOLOGY

Sports cross national and cultural boundaries more readily than perhaps any other form of entertainment, making their potential for consumption limited only by their reach. Sports coverage may promote nationalist agendas by the way athletes, teams, and events are presented. Real political events impact coverage; Cashmore (2005) points out that since 1956, every summer Olympics has been implicated in some kind of controversy. (In Athens during 2004, for instance, the US team stayed aboard a cruise ship because of perceived threats from Al-Qaeda.)

Research indicates that media commentary involving international sports is driven by nationalist agendas, as sports become a symbolic extension of the power and identity of participating countries. One way media accounts reflect nationalism is by stereotyping other countries and athletes from those countries. In one analysis of 340 hours of international even coverage, Sabo and colleagues (1996) found that American commentators accused other countries of having a political agenda in the games and made negative comments about how international athletes were sponsored. Also, Denham's (2004) study

of coverage of US track and field star Carl Lewis, accused of using performance-enhancing drugs in previous Olympics, found sympathetic coverage of him in American media but international stories that accused him of being sanctimonious, arrogant, and hypocritical.

Sociologists including Coakley (2004) and Sage (1998) have also argued that depictions of sports, through repetitive emphasis on men, the able-bodied, and certain ethnic groups to the exclusion of others, reinforce a *social hierarchy*. Although legal and social changes in many western countries have resulted in tremendous increases in sports participation by traditionally marginalized groups such as girls and women, racial and ethnic groups, and the disabled, a vast amount of research shows that in sports media depictions they are generally invisible or are stereotyped in unflattering ways (→ Stereotyping and the Media; Sex Role Stereotypes in the Media). Sports sociologists including Rowe (2003) and Messner (2002) have argued that such depictions (or lack thereof) are choices by media gatekeepers based on an ideology that devalues women and those who do not match the ideal body standard. Sports journalists and producers, such as Leonard Koppett (2003), however, have argued that such depictions reflect the reality of sports, in which able-bodied men are naturally dominant, and that such coverage is justified by audience demands. They argue that these demands are not shaped by, but instead drive, decision-making by media gatekeepers.

### **IMAGES OF WOMEN AND MINORITIES IN SPORTS**

Although women and girls make up 40 percent of overall sports participants in the US, they receive (at best) only around 10 percent of the media coverage of sports. This general pattern is replicated in other western countries and is irrespective of medium. An example of the diminished coverage women receive in comparison to men can be found in a longitudinal study (1989–2005) of sports-related television coverage on ESPN and major US television networks. The study found no increase in the number of stories about women's sports; for instance, on ESPN's flagship show, *SportsCenter*, just 1 in 20 stories involved women's sports (Duncan et al. 2005).

Many studies have reached the conclusion that *media accounts of women's sports* are often ambivalent (→ Gender: Representation in the Media) and position women as less suited for sports than men, although a handful of recent studies have documented equal treatment of male and female athletes, especially in Olympic coverage. Messner (2002) has asserted that an increased female presence in sports has turned the sports–media complex into “contested terrain,” with evolving depictions of women and alternatives to the traditional stereotypes of women in sports outlined by Griffin (1998). Complicating discussions of the stereotyping of women in sports media over the past decade, especially, has been the emergence of what has been called “pro-sex feminism,” which espouses individual choices by female athletes to present themselves in sexualized ways as empowering (Projansky 2001). Thus, the sex-symbol status in recent years of Russian tennis player Anna Kournikova, whose athletic career failed to net a major singles tournament win yet whose marketing and media presentation made her one of the most recognized (and lucrative) names in women's sports, can be read as either a diminishment of women in sports or a choice made by individual female athletes to best position themselves in the sports–media complex.

Grainger et al. (2006) suggest that *images of race* (→ Rhetoric and Race) presented in mediated sport may be the most significant way that individuals understand the contemporary racial order in society. Mediated sports provide some of the most prominent “actors” in contemporary entertainment, and many of them are athletes of color. The use of racist stereotypes in sports coverage, especially in the US, is less prevalent than it was several decades ago. The civil rights movement and increased sensitivity of media producers to their audiences has subdued blatant references to black people (including African-Americans) and members of other racial or ethnic groups as less intelligent than their white counterparts (→ Civil Rights Movement and the Media). Further, studies in recent years indicate that some racial groups (especially African-American men) are not marginalized, but are instead highly visible, although in limited roles, in the sports–media complex.

Still, according to Hoberman (1997) and Cashmore (2005), issues of representation exist in the reinforcement of racial ideologies, such as the reproduction of “natural” black superiority and that of the typical deviant or dangerous black man. Billings (2004), who examined commentary about quarterbacks in US college and professional football leagues, found that in televised games, references to non-white athletes have emphasized athletic ability in ways that imply diminished cognitive ability. Hoberman has argued that reinforcement of these images, coupled with the absence of people of color in other areas of the news, such as politics and business, has resulted in the false belief by black youths that sports – and sports alone – are their only path to upward mobility.

Although racial and ethnic minorities are visible, elite-level athletes who participate in adapted sports are virtually invisible. Although the Paralympics is second in scope and size only to the Olympics, it receives relatively little coverage in Canada, Australia, Europe, and Asia and is ignored in the US, receiving less coverage than sports such as billiards and bowling (→ Disability and Communication; Body Images in the Media). When adapted-sport athletes are covered, studies show that they are portrayed as objects of pity instead of as authentic sports heroes; an example is network coverage of Paralympian Hope Lewellen, which Schell and Rodriguez (2001) found focused far more on her disability than on her athletic accomplishments.

## **FUTURE DIRECTIONS**

Sports communication is dynamic and complex as it interacts with economics, technology, politics, and social life. Sports offer real-time drama, often on the world stage, in a language (the body in action) that can be read across cultures. A public appetite for “sportainment,” coupled with corporate desire to reach target audiences through sports programming, guarantees that offerings and opportunities will continue to grow. The infusion of interactive technologies makes the possibilities even greater.

As technology and social changes interact with the sports–media complex, communication scholars must recast their questions and seek to understand how new ways of mediating sports interplay with cultures. For instance, how will younger sports consumers and gatekeepers *define* sports? How will the increasing specialization of and interactivity between media producers and audiences, and the infinite opportunity for coverage and communities provided by the Internet, influence the ways ideology is reinforced? More

research that examines the motivations of producers and of audiences in relation to emerging sports–media texts is needed.

## Stage Fright

*John Daly*

*University of Texas at Austin*

Stage fright is the anxiety and nervousness people experience when delivering oral presentations. In the field of communication, stage fright has also been studied under a variety of rubrics including public speaking anxiety, reticence, and audience anxiety. It is one of the oldest topics that communication scholars have studied empirically (Clevenger 1959), perhaps because it profoundly affects so many. In survey after survey of people's greatest fears, giving speeches always appears toward the top of the list.

Given this, it is not surprising that stage fright is a popular topic in textbooks on public speaking. Speakers are not the only people who experience stage fright; musicians, actors, and dancers also often have it. The emphasis in this entry is on the stage fright experienced by speakers because that is where the bulk of communication scholarship is focused.

Stage fright is conceptualized in two basic ways. The first is as a trait-like disposition – some people are more uncomfortable and nervous when talking to audiences than others. The second is as a response to particular situations – everyone gets nervous sometimes when they make speeches.

### DISPOSITIONAL STAGE FRIGHT

#### Symptoms

The majority of academic research on stage fright focuses on dispositional anxiety. It is important to distinguish the research on dispositional stage fright from a larger body of scholarship on communication apprehension. While the roots of research on communication apprehension lie in stage fright, in the past two decades the communication apprehension construct has been broadened to incorporate fears individuals have about communicating in a variety of contexts (→ Communication Apprehension). Very few

researchers have studied what causes people to have dispositional stage fright. What is known is that among the contributors are: (1) inexperience in speaking in public, and (2) a history of aversive experiences when making presentations. There is also evidence that suggests some genetic predispositions for dispositional stage fright.

*Physiologically*, stage fright is often marked by sweaty palms, a nervous stomach, shaking hands, and a racing heart. Behaviorally, people with stage fright tend to pause more, stutter more often, and use more adaptors (nervous movements) when speaking in public. Cognitively, people with stage fright often have difficulty focusing on their presentations. They are less interested in knowing about upcoming presentations, and what they are interested in does not match what experts in public speaking think should be their primary concerns (e.g., they want information about how they will be evaluated and have a number of other self-related concerns). People with high levels of stage fright are less interested in environmental characteristics associated with a future presentation (e.g., nature of the audience, setting). Highly anxious people also select topics with which they have less familiarity (Daly et al. 1989). They tend to be much more self-focused when speaking than people without anxiety. It is not surprising that they give less effective speeches than people with less dispositional stage fright. Part of the reason their speeches may be less effective is that when preparing presentations they focus on things that are irrelevant to good presentations (Daly et al. 1995).

Interestingly, observers' ratings of speakers' anxiety and speakers' self-reports of their anxiety are, at best, only modestly correlated. Audiences do not see speakers as having as much anxiety as speakers report experiencing (Behnke et al. 1987). In fact, when speakers become aware of how inaccurate their judgments are, the quality of their performances improves (Savitsky & Gilovich 2003; → Speech Anxiety).

Public speaking anxiety is inversely related to emotional stability, extraversion, intellect, affect intensity, and self-esteem. Anxious people see audiences as less agreeable and fear negative opinions more.

### **Treatment of Dispositional Stage Fright**

Popular literature often recommends that nervous speakers simply face their fear – the notion is that if they get up and give some speeches, they will slowly overcome their anxiety. This works for people who have a limited degree of stage fright. But for those with extreme stage fright, this approach can backfire. If people are really scared of speaking in public, they probably will not expose themselves to many opportunities to give speeches. So when they do make a presentation, they are less likely to do well. That poor performance, in turn, confirms that they should be extraordinarily nervous about making presentations.

Most research suggests that skills training alone is not sufficient for reducing stage fright (Duff et al. 2007). But when skills training is done in conjunction with some of the treatments discussed below, there are significant reductions in individuals' level of stage fright (Allen et al. 1989). Importantly, skills training must follow, not precede, other therapies (described below) (Hopf & Ayres 1992). Some recent research has challenged the notion that therapies are any better than public speaking training in reducing dispositional stage fright.

There are *two major therapeutic approaches* to alleviating dispositional stage fright. The first is *systematic desensitization*, which seeks to link relaxation rather than nervousness to communicating. In the therapy, people suffering from stage fright sit in a slightly dark room, listen to peaceful background music, and practice deep muscle relaxation. When they are relaxed, the therapist gently presents a hierarchy of scenarios that might create nervousness (e.g., an initial prompt might be talking to their friend about the weather; a much later prompt would be giving a speech in front of their friends and family). The moment a scenario raises even a little anxiety, people are instructed to signal the therapist. The therapist tells them to again start relaxing and after they are relaxed, the process starts again. Over time, people begin to tie public speaking to thoughts of relaxation rather than nervousness. Critical to this method are making sure that people understand that relaxation is something they have control over, and belief that the treatment is a credible one.

A second technique is *cognitive restructuring*. This technique assumes that people suffering from dispositional stage fright have unrealistic or irrational beliefs about presentations, which create stage fright (e.g., “I know people will laugh at me,” “I know I will say something stupid”). The therapy gets people to change those beliefs to more positive ones. This is done, in part, by challenging the reality of the irrational beliefs (e.g., “How do you know people will laugh at you?” “Have people laughed at you when you spoke in the past?” “What’s the worst thing that would happen if people did laugh at you?”) and having people, instead, generate more positive beliefs (“Most people have some nervousness. It’s normal and really reflects excitement!”).

A closely related approach is Motley’s communication oriented motivation (COM) approach (Motley & Molloy 1994), which suggests that people experiencing stage fright are too focused on performing and that they should be more focused on communicating with audiences. In this treatment, people’s negative or dysfunctional beliefs about speaking are challenged (e.g., that speaking is a novel activity different from conversing, that it must be more formal, that audiences carefully scrutinize speakers) by ones that highlight the communicative value of speaking (e.g., speaking is an important way to accomplish your goals; speaking is not really that different from having conversations).

There are, of course, many other potential treatments including medical ones (e.g., the use of beta-blockers), visualization, meditation, and biofeedback (→ Communication Apprehension: Intervention Techniques).

## SITUATIONAL STAGE FRIGHT

Everyone, even very experienced communicators, experiences some degree of stage fright when giving speeches. Indeed, there are positive consequences to having some degree of arousal when making speeches. The causes of situational stage fright are numerous and include (1) inadequate preparation, (2) heightened sense of conspicuousness, amplified by (3) a sense of being evaluated, especially in high-stakes environments, (4) audience size, (5) audience status, (6) the novelty of the setting, (7) rigid rules about presentations, (8) perceived audience disinterest in the topic, and (9) nonresponsiveness on the part of audience members (Daly & Buss 1984; MacIntyre et al. 1997; Witt & Behnke 2006). Dispositional stage fright interacts with various situational variables to affect performance

such that for people high in dispositional stage fright these situational characteristics amplify situational anxiety and its consequences on performance.

In *coaching people* to overcome situational stage fright, popular techniques include familiarizing speakers with the setting and audience to reduce novelty; aiding people in choosing topics that are familiar to them; teaching presenters ways to better prepare presentations; encouraging speakers to relabel their arousal from fear to excitement; coaching presenters to focus more on audience members, shifting attention away from themselves to others; helping presenters develop relaxation skills (e.g., deep breathing) prior to presentations; guiding speakers to ignore or reject unrealistic or rigid beliefs about “rules” of speaking (e.g., you do not need to tell a joke at the start of presentations); and making presenters aware of the fact that audiences are not as negative as they might think they are. Speakers overestimate how critical audiences are.

# Stages of Change Model

Thomas W. Valente

University of Southern California

Some behaviors take a long time to change, and rarely do individuals progress immediately from awareness of a new product or idea to its use. Stages of change models document and specify the specific stages or steps a person goes through when they adopt or quit a behavior. At least four distinct stages of change models have been proposed: (1) diffusion of innovations (Rogers 2005); (2) hierarchy of effects (McGuire 1989); (3) steps to behavior change (Piotrow et al., 1997); and (4) transtheoretical model (Prochaska et al. 1992).

*Diffusion of innovations* (→ Diffusion of Information and Innovation; Rogers, Everett) is a theory that describes how new ideas, opinions, attitudes, and behaviors spread throughout a community (Rogers 2005). First developed by rural sociologists to study how farmers adopted new ideas, diffusion theory has grown into a robust science with applications in communications, health (→ Health Communication), → marketing, sociology, and many other arenas. Diffusion theory has many components, one of which is that individuals pass through stages during the adoption process. These five stages were labeled: *awareness*, gaining knowledge of the new behavior; *persuasion*, learning more about it; *decision*, making a conscious decision to use it; *implementation*, first use and experimentation with it; and *confirmation*, continued use of the behavior (see Table 1).

The *hierarchy of effects* (HE) and *steps to behavior change* (SBC) models were developed as expansions of the diffusion stages by increasing the number of steps in the behavior change process and being explicit about the relationship between steps. The full hierarchy model consisted of a table in which the rows were the components of the Shannon and Weaver (1949) communication model (source, message, channel, receiver, and destination) and the columns were hierarchy steps (exposure, → attention, comprehension, yielding, and behavior). The HE and SBC models are useful for three reasons: (1) they denote a more active → audience in terms of → information seeking and advocacy of the behavior, (2) they provide 12 or 16 specific, measurable steps in the behavior change process, and (3) the HE model proposed a rate at which individuals progressed through each step in the change process, advocating a model in which people could be expected to progress from step to step at a rate of 80 percent. Thus for a population exposed to a communication → persuasion message (→ Exposure to Communication Content), 80 percent of the population would progress through each step, with ultimately 6.9 percent experiencing the benefits of the new practice.

Stages of change and the *transtheoretical model* (Prochaska et al. 1992) also classified people into five stages: *pre-contemplation*, when they are not aware of the need to change behavior and do not intend to do it; *contemplation*, when they are aware of a problem but do not intend to change in the near future; *preparation*, when they intend to change their behavior in the near future; *action*, when they have made some behavioral modification; and *maintenance*, when they have made the behavior change for some period of time (usually six months or longer; → Health Behavior Change, Transtheoretical Model of).

Table 1 Stages of change models

Diffusion of innovations (Rogers 2005)	Hierarchy of effects (HE) (McGuire 1989)	Steps to behavior change (SBC) (Piotrow et al. 1997)	Stages of change (Prochaska et al. 1992)
1 Awareness	1 Recall 2 Liking 3 Comprehension	1 Recalls message 2 Understands topic 3 Can name source of supply	1 Pre-contemplation
2 Persuasion	4 Knowledge of behavior 5 Skill acquisition 6 Yielding 7 Memory storage	4 Responds favorably 5 Discusses with friends/family 6 Thinks others approve 7 Approves himself or herself 8 Recognizes innovation meets need	2 Contemplation
3 Decision	8 Information search and retrieval 9 Decision	9 Intends to consult a provider 10 Intends to adopt 11 Goes to provider	3 Preparation
4 Implementation	10 Behaving in accordance with decision	12 Initiates use 13 Continues use	4 Action
5 Confirmation	11 Reinforcement 12 Post-behavior consolidating	14 Experiences benefits 15 Advocates 16 Support practice in the community	5 Maintenance

There are three distinctions between the stages of change and the diffusion or hierarchy stages. First, the diffusion or hierarchy stages were derived from studies designed to determine attributes associated with early or later adoption of new techniques, whereas the stages of change model was derived initially from studies intended to get people to quit smoking. The emphasis in stages of change was to understand how people quit a behavior (smoking), not adopt a new one. Second, the stages of change model measures cognitive states and shows how these change during adoption, whereas diffusion focuses more on how information sources and knowledge vary during adoption. Finally, diffusion has a much more extensive history and application than stages of change and so has been tested in multiple settings, but the stages of change model is used much more today and more extensively in the health field.

There are at least three reasons why stages (or steps) are used so frequently in communication research. First, they provide a way to group people, compare these groups on factors that affect behavior, and develop interventions targeted at specific stages (→ Media Effects). Second, progression between stages can be used as an outcome rather than relying exclusively on behavior. Third, change is not continuous, but rather marked by distinct events, steps, or stages that signify progression to adoption.

One main challenge facing stage models is to be consistent in their measurement, since stages may be calculated via recall or via change from baseline to follow-up. A second challenge is to determine whether individuals progress steadily through the behavioral change steps. For example, it may be that progression between earlier steps is more rapid than progression through later ones.

# **Stakeholder Theory**

*Nigel de Bussy*

*Curtin University of Technology*

Stakeholder theory has provoked controversy for more than 70 years, even though the term “stakeholder” is itself of more recent origin. The theory raises a highly contentious question: in whose interests should a business corporation or other type of organization be run? Opponents stress the primacy of shareholder rights. Supporters claim corporations have wider responsibilities toward a broad range of groups and individuals with a “stake,” whether financial or otherwise, in the operations of the business. In the contemporary world, strategic stakeholder communication has become a key driver of → corporate reputation. Hence the stakeholder concept is a central concern for the field of → public relations (→ Organizational Image; Trust of Publics).

The *origins of the stakeholder debate* can be traced to scholarly disputes in the 1930s between Harvard law professor E. Merrick Dodd and management theorist Adolf Berle. Dodd contended corporate powers were held in trust for the entire community, while Berle argued the same powers should be held in trust for shareholders. In the 1950s, Berle conceded the argument to Dodd. The word “stakeholder” first appeared in the management

literature in an internal memorandum at the Stanford Research Institute in 1963. It was originally defined as “those groups without whose support the organization would cease to exist” (Freeman 1984, 31). Thus the initial conceptualization of a stakeholder extended to such groups as shareholders, employees, customers, suppliers, lenders, and society. The term was intended to broaden the notion that shareholders are the only group to whom management need be responsive. The term “stakeholder” was coined as a rhetorical device, designed to advocate an alternative perspective on business theory and practice – one that eschewed the traditional notion of serving the shareholder, or business owner(s), alone. The Stanford definition has come to be known as the “narrow” definition of a stakeholder.

The intense contemporary interest in the theory and current ubiquity of the term “stakeholder” began with the publication of R. Edward Freeman’s seminal 1984 book *Strategic management: A stakeholder approach*. In addition to sparking a voluminous body of scholarly and practitioner literature, Freeman (1984) introduced a new definition of “stakeholder,” greatly broadening its applicability. According to Freeman (1984, 25), a stakeholder is “any group or individual who can affect or is affected by the achievement of the firm’s objectives.” In other words, virtually anyone – even a terrorist – can be considered a stakeholder.

Since then definitions have proliferated, Mitchell et al. (1997) presented no fewer than 27 that have appeared in the literature over the past 40 years. Some authors have even extended the concept to nonhuman entities such as the environment. It is widely acknowledged that the lack of an agreed definition is one of the theory’s most intractable problems. Very broad definitions present obvious difficulties for managers actually attempting to implement the concept.

Current scholarship suggests the stakeholder concept represents a genre of theories rather than a single theory. Donaldson and Preston (1995) identified *three distinct types of stakeholder theory*, which they argued had always been implicit in the stakeholder debate but hitherto had been thrown together in an inappropriate manner. “Descriptive stakeholder theory” attempts to describe and sometimes explain aspects of corporate and stakeholder behavior. It is concerned with what managers and organizations actually do. “Instrumental stakeholder theory” relates to the potential connections between certain stakeholder management practices and the achievement of traditional corporate objectives such as profitability and growth. “Normative stakeholder theory” focuses on ethical guidelines for the operation and management of corporations. It endeavors to tell managers what they should do.

*Descriptive stakeholder theory* has made relatively little progress despite its potential significance. Some scholars have speculated that the vagaries of human behavior put the development of a descriptively useful stakeholder theory of the firm beyond reach. A number of published studies adopt an *instrumental perspective*; however, the extant evidence for the financial efficacy of stakeholder management remains sketchy and methodological difficulties abound. Several instrumental researchers have used → corporate social responsibility ratings published by an independent agency as a proxy measure, rather than attempting to tap stakeholder management practices directly. Others rely on case studies, with limited generalizability as a result. Many scholars have called for more empirical research from an instrumental perspective.

The *normative stakeholder literature* is voluminous, dwarfing the number of contributions from other perspectives. Many normative stakeholder theorists hold that conventional shareholder capitalism is simply immoral. Replacing it with a stakeholder model is therefore an ethical imperative. Critics of this position argue normative stakeholder theory is inimical to the fundamental purpose of business (i.e., to generate wealth for the providers of capital) and that stakeholder management amounts to a breach of fiduciary duties to shareholders, thus is itself unethical. To be a fiduciary to multiple stakeholder groups, critics claim, is to be a fiduciary to no one. Goodpaster (1991) identified what he called the “stakeholder paradox”: it is both essential, yet in some ways illegitimate, to orient corporate decisions by ethical values that go beyond strategic stakeholder considerations to multi-fiduciary ones. The paradox remains fiercely debated (→ Organizational Communication: Critical Approaches).

## **Standards of News**

*Hazel Dicken-Garcia*

*University of Minnesota*

News standards connote normative qualities, such as accuracy and decency (→ Ethics in Journalism), but the term specifically means the way information is gathered, made into

news reports, and presented (Dicken-Garcia 1989). For example, *objectivity* encompasses six standards: verified facts, fairness, non-bias, independence, non-interpretation, and neutrality (Ward 2004). Journalists develop standards to gain credibility in society, and standards change across space and time. For example, US news standards changed as the press shifted from partisan (→ Partisan Press) to event-centered to commercial during nineteenth-century industrialization. Accuracy and balance, of little concern to partisan journalists, became more important with the shift from producer to consumer society (→ Professionalization of Journalism).

Western hegemony spread news standards, which developed with the rise of capitalism and the middle class (Smith 1978, 1979). The need to sell news profitably required qualities the public would buy, and investments shaped standards as ties to political parties weakened. Around 1900, western journalism also became more about structuring than recording reality, resulting in image politics and an emphasis on objectivity (→ Objectivity in Reporting).

Whether the press serves primarily the government or the public affects standards. History shows more concern with printing itself than with news standards, especially in authoritarian societies (Siebert 1965; Martin 1969), because rulers feared its permanence and reach (→ Freedom of the Press, Concept of). France executed printers for criticizing religion or government as late as 1760. England shaped colonial news standards through libel laws and press licensing (Levy 1963), controlled reporting on Parliament until at least 1845, and monitored journalism thereafter. In open societies, norms and the market shape standards, although laws prohibit libel, obscenity, and breach of security (→ Media History).

Little is known about *journalism in transnational changes* like industrialization, the development of capitalism, the growth of imperialism, and globalization (Chapman 2005), and even less is known about news standards across nations and time (→ Globalization Theories; International Communication). Low literacy and resistance delayed printing in some non-western nations (Briggs & Burke 2005). Two examples are Russia, where mobs destroyed its first press, and Turkey, which treated printed religious material as sinful. In the east, readers developed conceptions of themselves as news audiences around 1900, and journalism growth thereafter followed western patterns.

News standards probably always existed. Before printing began in Europe, travelers and hired messengers carried news along trade and post routes. A concern for *accuracy* likely arose because information changes when relayed orally. Another standard, *verified facts*, appeared in 1 BCE when a messenger included gossip in summarizing Roman senate decrees.

Conditions essential for newspapers coalesced around 1600, and news writing became a full-time paid job soon after. But journalists could not assure accuracy when no fact-checking means existed. As late as the 1700s, journalists generally did not go to witness news except in Parliament, where shorthand made reports seem *accurate* and *neutral* while giving reporters a sense of serving readers. Some 1750s English critics raised at least five news standards in appeals for *truth* and *decency* without *scurrility* or *defamation* or *selling skills* to political parties.

Polemics shaped standards in partisan times, which occurred in much of the world. *Impartiality* before England's Civil War, for example, meant that journalists digested

various political stances and received no payment for publicizing them. People read newspapers for opinions until the “doctrine of hard facts” developed (Smith 1978, 148). The end of the newspaper tax in 1861 freed English journalists from political obligations just when accelerating production costs were exposing the futility of targeting narrow audiences of political elites.

News standards flow transnationally. After an English businessman imported a press from Europe in 1476, the influence of British journalism dominated well into the nineteenth century. American colonists took London newspapers as a model and imitated Bow Street court reporting (Mott 1950). English penny magazines provided a model for 1830s America (→ Penny Press), where newspapers adopted the English division-of-labor system (Hudson 1968). Englishmen established a Turkish newspaper in 1840, Japan’s first newspaper in 1861, and periodicals in nineteenth-century China, which had been the first country to develop printing and long-distance news collection. By the 1860s, Japan incorporated the western model, which Chinese people – sent to Japan for a western education in increasing numbers from the 1890s – applied in China (Zhang 2006).

Consumer-driven US news standards expanded to England and Europe after post-Civil War industrialization. Matthew Arnold coined the term *new journalism* in 1887 to imply standards that competitive markets shaped: being lively, sensational, and reporter-driven (Marzolf 1980). The London *Pall Mall Gazette* editor from 1881 and the American founder of *Le Matin* in Paris in 1883 used the American model. US standards influenced Chinese journalism in the decades after 1900, as Chinese students returned from study in America and US journalists and educators worked in China (→ Tabloidization). News standards crossing national boundaries likely meld with domestic cultural norms.

News standards under conditions of *convergence* (→ Convergence of Media Systems) remain underdeveloped. Old issues re-emerge with new urgency when fact-checking is non-existent and news-gatherers unknown. If Daniel Defoe was not a journalist because he wrote about events he never saw, then determining who is a journalist on the Internet has even greater implications for news standards.

## Stars

*Philip Drake*

*University of Stirling*

A star is an individual who is highly celebrated and deemed exceptional in a particular field or profession. The term has most commonly been associated with performers in popular media such as music, television, and, particularly, → cinema. Stardom is closely linked to fame and celebrity (→ Celebrity Culture), and these terms are often used interchangeably. The term “star,” which can be both noun (“a star”) and verb (“to star in”) originated in the popular American press of the early nineteenth century in relation to the expanding coverage of public figures and human interest stories. Articles in the so-called → “penny press” about popular performers of stage and vaudeville had the effect of expanding public interest in the names and qualities of these recognizable individuals. The film scholar Richard DeCordova (1990) has demonstrated that the institution of cinema was important to the expansion of stardom at the start of the twentieth century. He identifies an emergence of interest in “picture personalities,” and the subsequent naming of performers on screen and in film studio publicity material, as crucial in the development of the → Hollywood film industry and its star system.

It is often claimed that a publicity stunt in 1910 by the film studio IMP marked the *start of the Hollywood star system*. A false story about the death of popular actress Florence Lawrence was placed in the news press; the studio then denounced the article, drawing attention to her as their new star. Although revisionist historians have challenged the accuracy of these accounts, they acknowledge the emergence of a popular discourse on stardom by the 1910s. The circulation of stories about performers published during the late 1910s led to increased interest in the off-screen lives of leading actors, and by 1919 the Hollywood star system was sufficiently well established that a small group of powerful stars were able to found their own studio (United Artists). From this period until the 1950s it was commonplace for major Hollywood studios to sign named actors to long-term (usually seven-year) contracts, and the film industry promoted the circulation of famous performers – stars such as Humphrey Bogart, Lauren Bacall, Bette Davis, James Stewart, and many more – consolidating Hollywood's status as a globally dominant cinema. From the 1950s, spiraling costs and the popularity of television and other leisure activities brought an end to the long-term contract star system. Contemporary stars are self-employed, represented by powerful talent agencies, and hired on a per-project basis. By the start

of the twenty-first century, major “A-list” Hollywood stars were able to earn upward of US\$20 million per film plus gross profit participation, consolidating perceptions of the exclusivity of stardom. Stars remain important to the industrial function of the entertainment media as they offset risk by guaranteeing recognition (and audiences) for the products in which they appear.

Although Hollywood cinema is often viewed as a paradigmatic site of film stardom, *other countries* have their own star systems. Each has its own hierarchy of film, television, music, and sports stars, which have national if not always global appeal and recognition. British cinema, for instance, developed a distinctive film star system by drawing from theatre and music hall, promoting performers such as Margaret Lockwood, James Mason, and Diana Dors to popular stardom. Similarly, in France performers such as Max Linder, Brigitte Bardot, and Gérard Depardieu garnered star recognition. However, many European actors either moved to or worked in Hollywood to become global stars, for example Greta Garbo, Charlie Chaplin, Marlene Dietrich, Cary Grant, Elizabeth Taylor, and Anthony Hopkins.

Asian cinema offers some notable exceptions to this trend, maintaining distinctive and widely popular star systems. The popular Indian film industry promotes stars such as Amitabh Bachchan and Aishwarya Rai to global audiences, while both Chinese and → Hong Kong cinema have stars that are also popular worldwide, such as Jet Li and Jackie Chan (→ Bollywood).

Outside of cinema, national star systems operate across various media. For example, → television, → popular music, and sports all maintain distinctive hierarchical forms of stardom (→ Popular Culture). Although it has been argued that cinema offers the primary site for stardom, many of the most popular global stars are drawn from these other areas. Pop stars such as Michael Jackson, Bono, and Madonna and sports stars such as David Beckham, Muhammad Ali, and Tiger Woods are individuals celebrated not only for their achievements but also for their personal lives, and the stories that surround them are circulated through the mass media to an interested public (→ Audience).

Scholarly interest in stars has proliferated since Richard Dyer’s book *Stars* (1979), which argued that film stars could be understood as clusters of signs, or “star images,” that conduct ideological work by signifying cultural ideals, such as those connoting glamour, desirability, or beauty. However, work on celebrity pre-dates Dyer, such as the writing of social theorists Leo Lowenthal (1961) and Daniel Boorstin (1961). Boorstin famously argued that celebrity achieved through the mass media represented an artificial, manufactured fame; he called the celebrity a “human pseudo-event.” He contrasted this unfavorably with heroism: fame earned by (what he saw as) admirable skills or qualities. More recent research has illuminated the historical development of celebrity (Braudy 1997; Marshall 1997) as well as specific forms of film stardom (Gledhill 1991; Willis 2004). Writing on fan culture has also extended consideration of stardom by examining the forms of engagement audiences have with stars (Jenkins 1992; Gamson 1994; Stacey 1994). Current scholarly work on stardom and celebrity draws from a wide range of disciplines, and examines stars and their audiences in a variety of different media. Most approaches agree, however, that although stardom pre-dates modern communication technologies, the rise of the mass media facilitated a dramatic expansion of the sites and ways in which famous individuals can be consumed by audiences.

## **Statistics, Descriptive**

*Bertram Scheufele*

*University of Jena*

The original purpose of statistics was collecting data for government and administration. Thus, the term is used for, e.g., employment data or for censuses in general that provide data (statistics) about a population or nation. Scientifically, the term stands for different forms of presenting empirical data in charts, diagrams, or tables as well as for an academic discipline. In this respect, statistics is part of mathematics, but also an auxiliary discipline for other academic disciplines like communication research. Statistics serves for analyzing, presenting, and interpreting empirical data that have been collected by applying quantitative methods (→ Quantitative Methodology; Research Methods) like → surveys, content analyses (→ Content Analyses, Quantitative), or → observations in → experimental designs or field studies (→ Field Research). Statistics comprises of descriptive and explanatory procedures and aspects (→ Statistics, Explanatory).

### **SAMPLE, VARIABLES, AND SCALES**

Descriptive statistics deals with describing and characterizing empirical data from representative samples, i.e., mostly random samples (→ Sampling, Random). A sample is called random when all elements have the same chance of becoming or not becoming a member of it. This is a crucial condition for all statistical analyses, especially when it comes to

explanatory procedures. Observations or elements of a random sample can be, for instance, persons, newspaper articles, or television ads. In statistics, the attributes of these elements are called “variables.” They can take different values. An interviewee in a representative survey, for instance, can be male or female; his or her political interest can be weak, medium, or strong; and he or she can be 14 years, 52 years, or 79 years old. Gender, political interest, and age are variables, whereas “male/female,” “weak/medium/strong,” and  $\{1, 2, 3 \dots n\}$  are the values of these variables.

Variables can have different  $\rightarrow$  scales or levels of measurement, so one might say scales represent certain accuracies in measuring a variable ( $\rightarrow$  Scales and Indices; Measurement Theory). Usually, four *types of measurements or scales* are distinguished: nominal, ordinal, interval, and ratio scale. (1) Nominal scales or variables (e.g., gender, color) represent a difference or equality of values (e.g., “male” and “female” or “red,” “blue,” and “yellow”) but with no meaningful rank order among values. Dummy variables that can take 1 and 0 as value are often considered a special form of nominal measurement. (2) Ordinal scales (e.g., military rank, school grades) also represent difference/equality, but additionally include a rank order like “bigger/smaller” or “more/less.” But there are no precise differences between consecutive values. Thus, one cannot state that a strong political interest would be twice as much as a weak political interest. (3) This is, however, possible for interval scales (e.g., temperature), which have meaningful, i.e., equal distances between ranks or values. For instance, a temperature of 240 degrees Fahrenheit doubles a temperature of 120 degrees Fahrenheit.

(4) Finally, a ratio scale (e.g., weight, prices) is like interval measurement, but additionally with a meaningful, i.e., absolute zero value. Humans and animals, for instance, cannot have a negative weight. Therefore ratio scales represent not only equal distance, but equal proportions of consecutive values. Dummy, nominal, and ordinal scales are called non-metric, whereas interval and ratio measures are called metric measurements. For computer programs non-numeric values of measured attributes (e.g., “male/female”) are usually turned into numeric values (e.g., 1 and 2), i.e., they are coded to enable statistical procedures automatically.

After having collected data, e.g., in a survey, we ask questions like these: how old are interviewees in the survey sample? How often do they watch television? Is there any connection between media use and political interest? To answer these questions we can *describe empirical data* in two ways: on the one hand, by making charts, diagrams, and tables; on the other hand, by computing sample characteristics (e.g., means) or coefficients (e.g., correlation coefficient) that represent a certain feature of the sample (e.g., average) in one value. Both ways comprise of univariate and multivariate perspectives.

## UNIVARIATE STATISTICS

Univariate statistics deals with single variables. One can, for instance, examine the distribution of age among all interviewees in a survey. The original data show values of a variable (e.g., age) for each element in the sample, e.g., each interviewee. By grouping all elements (e.g., interviewees) sharing a certain value (e.g., 25 years) we obtain a *frequency table*: this lists all values (e.g., ages) in the first column and the corresponding frequencies (e.g., number of interviewees) in the second column. Tables of categorical data list classes

of values in the first column (e.g., “10–19 years,” “20–29 years,” etc.) and frequencies in the second column. Tables of cumulated data – whether categorical or not – add up frequencies starting from the top of the column and ending with the sum of all frequencies (100 percent) in the last row. All types of tables can be transformed into corresponding charts following the same logic, but giving a better impression of the distribution of a variable in the sample. Another way of characterizing a sample is calculating sample characteristics. Here, univariate statistics distinguishes between means and deviances. Both differ with the measurement level of a variable.

Strictly speaking, the term “mean” refers to an average of values, i.e., to the *arithmetic mean*: Here, we sum up all values of all interviewees in our survey sample and divide this sum by the number of interviewees. This type of mean value can only be calculated for metric measurement. The permissible mean value for the nominal level of measurement is called “*mode*.” It is the most frequent value in a sample: if “37 years” is the most frequent answer to the survey question regarding the age of the interviewees, then the mode is 37. Of course, the arithmetic mean can be computed for age as well. The mean value for ordinal variables is the *median*. It splits a distribution in half: the first 50 percent of all values rank below the median and the second 50 percent rank above. The median can also be considered a special form of a percentile: Those percentiles dividing a distribution into quarters – 25 percent, 50 percent, 75 percent, 100 percent of all values – are called quartiles and the median is simply the 50 percent quartile.

*Deviation characteristics* differ with level of measurement as well. For nominal variables we cannot compute a deviance from the mean value. For ordinal measurement the permissible deviances are the range and the interquartile range. The range is the difference between the highest and the lowest value in the sample, whereas the interquartile range represents the difference between the third and first quartile. For metric measurement we calculate the variance or its square root, called standard deviation. An example for a metric variable is the duration of watching television measured in minutes. The variance in television viewing represents the sum of squares of interviewees’ individual differences from the mean value of all interviewees.

## MULTIVARIATE STATISTICS

Multivariate statistics describes *correlations* between variables (→ Correlation Analysis). For instance, we can ask if the time subjects spend on watching televised debates increases with a growing political interest. With bivariate statistics the term “covariance” refers to the fact that the variance of one variable corresponds to the variance of the other variable, e.g., in the sense of “the more X, the more Y.” In other words, we focus on the joint distribution of two variables. Similar to univariate statistics, correlations between two or more variables can be described by charts, diagrams, and tables on the one hand and by calculating correlation coefficients on the other hand.

The correlation between two variables is called *asymmetric* if one variable can be assumed to be the impact factor of the other variable; otherwise the relation is called *symmetric*. Age has a possible impact on political sophistication, for example – but not vice versa. Correspondingly, some coefficients indicate only the strength while others also represent the direction of a correlation: Here, a positive (negative) value of the coefficient

indicates that an increase in value of the first variable is accompanied by an increase (decrease) in value of the second variable. In cross-tabulation, i.e., in contingency tables with two variables, the columns usually represent the values of the assumed impact factor, which is also called the predictor or independent variable. And the rows of the contingency table represent the values of the assumed affected variable, which is also called the response or dependent variable.

All correlation coefficients rely on the *general linear model*, which stipulates a linear relation between variables. Strictly speaking, the term “correlation” should only be applied to metric measurement. At the nominal level correlations are called “contingency,” and at with ordinal measurement they are called “association.” For nominal measurement one computes *contingency coefficients*. Here, the permissible coefficient is the phi coefficient  $\Phi$  with a four-cell table (two variables with two values each), and Cramer’s V with a table of more than four cells. Both are based on chi-square-statistics,  $\chi^2$ , i.e., the differences between theoretically expected frequencies (based on probability theory) and observed frequencies in the joint distribution of two variables. The values of both coefficients range from 0 (no contingency at all) to 1 (perfect contingency).

At the ordinal level different coefficients can be applied. In contrast to Kendall’s  $\tau$  (Tau-b/c) the gamma coefficient  $\gamma$  does not make an adjustment for either table size or ties. A more popular coefficient especially in agenda-setting research is *Spearman’s rank correlation coefficient*  $\rho$  (rho;  $\rightarrow$  Agenda-Setting Effects). In many agenda-setting studies several issues are ranked for all media on the one hand and for the aggregate of recipients on the other hand. Here, Spearman’s  $\rho$  indicates strength and direction of the association between media agenda and recipients’ agenda. Thus, values range from  $-1$  for perfect negative correspondence to  $+1$  for perfect positive correspondence, with 0 for no correspondence at all. At the metric level of measurement one can compute correlation coefficients or conduct a  $\rightarrow$  regression analysis. *Pearson’s product–moment coefficient*  $r$  indicates the strength and direction of a correlation between two metric measurements. The coefficient whose values range from  $-1$  to  $+1$  is obtained by dividing the covariance of both variables by the product of their standard deviations.

The product–moment coefficient can also be considered the square root of the so-called explained variance in *linear regressions*. This procedure examines the impact of one or more assumedly independent or explanatory variables  $X_1, \dots, X_n$ , etc. (predictors, regressors) on an assumed dependent variable  $Y$  (response variable, regressand). This must be a metric variable, whereas the explanatory variables can be of lower measurement.  $R^2$  is the determination coefficient and indicates the amount (in percent) variance in the response variable explained by  $X_1, \dots, X_n$ . Values of  $R^2$  range from 0 (no impact of the explanatory variables) to 1 or 100 percent (full impact). The “error”  $1 - R^2$  is also called unexplained variance and represents the square sum of all residuals. Since regression tries to keep these residuals or unexplained variation to a minimum (“least”) it is often called OLS regression (ordinary least squares). Additionally, beta values  $\beta$  can be computed for each explanatory variable. A beta value represents the strength and direction of the correlation between a regressor and response variable with values ranging from  $-1$  to  $+1$ . Since beta values are standardized coefficients, one can compare them for different regressors in one regression analysis, or for one regression between different regression models.

# **Statistics, Explanatory**

*Bertram Scheufele*

*University of Jena*

Explanatory statistics is also called inferential statistics or statistical induction and deals with inferences about the population from the characteristics of a random sample, i.e., with making (probability) statements about usually unknown parameters of a population. For instance, when taking a random sample (e.g.,  $n = 1,000$ ) of television viewers from the population of all TV viewers (e.g.,  $N = 1,000,000$ ), we want to know if the average time of TV viewing in the sample (e.g., 184 minutes/weekday) comes close to the average time in the population from which the sample was taken (→ Statistics, Descriptive; Sampling, Random; Generalizability).

### **ROOTS IN PROBABILITY THEORY**

Explanatory statistics includes point and interval estimation as well as hypothesis tests for statistical significance. They are based on probability theory (e.g., the work of Richard von Mises, Thomas Bayes, and Pierre-Simon Laplace). On the one hand, probability can be interpreted as the ratio of a favorable outcome and the number of possible outcomes. For instance, if one expects a “6” when throwing a single die once, the probability of getting a “6” is the ratio of this favorable outcome ( $n = 1$ ) divided by the possible outcomes ( $n = 6$ ) – thus  $p(\text{“6”}) = 1/6$ . Throwing a single die is an example of a random

experiment. It is called random since we do not know the outcome before having thrown the die. On the other hand, we can assume that the number of cases in which we get a “6” comes nearer to the probability  $p(\text{“6”})$  when throwing the single die many, many times.

Asking an interviewee how old he or she is can be considered a random experiment, since we do not know what he or she will answer. All possible outcomes are called the *sample space*  $\Omega$  of the random experiment. We do not know the outcome for the next interviewee, but we can tell the probability of a certain age. For another example: we cannot predict the outcome of “throwing a 5” for sure when playing dice, but we know that the probability of this outcome can be obtained by dividing the number of positive outcomes (throwing a 5) divided by the number of possible outcomes (throwing a 1, 2, 3, 4, 5, or 6) – thus the probability of “throwing a dice once and obtaining 5” is  $p = 1/6$ . Probability values range from 0 to 1. This is the first of the *Kolmogorov axioms*. The second postulates that the probability of the sample space  $\Omega$  is 1 – in other words, the probability that any of the possible outcomes will occur is 1. The third axiom claims that the probability of a sum of disjoint, i.e., “exclusive” events or outcomes is the sum of the single probabilities of each event or outcome: e.g.,  $p(\text{“throwing a 1, 2, or 3”}) = 1/6 + 1/6 + 1/6 = 1/2$ . From these axioms one can deduce lemmas or rules for calculating other probabilities. One lemma tells us that the probability of the impossible event (e.g., “throwing a 7 with one die”) is 0. A second lemma tells us that the probability of an event  $p(A)$  and the probability  $p(A^C)$  of the event’s contrary  $C$  (“not  $A$ ”) sum up to 1.

Attributes of sample elements, i.e., variables and values, can be treated in terms of probability theory: when interviewing someone, we do not know the answer to the question “How old are you?” before we ask. Thus, age is a random variable. It can take different values, which can be considered as outcomes of a random experiment with  $\Omega = \{1, 2, 3, \dots, n\}$ . Each outcome or event has a certain probability. Listing the outcomes consecutively, one obtains a table or diagram showing the probability distribution (or function), which is comparable to the sample distribution. And as cumulated frequencies in sample statistics do, the cumulated probabilities form up to a cumulated probability distribution, also called density distribution (or function). As in sample statistics, we can characterize probability distributions by parameters. The expected value  $E(X)$  is the average or mean value of a random variable  $X$ . Additionally, we can compute the variance  $\text{var}(X)$  or standard deviation of a random variable  $X$ .

Distributions differ with the level of measuring a random variable ( $\rightarrow$  Measurement Theory). Discrete random variables take finite or countably infinite values – like age:  $\Omega = \{1, 2, 3, \dots, n\}$ . Examples of discrete distributions are the Bernoulli or the binomial distribution. Continuous random variables can take an infinite number of real numbers within the limits of an interval – like “time spent watching a half-hour TV soap”:  $\Omega = \{0 \leq x \leq 30\}$ . The most prominent example of a continuous distribution is the *normal or Gaussian distribution* (named after Carl Friedrich Gauss). Normal distributions  $N(\mu, \sigma^2)$  vary in position due to the expected value  $E(X) = \mu$  and in form due to the variance  $\text{var}(X) = \sigma^2$ . All normal distributions can be standardized, i.e., z-transformed into a standard normal distribution (SND) with  $\mu = 0$  and  $\sigma^2 = 1$ . The SND is a key feature of statistics since many distributions tend toward a normal distribution when numbers get large. This is described by the central limit theorem, which postulates that the sum of

stochastically independent variables  $X_n$  – as well as  $X_n/n$  – is approximately normally distributed.

### POINT AND INTERVAL ESTIMATION

Empirical distributions are often assumed to be normally distributed for practical reasons. One can take the SND as a template for drawing inferences about population parameters from sample characteristics. For instance, one can compare the arithmetic mean of a random sample with the SND and then make a probability statement about the unknown mean value in the population from which the sample was taken. The SND provides a standardized template with  $\mu = 0$  and  $\sigma^2 = 1$ . In a diagram, the area below the curve of the SND represents 100 percent of the values. More important are the standardized intervals: Within the limits of  $\pm 1$  standard deviations we find roughly 68 percent of all values of the SND. Within  $\pm 1.96$  ( $\pm 2.38$ ;  $\pm 3.29$ ) standard deviations we find exactly 95 percent (99 percent; 99.9 percent) of all values.

These three limits represent the *levels of confidence*. If the mean value of TV viewing in a random sample is 184 minutes, for example, a confidence of 95 percent can be interpreted like this: if we would take 100 random samples of the same sample size, we would find exactly this mean of 184 minutes for 95 of the 100 random samples. Yet for 5 of the 100 random samples we would find a different average. Thus, we make a 5 percent error when stipulating that the result of our single random sample is “for sure.” This error probability is denoted  $\alpha$  and also called the level of significance. With the second lemma of probability theory, confidence and error probability are complementary, i.e., sum up to  $p = 1$  or 100 percent. Thus, corresponding to levels of confidence  $\alpha < 5$  percent (significant),  $\alpha < 1$  percent (very significant), and  $\alpha < 0.1$  percent (highly significant) there are three levels of significance. For an example: the sample average of 184 minutes is called very significant ( $\alpha < 1$  percent), when there is a probability of at least 99 percent that we would get the same value when taking another sample from the same population. Or in other words, with a probability of 99 percent the population average is 184 minutes.

This statement is an example of point estimation. Here, the sample statistics (e.g., mean value) are directly used as a point estimator for population parameters (e.g., mean value). Interval estimations are a similar but more “precise” inference about population parameters from sample characteristics. Here, one gives an interval based on confidence and thus calls it the confidence interval. With the example above one would say: starting from the sample mean and  $\alpha < 1$  percent, we can assume that the mean of watching TV for all subjects from the population (from which the sample was taken) lies within the boundaries of, e.g., 180 and 188 minutes. Logically speaking, this is the same statement as the probability statement in the last paragraph, since both are based on the same confidence level.

### TESTING STATISTICAL HYPOTHESES

Explanatory statistics also deals with statistical hypothesis or *significance testing*. Here, one asks questions like “How significant is the sample average of 184 minutes?” (one-sample test) or “Does the mean in TV viewing in the male group differ significantly from the mean in the female group?” (two-sample test). For significance testing, SND and other

distributions like the Student-t-distributions serve as test statistics. In practice, the statistical hypothesis test comprises several steps, which can be illustrated with the example of the two-sample (un)pooled t-test. First, one proposes a null and an alternative  $\rightarrow$  hypothesis. The null hypothesis  $H_0$  postulates “no significance” or “equality”: for instance,  $H_0$  might claim that the mean value in the first sample (e.g., people from New York) and the mean value in the second sample (e.g., inhabitants of Los Angeles) do not differ significantly, but by chance. Statistically speaking, the two samples were taken from the same population ( $\mu_{NY} = \mu_{LA}$ ). The opposite, i.e., alternative hypothesis  $H_A$ , claims significance by postulating that the two samples are taken from different populations ( $\mu_{NY} \neq \mu_{LA}$ ).

Second, we set the level of significance. With medicine testing, for instance, high levels of significance should be chosen to “insure” that a medicine has no side-effects. If we chose  $\alpha = 0.05$ , we test on the 95 percent level of confidence. It is important to mention that one tests  $H_0$  and not  $H_A$ . The third step is choosing a test statistic (test distribution). With the two-sample t-test one chooses the Student-t-distribution as a template for the test decision. Strictly speaking, the t-distribution is a group of distributions differing with the degrees of freedom (df) that represent sample size (e.g.,  $df = n_{NY} + n_{LA} - 2$  for a two-sample t-test). The fourth step comprises calculating the empirical value of the test statistics from the sample data. The empirical t-value  $t_{emp}$  is compared to a critical, i.e., theoretical t-value  $t_{crit}$  depending on  $\alpha$  and df. If  $t_{emp} \leq t_{crit}$ , we accept  $H_0$ . But if  $t_{emp} > t_{crit}$ , we reject  $H_0$  and accept  $H_A$ . So we can state that the group means differ significantly ( $\alpha = 0.05$ ) and claim that the groups are samples from different populations – with a probability of 95 percent.

Statistical tests all follow this logic, but vary with the test situation and test statistics being applied. If we ask for the significance of a single mean value, we usually choose t-statistics. This test situation is called a one-sample t-test and is applied if the population parameter  $\sigma$  is unknown – as is mostly the case. For a large sample size (usually  $n \geq 30$ ) and known  $\sigma$ , however, one can choose z-statistics based on SND, since under these conditions t-distributions are approximately normally distributed. This test situation is called a one-sample z-test. Comparing two means is the above-mentioned two-sample test situation. Another example is  $\chi^2$ -statistics, which is based on the differences of theoretically expected frequencies (based on probability theory) and observed frequencies in the joint distribution of two variables. On the one hand,  $\chi^2$  statistics is chosen if we ask for independence ( $H_0$ ) and association or contingency ( $H_A$ ) of two nominal variables (one-sample test). On the other hand,  $\chi^2$  statistics is chosen for the two-sample test, i.e., when asking for equality ( $H_0$ ) or difference ( $H_A$ ) of distributions in two samples. Here, for instance, we might examine whether the *New York Times* and the *Washington Post* differ in weighting political issues.

# Stereotypes

*Dominic Lasorsa*

*University of Texas at Austin*

Stereotypes are gross generalizations about people. A stereotype is a category-based cognitive response whose affective counterpart is prejudice and whose behavioral counterpart is discrimination. By judging others not on knowledge of their individual complexities but on their inclusion in an outgroup, stereotyping is categorical thinking that can engender racism, sexism, homophobia, xenophobia, and other types of intolerance.

Journalist Walter Lippmann coined the term, which he took from the “hot type” printing process prevalent at newspapers of his day. A stereotype is a plate constructed by making a mold of a printing surface and from that a cast in metal type. The stereotype enabled a newspaper to reproduce quickly and inexpensively many copies of a message. Lippmann regarded it as an apt name for his concept of a cognition that conforms to a fixed or general pattern and whose reproduction is easy. Lippmann said that to form an accurate picture of reality is a hopeless task because the real environment is altogether too big, too complex, and too fleeting for direct acquaintance. Instead, mass media present us with a simplified reconstruction of the world with which we can live (Lippmann 1922).

Stereotypes occur in a variety of environmental contexts, including social roles (e.g., gender), group conflicts (e.g., ideology), and power. Since the powerful pay less attention to the powerless than vice versa, the imbalance in attention allows the powerful to employ stereotypes as a controlling device, particularly when played out through the media. Stereotyping thus allows those with power to maintain and justify the status quo. The → “spiral of silence” theory of public opinion formation holds that a stereotype is a vehicle for spreading → public opinion. By crystallizing conceptions and opinions, stereotypes let everyone know when to speak up and when to shut up. In that way, stereotypes are engines of conformity.

Stereotypes arise from the need for a positive social identity with an ingroup that, in a form of compensatory narcissism, enlists an outgroup as a relative devalued contrast. Mass media are implicated in how social groups are labeled, defined, and framed (e.g., who serves as spokespersons and which group attributes are made salient; → Social Identity Theory).

Before children personally are able to evaluate stereotypes, they learn them from authority figures and peers, whose explicit or tacit approval for expressing stereotypes reinforces their use. Information processing in favorable conditions and through extensive practice becomes automatic, i.e., without intention or conscious awareness. Repeated encounters in different contexts thus allow a stereotype to become activated automatically.

Whether a person's personal beliefs complement or contradict cultural stereotypes, personal beliefs develop later in life and are less practiced, so they are not as automatic. The dissociation between cultural stereotypes and personal beliefs produces different dynamics for high- and low-prejudiced persons. Following automatic activation of a stereotypic idea, the low-prejudiced can control their response, forcing it to correspond to their unprejudiced standards. However, there is a cost. Suppression of stereotypical cognitions is an effortful process that taxes the perceiver's conscious resources. In categorizing a person merely through group membership, a perceiver uses stored information instead of making an effort to process new incoming information. This saves cognitive resources. Thus, while stereotypes complicate the life of the *stereotyped*, they simplify the information processing demands of the *stereotyper*.

Early conceptualizations of stereotyping viewed it as abnormal, as a motivated irrational response to frustration or the disorder of an authoritarian personality. Considerable evidence has amassed that stereotyping is a normal cognitive process and that people stereotype unless otherwise motivated or imposed upon by the demands of specific task environments. Nonstereotypical modes of thought can be engaged only if critical cognitive and motivational criteria are met, such as spare intentional resources, self-involvement, outcome dependency, and accountability. Absent such criteria, perceivers economize cognition through the application of stereotypes. Furthermore, this occurs without a perceiver's deliberate intention.

Generally, humans operate as "cognitive misers," overwhelmed by the complexity of the social environment and forced to conserve scarce mental resources. Humans are stingy in the allocation of online capacity, so they routinely resort to heuristic and peripheral information processing. Occasionally, however, humans are motivated to invest scarce cognitive resources in order to process information systematically and elaborately. Dual process models of information processing generally treat stereotypes as cognitive shortcuts. For example, rather than take the trouble to gather information about a candidate for public office, a person may use party affiliation as a heuristic. If, in the US, the candidate is a Democrat then one's stereotypical view of the qualities of Democrats is bestowed upon the candidate. A Republican candidate gets the same peripheral treatment.

Stereotypes are learned early, reinforced often, and encountered repeatedly, which allows them to occur automatically. As superficial as are most social encounters, stereotyping generally suffices. However, when motivated and able to process more elaborately and systematically, humans can think beyond stereotypes.

## **Stereotyping and the Media**

*Osei Appiah*

*Ohio State University*

Stereotypes are positive or negative generalizations indiscriminately attributed to members of a group (Tamborini et al. 2000; → Stereotypes). They have a significant impact on individuals' perception of and interactions with members of different social groups by conveying information about the social groups' capabilities (e.g., fast learners, good athletes), personalities (e.g., shy, violent) and/or socio-economic status (e.g., educated, powerful, poor).

While stereotypes may come from personal interaction, they are often acquired indirectly from exposure to mass media (→ Exposure to Communication Content). The media are powerful in developing, reinforcing, and validating stereotypical beliefs and expectations concerning certain groups, particularly when the audience's personal experience with those groups is limited (→ Media and Group Representations). Media conveniently package information about social groups into simple, identifiable images, thereby assisting → audiences to more easily accept and understand people and things they have not closely experienced. LaFerle and Lee (2005, 142) argue that “to provide an efficient path to cultural understanding, mass media employ stereotypes as a convenient categorization tool. The stereotypical → images found in media messages are easily accepted because they are usually simple and have little ambiguity.” They “act as self-perpetuating expectations about groups and their members, by directing attention to information that is consistent with the stereotypes. Information that is inconsistent, on the other hand, tends to be ignored, discounted, or interpreted so that it confirms the initial impression” (Peffley et al. 1996, 311; → Social Stereotyping and Communication).

### **FUNCTION OF SOCIAL STEREOTYPES**

Media from which audiences may receive stereotypical messages include → television, films (→ Film as Popular Culture), → newspapers, music (→ Popular Music), and any other source of mediated advertisement (→ Advertising), entertainment, education, or → news. In an effort to reach a broad audience with a clear message, the media often uses

stereotypical categorizations of individuals or groups based on attributes such as ethnicity, gender, class, employment, sexual orientation, religion, mental or physical disability, and age. These stereotypes are automatically activated when audiences encounter cues or symbols in mass media (Peffley et al. 1996; Abraham & Appiah 2006).

The media use *common cues* to help prompt the particular stereotype(s) to be applied in a given situation. This is useful since most groups are subjected to more than one stereotype. For instance, women may be portrayed in the media as nurturing mothers, aggressive businesswomen, or sexually alluring jezebels. Each portrayal has its own set of verbal and visual symbols to help the audience invoke the proper set of stereotypes.

Stereotyping is not inherently bad or harmful. In our complex world, stereotyping is necessary and helpful to simplify and organize the environment, enabling us to determine how best to respond in a given situation (→ Information Processing: Stereotypes). There are complimentary or positive stereotypes that have been shown to play an important role in intergroup relations and in countering negative stereotypes, leading to enhanced images of certain groups (Czopp & Monteith 2006; Kawai 2005; → Social Perception; Intergroup Contact and Communication). For example, although there is a dearth of empirical research on the use of media in reducing stereotypes, educational television programs that depict counter-stereotypic content have been shown to reduce children's negative stereotypes toward and increase their positive attitudes about ethnic minorities (Bogatz & Ball 1971; → Educational Media Content).

In the absence of primary information or knowledge, media stereotypes can help guide us through unfamiliar social situations or experiences with foreign cultures. For example, stereotypes about international businesspeople may help a job candidate decide what to wear to an interview with an investment banker or how to interact with corporate representatives during a meeting. Positive stereotypes about doctors' intelligence may help the patient feel more comfortable before surgery. A traveler who has never visited China may use Chinese stereotypes to help guide her interactions with Chinese natives until she has enough direct experience to confirm or refute her stereotypical impressions. It is generally not until stereotypes are used in negative ways – to serve as the foundation for negative prejudice – that stereotyping becomes particularly problematic, potentially leading to discrimination and intolerance of certain groups.

### EXAMPLES OF NEGATIVE STEREOTYPING

Some of the most blatant examples of negative stereotyping can be seen in the depiction of certain *ethnic groups in the media*. For example, negative stereotypes of Israeli–Palestinian relationships in the media have had dire consequences for children in the Middle East. Research has shown that exposure to ethnic media has been associated with Palestinian children's descriptions of Israelis as people who “want to put us in jail” and “shoot at us,” and with Israeli–Jewish children's descriptions of Arabs as “terrorists” and people who “want to take our land” (Cole et al. 2003). Similar negative stereotyping of Arabs can be found in Russian media. Yelenevskaya and Fialkova (2004) argue that since many Russians have had no direct contact with Arabs, the negative stereotypes Russians hold toward Arabs that characterize them as hostile, dogs, and dirty are borrowed from the mass media.

Other problematic ethnic stereotyping has been found in: German news media and cinema that negatively stereotype Turkish and Muslim women (Ewing 2006); Japanese children's books that negatively stereotype blacks as Sambos; American movies that ubiquitously portray Russians as evil (Molnar 1989); and Australian films that frequently describe ethnic minorities using negative racial epithets like "wog" and "chocko" that distinguish people with darker skin from lighter-skinned members of the ethnic majority (Speed 2005).

In American media, many of the most blatant examples of racial-ethnic stereotypes are associated with *black people*. In the early years of American television blacks were routinely characterized as lazy, untrustworthy, and unintelligent, relegated to largely demeaning roles designed to entertain white audiences, and shown living primarily in ghettos and slums (Mastro & Greenberg 2001). Even today, Crowds and Georgakas (2002, 9) argue that sitcoms like those appearing on the WB and UPN networks are often "borderline minstrel shows" that conjure up negative stereotypes of blacks "still acting as buffoons and coons" (→ Entertainment Content and Reality Perception).

Television news portrayals of blacks are far more negative, over-representing black perpetrators, under-representing black victims, and over-representing white victims (Dixon & Linz 2000). News stories make associations between blacks and negative issues such as violent crime, drugs, poverty, and welfare by situating these stories alongside noticeable images of blacks (Martindale 1996; Entman & Rojecki 2000). These news stories send powerful messages to audiences that most blacks are violent, criminal, drug-addicted, and on welfare, "and because these images come from the news media, which claim to represent reality and to provide unbiased information about society, Anglos tend to believe the images are true" (Martindale 1996, 21–22).

## EFFECTS AND CHALLENGES

Stereotypes in the media can *impact audience opinion* (→ Attitudes). For example, research on the effects of ethnic and racial stereotypes demonstrates that exposure to negative ethnic imagery in the media adversely influences later evaluations of ethnic minorities (Mastro & Tropp 2004). The simple exposure to stereotypical images of poor blacks in the media has led audiences to perceive greater disparity in socio-economic status between blacks and whites (Gandy & Baron 1998), and perceive that blacks are more economically disadvantaged than whites (Armstrong et al. 1992). Although whites' stereotypes of blacks as poor do not match actual poverty statistics, they do closely resemble racial representations in the news media that feature blacks as poverty-stricken (Peffley et al. 1996; → Television News).

It is important to realize that stereotypes are *permanent fixtures* in our mediated society and in our minds. Given that stereotypes are associated with a variety of groups and once formed are not easily dismissed, greater efforts should be made to disseminate accurate and diversified depictions of groups that appear in the media. Although media stereotypes can be negative, they are useful and necessary in providing information about unfamiliar people and places we might not otherwise encounter without the assistance of the media. Our challenge is to use stereotypes as convenient tools for navigating through millions of media messages, without succumbing to their most powerful shortcoming –

the tendency to ignore the diverse thoughts, behaviors, and contributions of the unique individuals behind the stereotypical images.

## Stimulus–Response Model

*Frank Esser*

*University of Zurich*

The stimulus–response model is associated with the assumption that the mass media has powerful effects. Also referred to as the “hypodermic needle theory,” “transmission belt theory,” or “magic bullet theory,” it can be considered one of the first general conceptions describing mass media effects (→ Media Effects, History of). Lowery and DeFleur (1995) summarized the basic assumptions behind the stimulus–response or hypodermic needle theory as follows: (1) people in a mass society lead socially isolated lives, exerting very limited social control over each other because they have diverse origins and do not share a unifying set of norms, values, and beliefs; (2) similar to higher animals, human beings are endowed at birth with a uniform set of instincts that guide their ways of responding to the world around them; (3) because people’s actions are not influenced by social ties and are guided by uniform instincts, individuals attend to events (such as media messages) in similar ways; and (4) people’s inherited human nature and their isolated social condition lead them to receive and interpret media messages in a uniform way.

In this model, media messages are seen as “symbolic bullets,” striking every eye and ear, resulting in effects on thought and behavior that are direct, immediate, uniform, and therefore powerful. According to the generally accepted history of media effects research, the stimulus–response model was the guiding perspective in the media effects field during the early days of communication study. Although this “received view” on the field’s history does not go unquestioned, it is still influential.

### ORIGINS OF THE MODEL

During the early decades of the twentieth century, communication scholars derived the stimulus–response model from a questionable interpretation of the psychological and sociological theories prevalent at that time (DeFleur & Ball-Rokeach 1982). *First*, so-called instinct psychology, developed shortly after the turn of the century, was interpreted to show that the media targeted stimuli toward internal, biologically determined drives, emotions, and other processes beyond rational control. Therefore, the same, or at least

similar, reactions were triggered in all individuals. *Second*, theories of mass society, prevalent during that time period, were construed to state that the audience existed in an urbanized and industrialized society that was volatile, unstable, rootless, alienated, and inherently susceptible to manipulation. As a result, people were regarded to be defenseless against and at the mercy of the capricious stimuli of the media. This was particularly the case as early ideas maintained that mass media were run primarily by people and organizations that were deliberately trying to exert a targeted influence upon recipients (like media tycoons, wartime governments, and advertisers; → Propaganda; Advertising).

The *third factor* contributing to a belief in all-powerful mass media was early propaganda research in the United States. According to → Harold D. Lasswell, who dealt with World War I propaganda in his doctoral dissertation, “the strategy of propaganda . . . can readily be described in the language of stimulus–response. The propagandist may be said to be concerned with the multiplication of those stimuli which are best calculated to evoke the desired response, and with the nullification of those stimuli which are likely to instigate the undesired response” (Lasswell 1927, 630). The standard history of the field interprets this quotation by Lasswell – who undoubtedly was one of the fathers of mass communication research – as representative of the mindset of the generation of media scholars at that time.

In the 1930s there was much concern in the United States over the success of Nazi propaganda in Hitler’s Germany. At that time there were also regular demonstrations by Nazi supporters in many places in the US, as, for example, in New York’s Madison Square Garden. For this and other reasons the Institute for Propaganda Analysis was founded in 1937, and social psychologist Hadley Cantril became its first president. Cantril’s study *The invasion from Mars* (1940) is generally seen as the *fourth* most impressive piece of evidence for the efficacy of the stimulus–response model: the right stimulus – a frightening media message – almost automatically led to a panic reaction on the part of the defenseless recipients. On October 30, 1938 a fictional radio drama unleashed mass panic. Orson Welles had staged H. G. Wells’s *War of the Worlds* in such a gripping and vivid manner that many radio listeners who had missed the announcement and beginning of the program were convinced their lives were threatened by an invasion from Mars. On the next day, the front-page headline of the *New York Daily News* proclaimed: “Fake Radio War Stirs Terror Through US.” *Finally*, Merton’s 1946 analysis of a Kate Smith war bond drive also reflects the assumptions of the stimulus–response model. Merton (1946) wrote that “never before the present day has the quick persuasion of masses of people occurred on such a vast scale . . . Masses of men move in paths laid down for them by those who persuade.”

Merton, Herbert Blumer, and Cantril also discussed intervening variables in the causal process but the standard history of the field interprets their studies as being motivated by an initial belief in the stimulus–response model of mass communication. How did this become the “received view” of the field? Because the first – and vastly influential – historical construction of media effects research stated that it was so. This refers to the book *Personal influence* (1955) in which → Elihu Katz and → Paul Lazarsfeld asserted that early effects research was guided by the following framework: “that of the omnipotent media, on the one hand, sending forth a message, and the atomized masses, on the other, waiting to receive it, and nothing in between.” Their account is seen as the “most important source” for the standard construction of media effects history (Delia 1987). Other research monographs (Klapper 1960), essays (Bauer & Bauer 1960), and

textbooks (DeFleur & Ball-Rokeach 1982) repeated this received history for generations of communication scholars.

### CRITICISM OF THE STIMULUS–RESPONSE MODEL

Recently, increasing numbers of scholars have been disputing this received view and arguing that the direct effects, or hypodermic needle, model was never endorsed by early mass communication research, but that it was instead a *straw man* invented by Katz & Lazarsfeld (1955) that they could easily knock down by demonstrating its weaknesses. Lang and Lang (1981) were the first to dismiss the standard history by stating: “Few, if any, reputable social scientists in the pre-World-War II era . . . worked with what was later described as the hypodermic needle model.” Even 15 years later, Lang (1996, 15) had still not managed “to find a footnote to a scholarly book or article that espouses it.” Indeed, authors who proclaimed that the stimulus–response model was the prevalent paradigm of this time cite not one study from the 1920s or 1930s that could be considered mass communication research and at the same time would support their stimulus–response claims. Hence, Chaffee and Hochheimer (1985) argue that the hypodermic needle model described by Katz and Lazarsfeld misrepresents the field’s history; indeed, that it was created as a foil against which their own limited effects model could be contrasted and presented as an impressive paradigm shift.

What are the critics’ arguments in dismissing the recorded history above? *First*, they doubt that early media effects researchers were strongly influenced by nineteenth-century European social theorists like Toennies, Durkheim, or Le Bon and their concepts of mass society – so much so, that some critics (e.g., Chaffee & Hochheimer 1985) voiced doubts that there were ever any serious proponents of mass society theory. As Czitrom (1982) concluded, “the whole notion of a theory of mass society was something of an artificial and spurious construct, an intellectual straw man created by its opponents.” Katz (1987), as a direct target of these allegations, recently admitted that empirical studies at the time were indeed not guided by mass society theory; nevertheless, he believes that “it was a highly prevalent image among both political and cultural philosophers.”

*Second*, critics of the standard theory have difficulty taking seriously the isolated reference that Lasswell makes to stimulus–response in his propaganda study. They point out that early propaganda studies were more descriptions of content and of execution than they were tests of effects, and that they had little to do with communication research as we know it (Lang & Lang 1981; Delia 1987). They also point out that Lasswell played no important role in media effects research of the time – he was cited in no significant effects study during this time period (Chaffee & Hochheimer 1985; Delia 1987).

The *third reason* lies in a diametrically opposite interpretation of early classic studies like Cantril’s *War of the worlds* study or the famous Payne Fund studies. Both investigations in no way discovered uniform stimulus–response effects. Instead, they recognized early on that there were individual differences in reactions to media stimuli. In addition, consideration of intervening and mediating variables (→ Media Effects: Direct and Indirect Effects) showed that these reactions had been based on conditional instead of direct effects (Lang & Lang 1981; Wartella & Reeves 1985). Bineham (1988) explains the differing interpretations of these early studies with the idea that advocates and critics of

the received view had a very different understanding of what the hypodermic needle model meant. Advocates see the recognition of intervening variables as mere elaborations upon the hypodermic model if the studies still assume that mass communication is a one-directional and linear process; critics of the received view see the recognition of differences among media audiences and the inclusion of mediating variables as a break from the established tradition (Bineham 1988).

It can be concluded that within the social science tradition of media effects research, the position occupied by critics of the received history has rapidly gained popularity and persuasiveness. However, the opposing camp has seen some changes. It is no longer populated by those early authors who adopted Katz and Lazarsfeld's (1955) first scheme without further reflection. Instead, it now consists primarily of critics of social-science-oriented media effects research. These are primarily representatives of a critical or cultural paradigm who see most social scientific or empirical effects research as an elaboration of the hypodermic model tradition because – in their view – it conceptualizes the sender, message, and receiver as isolatable elements and sees the receiver as a largely passive target of message manipulation (Bineham 1988; → Critical Theory; Cultural Studies). Bineham (1988) sees the *battle for the past* as a highly significant effort between opposing camps to define the history of mass communication research in specific ways in order to justify their current respective positions.

## Stock Photography

*Paul Frosh*

*Hebrew University of Jerusalem*

Stock photography is the name given to a particular type of standardized commercial imagery. This largely consists of clichéd photographs of consumer well-being or corporate achievement: the happy couples on sun-drenched beaches pictured in travel adverts, and the well-groomed businessmen shaking hands who tend to grace company brochures (→ Advertisement, Visual Characteristics of). Stock photography is also the name of the industry that manufactures, promotes, and distributes these images for use in → marketing, → advertising, publishing, and increasingly multimedia products, websites, and other digital platforms (for instance, the sunsets and cloud images one can find on mobile phones). Worth an estimated US\$2 billion annually, the industry continues to expand into new areas of image production and supply: its leading corporations own some of the most important historical photographic archives, manufacture and market stock film footage, and compete with traditional sources of → photojournalism. Despite the ubiquity of its products, and estimates that it supplies a majority of the photographs used in advertising and marketing, the stock photography industry is largely overlooked by researchers into photography and consumer culture (exceptions include Miller 1999; Frosh 2003; Machin 2004), and is invisible to the general public.

### THE EMERGENCE AND FUNCTIONING OF THE STOCK PHOTOGRAPHY INDUSTRY

Stock photography emerged as a full-fledged, self-conscious industry in the 1970s (on historical precursors see Hiley 1983; Wilkinson 1997). Its main commercial premise is that advertising agencies will find it cheaper, faster, and less risky to “rent” readymade

images from an archive than to commission photographers for specific assignments (“assignment photography” is a term used for original or unique product photography projects).

In the 1990s the industry underwent radical reorganization, accompanied by pervasive technological change. Large stock agencies were acquired by yet larger competitors and integrated into global conglomerates in a burgeoning, digitized “visual content” industry (→ Digital Imagery). Today stock photography is dominated by three US-based multinational “super-agencies”: in descending order of size, Getty Images PLC; Corbis (privately financed by Microsoft president Bill Gates); and JupiterImages. These conglomerates compete alongside small and medium-sized agencies in a range of specialty fields: lifestyle and marketing imagery, contemporary editorial photography, historical images, sport, celebrities, illustrations and fine art prints, and stock film footage. Getty, for instance, as well as selling clips from its own wholly owned film archives, also distributes footage from Universal Studios films (→ Culture Industries).

Two principal production models determine how stock images are made. In traditional “rights-controlled” or “rights-protected” stock photography, agencies “rent out” images to clients for a limited time period or usage. These images have themselves been acquired from freelance photographers, who get a share of the revenue (usually well below 50 percent) in return, ideally generating long-term income through the *multiple resale* of each image to many different clients. The images are kept in “stock” by the agency, duplicated, categorized, and keyworded according to content, style, photographer, and potential meanings, before being marketed – formerly through printed catalogs and CDs, today most frequently through agency websites. Prices are negotiated according to type of usage (whether the image is for a print advertisement, product packaging, corporate brochure, etc.), time period, region, and extent of exclusivity, and they can range from several hundred US dollars for use in a small brochure to several thousand for national advertising campaigns.

In the 1990s new digital technologies transformed possibilities for the relatively inexpensive storage, duplication, and distribution of images, giving rise to “royalty-free” (RF) photographs. RF is based on a pay-per-image principle, whereas rights-controlled stock is based on a pay-per-use principle: in contrast to rights-protected stock, when you purchase an RF image it includes a very broad license to use it for almost any purpose as many times as you want. Available individually online, or on CDs or downloadable “virtual CDs” containing anything between 50 and several hundred photographs, RF images are geared to media professionals looking for “low-end,” lower-cost, and instantly available images without the need for exclusivity.

Despite early concerns that RF images would take business away from rights-controlled stock, all the large super-agencies, and many smaller ones, operate both systems side by side. In fact, one of the most conspicuous characteristics of the stock industry in recent years has been the proliferation of new business and production systems. Some of these are borrowed from other media industries (for instance, traditional news wire services), such as paying monthly or yearly subscription fees for an unlimited supply of images, and some are initiatives apparently originating with photographers themselves, such as “community-based” (also called “micro-stock”) websites involving semi-professionals and proficient amateurs and selling images for as little as US\$1. In a radical departure from the stock industry’s usual emphasis on providing readymade images, Getty and

Corbis will also specifically employ photographers to make new images according to client specifications (assignment photography).

### THE LOOK OF STOCK IMAGES

Stock photographers have the difficult task of producing images that are simultaneously “generic” – an industry term denoting the photograph’s generality and its ability to be resold for multiple uses – and singular: uniquely suited to the purposes of a particular buyer. To borrow an analogy from the garment trade, a successful image needs to look off-the-shelf *and* tailor-made. Moreover, since a good example of what a successful stock photograph might look like is set by images that are *already* displayed in catalogs or websites, the easiest way to create a successful new image is to copy an old one. Hence, notwithstanding the marketing rhetoric of innovation and creativity commonly employed by agencies, the stock system is frequently accused – by clients and industry insiders as well as critics – of encouraging conservatism and the constant reproduction of formulaic images that reflect, construct, and reinforce cultural → stereotypes (→ Visual Representation). These images are primarily geared to the needs of consumer advertising, and they almost always focus on middle-class American and European leisure activities (such as beach vacations) and economically privileged and ethnically normative demographic categories (youthful, white, middle-class individuals and families), as well as seemingly universal depictions of “relationships” of kinship, friendship, and romance.

Nevertheless, shifts in advertising and marketing practices since the early 1990s have led to the appearance of less obviously stereotyped image styles and content, including more “realistic” (i.e., grainy and black-and-white) photographs, and images of “ordinary” (that is, not conventionally good looking), “ethnic,” and minority (e.g., gay and lesbian) subjects. These changes in stock images have nevertheless occurred within a limited framework, largely dictated by the cultural backgrounds of photographers and their primary clients, by advertising’s continued promulgation of images of consumer well-being, and by the orientation of many advertisements toward audiences with significant disposable income (which means that visibly affluent people tend to be depicted). This conservatism has even created the need for new kinds of niche agencies: not just those serving previously neglected ethnic groups and communities, but also artistic “high-end” agencies, such as Photonica, that specialize in “avant-garde” or “edgy” images: readymade stock photographs that do not look like stock photographs. The irony is that most of these images, edgy or otherwise, are currently subject to what some stock professionals are calling “thumbnail visibility”: the need for photographs to attract a potential client’s attention while occupying a relatively small area of virtual space as part of an image-crowded thumbnail gallery on a computer screen. This tends to discourage pictorial subtlety, and can lead to even more standardized pictures.

### STOCK PHOTOGRAPHY, PHOTOJOURNALISM, AND THE “VISUAL CONTENT INDUSTRY”

In the late 1990s and early 2000s a new term, the “visual content industry,” seemed to be emerging to describe the expansion of the stock industry’s super-agencies into new areas:

sport photography, celebrity photography, fine art reproductions, illustration, stock film footage, historical archives, and photojournalism. While the use of this term has not caught on, the expansion has become increasingly institutionalized, as has the apparent blurring of discursive and organizational boundaries between the three great photographic fields of art photography, advertising photography, and documentary photojournalism (known in the trade as “editorial → photography”).

It is in the case of editorial photography that this realignment of fields has become most conspicuous in recent years. This is partly because of the acquisition by Getty and Corbis of some of the main historical archives of news photography in the US and western Europe: Getty bought the Hulton Deutsch Collection in 1996 and subsequently renamed it the Hulton Archive. It comprises 15 million images from the major British newspaper and press archives of the nineteenth and twentieth centuries. Getty also acquired one of the largest North American historical photographic archives when it bought the Image Bank in 1999. Corbis, in the meantime, owns – among others – the 17-million-image Bettmann Archive. Both Getty and Corbis are digitizing these archives very selectively: the cost (including labor and keywording) is estimated at around US\$10–20 per image, making the digitization of whole archives economically unfeasible. Historical images selected for digitization are likely to be those that have the greatest commercial potential as crossover material for advertising and marketing use. Our collective visual image of the past may therefore be less and less varied, its putative historical accuracy made subordinate to its current commercial exploitability (→ Visual Culture).

However, the super-agencies are also aggressively expanding into contemporary photojournalism. Getty is leading the way, since 2003 steadily encroaching on the newspaper market long dominated by the global news agencies. Editorial sales accounted for 12 percent of Getty’s revenue in 2005, and the company sees its images in the major newspapers as invaluable advertising for its other products. This encroachment has been facilitated by the hiring of veteran wire service photographers and editors, and a global content sharing and distribution partnership with Agence France-Presse (→ News Agencies). Reuters and Associated Press (AP) have reorganized their photography divisions in response. AP has even returned fire on Getty’s core business, allowing its staff news photographers to use company equipment to shoot commercial stock images – non-news images of romantic couples etc. – in their spare time (→ Commercialization: Impact on Media Content).

It is tempting to conclude from these developments that the distinctions between documentary photography and advertising imagery are collapsing entirely, notwithstanding crucial differences between them. However, Getty is at pains to distinguish itself from the “generalist” approach of the wire services by emphasizing the role of specialization: its photographers will remain in their various areas of expertise, and one is unlikely to find photojournalists being encouraged to photograph happy families or make other commercial images in their spare time. Paradoxically, in order to promote itself as the ultimate “one-stop-shop” for all its diverse clients, Getty has shifted away from notions of “visual content” as an abstract universal and is reinstating discourses of *field-specific expertise*. This gives it a persuasive answer to an obvious question: why would a commercial photography corporation like Getty be any good at photojournalism? Rather than saying “because editorial and stock are types of visual content, and a Getty photographer can shoot both,” Getty says “because we recognize that photojournalism is *not* like stock, so

we've hired the best photojournalists.” Of course, a key upshot of Getty's and Corbis's expansion into photojournalism is that – just like the historical archive images they own – news and documentary photographs *do* therefore become more like advertising-oriented stock images: increasingly subject to a commercial logic, severed from immediate contexts of interpretation, and available for multiple resale and recycling in a plethora of contexts, journalistic and otherwise.

## **Storytelling and Narration**

*Tamar Katriel*

*University of Haifa*

Communication research has long recognized the centrality of storytelling in the construction of identities, relationships, and communities. Fisher (1987) went so far as to propose the metaphor of man as “homo narrans,” pointing to the narrativization of experience as a fundamental human cognitive strategy and social practice (→ Rhetoric and Narrativity). Narratives are made up of sequentially organized verbal and/or other types of signs (visual, musical, kinesthetic) that depict a temporal transition from one state of affairs to another (Ricoeur 1988). Using one or more modalities, they create a plot that incorporates the narrated events within a sense-making scheme. Thus, narratives interweave events, circumstantial elements, and emotions by imbuing them with a sense of meaning and order in terms of temporal coherence, causal links, and value orientations. Current research into narration as a socio-culturally situated activity is a multidisciplinary enterprise, spanning literary studies, psychology, sociology, anthropology, and linguistics. It encompasses both face-to-face and technologically mediated communicative encounters, as well as the poetics and politics of high-profile narrations and

everyday storytelling performances. While some scholars view the term “narrative” as an overarching category designating any explanatory system (such as science), reserving the term “story” to refer to one of its sub-genres, most studies of narration as a discursive activity embedded in social interaction use these terms interchangeably, as will be done here.

Recognizing the constitutive role of narrating, communication researchers have built upon, elaborated, and refined a range of perspectives originally associated with the study of myths, folktales, and oral performance. These seminal approaches have been inspired by structural-functionalist modes of analysis, whether they were textual or interactional in orientation (or both). A major analytic distinction that cuts through many approaches to the study of narration is that between the *narrated events* that constitute the referential building blocks of the story and the storytelling activity as a social practice (e.g., Young 1987). This distinction anchors a shift from the earlier concern with the study of story-as-text to a view of storytelling as a negotiated performance.

Broadly speaking, research into storytelling has involved the following analytic concerns, separately or in combination: (1) characterization of the discursive organization of narratives as structural units; (2) explorations of the socio-cultural functions of storytelling activities in different socio-cultural contexts; (3) investigations of the dynamic, negotiated construction of narrative as situated performances. The first two analytic foci have long shaped research on storytelling; the third represents recent developments in narrative research that focus on storytelling as an interactionally negotiated mundane accomplishment.

## NARRATIVE STRUCTURE

The study of narrative structure has been central to the exploration of storytelling in a range of research traditions concerned with the role of narration in social life. Thus, Lévi-Strauss (1955) analyzed culturally focal myths in terms of the basic underlying tensions between conceptual, binary categories, such as male vs. female, raw vs. cooked; Propp (1968) analyzed folktales in terms of the plot-generating functions of narrative clauses that identify the basic roles of actors and action types in the construction of a tale; Labov and Waletzky (1967) analyzed elicited personal experience stories as a series of sequentially organized clauses that refer to temporally ordered actions and events. Labov’s framework combines attention both to the referential function of the story clauses as pointing to background information (orientation) and plot structure (complicating action, resolution), and to the use of “evaluation” devices, which convey the narrator’s involvement in the storytelling activity and reflect the attempt to impress the recipients with its significance and relevance. This complex speaker- and recipient-oriented dynamics has been central to narrative research within the sub-field of language and social interaction, engendering a number of complementary research directions.

The interactional structure of naturally occurring narrations as they are embedded in the flow of talk has been explored by conversation analysts (→ Conversation Analysis) in terms of turn-taking mechanisms. Scholars have addressed the ways in which access to the conversational space required for telling a story is negotiated by interactional partners, often through the use of a preface signaling the desire for an extended turn-at-talk, and

how such access is ratified by the story recipients, who suspend their rights to the floor. The telling of a story is usually concluded with “exit talk” that indicates the speaker’s return to the conversational flow in which it was embedded (Polanyi 1989). This structural focus finds its complement in studies concerned with the function of stories and the meaning of storytelling activities.

### **FUNCTIONS OF STORYTELLING**

Storytelling activities are widely viewed as essentially anchored within a broader dynamic of social exchange (Bakhtin 1981), serving a range of personal, interpersonal, and communal functions. Most basically, storytelling serves as an important meaning-making mechanism by narrativizing out-of-the-ordinary, “reportable” events in such a way as to indirectly mark the taken-for-granted, the unremarkable order of things. It serves to span imaginary and everyday contexts by making possible worlds present to contemplation and feeling for both the narrators and the story recipients (Bruner 1986). It serves to link narrators and their audiences through the invitation to empathy and the display of understanding and appreciation.

Even while insisting on the universal significance of storytelling as a sense-making human activity, scholars have highlighted the social and cultural functions of storytelling activities in particular contexts of performance. Personal experience narratives have emerged as central to the construction of personal and collective identities (e.g., Langellier 1989), serving to integrate the self by creating a life story that is embedded within a culturally shared understanding of what constitutes a continuous, reasonable, proper, and worthwhile life trajectory. Studies of self-narrations show how narrators construct cognitively coherent accounts that help them and their audiences make sense of past events as temporally ordered, causally linked, and emotionally motivated. Notably, such narratives are grounded in a rhetoric of self-justification. By selectively presenting and organizing autobiographical materials in particular ways, by offering assessments of the actions, the plotlines, and the characters that inhabit their stories, narrators work to present themselves in a favorable light. In so doing, they invite story recipients to join them in probing the moral dimensions of human experience and the trajectories of morally acceptable identities and conduct.

Other scholars have focused on the role of storytelling in the construction of collective and institutional identities. Thus, for example, the stories exchanged in informal organizational settings serve important communal and interpersonal functions as they underscore notable chapters of institutional history and the people inhabiting it. Such stories shape members’ shared knowledge of the organizational landscape, demarcate the boundaries between those who do and do not belong in it, and socialize novices into the norms and values that ground social relationships and practical arrangements in the workplace.

In studying the role of storytelling in familial, institutional, and communal settings, scholars have mainly attended to the solidarity function of shared narratives. Some scholars, however, have begun to address the role of stories in argumentative and agonistic situations as well (→ Argumentative Discourse). The power of narrative to offer definitions of social situations, to inscribe particular versions of reality, and to endow

protagonists and their actions with a particular valence makes them effective tools in both interpersonal and collective struggles over domination and control. The politics of narration in struggles over meanings, values, and privilege is often couched in terms of clashes between competing narratives and counter-narratives. Hegemonic versions of national narratives and other deeply felt collective tales, which are routinely appropriated by individuals in both face-to-face and mass-mediated settings, provide idioms for the exploration and display of cultural identities. The narrating of alternative versions of present or past events can be viewed as an act of resistance (as, for example, in the circulation of personal blogs that narrate realities obscured by the mainstream media).

### **NARRATIVE PERFORMANCE**

Studies of the performance of narrative roles in face-to-face conversational settings indicate that they are often subject to ongoing modification by story recipients, who challenge, or elaborate upon, the main storyline (Mandelbaum 1989). The entitlement to tell a story is couched in knowledge claims that yield narrative authority. Such claims may be shared by interactional partners or unequally distributed among them. Co-narrations can have a powerful bonding effect, as they both reflect and reinforce a sense of mutuality through the joint enactment of shared ground. Recipient-driven collaborative storytelling, however, may also be associated with asymmetrical social relations. Story recipients may even change the direction or valence of the main teller's narration by introducing explicit challenge or previously unmentioned materials (e.g., in psychotherapeutic discourse or courtroom interrogations).

The study of storytelling rights – whether interpreted in terms of the management of rights to the floor, of access to knowledge about events, or of the right to express one's point of view – is anchored in a view of speech as a social resource. Questions concerning the obligations associated with storytelling as a form of social action must, however, complement the research focus on storytelling rights. A variety of social and institutional roles involve an expectation that their incumbents engage in storytelling activities. The obligation to recount past events is intrinsic to testimonial activities such as those included in legal proceedings, news reporting, or national commemorations. The exploration of such storytelling obligations has been marginal in studies of narrative activities, and deserves more research attention.

The foregoing analytical themes come together in studies concerned with storytelling as a discursive tool for the socialization of children and with socializing children to become participants in narrative events (→ *Intimate Talk with Families and Friends*). These studies focus on culturally designated occasions in and through which children are exposed to adult narrating and are invited to assume the narrator role, such as mother-child interactions and family dinners (e.g., Blum-Kulka 1997).

Thus, research on the social life of narrative has brought out the complex role played by storytelling performances as a form of social action, their role in the communicative production of personal and collective identities, and the ways in which narrative performances are interactionally negotiated in everyday settings. Current research seems to be building on this foundation in further investigating the role of storytelling activities as social practices in landscapes of cultural diversity and social struggle.

## **Strategic Communication**

*Derina Holtzhausen*

*University of South Florida*

Strategic communication is the study of how organizations or communicative entities communicate deliberately to reach set goals. Although the term “strategic communication”

has been in use for years, scholars are only now fully engaged in defining the field and its theoretical influences. Traditionally communication in its organizational context has been studied through various disciplines academically and functionally scattered over domains from management communication, → marketing communication, → advertising, → public relations, technical communication, → organizational communication, and → political communication, to → information or → social marketing campaigns (Hallahan et al. 2007; → Social Movements and Communication). It also covers the full spectrum of economic and social sectors, such as trade and industry, politics, nonprofit, government agencies, activist groups, and even celebrities in the sports and entertainment industries, all referred to here as communicative entities.

All these fields have one commonality: they engage in the *study or practice of deliberate and purposive communication* aimed at reaching goals such as winning market share, building a positive reputation, winning a political campaign, or enacting social change. This involves people who engage in deliberate communication practice on behalf of organizations, causes, and social movements, and thus has a definite focus on the practice of communication (→ Applied Communication Research). Strategic communication is planned and proactive, aimed as much at reaching organizational goals as at prevention of organizational crises.

The field faces a challenge in coordinating and integrating the communication activities of organizations, which are often scattered over several different reporting structures, particularly in large, complex organizations (→ Integrated Marketing Communications). Another challenge is the creation of a multidisciplinary but unified body of knowledge that better serves communicative entities in a society consisting of fragmented audiences and message delivery platforms. Strategic communication also has a significant impact on society at large. Strategic communicators can affect local and global outcomes in terms of every aspect of society, from democracy and political systems and markets to gender roles and cultural orientation.

### **“STRATEGIC” AND “COMMUNICATION” AS PRECONDITIONS FOR THE FIELD**

Generally, scholars in the United States tend to study the field as a process that includes goal setting, audience analysis, message design (→ Message Design Logics), communication channel selection, and assessment. European scholars are more likely to study it as a phenomenon that affects society, e.g., its effect in the public domain on political and policy outcomes. For both these schools of thought the terms “strategic” and “communication” remain central.

The term *strategic* originated in warfare. However, organizations originally used it to describe how they competed in the marketplace to gain competitive advantage and market share (Hatch 1997; Pfeffer & Salancik 1978). Supporters of this view see strategic planning as a rational process that starts with an analysis of the organization’s internal strengths and weaknesses and external opportunities and threats (popularly known as SWOT analysis). The SWOT analysis is used to set the organization’s goals, objectives, strategies, and tactics. Here the role of the practitioner is to replicate this process with the focus on how communication can be used strategically to support the organization’s overall goals. Managers

believe this enables them to exert control over the organization's environment. Critics argue this approach is manipulative and takes into account only managerial goals and intentions. It is viewed as a one-sided approach to management that is asymmetrical and excludes alternative perspectives, including societal interests. These critics challenge the very notion of rationality.

This is an unnecessarily negative view of strategy. Many view all communication as strategic in the sense that all communication is intentional and aimed at persuading (→ Persuasion). New perspectives on strategy formulation in organizations provide several alternative, and more inclusive, interpretations. Emergent strategy holds that strategy is based on prior experience and actions, and so should value the contribution of employees at every level of the organization. Strategy formulation should therefore be a bottom-up process (Quinn, 1978). In → learning organizations, strategy formulation is viewed as a more short-term and agile process that allows organizations to react quickly to developments in their environments, thus recognizing the importance of those environments.

The *communication part* of strategic communication is also contested. For instance, in the United States public relations is often viewed as "relationships with publics" (Ledingham 2003), whereas the European viewpoint focuses on communication that takes place in the → public sphere through public media (Bentele 1994). The European school argues that communication remains central to the study of the field, and that scholars in the United States ignore the fact that all relationships are formed through communication, thus ignoring the process of relationship formation. Communication also remains the core function of other disciplines such as marketing and campaigns of every nature (→ Consensus-Oriented Public Relations; Trust of Publics).

The study of strategic communication does not preclude these divergent viewpoints. An analysis at the macro- or societal level, the meso- or organizational level, and the micro- or actual communication level provides for a comprehensive application of the different theoretical and practical approaches to the field.

## **STRATEGIC COMMUNICATION AND SOCIETY**

The environment in which the communicative entity operates affects the way strategic communication is practiced. One common way to analyze the environment is to discern between the economic, legal-political, socio-cultural, competitive, and technological segments in the environment. These segments do not operate independently but are deeply interlinked. Several studies indicate that when environments are turbulent, the communication functions in organizations are required to become more strategic. Institutional theory and population ecology theory support the notion that organizational environments determine whether an organization will survive or not. By helping organizations adhere to the value systems of the environments in which they operate, strategic communicators help their organizations endure (Holtzhausen 2005). In terms of value systems, the socio-cultural environment is particularly influential in affecting the strategic communication process. Hofstede (1980) found culture has unique influences on organizations. These cultural influences necessarily affect how strategic communicators operate (→ Public Relations, Intercultural).

*Systems, chaos, and complexity theory* perspectives also often explain communication behavior, particularly in the study of crisis communication (Murphy 2000). From this application comes the concept of strategic communicators as boundary spanners who help organizations adapt to their environment by in turn representing the viewpoints of constituents and the organization. Thus strategic communicators form an inherent part of any change management team (→ Change Management and Communication; Systems Theory).

Although → Habermas (1979, 210) has somewhat softened his stance on strategic communication, he views it as a form of communication that is “pseudo-consensual.” He recognizes that strategic communication has become important in the public sphere, but remains critical of the ability of organizations, politicians, and lobbyists to employ strategic communicators that allow them to gain access to the media and so gain political influence. Strategic communicators help these already powerful people gain social capital that adds to their power. This requires the “actors of civil society” to also use strategic communication to affect the debate in the public sphere (Habermas 2006, 15).

Postmodernists in turn argue that all discourse is political and therefore strategic (Lyotard 1988). Foucault (1988, 168) says: “Every human relationship is to some degree a power relationship. We move in a world of perpetual strategic relations.” What these philosophers have in common is that strategic communication is a real and influential feature of the public sphere (→ Postmodernism and Communication).

## **STRATEGIC COMMUNICATION IN THE ORGANIZATIONAL CONTEXT**

Public relations theorists have led the way in studying the impact of organizational factors on strategic communication practice. Grunig (1989) determined that communication practice differed across organization type. Organic and mixed mechanistic-organic organizations are more likely to use advanced communication practices based on communication research and audience analysis. The structure of the communication function itself can have an impact on communication (→ Organizational Structure). A decentralized communication structure will more likely be able to improve information flow and communication climate in large, divisionalized organizations (Holtzhausen 2002). The worldviews of organizational leaders also affect communication practice and determine whether organizations have participative or autocratic communication philosophies.

Strategic communication requires a holistic approach to communication; therefore the communication function should be integrated into a single organizational function. This is difficult in complex organizations where communication functions are often scattered across divisions and departments. For instance, marketing communications might fall under marketing, community and media relations under public affairs, investor relations under finance (→ Financial Communication), internal communication under human resources, and → corporate social responsibility under an organizational foundation. This fragmentation is further exacerbated by the strict definition of roles within each of these disciplines, e.g., copywriter, media relations specialist, event coordinator, strategist, media planner, creative director, etc. (→ Public Relations Roles). In a strategic communication approach it is important that all these communicators work in a team, which is difficult when they have different reporting structures and strictly defined roles.

There are several *explanations for integration problems*. One is the strict differentiation of tasks typically associated with bureaucratic structures, which makes the coordination of communication activities difficult. This is intensified by the overly specialized approach to communication education, where marketing, public relations, advertising, and speech communication are seldom integrated into a single educational unit. Clegg (1990) suggests de-differentiation, which means the breaking down of the borders that separate these. Practitioners will have more opportunities to become multi-skilled in the field, which then makes them more employable. Thus de-differentiation, in practice and academe, will be necessary for the field of strategic communication to flourish.

*Power relations* within an organization are another stumbling block. Mintzberg (1996, 237) first defined the “strategic apex” of the organization as consisting of “those people charged with overall responsibility of the organization.” The marketing function is typically included in the strategic apex, while communication functions are viewed as support staff. This access to power gives marketing departments a decision-making advantage over other communication functions. Communication functions like public affairs often report to a marketing executive and do not have direct input at the top decision-making level of the organization. In this situation communication practitioners often find an overemphasis on consumers, while other, often more important audiences are ignored (→ Control and Authority in Organizations; Power, Dominance, and Social Interaction).

Organizations that are able to integrate their communication activities into a single, integrated unit that has influence at the highest level of the organization and represents all strategic audiences will have a competitive advantage. They can use the skills of all communicators while addressing every audience in the communication process in a coordinated way, insuring consistency of strategic messages and message delivery platforms (Grunig et al. 2002). This is true for multinational companies as well as nonprofit organizations, NGOs, activist groups, political campaigns, or government agencies.

## **STRATEGIC COMMUNICATION AT THE MICRO-LEVEL**

The micro-level is where the actual communication between communicative entities and audiences takes place, and it has always been the major focus of research and practice. The outcome of strategic communication at this level is aimed at reaching the goals set out in the strategic planning phase. Strategic communication goals vary according to the situation at hand. In the marketing context the focus is on → brand building and improving sales. Public relations focuses on reputation management (→ Corporate Reputation) through increasing awareness, maintaining positive attitudes and relationships, or changing negative behavior and poor relationships.

*Integrating marketing and public relations* is also a challenge at this level. Public relations scholars argue that → publics are very different from markets. Organizations choose their markets on the basis of product and service development and then communicate to consumers in specific market niches with the intent to persuade. Publics, on the other hand, engage organizations, often in a negative way because of some perceived transgression. Thus publics can be as diverse as environmental or social activists, shareholders, employees, suppliers of scarce resources, other businesses, and regulators. Members of publics might never be consumers of an organization’s products or services but might still have the

power to influence organizational outcomes. While marketing-oriented disciplines such as advertising focus on persuasion, public relations scholars believe communication with publics should be two-way, providing the opportunity for both the organization and stakeholders to mutually adjust their behaviors. Marketing communications usually takes place through highly controlled mediated channels or at retail level. In public relations the required outcome of communication is lasting and trusting relationships, which needs more direct involvement with publics and less mediated communication. Public relations practitioners typically have much less control over communication situations than marketing communicators.

The strategic communication process overcomes these divisions through a *holistic approach*. The process provides for both persuasive and collaborative communication, depending on the → audiences involved, while maintaining consistent messages. It adopts an audience-centered approach to communication, which is based on a thorough knowledge of the particular audience's characteristics. The ability of an organization to align its goals with those of its publics will thus be more effective in its communication efforts (Werder 2005).

A holistic audience analysis leads to → audience segmentation. Typically this involves defining the demographic, geographic, and socio-graphic profile of audiences, and also identifying social role players, such as activist groups, people in powerful regulatory positions, and even informal leaders. Employees form an integral part of all audience analyses in strategic communication. Many view this as an organization's most important audience. Another way of approaching audiences is to determine their information-processing or information-seeking behavior and their preferred use of communication channels (→ Information Processing; Information Seeking). Thus strategic communication requires knowledge of the full spectrum of communication theories on a continuum from persuasion to full collaboration, contingent on the audience type and situation. Relationships now belong in both the realm of public relations and marketing, which focuses on how employees at all levels interact with customers or how communication platforms enhance interaction with audiences (→ Audience Research).

A recent phenomenon that affects the ability to communicate strategically, and is shaped largely by new communication technologies, is the *network society*. New outlets make it possible for strategic communicators to reach broad but specific targeted audiences outside of the traditional media. As a result both media and audiences have become fragmented, which further necessitates an integrated approach to communicating. These technologies support networks, which Barney (2004, 2) describes as "a structural condition" that bring many people together in multiple, decentralized matrices. Audience members belong to different networks and each network represents a different identity of the audience member. As a result strategic communicators need to identify their target audiences through micro-segmentation (→ Communication Networks; Network Organizations through Communication Technology).

## MEASUREMENT OF STRATEGIC COMMUNICATION OUTCOMES

Traditionally the success of marketing communication has been measured in terms of return on investment (ROI). Public relations scholars argue this is too narrow an approach to measuring the outcomes of communication. First, the ROI principle is only applicable

to for-profit organizations. Return on communication investment, be it financial or time, in activist groups, nonprofit organizations, or political campaigns is measured in social change or election outcomes that require benchmark research to measure progress against. Second, strategic communicators, due to their long-term, proactive approach to communication often prevent crises (→ Crisis Communication). The financial implications are impossible to determine.

Public relations scholars in the United States have long argued that the status of organizational relationships effectively measures public relations outcomes. European scholars particularly focus on measuring trust and reputation. However, trust is inherent in both approaches, which indicates that measuring trust might be an effective way of measuring the outcome of a strategic communication campaign that targets both consumers and other stakeholders.

Some other theoretical concepts that provide measurement techniques in strategic communication would be gap analyses, message adoption, message comprehension, message and media effects, agenda setting, and framing (→ Message Effects, Structure of). These theoretical concepts are often used independently in public relations, advertising, and marketing contexts. Applying them consistently to all organizational strategic audiences allows communicative entities to better evaluate the successes and shortcomings of their communication strategies.

## Strategic Framing

Kirk Hallahan

Colorado State University

Framing is a rhetorical tool used by communicators to delimit the scope of a situation or argument. Although it is “media framing” that has received extensive attention since the late 1970s (→ Framing Effects; Framing of the News), the framing construct is employed to understand communication in a wide range of disciplines, including speech, organizational behavioral, economics, political science, psychology, and sociology. “Strategic framing” involves the purposeful use of this technique by rhetors, social advocates, and communications professionals in fields such as → public relations and advertisers (→ Advertising). The goals of strategic framing are to telegraph → meaning and to focus audience attention on particular portions of a message or aspects of a topic in order to gain a favorable response.

Framing is a critical element in constructing social reality because it helps shape perceptions and provides a context for processing information (→ Information Processing). As a surrounding picture frame delimits a landscape painting, so strategic communicators use message frames to create salience for certain elements of a topic by including and focusing attention on them while excluding other aspects.

Message framing provides “contextual cues” that bias cognitive processing and decision-making. These cues can operate at the conscious or subconscious level during the pre-attention and focal attention phases of processing by message recipients. Framing effects are mediated through the psychological process of “priming” (→ Priming Theory) whereby messages activate particular → schemas (networks of associations and knowledge stored in → memory). Strategic framing thus prompts people to think in particular, desired ways about a topic and to use only a portion of their extant knowledge stored in memory. In so doing, framing shapes inferences made about situations’ definition, causes, and remedy (Entman 1993).

Framing has been cited as a textual, psychological, or socio-political construct in more than 1,000 citations related to the strategic use of framing. These can be categorized into a typology of seven models of framing.

### **FRAMING OF SITUATIONS**

Anthropologist Gregory Bateson (1972, 191) first defined a *psychological frame* as a “spatial and temporary bounding of a set of interactive messages” that operates as a form of meta-communication. Erving Goffman (1974, 21) defined frames as “schemata of interpretation” that provide a context for understanding information that enables individuals to “locate, perceive, identify and label.”

Strategic framing by participants has been recognized as a critical element in the analysis of → discourse, language, and literary storytelling. In the context of → organizational communication, strategic framing is used by managers to impose on others their version of the enacted environment in which the organization operates. In negotiation research, bargaining has been examined as a process of framing and reframing a problem, while linguistic and semantic analysis (→ Linguistics) has been used to examine how problems and solutions can be best stated to the advantage of each of the parties.

### **FRAMING OF ATTRIBUTES**

Semantic framing (i.e., the characterization of objects, events, and people) is a fundamental strategy in promotional communication. Marketers, for example, have a choice of promoting ground beef as either “75 percent lean” or “25 percent fat.” A result can be stated as either “90 percent success” or “10 percent failure.” Evidence suggests that positive framing of attributes such as these almost always leads to more favorable responses.

Advertisers routinely and purposefully place frames around and captions below illustrations to call attention to particular elements of featured products. Advertisers also attempt to characterize (frame) consumer problems as being of a particular type that can be solved by a proffered solution (→ Advertising as Persuasion; Advertising Effectiveness).

Research suggests that a user's prior experience and satisfaction can be primed to link prior experience to an offer and that messages can transform how people perceive and thus justify the subsequent consumption of a product. *Product positioning* is an especially prevalent aspect of framing, in which marketers focus on particular benefits of one brand versus other benefits that might be promoted by other brand-makers in the same product category (Ries & Trout 1981; → Branding).

Attribute framing also has been used by neo-classical economists to investigate decision-making. *Theories of institutional framing*, for example, suggest that focusing on issues such as fairness or environmental friendliness shapes public perceptions of organizations and impacts public choices. In the arena of public issues, McCombs (2004) argues that media framing is equivalent to second-order agenda setting, which prompts people to think about the attributes of a topic, i.e., *how* to think about a topic, not merely *what* topics to think about (traditional or first-order agenda-setting; → Agenda-Setting Effects).

### FRAMING OF RISK

The framing of potentially risky choices has been researched extensively in conjunction with *prospect theory*, which deals with the likelihood that a gain or loss will result from a decision (→ Risk Perceptions; Risk Communication). Kahneman and Tversky (1979, 263) defined a frame as a decision-maker's perception of "the acts, outcomes and contingencies associated with a particular choice." *Prospect theory* posits that people tend to avoid risks when a choice is stated in terms of gains but will take greater risks when choices are stated in terms of losses. Aversion to a hypothetical health risk was the focus of the original psychological experiments related to prospect theory. Not surprisingly, health communication practitioners subsequently have found that framing health arguments in terms of negative consequences generally is more effective than focusing on positive outcomes. Patients are willing to select greater risks if their decision means saving a life or reducing suffering.

There have been similar findings in the domains of strategic bargaining and organizational behavior. Mediators favor bargainers who frame issues in terms of losses rather than gains, resulting in higher values of settlements. The framing of a mediator's role also influences parties' willingness to seek the greatest possible consensus. Business leaders also take greater risks to avoid losses than to seek gains.

### FRAMING OF ACTIONS

Whereas the framing of attributes involves focusing attention on inherent qualities of an object, and the framing of risky choices involves the willingness of individuals to make choices, the framing of actions entails how to best propose actions to achieve compliance with a desired goal.

Parallel to the framing of risky choices, framing of actions in terms of negative consequences appears to be generally more effective than posing positive outcomes. For example, a university might wish to encourage students to pay tuition early in a lump sum instead of paying a slightly higher amount in installments. The university might

frame the early-payment option as a “discount” or the installment plan as a “penalty.” The explanations are different semantically, but the choices are the same. Some evidence suggests that this effect results because negative framing invokes more elaborative processing (→ Negativity). On the other hand, people who engage in less detailed processing or who are high in self-efficacy might actually respond better to positive framing (as with the framing of attributes).

## FRAMING OF ISSUES

Framing plays a critical role in the creation of and public discourse about social problems. Social constructionists argue that activists identify problematic conditions in society and frame them in ways to effect desirable social changes. Activists engage in a variety of *agenda-building activities* and use frames to mobilize support, build coalitions, manipulate symbols, make claims, typify problems, seek publicity, and gain access to the public policy agenda (→ Agenda Building).

*Social movements research* suggests advocates engage in frame enterprise and frame sponsorship. Activists engage in diagnostic, prognostic, and motivational framing processes and mobilize support through frame alignment, bridging, amplification, and extension (Snow & Benford 1992). Differences between competing groups result in frame contests (Ryan 1991; → Social Movements and Communication).

Related research pertaining to framing of issues has also been conducted examining topics ranging from negotiating to persuading jurors. Economists have examined the framing of fairness as a particular issue that can influence judgments on matters such as tax and income equity, willingness to pay for public goods, and social conflicts pertaining to environmental and public health risks.

## FRAMING OF RESPONSIBILITY

*Attribution theory* examines how people ascribe causes to events. When engaged in disputes or public discussions, a common strategy for both individuals and organizations is to take credit for successes and to avoid blame for failures while ascribing blame to others. How a problem is stated biases attributions about culpability dramatically (→ Attribution Processes).

The causation of events can be attributed to a social actor, the object upon which the action is taken, or the environment or circumstances in which the event occurs (Kelley 1967). Similarly, actions can be labeled (framed) as controlled or uncontrolled, internally or externally originated, or a result of stable or unstable conditions within an individual or environment.

In most societies, citizens frame issues to portray the overall social system as fundamentally sound and prefer to attribute problems to corrupt, inept, or irresponsible individuals. As a result, remedies are often focused on treatment rather than prevention or elimination of underlying systemic causes. In this same vein, news has been criticized for excessive personalization and dependence on “episodic” rather than “thematic framing” (Iyengar 1991). *Investigative news reports* (→ Investigative Reporting) have been characterized as a process of “diagnostic framing,” in which a story is identified as being part of a particular

investigative genre and is typified as an example of a particular, well-known problem (Protest et al. 1991).

## FRAMING OF NEWS

A final important application of strategic framing involves how groups and organizations vie for news coverage and how stories about controversies and disputes are portrayed in the media. Traditional news-framing research focuses on framing as an activity of journalists grounded in their cognitive understanding of the world and their desire to arrange random events into a meaningful, organized interpretive package (Gamson et al. 1992; Graber 1988; Tuchman 1978).

From a strategic perspective, news framing also creates opportunities for groups or organizations to interpret issues or disputes from their perspective. *Publicists and advocates* for causes thus become “frame sponsors” seeking to have their preferred worldview presented and engaging in frame contests in the media.

Successful promotion of a particular news frame requires understanding of the genres and conventions of news work, including the process of frame selectivity by media workers (→ News Routines). When pitching stories to news media, for example, it is essential for strategic communicators to understand what is newsworthy (→ News Values) and to capitalize on the culturally resonating elements of a particular story in order to make it attractive to media gatekeepers and → audiences (→ Gatekeeping). This involves manipulating *framing devices* such as metaphors, catch phrases, exemplars, depictions, and visuals (Gamson & Modigliani 1989; → Exemplification and Exemplars, Effects of; Nonverbal Signals, Effects of).

## Structural Equation

Annette Fahr

Ludwig Maximilian University of Munich

Structural equation modeling (SEM) is a statistical technique that allows tests of complex relationships between large numbers of variables. The term “structural equation modeling” is closely related to terms like covariance structure analysis, causal modeling, or path analysis. According to Kline (2005), the main characteristics of SEM are as follows. First of all, there has to be a model that shows how variables are related; it has to be specified prior to statistical analysis. The idea of the model may come from theory, from prior research, or from researchers’ specified knowledge and experience. The procedure is mainly confirmatory, and generally researchers decide which are dependent and independent variables and how they are linked by causal relations.

When specifying a model one must distinguish between observed and latent variables, or at least explicate at which level a variable is located. Most standard procedures do not allow differentiation between observed and latent variables. As an example, if you want to measure how *political orientation* influences *newspaper usage*, you have two abstract constructs that cannot be measured directly. These constructs – or latent variables – have to be operationalized through indicators, or observed variables. So political orientation may be measured through statements like “I want to know what is going on in the world” or “I want to know the relevant arguments of current political discourse,” and newspaper usage may be measured through “newspaper reading per day in minutes” or “individual

importance of daily newspaper reading.” The strength of SEM in incorporating observed as well as latent variables lies in the validation of constructs that can be achieved through confirmatory → factor analysis. Then, the influence of one construct on another can be measured through structural → regression analysis. The → hypotheses about the modeled relationships can be tested with several indices.

### VALIDATION OF CONSTRUCTS

Constructs in the social sciences may consist of one or more factors, each being represented by one or more indicators. In our example, *political orientation* can be conceived as a one-factorial construct represented through two indicators: “knowing what is going on in the world” and “knowing the relevant arguments of current political discourse.” As valid constructs are the basis of statistical testing of hypotheses – especially at a higher abstraction level – this part of the modeling is very important for the whole SEM process. First, the dimensionality of given indicators can be tested through exploratory factor analysis. After a → reliability test (e.g., with Cronbach’s Alpha), unsuitable indicators can be sorted out in order to strengthen the internal consistency of the construct. Then, construct → validity can be tested statistically through confirmatory factor analysis. This particular application of SEM shows to what extent the measurement model matches empirical data. There are several criteria for a good model fit: global criteria for the fitting of the complete measurement model and single criteria for every indicator to explain a construct. The procedure aims at explaining indicator reliability, factor reliability, and the average variance of a factor. If correlation within one factor is high, then one can speak of high convergent validity. If correlation between factors is low, one can speak of high discriminant validity. If the construct is complete (no relevant variables are missing), the indicators relate only to one construct, and if there are no systematic errors (because of bias in either measurement or sampling), one can speak of a fairly validated construct, which can then be used for further modeling.

### STRUCTURAL REGRESSION ANALYSIS

A structural regression model is the most general kind of structural equation model. It contains hypotheses about several aspects:

- whether there is an influence at all;
- how strong the influence is;
- whether effects are direct or mediated by other variables;
- whether there is reciprocity in effects;
- whether the impact is weakened or strengthened by a mediator.

A structural equation model can also be called a hybrid model, as it incorporates a measurement and a structure model. These models are commonly tested with programs like LISREL or AMOS. It allows testing for both direct and indirect causal effects. An example of a direct effect would be the impact of *political orientation* on *newspaper usage*. An example of an indirect effect would be the impact of *political orientation* via

*interpersonal communication on newspaper usage*. The difference from path analysis is that effects can involve latent – not only observed – variables. This setting can test effects from observed to latent variables and vice versa within a single model, and therefore proves more flexibility than do other procedures. The (causal) relationships between variables are conceptualized and illustrated as paths. Those paths can be expressed as mathematical functions. The methodology of SEM thus can show whether there are significant effects in the relationship between two variables. This principle is commonly known from regression analysis; SEM, however, is more powerful, as the impact of a variable on several target variables can be estimated simultaneously.

In order to conduct a structural regression analysis, two approaches are needed: (1) the features of path analysis to test the structural model, and (2) the features of confirmatory factor analysis to test the measurement component (of the factor model). The *measurement model* consists of the a priori specification of latent factors and the scores on their indicators. The *structural model* incorporates direct effects between the factors (i.e., latent variables). As in regression analysis, we have preconceptualizations of the direction of effects. According to the underlying theory and model, it can be specified which factor has effects on other factors. So the target factors are called *endogenous variables* whereas the influencing factors are called *exogenous variables*. It is important to note that each structural model contains *measurement errors* and *disturbances*. The measurement model – i.e., the confirmatory factor analysis – contains measurement errors for each indicator, whereas the error between the effect of one factor and another is called disturbance. A disturbance is not to be understood as a measurement error but rather as an omitted cause. It is something that has not been incorporated into the model but would have contributed to accounting for a large part of the variance. In the SEM procedure, the relationships are freed from measurement error because the error has been estimated and then removed, leaving only common variance. So the options of decomposition of effects and errors exceed the possibilities of conventional techniques like path or regression analysis (Bollen 1987). Thus, when the phenomena of interest are complex and multidimensional, SEM is the only analysis that allows complete and simultaneous tests of all relationships.

## MODEL TESTING

Many standard operations in multivariate statistics, such as multiple regression, analysis of variance, or canonical correlation, are special cases of SEM. All the stated procedures actually stem from the principle of the general linear model (GLM). Thus, the generality of SEM is very broad. As in regression analysis, the relationship between two variables can be expressed as an equation, e.g.,  $Y = BX + A$ . Most statisticians agree that SEM requires large samples. There are several factors that affect sample size, so it is not easy to answer the question of how large a sample needs to be. The analysis of a complex model requires a larger sample than the analysis of a simpler model. Models with greater complexity and more interrelations require the estimation of more statistical effects, and thus larger samples are necessary in order for the results to be reasonably stable. The type of estimation algorithm used in the analysis also affects sample size requirements. There are quite a few different estimation methods in SEM, and some of these may need

very large samples. However, some rough guidelines can be offered. Using fewer than 100 cases hardly leads to a reasonable test. A size of 100 to 200 cases is regarded as a minimum, but this is not absolute, because the model's complexity must also be considered. Furthermore, a small sample size means that the power of statistical tests may be very limited.

There is a great variety of effects that can be tested for significance in SEM. Options range from the variance of single variables up to the evaluation of entire models across several samples. However, tests for statistical significance are less relevant in SEM than to other techniques. Although single effects of related variables can be tested, SEM usually operates on a higher abstraction level. The question is not so much how strong an effect is; the analysis rather concentrates on the whole model, and the questions are whether it is acceptable or whether it had better be rejected – whether it should be modified, and if so, how. The big picture has priority over specific details such as the single path coefficients of two related variables. Furthermore, the significance of effects is not of so much help to the researcher in evaluation, as larger samples are more likely to produce significant results, even if the absolute effect size is minimal. In this case, the significance would only confirm the large sample (see also Tanaka 1987).

The methodology of SEM offers quite a lot of options for evaluating the fit of the estimated model with empirical data. Among the numerous fit indices, the most commonly used include chi-square value, the goodness-of-fit-index (GFI), the adjusted-goodness-of-fit index (AGFI), and the root mean square error of approximation (RMSEA). If indices show a good model fit, the model thus can be accepted. If the test produces implausible values, however, either model or data are insufficient. In any case, checks for logical and theoretical plausibility of the modeled parameters are recommended. Structural equation models are mainly used for confirmatory purposes. As many communication theories are not sufficiently validated, researchers may feel the need to use SEM in an exploratory way (Holbert & Stephenson 2002). Even then, researchers should have some idea about relationships and effects between constructs. To properly evaluate the quality of a model, analyses with SEM need replication. If similar results are achieved through cross-validation with different datasets, the model structure is proved to be reasonable. Finally, it is important to note that SEM does not prove causality in the same way as experiments do (→ Experimental Design). Causality is always a question of design and not of statistical testing.

# Structuralism

*Klaus Bruhn Jensen*

*University of Copenhagen*

Structuralism is a tradition in the history of ideas that rose to special prominence during the twentieth century within the humanities and social sciences. A shared assumption of structuralist approaches to communication, culture, and society is that interactions, discourses, and social groupings are best understood as relatively self-contained systems or structures. Their formation and transformation are accounted for by certain general, immanent principles, rather than by their concrete constituents, or by any external influences.

## DEFINITIONS

In his review of the development of structuralism, Jean Piaget (1971, 5) identified three distinctive features of a structuralist perspective. First, it emphasizes the *wholeness* of a structure of elements; compare the common saying that the whole is more than the sum of the parts. Second, structures are subject to *transformations*: the rules governing them are simultaneously *structured* and *structuring*. Third, structures are *self-regulating*, bounding and maintaining the system in question. To exemplify, an ordinary conversation amounts to a whole, accomplished by two speakers; it represents a contextual selection and transformation of particular linguistic resources; and, to succeed, it requires continuous adjustments, regulating the contributions of the two speakers.

Responding to the likely criticism that structure might be a vacuous concept since, for example, all the units examined by the social sciences can be considered “self-regulating transformational totalities” (1971, 97), Piaget further distinguished between a weak or *global* form of structuralism and a strong or *analytic* and more “authentic” structuralism. Whereas the sociologist Émile Durkheim’s structuralism is weak, speaking of the social whole as emerging from a union of components, the anthropologist Claude Lévi-Strauss’s structuralism is strong because it refers to specific rules of composition that account for particular cultural practices. Most important, structuralism proper assumes that the diverse observable aspects of social life bear witness to generative *deep structures*. While this notion is familiar from linguistics, in which the concrete sentences at the “surface” of language are said to derive from transformations of a general “deep” structure, it has been applied in several other disciplines and fields as an explanatory framework.

## INTERDISCIPLINARY STRUCTURALISMS

Although Piaget (1971) noted structuralist positions in his own developmental psychology as well as in mathematics and logic, it is especially humanistic and social scientific inflections of structuralism that have informed communication research. The linguist Ferdinand de Saussure originated the prototypical formulation of structuralism, describing language as a combinatorial system of paradigms and syntagms, and as a two-tiered structure of concrete expressions (*parole*) and an underlying system (*langue*; → Semiotics). The transformational-generative grammar of Noam Chomsky has been a particularly influential variant of a strong, analytic structuralism in → linguistics since the 1950s. It is, however, in analyses of social interactions and extended discourses that the influence of structuralism has been most in evidence within communication studies (for an overview, see Hawkes 1977).

Perhaps the most elaborate application of structuralist principles to the study of social and cultural life occurred in anthropology, as formulated by Lévi-Strauss (e.g., 1963). He accounted for *myths* in terms of their constituent units by analogy to sentences. It is the combination and transformation of such constituents into specific meaningful wholes that characterize the practices and rituals of different cultures, subcultures, and communities. As processes, myths further help to explain how social order is maintained, and conflicts resolved, through the continuous production of meaning. In a characteristically structuralist formulation, Lévi-Strauss aimed “not to show how men think in myths, but ‘how myths think in men, unbeknown to them’” (cited in Hawkes 1977, 41). Being discursive as well as cognitive entities, myths can be understood as deep structures of culture that are articulated in discourse, exchanged in communication, and enacted in social structures.

Structuralist approaches have been especially manifest in critical traditions of the social sciences (→ Critical Theory). This is in spite of the fact that, for instance, the concepts of structure and function in Talcott Parsons’s work are compatible with central tenets of structuralism (Piaget, 1971, 102); there is at least a family resemblance between structuralism and functionalism (→ Functional Analysis). The key figures of structuralist social theory, however, have emphasized conflictual rather than consensual views of structure. Building on Marx, Louis Althusser conceived the social totality as an interconnected complex of economic, political, and ideological practices that privileges certain social groups in relation to the means of production and to the institutions of power (Althusser 1977). He counted the media among the ideological state apparatuses serving to legitimate the social status quo (Althusser 1971). Modifying the economic determinism of much of the Marxist tradition, Althusser borrowed the concept of overdetermination from Sigmund Freud to suggest the multiple determinations of particular events in different social domains. On the one hand, societies may be governed by their economic mode of production in the final instance; on the other hand, the relative autonomy and efficacy of political, cultural, and other social practices should be accounted for, not just as structured by, but simultaneously as structuring the social totality and its historical trajectory.

Another key figure – Michel Foucault – marked a transition from structuralist to poststructuralist social theory (e.g., Foucault, 1972). Where structuralism represents an

ambition of discovering explanatory categories concerning the deep structures and basic processes of culture and society, *poststructuralism* begins to question the feasibility of any such categories, whether in everyday consciousness or in scholarly analysis (→ Post-modernism and Communication). Taking a radically constructivist position (→ Constructivism), Foucault shifted attention toward the frames of reference – the *epistemes* – that can be considered dominant in different historical periods. Such frames condition what will be understood as social reality in the first place; they change decisively from one epoch to the next; and they set limits to what can be known, in science as well as elsewhere. Although much of Foucault's work critically examined the concrete → *discourses* in which the understanding of, for example, madness, crime, and sexuality has been articulated, he approached these discourses as structures unto themselves, rather than as components of a combinatorial system involving human agents and material resources within observable social practices. From a poststructuralist perspective, ultimately, the structures of discourse do not allow for human subjects as either autonomous actors in a reality beyond signs, or independent observers of either subjects or structures.

### **STRUCTURALISM IN MEDIA AND COMMUNICATION RESEARCH**

In the strong or analytic sense identified by Piaget (1971), structuralism became a major influence particularly on two interrelated forms of media and communication research from the 1960s onward – qualitative textual studies and cultural studies. While research on media texts may be considered the primary inheritor of the analytical principles of Saussurean linguistics, cultural studies incorporated these principles, developing a conception of cultural practices, everyday life, and, indeed, the entire social system *as texts* to be read and interpreted.

During the 1960s, literary theory was revitalized by the rediscovery and redevelopment of several linguistic and formalist models of analysis; it was in this shape that literary theory fed into media theory (→ Text and Intertextuality). In addition to the work of Saussure, Russian Formalism drove home the point that form carries content – that the structures of narratives and other genres hold meanings. The prototype of such research was offered by Propp (1958) in his study of the constituents and variants of Russian folktales. A wide variety of popular media and genres lend themselves to the systematics of formalist analysis, as exemplified by Umberto Eco's (1987) early study of the James Bond stories. Other contributions included A. J. Greimas's structural analysis of semantic units, including those beyond the sentence (Greimas & Courtés 1982), as well as → Roland Barthes's models of meaning and narrative analysis. Partly overlapping with the structuralist enterprise, further work in film and other media theory from the 1980s onward explored the interrelations between textual and cognitive structures (e.g., Bordwell 1985; → Film Theory). As systematic approaches to the texts and genres of media, both structuralist and cognitivist models represented significant advances in *qualitative media text analysis*.

Summarizing the tradition of → *cultural studies*, Hall (1980) identified structuralism as one of its two constitutive paradigms, the other being culturalism. Combining a structural analysis of media texts and a critical, structuralist theory of society with a processual conception of culture, cultural studies has explored the margins of indetermination in the

social production of meaning. Even if the media, being part of the social *whole*, may offer a unitary representation of society – *regulating* the status quo in the interest of the powers that be – they still provide a potential source of discursive and material *transformation*.

### THE STRUCTURALIST LEGACY

Structuralism was a moment in the development of communication research, with a “classic” period from the 1960s to the 1980s. In retrospect, a strong version of structuralism appears difficult to reconcile both with the multiple types of structures bearing on human communication, and with the historical and cultural variability of communicative practice. Anthony Giddens (1984), for one, while retaining the tradition of semiotics, has questioned the determinist implications of structuralism, re-emphasizing the duality of structure and agency as part of an ongoing process of social *structuration* (→ Structuration Theory). From the outset, 1960s structuralism had been challenged by post-structuralism, which rejected the possibility of stable structures of communication, subjectivity, and society – and, indeed, of science and human knowledge as such (for an overview, see Coward & Ellis 1977). Though present as an epistemological concern in cultural studies and some other communication research, poststructuralism, arguably, has been less influential across the wider theoretical and methodological field. Instead, specific structuralist models and methods continue to offer analytical resources regarding various practices and institutions of communication, at different levels of ambition on a scale from strong to weak structuralism. Piaget (1971) had already suggested that structuralism is not a doctrine or theory, but a method.

The appeal of structuralism, both before and after the classic period, can be interpreted in the context of the history of ideas. The twentieth century witnessed an unprecedented – and massively communicated – degree of social *complexity*, which coincided with a growing *secularization* of both society and science in much of the world. Structuralism provided a conceptual matrix that might account for the combined dynamism and stability of contemporary culture and society – without recourse to transcendental first principles. While familiar from the history and taxonomies of natural and other empirical sciences, the notion of generative matrices could be radicalized with reference to language and other communications as the key mediators of both individual cognition and social interaction. As a prototype of twentieth-century interdisciplinary scholarship, structuralism developed alongside and in dialogue with communication research.

# Structuralism in Visual Communication

*Linus Abraham*

*African University College of Communication*

As a body of work structuralism assumes that social life and meaning are organized by a set of deep structures that frame understanding and perceptions of reality. Social meaning is the product of systematic conceptual structures through which we apprehend reality (→ Structuralism). Structuralism traces its existence to the work of Swiss linguist Ferdinand de Saussure, who set out his principles on language in his *Course in general linguistics* (published 1959, after his death). Saussure's interest was in the study of language as a system, and he made a distinction between *langue* (the formal structures of language) and *parole* (the way language is employed in varied and individuated ways in actual speech). His argument was that while the individual instances of use (*parole*) may vary, underlying all of them is a formal set of consistent codes and conventions of language (→ Code; Language and Social Interaction).

## STRUCTURALISM IN VISUAL COMMUNICATION

Structuralism, of the kind influenced by Saussure, emphasized signifying systems, taking the production of meaning to be central to social life. Structuralism therefore puts communication at the center of society and is concerned with the identification of systems that generate meaning (→ Sign Systems). While its central theoretical influences were in → linguistics, the general emphasis on signification has allowed the extension and application of Saussure's theories to the language of cultural signs in general. Thus cultural → artifacts, objects, and practices, including visual modes of communication in their varied forms (art, → television, film, → cartoons, etc.) have all been analyzed using the structuralist approach (→ Visual Communication; Film as Popular Culture; Culture: Definitions and Concepts).

As a body of work structuralism shares a formalist approach to language and cultural practices, emphasizing the laws, codes, formulae, and conventions that structure systems of → meaning creation. Because they sideline issues of → aesthetic worth or value and

concentrate more on the underlying rules and conventions determining meaning, → semiotics and structuralism have afforded visual critics rigorous and systematic tools for engaging in the visual analysis of various media, including film and television (→ Cinema; Content Analysis, Qualitative). Saussure's ideas have been explored by film scholars and theorists of images, including → Roland Barthes, to understand the nature of visual systems of representation. Film scholars have adapted Saussure's methods to analyze films as constructed medium, created through an underlying set of codes and conventions that shape their meanings (→ Film Theory). Thus semiotics and structuralism have helped open up the inner workings of various visual media (Andrew 1984).

### MAIN TENETS OF STRUCTURAL ANALYSIS

Structuralism as a method of cultural analysis entails two important steps adopted from Saussure's work. The first is a concern with revealing the underlying grammar or conventions that structure the meaning of a cultural text, and the second is the idea that meanings are dialectically constructed around a set of binary opposites.

Thus one of the principal tasks in engaging in structuralist analysis is to identify the formal structures, the system of hidden codes and conventions (*langue*), that shape the various instances of cultural practices and texts (*parole*). For example, Vladimir Propp (1968) identified the formal set of structural features that underlie Russian folklore tales. While each folklore story may seem different in its individual manifestation (*parole*), the stories' meanings derive from a common set of characters (the hero, princess, helper) and their functions. Umberto Eco (1976) similarly identified the common structure of plot moves and characters (and their functions) – the girl, foreign villain, supportive second agent – that underlie all the James Bond novels, no matter how much the details of the stories change. Christian Metz (1974) applies structuralism to cinematic studies, identifying the language-like system of cinematic codes that help create meaning in film.

Turning to the second important step identified above, according to Saussure, all languages and the meanings they structure work *paradigmatically* (i.e., by selecting from a group of conceptually related signs) and *syntagmatically* (i.e., by combining the selections of signs according to a set of socially conceived rules that determine their combination). For structuralists the paradigmatic organization and selection of signs is paramount to meaning-making. Cultural elements or signs do not mean by themselves; their meanings are produced by their difference from other elements within a paradigmatic system. Thus, Lévi-Strauss, who famously applied structural approaches to the study of culture, argued that the fundamental way in which we make sense is through a system of binary oppositions. As Seiter writes, “characteristically, structuralist analysis proposes binary oppositions such as individual/community, male/female, nature/culture, or mind/matter and argues that every element within the system derives its meaning from its relationship to these categories” (1992, 50).

### EXAMPLES OF STRUCTURALIST STUDIES IN VISUAL COMMUNICATION

There are numerous examples that illustrate the use of structuralism in visual analysis. In his application of the structuralist perspective to the analysis of the film musical *Top Hat*

(1935, featuring Fred Astaire and Ginger Rogers), Rick Altman (1989) draws attention to the unconscious processes at work in engendering cultural meanings, by revealing the latent structure of the conventions of → Hollywood musicals lurking beneath the film text. He also argues that the film's meanings are organized around binary oppositions. For example, he explores how the dually opposed concepts of restraining social conventions (manifest in the European, stuffy old ways of Rogers) versus its opposing notion of freedom (made manifest in the American, new-world attitudes of Astaire) undergird meanings throughout the film, with meanings resolved in the direction of the superiority of Astaire's American freedom attitudes.

In their applications of semiotics and structural methods to the television cartoon *Fangface*, Hodge and Tripp (1986) also find that the abstract binary axis of nature/culture, and their more concrete manifestations as animals/humans, inform much of the meaning in the cartoon. Lévi-Strauss's analysis of myths and other cultural practices found the binary trope of nature/culture to be a highly significant structure that informed meanings at very abstract and unconscious levels (→ Cultural Studies; Popular Culture).

Analyzing the Western film *The Searchers*, Fiske (1990) demonstrates how the opening sequence of the film constructs a structure of binary oppositions that undergirds the whole narrative (and for that matter the genre of Western films; → Film Genres). The opening shots, which visually juxtapose and oppose the environment of homestead and the wild landscape, "is quickly established as a concrete transformation of the more abstract oppositions between the developed East and the 'raw' West, between whites and Indians, between law-and-order and anarchy, between humanity and cruelty, and, more problematically, between femininity and masculinity, between society and the individual" (1990, 124). All of these oppositions are seen as deriving from a much deeper and more abstract, structured opposition between culture and nature. The deeper set of abstract opposites is concretized in specific events and objects in narratives, which are then naturalized through their relationship with the underlying structure of abstract concepts that inform them.

Laura Mulvey's (1975) pioneering work, "Visual pleasure and narrative cinema," which has been very influential in the area of feminist studies and visual analysis (→ Feminist and Gender Studies), adopts a structuralist perspective in revealing how cinematic conventions structure gendered perceptions of reality. In discussing how these conventions structure cinematic action and gaze, she argues that, invariably, the male is constructed as active with the female as passive (→ Spectator Gaze). Similarly, the cinematic gaze is constructed as male, while the female becomes the object of the gaze.

### **CRITICISM OF STRUCTURALISM**

The vocabulary and special procedures of semiotics and structuralism "have allowed us to describe the workings of cultural communication with greater accuracy and enlarged our recognition of the conventions that characterize our culture" (Seiter 1992, 32). However, structuralism has been criticized for prescribing dominant and absolute meanings, for abolishing the reader from processes of meaning creation, and for being ahistorical. The tendency of structuralism to reduce cultural practices to basic formal elements causes the analyst to lose sight of other complex factors that may be shaping meanings. Because they derive their influences from Saussurean linguistics, which is a synchronic model for the

study of language, semiotics and structuralism study sign systems at a given moment in time, and tend to ignore change over time.

Structuralism as a theoretical perspective and method of analysis has given way to the more popular notions of poststructuralism. While accepting the notion of language as fundamental to social life and meaning-making, poststructuralism critiques structuralism for emphasizing structure at the expense of other elements that do not fit neatly into its formulae or conventions. Poststructuralism rejects the idea of an underlying, stable structure that creates fixed meaning through binary oppositions.

Today, structuralism is still useful as a method of opening up cultural forms, including visual artifacts, for interpretation, but it is seen as more useful if it takes into account poststructuralist critiques and is combined with other approaches. A good illustration of the application of poststructuralist approaches and other methods in visual analysis can be found in Yvonne Tasker's work on action movies. In *Spectacular bodies: Gender, genre and action cinema* (1993), Tasker draws on structuralism to identify the generic codes (in films such as *Die Hard*, the *Rocky* series, and *Lethal Weapon*) that characterized Hollywood action movies in the 1980s (→ Spectacle). But, she also draws on feminist and other theories to show that, rather than the series of action films simply reproducing dominant ideologies of masculinity constructed around fixed binary structures, the films play with such categories, allowing for multiple and contradictory meanings that challenge dominant meanings (Johnson et al. 2004; → Gender: Representation in the Media). Rather than being created around fixed oppositions, meanings are constantly deferred.

Roland Barthes's essay on the Eiffel Tower, in *The Eiffel Tower and other mythologies* (1982), provides us with the application of a structuralist perspective tinged with a measure of poststructuralism. The essay, concerned with the experience of "seeing" Paris from the Eiffel Tower, provides us with an understanding of the structuralist aesthetic of seeing. Barthes contends that "Every visitor to the Tower makes structuralism without knowing it . . . Paris offers itself to him an object virtually prepared, exposed to the intelligence, but which he must himself construct by a final activity of the mind: nothing less passive than the overall view the power gives to Paris" (1982, 9–10). The meanings visually afforded the viewer are constructed around a set of binary opposites, which are revealed in the analysis – Paris is constructed as man-made landscape (artificial), one that is opposed to a natural landscape (nature); the vision afforded the viewer from the tower is a "bird's-eye view" (one that permits a "transcendental sensation"), as opposed to an eye-level view (which thrusts one intimately into the midst of sensation); and the observer becomes a "reader" of rather than a dweller in the city. In a move reminiscent of poststructuralism, Barthes goes beyond the synchronous structural analysis of the bipolar opposites structuring the view to acknowledge the diachronic – the four major historical epochs of Parisian history and development that have shaped and characterize the various sites that face the observer from the Eiffel Tower.

## **Structuration Theory**

*Steven R. Corman*

*Arizona State University*

The theory of structuration by Anthony Giddens is one of the most influential perspectives of the late twentieth century in the communication discipline. Its main argument is that communication in social systems is not simply a matter of individual action or social structure but a joint product of both these moments: social action, including communication, is an outcome of structuration, or the production and reproduction of structure in social interaction. Giddens's theory (see Giddens 1984 for the most comprehensive statement) embeds this core phenomenon within a wide-ranging, integrative, institutional framework that encompasses many concepts of interest to scholars of human communication, including agency, identity, power, and → modernity.

## MAIN ARGUMENTS AND CONCEPTS

The signature contribution of structuration deals with the classic disagreement in social theory between perspectives that privilege action and those that privilege structure. Some positions assign primacy to the individual and his or her perceptions, experiences, and actions. For example, → phenomenology takes the intuitive experience of the individual as its starting point, building from there to explain more aggregate features of the social world. Other perspectives take social structure as their starting point. Functionalism, for instance, holds that social institutions exist to serve social needs, like the need to live in an orderly society (→ Functional Analysis). Thus action- and structure-based explanations form a “dualism” in traditional social theory, always beginning at one of the points and moving to explain the other. Giddens’s innovation is to argue that action and structure in fact form a “duality”: they are part of a mutually constitutive system in which social structure is produced and reproduced in social interaction, with social structures constituting rules and resources that social actors use to accomplish interaction. Language illustrates of this process: interacting with others, we draw on language and its rules of use to make ourselves understood; however, these structures are not an absolute constraint. We can use words in novel ways or invent new ones, and bend the rules of grammar to suit our purposes, creating new rules and resources that are in play during future social interactions (→ Language and Social Interaction). To account for social phenomena as they change over time we must consider both existing structure and individual action.

This is not to say that all structures are equally fluid. Some structures are “chronically” reproduced, becoming sedimented over time, resulting in institutions (→ Institutional Theory). These structures are not impervious to change, but are resistant because of other structures that depend upon them and favor their reproduction. Giddens defines the three main institutional dimensions of structure as signification, domination, and legitimation, which correspond to phenomena of communication, power, and sanction in the domain of social interaction. Three modalities of interpretive schemes, facilities, and norms are responsible for the translation of phenomena from one domain to the other.

The dynamics of structure leads to two more key concepts: “agency” and the associated concept of “power.” The production and reproduction of structure in interaction is the work of human agents who have the ability to “act otherwise” (i.e., in ways other than those dictated by structure), because they have power. Though their power varies, all agents – except in unusual cases like torture – have some power, and this is what potentiates change in structuration.

However, their power is partly constrained in the stratification model of the agent. At base, agents are motivated to act on a number of conscious and unconscious grounds. Agents make sense of these motivations through the rationalization of action, relating their rationalizations to the consequences of what they do through a reflexive monitoring process. Yet the limitations of consciousness and cognition make this process imperfect, creating the possibility of unintended consequences of action that cannot be explained by agents’ rationalizations and associated motivations. This in turn creates the possibility of unacknowledged conditions of action. Together these phenomena explain how structures that nobody wants or intends can be created and perpetuated through the actions of powerful agents.

## MODERNITY AND IDENTITY

Two other structuration concepts are especially relevant to theory and research in communication. Many social theorists believe that we live in a postmodern period of history (→ Organizational Communication: Postmodern Approaches; Postmodernism and Communication), but Giddens regards this idea as questionable and argues instead (Giddens 1991) that we are in a period of “high modernity” (some believe “hypermodernity” may be a more apt label). The processes of modernity have not been surpassed or transcended; rather, they have reached their zenith and verge on spinning out of control.

Chief among the processes of high modernity is *time-space distanciation*. Whereas in premodern times social interaction was always firmly anchored in particular times and places, modernization has progressively and relentlessly ripped it from these moorings. Written language allows events at one time and place to influence events in the future and perhaps in different locations. As this and other innovations accumulated, social relations became progressively disembedded from the here and now. Given recent trends toward globalization, distanciation has progressed to such a degree that our lives are radically coupled to events that happen far from us in time and space, making the world seem increasingly incomprehensible, erratic, and unmanageable (→ Globalization of Organizations).

*Abstract systems* constitute the primary disembedding mechanisms of modernity, and Giddens distinguishes two types. Written language is a system of *symbolic tokens* (money is another example). *Expert systems* comprise complex assemblages that are based on expert technical knowledge. Examples include legal systems, governments, universities, and even the international air travel system. Whereas we engage symbolic tokens directly, our dealings with expert systems are mediated by access points, human agents – like lawyers, representatives, professors, and pilots – who represent, help us understand, and provide entrée to expert systems.

These features of modernity connect to identity through the concept of *ontological security*. This security-in-being is a natural consequence of interaction in circumstances of co-presence, instilled in us as children by close relationships with caregivers. As social relations move away from these circumstances through the operation of disembedding mechanisms, trust in others and in the systems with which we interact becomes increasingly relevant to our sense of ontological security. This sense of security allows us to develop a sense of *self-identity*, meaning “the self as reflexively understood by the person in terms of her or his biography” (Giddens 1991, 53).

Because of its radical decoupling of social relations from contexts of interaction, high modernity constitutes a grave source of risk. It forces us to deal with a world that we cannot completely understand, often once removed through the access points of abstract systems. This unpredictable and unreliable social world diminishes our bases for trust and creates threats to our ontological security, which in turn disrupt our sense of self-identity. High modernity, therefore, creates conditions wherein self-identity is subject to constant reflection, reinterpretation, and change. Identity is radically socially constructed, and this makes the communicative processes that govern the construction process extremely important to understand (→ Constructivism).

## STRUCTURATION IN COMMUNICATION THEORY AND RESEARCH

While there has been some debate about whether structuration is an ontology or a full-blown meta-theoretical perspective, in practice it has been most often applied to communication problems of the middle range as a general pattern for theory building. As a grand theory of society, it has most traction in the more collectively oriented sub-fields of organizational, small group, and mass communication (→ Organizational Communication; Group Communication), though there are some examples of its use in → interpersonal communication.

Structuration theory finds its greatest application in organizational communication (see Poole & McPhee 2005 for a complete review), and is most commonly used to help *explain the development of communication structures in organizations* (→ Organizational Structure). Structural-functional accounts of organizations came under heavy criticism with the rise of social-constructionist perspectives in the early 1980s. Structuration theory is something of a midpoint between these perspectives because it emphasizes the duality of structure and the role of active agents but at the same time allows for reproduction of structure and even institutional sedimentation.

Structuration has been used to *explain structures* like vertical communication chains in organizations. Studies have shown that organizational hierarchy is produced and reproduced in these chains, giving a somewhat different picture of the hierarchy at different levels of the hierarchy, but still providing a unifying structure overall. Structuration has been used to explain → communication networks as structures in the domain of social relations. Empirical tests have shown, for example, that informal hierarchies are produced and reproduced by organizational activity systems even when no formal hierarchies are specified. The theory has been applied as well to the development of concrete, formal structures such as family leave policies.

Structuration has also been applied to → *organizational identification*, reframing the distinction between identity and identification and explaining how communication differentially reproduces identity across different organizational contexts and situations. Scott et al. (1998) introduce this idea by arguing that identity functions as a set of rules and resources that agents use for acts of communicative identification with organizations in concrete settings of interaction. Outside a formal organizational setting, structuration has been used to explain the identity of particular social groups.

Another topic in organizational communication where structuration has seen significant application is *organizational climate*. Against the traditional view of climate as a characteristic or property of an organization, a structuration approach conceives of it as a set of rules and resources that members use to construct communication about the organization (Poole & McPhee 1983). Structuration theory has been applied, both theoretically and empirically, to the related concept of → organizational culture, and was used in an extensive study to help explain the development of interorganizational structures (Browning & Shetler 2000).

Structuration theory has also had a significant impact on the study of small group communication (see Seyfarth 2000 for a complete review). A major research program by Poole and DeSanctis (DeSanctis & Poole 1994) developed the concept of *adaptive structuration theory* (AST) to explain how groups use information technologies in

task-related activity. Studying group decision support systems (GDSS), they employ structuration concepts at the micro-level by tracking how members produce and appropriate features of the GDSS in their interaction, and at the macro-level by studying the course of whole decisions or series of decisions through multiple sequences of decision-making phases (→ Meeting Technologies).

Structuration has been employed to explain how communication serves as a resource in *group interaction* (→ Group Communication and Problem-Solving; Group Communication and Social Influence). Earlier works used it to theorize the impact of communication on group decision-making in general. Later empirical papers studied the use of arguments as resources in group interaction and values as resources in negotiations.

Structuration theory has had a lesser impact on two other areas of the discipline. There are several examples in mass communication and → public relations, often mirroring applications in organizational and small group communication. For example, some studies explain the structure of news organizations. Others explain the appropriation of technology by news organizations, and the development of public media policy. Still others use it as a framework for case analysis in mass media and public relations. Finally, structuration has made small inroads into interpersonal communication research. In this context it is used as a framework for explaining the impact of family structures on interpersonal relationships (→ Family Communication Patterns).

## **CRITIQUES AND FUTURE DIRECTIONS**

For a more comprehensive review of critiques of structuration theory, see Held and Thompson (1989). Poole and McPhee (2005) and Seyfarth (2000) also provide more detailed analysis of arguments for and against structuration in organizational and group communication, respectively. Two more common classes of critique are briefly reviewed here.

One argument says structuration does *not facilitate empirical work*: it is a good basis for “think pieces” but not much of a guide to empirical research. This critique was common when structuration was first introduced to the discipline and may have been more justified then. Yet it is still heard today even though it is surely no longer valid. Theoretical pieces have been regularly matched by empirical studies investigating their claims. The research discussed above, dealing with organizational structures, identification, group appropriation of technologies, and studies of media cases, are all examples.

A second critique is that structuration either *overemphasizes action or overemphasizes structure*, giving an imbalanced view of structure. Some critical theorists argue that Giddens privileges action, underemphasizing the constraints presented by structure and overestimating the power of individuals to overcome their influence (→ Organizational Communication: Critical Approaches). This leads to positions that, according to these critics, are too politically moderate and not focused enough on emancipation. Others with more postmodern or neo-systems sensibilities argue that structuration theory overprivileges structure and institutional constraints, producing explanations that undertheorize the role of agents in producing new structures and potentiating social change.

To the extent to which these criticisms are valid, they result more from the proclivities of communication researchers who have deployed structuration than from the unavailability

of resources in the theory itself. Giddens is a bona fide critical theorist. His books published prior to *The constitution of society* show that his perspective is more than adequately equipped for pursuing a critical agenda. At the same time he maintains that agents (to a greater or lesser extent, based on circumstances) have the power to act in ways other than that dictated by structure, and that even deeply sedimented structures are changeable through the accumulation of small actions, the influence of unintended consequences of action, and so on, casting doubt on the criticism that structuration is too conservative.

Looking to the future, two predictions seem prudent. First, with respect to sub-fields in communication, structuration theory will remain an attractive perspective for those working in organizational, small group, and mass communication because of its broad and inclusive position on structure, and its detailed explanations relating individual action to collective structure. Its applicability to the family context portends greater use of the perspective in interpersonal communication too. Surprisingly, it has not seen significant application to date in the area of intercultural communication. Given the strengths of structuration theory in explaining collective social structures and identity, intercultural communication represents a fertile area for future applications.

Second, with the partial exception of some of the identity studies described above, Giddens's perspective on modernity has not been fully embraced in communication theory and research. Yet the subject of globalization (→ Globalization Theories) is becoming an increasingly important topic in the discipline, and Giddens's perspective provides a wealth of resources for explaining its effects and the important role of communication processes in producing them. Communication and information technology is also an important disembedding mechanism, and the field's growing interest in that topic is also likely to raise the stock of structuration in coming years.

# Student Communication Competence

Sherwyn P. Morreale

University of Colorado at Colorado Springs

Scholars and teachers have endeavored to understand communication competence by defining it conceptually and identifying the components that comprise it. Some researchers have studied why communication competence is important for students, while others have collaborated with employers and policymakers to develop “lists” of basic and advanced student communication competencies. As a result of public mandates from accrediting agencies and academic administrators, still others have examined how to assess students’ communication competence. While these studies were mainly carried out in the US, scholars in other countries have demonstrated keen interest in understanding intercultural communication competence – communicating across cultural differences. Finally, some researchers, in and outside the US, are considering variations in communication competence based on the impact of culture, the information society, and emerging technologies.

Communication researchers have defined communication competence as the extent to which people achieve their desired goals through communication that is acceptable in the situation. This competence involves the use of verbal and/or nonverbal behavior to accomplish the preferred outcomes in a way that is appropriate to the context and the communicators (Morreale et al. 2006). These definitions suggest that communication is competent when it is perceived by the communicators as both appropriate and effective. Appropriate communication means the communicators act in ways suitable to the norms and expectations of the context and situation. Effective communication means the communicators are able to achieve the most desirable objectives or outcomes in the context.

One of the more widely recognized models of communication competence identifies *three critical components of communication messages* that are perceived as appropriate and effective (Spitzberg & Cupach 1984). First, the communicators must be motivated to communicate competently. Second, they must be knowledgeable about the communication situation and the kinds of messages expected, permitted, or prohibited in the situation. Third, they must be skilled at actually communicating messages in that situation. This description suggests that motivation, knowledge, and skills are the foundations of competent communication whether in interpersonal, group, public, mass-mediated, or technologically mediated communication situations. Motivation involves the extent to which communicators want to communicate. Knowledge in communication helps communicators understand what to say and do. Skills are repeatable and goal-directed behaviors.

## THE IMPORTANCE OF COMMUNICATION COMPETENCE FOR STUDENTS

Competence in communication is prerequisite to students’ academic, personal, and professional success in life. For instance, teachers deliver most instruction for classroom procedures orally and students with poor listening skills are disadvantaged (→ Listening).

Their problems are intensified by ineffective speaking skills. Students who cannot clearly articulate what they know may be wrongly judged as less intelligent or poorly informed.

Beyond the confines of school and as students mature to adulthood, numerous US national surveys and studies highlight the importance of communication competence and its instruction. A meta-analysis of nearly 100 articles, commentaries, and publications calls attention to the importance of the study of communication in contemporary society (Morreale et al. 2000). Four themes in the bibliography provide support for the importance of communication education and communication competence to: the development of the whole person; the improvement of the educational enterprise; the development of responsible world citizens, both socially and culturally; and succeeding in one's career and in the business enterprise. In sum, students should learn to communicate competently "at a level that will serve the student both within the university and in postgraduate professional and personal life" (Kenny 2002).

Given this importance of communication competence, various academic associations and researchers, federal government agencies, and research centers in the US and many other countries have worked to identify the specific communication competencies necessary for students to be effective at work, in society, and in their private lives.

In 1990, members of the National Communication Association (NCA) in the US developed a set of expected student outcomes for college students taking a basic communication course or receiving communication instruction in the general education curriculum. Those competencies primarily relate to speaking, listening, interpersonal, and delivery skills. While these skills do comprise much of what is often referred to as communication competence, other communication skills and behaviors are also important to educational, personal, and career success. For example, competent communicators need to be able to discern and understand values and ethics, develop cultural awareness and sensitivity to diversity, receive and understand mediated messages, and seek and send information using computerized media and the array of emerging communication technologies.

Three other sets of competencies were developed through national research projects in the US where over 600 researchers, educators, employers, and government policymakers evaluated the importance of specific skills and competencies. These projects produced the following *communication expectations* specifically for college graduates: basic communication skills (Jones 1995); persuading, informing, and relating skills (Rubin & Morreale 1996); and advanced communication skills (Rubin & Morreale 1996). Basic skills are minimal competency expectations and represent abilities, core knowledge, and attitudes necessary for effective functioning in society and the workplace. By contrast, advanced skills are more than just knowing, doing, or feeling. They are blends of knowledge, skills, and attitudes and they require greater levels of behavioral flexibility and adaptability.

The 1990 NCA communication outcomes for undergraduates and the three sets of competencies for college graduates are downloadable from the NCA website ([www.natcom.org/nca/files/ccLibraryFiles/FILENAME/000000000085/College%20Competencies.pdf](http://www.natcom.org/nca/files/ccLibraryFiles/FILENAME/000000000085/College%20Competencies.pdf)) and the college graduate competencies are synthesized in the following list.

#### *Essential communication skills (Jones 1995)*

##### 1 Basic communication skills:

- a General skills such as: state ideas clearly, be aware of bias, communicate ethically, etc.
- b Develop and organize messages effectively.

- 2 Public speaking skills:
  - a Analyze speaking context.
  - b Support the message.
  - c Understand different message types.
- 3 Interpersonal and group communication skills:
  - a Analyze situation.
  - b Manage relationship effectively.
  - c Exchange information effectively.
  - d Manage conversation open-mindedly and enthusiastically.
  - e Work collaboratively in groups.
- 4 Communication codes:
  - a Use pronunciation, grammar, and articulation appropriately.
  - b Use appropriate and effective vocal behaviors.
- 5 Oral message evaluation:
  - a Listen attentively, with an open mind.
  - b Distinguish facts from opinions.
  - c Identify and distinguish main points.

*Basic skills for persuading, informing, and relating (Rubin & Morreale 1996)*

- 1 General skills for all three purposes:
  - a Students can encode clear messages using appropriate language, articulation, pronunciation, paralanguage, and organizational patterns.
  - b Students can decode messages correctly, understand others' nonverbal cues, critically evaluate messages, and distinguish among various communicative purposes.
- 2 Persuading skills:
  - a Students can construct a persuasive message, adapted to audience, purpose, and context/situation; present the message using effective delivery, reasoning, and organizational pattern; and achieve their persuasive goals.
  - b Students can tell when someone is trying to persuade and can critically evaluate attempts to influence.
- 3 Informing skills:
  - a Students can present information, answer questions, give directions, and give assistance clearly and effectively.
  - b Students can recognize when others do not understand, can understand others' messages, ask questions, and follow directions.
- 4 Relating skills:
  - a Students can develop, maintain, and nurture interpersonal and small-group relationships with others; fulfill their own interpersonal needs; and manage conflict while respecting all interactants' rights.
  - b Students can respond to others' attempts to build relationships and reciprocate by self-disclosing, focusing on the other, empathizing, and displaying affinity.

*Advanced communication skills (Rubin & Morreale 1996)*

- 1 General skills:
  - a Identify and adapt to changes in audience characteristics.
  - b Incorporate language that captures and maintains audience interest in message.

- c Identify and manage misunderstandings.
  - d Demonstrate credibility.
  - e Demonstrate competence and comfort with information.
  - f Recognize time constraints.
  - g Manage multiple communication goals.
  - h Demonstrate attentiveness through nonverbal and verbal behaviors.
  - i Adapt messages to the demands of the situation or context.
- 2 Speaking in public:
- a Incorporate information from multiple sources.
  - b Use appropriate statistics.
  - c Use motivational appeals appropriate to the audience.
  - d Develop messages that influence attitudes, beliefs, and actions.
- 3 Relating to others:
- a Manage and resolve group conflicts effectively.
  - b Approach and engage in conversation with new people in new settings confidently.
  - c Negotiate effectively.
  - d Be open-minded and allow for and understand different views (often referred to as perspective-taking).
  - e Assert self while respecting others.
  - f Convey empathy.
  - g Understand and value differences in communication styles.
  - h Motivate others and work effectively in a team.
  - i Use methods of building group consensus.
  - j Set and manage realistic agendas.
  - k Lead meetings effectively.
  - l Understand and adapt to people from other cultures, organizations, or groups.
  - m Identify important issues/problems, draw conclusions, and understand other group members.

Finally, the College Board, a primary agency for college entrance testing in the US, worked for two years with communication experts from around the US to develop and publish a set of twelfth-grade performance expectations for reading, writing, speaking, listening, and media literacy that clearly state what students should know and be able to do in order to succeed in college. The Language Arts College Board Standards for College Success are available in their entirety on the College Board website ([www.collegeboard.com](http://www.collegeboard.com)). They are derived from NCA's 1998 K–12 Standards and Competencies for Speaking, Listening, and Media Literacy, which are available on the NCA website at [www.natcom.org/nca/files/ccLibraryFiles/FILENAME/000000000119/K12%20Standards.pdf](http://www.natcom.org/nca/files/ccLibraryFiles/FILENAME/000000000119/K12%20Standards.pdf).

While these efforts were underway in the US, scholars in other countries also were focusing attention on media literacy and communication competence in the information society. One study examined how to build confidence and develop communication competence for *all* citizens in Sweden's twenty-first-century information society, rather than just students' competence (Olsson et al. 2003). And a researcher at the University of Helsinki endeavored to understand what is meant by new forms of literacy like "media literacy," and what importance media competence and communication skills have in the information society (Varis 1996).

## ASSESSING AND STUDYING COMMUNICATION COMPETENCE

The sets of communication competencies just described could be used to develop expectations for students from communication as well as other academic disciplines, such as the other social and behavioral sciences; humanities; science, engineering, and math; health-care and helping professions; and the law. Any discipline could examine the competencies, determine which are most applicable and relevant for their graduates, and then designate them as learning outcomes to be expected of all graduates in the discipline. The next step would be to determine how to assess students' achievement of the competencies.

Assessment of communication should be viewed as a gestalt of the *three foundational components of competence* – motivation, knowledge, and skills – with an assessment strategy particular to each component. Assessment of competence should include: an evaluation of the individual's motivation and attitude toward communication (e.g., value placed on oral communication, apprehension, → reticence, willingness to communicate, readiness to communicate [→ Communication Apprehension]); an assessment of knowledge (understanding communication processes; comprehension of the elements, rules, and dynamics of a communication event; awareness of what is appropriate in a communication situation); and an assessment of skills (the possession of a repertoire of skills and the actual performance of those skills).

The *method of assessment* should be consistent with the component of communication competence being assessed. Knowledge and motivation/attitude may be assessed in part through self-report by the individual being assessed, paper-and-pencil instruments, and surveys, but speaking and listening skills are best assessed through actual performance of the skills being assessed (speaking before an audience, undergoing an interview, participating in a group discussion, etc.). And, because oral communication is an interactive and social process and often involves performance, assessment could also include the judgment of a trained assessor or evaluator as well as the impressions of others involved in the communication act (audience, interviewer, other group members and conversants). A collection of useful communication assessment resources is available on the NCA website at [www.natcom.org/nca/Template2.asp?bid=264](http://www.natcom.org/nca/Template2.asp?bid=264).

While communication researchers use a variety of quantitative and qualitative methods to assess students' communication competence, a tendency to use self-report instruments results from the logistics and expense of training and using evaluators and observers other than self. The following studies are representative of this research program.

One study contrasted the communication apprehension and self-perceived communication competence of at-risk students and academically talented students. Academically talented students reported lower communication apprehension and perceived themselves as higher in communication competence than at-risk students (Rosenfeld et al. 1995). Three other studies of the impact of classroom instruction on students' communication competence reported the following findings. One reported that instruction in a basic public speaking course increased students' level of communication competence and self-esteem (Morreale et al. 1995). A second study also reported a favorable influence of instruction in a basic communication course on students' communication competence, apprehension, and academic success (Rubin & Rubin 1997). In this study, high-apprehension and low-competence students experienced greater favorable changes in apprehension

and competence than did their low-apprehension, high-competence counterparts. A third study reported that instruction in a basic interpersonal course also increased self-perceptions of communication competence, self-esteem, and willingness to communicate (Morreale et al. 1998). In methodological contrast, a longitudinal study of college students' communication competence did make use of trained observers (Rubin et al. 1990). That study observed a significant decrease in competence during the sophomore year, but increases during the junior and senior years.

### **VARIATIONS IN COMMUNICATION COMPETENCE**

When observing and evaluating student communication competence, faculty and administrators should be aware of: (1) variations in how students communicate based on their cultural background (age, gender, ethnicity, race, etc.; → Communication Skills across the Life-Span); and (2) students' competence in using emerging technologies to communicate.

Intercultural communicative competence is increasingly a topic of scholarly and instructional interest in many countries. To be considered competent intercultural communicators, students need to be aware of cultural differences in communication and to be able to communicate effectively and appropriately with people from cultures different than their own.

Research on self-perceived communication competence, communication apprehension, and willingness to communicate, conducted in a wide variety of cultures and countries, indicates that cultural expectations and norms significantly shape what is considered competent communication. Any type of cultural variations may significantly impact interpersonal and intercultural communication. For example, researchers discovered substantially lower self-perceived communication competence when using a second language than when using one's first language (Burroughs et al. 2003). Another study identified age and sex differences in willingness to communicate, communication apprehension, and self-perceived communication competence using three age cohorts drawn from junior high, high school, and university student populations (Donovan & MacIntyre 2004).

In addition to culture and competence, faculty and administrators also should consider students' ability to communicate competently using the many emerging technologies now ubiquitous in the US and other countries (Friedman 2005). This form of communication competence involves any human communication through digitally based and technological media as opposed to what are termed natural media. Natural media are those media that send and receive messages using only our bodies and minds, such as spoken words, gestures, and posture. Technological media are those that translate, amplify, or otherwise alter the message and typically include telephones (landlines and mobile phones), instant messaging, teleconferencing, videophone, videoconference, email, and other computer-assisted interactions such as telemarketing, group-decision systems, computer chatlines, blogging, social networking programs, and some virtual reality systems (→ Technologically Mediated Discourse).

Communication competence in a world of these emerging technologies, as in all contexts, is dependent on the students' motivation to use technology to communicate;

their knowledge of how to use it, the context in which the communication occurs, the nature of the message itself; and the skills with which the students send and receive messages using technology. Studies of communication competence are now focusing on what it means to be competent when using emerging technologies.

This form of communication competence also subsumes → information literacy in the curriculum and what competencies college students need in order to search academic literature electronically, in electronic databases, and on the Internet (Rubin & Rubin 2006).

## Style and Rhetoric

*Jeanne Fahnestock*

*University of Maryland*

Under the term *style* in rhetorical studies are grouped all those concerns with effective language that have been part of the rhetorical tradition from its beginnings in ancient Greece (→ Rhetoric, Greek). In rhetorical manuals from antiquity through to the present, language issues are typically discussed at the levels of word choice, sentence structure, and passage arrangement according to certain broad principles guiding selection, such as clarity or vivacity. Rhetorical stylistics also describes linguistic devices that can help construct the interaction between rhetor and audience (e.g., *apostrophe* or direct address), express states of mind (e.g., *dubitatio*, the expression of doubt), or even control the flow of discourse (e.g., *transitio*, marking the movement from one section to another). Many of these rhetorical *figures of speech* survive in the everyday vocabulary of language awareness (e.g., *rhetorical question*), while others are studied as literary devices achieving aesthetic effects (e.g., *personification*, extending human attributes like speech to the inanimate and nonhuman).

In the last 20 years, one particular device of word substitution, *metaphor*, has been promoted as a conceptual principle organizing areas of → meaning. In the rhetorical tradition, however, language principles and features are identified for their functional, persuasive potential. Scholars interested in rhetorical stylistics have studied principles of effective language primarily through recovery work in the many texts produced in the 2,500 years of the rhetorical tradition. In the last 50 years, other disciplines, e.g., discourse analysis, pragmatics, sociolinguistics, informal logic, and natural language philosophy, have rediscovered many of the principles of rhetorical stylistics without an awareness of this tradition.

Principles of effective language use, established in antiquity, begin with remarks on the power of language in the speeches of the sophists. But it is the third book of Aristotle's *Rhetoric* that introduces features of persuasive language that still dominate the discussion,

including the *period* as a rhythmic unit of language made up of smaller cola (clauses or phrases), and the two contrasting styles based on the connections between successive periods: the additive or paratactic style and the connected or hypotactic style, the former typical of narrative and the latter of reasoned discourse. Aristotle also discusses effective word choice by pointing out the explanatory power of metaphor, and praises language that brings things “before the eyes” and conveys activity. He nominates the *antithesis*, parallel phrasing with contrasting word choice, as an effective device in argument.

In the centuries following Aristotle, Greek rhetoricians expanded the study of style, but their notions survive principally in a Latin manual from the first century BCE, the *Rhetorica ad Herennium*. Falsely attributed to Cicero, this succinct treatment of all the parts of rhetoric remained in use through the sixteenth century and has seen some revivals; St. Paul probably studied it, as did Shakespeare. Its fourth book sets principles of selection for effective language: correctness, clarity, appropriateness to situation and audience, and forcefulness. Under appropriateness the *ad Herennium* introduces the influential notion of levels of style: the grand style, suitable to the most important and emotionally intense subjects; the middle style, typical of exposition and reasoning; and the simple style, matching everyday informal conversation. A single speech should vary its style, rising, for instance, to the grand style in the emotionally charged conclusion of a speech. Under the notion of forceful expression, the *ad Herennium* offers the first listing of some 64 devices, including many of the word- and sentence-level figures of speech that are still familiar, but also many other devices that yield paragraph-length units of discourse, accomplishing such goals as vividly describing the consequences of an action (like the fall of a conquered city) or elaborating on a premise–conclusion pair to produce a five-part *epicheireme* or argument. An even fuller treatment of the levels of style and their abuses, and of the figures and their effects, can be found in Quintilian’s first century CE *Institutio oratoria*, which summarizes earlier Greek and Latin treatises since lost. For Quintilian, examples of effective language are drawn frequently from the political and forensic speeches of Cicero, whose own rhetorical treatises tend to merely list what were then widely known stylistic devices.

In late antiquity, writers on rhetorical style expanded the notion of levels (grand, middle, simple) into *types* of style, patterns of language selection that would produce overall effects, such as Hermogenes’ clarity, grandeur, beauty, rapidity, character, sincerity, and force. Scholars in the early modern period, recovering the texts of antiquity with honed philological skills, nevertheless made their own contributions to rhetorical stylistics. They emphasized the goal of amplifying a subject and expanded the taxonomy of rhetorical devices; a typical early modern style manual, like Henry Peacham’s *The Garden of eloquence* (1593), contains well over 100 figures of speech, many of them codifying potential *speech acts* that a rhetor might want to achieve.

In the twentieth century, many literary scholars, working in isolation, reinvented pieces of a rhetorical approach to language, but in the process they also achieved fresh insights in new terms. The Russian critic → Mikhail Bakhtin introduced the notion of *heteroglossia*, the amalgamation of different registers characteristic of different genres or discourse communities into a single text, which then becomes a pastiche of multiple voices. The American narrative theorist Wayne Booth and other “reader response” theorists looked at narratives as persuasion, discovering the linguistic dimensions of ethos and pathos in

novels, etc. Also in the 1970s and 1980s, a group of British literary scholars, influenced by the linguist M. A. K. Halliday, began to study style in a particularly functional and critical way. These practitioners of literary *stylistics*, including language critics like Walter Nash and Roger Fowler, eventually turned their attention to non-literary genres, producing useful analyses of style in news reporting, bureaucratic announcements, instructions, and the like.

While the process of recovering and debating the rhetorical tradition is well underway, the work of mining that recovery for principles of effective style accessible in different contexts is patchy. There are many descriptions of rhetorical stylistics in different periods, but no accessible overviews of durable *rhetorical* principles of style that would be useful to current practitioners in applied fields.

## **Subaltern Communities, Communication in**

*Gabriela Martínez Escobar*

*University of Oregon*

In most of Latin America, subaltern populations are those whose primary origins are indigenous, including lower-class *mestizo* people (i.e., people of mixed origins – indigenous with European) and the urban poor of predominantly indigenous background. Internal migration, urbanization, and modernization are three elements that have influenced transformations in popular communication. For instance, in Peru, television has changed due to socio-economic and political factors. Television came about in 1957 with the altruistic ideal of education, as a plan for modernization, and with → UNESCO's financial and technical aid (Perla 1995). However, within a year of the birth of television in Peru, US → television networks NBC and CBS began lending money and providing content for the recently formed local stations. At that point it was clear that television would be primarily a commercial and entertainment enterprise targeting the middle and upper classes rather than subaltern groups (→ Brazil: Media System; Bolivia: Media System).

For decades, subaltern populations have been excluded from the small screen (→ Television). Local programming generally featured light-skinned people who spoke standard educated Spanish. In the mid-1990s, however, the advent of → cable television substantially changed the face of broadcast television, as audiences with the most purchasing power switched to cable and local advertisers followed. Broadcasters were forced to cut costs in their domestic production, which helped create a space for the subaltern.

Other factors have contributed to the inclusion of subaltern groups in contemporary media. Various social and political struggles in the past 35 years have created internal migration and displacement of populations, changing the makeup of most urban areas. In the 1960s broadcast television began reflecting the realities of Lima's lower class and of migrants. These programs, mostly comedy shows, represented different situations in tenement houses. The main characters were gossipy women, soft-core thieves, and hard-working, macho men with dominated wives (Vivas 2001). Later, the *cholo* (see below) character made a transition from radio to television (Gargurevich 1987; Jochamowitz 1998).

In 1963, *Tulio Loza's show* introduced Nemesio, the first *cholo* ever on national television. Literally, *cholo* means *mestizo*. However, *cholo* is used in Peruvian society to degrade people whose socio-cultural background and physical phenotype are those of indigenous people. Nemesio's adventures came to symbolize the changing social landscape of Lima (Jochamowitz 1998; Vivas 2001). The producers of this program made Nemesio into a modernized *cholo* who changed his *ojotas* (indigenous sandals) for moccasins and his *huayno* (an indigenous folk dance) for the twist (*El Comercio Grafico*, 1964, cited by Jochamowitz 1998; → Modernity). Nemesio spoke a broken Spanish with a thick accent from his mother tongue, *Quechua*.

It was not until 1998, however, that most networks jumped on the bandwagon and brought *los cholos de la calle* to the screen. Broadcasters, desperately seeking to cut costs and gain new audiences, began using popular street skits known as *street theater* as their primary source for new comedy shows. The networks saw in these street comedians an alternative to the economic crisis affecting their stations, and the street actors saw an incredible opportunity to have a steady salary greater than what they could ever earn in the streets (→ Media Economics). Street actors combine oral storytelling with the kind of urban street savvy required to survive the big city. This street theater represents a humorous look at the tribulations of rural migrants and their hybrid culture that has developed from mixing rural and urban cultures. Most of these skits use coarse language and mirror violent aspects of life in the city.

In 1998 Frecuencia Latina hired Juan de los Santos Castellano, also known as "*Tripa*" (Guts), an established street comedian. "*Tripa*" and his troupe created the show *El show de los cómicos ambulantes*. A few months later, Frecuencia Latina's competitor, Channel 13, hired the troupe *Los Reyes de la Risa*. In less than six months this troupe was offered more money and moved to the second-largest network in the country, Panamericana Television, creating the show *Los ambulantes de la risa*, which came to be one of the most popular shows in its time.

A few other television stations created cheap popular programming. Channel 9 hired "*Cholo Cirilo*" and "*the Poet*" to create *Los cómicos de la calle*; Channel 4 hired Ernesto

Pimentel to telecast *La chola Chabuca* (Vivas 2001). Other shows have appeared, but have not gained the success of the first ones and have lasted for only one or two seasons. Examples include *La chola Jacinta* and *La chola Cachucha*, a response to *La chola Chabuca*, where the character of the *chola* is less hybrid and more “authentic” (→ Hybridity Theories).

Having subaltern people on television and representing themselves would appear to be a double triumph. Indeed, these shows have inserted indigenous and hybrid cultural backgrounds and phenotypes, mirroring the majority of the Peruvian population. These comedy shows have brought strong attention to the daily lives and vicissitudes of the poor living in Lima. However, the positive aspects of having the subaltern on national networks is overshadowed by the racist and homophobic stereotypes these shows promote. “Ignorant migrants,” “stupid *cholos*,” and “grotesque transvestites” are the butt of every joke (→ Gender: Representation in the Media). Machismo and overt verbal and physical violence against such characters are blatant, reflecting, at a deep level, Peruvian society’s attitudes toward these people in everyday life. What is problematic here is that while these shows apparently subvert the local hegemony, they use hegemonic representations of subaltern populations and thus reinforce stereotypes about them.

Perhaps it is no surprise that what the popular street actors are producing for television reflects Peruvian hegemonic ideology about the masses today, since what gets put on television comes from above and, as Martín-Barbero (1993) reminds us, “the syntax of that culture is not truly from the popular classes, but represents the disgust and disdain of the upper classes regarding the popular.” The idea of gaining a voice is somewhat false because the subaltern voices are talking, but saying what the middle and upper classes think of them. This is a central contradiction the subaltern face every day in Peru, particularly when creating popular culture that gets transferred to mass-mediated cultural industries.

# Subsidies for the Media

*Robert Picard*

*Jönköping University*

Subsidies for the media involve state financial support for media operations and content. Although generally considered undesirable from freedom of expression and economic standpoints, they are sometimes necessary to pursue social and cultural goals that markets fail to serve.

## TYPES OF SUBSIDIES

A wide variety of subsidies are provided to media, but the types and patterns differ depending upon the types of media involved and the political and market orientation of individual nations. Subsidies are provided to promote media industries, support political activities, spur cultural development, meet the needs of minority linguistic and ethnic groups, assist religious and other organizations sanctioned by states, and reward political allies.

The term “subsidies” more precisely refers to state intervention that affects the economics of media, including indirect subsidies, such as tax reductions or reduced charges for state services that reduce costs industry-wide, and direct subsidies provided to specific units of media. Regulatory relief that exempts media from regulations faced by other industries can also be a form of subsidy.

Media subsidies are found worldwide in nations with widely varying political economic philosophies – ranging from those with high levels of market capitalism to those with strong centrally planned economies – and in countries with widely differing degrees of freedom of expression (→ Freedom of the Press, Concept of). The patterns of subsidization are related to national economic and industrial policies, and the levels and significance of intervention differ widely. These differences among national policies can be attributed to cultural factors and to economic policies toward industries overall (→ Media Policy).

Subsidies have existed since the first appearance of the print media, but their scale and scope have changed over time as states have responded to national concerns over press developments. Most print subsidies support → newspapers, but some also support → magazines and journals. Subsidies in western nations were originally given to press sympathetic to governments, but these later evolved into support designed to aid the press generally. Three decades ago, after a wave of newspaper mortality, a number of European nations constructed extensive subsidy mechanisms in efforts to reduce the demise of newspapers and the concurrent concentration in the newspaper industry (→ Concentration in Media Systems). In the 1980s and 1990s, concerns over minority languages led to additional subsidies for those purposes in many nations.

The ability of subsidies to solve press mortality problems is debatable because the number of newspapers has continued to decline despite subsidies. Studies have shown that (1) subsidies often have not addressed the underlying economic problems of the

press, (2) subsidies have tended to diminish over time, (3) dependence on subsidies can harm the ability of publications to improve and grow, and (4) there is difficulty maintaining political support for subsidies.

A significant change in subsidization occurred when policy changes privatized post administrations in western nations and thus ended or reduced the postal subsidy, which was the largest subsidy in most nations. Another change is occurring because there are considerable concerns that direct press subsidies – especially operating subsidies – violate contemporary competition policy on state aid due to rulings in other industries in the European Union (→ Communication Law and Policy: Europe; European Union: Communication Law). There are also concerns that the aid primarily benefits commercial firms that do not serve specific social purposes and that aid mechanisms have been used by publishers and dominant political parties to benefit their own purposes.

### **SUBSIDIES FOR BROADCASTING AND FILM**

Broadcasting has typically had a higher degree of state involvement than print media so various types of subsidies to broadcasters exist in most nations. In many nations radio and television began as state or government-supported broadcasting. Even in nations in which broadcasting was private, however, there has been a significant level of government oversight and intervention. Typical subsidies to broadcasting have been free use of radio spectrum, state grants and allocations to support channels and program production, and requirements for audience-paid license fees – a form of taxation – designed to raise funds for broadcasting (→ Radio Broadcasting, Regulation of; Television Broadcasting, Regulation of).

In the United States, for example, federal funding for broadcast programming is provided to the Corporation for Public Broadcasting, and the government has funded production grants for some content through the National Endowment for the Humanities. These fall into the categories of indirect and direct subsidies, respectively. In Korea, support for public broadcasting is raised by a television license fee administered by the Korean Broadcasting System (→ Public Service Broadcasting: Law and Policy).

Subsidies for production of *motion pictures* exist for both economic and cultural purposes and are designed primarily to spur domestic production and marketing of films. Tax breaks for investments in film production in Germany induced institutional investors to finance both domestic and co-productions with foreign firms in the last decades of the twentieth century. Another example of film subsidy is the Irish government financing of the Irish Film Board, which provides production loans and equity investments in motion pictures that promote Irish culture and provide domestic employment.

Much of the development of telecommunications worldwide has occurred because telephony was typically operated by government or given regulated monopoly status. Research and development of new services and technologies was often encouraged by special requirements, grants, or tax advantages. Creation of the → Internet was made possible by funding from the US military, and development of the world wide web was funded by the joint nuclear research organization of European governments. Today, many countries provide tax breaks or do not apply taxes on services to Internet services. In other cases, exemptions from sales taxes on e-commerce exist.

## EFFECTS OF SUBSIDIES

The primary effects of subsidies are the provision of additional resources and reduction of costs to a media industry or a specific media firm, and support for creation of individual content products. Support to individual firms affects company finances, allowing firms to use the financial resources to pay expenses or to improve their balance sheets. To fully understand the impact of a specific subsidy, one needs to consider how it enters and affects the operating statements and balance sheets of firms and the effect it has on the financial performance of the company (→ Media Economics).

Most types of support simply help pay variable costs rather than fixed costs so aid does not significantly affect the fundamental economic and market conditions (→ Cost and Revenue Structures in the Media). In such cases, subsidies have little effect on the overall financial or market situations and thus create dependence on the handout of subsidies. State intervention can only support sustainability if it changes the financial and market conditions of the recipients by helping them restructure their operations, expand markets, or acquire cost saving technologies.

Part of the difficulties in achieving intended goals with indirect general subsidies is that they do not change the competitive situation of firms. Because dominant media in a market also receive the subsidy, it provides an additional revenue stream and gives greater resources that can be put to use to provide advantages against secondary media in the market.

State support can promote competition, have no effect, or harm competition in both the economic and information/idea markets. Most subsidies provided by states fall into categories that have no significant effect or actually harm either the economic or information market, and few actually promote competition.

Because subsidies provide financial advantages to firms that receive them that non-recipients do not enjoy, they can affect the rivalry of firms in competitive media markets. Subsidies present trade issues because the *World Trade Organization* policy restricts state aid that affects international trade, but debates over trade in media products there have to date focused primarily on content quotas and ownership restrictions, because the effect of media subsidies in international markets is currently limited.

The *European Union*, in its efforts to create a common and competitive marketplace among European nations, has targeted subsidies in all industries for competition law enforcement if they distort competition in the market. European states have historically supported media industries more than the US and have a broader range of subsidies for media. Regulators in the EU have constrained the use of subsidies in motion picture production and broadcasting, particularly public service broadcasting, but have not yet addressed print media subsidies.

Although the US government provides few direct subsidies, it does provide a range of support, including postal rate reductions, tax advantages, and free use of airwaves. These, however, are provided to all firms in the industries and tend not to have significant market effects other than generally lowering costs of operations. As a result, they have only in rare circumstances been seen to be in conflict with competition law.

Research on the utility of subsidies indicates that state support can be successful in the long run only if it is utilized as more than operating aid that covers losses – that is, only

if it results in a change in managerial and market strategies and is accompanied by a restructuring of the costs of operations. If used merely to pay operating costs and cover losses, subsidies ultimately lead to resource dependency on the state aid and the firm loses market incentives to improve its product and operations.

The optimal outcomes from the policy standpoint are for subsidies to enhance the condition of media so that their cost structures and market situations improve and so they make reinvestments that enhance sustainability. Negative outcomes are inability to preserve competition, long-term dependency on aid, or overprovision of subsidies that transfer wealth to produce unearned profits. This has occurred in many cases where subsidies are given to commercial and profitable enterprises.

For subsidies to be effective, they need clarity in purpose and must address the fundamental causes of the problems they are intended to solve. In the contemporary environment of the so-called information society – with the largest amount of types of media ever available and its enormous number of content providers – explicit purposes and unambiguous rationales for providing subsidies need to be provided, and specific objectives and goals need to be presented.

Subsidies need to be constructed to actually address the underlying economic and market issues that have led to the purposes and rationale for subsidies, and designed to produce effects that make it possible for subsidized media to free themselves from state support at some point in their future.

### **ENVIRONMENTS OF MEDIA SUBSIDIES**

In considering policy and its potential benefits, we need to recognize two distinct environments of media subsidies. First, there is an environment in which market failure results from a general lack of interest and support by audiences because of their preferences to use other media. In the second environment, market failure results from structural and financial challenges despite interest and support by audiences.

The difficulties in the first environment cannot easily be solved by offering subsidies because the state subsidizes something that the public neither desires nor consumes – thus the policy merely expends limited public resources and does not produce the intended benefits. Subsidies to address problems facing the second environment can produce benefits, however, particularly when they are intended to support regional and secondary languages and cultures that may be less interesting to national and international advertisers. To do so, however, requires the presence of strong local identity and audiences willing to consume. If those are absent, they must first be built through cultural organizations and educational institutions before benefits can be produced through subsidies.

Subsidies for print media appear to work best when provided to book literature and magazines because these media have low fixed costs and the subsidies can easily be provided on a project or fixed-term basis. Subsidies in broadcasting and motion pictures appear to be most successful when they aid specific programs and individual film production and are given on a project basis with open competition for funding among producers.

In making contemporary policy, one needs to recognize that this changing media environment is presenting more choices to audiences and significantly altering media use

patterns (→ Exposure to Communication Content). This raises the question of whether subsidies are the most effective means for serving the laudable social purposes that often prompt interest in them. Policymakers need to consider whether their existing or planned subsidy systems are designed to preserve a certain *form of communication* (newspapers, for example) or to preserve its *functions* (facilitating social, political, and cultural interaction and development). If the latter is the purpose, they will have to consider broader options involving other media rather than focusing solely on one type of media.

Judiciously used subsidies can help media make short-term adjustments to the changing environment, and well-placed support can serve some public goals. Relying upon subsidies alone to produce and maintain the desired social benefits in media structure and content, however, will be insufficient, and a range of other policy options will need to be employed as well.

# Supervisor–Subordinate Relationships

*Patricia M. Sias*

*Washington State University*

Hierarchy is a defining characteristic of organizations. The earliest formal theories of organization – bureaucratic theory and administrative management – held hierarchy at the core of management processes, emphasizing chain of command, order, control, and discipline (→ Bureaucracy and Communication; Control and Authority in Organizations). These processes occur in the context of supervisor–subordinate relationships.

Supervisor–subordinate relationships are workplace relationships in which one partner (the supervisor) holds direct formal authority over the other (the subordinate employee). Early research tended to treat management/supervision and leadership as synonymous terms. Both “processes” involved leaders (supervisors/managers) eliciting the optimal (i.e., most productive) attitudes and performance from followers (subordinate employees). In the early 1980s, scholars began to distinguish between management/supervision, which centers on day-to-day direction of departmental activities, and leadership, which centers on vision and organizational change (→ Leadership in Organizations).

## FUNCTIONS OF SUPERVISOR–SUBORDINATE RELATIONSHIPS

Early studies of supervisor–subordinate relationships, conducted by both leadership and management scholars, tended to be unidirectional and focused on the functional aspects of such relationships. This research attempted to identify *supervisor* qualities and behaviors that lead to improved employee attitudes, motivation, and job performance.

Early leadership theories focused either on “traits” or “styles.” *Trait theories of leadership* assumed “great leaders” possess particular personality traits (e.g., charisma, intelligence, courage) that enhance leadership ability (Ghiselli 1963). The follower (subordinate) was largely irrelevant in these theories. A great leader could lead anyone effectively.

“Style” or “behavioral” theories of leadership focused on leader behaviors, rather than traits, arguing that people can learn to be effective leaders. These theories fall under the broad category of “average leadership style” (ALS) theories in that they assume, to varying degrees, that leaders/supervisors tend to adhere to a general supervisory style. The Ohio State leadership studies, for example, indicated that leaders who exhibit a high level of consideration for employees (e.g., trust, warmth, respect) and a high level of initiating structure (e.g., focus on the task) were the most effective (Hemphill 1955).

*Style theories of leadership* differed with respect to the role of the subordinate employees. Managerial grid theory, for example, assumed effective leadership behaviors were universal; that is, all employees would respond similarly to such behaviors, giving subordinate employees a passive role in the leadership/management relationship. In contrast, life-cycle theory (Hersey & Blanchard 1982) assumed certain leader behaviors would be effective only with certain types of employees. For example, research indicated that mature and confident employees respond best to a “delegating” leadership style, while employees lacking maturity and confidence respond best to a “telling” or more

directive leadership style. Although subordinate employees began to play a more active role in these theories, the effectiveness of the relationship was still conceptualized as being in the supervisor's control. He or she only had to determine which behaviors to use with which employees.

In the mid-1970s, Graen and colleagues introduced *vertical dyad linkage (VDL) theory* (Graen & Cashman 1975). VDL theory questioned the prevailing assumptions that supervisors treat employees similarly and that subordinates are generally passive. Instead, VDL theory maintained that supervisors form different types of relationships with their various employees and these relationships vary with respect to quality. In general, high-quality supervisor–subordinate relationships (also known as “ingroup” relationships) are characterized by higher levels of mutual trust, respect, and obligation among the relationship partners than are low-quality relationships (also known as “outgroup” relationships). In high-quality relationships, leaders and members rely on one another for support and encouragement. Such relationships function more as “partnerships” where “members move beyond their own self-interests to focus on larger mutual interests” (Graen & Uhl-Bien 1995). Moreover, leader–member relationships (i.e., supervisor–subordinate relationships) represent a type of “exchange” relationship in which *both* partners negotiate their relationship on an ongoing basis. The theory was eventually renamed “leader–member exchange” (LMX) theory to emphasize the negotiated nature of supervisor–subordinate relationships.

Parallel to the evolution of theory regarding leadership and supervisory relationships, scholars conducted a great deal of research on *supervisor–subordinate communication*. This body of work focused on identifying supervisor–subordinate communication patterns and functions that were more or less effective (with effectiveness typically measured with respect to employee productivity, turnover, and satisfaction). Research indicates that supervisors' and subordinates' openness with respect to both providing and receiving information is associated with higher employee morale and satisfaction with the supervisor–subordinate relationship, and lower employee turnover. Communication openness also contributes to supervisors and subordinate employees having more similar understandings of their tasks, abilities, and responsibilities. Employees perceive effective supervisors to be skilled communicators, viewing them as “communication minded,” skilled listeners, sensitive to their employees' needs and feelings, and skilled at persuading, rather than demanding (Jablin 1979, 2001). Communication research also indicates that information exchange is a crucial function of supervisor–subordinate relationships. Supervisors are one of the most important sources of information for both newly hired and veteran employees (Jablin 2001; → Organizational Assimilation). Likewise, supervisors depend on subordinate employees for information to ensure they make appropriate decisions (Sias 2005). Much research has centered on identifying supervisor and subordinate information-seeking and information-giving tactics (Miller & Jablin 1991).

## POWER AND INFLUENCE

Because hierarchy is a defining characteristic of the supervisor–subordinate relationship, much research has examined power and influence processes among supervisors and subordinate employees. Again, early work tended to be unidirectional, focusing on how

supervisors control and influence employees. Early management theories conceptualized the supervisor–subordinate relationship as a power relationship in which the supervisor held legitimate authority to direct and control the subordinate employee's behavior. Power was conceptualized as a relatively simplistic downward process in which supervisors gave orders to employees and employees were disciplined if they failed to carry out those orders effectively. Later theorists in the human resources movement, such as Mary Parker Follett and Rensis Likert, maintained that subordinate employees are more competent and knowledgeable than earlier theories suggested and not easily or effectively controlled through direct orders. They advocated *participatory processes* in which subordinates participated in decisions and exerted greater control over their tasks and work processes (→ Participative Processes in Organizations).

Conceptualizing subordinates as participants in power and control processes, many scholars have studied “upward influence” and identified several tactics subordinate employees use to influence their supervisors. The tactics fall into three broad categories: hard (e.g., assertiveness, upward appeals, coalitions), soft (e.g., ingratiation, self-promotion), and rational (e.g., providing rational evidence and arguments). A recent → meta-analysis (Higgins et al. 2003) revealed that rationality and ingratiation tend to be the most effective tactics with respect to garnering positive performance assessments from supervisors and greater extrinsic success (i.e., salary increases and promotion). Research also shows that employees with higher quality relationships with their supervisors have more influence on supervisors' decisions than do employees in lower quality relationships.

## DEVELOPMENTAL PROCESSES

Studies of supervisor–subordinate relationship development began largely with the introduction of LMX theory, which maintains that supervisors form different types of relationships with their various subordinate employees. An important issue, therefore, is how and why some employees develop higher (or lower) quality relationships with their supervisor than other employees. Research indicates a process by which supervisor–subordinate relationships evolve from “stranger” to “acquaintance” to “maturity” status (Graen & Uhl-Bien 1995). In the “stranger” phase, the relationship is characterized primarily by “role-taking,” wherein leaders/supervisors and members/employees behave strictly within the bounds of their prescribed jobs. After a time, one of the parties “offers” an improved relationship (e.g., the supervisor seeks employee input on a decision or the employee shares increased information or performs tasks beyond his/her prescribed role). Thus, role-taking transforms to “role-making” and the relationship moves from purely contractual (stranger phase) to a closer, more multifaceted relationship (the “acquaintance” phase). As the relationship grows closer, it enters the maturity, or “role-routinization,” phase, where the relationship develops an emotional, rather than solely instrumental, quality. The supervisor and subordinate exhibit mutual trust, respect, and support for one another. Those who reach the “maturity” stage develop the high-quality LMX relationship discussed earlier.

Not all supervisor–subordinate relationships reach the maturity phase, however, and scholars have examined the factors that affect this developmental process. A subordinate employee who fails to perform a task independently, for example, may lose the trust of the

supervisor, hindering movement to the acquaintance phase (Deluga & Perry 1991). Gender, liking, and similarity also influence the development of leader–member relationships. Specifically, supervisors are more likely to form higher quality relationships with employees of the same sex, whom they like, and with whom they perceive similarities (Graen 1989; Bauer & Green 1996).

Communication scholars conceptualize relationship development as a communicative process. Gail Fairhurst and her colleagues demonstrated that supervisor–subordinate relationships are socially constructed during routine conversations. The differential nature of such conversations constructs differential relationships (→ Interaction; Symbolic Interaction). Research indicates, for example, that *high-quality relationships* are characterized by communication in which supervisors and subordinates minimize power distance, using communication patterns such as insider talk, value convergence, and nonroutine problem solving. Low-quality relationships, in contrast, are constructed via conversations that emphasize power distance between the supervisor and subordinate, including communication patterns such as performance monitoring, face-threatening acts, and competitive conflict (Fairhurst & Chandler 1989).

Communication also enables individuals to *maintain stability* in their supervisor–subordinate relationships. Strategy use varies depending on the quality of the supervisor–subordinate relationship (e.g., high or low quality). In general, ingroup employees tend to rely on personal and direct communication tactics to maintain their leader–member relationship, while outgroup employees rely more on “regulative” tactics (e.g., talking superficially, avoiding discussion of problems, etc.).

Supervisor–subordinate relationship quality has important consequences for both supervisors and subordinate employees. Employees who perceive they have a high-quality relationship with their supervisor tend to experience faster career progression, higher levels of organizational commitment, job satisfaction, influence on decision-making, and job enrichment (Duchon et al. 1986), lower levels of turnover (Kramer 1995), and they tend to receive more and higher quality information (Sias 2005) than employees in lower quality relationships.

## Supply and Demand in Media Markets

C. Ann Hollifield

University of Georgia

The concepts of supply and demand and the relationship between them are the cornerstones of the field of economics. Economic theory holds that supply of a specific product will reach equilibrium with the demand for that product because of the mediating effect of price. As prices rise, the quantity of a product demanded by the market will fall, and as prices fall, the quantity of the product demanded will rise. This relationship is known in economics as the *law of demand*.

An imbalance between supply and demand in the market will affect prices. If demand for a product rises faster than supply, prices will rise. The increase in price will cause demand to fall until the balance between supply and demand is re-established. Conversely, if supply of a product rises faster than demand, prices will fall, leading to an increase in demand.

One reason demand for a product falls when the price rises is that consumers switch to substitute products. The degree to which changes in price affect levels of demand for a particular product is known as *elasticity of demand*. The level of elasticity of demand varies from product to product. If the decrease in demand is greater than the increase in price – that is, if the percentage of change in demand when divided by the percentage of change in price is greater than 1 – then demand for that product is said to be *elastic*. If it is less than 1, demand is said to be *inelastic*. When consumers are able to substitute one product for another, there is *cross-elasticity of demand* between the two products.

Price also affects the supply of products. As prices rise, new suppliers enter the market to capture the higher profits created by increased prices. As the number of suppliers in the market grows, the increase in supply relative to demand puts downward pressure on prices. As prices fall, suppliers exit the market, until a new equilibrium between supply, demand, and price is established. This is known as the *law of supply*.

In addition to price, a number of other factors affect the supply of products in general, and media products specifically. One of those factors is the costs of inputs. If production or distribution costs fall (→ Distribution; Online Media), new suppliers may enter the market in an attempt to capture the profits created by the gap between the established market price and falling production costs. For example, as the costs of music production software and CD burners fell in the 1990s and the world wide web emerged as a low-cost avenue for marketing and promotion, more musicians began producing and distributing their music directly to audiences without going through record labels. Consequently, the total number of suppliers selling music in the market rose (→ Music Industry; Internet).

The development of new technologies also can affect supply. The advent of → cable television technologies in the 1970s and 1980s dramatically increased the supply of television programming available to audiences by providing a new way of delivering that programming (→ Satellite Television). The development of DVD and broadband technologies made films, → videos, and → news more accessible, while the emergence of satellite → radio vastly expanded the supply of radio signals from which audiences could choose (→ Radio Technology). These technologies increased the capacity of various media distribution systems, allowing for an increase in the supply of content reaching audiences.

## THE SPECIAL SITUATION OF MEDIA MARKETS

For many media products, however, the expected relationships between supply and demand are disrupted. The problem stems from several causes. First, media are a *joint commodity*. A joint commodity is a product that is sold into two different markets simultaneously. In the case of media, most media products are sold to both advertisers and → audiences, with advertisers paying most of the production costs for the media content through their purchase of → advertising time or space. As a result of advertising subsidies, the prices audiences pay for media content do not reflect actual production costs. The artificially low prices of media products lead to overconsumption by audiences relative to the actual utility of media to them. Audiences use media more, and perhaps differently, than they would if they had to directly pay the full costs of media production.

Advertising subsidies distort the relationship between the supply and demand of media products in another way. Because advertisers pay most of the costs of media production

(→ Cost and Revenue Structures in the Media), producers of advertising-subsidized media focus on creating the media products for which advertiser demand, rather than audience demand, is highest. Content is created to attract the audiences that advertisers are most interested in reaching (→ Audience Commodity). However, not all audiences are of equal value to advertisers. For example, low-income people are of relatively little interest to advertisers because of their lack of disposable income, while older audiences are less valuable because they are believed to have already established brand loyalties. Thus, advertising subsidies lead to a systematic undersupply of media content targeted to audience groups advertisers do not value. Demand within those audiences for media content has little effect on the market's supply of that content (→ Access to the Media).

Supply and demand relationships in media markets also are affected by government regulation. In broadcast markets, the requirement that broadcasters be licensed in order to operate creates a barrier to entry that limits the number of suppliers regardless of level of demand (→ Radio Broadcasting, Regulation of; Television Broadcasting, Regulation of). In some countries, regulations limit the number of minutes of advertising that can be sold by broadcasters, regardless of the level of advertiser demand (→ Advertising Law and Regulation). Similarly, content regulations such as obscenity and decency regulations limit the supply of certain types of content over broadcast media, even if such content wins higher ratings than "family friendly" content (→ Pornography, Media Law on).

The expected relationships between supply and demand in media markets also are disrupted by the *externality* value of media. In economic terms, externalities are the value of the ripple effects that a product has that are not included in its price. Media products have significant externality value in society. For example, effective, independent news organizations that serve as watchdogs on government act as a check on government power and corruption. Therefore, the true economic value of high-quality journalism products includes the economic value of effective democratic government and efficiently used public monies. Similarly, textbooks are central to educational processes, and higher levels of education are associated with positive economic effects ranging from higher wages to lower health-care costs. The actual value of textbooks, then, includes the long-term economic benefits that a person realizes as a result of being educated and that society realizes from having an educated population.

The problem with economic externalities is that they are difficult to recognize and measure. Consequently, the full value of media products that produce positive externalities cannot be captured in their price, leading to an undersupply relative to their actual value. For media products that have negative externalities, the full costs to society are not incorporated into the price of the content, leading to an oversupply.

The relationship between supply and demand in media markets also is distorted by the non-economic externalities associated with owning media companies or producing media content. The laws of supply and demand are based on assumptions of economic rationality. Specifically, the law of supply assumes that producers respond to economic signals and will stop producing when prices fall below what is called *normal profit*. Normal profit is the point at which profits are high enough to keep existing suppliers in the industry but not high enough to attract new suppliers.

Media owners and producers, however, sometimes produce content for non-economic reasons such as recognition, creative expression, or power. Owners of newspapers or broadcast

stations may use their media organizations to gain social prestige, pursue personal political agendas, or promote other businesses they own. Such motivations may induce a media owner to continue to produce media in a market even in the face of financial losses. In developing and transitional countries, the number of media organizations supplying the market often far exceeds audience and advertising demand in the market. The number of suppliers does not substantially fall, however, because political parties, nongovernmental organizations, corporations, and even criminal organizations subsidize unprofitable media companies in pursuit of goals other than profit from the sale of media products (→ Competition in Media Systems).

Similarly, the percentage of people supplying content to the world wide web has grown exponentially. The growth of the *blogosphere* and of *wiki-media* occurs even though few of the individual content suppliers receive profits. Producers create and distribute content because they are motivated by such externalities as the desire for recognition, a creative outlet, or an audience for their opinions, rather than economic returns. The presence of a large supply of free content on the Internet puts downward pressure on both the price and demand for content sold by traditional media companies (→ Blogger).

### ISSUES OF SUPPLY AND DEMAND IN MEDIA MARKETS

The lack of focus on economic returns by many producers and the development of new distribution technologies have led to an exponential increase in the supply of media content available relative to existing demand. Between 1995 and 2002, the average number of channels available to basic or expanded basic cable subscribers in the United States jumped from 38 to 63, while the average number of cable channels viewed by those subscribers rose much more slowly during the same period from about 12 to 16. In 1971, five countries in western Europe had only one television channel and only two countries had more than two channels. By the end of the century, there were at least 700 channels available in Europe through cable and satellite distribution, many of them on the air 24 hours a day. Since the Internet was opened to public access in the mid-1990s, billions of pages of content including audio and video productions have been generated, although relatively few suppliers of that content make a profit on its sale to audiences or advertisers. This rapid growth in media supply has created audience fragmentation and lower demand on average for individual media products as measured through circulation, ratings, and other audience metrics.

Economic theory argues that oversupply, i.e., too much competition, is impossible because increases in supply always benefit consumers by giving them more choices at lower prices. However, research is beginning to challenge that view as it relates to media markets. While highly competitive markets characterized by multiple suppliers may provide high levels of consumer choice among channels, they do not necessarily provide high levels of product quality or even broad ranges of content diversity. The economics of content production are such that as the sizes of audiences fall in the face of audience and advertiser fragmentation, so do revenues and, consequently, the amount of money producers have to invest in product quality. For the producer, there are diminishing returns on investing in quality in terms of incremental increases in the size of the audience that will be attracted and the amount of profit that can be generated (→ Media Performance).

In entertainment programming, this can lead to *excessive sameness* in low-quality programming as producers attempt to generate the largest possible audiences while investing the minimal amount in production. Thus, a programming genre or concept that generates comparatively high ratings will be reproduced by multiple suppliers across the market as spin-offs and sequels in the struggle to carve off a piece of an established audience. As a result, the total number of channel choices available to audiences may be high, while the actual range of choices between program types and content quality declines.

A similar effect has been observed in news media markets. Moderate competition among suppliers has been found to increase media organizations' financial commitment to news production. Increases in financial commitment are associated with increases in the quality of news products as measured by reporter workloads, the amount of time that reporters have to work on stories, the number of sources and points of view included in stories, and the amount of local and enterprise news coverage generated, among other measures (→ News Sources; Quality of the News).

Conversely, as supply and competition become high enough to significantly erode news organizations' profits, financial commitment to news production appears to fall. During the 1990s and early years of the twenty-first century, declining newspaper circulation and broadcast news ratings were associated with news staff reductions and the closing of news bureaus. In some markets, the presence of large numbers of news organizations relative to audience and advertiser demand has been associated with an increased emphasis on → sensationalism, celebrity (→ Celebrity Culture), sports, sex, ideologically slanted news (→ Bias in the News), and other low-cost news-production strategies.

The ongoing development of new media distribution technologies and the growing popularity of user-contributed content sites on the Internet suggest that media markets will continue in the foreseeable future to be characterized by high levels of content supply relative to demand. Issues of media supply and demand, and their relationship to content quality, diversity, and effects on society, will continue to be among the central questions facing communication researchers and professionals.

## Support Talk

*Christopher Pudlinski*

*Central Connecticut State University*

Problems and troubles are a common aspect of human life; descriptions of these problems and troubles usually make relevant some kind of affiliative or supportive response. The study of support talk examines how interactants seek and obtain aid in a variety of informal and institutional settings. Support talk occurs when interactants attempt to aid, assist, or help another by addressing troubles that can be mutually shared and mutually solved. Support provided can be informational (e.g., advice), emotional (expressions of caring, concern, empathy, and sympathy), or tangible (offers of goods or services). One challenge in distinguishing support talk from other forms of talk in interaction is that routine talk, especially in close relationships, can also serve a supportive function (→ Intimate Talk with Family and Friends).

Advice-giving involves recommending, suggesting, or describing a course of action for remedying another's troubles. In situations where the advice-giver is clearly the authority, advice tends to be strongly prescriptive, including overt recommendations, imperatives ("always be very very quiet at night"), and modal verbs of obligation ("should," "ought": → Directives). Giving advice in these ways implies an asymmetry of roles: the advice-giver plays the role of knowledgeable advisor, while the advice recipient's role is one of lacking competence and needing help. Advice may often be resisted by recipients so as to reassert their autonomy and/or competence, despite their stated troubles.

In situations where the advice-giver wishes to be seen as a friend or equal, more mitigated methods are typically used, such as presenting advice as an allowable alternative ("if you . . ."), placing a recommended action within the format of information or a query (e.g., "did you see the doctor?"), or telling a second story. These allow the advice recipient to determine whether the information/advice/story is relevant to their specific circumstances.

Empathy involves understanding another's situation and/or feelings and, preferably, displaying understanding in such a way that the other feels understood. In response to troubles telling, "how awful" and standardized *oh*-prefaced assessments such as "oh God" and "oh no" display understanding of another's situation as troubling. Formulations (e.g., "sounds like you were really frightened when you discovered that lump") demonstrate

more significant understanding and contribute in meaningful ways to subsequent disclosures of delicate matters, especially if seen as an accurate paraphrase of the trouble's nature and intensity, and placed at the seeming end of a troubles telling.

Sympathy involves relating to another person's trouble by sharing feelings beyond basic concern. Basic expression of one's own feelings (e.g., "I'm sorry to hear that"), sharing similar reactions, and/or telling second stories (i.e., sharing one's own similar experience) convey sympathy. These second stories seem best fitted to peer support. So as to avoid telling second stories, doctors sympathize by describing some possible consequences of the patient's circumstances, implying access to an equivalent experience (→ *Bad News in Medicine, Communicating; Doctor–Patient Talk*).

Troubles tellers also seek tangible aid, often through calls for emergency assistance or customer service. On an emergency assistance line, callers request help as one requests food for delivery, while call takers require proof of a need for assistance before providing it. An interrogative series that, for the call taker, facilitates provision of appropriate assistance, for the caller delays the arrival of help. This dilemma is common to service encounters, whereas a troubles recipient, concerned about the troubles teller's feelings and experiences, and an advice-giver, oriented to a problem to be solved, are seemingly separate and contradictory roles. Methods that address this dilemma often blend these distinctive roles; for example, emergency assistance workers still interrogate but for a condensed period of time (→ *Telephone Talk*).

While conversation analysts and discursive psychologists have described interactional difficulties and nonaffiliative responses that indicate lack of successful support, support talk typically distinguishes itself from the study of social support by focusing not on outcomes but on what is said and done. Compared to the larger literature on social support, studies of support talk are in their adolescence. This area is ripe for language and social interaction contributions, with the recognition that appropriate supportive responses, demonstrated on a case-by-case basis, can improve the health and well-being of others.

## Survey

Michael W. Traugott

University of Michigan

Surveys are one of the standard forms of collecting data on individuals. The process is uniquely suited to the collection of knowledge, attitudes, and opinions, but there are many circumstances where it is the only way to obtain information about behaviors as well. Surveys are sometimes distinguished from polls (→ Public Opinion Polling) because they are more likely to be conducted by academic than commercial researchers or because they tend to be longer. This distinction is not applied here.

### APPLICATIONS

In *political research*, for example, there are many ways to obtain information about voter turnout – how many people went to the polls – including official government statistics. But governments do not collect information on candidate or party preferences, and surveys are required to obtain such information, as well as on other personal characteristics such as age, race, or sex, and attitudes about issues of the day or specific policies. The only way that the impact of such personal characteristics on voting behavior and preferences can be pursued is through surveys (→ Election Surveys). In the area of *economic research*, as another example, sales data can indicate the preference of consumers for one product over another or the relative market share of each. But the only way to obtain systematic data on the nature of preferences underlying these purchases or the demographic characteristics is through surveys (→ Marketing). In these instances, the turnout data and the purchase and market share data from an external source can provide an external validation of some of the measures derived from surveys, a useful check on the overall quality of the data.

Surveys are typically used to collect data in areas where other sources of information are unavailable. In the area of *consumer research*, for example, economists now understand

that expectations have just as important a role in determining purchases as do available economic resources. So the measurement of consumer expectation or the national economy as well as consumers' own resources is an important element of economic forecasting. Another area in which surveys are especially relevant is in the measurement of trends and reactions to them; surveys can be used to assess reactions and responses to things that *might* occur in the future or to different policy options that the government might pursue. This applies equally well to the possibilities of new technologies and how they might affect our daily or working lives.

One special and frequent application of surveys is the collection of data by *media organizations*. Their primary interest is to obtain information that is useful for producing news content to add to their coverage of current events (→ Audience Research). But their dissemination of such information provides important social and political cues about → public opinion to elites as well as a small segment of the general population that is interested in what their fellow citizens think. This can have important effects on subsequent measurements of opinion as well as consequences for specific policies that the government pursues.

Surveys have been an important and growing part of news gathering and social science research for more than 70 years. And increasingly, data from a variety of sources have been saved in data archives where they are available for secondary or extended analysis. As a consequence, more and better data are available for the analysis of trends and the comparison of public opinion across political and media systems for relatively long periods of time. Because of data archiving, it is now possible to trace the development of party systems and party identification across this period in individual countries, across countries that differ in their forms of government, or across countries that differ in their stage of democracy, as just one example. Because of the preservation of surveys in this way, there is an added value to the data for such analyses that is greater than the value for which any single survey was conducted (→ Comparative Research).

## **GENERAL SURVEY METHODOLOGY**

Surveys are appropriately seen as a system for data collection that involves several steps or stages. Among the major steps are selection of a mode of interviewing, sampling, questionnaire design and pre-testing, training of interviewers, preparation of the final questionnaire, fieldwork for data collection, and data analysis (→ Interview, Standardized; Interview, Qualitative; Sampling, Random; Sampling, Nonrandom). In a general sense, a survey involves a sequential process of completing these steps, but there are often iterative stages of the process such as when pre-testing of the questionnaire suggests changes that should be made to it, necessitating an additional pre-test of the new instrument.

### **Mode of Data Collection**

The mode of data collection comes at the front of the sequence because so many other issues follow as a result of this decision. Data can be collected through *face-to-face interviews* where the interviewer and the respondent engage in direct personal contact; this is a useful approach when objects such as handout cards with measurement scales,

illustrations, or photographs can be given to the respondent. It is an expensive form of data collection because of travel costs, especially to revisit or recontact respondents who were not available the first time. Data can also be collected on the *telephone*, which is generally a much less expensive form of data collection because of decreasing phone charges. Telephone interviews are usually shorter and consist primarily of closed-end questions. Interviewers have to read the scale options to the respondents, however, and handouts are obviously impossible. Telephone interviewing can usually be done in a shorter period of time, making it a preferred form of data collection for many applications, because it significantly reduces the possibility of the occurrence of external events impeding data collection in a way that makes the later interviews different from the earlier ones.

*Pencil-and-paper surveys* can be administered in person or by mail. Mail surveys are often employed because they are inexpensive and are sometimes preferred for asking about sensitive topics, because there is no interaction between an interviewer and the respondent. One problem with a pencil-and-paper survey is that the respondents can move back and forward through the questionnaire, trying to bring some consistency to their responses, often changing earlier responses to conform to later ones; this is not possible with face-to-face and telephone interviews. The fact that an interviewer is not present can be a problem if the respondent has a question or needs additional information, as no one is available to answer such a query. Handouts are also a difficulty in this mode for the same reason.

*Surveys on the Internet* are another mode; they permit rapid data collection and are very amenable to the use of examples and illustrations. They can also incorporate the use of color and different kinds of fonts to guide the respondent through the questionnaire. In fact, they can also include embedded video and audio segments, which is not possible with most other forms of data collection. A significant push toward data collection on the Internet is currently underway, primarily because of cost and reduced field periods; but there are also significant methodological issues about other aspects of this mode, primarily because of sampling issues.

Many surveys are increasingly employing a *multimode design*. Studies begin with a face-to-face or mail design, for example, but at the end of the process respondents who are difficult to reach are pursued on the telephone in order to obtain an interview. In some instances, the questionnaire is actually shortened for these late interviews as another accommodation to obtaining the most important measures in the survey.

## Sampling

One reason that the mode of data collection is a primary concern is that so many additional choices are affected by it. Sampling is a prime example. In face-to-face interviews, *multi-stage area probability samples* typically have to be designed, where clusters of households in the same neighborhood are selected in order to reduce travel costs. The design of these samples is laborious and time-consuming.

For telephone surveys, on the other hand, a list of phone numbers can be developed or purchased from a commercial vendor, often on the same day a decision is made to field a study. These samples can have true random dispersion across a nation, for example,

because the call rates are cheaper and do not vary with distance to the same extent that travel costs typically do. Procedures have to be followed to insure that unlisted numbers are incorporated into the sample, but these are now pretty well standardized. The use of mobile phones as the only means of contact is a growing problem in many countries.

In mail surveys, lists of addresses sometimes have to be located and often have to be checked independently for currency. Specific procedures have been developed for pursuing mail surveys that can maximize response rates, often making them comparable with other modes of data collection.

### **Total Survey Error Perspective**

Another advantage of seeing a survey as a process is that it provides the basis for reviewing and controlling potential data quality through a *total survey error (TSE) perspective*. A common misperception is that the main source of error in surveys comes from sampling, including design and coverage issues. This view is fostered by the fact that sampling error is the most easily quantified form of error.

But the TSE approach acknowledges that errors can also derive from poorly worded questions, inadequate training of interviewers, or poor supervision of the interviewing process. The approach also permits available resources to be invested effectively at different stages of the process, often based upon the nature of the topics being covered, in order to reduce likely errors. Every survey involves a series of cost–benefit calculations, usually involving decisions about how much of a limited or fixed budget should be devoted to various steps in the process. In the simplest case, a researcher faces a decision about how many questions to ask (improvement of the measurement or the number of relationships to be investigated) as opposed to how many respondents to interview (greater precision in the estimation process). But the TSE approach adds other possibilities: how much to invest in the training and monitoring of interviewers, as opposed to how often to pre-test the questionnaire, as opposed to how persistent the staff should be in trying to raise the response rate.

## **THE MANAGEMENT AND CONDUCT OF SURVEYS**

As the preceding discussion suggests, the organization and management of surveys is a complex and expensive process. As a result, there are very few organizations within any country that can offer on-site services that encompass under their direct supervision all of the steps in the process for different modes of data collection; the capitalization and administrative costs are just too great. This has produced *two trends in the survey industry*: specialization among organizations, by mode and in the production of services, and a movement toward telephone surveys because of an increased ability to cover capital and administrative costs.

Surveys can be pursued in a number of ways, especially since most researchers do not belong to organizations that engage in their own data collection. A researcher can construct a general design of all the elements of a survey and then put the study out for bids, eventually contracting with a firm that offers the best quality within the constraints of the available budget. The services offered range from having the original researcher interact

with the survey organization all the way through the process to simply having a final report and a dataset delivered at the end. Many firms offer a full range of services, although they may not in fact have all of the facilities on site or under their direct supervision. Some firms have developed that specialize in the provision of samples, starting with telephone numbers and increasingly moving toward supplying email addresses from recruited panel participants. Other firms specialize in the production and fielding of questionnaires by operating telephone facilities, direct mail operations, or questionnaire design for computer-aided telephone interviews (CATI) or web-based formats. Smaller numbers of firms offer services such as advanced data analysis facilities.

## **Suspense**

*Gerhild Nieding*

*University of Würzburg*

Which elements of films, novels, or plays are able to produce suspense in the viewer or reader? (We will use the term “viewer” in the rest of this entry to cover viewers, readers, and users.) This question immediately indicates that the concept of suspense has to be treated on multiple levels because it is a multilayered phenomenon. First, suspense is a cognitive-emotional strategy in the dramaturgy of a written, auditive, audiovisual, or performed “text,” which usually possesses a narrative structure. Second, the recipient has to be able to experience the suspense potential of this text. In order to manage this task, her or his cognitive architecture and socio-emotional as well as motivational makeup have to fulfill specific prerequisites. Finally, if the suspense construction has achieved its effect, the question that follows is which processes take place in the viewer. Usually cognitive analyses of suspense phenomena are carried out by focusing either on the text, as a calculated structural proposal for → information processing by the viewer, or on the viewer’s reception process.

The best-studied case for a suspense-evoking text is a film telling a single narrative, prototypically a thriller in the style of Alfred Hitchcock. This prototype also defines a single genre: suspense (→ Film Genres). But → television serials like *24* also unfold a broad range of (new) suspense-inducing techniques, and suspense may be evoked by non-narrative events, e.g., news stories or sports events.

Most *theories of suspense* concentrate on cognitive structures and functions, but it is not always precisely clear which analytical level is exposed: the text or the viewer's information processing. All cognitive theories of suspense focus on one or another aspect of uncertainty. Suspense will arise if the further development of a plot is uncertain. It will also arise if the possible outcomes for a protagonist in a specific scene are unsure. Some scholars (e.g., Ohler & Nieding 1996) assume that suspense peaks when the odds for a positive or a negative outcome for a protagonist are 50–50; others (e.g., Carroll 1996) assume that the highest degree of suspense will be experienced when one outcome for the protagonist is positive but unlikely and the other bad but highly probable.

*Cognitive approaches* differ in explaining suspense experience via different cognitive processing mechanisms (→ Cognition). Two examples may be mentioned briefly. Gerrig (1996) assumes an analogy with problem-solving processes: viewers will experience more suspense if possible problem solutions for the protagonist have been cut off. Ohler and Nieding (1996) model the experience of suspense using schema theory: viewers will experience more suspense if some slots in the multiple schemas that are activated during story comprehension cannot be filled with values. This effect peaks at the turning points of plots and when the expectations of the viewers are transcended systematically by the suspense narrative.

Other approaches suppose that *emotional processes* play an important role in the experience of suspense (→ Emotion; Affects and Media Exposure). For Zillmann (1996), viewers develop affective dispositions toward protagonists (positive) and antagonists (negative) by salient cues offered from the beginning of a narrative. This leads to reactions of empathic stress when the probability of a liked protagonist's positive outcome in his fight against antagonistic forces is reduced (high subjective certainty of a negative outcome). This is followed by euphoric feelings when the liked protagonist has against all odds been able to overcome the invincible obstacles. The reverse pattern holds for antagonists. The viewer fears their highly probable positive outcomes and is euphoric about their highly improbable failure. The seeming paradox that most viewers like to expose themselves to suspense narrations despite their evocation of dysphoric affects is solved in this approach via Zillman's (1983) → excitation transfer theory.

Vorderer (1996) points out that protagonists are often not portrayed as unambiguously sympathetic. It therefore seems not to be necessary to assign a specific morally good–bad dimension (morally correct but improbable outcome tied to the protagonist) to every scene as Carroll (1996) demands. New serials like *24* prove impressively that Vorderer's claim to replace Zillmann's sympathy variable with one like "viewers' subjectively (parasocial) experienced relationship with protagonists" is very profound.

One specific phenomenon requires special attention: suspense can also arise when you read a book or view a film for the *second time*. Brewer (1996) was able to show that rereading short, written suspense narrations leads to a strong overall reduction in suspense ratings. An interesting question is whether this would also be the case in re-viewing a suspense

thriller. Newer results in the neurosciences concerning mirror mechanisms in the human brain (e.g., Gallese et al. 2004) allow the prediction that viewing a protagonist automatically establishes a neurophysiological internal simulation of his actions and emotions. As a consequence a viewer will experience a higher degree of empathy than will a reader (→ Empathy Theory). Therefore in re-viewing films the suspense experience may be on a higher level.

So far only one compendium of the different approaches to suspense and problems associated with the concept exists (Vorderer et al. 1996).

## **Suspension of Disbelief**

*Saskia Böcking*

*University of Zurich*

In general, suspension of disbelief is understood to be an audience's tolerance of the fictionality of media content (→ Fiction). The phrase means that the audience accepts

limitations in the presented story, sacrificing → realism, and occasionally logic and believability, as well as the media content's aesthetic quality for the sake of enjoyment. Originally, the term traces back to the British Romantic and literary critic Samuel T. Coleridge (1772–1834), who used it to describe the necessity for readers of poetry to accept the fictive world proposed in literary work. Although Coleridge proposed suspension of disbelief as a stance a user has to adopt willingly – he speaks of the “willing suspension of disbelief for the moment, which constitutes poetic faith” (Coleridge 1960, 169) – in later publications the “willing” is often omitted. Only recently, suspension of disbelief has also been connected with the usage of electronic media such as → virtual realities and movies, or, more generally, of narratives (→ Presence; Cinema; Transportation Theory; Storytelling and Narration).

Since Coleridge had introduced the idea of suspension of disbelief, various authors, especially literary and theatrical scholars, have referred to it again and again. Some of them remained purely descriptive, describing the fundamental idea of suspension of disbelief and the background of Coleridge's thoughts, but without explaining the phenomenon. Others emphasized the → audience's surrendering reality-testing when suspending disbelief (→ Entertainment Content and Reality Perception). Literary scholars in general assume that this abdication of reality-testing is a stance of basic trust users adopt directly before they start reading.

In the field of communication, researchers also refer to the notion of suspension of disbelief. In contrast to the considerations of the literary scholars, however, communication scholars connect suspension of disbelief more closely with the process of using fictional media content, especially narratives. Yet there is some disaccord concerning the usefulness of the construct. While Zillmann (2006) negates the necessity of suspending disbelief for evoking emotional reactions (→ Emotion; Emotions, Media Effects on), the construct's value for → persuasion research is emphasized. Slater and Rouner (2002, 180) argue that suspension of disbelief – which they see as the counterpart of counterarguing, i.e., “the generation of thoughts that dispute or are inconsistent with the persuasive argument” – provides an opportunity to influence individuals who would ordinarily be resistant to persuasion. Similar is the reasoning of Shrum et al. (2005) when connecting suspension of disbelief – which they regard as the reduction of counterarguing – to → cultivation effects (→ Cultivation Theory). The reason for suspending disbelief, or in more general terms not critically evaluating a narrative, is universally seen in the individual's desire not to destroy a pleasurable experience, such as involvement in or transportation into the story (→ Involvement with Media Content). In taking up these considerations, Böcking and Wirth (2005) suggested a tripartite model of narrative processing consisting of the components belief, disbelief, and suspension of disbelief. Belief is understood as a form of uncritical processing of a narrative's content regarding its reality adequacy and plot consistency. On the basis of insights into → information processing it is considered to take place mostly automatically and unconsciously. Disbelief, on the other hand, is the individual's critical thinking about both aspects. It arises if the user notices flaws or inconsistencies in the narrative and considers them to be disturbing. Suspension of disbelief, finally, is the user's not focusing on violations of realism aspects and plot consistency, although he or she has noticed them.

# **Sustainable Development**

*Jody Waters*

*Southern Oregon University*

The idea of sustainable development has, for several decades, held out the promise of reconciling the competing goals of economic growth and environmental preservation. The term proposes that economic growth should not be carried out without consideration of environmental and social concerns. This represents a departure from traditional development thinking that suggests that social and political stability will follow the achievement of a robust economy.

However, sustainable development has been difficult to attain and measure. It has been constrained by diversity of interpretations and definitions of the concept, as well as its application. Further, in practice, critics have noted that sustainable development projects

focus on local-level change and imply that the behavior of the poor is the key problem, not poverty and its causes. As a “new” approach to development, sustainable development, for many, goes no further than traditional paradigms by implying that the poor fail to safeguard the earth for future generations.

### **HISTORY AND EVOLUTION OF THE CONCEPT OF SUSTAINABLE DEVELOPMENT**

*Our common future*, the report of the World Commission on Environment and Development (WCED 1987, 43), defined sustainable development as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (→ Development Institutions). While sustainability typically refers to the more general goal of seeking to use resources and effect change at levels that can be sustained, both suggest that the interconnection across physical, social, and political systems be brought to bear when defining development needs and how best to address them.

The term “sustainable development” gained prominence in international development policy circles following the release of *Our common future* and the significant media attention given to the United Nations Conference on Environment and Development (UNCED) or “Earth Summit” held in Rio de Janeiro, Brazil, in 1992. But, it is important to recognize that both the concept of “sustainable,” and *sustainability* as a practical and policy goal, pre-date these events.

At the 1949 *United Nations Scientific Conference on Conservation and Utilization of Natural Resources*, for example, delegates explored the problem of combining economic growth with sound management of natural resources. Throughout the 1950s and 1960s, various attempts to place the environment and concerns for the earth’s carrying capacity on the agenda of major multilateral and international entities emerged from both developed and developing nations. But even during these early discussions, the prospect of reaching equitable global cooperation and intergenerational equity in addressing environmental concerns was considered dubious by many poorer nations. A main concern was that priorities and approaches to sustainable development would likely reflect the needs of the industrialized north and west.

The global *United Nations Conference on the Human Environment* in Stockholm, Sweden, in 1972 was pivotal in entrenching the ideas of sustainability in international policymaking. Its goals were, first, to attain greater awareness of and attention to the growing urgency of environmental issues; second, to identify issues and needs that could best be addressed through international cooperation; and third, to achieve common goals and objectives to meet these needs. The main outcome of the Stockholm conference was the declaration of 26 principles that expressed the conference’s call for “Governments and peoples to exert common efforts for the preservation and improvement of the human environment, for the benefit of all the people and for their posterity” (UNEP 1972).

But at a lesser-known meeting held in 1974 in Coyoac, Mexico, delegates (many of whom represented the group of 77 nonaligned and developing nations) raised questions about the viability of these goals within an unequal global structure. Convened jointly by the United Nations Environment Programme (UNEP) and the United Nations Conference on Trade and Development (UNCTAD), the conference’s final declaration raised the issue

of environmental justice and connected the goals of safeguarding the natural environment to the global redistribution of economic, political, and social power.

While the Stockholm declaration foregrounded international cooperation, the Cocoyoc statement drew attention to the *relationship between the international economic system and environmental degradation and poverty* in the third world. It noted that growth in the developed world had tended to exact a steep price in nations where, for example, extreme poverty had led people to cultivate crops in destructive ways to meet market demand for cheap raw materials. Problems such as soil erosion, deforestation, rapid urbanization, use of hazardous chemicals, and poor waste management protocols were a direct result of the failure of the global market economy to enable a system in which sustainable and just growth could reasonably be expected. The statement concluded that a new social and economic order would be needed to attain the goals of sustainable development.

The *Brundtland Commission* was attentive to such critiques, noting that concerns for the sustainable use of physical and natural resources demanded greater awareness of social equity between generations *and* between nations. On the basis of this and other recommendations, the UN determined that UNCED would be held in 1992 to further the goals of sustainable development. UNCED was intended to examine the institutional, legal, and political capacities of the global partners committed to making sustainability a reality, but also to address a fundamental conflict between developed and developing nations and the role that this conflict played in preventing implementation of sustainable development in practical terms.

The statement issued following the 1992 Earth Summit identified the establishment of “a new and equitable global partnership through the creation of new levels of cooperation among States, key sectors of societies and people” as the path to the creation of new international agreements that respect all interests and “protect the integrity of the global environmental and developmental systems” (UN 1993, 1). Leaders of 179 governments signed off on Agenda 21, the “blueprint” for actions implementing the Earth Summit goals. Subsequent UNCED conferences held in New York, USA, in 1997 and Johannesburg, South Africa, in 2002 reaffirmed the resolve of many nations and the UN to achieve sustainable development in the twenty-first century.

The scope of sustainable development has expanded considerably since the 1970s and the term has come to encompass a broad range of concerns. The UN’s 2005 World Summit Outcome Document defined three “interdependent and mutually reinforcing pillars” of sustainable development as economic development, social development, and environmental protection, with → UNESCO adding cultural diversity as a fourth aspect, needed for nations and communities to achieve a higher intellectual, emotional, moral, and spiritual existence.

Outside the arena of international agreements and policy statements, local, national, and international development agencies have integrated sustainability as a criterion for the successful implementation of programs and projects, and it became a powerful development “buzzword” during the 1990s. Many agencies came to demand a “sustainability strategy” in project proposals, for example, to ensure that projects could carry on once funding ended. But viable indicators and measures of sustainability that adequately demonstrate how the concept can be applied in direct, measurable, and appropriate ways continue to elude organizations at both micro- and macro-levels.

## CRITIQUES OF SUSTAINABLE DEVELOPMENT

Sustainable development has propelled environmental concerns to the forefront of development discourse and practice. The many meetings, conferences, agencies, and institutions that have formed to promote the concept have led to significant global change, including the United Nations Framework on Climate Change, first signed during the Rio Earth Summit in 1992, upon which the Kyoto Protocol was based.

But the broad and complex goals of sustainable development, presented within a seemingly simple framework, do not lend themselves well to uniform understanding and interpretation. The lack of a widely accepted understanding of what sustainable development entails and how to achieve it seems to be one of only a few key points on which agreement exists. Further, critics suspect that the term has been over-used, poorly understood, and vague. With little common ground on how to best understand and apply the term, a common future seems difficult to achieve.

In the 1980s and 1990s, sustainable development became intellectually and politically allied with other “alternative approaches.” Several of these were characterized by greater attention to the needs and capacities of local communities, such as approaches centered on participation in development (→ Participatory Communication), women in development, and gender and development (→ Development, Gender, and Communication). Others sought distance from the technological-economic focus of the modernization paradigm (→ Modernization), and a more far-reaching and holistic definition that encompasses social, cultural, political, and environmental concerns. However, faith in the guiding role played by mainstream development organizations and the state was not challenged by the ways that the concept was discussed and applied by the large institutions that promoted sustainable development at the program level (Melkote & Steeves 2001). Further, the increasingly interwoven global marketplace brought the multinational corporation into a process that was felt by many to be already dominated by large and powerful institutions.

Although the discourse of sustainable development articulates the need for cooperation across agencies, nations, and communities, the voices that are most closely connected with on-the-ground initiatives are marginalized from discussion at policy and program levels (Escobar 1995; Sachs 1992). Critical scholars remain convinced that urgent environmental limitations and problems threaten the survival of *all* human populations. But the widening gap between rich and poor areas of the world means that these problems pose a greater threat to the poor, and simultaneously hinders them from participating in attempts to meet these challenges (→ Development, Geometry of).

The privilege of designing sustainable approaches to development has tended to be afforded to richer nations, while the responsibilities of implementing these approaches, and living with their implications, falls to the poor (Escobar 1995). Critics have noted that while sustainable development, sustainability, “green” development, and other such approaches articulate greater concerns for the well-being of human populations *and* the natural environment, there is little within them that challenges the normative basis of traditional approaches to development that legitimize economic growth within the system of global capitalism (→ Modernity). “Sustainability in this context does not

involve recognition of the limits of nature and the necessity of adhering to them. Instead, it simply means ensuring the continued supply of raw materials for industrial production, the ongoing flow of . . . commodities [and] the indefinite accumulation of capital” (Shiva 1992, 217).

The Brundtland Commission report argued that sustainable development could be built on new options that enable “change in attitudes and reorientation of policies and institutions” (WCED 1987, 343). As a new approach to development, its architects suggested that it would redress many of the perceived failures of traditional models to address poverty, marginalization of the very poor, of women, and of indigenous and other groups, and increased stress on the environment and natural resources. However, its bias is thought by many to *reproduce* prevailing development models by proposing a new way to manage the environment and the people who are most challenged by its limitations (→ Development Discourse). In other words, the discursive frame or “semantic constellation” of development as a process through which societies and people reach greater potential remains untouched (Sachs 1992, 8).

# Switzerland: Media System

*Heinz Bonfadelli*

*University of Zurich*

Switzerland is a small, federal, non-EU-member country in the center of Europe. It has a population of 7.4 million people, about 21 percent of whom are foreigners, and four official languages, namely German (the first language of 64 percent of the population), French (20 percent), Italian (6.5 percent), and Romansh (0.5 percent). The media inflow from the three big neighboring countries is considerable.

A politically opinionated *press* developed in the nineteenth century in the controversy between the absolutist state and the bourgeois class, then in revolt. A small-scale commercial and party-oriented press was established, as a result of this struggle for autonomy from the state and for press freedom, in the second half of the nineteenth century, although with limited circulation. After this founding phase of liberal and conservative papers, new so-called general advertising journals entered the market, like the *Tages-Anzeiger* in Zurich, still in existence today. At the beginning of the twentieth century, there were about 120 daily newspapers, mostly with local distribution only. The changing society of the 1960s transformed the press in manifold ways: There was a weakening of the former party and confessional ties, together with a transformation toward so-called *forum papers*, expressing the whole variety of existing political opinions in a neutral way. Then there was a first wave of expansion and concentration, together with the total disappearance of the small-scale party press. A second wave of concentration in the 1980s favored the big supra-regional papers with circulations over 100,000, and strengthened a few big multimedia companies. New developments become manifest with the launch of free commuter papers (e.g., *20 Minuten*), which have been surprisingly successful.

The year 1922 was the official beginning of *radio broadcasting* in the city of Lausanne. The pioneering station had already requested a license under the federal telegraph and telephone traffic law that came into effect later in the same year. By 1926, four more radio associations had been founded; these were transformed in 1931 into the Swiss Broadcasting Corporation (Schweizerische Rundfunkgesellschaft, SRG). Due to the multi-language nature of the country the corporation today has four different names: besides the German one, there is the French name, Société Suisse de Radiodiffusion et Télévision, the Italian Società Svizzera di Radio-Televisione, and the Romansh Societad Svizra da Radio e Televisiun.

In 1952 the corporation received a temporary license for broadcasting *television* programs. This license was extended until 1957, when Swiss citizens rejected the anchoring of radio and television in the federal constitution for the first time. Despite the successful diffusion of television and the rapid growth of SRG in the 1960s, it took another 20 years before the broadcasting media obtained a legal foundation, in article 55 *bis* of the Swiss constitution in 1984. Between 1983 and 1988, there was an experimental phase with commercial local radio and television stations.

The SRG still dominates the electronic media, with two television and three radio programs for each language region. The corporation is still in the form of a regional public association, but with a professional organization. In 2005, its share of the

television market in the German part of Switzerland was 35 percent and that of the radio market 62 percent. In addition, there are around 45 local and regional *commercial radio* stations and a smaller number of *commercial TV* stations operating. Most of these private electronic media are owned by regional publishers, and most of these publishing companies also operate online media.

Three articles in the new *federal constitution*, which came into effect on January 1, 2000, are dedicated to the media. Article 16 guarantees the right of the citizens to form, express, and communicate opinions in freedom, and article 17 prohibits censorship and guarantees business freedom for press, radio, and television. Furthermore, article 93 formulates a legal framework for radio and television. (1) The electronic media are subject to federal legislation. (2) They have to make a contribution to education, cultural development, the formation of opinions, and entertainment; to take into account the characteristics of the country and the needs of the cantons; and to represent events factually and express the full diversity of opinions adequately. (3) The independence of radio and television is guaranteed, together with the autonomous creation of programs. (4) The situation and functions of other media, especially the press, have to be respected. (5) Complaints about programs can be submitted to an autonomous complaint commission. This general media political framework is specified in a *federal radio and television law* that came into effect in 2006. It gives substance especially to the performance obligations of public broadcasting, and to the way the supervision and control of programming are organized and handled.

Today in Switzerland about 100 newspapers are published at least four times a week, with a total circulation of about 2.2 million. However, the number of these titles is reduced to 39 if one counts only the general editions and not the local ones. Switzerland has one supra-regional or quality daily (→ Quality Press) in German (*Neue Zürcher Zeitung*) and one in French (*Le Temps*), two supra-regional tabloid papers (*Blick*, *Le Matin*), and one leading forum paper in each of the main regions (e.g., the *Tages-Anzeiger* in Zurich). In addition, there are three weekly political magazines, three Sunday newspapers in German, and other popular magazines, specialized financial papers, and two new free commuter papers. Furthermore, there are many popular and lifestyle magazines available at newsstands, imported mostly from Germany, France, and Italy. In addition, smaller local newspapers are still important within this federally structured and locally oriented country.

## Symbolic Annihilation

*Robin R. Means Coleman*

*University of Michigan*

*Emily Chivers Yochim*

*University of Michigan*

Symbolic annihilation is used to highlight the erasure of peoples in → popular communication. George Gerbner coined the term to describe the “absence” (1972, 44; Gerbner & Gross 1976; → Gerbner, George), “condemnation,” or “trivialization” (Tuchman 1978, 17) of a particular group in the media. Generally applied to women and racial and sexual minorities, symbolic annihilation points to the ways in which poor media treatment can contribute to social disempowerment and in which symbolic absence in the media can erase groups and individuals from public consciousness.

To illustrate, popular communication often overlooks, stereotypes, or ridicules black people, who have been confined to the roles of coons, mammies, jezebels, brutal bucks, etc. (Bogle 2001). Language use in the media also contributes to the trivialization and condemnation of racial groups such as black people in popular communication. For example, in a critical, cultural analysis of the → news, it was concluded that reporters may ignore the effects of (neo-)colonialism by describing African countries as “third world” and “underdeveloped” rather than “overly exploited.” Comparatively, the US and western Europe are referred to as “first world” and as “superpowers” (Moore 1992). Survey research has exposed how Native Americans also experience symbolic annihilation through absence (→ Survey). However, when included, Native Americans are treated by the media as a monolithic group of “Indians” – lazy, savage, stupid, drunk, etc. (Merskin 1998). Arabs, too, experience representational absence and condemnation. They are largely invisible unless they are depicted as villains, terrorists, sexually wanton women, or corrupt oil sheikhs (Shaheen 2001). Symbolic annihilation has been extended to examine, for example, academic literature and census reports where distinct racial and ethnic groups such as Eskimos, Aleuts, and Native Americans have been homogenized and thus symbolically annihilated through the use of categories and descriptors such as “Non-Whites” (Ohye & Daniel 1999).

A discursive analysis of the news and popular → magazines reveals that racial groups escape condemnation only when aligned with the purported value system of “Americanized whiteness,” as witnessed by the model-minority → stereotype of economic success some Asian-Americans encounter (Chen 2004). Otherwise, Asian-Americans face symbolic annihilation as ruthless gang or “triad” members, whose primary contribution to culture is the martial arts (think *The Karate Kid*). The media are becoming aware of their power to influence the public’s knowledge and beliefs about races and ethnicities. As a result, media disclaimers stating that images do not represent any particular racial or ethnic group have been linked to the films *Godfather* (Italians), *Scarface* (Cubans), and *Year of the Dragon* (Chinese; → Media and Group Representations).

While the assumptions underlying the development and application of symbolic annihilation are key to our understanding of the relationship between media and social reality, in the scholarly literature they have not been well interrogated. While Gerbner and Gross (1976) simply repeat Gerbner’s basic definition of symbolic annihilation, their beliefs about the relationship between media and reality differ in subtle but important ways. Gerbner’s (1972) chapter explicitly situates the media as symbolic agents that do not mirror society but operate to maintain power; Gerbner and Gross (1976) suggest that because → television content is presented in a context of realism, viewers will regard it as such (→ Cultivation Theory). The combined effect of its underlying assumptions and its frequent use as shorthand for “bad representation” is that symbolic annihilation is limited in its ability to address more complex popular communication representational concerns. For example, non-stereotypical and seemingly “positive” television → situation comedy characters such as the African-Americans Julia of *Julia* and the Huxtables of *The Cosby Show* have been criticized for being “white Negroes” and assimilationist (Jhally & Lewis 1992). Symbolic annihilation as a concept is ill equipped to address nuanced representational concerns.

Still, symbolic annihilation’s strong connotation should prompt important questions regarding the relationship between representations of race, media ownership, and racial groups’ participation in image-making (→ Identity Politics). Overall, the concept of symbolic annihilation of race is powerful in that it elucidates exceptionally well the destructive consequences of poor or absent media attention. When using this compelling turn of phrase, scholars must continue to interrogate more broadly how infrequent and inadequate depictions contribute to groups’ social and political efficacy and how these depictions might be remedied.

## Symbolic Convergence Theory

*Donald C. Shields*

*University of Missouri-St. Louis*

Symbolic convergence theory (SCT), a general communication theory (→ Communication Theory and Philosophy), explains the emergence of a common symbolic consciousness – one that contains shared meanings, → emotions, values, and motives for human action – among participants in a small group (→ Group Communication), organization (→ Organizational Communication), or other rhetorical community. SCT, as developed by Ernest Bormann, John Cragan, and Donald Shields, among others, is a message-centered theory grounded through the observation of symbolic facts in communication. Observers noted the sharing of dramatized messages, called fantasy themes, within small-group communication, in mediated communication, and among the communicating memberships of organizations and other large publics (→ Rhetoric and Narrativity; Storytelling and Narration). Within each context, researchers found that people shared, reiterated, and wove fantasy themes to form a larger, more complex view of reality called a *rhetorical vision* (e.g., the Cold War, global warming, or neo-conservatism). A *rhetorical vision* contains many fantasy themes that depict heroes and villains in dramatic action within a scene. Within a group such a vision establishes identity, cohesion, and culture (→ Culture: Definitions and Concepts).

People create and reproduce fantasy themes in conversations – the hallmark of human communication (→ Language and Social Interaction). Fantasy themes often ignite, catch up others, and chain out from person to person within a group or community. People share rhetorical fantasies to account for human experience, repeat them, embellish them, and accept them as their view of reality. The rhetorical principles of novelty, critical mass, and channel access advance symbolic convergence. Symbolic cues, fantasy types, and sagas are specialized fantasy themes. A *symbolic cue* is a shorthand, rhetorical indicant that stands for a fantasy theme (such as a group’s inside joke of “U\$A” for materialist America). A *fantasy type* is a stock scenario that explains new events in a well-known dramatic form, such as Watergate becoming Iran-gate or Whitewater-gate for groups of news reporters explaining new instances of governmental corruption and cover-up. Similarly the initial “perfect storm” material fact, made famous in the book and film of the same name, now denotes new symbolic facts in which a complex series of unlikely events come together to cause economic disruption, political upheaval, educational turmoil, etc. A *saga* is the repeated telling of the achievements in the life of a person, group, community, organization, or nation, such as, in the USA, the *genesis* saga of the first “Thanksgiving.”

SCT’s message-structure concepts include a rhetorical vision’s *dramatis personae*, scene elements, plotline depictions, and sanctioning agent(s). *Rhetorical visions* reflect a life cycle containing stages in which consciousness is created (birth), is raised (critical mass), is sustained (repetition, reconfiguration, and embellishment to maintain commitment), declines (loss of interest or links to reality), and reaches a terminus (implosion). Rhetorical visions exist along pure-to-mixed, inflexible-to-flexible, intense-to-passive, secretive-to-proselytizing, and paranoid-to-healthy continua. Other concepts flesh out the message structure of a rhetorical vision. The *dramatis personae* are fantasy theme depictions of the characters in the vision. *Scene* is found by looking for fantasy themes that detail the symbolic location of the action portrayed in the vision (such as “a smoke-filled room”). *Plotline* is to be found in those fantasy themes that portray the action of the vision, such as “restoration” or a “new day.” The *sanctioning agent* (e.g., “God,” “the Constitution,” or a “code of ethics”) is specified in those rhetorical fantasies that legitimize the vision’s symbolic reality. SCT’s dynamic concepts are the warring righteous, social, and pragmatic master analogs undergirding rhetorical visions. *Righteous* visions depict the correct or moral way of doing things, *social* visions portray a humane or compassionate way, and *pragmatic* visions present an efficient or cost-effective way. The communicator structure concepts are *fantasizers*, who co-join in dramatizing; a *rhetorical community* or group made up of the adherents to a rhetorical vision; *communication style*, or the broad language use of a rhetorical group or community; and *propensity to fantasize*, or the ease with which people use dramatized messages. The media that help propagate symbolic convergence are the small-group and public interaction processes that promote fantasy-chaining (repetition, embellishment, reiteration) and thus convergence and acceptance of the dramatized message.

SCT posits three evaluative concepts. *Fantasy theme artistry* prompts one to judge the rhetorical novelty, consistency, and creativity of fantasy themes, symbolic cues, fantasy types, and sagas. *Shared group consciousness* reminds those using SCT to check for the occurrence of convergence by identifying fantasy themes that are created, told, embellished, reconfigured, and reiterated by the members of a rhetorical group. *Fantasy theme–*

*reality links* tie rhetorical visions and rhetorical fantasies to the objective reality of the authentic record and material facts. Such links remind those using SCT to assess the → sense-making capacity of fantasy themes and rhetorical visions present in group or public communication.

SCT's attendant qualitative method (→ Rhetorical Criticism; Qualitative Methodology) is called fantasy theme analysis (FTA). The fantasy theme is the basic analytical unit when conducting an FTA. The fantasies one is searching for are rhetorical in nature (in the words) as opposed to psychoanalytic (in the subconscious) or psychological (in daydreams). One knows a rhetorical fantasy by its qualities, whether substantive (actual content of a theme, type, cue, or saga), structural (a rhetorical vision's dramatis personae, plotline, scene, sanctioning agent) or stylistic (the linguistic dress of a fantasy theme, such as an animated, boisterous, chaining fantasy in small-group communication or an embellished, repeated, or reconfigured fantasy in public communication).

# Symbolic Interaction

Kent Sandstrom

University of Northern Iowa

Symbolic interactionism is a sociological theory that emphasizes the centrality of meaning, interaction, and human agency in social life. This theory emerged out of the American philosophical tradition of → pragmatism, an approach developed in the late nineteenth century by Charles Peirce, William James, and John Dewey. Challenging the assumptions of classical rationalism, these scholars saw “reality” as dynamic and pluralistic, viewed people as actors rather than reactors, tied human meanings to social acts and perspectives, and regarded knowledge as a key resource for addressing problems and improving the social world.

## FOUNDING FIGURES

John Dewey, who emphasized the importance of human communication, had a profound intellectual impact on several of his colleagues at the University of Chicago, particularly George Herbert Mead, who was a friend and fellow philosopher. Drawing on Dewey’s ideas, as well as the related insights of Charles Darwin, Charles Horton Cooley, and Wilhelm Wundt, Mead revealed how human consciousness, selfhood, and behavior are grounded in and emerge out of processes of symbolic interaction, or communication.

Mead stressed that human beings are distinct from other creatures because they have the capacity for language and thus can think, reason, communicate, and coordinate their actions with others. While these abilities rely on certain biological characteristics, Mead suggested that humans have evolved in a way that has freed them from some of the constraints of other animals and allowed them to create social worlds separate from the demands of nature. Unlike other animals, which respond to one another primarily through instinctive gestures, such as chirps, growls, or nips, people communicate through exchanging symbols. When using words or gestures that call forth the same meaning for others as they do for themselves, people employ “significant symbols.” According to Mead, most interactions among human beings are based on the exchange of significant symbols. As a result, these interactions require the persons involved to engage in complex processes of interpretation, role-taking, and negotiation.

Mead presented his distinctively sociological account of human consciousness and behavior in a series of classroom lectures that became the foundation for his most famous book, *Mind, self, and society* (1934). His ideas impressed many of his students, most notably Herbert Blumer, who later became a prominent sociologist. Blumer originally coined the term “symbolic interactionism” while writing an essay on social psychology for a social science text in 1937. In that essay, Blumer emphasized how Mead’s work provided a foundation for a new social psychological approach that could transcend the two dominant approaches of the time – behaviorism and evolutionary theory. In turn, Mead is usually credited as the founder of symbolic interactionism, even though Blumer’s analysis drew heavily on the ideas of other theorists and, according to some critics, differed in important respects from Mead’s approach.

### GUIDING PREMISES AND ASSUMPTIONS

In the 1960s, Blumer (1962, 1969) articulated three key premises that serve as the cornerstones of the symbolic interactionist perspective. The first premise is that people act toward things on the basis of the meanings they have for them. The second is that the meanings of such things are derived from people's interactions with others. The third is that these meanings are managed and transformed through the processes of interpretation and self-reflection that people use to make sense of and handle the things they encounter. Embracing these premises and reflected in most interactionist analyses are the following orienting assumptions.

- 1 *People are unique creatures because of their ability to use symbols.* Guided by Mead and the pragmatist founders, symbolic interactionists stress the significance of people's symbolic capacities. Because people rely upon symbols, they do not simply react to stimuli; instead, they give → meanings to the stimuli they experience and then act in terms of these meanings. Their behavior is thus distinctively different from that of other animals or organisms, who act in a more instinctive or reflex-based manner. As Blumer pointed out, things do not have intrinsic meaning. Rather, the meanings of things are learned through, and arise out of, social interaction. Through communication, people learn how to define and act toward the objects and experiences that make up their environment. In essence, they learn to respond to symbolically mediated "realities" – realities that are socially constructed.
- 2 *People are conscious and self-reflexive beings who actively shape their own behavior.* The most important capacities that people develop through their involvement in society, which exists in and through communication (Dewey 1916), are the "mind" and the "self." As Mead (1934) observed, humans form minds and selves through the processes of communication and role-taking: individuals develop the capacity to see and respond to themselves as objects and, thus, to interact with themselves, or think. Because people can think, they have a notable degree of autonomy in forming and directing their actions. Through thinking, individuals actively shape the meaning of things in their worlds, accepting them, rejecting them, or changing them in accord with how they define and respond to them. A person's behavior, then, is constructed, on the basis of which stimuli and objects she or he takes into account and how she or he defines them. This implied voluntarism does not mean that interactionists think people's actions are unaffected by forces beyond their control. In fact, interactionist scholars highlight how a variety of social factors, such as language, culture, class, ethnicity, and gender, constrain people's interpretations and behaviors.
- 3 *People are purposive creatures who act in and toward situations.* Interactionists have illustrated how people's actions and interactions are based on the meanings they attribute to the situation in which they find themselves. This "definition of the situation" emerges out of their communications with others. Individuals determine the meaning of a situation (and their subsequent actions) by taking account of others' intentions, actions, and expressions. As people negotiate and establish a definition of a situation, they also decide what goals to pursue in that situation. Once they begin acting, individuals may encounter obstacles and contingencies that obstruct or divert

them from their original objectives and direct them toward new ones. People's goals, actions, feelings, and communications are thus mutable and emergent. They can make ongoing adjustments in thought, feeling, and behavior, and they can create new ways of thinking, feeling, and acting as they respond to changing circumstances. Above all, people "can modify the social matrices within which they act, and thus . . . are agents of change" (Maines 2001, xiii).

- 4 *The "social act" should be the fundamental unit of research analysis.* Interactionists contend that the "social act," or what Blumer called joint action, should be the central focus of social scientific study. A social act refers to behavior that in some way takes account of others and is guided by what they do; it is formulated so that it fits together with the behavior of another person, group, or social organization. It also depends on and emerges through processes of communication and interpretation. This covers a broad spectrum of human conduct, ranging from a kiss, a punch, and a medical exam to a sermon, a baseball game, and an international war. Whenever people orient themselves to others and their actions, regardless of whether they are trying to hurt, help, convert, or destroy these others, they are taking part in a social act. In doing so, they may be acting as individuals or as representatives of a larger group or organization.
- 5 *To understand people's social acts, researchers need to use methods that enable them to discern the meanings people attribute to these acts.* Because interactionists emphasize that people act on the basis of the meanings they give to things in the world, they believe that researchers must become familiar with the worlds of meaning inhabited by the individuals or groups they choose to study. More specifically, researchers must "take the role of" the social actors they are investigating, immersing themselves in their everyday worlds and discourse, and observing their interactions in an unobtrusive way (→ Emic vs Etic Research). Through adopting this approach, researchers can better understand and describe how these social actors define, communicate, and act toward the "realities" that constitute their daily worlds.

## **INTERACTIONISM AND COMMUNICATION STUDIES**

The following discussion highlights three of several significant arenas of interactionist research in communication studies.

### **Self-Development, Self-Presentation, and Emotion Work**

Guided by Mead's insights, interactionist analysis has always emphasized the social and communicative roots of the self, revealing how individuals acquire the capacity for self-reflexivity through their symbolic interactions with others. Interactionists have also highlighted the dialectical relationship of the self and communication, noting that while the self emerges and develops through communication with others, it also directs a person's communications with others and informs his or her interpretations of their communicative responses.

In elaborating the dynamic interplay between the self and communication, some interactionists have focused attention on how people construct and stage selves in specific

situations. Following Erving Goffman (1959), these scholars have proposed that social life is analogous to the theater, with people being much like actors on a stage. To express and realize desired selves, people must translate their intentions, feelings, and self-images into communicable form, engaging in elaborate rituals and drawing on a variety of dramaturgical resources, including words, gestures, props, scenery, scripts, clothing, and other features of their appearance. In doing so, people participate in the arts of impression management, tailoring their role performances to communicate their intentions, understandings, and preferred identities to the audience in a given situation.

In recent years, interactionists have extended Goffman's dramaturgical approach, elaborating the dynamics of *identity work*, or the techniques actors use to create and sustain identities, both individually and collectively (Benford & Hunt 1992; Sandstrom et al. 2002; Snow & Anderson 1993). These researchers have illustrated how individuals and groups draw on various resources (ideologies, rhetorics, and support networks), interactional strategies (scripting, passing, covering), and forms of talk (distancing, disavowal, embracement, and fictive storytelling) to announce and preserve cherished identities. Some interactionists have also highlighted how people manage and communicate *feelings* in their ongoing identity work, using emotions as strategic methods in their daily interactions. As Hochschild (1983) observed, individuals learn the feeling rules that prevail in their groups and develop skills in two forms of emotion work: "surface acting" (acting as if they feel a particular way, even if they do not) and "deep acting" (calling forth the feelings and feeling displays expected in the situation and suppressing emotions or emotional displays deemed to be inappropriate). Drawing on these skills, individuals proactively control their bodily sensations and emotional experiences. They respond to their emotions as social objects – objects they can shape and manipulate not only to meet others' expectations, but also to influence and direct others' responses. Emotions, then, become a vital channel of communication through which people convey and negotiate definitions of self, others, and situations.

### **Narrative Constructions of Emotion, Identity, and Biography**

While some interactionists focus on how people manage and display their emotions in social interactions, others investigate how emotions are felt by individuals as bodily experiences that affect one's existence and self-understandings. As Denzin (1983) proposes, emotion is *self-feeling*, affecting a lived body and given meaning by a reflexive actor. Emotion represents a window into the self, grounded in felt experience, which connects the individual to a larger community.

To appreciate the personal and interpersonal implications of emotion, a group of interactionists have developed a methodological strategy known as "auto-ethnography," which refers to the study of oneself and one's own experiences, including one's feelings. Drawing in part on introspective strategies used in the early 1900s by scholars such as Charles Horton Cooley, these interactionists seek not only to enhance their self-understandings, but also to extend the boundaries of ethnography and communication studies, particularly by offering unique insights gleaned from a self-reflexive and sociologically informed reading of one's own life. One prominent scholar employing this approach is Carolyn Ellis. She has crafted several auto-ethnographies, including a poignant account of her

partner's illness and eventual death (Ellis 1995). Ellis wrote this auto-ethnography in an effort to examine and convey how individuals (beginning with herself) come to terms with grief, loss, and life-threatening illness.

Other auto-ethnographers have addressed a variety of topics, ranging from struggles with bulimia or cancer to experiences working as an erotic dancer. Above all, in doing auto-ethnography, these scholars seek to illustrate alternative possibilities for methodological practice and expression. They also privilege emotional evocation over analytic abstraction; that is, they seek to engage readers personally, moving them to resonate with the sorrows and triumphs of others and, in so doing, to *feel* a sense of caring, desire, or connection. These writers want to help readers not only to resonate with the experiences and biographies of others, but also to use these experiences and biographies to reflect on their own, thereby enhancing their capacity to cope with life's complexities, ambiguities, and contingencies (Ellis & Bochner 1996).

In addition to resurrecting and refining auto-ethnography, interactionists have developed or extended a number of other ethnographic methods, including narrative analysis, discourse analysis, ethnographic content analysis, and interpretive biography (→ Qualitative Methodology). In the process, they have illuminated the formulae, institutional discourses, media formats, and information technologies that individuals draw upon as they construct narratives of identity and biography. They have also revealed the "rhetorics of self-change" that often inform and shape people's stories of identity transformation (Frank 1993).

### Media Logic, Formats, and Frames

Interactionists are often criticized for having a micro-level orientation but, because they focus above all on social acts, they do not limit themselves to investigating the emotions, behaviors, and discourse of individuals or small groups. While they sometimes study these phenomena, interactionists also examine the outlooks, actions, and communications of crowds, political parties, school systems, hospitals, corporations, occupational groups, and social movements. In addition, they devote significant research attention to the conduct and communications of the mass media, and to the impact that prevailing media formats have on social perspectives and practices.

In their analyses of the mass media, interactionists have been guided by *three key foci*. First, they have investigated the processes and practices through which journalists and other media workers construct the news. In doing so, they have shown how an organized production process directs news reporting and programming, as well as entertainment programming. One of the central aspects of this production process is the development and use of *formats*, or rules and codes for selecting, organizing, and presenting information that shape audience assumptions and preferences (Altheide 2002). Interactionists have highlighted how people learn these formats and, most crucially, come to expect that events and issues will fit with them and have a "proper media look" (Altheide & Snow 1991). In essence, people learn to gauge the importance of an issue or event as much by the structure and organization of the messages about it as by the content of those messages.

Second, and relatedly, interactionists have examined how prevailing media formats, as well as the → media logic that informs them, have altered social assumptions, institutions, and relationships. “Media logic” has become a way of seeing and defining reality in contemporary societies. People tend to trust that they can express and interpret the events of their everyday lives through media formats and information technologies (Altheide & Snow 1991). Moreover, the nature and practices of social institutions, including religion, politics, sports, education, and news, are affected by media logic and technologies. For example, wars and natural disasters have become television events, major sporting events have become media spectacles, and many church services and classroom lectures have become multimedia productions.

Finally, interactionists have investigated how media frames shape the public parameters for interpreting specific events, particularly social problems and issues. As David Altheide has noted, the entertainment format of news has, in many ways, given rise to the “problem frame.” This frame is an important innovation that satisfies the entertainment emphasis that now permeates the news, promoting fear and victimization as widely recognized social realities. According to Altheide (2002, 47), the news media have created the problem frame as “an organizational solution to a practical problem: How can we make real problems seem interesting? Or, how can we produce news reports compatible with entertainment formats?”

What makes interactionist analyses of the mass media distinctively different from other approaches is that they study → “media effects” in terms of the logic, assumptions, and perspectives that individuals share with others because of media logic and frames. These analyses also focus on the interaction between media and non-media segments of society, concentrating on how specific features of media logic, conveyed in media formats, intersect with particular institutional practices to produce and reproduce a media culture. In examining these themes, interactionists reject approaches that construct media audiences as passive entities who are conditioned by media messages. Instead, they stress that audiences are active interpreters who can disregard, reject, or reshape media messages (→ Interactivity in Reception), although their interpretations are influenced by the broader media logic and formats they share with communicators.

## Symbolic Politics

*Ulrich Sarcinelli*

*University of Koblenz-Landau*

In habitual language use, symbolic politics means a publicly displayed deception or surrogate action that is used to detract from actual political reality. In this sense symbolic politics is considered to be a surrogate for politics. Symbolic politics differs from substantial policy. As a policy of → signs (terms and slogans, badges, banners and pictures, gestures, ritual acts, and political staging), symbolic politics evolves in a semantic field. Substantial policy, by contrast, consists of a revisable succession of political decisions (e.g., legislation, contracts, taxes, etc.). Symbolic politics and substantial policy can be related to each other. On the one hand, symbolic politics can have an impact on substantial policy. On the other hand, substantial policy can be communicated, implemented, or averted by symbolic politics.

The negative connotation of symbolic politics, which is meanwhile consolidated in public opinion, does not correspond to the more sophisticated view of symbolic politics in → cultural studies and social sciences, for symbolic politics in a broader sense also means the strategic use of signs to meet society's requirements of political orientation. Attention may be attracted; willingness for political action, loyalty, or protest may be shown by symbolic politics. In the process, the symbolic worth of signs is converted into political power.

Symbolic politics is part of → political communications and, for this reason, an element of a → sense-making process (→ Symbolism). The use of symbols in politics is the expression of a fight for a certain political view of life. Thus, questions of domination or subordination are concerned, tending to unilaterally implement or achieve by mutual agreement what should be generally binding. Symbolic politics as a strategic use of symbolic instruments in politics does not simply aim at achieving → interaction. It is

neither decorative attachment nor ideological ballast, in contrast to “real” politics, but rather an integral part of political communications and thereby of policy in general.

An important impetus to international debate about symbolic politics was given by Murray Edelman in his works *The symbolic uses of politics* (1964) and *Politics as symbolic action: Mass arousal and quiescence* (1971). He understands political actions as playing certain roles, which find their expression in dramatic performances, rituals, and symbols (→ Political Symbols). In his analysis he connects subjective and intersubjective forms of interpretive patterns (micro-phenomena) with the production of binding political decisions (macro-phenomena). Referring to → Walter Lippmann’s classical study of → public opinion (1922), Edelman’s conclusions rest on the premise that politics are too complex to be accessible to the general public. Instead, a surrogate world of political → spectacles as a set of symbols and signifiers is constructed. Yet symbolic politics could refer to objective reality (“referential symbols”). But then there are “condensation symbols” that deceive about reality. Permanently installed democratic rituals encourage the belief in political participation and rationally founded acts of state, even though they are instruments of political “quiescence.” Political elites use language and symbols as instruments of manipulation shaping citizens’ realities, how they think and feel about politics (→ Political Language).

There has been little success within the critical debate initiated by Edelman in correlating the assumed real politics and their legitimation by symbolic politics. Furthermore, symbolic politics has to deal with collective actors and institutions that are symbolic regimes themselves, being central elements in forming, stabilizing, and transforming social relationships. Symbolic politics is successful if it refreshes a specific repertoire of interpretation that can be affiliated to the culture of political interpretation or “symbolic space” (Bourdieu 1991). So symbolic politics in the sense of pseudo-politics is just a special case of a basal aspect of political acting, which always has instrumental and expressive parts.

Four fundamental functions of symbolic politics can be defined (see Sarcinelli 1987). (1) Symbolic politics has a *signal function*, attracts attention, breaches routines for providing or placing information, organizes the perception of politics, and thus contributes to the reliability of behavior. (2) By decreasing complexity it provides a *regulator* to cope with the mass of information. (3) It not only aims to denominate political circumstances but is also *part of the political fight* for the disposal of denomination. (4) By perceiving symbols in a mode of suggestive immediacy, it not only addresses rationality but *activates* → *emotions*.

Symbolic politics is policy and as such neither principally good nor principally bad. It is an essential component of political communication and not just the invention of a media society (→ Media Democracy). Yet modern mass media, through their omnipresence and visual presentation formats, provide means of influence and “symbolic power” (Bourdieu 1991) that have never before been available in history. But it would be a misunderstanding if symbolic politics were regarded in a dualistic frame as being a phenomenon of political acting on stage while “real” politics are seen as taking place backstage. Politics, including symbolic politics, is played on many different stages at the same time. In this action politicians can only succeed if they know how to play different roles and are able to use symbolic politics.

## **Symbolism**

*Scott Robert Olson*

*Minnesota State University*

Symbols are linguistic devices in which complex, culturally specific meanings are communicated simply. Nearly all human utterance is in some ways symbolic, and for many who study communication, symbolizing is the most fundamental attribute of being human (Burke 1966). Peirce defines a symbol as “a sign which refers to the Object that it denotes by virtue of a law, usually an association of general ideas, which operates to cause the Symbol to be interpreted as referring to that Object” (1965, 143). In other words, when cultural conventions define how a → sign is to be associated with an idea or object, then that sign is a symbol. Generally, the connection between signifier and signified in a symbol is arbitrary, necessitating a cultural context for understanding. Because nearly every image has symbolic aspects, symbols are especially important in the visual media (→ Visual Communication).

As in the Magritte painting entitled *Ceci n'est pas une Pipe*, which depicts a pipe yet declares “this is not a pipe,” all communication stands in for something else: nothing is precisely equivalent to what it conveys. With symbols, a simple object represents something complex. Therefore, understanding how a symbol conveys → meaning is essential to making sense of it. As Eliade states, symbols express “a complex system of coherent affirmations about the ultimate reality of things, a system that can be regarded as constituting a metaphysics. It is, however, essential to understand the deep meaning of all these symbols . . . in order to succeed in translating them into our habitual language” (1974, 3). For Jung (1980), a symbol is at once familiar and alien, an everyday, conventional use of language (→ Rhetoric and Language) that is filled with connotations far beyond its denotative simplicity. In fact, the power of symbols is their ability to express complex concepts simply through “deep meaning” extraction.

In → semiotic terms, *symbolism is a type of sign* where the following conditions generally pertain: (1) the symbolic signifier is substantially different from the signified by type and

Table 1 Types of symbol

Signified	Iconic	Metonymic	Representational	Lexical
Narrative	Star of David	Cross	Crucifix	“Darmok”
Affect	Color blue	Smiley face	Sims diamond	Emoticon
Idea or ideology	Swastika	Crown	Statue	“We the people”
Place	Flag	Bear	Maps	“Purple mountains’ majesty”

domain; (2) the relationship between the symbolic signifier and signified is asserted, not natural or intrinsic; (3) a cultural  $\rightarrow$  code is needed to extract the signified from the signifier; (4) this signified is commonly a narrative, an affect, an idea or ideology, and/or a place – symbols often evoke many of these signifieds simultaneously; (5) the device of the symbolic signifier is metonymic, iconic, representational, or lexical – indexical signifiers are not generally associated with symbols except through the most basic level of symbolic embodiment, e.g., onomatopoeia, or through naturally occurring symbols, such as smoke denoting fire; (6) the symbolic signified is not otherwise easily represented; and (7) the symbolic sign is especially connotative, conjuring expansive meaning from a simple denotation.

## SYMBOL TYPES

Symbols can be divided into various types based on the relationships between their signifiers and signifieds, as illustrated in Table 1.

*Iconic symbols* are those where the signifier has a strictly arbitrary relationship to the signified ( $\rightarrow$  Iconography). An example of an iconic narrative symbol is the Star of David, a shape that conveys the history of a people that is not specifically a narrative element. An example of an iconic affect symbol is the color blue, meant to convey sadness, but unrelated to that mood. A swastika is an example of an iconic ideology symbol, intrinsically unrelated to the Nazi ideology it has come to signify, while a plus symbol (+) is a signifier of the idea of addition in mathematics. A flag is an iconic place signifier because its colors and pattern have no intrinsic relationship to what they represent.

*Metonymic symbols* are those where the signifiers embody a particular aspect or attribute of the signified, using that aspect to stand in for the whole ( $\rightarrow$  Metonymy). A cross, for example, is an element in the Christian crucifixion narrative that has come to stand in for all of that narrative. A yellow “smiley” is an indication of happiness that reduces the emotion to one indicator of it, a smile. An example of an ideological metonym is a crown, which is one thing worn by a monarch but signifies the monarchy. A bear is sometimes used as a metonymic symbol of Russia, though a bear is just one of many species found there. A sound can also serve as an iconic or metonymic symbol. For example, the ringing of a bell is an icon that can symbolize the serving of dinner, and the sound “hiss” is an onomatopoeic symbol for a snake that is also a metonym of the sound a snake makes.

*Representational symbols* are those where the signifiers illustrate narrative elements of the signified. Unlike a cross, a crucifix is an illustration of a part of the story in the Christian narrative, not merely an artifact within it. In the computer game “The Sims,” a

rotating diamond levitates over the heads of the characters, symbolizing their mood: green means happy, red means miserable, and so on. A civic statue is often a representational symbol that embodies an idea or ideology, such as the golden statue of Kim Il-Sung in Pyongyang. Maps are a representational symbol of place because the images on a map correspond to and illustrate geographic features.

*Lexical symbols* are those where words or sounds, rather than images, are used as signifiers. An episode of *Star Trek: The Next Generation* called “Darmok” illustrates lexical symbols. The human crew of a space ship encounters space aliens with whom they find it impossible to communicate. The alien captain keeps saying things that seem nonsensical to the humans, for example “Darmok and Jalad at Tenagra.” It turns out that these phrases are lexical symbols that refer to particular stories in the alien’s mythology. The whale Moby-Dick from Melville’s novel is an example of a particularly complex lexical symbol whose signifier has many signifieds. The whale can be seen as the embodiment of fruitless quests, Ahab’s madness, the greatest glory, a competing god, evil personified, or other signifieds. In a more simple way, phrases like “it was a dark and stormy evening” are used to represent emotions, phrases like “we the people” are used to represent ideologies, and phrases like “purple mountains’ majesty” are used to represent a place.

## DECODING SYMBOLS

For Peirce (1965), symbols find their origins in and evolve from indexical and iconic utterances, relying on complex interactions of sign systems known within a cultural context. As such, symbols are generally *polysemic*, which means they are open to divergent interpretations. The polysemic nature of symbols comes from their unique occurrence within their connectedness to the culture and to other symbols. For example, the swastika in Europe has a very different meaning than it does in India. This is in part because different users of the symbol use it differently. Saussure (1959) examined how symbols emerge from a language (*langue*) but iterate as a single utterance (*parole*) – each utterance relates back to the pre-existing language but also modifies and adds to it.

Hence, the pop singer Madonna’s use of a Christian crucifix in the music video “Like a Prayer” as a single utterance both relies on and inverts the symbol as found in the *langue*. Other uses of a crucifix are more conventional, yet still unique, utterances of the language of the crucifix symbol, such as a highly stylized crucifix that might be found in a modern church or the crucifixion scene in Salvador Dali’s painting *Christ of Saint John of the Cross*. To use Stuart Hall’s (1980) taxonomy of codes, Madonna’s might be considered an oppositional reading of the crucifix symbol, because it rejects the dominant understanding of its meaning; Dali’s painting is an example of a negotiated reading of the symbol because it modifies it into a different context; and the hanging of the crucifix in a church is an example of a hegemonic reading, because it reinforces the dominant sense of its meaning.

The Tibetan Buddhist mandala is an example of a symbol where the correct cultural code, and therefore a prescribed manner of decoding, becomes essential. Over a period of many days, Tibetan monks construct an elaborate depiction of the cosmos out of brightly colored sand, one grain at a time. Upon its completion, the ornate mandala symbol is ceremonially swept away to become a pile of brown dust. To western observers, whose system of symbols and myths prizes eternity, this gesture of destruction can be perplexing

and meaningless, because of the destruction of a time-consuming work of art. To Buddhists, the destruction of the mandala is inextricably part of the mandala, because it symbolizes the temporal nature of existence: nothing, not even the cosmos, is permanent.

### SYMBOLS IN CONTEXT

The specificity of meaning of a symbol varies with its level of analysis. Morris (1970) divides the way signs are understood into three categories: semantics, which examines the relationship between a signifier and what it signifies; syntactics, which examines the relationship between signs in formal structures; and pragmatics, which examines the relationship of signs to those who interpret them. Applying this to symbolism, the semantics of symbols relate to how they are constructed within a cultural context (→ Culture: Definitions and Concepts), the syntactics of symbols relate to how they are used linguistically, and the pragmatics of symbols relate to how symbols are understood. Put another way, cultures create genres of symbols, artists and authors create linguistic uses of symbols, and readers create interpretations of symbols. Therefore, → genre theory, auteur theory, and reception theory are all useful approaches to understanding how symbols function.

Substantial literature exists in two of these three domains. Anthropological and psychological approaches focus primarily on the cultural role of symbols. Literary and artistic approaches focus primarily on interpreting symbols created by individual artists and authors. The communication field has done more work on reader responses to symbolism than most other fields, and there are numerous examples of symbolic meaning being created by users. Examples include the symbolism of Paul McCartney's alleged demise found on the *Abbey Road* album cover, of drug use found in the Beatles song "Lucy in the Sky with Diamonds," and of patriotism found in the Bruce Springsteen album *Born in the USA*, all of them connotations unintended by the creators.

Symbols serve such a profound sense-making function that there has been some theoretical discussion of whether symbols are "hard-wired" into the communication circuits in the human brain. Cognitive scientists such as Steven Pinker have argued, for example, that human intelligence is a product of the ability to manipulate symbols (Pinker & Mehler 1988). Through their ability to create abstractions and store meaning in simple ways, symbols certainly serve an important cognitive function, leading Condit (2004) to suggest that both biological and textual approaches are needed to understand symbols as communication.

## Synchronization of the News

*Klaus Schoenbach*

*University of Amsterdam*

“Synchronization” means the selection and presentation of news to favor a medium’s marked editorial policy or stance. “Synchronized” news, then, is news selected and presented to support a medium’s anti- or pro-government sentiments, for instance, or its liberal or conservative philosophy (Schoenbach 1977).

The principle of “comments are free; facts are sacred” is supposed to keep journalists from mixing the facts of a news story with evaluations of those facts. Their own opinion has to stay out of the news, and so has the editorial stance of their media organization or the preferences of other persons or institutions. News is supposed to be factual and sober. What its producers or other people think about it, how they judge it, is limited to → commentaries and editorials, explicitly marked as such.

What at first sight sounds merely like a style restriction on news (“Do not use judgmental words in your news story!”) is just *one* requirement for a much more ambitious goal of that professional imperative – to enable the audience to make up its own mind, without being manipulated. This is why the norm of separating facts and opinion also concerns the *selection* and *prominence* of the facts presented. Journalists are supposed to select and present facts and opinions for their truth to reality and not to support specific views of the world.

Synchronization thus actually describes two mechanisms of a specific form of news bias. First, synchronization by *selection* means that facts or arguments supporting the editorial policy of a medium are put forward in the news more often than facts not supporting that perspective. Research shows that methods of that type of synchronization include the use of “opportune witnesses” – i.e., sources in favor of the editorial policy get a better chance to be quoted (Hagen 1993) – and → “instrumental actualization” (Kepplinger et al. 1991; Staab 1990) – i.e., invoking former cases, examples, and events that seem to confirm the medium’s interpretation of what is going on in the world.

Second, synchronization by *prominence* means that facts or statements unfavorable to what a medium regards as its editorial stance are not suppressed completely but presented in a way that renders them unimportant. They may be hidden away in the middle of a lengthy article, not be accompanied by visual material on television, or be attributed to obscure sources.

Synchronization is a more dangerous variant of violating the separation principle, because it does not work with explicit evaluations that an audience could easily recognize as such. Instead, synchronized news looks like factual news. The audience often has no chance to know that important facts and views are systematically omitted or played down, and unimportant ones blown up, in order to make the editorial policy of the medium look reasonable and plausible.

Measuring synchronization of the news and editorial policy is difficult. One might quickly agree that a journalist has openly expressed the political philosophy of his or her newspaper in a news story. But how can it be claimed that facts were missing or presented less prominently than they deserved, in the absence of some agreed-upon external standard?

Two criteria have to be met to demonstrate a synchronization of news and editorial policy. First of all, the selection and presentation of arguments in the news have to resemble the selection and presentation of the arguments used in editorial pieces. This is the easier requirement in an attempt to measure synchronization. It simply means comparing the profiles of reasoning in the news and, for instance, in commentaries where editorial policy can be expressed openly.

The second, more demanding, requirement for demonstrating synchronization deals with its harmful nature. As long as the editorial line is just middle-of-the road or balanced, as long as there is actually no distinct editorial stance, news may not be regarded as problematic by many if it is synchronized with the editorial line and thus also balanced. In a study on synchronization in 22 German media, Schoenbach (1977) suggested a measure for a *biased* synchronization, one that does not simply present a balanced picture of the world both in the news and in opinion content. He used a proxy for that bias: the coverage of other media. If a medium, he argued, systematically omits facts that do not fit its editorial line, but if those facts are present in other media, would that not indicate a harmful synchronization of facts and opinion? As a standard measure, Schoenbach (1977) used the profile of the information offer of all four German prestige newspapers combined. Prestige or quality newspapers (→ Quality Press) are prestigious because of their claim to be as complete as possible, and in the case of Germany, the four prestige papers cover the left–right political spectrum quite well, as surveys show.

Schoenbach (1977) found some systematic characteristics of media that synchronize their *political* news and their own – and distinct – editorial policy more often: they are media with a small newsroom staff and serious local competition, and they are well known for their political stance. He explained those results by the attempt of news organizations to get their journalists to obey organizational rules. Self-selection of journalists, their recruitment by the medium, their socialization in the newsroom, and finally mechanisms of social control (see also Breed 1960) are the steps that lead to compliance with the political preferences of a medium in selecting and constructing news.

## **Systems Theory**

*Klaus Krippendorff*

*University of Pennsylvania*

The word “system” is widely used. We speak of planetary systems, transportation systems, nervous systems, number systems, filing systems, political systems, systems of checks and balances, systems of grammatical rules, systems of weights and measures, and so on as if they shared the same reality. Their common denominator is a multitude of component parts, depending on each other, working together in complex ways, and functioning as wholes. Beyond these commonalities, such systems exhibit at best Wittgensteinian family resemblances.

Systems theory is an interdisciplinary field. It was founded by Ludwig Bertalanffy (1968) in the 1950s and soon attracted other scholars, notably the economist Kenneth Boulding, mathematician Anatol Rapoport, biologist James Grier Miller, architect Russell Ackoff, management scientist West Churchman, and the sociologist Talcott Parsons, to name only a few. The early *dream of finding a general theory* of all systems turned out not to be realizable. Now, several specialized systems theories are recognized. What has kept these and many other scholars together is what is increasingly called systems thinking: the use of a common language and principles to address complex issues.

Systems theory and → *cybernetics*, often mentioned together, have radically different epistemologies. According to Ross Ashby (1956, 1981), whereas cybernetics attends to all possible systems and is informed when some of them cannot be built or found in nature, systems theory seeks to generalize from organizations that exist or function in the world.

Bertalanffy was a biologist and, unlike cybernetics, systems theory is steeped in biological metaphors. Bertalanffy noted that scientists traditionally isolate their objects of research, for example, living organisms, economies, media effects on audiences, or mathematical systems – not realizing that none of these exist in isolation. Closed systems are artificial and inadequate constructions. Thermodynamics, for example, theorizes systems as closed to energy. However, treating living organisms as closed systems would violate the second law of thermodynamics: they do not decay into entropy, but grow in complexity while living (Prigogine 1961). *Open systems theory*, to Bertalanffy, must account for the possibility that systems are more or less open to energy, information, and/or organization. In contemporary systems thinking, therefore, systems are usually conceived of as operating in an environment. This biological conception goes back to Alfred North Whitehead (1929/1979), who, after characterizing European philosophy as a “philosophy of the organism,” suggested that what the organism is *not*, participates in what it *is*.

One maxim of systems theory is that all the parts of a system interact with each other directly or indirectly. Changes in one part affect all other parts. Herbert Simon qualified this maxim by suggesting ways to decompose complex systems into subsystems such that interaction within subsystems is strong while interaction between them is weak. The system/environment distinction is seen as convenient because it recognizes this property.

Systems theory is *holistic*. By definition, systems are wholes composed of parts. For each part, all other parts constitute their respective environments. Parts may be composed of sub-parts, just as any system may be part of a larger super-system. This leads systems theory to acknowledge levels of organization; for example, cells, organs, organism, and species, or individual, family, social group, local government, and the state.

Systems theory privileges wholes over their parts, as in the familiar instruction to “act locally but think globally,” the idea that parts could be replaced to preserve the whole, and the belief that wholes are more than the sum of their parts. However, by most measures, wholes and the sum of their parts merely differ – the difference is explained by their organization, i.e., patterns of interaction or networks of communication. General systems theorists attempt to generalize organizational principles across levels; others consider such generalizations category mistakes or settle this possibility empirically.

Part-whole relationships favor *functional explanations* (→ Functional Analysis). Functions are always assigned to parts in the context of the well-being (purpose, preservation, or identity) of the whole. Functional explanations may well be appropriate in biological or technological systems whose part-whole relations are relatively fixed. In social systems, however, functional explanations favor top-down hierarchies – parts having to be responsible for their whole. They demand consistency, harmony, and efficiency: parts that deviate from these values are considered dysfunctional and undesirable, if not dispensable. And, if levels of organization are not mere observer’s abstractions – as in biology – representing instead what different people are in charge of, functional explanations favor governing elites, for example, the status quo of their power relations. This has been the criticism of Parsons’s sociological systems theory of actions, but it holds for structural-functional explanations more generally.

By celebrating the organismic values of collaboration and integration in larger wholes, conflicts, revolutions, and structural innovation easily escape biological metaphors. Such deviances are typically treated as illnesses in need of curing. Even in ecological systems,

where species thrive by successfully competing with each other for scarce resources, including consuming each other, ecological systems theories herald balances, equilibria, and stable distributions of species, sounding alarms in their absence. Similarly, the mathematical or computational representation of systems – networks, linear equations, or nonlinear dynamics – are comprehensible only if the relationships between parts are regular and proceed unchallenged.

Systems theories can be formulated on vastly *different levels of abstraction* depending on the interests of the theorist or the problems to be addressed. Medical research, for example, is primarily focused on the effects of interventions and, assuming some kind of biological normalcy, systems theory is conservative. Technology tends to be designed for particular purposes, and technical systems can be evaluated accordingly. An aircraft control system, consisting of a vast network of people and equipment, can be evaluated in terms of their capacity and number of air traffic accidents. The sociologist Niklas Luhmann (1984) developed a highly abstract systems theory that avoids the usual conservatism by focusing on how society understands itself. For him, society consists not of individual actors, as in Parsons' system, but of communications. Whatever complexities might exist outside society, they are reduced to communicable meanings. By selectively reproducing these meanings internally, society defines its own identity relative to what it is not, yet this distinction is always understood from within, as reproducible communications.

Such disembodied abstractions are opposed by what Robert Flood and Norma Romm call *critical systems thinking*. It entails three commitments: (1) critical awareness – examining taken-for-granted assumptions along with the conditions that give rise to them; (2) emancipation – ensuring that research addresses “improvement,” defined temporarily and locally, accounting for power relations; and (3) methodological pluralism – using a variety of research methods to address a corresponding variety of issues – without becoming entrapped in any one conception (Flood & Romm 1996). This kind of systems thinking does not shy away from abstractions, but regards them as embodied in the lives of the human constituent of the social systems under consideration.

## Tabloid Press

*Maria Elizabeth Grabe*

*Indiana University*

Tabloid means compact size. In reference to the press it describes smaller sized newspapers. Yet in contemporary journalism the term tabloid refers to both → newspapers and television and carries a strong normative evaluation of news work (→ Television News). In many respects, the term tabloid has become removed from its original meaning and attached itself to the idea of sensational news coverage (→ Scandalization in the News; Sensationalism). Slogans like “if it bleeds it leads” and “bodybag journalism” refer to emphases on death and destruction and are commonly used in reference to tabloid news. An assessment of public debate among media critics and academics about this journalistic style reveals sweeping declarations about its corruptive influence on journalism. Periods of public outrage about tabloid news have become a frequent ritual in many countries around the world. At the heart of this debate are two popular concerns: tabloid journalism violates notions of social decency, and it displaces socially significant stories.

Tabloid news content is often defined as that which amuses, titillates, and entertains, whereas “proper” news is commended for its assumed ability to enhance the political and social knowledge of the audience by appealing to reason rather than emotion (→ News as Discourse). Stories dealing with celebrities, crime, sex, disasters, accidents, and public fears have consistently been labeled as tabloid topics (Ehrlich 1996; Djupsund & Carlson 1998; Uribe & Gunter 2004; Wang 2004; Vettehen et al. 2005). A number of *dichotomies* have been employed over the years to assist in drawing the line between tabloid and “proper” news topics. These include entertainment versus information, infotainment versus edutainment, human interest versus public affairs, situational versus timeless issues, soft versus hard news (→ Soft News), opinion versus fact, and unexpected events versus issue coverage. Not only is the topical focus of tabloid news seen as trivial but it is believed to displace important news, conducive to informing citizens. And, indeed, some traditionally non-tabloid news outlets are adopting the tabloid news menu to draw viewers.

Tabloid journalists not only focus on sensational topics but use *packaging techniques* to further enhance the titillation of the content. For newspapers these include large headlines, photos with graphic and often disturbing content, and placement of sensational

stories on the front page and as the lead story (→ Newspaper, Visual Design of; Photojournalism). In television news, slow motion video, music, sound effects, and other digital visual effects are employed to dramatize content (→ Television News, Visual Components of). Critics view this as a flagrant attempt at drawing readers and viewers, thereby further abandoning the journalistic mission to inform, not to entertain or titillate. The profit motive is most often identified as the impetus for sensational journalistic practice ratings (Brants & Neijens 1998; Esser 1999; → Commercialization: Impact on Media Content). But there are also concerns about the moral and psychological influences of tabloid reporting. In fact, scholars have described the sensational tabloid approach to reporting as provoking “unwholesome emotional responses” (Mott 1962, 442), complaining that it shocks and thrills our moral and aesthetic sensibilities (Tannenbaum & Lynch, 1960), and emphasizes “emotion for emotion’s sake” (Emery & Emery 1978). According to Daniels (cited in Tannenbaum & Lynch 1960, 382), sensational news stories are “underdistanced” – that is, they provoke more sensory and emotional reactions than what is deemed proper for audience members to desire or experience.

It has been argued that sensationalism plays an important *role* in maintaining a society’s commonly shared notions of decency and morality by publicly showcasing what is unacceptable (Stevens 1985). Thus, instead of corrupting the standards of public decency, tabloid news offers morally conservative commentary on the titillating issues that it covers. Moreover, respected journalists readily admit that they intentionally arouse emotion in readers with the hope that they will channel audience excitement into efforts to right social wrongs. The “muckrakers” of the early 1900s in the US, now celebrated for their socially responsible journalism, practiced investigative reporting with the aim of arousing emotion and to incite the public to act against perceived injustices (→ Muckraking).

The legitimacy of what is defined as socially significant news has also been questioned. Stories about family conflicts, substance abuse, violence, disaster, and other disruptions of everyday life are regarded as more significant to the lives of ordinary people than the traditional political and economic issues that elites prescribe as important information for the masses (Bird 1992; → Violence as Media Content). Like the → “penny press” papers of the 1830s, today’s tabloid outlets have made news accessible and popular among non-elite audiences, serving a democratizing function. Interestingly, in the People’s Republic of China, tabloids have exploded in popularity since the mid-1990s and have tested the limits of press censorship by taking editorial positions critical of the government and by engaging in critical investigative reporting (→ China: Media System).

Media critics seem both skeptical and concerned about the news viewers’ ability to distinguish between “proper” and sensational journalism but there is evidence that the audience is able to make this distinction using production features of television news as cues. In an experimental investigation, Grabe et al. (2000) found viewers rated stories packaged with lavish production features less believable and informative than stories without them. In this sense, production features seem to play an important reflexive function in helping audiences categorize television news as either trustworthy or lacking credibility. Moreover, adding tabloid production features to dull public affairs stories has been shown to enhance memory for news content, furthering the information function of news (Grabe et al. 2003).

## **Tabloidization**

*S. Elizabeth Bird*

*University of South Florida*

“Tabloidization” is a vaguely defined term that since the 1980s has been used to describe stylistic and content changes in → journalism, usually perceived as representing a decline

in traditional journalistic standards (→ Quality of the News). To grasp the significance of the term, it is first essential to understand its root form – the tabloid (→ Tabloid Press).

Although the term “tabloid” strictly refers only to certain newspapers’ half-broadsheet size, it has come to define a particular kind of formulaic, colorful narrative related to, but usually perceived as distinct from, standard, “objective” styles of journalism. The tabloid style is consistently seen by critics as inferior, appealing to base instincts and public demand for → sensationalism. True “tabloids” emerged in Britain during the first decade of the twentieth century, and in the United States in the 1920s. Entertainingly sensational, they were written in the idioms of the people, as William Randolph Hearst proudly declared when launching the American *Daily Mirror* in 1924 (Bird 1992). The tension between a perception of tabloid style as representing the legitimate desires and voice of the people, or as representing a vulgarization of public → discourse, has been at the heart of the debate about tabloidization ever since.

The tabloid is not defined by content; tabloids may cover the same topics as mainstream journalism, although typically more briefly and flamboyantly (Bird 2002). British daily tabloids, such as the *Sun*, cover politics and “hard” news, although much more briefly and superficially than “quality” newspapers (→ Quality Press), while much of their space is devoted to celebrity news, sensational human interest stories, advice, and so on. Their US daily counterparts, such as the *New York Daily News*, have a similar mix of news and entertainment, while US weekly supermarket tabloids, such as the *National Enquirer* or *Star*, rarely touch hard news at all. Publications recognizable as tabloids across the world contain variable mixes of news, entertainment, sports, and other features (Sparks & Tulloch 2000), usually with heavy use of illustration.

If “tabloid” has come to mean a specific style, “tabloidization” is a more recent term developed to describe an inexorable move toward that style by “real” journalism. Long before the term was actually coined, tabloidization was a focus of criticism and concern that began with the emergence of more popular journalistic formats, such as the → “penny press” of the 1830s, whose writers drew on the formulaic conventions of broadsheets and ballads to produce dramatic, human interest news of crime and mayhem, frequently with an implied or overt moral. In the nineteenth and early twentieth centuries, critics bemoaned the cheapening of public discourse represented by such popularization of the news, and this lament has gathered momentum over the last 100 years. In the late twentieth century, the term “tabloidization” appeared, and has come to connote a serious decline in journalistic discourse, whether in television or print. As Sparks (2000, 1) writes, there is a growing perception that “the high standards of yesterday are being undermined by sensationalism, prurience, triviality, malice, and plain, simple credulity.”

## DEFINING TABLOIDIZATION

Neither journalists nor critics agree precisely what tabloidization is, or whether it is invariably a negative force. Indeed, as Sparks (2000) writes, empirical attempts to demonstrate the process have been inconclusive. However, there appear to be some key areas in which most people recognize the phenomenon. Generally, these can be discussed as issues of either style or content, although these are clearly closely related. Under style,

we can look at writing techniques, observed in a movement away from longer, complex, analytical writing into shorter, punchier sentences, primarily in a narrative rather than analytical mode. Second, we see an increasing emphasis on the personal; for instance, journalists handle major economic themes through personal stories about individual people and the way they cope. A third symptom of tabloidization is a greater use of visual images, including photos, artists' sketches, and so on, as well as increased reliance on such techniques as re-enactments and dramatizations, primarily in electronic news.

Tabloidization of content is usually framed in terms of increasing trivialization. For instance, celebrity news and gossip are seen to be crowding out serious news, and human interest stories receive more coverage than important international events. Critics also point to changes such as the move toward covering political debate as horse races (in election coverage; → Horse Race Coverage) or as shouting matches on talk shows and other venues, both of which detract from serious and nuanced debate and analysis (Krajicek 1999; Kurtz 1994).

The term "tabloidization" arose in the specific context of changes in traditional news; for instance, it was used widely in the United States to describe and often decry the emergence of the national newspaper *USA Today*. The paper was launched in 1982 by Al Neuharth, then heading the Gannett chain, and featured innovations such as short, snappy text, extensive use of color photos, dramatic sports coverage (→ Sports as Popular Communication; Sports and the Media, History of), and a detailed weather map. Many critics despised the paper, but it went on to become a great success, and by the early 2000s Neuharth enjoyed the status of a press elder statesman. Without a doubt, *USA Today's* stylistic innovations led to significant changes in print journalism, where more eye-catching design, shorter stories, and use of color and visuals have become standard. By now, such changes are generally regarded as positive and enriching to journalism generally. This progression points to the way in which the very meaning of "tabloidization" continually shifts, as changes once seen as evidence of decline become mainstreamed, if they are successful.

### **TABLOIDIZATION: BEYOND TRADITIONAL MEDIA**

Tabloidization, like most changes in any media form, is primarily audience- and advertiser-driven. This is especially true in print journalism, whose audiences are both declining in numbers and aging, with younger readers apparently not taking up the habit of newspaper reading as they grow older (→ Readership Research). The competition for news has become increasingly fierce, with proliferating broadcast outlets, as well as the enormous impact of the Internet, which has led traditional media to rethink many of their familiar practices (→ Internet News). It seems to be an indisputable fact that "tabloid"-style news, whether about celebrities or sensational crimes (→ Crime Reporting), simply appeals to larger audiences than does serious reporting. The economics of the news business also drives the move toward relatively cheap stories that can have a broad appeal in many different formats rather than, for example, the expensive and time-consuming enterprise of investigative or foreign reporting (→ Investigative Reporting; Foreign Correspondents). For instance, US media in the early twenty-first century gave huge coverage to such stories as the May 30, 2005, disappearance of Natalee Holloway in

Aruba, or the April 2005 Jennifer Wilbanks “runaway bride” saga, both of which consumed both mainstream and tabloid print media, as well as cable news, talk shows, talk radio, and Internet forums. Stories such as these, which invite endless speculation and audience participation, are especially typical of the tabloidized genre.

The spread of these kinds of stories in so many different genres has widened the term “tabloidization” to encompass condemnation of the kind of “chatter” that has become typical of the contemporary media age. News outlets have proliferated across literally hundreds of cable and satellite channels and the Internet. While this democratization raised hopes that this would offer a much greater variety of serious, international news (and to some extent it has), it seems clear that more time has simply been devoted to these narratives. Fears about tabloidization seem now to be less focused on print media, and more on a general decline toward “tabloid culture” (Langer 1997) or “argument culture” (Tannen 1999). An important element in the criticism is anxiety about the free-for-all information market now offered through cable and the Internet; if anyone can be a reporter, surely this is a threat to the hard-fought-for professional status to which journalists have aspired. Journalists have always sought to define “real” journalism by comparison with tabloids, drawing lines between their techniques and those of their tabloid counterparts, in terms of both journalistic style and ethical standards, such as payment for stories or adequate sourcing (Bird 1992). The new media environment blurs boundaries even more, offering many more ways to attempt to redraw the lines through accusations of tabloidization.

### **TABLOIDIZATION AS A MEANINGFUL TERM**

However, it is also important to consider tabloidization in context. A movement to clearer, more accessible news that speaks more directly to readers does not necessarily equate with a decline in standards. For instance, Hallin (2000) reports that in Mexico, these kinds of stylistic changes have signaled positive forces for social reform and democratic participation, as elite controls on news have loosened. Similar changes are noted in former eastern bloc nations, where the emergence of more personal, snappier, and tabloid-like styles go hand in hand with a more open and accessible press. Several commentators, including Macdonald (2000), have pointed out that if done well, “tabloid” features, such as emphasis on the personal over the institutional, can make news more direct and effective.

Thus it is important to understand cultural specificities when discussing tabloidization, or any other journalistic quality. Even in two societies as apparently similar as Britain and the United States, there are significant differences in tabloid media, and thus the implications of tabloidization can also differ. For instance, US supermarket tabloids and UK daily tabloids feature similar layouts, writing styles, and celebrity focus, and journalists have moved comfortably between the two genres for years. However, they are in many ways different, reflecting quite distinct cultural milieus. British tabloids are explicit, visually and verbally, about sex, while American weeklies avoid direct references. Ironically, critics decried the tabloidization of mainstream journalism during coverage of the 1998 Bill Clinton/Monica Lewinsky scandal, while in fact the mainstream press offered far more explicit details than did the tabloids. And while some American weeklies are far more interested in paranormal and religious topics, such as Biblical prophecies

and faith healing (→ Religion and Popular Communication), British tabloids reflect a much greater sense of working-class consciousness than those in the United States, where “everyone is middle-class.” Tabloid-type media in other countries also reflect a range of social, political, and cultural characteristics; when we discuss “tabloidization,” we may mean very different things depending on context.

It is clear that “tabloidization” is a term that lacks a single, clear definition. When broken down to its constituent elements, such as changes in style and a move toward accessibility and personalization, it becomes a difficult target to see clearly. In part, this is because, although tabloidization is usually seen as antithetical to traditional journalistic standards, there has always been a tension between journalism’s twin impulses to inform and to entertain. For instance, journalists have long been encouraged to see large issues in personal terms; engaging narratives are far more effective in communicating than dry, statistical accounts. Members of the public are not well informed if they simply reject the news out of boredom. The issue seems to hinge on an almost impossible set of questions: when has the balance between entertainment and information shifted too far? At what point has the trivial pushed out all serious discourse? How will we recognize a “media circus” when we see it (Kurtz 1994)?

There are no clear answers to these questions, and thus there can be no clear definition of the term “tabloidization.” As they do with obscenity, critics claim to “know it when they see it.” Essentially the term has become a shorthand way of describing any trend in news production and reception that represents trivialization, cheapening, and a decline in standards; the exact nature of that decline may depend on the point of view of the critic.

## Tailoring, Communication and

*Marci K. Campbell*

*University of North Carolina at Chapel Hill*

Tailored messages are formal individual messages in which the content and/or style of the materials have been created based on data specific to the individual. Tailoring is distinguished from targeting, in that targeting refers to audience segmentation and development of group-specific messages, whereas tailoring involves individual-specific assessment and feedback driven by that assessment. Individual computerized tailoring for health promotion typically combines health behavior change theory (→ Health Communication; Health Behavior Change, Transtheoretical Model of), communication theory, social → marketing principles, and computer-based programs and algorithms, in order to produce personally relevant health messages for each project participant. Information obtained from each individual is accessed and assembled using specially created software to generate customized messages for each person that are designed to promote healthy behavior changes (Campbell et al. 1994; Kreuter et al. 2000a). Providing individualized messages means the information can be tailored so that it is particularly relevant, interesting, culturally appropriate, and credible to the message recipient (Skinner et al. 1999).

In tailoring, appropriate messages for an individual are drawn from a “library” of pre-created messages, which can include text, graphics, photographs, audio or video information, or other types of message files. Each message is developed to address the demographic, health, behavioral, psychosocial, and/or cultural characteristics and determinants considered important for promoting change in a specific behavior or combination of behaviors. The messages are then turned into a single coherent communication by use of computer software that searches, selects, and assembles the messages on the basis of matching rules (algorithms). The development of tailored messages can be resource intensive; however, once developed, the production and delivery are usually of relatively low cost and the messages can be widely disseminated on a population basis.

The development of tailored messages typically involves a number of steps, beginning with identification of the target population, epidemiologic and/or clinical assessment of health risks and targets for change, and formative research to identify salient issues, barriers, preferences, beliefs, and other determinants of behavior change. Next, an assessment tool

is developed that measures the tailoring variables validly and reliably and provides finite data points that determine the range of participant responses for which tailored feedback elements should be created. Typically, “macro-tailoring” involves tailoring a section or block of feedback, such as a page of a newsletter or website, to a particular variable, such as stage of readiness to change or barriers to change. “Micro-tailoring,” on the other hand, usually involves smaller variations of the feedback that are determined by additional variables relevant within a larger tailored section. For example, a tailored feedback segment might be macro-tailored to the participant’s level of perceived social support for increasing physical activity, and then micro-tailored to participant responses to one or more other questions, such as the person who would be most useful to provide that support (spouse/partner, family member, friend, co-worker, etc.). In creating tailored feedback, a parsimonious approach is recommended that focuses on a subset of key variables for which evidence indicates tailoring will make a difference. Once the → survey and the message library are created, pre-testing is recommended by members of the target audience in order to assess factors such as acceptability, usability, and comprehension. Algorithms or instructions are then written by the research team and programmed, using computer-based software, to select the appropriate message files and tailored elements for each individual from the overall message library, and incorporate them into a pre-determined format, layout, or sequence, depending upon the medium of delivery (print, web, video, etc.; Kreuter et al. 2000a).

Research and theory suggest that tailored messages are more likely to be effective than generic materials because they provide personally relevant information that meets the exact information needs of readers and excludes irrelevant or superfluous facts (Brug et al. 2003; Skinner et al. 1994). It follows that when these needs are more closely met, an individual will be more likely to make the desired changes in knowledge, belief, and attitudes, and to move toward the action and maintenance stages of behavior change. A number of recent reviews have concluded that tailored messages are effective in promoting a variety of health behavior changes including diet, physical activity, smoking cessation, and cancer screening (Skinner et al. 1999; Brug et al. 2003). The strongest effects are seen when tailoring is compared to a no-intervention control condition; smaller effects are found when tailored messages are compared to non-tailored or targeted health information on the same topic. Receiving multiple tailored messages versus one dose of tailored feedback has been shown to produce more effect in promoting dietary change (Heimendinger et al. 2005). In addition, tailored messages have shown promise for addressing health disparities among minority and underserved populations (Skinner et al. 1994, Campbell & Quintiliani 2006). Tailored print messages have been most widely studied; however; tailored health behavior feedback systems also have been developed and delivered via the telephone, → Internet, CD-ROM, and other media. Evidence suggests that short-term effects of tailoring via these media are comparable to print; however, longer-term studies seem to favor print over electronic media for maintenance of change (Kroeze et al. 2006).

Refining the theoretical basis of tailoring and choices of variables, media, channels, and other variances of tailored messages will be important for increasing effectiveness and cost-effectiveness. Research is ongoing to investigate issues such as theoretical models and pathways through which tailored messages exert their effects, innovative variables

and algorithms for determining tailored feedback, optimal amounts and timing of tailoring, combining tailoring with other intervention modalities, and effective dissemination of evidence-based tailored messages to achieve broad public health impact.

## **Taste Culture**

*Diana Crane*

*University of Pennsylvania*

The idea that → popular culture consists of distinct “taste cultures” was developed by Herbert Gans (1974) as an alternative to the then dominant theory of mass culture. Mass culture theorists (Horkheimer & Adorno 2001) viewed popular culture as a commercial enterprise that represented a debased form of high culture. They claimed that mass culture targeted a mass audience that was passive and uncritical and thus susceptible to mass persuasion, with potentially dangerous consequences for society as a whole (→ Culture: Definitions and Concepts).

Gans argued that the concept of mass culture was an oversimplification. Popular culture exists in various forms that appeal to → audiences with different educational backgrounds and tastes. High culture requires a sophisticated audience and, inevitably, appeals to a minority of the population; most people prefer popular culture.

Gans developed a typology of “taste publics” that consume “taste cultures” appropriate for their educational level and social background. A taste culture consists of values and aesthetic standards for culture, cultural forms that express those values, and the media in which they are expressed. *Five principal taste cultures*, stratified by social class, represented American culture in the 1970s. “High culture” comprised both classics and contemporary styles in literature and the arts. Its taste public included creators and highly educated upper- and upper-middle-class people. “Upper-middle culture” was associated with an upper-middle-class taste public, who were uninterested in the relatively esoteric aspects of high culture, preferring forms of culture that spoke to issues that were relevant to their personal lives. “Lower-middle culture” was America’s dominant taste culture. Its taste public provided the major audience for mass media and sought content that confirmed its worldview, particularly its moral values. The taste public for “low culture” consisted of older, lower-middle-class people who preferred entertainment that dealt with traditional working-class values. “Quasi-folk low culture” was a simpler version of low culture. Its taste public consisted of unskilled blue-collar and service workers with little education.

Thirty years later, Gans’s theory of taste cultures has been eclipsed by subsequent developments in the discipline. *Bourdieu* (1984), who was also interested in identifying social groups with different levels of taste, developed an elaborate theory to explain how social class and education influence cultural choices. According to Bourdieu, the capacity to appreciate different forms of culture is developed through socialization in childhood. Families provide different cultural environments for their offspring, ranging from the culture of distinction in the upper class to the culture of necessity in the working class. Members of the upper class and members of the lower class have different tastes and different perceptions of the same forms of culture. Consequently, arts and culture consumption can be used to legitimate social class differences and as a form of “capital” to advance one’s social position.

Recent research reveals that many people do not restrict their attention to a particular type of culture, possibly because of the enormous *variety of cultural choices* that are now available (Peterson 2005). Studies of tastes for different types of popular music show that “omnivores” consume a wide variety of cultures, both highbrow and lowbrow. “Univores” restrict their attention to a single form of culture, either highbrow or lowbrow. Omnivores and highbrow univores have more education and social status than lowbrow univores.

Today, the most widely used approach for the location of social groups with specific cultural tastes is through the *identification of lifestyles*. In this approach, the emphasis tends to be placed on factors affecting the selection of consumer goods. Differences among lifestyles within the same social class as well as across social classes are anticipated. One approach to the identification of lifestyles is that of matching America’s 36,000 zip code areas with census data and consumer surveys. This produces 40 “lifestyle clusters” that can be differentiated from one another very precisely in terms of income, race, education, leisure activities, media usage, food preferences, and political leanings (Weiss 1989; → Audience Research; Audience Commodity).

In both the US and Europe, market researchers have identified lifestyle clusters on the basis of demographic variables, such as education, income, and age, and surveys that assess people's values, attitudes, and behavior toward work, family, leisure, money, and consumption. For example, in the US, research using Market Statistics' *GeoVALS system* has identified eight American lifestyles on the basis of personal orientations and resource constraints such as education, income, and age (Waldrop 1994). Traditional as compared to modern or liberal values have proved to be important influences on cultural preferences. The lifestyles of over half (57 percent) of the American population were influenced by traditional values. In Europe, the *Sinus-Milieus* approach also combines structural and cultural variables to map lifestyles and detect differences in consumer behavior in different countries (Sociovision n.d.). This approach differs from the American research through its use of ethnographic data to identify more precisely the characteristics of the specific milieus or contexts which shape people's behavior, on the grounds that the life contexts of people with similar socio-economic backgrounds can be very different.

Gans's typology of taste cultures was not based on survey research. Lifestyle research creates typologies that are based on sophisticated quantitative techniques for identifying clusters and indices based on census data, consumer surveys, life histories, in-depth interviews, focus groups, and ethnographic research (→ Cluster Analysis; Scales and Indices; Quantitative Methodology).

# Teacher Affinity Seeking

Linda L. McCroskey

California State University, Long Beach

McCroskey and Wheelless, the first to introduce the concept of “affinity” in the communication literature, defined it as “a positive attitude toward another person” (1976, 231). Bell and Daly expanded research in the area of affinity seeking in interpersonal communication. They defined “affinity seeking” as “the active social communicative process by which individuals attempt to get others to like and feel positive toward them” (1984, 91). These pioneers pursued this research stream as it gained momentum, clearing, defining, and redefining a swath so significant that not only did their efforts spawn decades of affinity research, but these early efforts appeared to support the idea that gaining “affinity” may be the single most important reason why we engage in → interpersonal communication (→ Interpersonal Attraction). That the fledgling discipline could assert a simple explanation for what motivates communication interaction is impressive. A more far-reaching impact was felt as interpersonal communication research shifted focus to specialized contexts such as the classroom or workplace. Because the seminal affinity research was conducted by scholars interested in communication education and instruction, affinity research in the instructional context set the agenda for its application to other interpersonal contexts.

Drawing from Bell and Daly, McCroskey and McCroskey (1986) expanded this research area specifically to classroom teachers. Their research indicated that teachers use 10 of the 25 interpersonal affinity-seeking techniques to obtain affinity with students. Frymier and Wanzer (2006) summarized the *10 strategies*:

- 1 Facilitate enjoyment. When teachers are able to make classroom activities enjoyable, students appreciate it and respond positively.
- 2 Optimism. Being optimistic and having a positive outlook has consistently been related to positive affect in the classroom.
- 3 Assume equality. In effect, this is when a teacher de-emphasizes her or his higher status and treats students as equals.
- 4 Conversational rule keeping. This strategy is consistent with assuming equality. When teachers use conversational rule keeping, they are being polite and treating students with respect.
- 5 Comfortable self. A teacher using comfortable self appears relaxed and confident and may help students to also feel comfortable in the classroom.
- 6 Dynamism. Teachers who are dynamic and enthusiastic consistently elicit greater liking from students.
- 7 Elicit other’s disclosure. When teachers use this strategy they are paying individual attention to students and showing interest in them as individuals. Most people find it confirming and complimentary to have someone of higher status showing interest in them.
- 8 Altruism. When teachers attempt to be helpful, students like them better. Students may not expect teachers to go out of their way to be helpful, so when they do, it is particularly appreciated.

- 9 Listening. Listening goes hand in hand with eliciting others' disclosure in terms of communicating confirmation to the student.
- 10 Sensitivity. Sensitivity involves expressing empathy and caring toward the student. Like listening, this strategy involves focusing attention on the student.

Gorham et al. (1989) replicated the earlier research and confirmed that the *most frequent affinity-seeking strategies* teachers use are physical attractiveness, sensitivity, eliciting others' disclosure, trustworthiness, nonverbal immediacy, conversational rule keeping, dynamism, and listening. Later research indicated that students perceived graduate teaching assistants as using somewhat different affinity-seeking strategies. They indicated that graduate teaching assistants assumed equality, conceded control, elicited others' self-disclosure, and used self-inclusion more frequently than their professors. Based on this and subsequent research, it became clear that teachers regularly employ affinity-seeking strategies to establish good relationships with their students (→ Classroom Student–Teacher Interaction).

To date, subsequent studies in the educational context have investigated how affinity-seeking behaviors influence, or are associated with, student affective and cognitive learning, student motivation, teacher credibility and competence, learning climate, and cross-cultural classroom distinctions (→ Learning and Communication). The seminal research results are summarized in the remaining paragraphs (for review, see Frymier & Wanzer 2006).

The first research applications examined the *effectiveness of teacher affinity seeking* in college classrooms. The results indicated that affinity seeking was significantly correlated with affective learning as well as cognitive learning and with student motivation. It was also found that using multiple strategies could enhance students' motivation to study. There were substantial correlations between student motivation and facilitating enjoyment, assuming equality, optimism, self-concept confirmation, and nonverbal immediacy. These strategies as well as others were found to be positively associated with learning as well. Related research determined that teachers' use of affinity seeking led to increased perceptions of teacher credibility (→ Teacher Communication Style; Teacher Socio-Communicative Style). The relationships with teacher character and credibility were strong and moderate, respectively. This research also indicated substantial correlations between teachers' use of affinity-seeking strategies and students' substantially increased motivation to study.

In an effort to extend this research to examine the relationship between teacher affinity-seeking strategies and student communication in the classroom, as well as students' perceptions of teachers' competence, research results indicated that both of these were very substantially increased by the affinity-seeking strategies. Similar results were obtained with teachers' affinity seeking having a positive impact on their perception of the classroom climate. Nineteen affinity-seeking strategies impacted on perceptions of classroom climates. In 2001 Roach and Byrne extended the teacher affinity-seeking research to the German culture. They found that German instructors were perceived to use substantially fewer affinity-seeking strategies than had been observed in the earlier US research. They also found that the relationship between affinity seeking and student cognitive learning was substantially weaker for German students. However, German students' affective learning was substantially benefited by teacher use of affinity seeking. It was virtually equal to the impact in the US research.

Conclusions which can be drawn from this body of research are as follows: (1) when teachers use affinity seeking with students, the classroom climate improves and students are more motivated to study and have higher affective learning; (2) students perceive instructors who use affinity seeking as more credible; (3) the 10 strategies were perceived as positive strategies in the research on teacher affinity seeking.

## **Teacher Assertiveness**

*Candice Thomas-Maddox*

*Ohio University, Lancaster*

Assertiveness, one of the three primary dimensions studied under the rubric of → teacher socio-communicative style (the others are responsiveness and versatility), refers to an ability to use effective and appropriate communication in making requests and defending one's position. It involves a willingness to speak up for one's own beliefs without impinging on the rights of others. In the classroom, assertive teachers demonstrate confidence in speaking and presenting, facilitating class discussions, engaging in effective classroom management, and presenting an overall positive, authoritative image (→ Pedagogy, Communication in). Teacher assertiveness varies along a continuum from high to low levels of the behavior. When measured in conjunction with responsiveness, a teacher's level of assertiveness provides an overview of communication effectiveness.

Teacher assertiveness is typically associated with task orientation, thus instructors who are assertive in the classroom tend to demonstrate more authority and control. As a result, students often perceive assertive teachers as being more competent. Their focus

is on accomplishing classroom tasks and assignments. Assertive teachers demonstrate excellence in their own work while expecting the same from their students. Some nonverbal indicators associated with teacher assertiveness include increased use of gestures and smiling, greater vocal volume, more frequency of eye contact, and a faster rate of speech (→ Eye Behavior; Facial Expressions; Gaze in Interaction; Gestures and Kinesics; Gestures in Discourse; Nonverbal Signals, Effects of; Rhetoric, Nonverbal). Variables that are associated with the verbal aspects of assertiveness include increased use of humor and immediacy in the classroom (→ Teacher Immediacy; Teacher Use of Humor). To explain the relationship between teacher assertiveness and immediacy, Thomas et al. (1994) found that students perceive teachers as being more immediate when a combination of both assertive and responsive behaviors is employed in the classroom.

On the initial foundation of research focusing on social style (Lashbrook 1974), instructional communication scholars have identified several factors that answer the question of why teachers vary in their level of assertiveness. Focusing specifically on communication traits and behaviors, teachers with low levels of communication apprehension tend to be more assertive in the classroom (→ Communication Apprehension and Social Anxiety; Communication Apprehension). This confidence in speaking allows instructors to display communication behaviors that cause them to be perceived as more outgoing and confident. Additional research has identified a relationship between teacher assertiveness and argumentativeness, with assertive instructors more likely to argue for their position (Myers 1998).

Several studies have provided an understanding of the impact of teacher assertiveness from the student perspective. Students who perceive a teacher to be assertive report increased cognitive, affective, and behavioral learning. In examining the relationship with affinity seeking, assertiveness is positively correlated with a number of strategies. Teven (2001) identified a positive relationship between assertiveness and perceived teacher caring. Overall, students perceive assertive teachers to be more challenging and more deserving of their respect.

Less positive perceptions of assertiveness have been identified as well. Students report that assertive teachers are sometimes viewed as being more open to imposing punishment for student behaviors. Further, they perceive assertive teachers as more willing to inflict guilt for student performance or behaviors. A lack of assertiveness may also produce negative ramifications. Wanzer and McCroskey (1998) found that students view less assertive teachers as engaging in more teacher misbehaviors in the classroom. When focusing on out-of-class communication, students report that they are less likely to engage in self-disclosure or socialize with teachers who exhibit a high level of assertiveness in class (→ Classroom Student–Teacher Interaction).

Despite information on the benefits associated with teacher assertiveness, it is important to examine the concept in conjunction with teacher responsiveness in order to gain an accurate understanding of its potential implications in the classroom.

## **Teacher Clarity**

*Joseph L. Chesebro*

*State University of New York at Brockport*

Teacher clarity is the extent to which the meaning stimulated in students' minds by an instructor accurately matches the meaning an instructor intends to convey. In their article on teacher behaviors, Rosenshine and Furst (1971) identified teacher clarity as the most important aspect of teaching that researchers should investigate. Since that article, research programs originating from both education and instructional communication have examined teacher clarity in a variety of ways and have demonstrated that it is one of the most significant teacher behaviors affecting student learning (→ Classroom Student–Teacher Interaction; Learning and Communication).

A number of *research programs* have investigated teacher clarity (for a more complete review, see Chesebro & Wanzer 2006). The first major tradition emanated out of Ohio State between 1975 and 1985 (for a more complete review of these studies, see Cruickshank & Kennedy 1986). The researchers began by having junior high-school students recall their most clear teacher and identify five things the teacher did when teaching. Using items

identified in this first study, the researchers then created items to discriminate between clear and unclear teachers, and, in the process, they discovered two dimensions of clarity: (1) explaining and (2) providing for student understanding. In a subsequent study they found a moderately strong link between the teacher clarity behaviors and student achievement and satisfaction. These results support the importance of the clear teaching behaviors identified by earlier research studies in this program.

Another program – headed by Smith and Land – examined clarity with a more narrow focus by examining specific behaviors that signal a lack of clarity, such as *disfluencies*, *tangents*, and *vagueness*. Land (1979) found that students of teachers exhibiting these low-clarity behaviors scored lower on tests of recall immediately following a video-taped lecture. Further research in this program identified the effects of “mazes” (Land & Smith 1979), discontinuity (Smith & Cotten 1980), and vagueness (Smith & Land 1981). Each of these variables inhibited clarity and was related to lower achievement scores.

Although Kenneth Kiewra’s work on student note taking does not focus on the teacher clarity variable, it does demonstrate the additional ways in which teachers may make their material more clear for students. Research in this area has helped identify the importance of using *lecture cues* (signaling important ideas, whether verbally, or in writing using visual aids) during lectures in order to help students improve their note taking. These efforts to improve student note taking are important because improvements in student note taking have been linked to greater recall of lecture material (Kiewra 1985; Kiewra & Benton 1988). In addition, research in this area has suggested the importance of providing skeletal outlines to students to guide their note taking (Kiewra 2002). In addition, Titsworth (2001a, b) has demonstrated the positive effect of lecture cues on both affective and cognitive learning.

From the instructional communication discipline, one program involving Chesebro and McCroskey has examined clarity from a variety of perspectives (for a more complete review, see Chesebro & Wanzer 2006). The program posited a *model of clarity* (based on previous research) that consisted of both a structural element (involving the organization of messages, use of previews, transitions, reviews, etc.) and a verbal element (involving the use of examples, the clarity of explanations, staying on-task, etc.). Research using written scenarios, student surveys, and experimental approaches have demonstrated a strong relationship between teacher clarity and important classroom outcomes, such as reduced receiver apprehension, improved student affect for teachers and course material, greater motivation to learn, greater perceptions of learning, and actual learning.

Although teacher clarity has been researched by different teams using different methods, the research consistently has demonstrated the benefit of teaching clearly, and supports Rosenshine and Furst’s (1971) assertion that clarity is one of the most important teacher behaviors in the classroom.

## Teacher Comforting and Social Support

Nichole Egbert

Kent State University

The communication of *social support* is central to relationships in and outside of the classroom. Although scholars offer many definitions, social support is widely understood to be resources – time, money, comforting – that people possess and extend to others. These resources can be further defined by the type of help that is provided, using categories like emotional, informational, instrumental, and appraisal support (House 1981). *Emotional support* can be acts that demonstrate concern, empathy, trust, and caring. For teachers, emotionally supportive behaviors can also include being sensitive, positive, involved, and flexible (→ Teacher Communication Concern). *Instrumental support* refers to providing tangible resources (such as gifts or loans) or time. *Informational support* can include advice, counsel, or information that assists another person, whereas

*appraisal support* consists of evaluative feedback and/or social comparison. One other type of support relevant to classroom interactions is *instructional support* – reading to and with students, providing high-quality feedback, leading interactive discussions, and encouraging students to take responsibility in the classroom (Hamre & Pianta 2005).

Some of the most obvious benefits of providing students with a supportive environment are improved attendance and grades. When students perceive that their teachers have positive attitudes, are willing to work with students after class, and appreciate diversity among their pupils, students' grades increase (Bowen & Bowen 1998). In addition, when students feel that their teachers care about them and are supportive emotionally, students have better attendance, spend more time studying, and are more likely to avoid problem behavior such as disrupting class (→ Learning and Communication).

These positive outcomes are even more pronounced among at-risk students. In some cases, teacher support can reduce the effects of factors that mark students as being "at-risk," such as mother's lack of education or other demographic characteristics (Hamre & Pianta 2005). Instructional and emotional support can increase students' achievement and improve the teacher–student relationship. Overall, at-risk students who report no or only low amounts of social support have lower attendance rates, spend less time studying, have less ability to overcome school problems, and report lower self-esteem (Rosenfeld et al. 1998). Overall, support from teachers seems to be a key factor in obtaining positive outcomes among at-risk students (Rosenfeld et al. 2000).

Some additional benefits that have been associated with teacher social support are less concrete but equally gratifying. Emotional support from teachers can enhance students' satisfaction with school (Rosenfeld & Richman 1999); students' feelings that they can understand, manage, and find meaning in their studies (Bowen et al. 1998); and students' perceptions of *school engagement*, or a sense of attachment, belonging, and involvement in school (Brewster & Bowen 2004).

Some techniques for enhancing the social support students receive from teachers intuitively flow from other efforts to improve communication in the classroom. For example, teachers can receive training on the importance of social support and how to convey caring, warmth, and respect in a positive classroom environment (Bowen & Bowen 1998). These types of training programs alone can contribute to a sustained and systematic improvement of student outcomes such as those outlined above. As for student training, Rosenfeld et al. (2000) suggested that students can be taught social skills such as how to know when a person might be available for a supportive conversation and how to initiate such a conversation.

Teachers are not the only potential sources for social support in the lives of their students. One of the best ways teachers can help students form supportive networks is by partnering with other important persons in students' lives such as parents, guardians, community leaders, and school administrators. Studies show that when students feel supported by a variety of network members, positive outcomes are even more pronounced (Rosenfeld et al. 2000).

Finally, it should be noted that social support needs vary by student, and therefore teachers' strategies for providing support should be tailored to meet the needs of each individual student (Rosenfeld & Richman 1999). Although it may seem arduous and impractical to develop individualized plans for each student, utilizing some of these

simple assessment techniques may not only help students to succeed academically, but also assist them in building the self-esteem and other life skills that will sustain them well into their adulthood.

## **Teacher Communication Concern**

*Jerry D. Feezel*

*Kent State University*

Teacher communication concern (hereafter abbreviated TCC) is a concept and research line that developed from attempts to describe specific behaviors of teachers that could influence student learning. Initially conceived as three factors of worry or anxiety about self (confidence and competence as teacher), task (mastering the specific skills),

and impact (affecting learning), it is an area that is part of the general category of instructional communication (→ Communication Education, Goals of), which is the interaction of teacher and student talk in classrooms (→ Classroom Student–Teacher Interaction).

For more than 50 years, from the 1950s on, researchers have been studying variables such as patterns of verbal and nonverbal interaction, teacher communication moves and student communication responses, asking and answering questions, giving directions and information, accepting and rejecting student behavior, positive and negative reinforcement, and so on. How teachers used communication in their various roles was a major focus of study (e.g., lecturing, leading discussions, giving feedback, tutoring, disciplining, etc.) (→ Pedagogy, Communication in). In short, the questions of interest related to the process of communication in classrooms as conducive or not to student learning.

Even though student learning was the goal, the students were not the focus of study except in the research and theory involving learning styles. Most of the pedagogical research and theory has focused upon the characteristics of teaching that were considered effective, e.g., teacher → communication apprehension, communication style, uses of reinforcement, and classroom interaction patterns (→ Teacher Socio-Communicative Style).

### ORIGINS OF THE CONCEPT

TCC involves a kind of self-reflection by a teacher as to aspects of the teaching role that they might be worried about. Although professional practice was analyzed in teacher education it was not until Donald Schön (1983) conceptualized the “reflective practitioner” that this received prominence. As professionals, we should think actively and critically about what we do in teaching before, during, and after a class session. Such reflective practice serves as the context for teacher self-analysis of teaching acts, strengths, and weaknesses.

The TCC term and concept emerged in a qualitative research line examining what teacher education students expressed as their concerns about teaching (Fuller 1969; → Qualitative Methodology). Questionnaires were given to the neophyte teachers asking various questions about their anxieties or worries in facing their professional responsibilities. The responses were then analyzed to construct the common themes of concern that emerged. This research used the constructivist approach to educational research (→ Constructivism).

From the results of several studies (Fuller 1969; Staton-Spicer & Bassett 1978), *three areas or dimensions of concern* emerged. It seemed that developing teachers were concerned about (1) themselves meeting their responsibilities, (2) how they would fare with the specific teaching tasks, and (3) the influence or impact they would have on students. So the primary teacher communication concerns were classified as self, task and impact. Further, the results supported a developmental sequence for teacher trainees moving through the three stages – from self concerns to task concerns to impact concerns. Two of the earliest uses in communication of Fuller’s concept were by Staton-Spicer and colleagues. One study used the Fuller questionnaire (Staton-Spicer & Bassett 1978) and another was a case study relating TCC to teacher classroom behavior (Staton-Spicer & Marty-White 1981). These were not fully quantified analyses, however.

## MEASUREMENT

The next step in the research was operationalizing TCC into a measurement instrument (→ Operationalization). Researchers structured items for and tested a three-dimensional scale, which proved to be valid and reliable (→ Scales; Scales and Indices). The first such formulation of scales was carried out by Staton-Spicer (1983). It was subsequently used in several studies by the developers and others.

An *expansion of the measurement instrument* occurred with the application of TCC to graduate teaching assistant (GTA) training. Myers (1994) used the three-dimensional scale in his dissertation, but found evidence in his qualitative analyses suggesting another developmental area of role conflict concerns. GTAs are students but also serve in the complementary role of teachers and teacher aides. Balancing these separate demands (as well as those of a personal, family, or social life) can invoke “role conflict concerns.” In juggling their multiple roles, GTAs expressed communication concerns about coping with those dilemmas and conflicts. Hence one line of research has added this as a fourth dimension of measurement (Feezel & Myers 1997). After testing and validation (→ Validity), the four-dimensional scale has been applied to enable a pre/post-assessment of the developmental process of orientation and socialization. GTA training combined with natural maturation and adaptation should lead to reduced concerns over time. Such has been found to be the case in applications of the GTA–TCC scale.

## APPLICATION

Although occasional studies may be found in other fields, most of the applications have occurred in communication. As an example of the former, a quantitative study of the concerns of nurses in training was presented at a conference in 1992 (Owens et al.; → Quantitative Methodology). Two studies reported here had results contrary to the typical developmental ordering of concerns previously postulated by Fuller and her colleagues. A science education study of new approaches by Hand & Treagust (1995) did not use Fuller’s scale but a constructivism analysis showing that concerns shifted with in-service training from themselves to how to involve their students and maximize their learning. Capel (1998) made a longitudinal study of physical education students in teacher training (→ Longitudinal Analysis). Using two concerns and anxiety scales, she found that self and impact concerns remained strong and did not change over four different school experiences in their training. Other studies in teacher education found that primary school teachers’ self concerns reduced while impact and class control concerns emerged (Ballantyne & Hansford 1995), or that all three concerns reduced after a teaching practicum experience (McCormack 1996). These publications were applying the Fuller conception and not the TCC as developed by Staton-Spicer and Bassett. Some other studies were found to be talking about teaching concerns but not directly applying either the Fuller or TCC construct.

*Applications in communication* have included elementary and secondary education, college basic communication courses, and the work on GTA development described above. In one of the earliest studies in communication, Staton-Spicer & Bassett (1978) examined elementary teachers in three stages of their training. They found that even though the

concerns of pre-service student teachers and in-service elementary teachers tended to correspond as theorized by Fuller, all three categories of concern did occur with each stage. A case study of one college research methods instructor, the Staton-Spicer & Marty-White (1981) research, confirmed the three types of concern and found relationships to teacher behavior. When formulating the scales for the TCC instrument in 1983, Staton-Spicer conducted research in secondary-level communication classrooms. She found positive relationships between the measured communication concerns and attitudes about teaching, indicating the value of the three types of concern as well as their validity and reliability. Further research applied the TCC instrument to college courses in basic communication (Hiemstra & Staton-Spicer 1983). Again, the three types of concern were operable, but not in the precise developmental pattern that Fuller and others had found.

TCC has been established as an important construct in communication education, having significant connections to other variables in teaching. However, there is no large body of publications using the construct in either its three- or four-dimensional form. Although it has been established as reliable and valid to measure in relation to teacher development, behavior, anxiety, and other elements, it has not been as widely pursued as some other variables. This is puzzling, since other studies have talked about the concerns of teachers without using this well-established tool to probe those issues more fully. Further research is needed to clarify the psychological value of the TCC construct and better understand its function in instructional communication and teacher development. Thus far, it may have been used too generally under the term “concern,” and perhaps there are more complex aspects of concern, such as the differences between feelings of worry, anxiety, fear, insecurity, or inadequacy. Such feelings of teachers about themselves and their communication are very important to examine more closely, as they may mark the differences between those who are effective and those who are ineffective, those who survive and those who burn out.

## Teacher Communication Style

*Jon F. Nussbaum*

*Pennsylvania State University*

*Ladori Lara*

*Pennsylvania State University*

Education scholars interested in the communication that transpires within the classroom have often mentioned the importance of studying the teacher as a pivotal source of that communication (→ Classroom Student–Teacher Interaction). After searching the literature, Norton (1977) wrote that very few studies had specifically investigated teacher communication style as it relates to teacher effectiveness, though many of the exciting investigations did allude to the various components or sub-constructs that entail stylistic aspects. To fill this void within the literature, Norton (1977) utilized his conceptualization of → communicator style to investigate teacher effectiveness as a function of the way a teacher communicates within the classroom (Norton 1978).

Specifically, Norton studied both teacher and student perceptions of teacher communicator style using the eleven independent variables/sub-constructs (dominant, dramatic, animated, open, contentious, relaxed, friendly, attentive, impression leaving, precise, and voice) and the one dependent variable (communicator image) that operationally define communicator style. Results from this initial investigation into the relationship between teacher communicator style and teacher effectiveness indicated that teacher effectiveness was indeed related to the way a teacher communicates within the classroom. A second result revealed that both teachers and students rated the teacher's communication style in

similar ways. Thus, teachers who perceived themselves as being dramatic and attentive were also perceived as behaving in dramatic, open, and attentive ways by the students. The final result of the study indicated that effective teachers tend to be attentive, impression leaving, not dominant, friendly, relaxed, and precise. Norton concluded that the findings of this investigation provided strong evidence that “perceived effectiveness in teaching is inextricably related to one’s style of communication” (1977, 541). In addition, he speculated that if this link between teacher communication style and teacher effectiveness exists, then the quality of classroom teaching can be improved by improving those specific teacher behaviors related to the styles that predict teacher effectiveness.

### **RESEARCH ON TEACHER STYLE AND EFFECTIVENESS**

A series of studies followed Norton’s original test of the link between teacher communicator style and teacher effectiveness utilizing his original operationalization of the communicator style construct. Nussbaum and Scott (1979, 1980) and Anderson et al. (1981) found that perceptions of teacher effectiveness and perceptions of student cognitive, affective, and behavioral learning were related to perceptions of active and open stylistic communication dimensions. In addition, these particular studies located teacher communication style within a much larger teacher–student relational context within which a teacher’s style of communication plays a pivotal role. In essence, a teacher’s communication style can have direct positive impact upon perceptions of student learning and student ratings of teacher effectiveness, and, at the same time, add significantly to the overall classroom relationship between the student and teacher that can further help produce positive student outcomes.

Kearney and McCroskey (1980) pointed out that the concept of communicator style utilized by Norton and others in their investigations of classroom communication was not solidly grounded within instructional communication theory. They grounded their notion of *teacher communication style (TCS)* within instructional communication theory, and defined TCS as “the collective perceptions of a teacher’s relational image in the classroom” (Kearney & McCroskey 1980, 533). TCS was measured with a survey instrument composed of three dimensions: assertiveness, versatility, and responsiveness. Findings revealed that students who perceived their teacher to be assertive, versatile, and responsive also reported greater affective and behavioral commitment toward the class, content, and instructor. In addition, students who perceived teachers as more versatile and responsive reported lower fears about communicating in class.

Norton and Nussbaum (1980) investigated the link between dramatic teacher behaviors and effective teaching. Nine *dramatic behaviors* were studied within this study: controls mood; pokes fun; tells good stories; is sarcastic; gets others to fantasize; catches others up in stories; gets others to laugh; is entertaining; and performs double takes (→ Teacher Use of Humor). A measure of dramatic style behaviors was constructed and then administered within the classroom. Norton and Nussbaum (1980) found that two dramatic style behaviors related strongly to effective teaching (both by conventional statistical analysis and exploratory data analysis): the teacher is entertaining and the teacher performs double takes. In addition, several other teacher dramatic behaviors were

shown to be utilized by highly effective teachers: story telling; gets others to laugh; catches others up in stories; pokes fun; and is sarcastic. The authors concluded that highly effective teachers appear to be doing something qualitatively different in terms of their dramatic style behaviors within the classroom than teachers who are not as effective. An additional investigation by Nussbaum (1982) utilizing causal modeling reinforced the finding that teacher dramatic style predicts effective teaching.

Nussbaum (1983) attempted to utilize the research evidence suggesting a link between a teacher's communicator style and teacher effectiveness by conducting a systematic experiment that trained teachers to modify their in-class behavior, then observed the resulting teacher effectiveness and student test scores (→ Experimental Design). Several teacher behaviors that had been associated with teacher dramatic and immediate behaviors (teacher movement, teacher gestures, and teacher eye contact) were manipulated with the use of in-class video tapes during a semester-long teacher training process for five graduate student teachers. Two significant results emerged from this intervention study. First, all five teachers changed their in-class behavior to become more dramatic and immediate after participating in the video-tape feedback training sessions. Second, these behavioral changes were shown to improve student evaluations of teacher effectiveness and student test scores as the semester progressed. While these results must be interpreted with some caution, this investigation does point toward the possibility that teacher communicator styles can be changed and that this change can produce positive outcomes within the classroom.

Javidi (1987), Nussbaum et al. (1987), and Downs et al. (1988) investigated whether highly effective teachers utilized different verbal behaviors within the classroom when compared to ineffective teachers. A coding scheme was developed to count the use of teacher humor, → teacher self-disclosure, and teacher narratives. It was reasoned that each of these verbal behaviors contributed to both the dramatic and open style components of the teacher's communicator style. Results indicated that highly effective teachers did utilize humor, self-disclosure, and narrative more frequently than ineffective teachers. In addition, highly effective teachers knew when to use humor, self-disclosure, and narratives appropriately to draw attention to and reinforce course content. It is also important to point out that the teachers studied within these investigations not only taught quite different content (from economics to music) but also taught at different grade levels (from middle school to graduate school). The common thread across content and grade level was the association between highly effective teaching and the appropriate and frequent use of humor, self-disclosure, and narratives.

Myers and Horvath (1997) have more recently investigated the relationship between Norton's original operationalization of teacher communicator style and student affective, behavioral, and cognitive learning. Noting that the great majority of teacher communicator style research had been conducted over 15 years before this particular study, Myers and Horvath reasoned that not only had the communication dynamics of the classroom changed since the previous research was conducted, significant progress had also been made in the measurement of student learning utilized by instructional scholars (→ Measurement Theory). In this investigation, undergraduate participants completed a series of measures, including Norton's communicator style measure and updated versions of scales measuring affective and cognitive learning. Results did indeed indicate several

significant differences from the much earlier studies. Rather than the dramatic and attentive styles predicting positive student outcomes, Myers and Horvath found that teacher styles that were friendly, relaxed, and impression leaving resulted in students having more positive attitudes about course content. These results reinforce the findings of Potter and Emanuel (1990), who previously had found that high school students preferred teachers who were perceived to be friendly and relaxed, and who had the ability to maintain control (the dominant style) within the classroom.

The relationship between why students are motivated to communicate with their teachers and their perceptions of teacher communicator style was investigated by Myers et al. (2000). It was reasoned that communication context plays a significant role in how individuals are motivated to communicate. Because teacher communication style can affect numerous student outcomes within the classroom and can have a significant impact on classroom climate, perceived instructor communicator style should have an impact on why students choose to communicate with their instructors. Undergraduate students completed Norton's communication style measure as well as the Student Communication Motives scale. Results revealed that five teacher styles affected student motivation to communicate with instructors: impression leaving, friendly, contentious, animated, and attentive.

A series of investigations were conducted by Scott Myers and several colleagues to investigate the relationship between teacher argumentativeness, teacher verbal aggressiveness (→ Teacher Assertiveness; Verbal Aggressiveness), and positive student outcomes within college classrooms (Myers 1998, 2002; Myers & Knox 2000; Myers & Rocca 2001). Teacher argumentativeness was conceptualized as the predisposition to defend one's position while attempting to refute another's position and is considered to be a positive communication trait. Teacher verbal aggressiveness is any message that attacks a student's self-concept to deliver psychological pain and is considered to be a negative communication trait. The results of these investigations do support the notion that perceived instructor argumentativeness in the classroom is positively related to student outcomes while teacher aggressiveness is negatively related to positive classroom outcomes. Related to this work is the finding by McPherson et al. (2003) emphasizing the distinction between teacher assertive displays within the classroom, which are perceived by students to be appropriate, and teacher aggressive displays within the classroom, which are perceived to be inappropriate.

Numerous additional variables related to teacher communication style have recently been investigated and related to positive student and teacher outcomes within the classroom. For instance, teacher self-disclosure (Cayanus 2004), teacher humor (Wanzer & Frymier 1999), and positive facework by teachers (Kressen-Griep 2001) have all been shown to produce positive student and teacher outcomes within the classroom.

## Teacher Confirmation

*Kathleen Ellis*

*University of Colorado at Colorado Springs*

Teacher confirmation is the transactional process by which teachers communicate to students that they – the students – are valuable, significant individuals. Like other affective variables such as teacher immediacy and teacher caring, studies indicate that perceived teacher confirmation plays a very important role in students' learning (→ Teacher Communication Concern; Teacher Immediacy).

Philosopher Martin Buber (1957) was the first to write about confirmation in an interpersonal sense. He argued that confirmation may well be the most significant feature of human interaction, and that it is the interactional phenomenon by which we discover and establish our identity as humans. British psychiatrist Laing (1961) further developed the construct and emphasized that confirmation includes *actions* on the part of others that cause individuals to feel *endorsed*, *recognized*, and *acknowledged* as unique, valuable human beings. Disconfirmation, on the other hand, negates the other as a valid message source and communicates to the other that he or she is less than human, that he or she is merely a *thing*, an object in the environment, worthless and insignificant as a human being.

Although empirical research about confirmation is limited, much progress has been made toward the clarification of confirmation theory and the identification and systemization of specific communication behaviors that are likely to influence individuals in such a way that they feel confirmed or disconfirmed. Sieburg (1973, 1975) initiated this effort when she extracted the basic dimensions of confirmation and disconfirmation from the conceptual framework provided by Laing (1961) and the descriptive work by Watzlawick et al. (1967). According to the Sieburg (1975) and Cissna and Sieburg (1981) typology, confirmation includes the interrelated clusters of (1) recognition, (2) acknowledgment, and (3) endorsement. Disconfirmation includes (1) indifference, (2) imperviousness, and (3) disqualification of the speaker, his or her message, or both.

Empirical work is just beginning regarding the role of confirmation in instructional settings. Building upon the theoretical underpinnings just described, Ellis (2000) developed a typology of teacher confirmation behaviors and validated a measure of perceived teacher confirmation that delineates specific teacher behaviors students identified as confirming or disconfirming. Analysis of data obtained through student focus groups revealed four general categories of behavioral patterns through which teachers communicate confirmation: (1) teachers' response to students' questions and comments

(→ Teacher Feedback), (2) demonstrated interest, (3) teaching style (→ Teacher Communication Style), and (4) absence of disconfirmation. Teachers' response to students' questions includes taking time to answer students' questions fully and listening attentively when students ask questions or make comments during class. Demonstrated interest includes making an effort to get to know students, showing interest in whether they are learning, and communicating a belief that students can do well in the class. A confirming teaching style is interactive and employs a variety of teaching techniques to help students understand course material. Absence of disconfirmation includes the avoidance of teacher behaviors such as rudeness, belittling, and embarrassing students in front of the class.

Using two samples, Ellis (2000) explored the relationship between perceived teacher confirmation and learning (→ Learning and Communication) and found that perceived teacher confirmation is a strong, significant predictor of learning, uniquely explaining 30 percent of the variance in affective learning and 18 percent of the variance in cognitive learning. She also found that the effect on cognitive learning was mediated through affective learning. In subsequent studies, Ellis (2004) examined students' actual feelings of being confirmed and disconfirmed as a function of the perceived teacher behaviors previously identified. Findings indicated that 61 percent of the variance in students' feelings of confirmation was attributable to perceived teacher confirmation. Ellis (2004) also examined *how* teacher confirmation operates in the instructional process to influence students' receiver apprehension, state motivation, and learning. She found a very large and direct effect of teacher confirmation on receiver apprehension and large indirect effects of teacher confirmation on motivation, affective learning, and cognitive learning. Thus, the effect of teacher confirmation on learning appears to be mediated through receiver apprehension.

Results of these early studies clearly attest to the importance of teacher confirmation in instructional settings. One may reasonably ask, however, how confirmation differs from immediacy. Although Ellis (2000) demonstrated that the constructs are not completely redundant, given the potency of teacher confirmation reported in the existing studies, it is not unreasonable to speculate that confirmation may actually include immediacy. Confirmation may well be the underlying latent variable of immediacy as well as of several other affective variables that appear in instructional communication literature. All are conceptually and empirically overlapping, yet each is important and contributes to our knowledge of communication behaviors that characterize effective teaching.

## Teacher Feedback

*Timothy P. Mottet*

*University of Texas-Pan American*

Teacher feedback is considered one of the most powerful instructional variables in terms of enhancing student achievement (Hattie 1993). Because teaching and learning are relational processes, teachers are both sources and receivers of feedback (→ Classroom Student–Teacher Interaction). Teachers provide feedback to their students about their learning and they receive feedback from their students about their teaching.

Ilgen et al. (1979) defined feedback from a source to a recipient as information about the correctness, accuracy, or appropriateness of the recipient's past performance. As sources of feedback, teachers encode and convey verbal and nonverbal messages to students either face-to-face or through some form of mediation, such as written comments, regarding students' past performance. As receivers of feedback, teachers receive and decode messages from students either face-to-face (i.e., students' responsive behaviors) or through some form of mediation (i.e., teacher evaluations) regarding teachers' past performance.

### CHARACTERISTICS OF EFFECTIVE FEEDBACK

Feedback messages have a number of common characteristics: valence, timeliness, specificity, frequency, and sensitivity (Cusella 1987). Feedback valence refers to perceived attractiveness or value of the information conveyed. Positively valenced feedback consists of messages implying that the recipient's behavior or performance was satisfactory. Negatively valenced feedback consists of messages implying that the recipient's behavior or performance was unsatisfactory. Although the valence of the feedback may be the most important characteristic influencing how students accept teacher feedback, the timeliness, specificity, frequency, and sensitivity have also been shown to enhance acceptance. Timeliness centers on how quickly a feedback source provides feedback after the performance occurs. Specificity refers to the level of detail contained in the feedback

and focuses on what behaviors need to be changed. Frequency refers to the number of times feedback is given. Sensitivity refers to whether or not the feedback demonstrates a concern for the recipient's feelings. Students learn more and are more motivated to learn when their teachers provide them with feedback that is timely, specific, frequent, and sensitive (Kluger & DeNisi 1996).

## TEACHERS AS SOURCES OF FEEDBACK

### Types and Effects of Teacher Feedback

Researchers have identified three large classifications of teacher feedback: classroom management feedback, teacher–student interaction feedback, and competency-based feedback. *Classroom management feedback* functions to manage students' behavior and work habits. It tends to be negative, reactive, and focused on procedures rather than academic performance. Examples of this type of feedback include reprimand, criticism, and disapproval focusing on students' neatness, deportment, timeliness, compliance, attention, and work completion. Morgan (2001) concluded that negative managerial feedback decreased students' activity interest, self-perceived competence, liking for the teacher, and willingness to work with the teacher. Another type of classroom management feedback is referred to as behavioral alteration techniques (BATs; → Classroom Management Techniques; Classroom Power). This type features 11 pro-social and 7 antisocial techniques that are directed at managing students' on-task behavior (Kearney et al. 1984). Pro-social techniques are feedback messages that students perceive as potentially rewarding; students perceive antisocial techniques as potentially punishing. Numerous studies confirm the benefits of pro-social strategies, including increased student learning, motivation, and compliance, and reduced student resistance (Roach et al. 2006; → Teacher Influence and Persuasion).

*Teacher–student interaction feedback* occurs within the context of a teacher–student dialogue and involves feedback that teachers give to students when they answer teachers' questions. This type of feedback functions to enhance student learning and critical thinking. Three types of interaction feedback have been identified: three-term contingency feedback, differential feedback, and instructive feedback. Three-term contingency feedback is when a teacher asks a student a fact-based question, the student responds with an answer, and the teacher immediately comments on the correctness of the student's response (→ Classroom Questioning). Differentiated feedback is when teachers vary their feedback based on the type of response they receive from the student. For example, if a student's response is correct, quick, and firm, then a short statement of acknowledgment is appropriate. If a student's incorrect response is due to a lack of knowledge or understanding, prompts or cues that lead the student to the correct response are appropriate. Instructive feedback is when teachers consistently add supplemental information to students' responses, allowing students to acquire more information while using the same amount of instructional time it takes to simply recognize that the response was correct.

*Competency-based feedback* functions to enhance students' academic ability and performance. There are two types of competency-based feedback – process and product. Process

feedback (also known as formative feedback, corrective feedback, or elaborated feedback) is the feedback that teachers provide to students while students are preparing their assignments. An example of this type of feedback would be students submitting drafts of their work to their teacher before the due date, which allows the teacher an opportunity to provide corrective feedback while the student develops the assignment. Research suggests that there is a positive relationship between formative feedback and student learning (Bloom 1976). Mastery learning occurs when students perform at the optimal level and is promoted by teachers incorporating a number of feedback loops into the development of an academic product (→ Learning and Communication). Mastery learning is also more likely to occur when teachers use elaborated feedback, which includes specific, detailed, and timely information on how students can enhance the quality of their work.

Product feedback (also known as summative feedback, outcome feedback, or knowledge of results feedback) is the feedback that teachers provide to students once students are finished with their assignment or academic product. This type of feedback is to inform students of the correctness or the incorrectness of their work. One type of product feedback is speech evaluation, or the feedback teachers provide to students following an oral presentation (Rubin 1999). Speech evaluation feedback can be given to students in an oral (a conversation) or written (using checklists, rating scales, or open-ended critiques) manner. Although students appreciate receiving positive rather than negative feedback about their speech performances, they remain receptive to negative feedback that is specific and impersonal. Specific feedback is detailed and concrete, and addresses in a step-by-step manner the speaking behaviors that need to be changed. Feedback that focuses on fewer behavioral changes is more effective than feedback that includes a long list of behaviors. Impersonal feedback or comments that focus on aspects of the speech rather than on the speaker are more helpful than personal ones, especially when the feedback is directed at aspects of delivery (Rubin 1999).

### **Student Characteristics that Impact Teacher Feedback**

Teachers provide different types of feedback to male and female students. A comprehensive meta-analysis conducted by Jones et al. (2006) found that although teachers initiated more overall interactions with male than with female students, teachers also reprimanded and negatively critiqued male students more than female students. This research analysis did not reveal any significant differences in the amount of positive teacher feedback between male and female students.

Teachers also provide different types of feedback to students based on their own expectations for student achievement. An expectation is an inference that teachers make about the present and future academic achievement and general classroom behaviors of their students (Rosenthal & Jacobson 1968). Expectations are formed by such individual differences as student personality, social style, physical attractiveness, seating location, writing neatness, nonverbal responsiveness, and speech characteristics (Brophy & Good 1974). These effects were first reported in Rosenthal and Jacobson's (1968) classic study examining how teacher expectations of students influenced their teaching and interactions with students.

Teachers have been shown to provide high- and low-expectation students with different types of feedback:

- Teachers respond to incorrect answers from low-expectation students (more so than those from high-expectation students) by giving them the answer or calling on another student to answer the question.
- Teachers respond to incorrect answers from high-expectation students by giving them additional time, repeating the question, providing a clue, or asking a new question.
- Teachers criticize low-expectation students proportionately more frequently than high-expectation students when they provide wrong answers.
- Teachers are less likely to praise low-expectation students when they provide a correct answer than high-expectation students, even though they provide fewer correct responses.
- Teachers are less likely to publicly confirm or reaffirm the correct responses of low-expectation students.
- Teachers are less nonverbally responsive (less eye contact, smiling) to low- than to high-expectation students (Brophy & Good 1974).

### **TEACHERS AS RECEIVERS OF FEEDBACK**

Because of the relational nature of teaching and learning, teachers are also receivers of two types of student feedback. Process-related student feedback is the feedback that students provide teachers while they are teaching. Product-related student feedback is the feedback that students provide teachers once the grade level or course is completed. Both process and product forms of student feedback have been shown to impact teachers and their teaching.

Students provide process feedback to their teachers while they are teaching in the form of responsive behaviors. Verbal responsive behaviors include answering the teacher's or other students' questions. Positively valenced nonverbal responsive behaviors include forward body leans, head nods, note taking, and vocal assurances. Many teachers are aware of student responsive behaviors and use these behaviors as feedback information to enhance their teaching effectiveness.

Students' responsive behaviors, especially nonverbal responsive behaviors, have been shown to affect teachers' self-perceptions, perceptions of students, and instructional behaviors (Mottet et al. 2006). As students' positively valenced responsiveness increases, teachers report being more satisfied in their teaching career, consider themselves to be more self-efficacious in their teaching, and are more motivated to teach. Teachers perceive responsive students to be more intelligent, caring, trustworthy, and likeable than less responsive students. Teachers are more willing to let their responsive students influence them and their teaching behaviors than their less responsive students. Finally, as student responsiveness increases, teachers are more willing to comply with students' requests and are more lenient in how they evaluate students' written work and oral presentations (Mottet et al. 2006).

Students provide product feedback to their teachers at the end of a grade level or once the course is completed, in the form of student grades and students' teacher evaluations.

Both of these sources of product feedback have been shown to affect teachers and their teaching behavior. With primary and secondary teachers, high-achieving students positively impact teacher attitudes as well as teachers communicating positive expectations to students' next grade level instructor (Brophy & Good 1974). In higher education, students' teacher evaluations have been shown to affect instructor grading leniency (Eiszler 2002) as well as tenure and promotion decisions (Kennedy 1997).

# Teacher Immediacy

*Janis Andersen*

*Emerson College*

*Peter Andersen*

*San Diego State University*

Teacher immediacy is the term used to describe communication behaviors that reduce the perceived distance between teacher and students. By definition, immediacy behaviors convey teacher warmth, communicate positive relational affect, signal approach and availability for communication, and create increased physiological arousal in receivers. Introduced in research based on her dissertation, J. Andersen (1979) identified teacher immediacy as a nonverbal construct and sought ways to measure the impact of teacher immediacy on instructional outcomes. Now, with the accumulation of nearly three decades of research on teacher immediacy, the substantial influences of teacher immediacy in creating positive instructional outcomes are well understood (Witt et al. 2004).

The construct of teacher immediacy was theoretically grounded in → interpersonal communication research on immediacy, interpersonal warmth, and intimacy (→ Intimate Talk with Family and Friends). A parallel body of literature has developed detailed theoretical models that explain the processes of intimacy exchange and describe how the immediacy behaviors function in close relationships (P. Andersen et al. 2006; → Relationship Development). Theoretically, immediacy is encoded and decoded as a “gestalt,” meaning that perceptions arise from an overall impression of the degree of immediacy behaviors rather than from single cues. Nonverbal cues that contribute to the gestalt impression of immediacy include increased eye contact, smiling, positive head nods, closer distances, more direct body angles, greater vocal variation, more touch, more time spent together, and increased gestural animation (→ Rhetoric, Nonverbal; Nonverbal Communication and Culture; Nonverbal Signals, Effects of). Verbal immediacy involves the use of inclusive first-person plural pronouns (e.g., *we* rather than *you and I*), of informal forms of address, of names, of self-disclosure, and the confirmation of others’ statements (Andersen 1998; → Classroom Student–Teacher Interaction).

Several approaches have been used to *measure teacher immediacy*. Most of the research-based claims about nonverbal teacher immediacy have employed summative Likert-type instruments that ask participants or observers to rate their perceptions of a group of nonverbal immediacy behaviors (Andersen & Andersen, 2005; → Scales; Scales and Indices). A few studies have employed → coding of actual teacher behaviors, often in combination with perceptual measures, and some have used holistic or “molar” generalized immediacy measures. Verbal teacher immediacy (Gorham, 1988) has employed similar summative self-report methodologies. Although the → validity of verbal immediacy measurement has been questioned (Robinson & Richmond, 1995), research continues to explore verbal immediacy. Finally, some researchers have utilized a combined measure of nonverbal and verbal immediacy.

Historically, more research has been done on nonverbal immediacy than on either verbal immediacy or the combination of verbal and nonverbal immediacy (McCroskey et al. 2006). This *emphasis on nonverbal communication* in immediacy studies is consistent with research on nonverbal communication generally that suggests that nonverbal behavior is the primary vehicle for the communication of affect. The primary finding from this large body of research is that teacher immediacy has a major positive effect on classroom affect, or liking. The evidence is extensive and consistent that immediate teachers produce increases in affective-based student learning outcomes. Students evaluate the class, the teacher, and the subject matter more positively when teachers display more rather than less immediacy. Immediate teachers are more motivating to students and students are more likely to develop positive attitudes toward the class, attend class more, and approach rather than avoid the subject (Witt et al. 2004; → Learning and Communication).

More immediate teachers also produce positive consequences for *cognitive learning*, but the effect is smaller than that for affective outcomes and less consistent. When student perceptions of cognitive learning are employed as the dependent variable, studies demonstrate moderately large increases in perceived cognitive learning. Smaller and less consistent impacts of immediacy on cognitive learning have been observed in other studies that employ more direct, objective measures of cognitive learning. These small effects may nevertheless be important. Immediacy can motivate cognitive learning in some settings and not others due to the variability of complex, naturally occurring instructional settings. Furthermore, the real impact on cognitive learning may be delayed because student affect increases motivation, which mediates long-term learning. Finally, some of the impact of teacher immediacy on cognitive learning may be attenuated by other more influential factors that predict test and grade outcomes, such as effort, intelligence, and background.

For the studies in the US, the relationship between teacher immediacy and teacher effectiveness is at some point a curvilinear one, with extreme immediate behavior perceived as inappropriate, resulting in negative outcomes even on perceptions of affect. Furthermore, Titsworth (2004) found that naturally occurring low immediacy was actually better than high immediacy in predicting the extent of note taking and note organization in a lecture environment, suggesting a possible distraction effect of immediacy. The power of teacher immediacy has been abundantly demonstrated in American instructional settings. The few findings from global settings suggest that immediacy generally *functions similarly across the world*, though the effects may be smaller.

## Teacher Influence and Persuasion

Patricia Kearney

California State University, Long Beach

Teaching is a social influence process. Teachers influence students to learn. Influencing students to learn requires teachers to find ways to change students' existing attitudes, beliefs, and behaviors. Teachers may need to induce a positive attitude toward learning mathematics or science. They may need to alter students' beliefs about the causes of World War II. Teachers may need to encourage students to read more books. In order to effect such changes, teachers need to strategize ways to influence, motivate, or persuade students.

This process of → persuasion, or the selection of verbal and nonverbal messages to effect change, is fundamental to teacher effectiveness. Persuasion always involves communication. The source of communication, or the teacher, seeks to elicit a particular, desired response from the receiver, or the student. The purpose of the communication is to change, modify, or shape the student's responses. Classroom persuasion involves a conscious effort to influence students' thoughts and behaviors.

Influence involves change; intentional influence involves a plan, a strategy, application, and persistence. From this perspective then, effective teachers are proactive and skilled persuaders. The teacher identifies specific attitudes, cognitions, or behaviors to be targeted, and deliberately designs messages intended to elicit those changes in the student. Most of what we know about learning is a product of persuasion. Influencing students to learn, then, is, by definition, what teachers do.

## HOW TEACHERS INFLUENCE

Researchers have examined the various approaches teachers use to influence students to learn, both in and out of the classroom. *Classroom management strategies*, for instance, are designed to influence active student involvement, minimize student interference, and maximize efficient use of teacher time (→ Classroom Management Techniques). The appeal of this perspective has its roots in a line of research in educational psychology demonstrating that the single best predictor of learning is academic engagement time (Woolfolk 2001). For example, teachers who are “with it” are keenly aware of what is going on in the classroom at all times, allowing them to notice problems early and put a stop to them. Being able to deal with more than one task at a time, or what Kounin (1970) calls overlapping, is another characteristic of effective classroom managers. Momentum is measured by the absence or presence of downtimes or slowdowns during instruction. During downtimes, students are likely to find alternative off-task behaviors more entertaining and engaging (Burden 1995; Charles 1996; Plax & Kearney 1999). In these and other ways, teachers are deliberately and proactively influencing students’ on-task behaviors (→ Learning and Communication).

Another type of teacher influence occurs during *mentoring* (Waldeck et al. 1997). Students who are mentored receive academic, career, and social support, influencing greater student retention, persistence, and success. Similarly, teachers who make content relevant intentionally influence students’ willingness to attend, perceive, and retain information important to them. Teachers might also influence students in ways that *motivate* them to come to class prepared, study for tests, and enjoy the process of learning. Teachers who communicate *caring* or concern stimulate and influence student perceptions of teacher trust. At the same time, students evaluate the course and teacher positively and report greater learning with caring teachers (Teven & Hanson 2004; → Mentoring).

Teachers also avail themselves of a number of *power-based strategies* designed to obtain student compliance (→ Classroom Power). Conceptualized and operationalized as behavioral alteration techniques (BATs) and behavior alteration messages (BAMs), these strategies are used by teachers to influence or manage students’ behavior and misbehavior (Kearney et al. 1984; Kearney & Plax 1992). In all of these ways and more, teachers strategically and proactively influence their students’ attitudes, beliefs, and behaviors.

## HOW STUDENTS RESIST TEACHER INFLUENCE

Research indicates that students are not entirely open to teacher influence. In fact, US elementary and secondary public and private schoolteachers cite student discipline and disruptions as important reasons for leaving the profession (Ingersoll 2001). Even college professors are not immune to student problems, with one in five students reporting resistance attempts. Inductively deriving from college students themselves the ways they have resisted teacher influence attempts, Burroughs et al. (1989) identified 19 different student resistance techniques. Strategies range from avoidance and reluctant compliance to deception, disruption, and excuses. Further efforts to define the underlying dimensions of resistance resulted in two primary types: teacher owned and student owned. Teacher-owned strategies are those where students assign responsibility or blame to the teacher

(e.g., “The teacher is incompetent”); student-owned techniques are those where the students assign ownership or blame to themselves (e.g., “I forgot to do my homework”).

Subsequent research examined the predictors of students’ resistance decisions and the strategies they select (Kearney et al. 1991). These researchers reasoned that students make decisions about whether to resist or comply as a function of what their teachers say and do. In addition, they argued that students will selectively choose how they resist based on the attributions they make of their teachers (Kearney & Plax 1992). They discovered that students are more likely to comply with nonverbally immediate teachers or those who are approachable, warm, and open, but are more likely to resist those who are non-immediate or who appear as unapproachable and distant. Compliance or resistance was also a function of the type of persuasive strategy the teacher used (→ Persuasion and Resistance). Teachers who relied on more pro-social or positive persuasive techniques were associated with greater student compliance; those who used more antisocial or punishment-based techniques were associated with greater resistance. Of the two predictors, immediacy and strategy type, immediacy dominated students’ decisions to comply or resist. Moreover, immediacy was the more powerful predictor of how students chose to resist, with students opting for student-owned techniques with immediate teachers and teacher-owned techniques with non-immediate teachers. Important to this program of research, these findings demonstrated that teachers can control whether students decide to comply or resist, and they have the potential to control the ways in which students choose to resist (→ Teacher Immediacy).

### PREDICTORS OF TEACHER INFLUENCE EFFECTIVENESS

The ability to influence students effectively is a function of a number of teacher antecedents, including immediacy, credibility, and confirmation, among others. Defined as physical and/or psychological closeness, nonverbal immediacy signals relational perceptions of approach, friendliness, warmth, and interpersonal closeness. *Nonverbal behaviors* indicative of immediacy include positive head nods, smiles, eye contact, vocal expressiveness, overall body movements and physical gestures, direct, relaxed, and open body positions, and close physical distances (→ Nonverbal Signals, Effects of). Without exception, the research on teacher immediacy has established a substantial and positive association with students’ affect toward the teacher, school, and course content, and to a lesser extent, with students’ cognitive learning (Rodriguez et al. 1996). Moreover, students are more compliant or less resistant to immediate, as opposed to non-immediate, teachers (Kearney & Plax 1992). Immediate teachers, then, have more influence potential than non-immediate teachers.

When persuading an audience, Aristotle argued that a *source’s credibility* may be the most powerful rhetorical strategy available. Typically defined as perceived believability (McCroskey 1998), credibility encompasses perceptions of competence, character or trust, and caring. When students find their teacher knowledgeable about the content, trustworthy and honest, and communicating concern about their learning, it is not at all surprising that they would be likely to do what the teacher wants. Credible teachers have the potential to exert a great deal of influence in the classroom. Students report being motivated and learning more from a highly credible teacher; they also evaluate the

teacher highly, enjoy the course, and recommend their more credible teachers to other students (Martin et al. 1997; Pogue & AhYun 2006). The list of positive associations goes on. Teachers perceived as highly credible have a better chance of persuading students to learn and to enjoy the process. With credible teachers, students are motivated to make a good impression and to demonstrate that they are content competent (Myers & Martin 2006).

Yet another social influence strategy available to teachers is → *teacher confirmation*. Defined as those teacher messages designed to endorse, recognize, and acknowledge learners as valuable and significant (Ellis 2000), teacher confirmation is associated with a variety of instructional outcomes. Teachers confirm students in four primary ways. They confirm by responding to students' questions with interest and openness, and by demonstrating a sincere interest and concern for their students. Further, they may use their teaching style to confirm by using a variety of techniques to ensure students' understanding of the course content. Finally, teachers confirm by avoiding disconfirming behaviors, such as rude and embarrassing comments. Teachers who engage in confirming behaviors are also associated with students' motivation to learn, reduced apprehension to communicate in class, increased affective and cognitive learning, and greater power to influence (Ellis 2004; Turman & Schrodt 2006; → Communication Apprehension).

## Teacher Self-Disclosure

Jennifer H. Waldeck

Chapman University

Teacher self-disclosure occurs when teachers intentionally or unintentionally reveal information about themselves to students (Nussbaum & Scott 1979), often concerning their education, experience, family, friends and colleagues, beliefs, opinions, leisure activities, and personal problems (Downs et al. 1988). Moreover, these early studies suggest that teacher self-disclosure is related in various ways to student learning and teachers' overall effectiveness.

Borrowing the construct from the interpersonal literature, in which scholars describe self-disclosure, the act of revealing personal information, instructional researchers Nussbaum and Scott (1979) reasoned that → interpersonal communication is important in the classroom. Thus, they were interested in the nature and effects of teacher self-disclosure; they found that college teachers do self-disclose in the classroom, and that students evaluate those disclosures as intentional/unintentional, entertaining/self-indulgent, risky/safe, and relevant/irrelevant to coursework.

Subsequently, researchers studied the relationships among student perceptions of teacher self-disclosure and a number of *instructional outcomes*. For example, Scott and Nussbaum (1981) reported that student perceptions of instructors' honesty in self-disclosure, combined with their perceptions of teacher style and communication competence, are highly related to students' overall assessment of teacher effectiveness (→ Teacher Communication Style). Downs et al. (1988) reported that teachers who self-disclose and use humor positively influence student perceptions of teacher clarity, but only when the humorous disclosures are relevant to course material (→ Teacher Use of Humor). In another study, Sorensen (1989) found a positive relationship between teacher self-disclosure and student perceptions of affective learning (i.e., student attitudes toward the teacher and course; → Learning and Communication).

At the end of the 1980s, researchers had a *conceptualization of teacher self-disclosure* and an understanding of its role in learning. Researchers then started to incorporate self-disclosure into larger theoretical frameworks that attempt to explain the process and product of instructional communication. For example, Gorham (1988) found that self-disclosure is one verbal strategy that heightens student perceptions of teacher immediacy, a predictor of student affective and cognitive learning and behavioral intent (Christophel 1990; → Teacher Immediacy).

Fusani (1994) was the first to focus on teacher self-disclosure as a dimension of teacher–student interaction outside the classroom in a theory of *extra-class communication* (→ Classroom Student–Teacher Interaction). Bippus et al. (2003) subsequently indicated that undergraduates are much more likely to predict a successful outcome to extra-class mentoring experiences when teacher-mentors provide psychosocial functions, which include self-disclosures (→ Mentoring). More recently, researchers studied the role of self-disclosure in mediated communication. Waldeck et al. (2001) found that “informal and personal communication” is one of three student-reported motivations for using email with instructors, thus revealing another medium for teachers to share relevant personal information that students value (→ Classroom Instructional Technology).

Too much teacher self-disclosure and discussion of certain personal topics may have a *negative influence* on learning outcomes. Specifically, students dislike situations in which teachers stray from the subject with their disclosures, use class time to give personal opinions on unrelated matters, or engage in inappropriate disclosures (e.g., about sexual activity, their feelings about other students, and negative parts of their personality; Kearney et al. 1991). And although teacher disclosures appear to be positively related to student evaluations of all teachers, more experienced, award-winning teachers self-disclose less than other teachers (Downs et al. 1988).

Teacher self-disclosure may be *measured* by (1) quantifiable verbal coding schemes (e.g., Nussbaum et al. 1985), (2) other-reports such as the Perceived Self-Disclosure of Another Person scale (Nussbaum & Scott 1979), or (3) self-reports (Wheless 1978). With the exception of Nussbaum et al.'s scheme, these scales must be modified for the instructional context. Cayanus and Martin (2004) developed and validated an 18-item Instructor Self-Disclosure scale.

Research on teacher self-disclosure has been confined to the college and university setting in the United States. Thus, our understanding of how culture impacts teachers' tendencies to self-disclose and students' perceptions of those disclosures is limited.

Despite the richness of existing work on teacher self-disclosure, more research in diverse and global instructional situations is needed, as is a greater understanding of teacher self-disclosure in the lower grades.

# Teacher Socialization

*Ann Q. Staton*

*Texas Woman's University*

Teacher socialization is a complex, communicative process by which individuals selectively acquire the values, attitudes, norms, knowledge, skills, and behaviors of the teaching profession and of the particular school or educational culture in which they seek to work. It is a widely held view that the effectiveness of teachers, and thus the quality of education, is related to teacher preparation and early teaching experiences. Unlike primary socialization, which occurs from birth, teacher socialization is a form of secondary socialization, a subsequent, ongoing process in which people continually socialize into new realms of their lives. Prospective and beginning teachers have been the main focus of teacher socialization research, on the assumption that socialization occurs during teacher training and the initial years in the teaching position. Researchers acknowledge, however, that teacher socialization also continues throughout the career as veteran teachers change roles and enter new educational environments.

## CONCEPTUALIZATIONS

Communication scholars have utilized various conceptual categories to describe teacher socialization. These include dimensions, phases, and intellectual traditions.

### Dimensions of Socialization

Within the socialization experience of teachers are two distinct, yet interrelated dimensions: role or occupational socialization, and organizational or cultural socialization. Prospective teachers engage in a decision-making process during which they make a cognitive commitment to enter the teaching profession and become members of the occupational group known as teachers. To do so involves at least a tacit assent to learning the role or occupation (i.e., the requisite knowledge and skills necessary to teach effectively; the expectations, functions, and requirements of the teaching profession). This essential dimension is *role or occupational socialization*, which Sarbin and Allen (1968) termed role acquisition or role learning (→ Teacher Training in Communication).

In addition to learning the teacher role, a newcomer must also socialize into an individual school organization and learn the culture of the particular school system. *Cultural or organizational socialization*, a second dimension of teacher socialization, involves learning the norms, social practices, collective understandings, and values of the particular teaching context and educational organization (→ Organizational Culture). In most societies worldwide, educational systems are structured as social institutions, on the assumption that individuals learn through interaction with others. Even as higher education increasingly occurs in online forums, most instruction of children and adolescents occurs within the context of schools, which are social organizations. Thus, not only does socialization involve learning the role or occupation of teacher, the process also requires an individual

to become a member of the particular organization, to learn the culture of the individual school and school system in which she or he teaches or plans to teach (Louis 1980).

Role or occupational and cultural or organizational learning occur as individuals engage in a *range of communication strategies* that Berger (1987) termed passive, active, and interactive. Passive strategies are those such as unobtrusive observation, in which there is an absence of actual contact between individuals. Active strategies involve encounters with others, but with a third party rather than with the most direct source of information. Interactive strategies entail direct engagement between a person seeking to learn a role and a person who has the information or cultural knowledge being sought.

### Phases of Socialization

Teacher socialization is often characterized as a process that occurs in three phases. *Anticipatory socialization* refers both to the choice phase of role socialization, during which a person decides to enter the teaching profession, and to the decision phase of organizational or cultural socialization, during which an individual considers becoming a member of a particular educational institution. An individual first decides to become a teacher, and then selects a school setting.

A second phase of socialization is that of *entry or encounter*, during which a novice experiences a new teaching situation, either the initial teaching role or the first entry into a new school (→ Initial Interaction). *Continuance or adaptation* is the third stage of socialization, during which a novice teacher or a veteran in a new situation makes whatever changes are necessary in order to remain in the profession and/or in the school setting. As the initial reality shock becomes the routine reality, teachers who want to stay in the role and in the environment make adjustments in order to continue. Although adaptation often involves acquiescing to the status quo, another way of adjusting is advocating and effecting change.

### Research Traditions

Three dominant paradigms or intellectual traditions have guided research on teacher socialization: functionalist, interpretive, and critical (Zeichner & Gore 1990). The oldest, most widespread is the *functionalist tradition*, which suggests a deterministic view of teacher socialization as a phenomenon that fits the individual to society, with teachers considered as passive objects of socializing agents (→ Functional Analysis). Research in this tradition focuses on outcomes of socialization and the agents who are influential as catalysts.

A frequently identified outcome is that of dramatic attitude shifts in beginning teachers from progressive and humanistic at the start of their first year to less permissive and more custodial by the end of the year. Agents identified as instrumental in effecting such outcomes include veteran teachers, administrators, and students. For pre-service teachers engaged in internships, critical agents are university supervisors and the cooperating classroom teachers. Inherent in the functionalist tradition is a view of communication as an action in which pre-service and new teachers are objects of socialization and recipients of messages sent from various socializing agents.

The *interpretive* tradition (also known as “conflict” or “dialectical”) stresses the importance of teachers as proactive, creative agents who shape their own roles and environments. Lacey conceives of socialization as going beyond the explanations provided by the functionalists, and presents it as “a more complex, interactive, negotiated, provisional process” (1977, 22) in which individuals engage in conscious choices about their own socialization. Thus, the focus is on understanding the process of socialization, the ways in which it occurs, and the perspectives of the individuals involved, rather than on the outcomes and agents of socialization. The view of communication assumed is that of a dynamic, interactive, transactional process in which novice teachers are active in shaping their own roles as well as the organizational and school culture. Unlike a functionalist tradition, the emphasis in the interpretive tradition is not on the socializing agents, nor on beginning teachers as recipients of communication messages, but on what happens between socializing agents and novice teachers. In this approach, socialization cannot be considered as something that “happens” to newcomers, but is viewed as a dynamic and complex process of communication.

The *critical tradition* is one that “addresses the interplay of micro and macro forces, inside the classroom and beyond, those that social actors are conscious of and those that are taken for granted” (Sprague 1992, 182; → Critical Theory). In this approach, teacher socialization is examined in the context of a person’s biography; in the social, political, and historical context; power; and in the context of ideology. The communication perspective inherent in the critical perspective is not inconsistent with the notion of teachers as active agents, yet also brings to the fore issues of power, gender, race, and class that are embedded in teacher socialization and are considered to be in need of transformation.

### COMMUNICATION FRAMEWORKS

Although communication is considered to be central in the teacher socialization process, there are various theoretical and conceptual frameworks for examining communication in socialization. *Three frameworks* are communication functions, uncertainty reduction, and communication concern.

As a way of examining communication → interactions at a micro-level, communication researchers have utilized Greenbaum’s (1974) descriptive typology of four *communication functions* or purposes. The informative are communication activities and talk related to the exchange of information about tasks – seeking, receiving, clarifying, elaborating. The regulative are communication activities and talk that involve the organizational hierarchy and are related to control, order, direction, and feedback between teachers and subordinates (students) and between teachers and superiors (school principal) in work-related activities. The integrative are communication activities and talk related to the social and relational sphere, maintaining morale, group acceptance, camaraderie, and developing a social support system. The innovative are communication activities and talk related to change, generating new ideas, doing things differently. Analysis of discourse utilizing a typology such as this provides a mechanism for identifying and understanding the process and development of role and cultural socialization.

Originally utilized in communication research by Berger and Calabrese (1975) as a perspective for understanding the early stages of interpersonal interaction in which strangers

meet, the assumption of → *uncertainty reduction theory* is that people seek to reduce their uncertainty about others through communication. Anticipatory and entry phases of socialization are times of uncertainty in which novice teachers face new situations, expectations, people, and environments. There is generally a high need to obtain information about both the teacher role and the culture of the new organization. An examination of communication strategies used to gain information to reduce uncertainty provides a lens for understanding socialization (→ Information Seeking).

A variety of research on the communication concerns of pre-service and in-service teachers supports a conceptual model of teacher concern about self as a teacher, the task of teaching, and the impact of teaching (→ Teacher Communication Concern). *Communication concern* is defined as a constructive frustration or anticipation of a future problem situation that involves interaction with others. Several studies indicate that during the anticipatory and entry phases of socialization, self and task concerns are of foremost importance to novice teachers. Self concerns revolve around both role socialization (e.g., such aspects as their credibility in the teacher role, anxiety about their job performance), and socialization into the new organization (e.g., feelings of not being an integral part of the school culture).

Task concerns also center on both the teaching role (e.g., how to maintain discipline in the classroom) and socialization into the organization (e.g., how major disciplinary problems are handled in the particular school environment). It is through communication that newcomers learn the role expectations and the cultural norms. A communication concerns perspective is also a window for observing and understanding socialization.

Although teacher socialization generally refers to the socialization of pre-service or in-service teachers at the elementary and secondary levels, the experience is a universal one across the range of teaching positions, including community college instructors, graduate teaching assistants, and college or university professors. While the majority of research has been conducted on K–12 teachers, there are studies examining socialization within higher education. Regardless of the educational level or context, teacher socialization is widely considered to occur through communication.

## Teacher Socio-Communicative Style

*Matthew M. Martin*

*West Virginia University*

Socio-communicative style is a presentational communication trait. Teachers with a particular style should communicate in a consistent manner, demonstrating that style over time and in different situations. The constructs of teacher socio-communicative style (how a teacher would perceive himself or herself) and teacher socio-communicative orientation (how students would view the teacher) are based on earlier research into psychological androgyny, social style, personal style, and → communicator style (→ Teacher Communication Style). Measurement of teacher socio-communicative style is based on teachers' levels of assertiveness and responsiveness.

People who are assertive communicators are strong in their interaction management skills; they are able to initiate, maintain, and terminate conversations skillfully. Assertive people are also able to speak up for what is rightfully theirs and are focused on being successful and achieving their goals. Being competitive, dominant, forceful, and independent are characteristic of being assertive (→ Teacher Assertiveness).

Assertive teachers would have control of their classrooms. Others would perceive these teachers as being the leaders of the classroom. Although there may be plenty of student discussion and participation in their classrooms, assertive teachers would make sure the class focused on the task and accomplished the objectives for the class period. Assertive teachers would stand up for their own rights, as well as for the rights of their students.

Figure 1 Individuals classified by style

People who are responsive are other-oriented and considerate of others' feelings. Responsive individuals listen to others and show a general concern for the success of others. Being helpful, compassionate, friendly, and sincere are characteristic of being responsive.

Responsive teachers would be sensitive to the educational and personal needs of their students. These teachers would be viewed as being student oriented or student centered. Responsive teachers would be verbally and nonverbally immediate. Students would describe these teachers as caring and approachable.

Merrill and Reid (1981) classified individuals into one of four styles based on their assertiveness and responsiveness (Fig. 1). *Amiables* are those high in responsiveness but low in assertiveness; *expressives* are high in both responsiveness and assertiveness; *analyticals* are low in responsiveness and assertiveness; and *drivers* are low in responsiveness but high in assertiveness. While the expressive style would appear to be more appealing because of being high in both responsiveness and assertiveness, there are positive and negative characteristics for possessing – or being able to communicate – only in one style. To be successful, people need to be flexible and adapt their style to the situation.

In instructional research involving socio-communicative style – following the lead of Richmond and McCroskey (1990) – the four styles are often relabeled. Amiable becomes *submissive*, expressive becomes *competent*, analytical becomes *noncompetent*, and driver becomes *aggressive*.

Research has shown that, in the classroom, both teacher assertiveness and teacher responsiveness are positively correlated with nonverbal immediacy. Students view assertive

and responsive teachers (i.e., competent) as being more trustworthy and credible. Teachers perceived as having the aggressive style are perceived as being low in character. When teachers are perceived as having the noncompetent style (neither assertive nor responsive), students perceive them as being low in competence and caring, and also express less situational motivation.

Additionally, teachers who engage in both assertiveness and responsiveness are perceived to be more argumentative (→ Argumentative Discourse), whereas instructors low in those constructs (i.e., noncompetents) are viewed as more verbally aggressive (→ Verbal Aggressiveness). Teachers who are argumentative would focus on the content of a disagreement when discussing controversial issues with others whereas teachers who are verbally aggressive would be more likely to make personal attacks on those with whom they disagree. Students also claim that their competent teachers are clearer and that they learn more from competent teachers. Students are more willing to communicate with their teachers inside the classroom, as well as outside the classroom, when they believe their teachers are assertive and responsive.

Although research has demonstrated the value of teachers being both assertive and responsive, researchers have also noted the need to be flexible. There might be situations where a teacher does not want to be assertive, and where assertive communication could actually prohibit the teacher from being successful. The truly competent teacher would have the ability to be assertive and responsive, as well as the knowledge and willingness to be flexible, communicating appropriately and effectively in a given situation.

# Teacher Training in Communication

Pamela Cooper

University of South Carolina Beaufort

An important part of the history of communication, particularly in the US, focused on how to train teachers to teach this subject. From the first issues of the academic journals in the early 1900s (*Quarterly Journal of Public Speaking*) until today, when entire journals provide research reports for and about teachers, the topic has been at the forefront of professional associations, as evidenced in their publications (e.g., *Communication Education, Feedback, Journalism and Mass Communication Educator*) and association names. For instance, the National Communication Association (NCA) began as the National Association of Academic Teachers of Public Speaking (1914–1922) and then the National Association of Teachers of Speech (1923–1945). And the Broadcast Education Association and the Association for Education in Journalism and Mass Communication continue to promote education in their association names.

Despite similar interests around the world, the focus on education has not been reflected in communication publications or learned societies as much as it has in the US (→ Communication as an Academic Field: USA and Canada; Communication as a Field and Discipline; Speech Communication, History of; Educational Communication). Since the roots of teacher training lie in the speech communication field, this entry will concentrate on the three main facets of teaching speech communication: training of speech-theatre teachers, teacher communication competencies, and instructional communication.

## TRAINING OF SPEECH-THEATRE TEACHERS

Until the early 1970s, the training of speech-theatre teachers was termed “speech education.” At that time, most speech communication educators were engaged in secondary teacher education at the pre-service and in-service levels, focusing on the content and skills necessary to teach public speaking, group discussion, debate, oral interpretation, and theatre (Wallace, 1954). For example, teachers were trained in evaluating speeches, directing plays, and directing co-curricular activities. In 1973 speech communication educators met in Memphis, Tennessee, to shape the future of speech education within the speech communication community. Their work resulted in the publication *New Horizons for Teacher-Education in Speech Communication*. The recommendations focused on professional education – rather than on specific skills – for communication educators in three areas: research, pre-service education, and in-service education.

A decade after the Memphis conference, leaders in the field of speech communication envisioned a second national planning conference, the Flagstaff conference. The participants of the Flagstaff conference developed several recommendations for each of the goals. The major recommendations for the speech communication preparation of all teachers and of speech communication specialists focused on the widespread dissemination of the *Teacher Certification/Preparation Guidelines*, endorsed by the NCA. These guidelines included preparation in (1) fundamentals of communication, such as effective listening and ethical standards; (2) public and presentation speaking, such as organizational patterns and

evidence in reasoning; (3) oral interpretation, such as forms of performance literature and voice and movement; (4) argumentation and debate; (5) interpersonal and small-group communication, such as development of self-concept and managing conflict; (6) forensics, such as directing a co-curricular program; (7) mass communication, such as media literacy and media influence; and (8) theatre/drama such as history and performance skills. In addition, the attendees urged the continuing development of certification standards and preparation guidelines for elementary and college-level teachers.

In 2000, the NCA published *Communication Teacher Education Preparation Standards and Guidelines*. This document focused on assessing speech communication teacher education programs. Six quality standards are used to assess the speech communication teacher preparation programs: (1) structure of the program, (2) general studies component, (3) knowledge of communication, (4) professional education and pedagogical studies, (5) professional collaboration and growth, and (6) field-based experiences for communication.

### TEACHER COMPETENCY

In 1973 a joint task force by NCA and the American Theatre Association produced two documents intended to improve pre-service and in-service teacher education and to provide guidelines for certification and hiring. The first, *Competency Models in Speech Communication and Theatre for Preparation and Certification of Elementary and Secondary School Teachers*, provided guidelines for generating specific competency statements and assessment procedures in local programs. It addressed the preparation of speech-theatre media specialists as well as the speech-theatre competencies needed by all teachers. The second, *Guidelines for Speech Communication Theatre Programs in Teacher Education*, focused on the components necessary for an effective theatre education program.

In 1988, an NCA subcommittee of the Committee on Assessment and Testing released a document describing the competencies and skills necessary in teaching (Cooper, 1988). According to this report, teachers should be able to send and receive messages that are: (1) informative (e.g., structure information by using preview questions and comments, transitions, internal summaries, and concluding summaries; and identify the main point of students' informative messages); (2) persuasive (e.g., offer sound reasons and evidence in support of ideas, and recognize underlying assumptions in the arguments of others); (3) affective (e.g., demonstrate openness, warmth, and positive regard for students; be nonjudgmental in responding to students' feelings); (4) imaginative (e.g., use vivid descriptive language and respond to students' use of imagination with appreciation); and (5) ritualistic (e.g., demonstrate appropriate behavior in performing everyday speech acts such as greeting, taking turns in conversation, and taking leave; comment favorably when students perform everyday speech acts appropriately).

### INSTRUCTIONAL COMMUNICATION

Over the past 30 years research in the training of speech/theatre teachers has become nearly nonexistent in the US, while instructional communication has increased substantially. Instructional communication concerns are identified increasingly as the province of communication education. Staton-Spicer and Wulff (1984) list three *categories of research*

*in the area of teacher characteristics*: first, studies of the relationship between various teacher characteristics and student learning; second, teacher characteristics and teacher effectiveness; and third, teacher attitudes and expectations.

While much of the early research in instructional communication focused on individual differences in students (for example, levels of communication apprehension; → Communication Apprehension: Intervention Techniques), much of the research in recent years has focused on the behaviors and orientations of teachers related to communication instruction (→ Classroom Management Techniques; Classroom Power; Teacher Communication Style; Teacher Immediacy; Teacher Influence and Persuasion). Although no general theory of instruction communication has guided this research, two general approaches (relational and rhetorical) have dominated much of the research in instruction communication (McCroskey & McCroskey, 2006).

The *relational approach to instructional communication* has derived from scholarship relating to interpersonal communication, particularly the transactional model of interpersonal communication. This model assumes that teachers and students mutually and simultaneously exchange information and ideas, which results in shared meaning and simultaneous learning. An example of this approach is the “learning communication culture” advocated by Book & Putnam (1992).

The second approach – the *rhetorical approach to instructional communication* – is derived from classical rhetorical theory (→ Rhetorical Studies). The rhetorical model assumes that in instruction, teachers are the primary source of information (including teacher-selected reading material and other instructional aids) and that students are the receivers/learners. Instructional communication according to the rhetorical approach is seen as a teacher-controlled, linear process, where the teacher is the person primarily responsible for creating messages that will stimulate teacher-selected meanings in students’ minds (that is, learning). The teachers carefully design instructional objectives, with specific expectations that students will master the knowledge represented by those objectives. This model is used primarily in the scientific and social-scientific disciplines where specific facts and processes are being taught.

Increasingly, courses are being taught using the findings of both the relational and the rhetorical approaches to instructional communication (Cooper & Simonds 2007; Hunt et al. 2002). These courses are designed to foster the communication competencies of all teachers and are generally *focused on three major areas*: (1) communication competence – classroom communication, interpersonal communication, listening, and verbal and nonverbal communication (→ Student Communication Competence); (2) instructional strategies – the sharing of information, leading classroom discussions, small group communication, and storytelling and communicative reading (→ Classroom Questioning; Classroom Student–Teacher Interaction; Pedagogy, Communication in; Teacher Feedback); (3) communication impact – ethical considerations of influence on students and issues of influence such as power, conflict, handling student misbehaviors, sexism, racism, class, ethnicity, children with special needs, and ways to create a positive classroom climate (→ Learning and Communication).

## **Teacher Use of Humor**

*Melissa Bekelja Wanzer*

*Canisius College*

When teachers use verbal and nonverbal messages to elicit laughter and smiling from students, they employ a teaching strategy labeled *instructional humor*. Classic and contemporary scholarship on this topic has shed light on the benefits of teacher humor, how teacher humor relates to student learning, challenges of studying the relationship between humor and learning, and different types of teacher humor. Instructional communication researchers recognize teacher humor as an important type of immediacy behavior often used to reduce psychological distance between students and teachers and facilitate student learning.

There are a number of benefits connected to the use of humor in the classroom. For example, use of teacher humor can improve the student–teacher relationship by reducing student tension and anxiety and creating more favorable impressions of teachers. Not surprisingly, award-winning teachers use moderate as opposed to excessive amounts of humor in their lectures. Also, college students are more likely to engage in communication outside of the classroom setting with professors who use humor as part of their regular teaching style. The most extensively studied advantage of teacher humor has been its connection to student learning. One explanation for the relationship between humor and learning is the attention-gaining function of humor originally advanced by Ziv (1979). When teachers insert humor into their lectures, students express more interest in the material and are able to maintain their attention for longer time periods than when humor is not used. Additionally, students appear to have an easier time recalling course material later when it is connected to some type of humorous content.

Another explanation for the relationship between teachers' use of humor and student learning is that humor is a type of immediacy behavior that helps gain the students' attention and improve the student–teacher relationship. Immediate teachers enact verbal and nonverbal behaviors strategically to reduce physical and psychological distance between themselves and their students. For example, highly immediate teachers will maintain eye contact, use appropriate gestures, and provide appropriate self-disclosures throughout their lectures (→ Teacher Self-Disclosure).

Research on teacher immediacy has provided almost unequivocal support for the relationship between teacher immediacy and student learning. Instructional researchers note that highly immediate teachers are 63 percent more likely to use humor than teachers low in immediacy (Gorham & Christophel 1990). Highly immediate teachers are also seven times more likely than low immediacy teachers to use noticeable humor such as physical and vocal types. Thus, immediate teachers are able to use humor as a means of establishing relationships with their students and simultaneously affecting arousal, retention, and learning in the classroom (Gorham & Christophel 1990; → Teacher Immediacy).

Results from the humor (teacher)–learning (student) investigations conducted over the years have been quite mixed. Ziv (1988) examined 18 studies that tested the *humor–learning relationship* and identified 11 that found either a direct or indirect relationship between humor and learning and 7 that failed to identify any significant relationship. One explanation for the failed relationship between humor and learning was the short length of some of the studies. In several studies, the length of time individuals were exposed to humorous stimuli may have been too short (e.g., 10 minutes) to affect students' ability to retain information. Another important methodological concern expressed by Ziv and others was the extent to which the humorous stimuli were actually perceived as funny by the study participants. If the humorous material was not perceived as funny, participants may not have been aroused enough to pay attention to the material in the humor condition. Differences in earlier study results may be best explained by examining how studies were conducted as well as how humor was operationalized.

In an effort to sort out why teacher humor may not always affect student learning, researchers began to develop detailed explanations of the different *types of humor* used in the classroom. Bryant et al. (1980) asked students to record and later analyze their

professors' use of humor. The researchers identified six different categories of teacher humor, which they labeled jokes, riddles, puns, funny stories, humorous comments, and an "other" category. The researchers also found that male teachers who used humor were evaluated more favorably than female teachers. Gorham and Christophel (1990) expanded on the Bryant study and found 13 different categories of teacher humor. Examples of teacher humor included, among others, brief tendentious comment directed at a specific student, the class as a whole, or the university, personal anecdotes related or unrelated to the subject matter, and physical or vocal comedy. Gorham did not find any differences in student evaluations of male and female teachers who used humor.

While Gorham and Christophel were able to expand on the types of humor teachers typically use in the classroom, their research did not distinguish between appropriate and inappropriate types. Wanzer and her colleagues asked students to generate examples of *appropriate and inappropriate types* of teacher humor (Wanzer et al. 2006). From this study, four categories and 25 sub-categories of appropriate teacher humor emerged. The four categories of appropriate teacher humor were related humor, unrelated humor, self-disparaging humor, and unintentional/unplanned humor. There were four categories and 27 sub-categories of inappropriate teacher humor identified. The four categories of inappropriate humor were offensive humor, disparaging humor targeting students, disparaging humor targeting others, and self-disparaging humor.

Disposition theory explains why students perceived teachers' use of disparaging humor as inappropriate for the classroom. According to disposition theory, individuals determine whether messages are humorous by considering who is targeted in the humor attempt. Humorous messages that target liked or similar others are typically not perceived as funny by recipients. Wanzer et al. (2006) suggested that teachers use neither humor that disparages the groups that students belong to nor the students themselves.

Now that researchers have a better understanding of the types of humor considered appropriate for the classroom, they can begin to investigate the impact of these types on student attendance, learning, motivation, and quality of the student–teacher relationship.

## Technologically Mediated Discourse

Ian Hutchby

University of Leicester

Communication in today's world is mediated by technologies in a multiplicity of ways. Telephones and mobile phones are integrated into the very cultures of sociability and personal connectivity, especially in large-scale industrialized societies where contacts and relationships are maintained across significant distances. Hopper (1992) characterized such populations as “people of the phone” in an attempt to encapsulate the extent to which telephone conversation is relied upon and even actively sought after, as persons are prone to abandon almost any other activity in order to answer the telephone's summons. Increasingly, too, Internet message exchange systems are coming to play a pivotal role in everyday sociability networks, in the light of growing accessibility of computer hardware and software, burgeoning of technological sophistication, especially among the younger population, and expansion of broadband connectivity linking home computers to the Internet.

In a wider sense, the interface between ordinary people and the professional spheres of politics, finance, education, health, and so on operates more and more via technological mediation: for example, television and radio news and interview broadcasts, automated inquiry systems, web-based information gateways, and interactive electronic devices of numerous types. In the world of work (particularly white-collar work), communication is increasingly technologized: from the ubiquitous office phone and email systems, to Internet and video conferencing, to the expert systems frequently deployed in command and control centers for public utility and transport services.

For language and social interaction researchers, broad sociological themes such as these translate into questions of the relationship between structures and patterns of interpersonal communication and the enablements and constraints – or *affordances* (Hutchby 2001) – of technologies used in mediating social interaction. The main areas in which researchers have turned their attention explicitly toward the nature of technologically mediated discourse are radio and television broadcasting, telephone conversation and mobile communications, computer-mediated interaction, and expert systems at work.

### **RADIO AND TELEVISION: COMMUNICATION AND THE OVERHEARING AUDIENCE**

Radio and television talk has a specific character which serves to differentiate it from the vast majority of institutional forms of discourse, and which therefore provides a

specialized set of questions to which researchers in language and social interaction have been drawn to address themselves (→ Broadcast Talk). One feature of particular relevance stems from the fact that its principal intended recipients are not co-present but distributed, physically, geographically, and often temporally. There may be co-present audiences in the studio setting, and that collection of recipients may act as a “mass” audience in the traditional sense. But even then there is a further layer of recipients who are not only physically absent but individually distributed. Given these conditions of production and reception, the issue is one of how broadcast talk is mediated and distributed to its various recipient constituencies.

Much of the work in this area has begun from the perspective of → conversation analysis (CA). For CA, broadcast talk is a form of institutional discourse and its different genres are characterized according to the relative formality or informality of their turn-taking systems. For example, in the case of news interviews, a particular type of question–answer structure provides the oriented-to means by which the institution of the broadcast interview is produced and sustained by participants, but also the means by which interviewers can be adversarial within the constraints of journalistic neutralism (Clayman & Heritage 2004). In the case of radio phone-ins, a much more informal system of turn exchange nevertheless yields observable features of institutionality and orientation to the public, broadcast nature of the talk (Hutchby 1996). In the case of genres such as audience participation debate shows, structures of turn-taking and utterance design can reveal ambivalence in the nature of broadcast talk (Tolson 2001). On the one hand, during confrontations being played out face-to-face on the platform, it is not obvious to what extent the speakers exhibit a mutual orientation to the relevance of an overhearing audience. On the other hand, the design of hosts’ turns in particular reveals an orientation to framing confrontations in terms of the involvement of an audience (both absent and co-present). The question of how broadcast talk is designed for reciprocity by an absent, “overhearing” audience has been central to many studies in this area (Hutchby 2006).

### **TELEPHONY: INTIMACY AT A DISTANCE**

The telephone is a technology that for over a century has allowed people to speak with the intimacy of face-to-face conversation without being physically co-present (→ Telephone Talk). Conversation analysts have investigated the nature of talk and reciprocity on the telephone in some detail (Hopper 1992; Hutchby 2001). While most of the sociological attention that has been given to the telephone has focused on questions of the broad social and cultural impacts of the technology without paying much attention to telephone interaction in itself (Pool 1981), language and interaction researchers have focused on revealing the technology’s impacts at a more local interactional level.

For instance, around the telephone’s affordance for intimacy at a distance there have evolved distinctive forms of conversational opening and closing sequences. In relation to this, the properties of the telephone’s ring itself can afford novel possibilities for patterns of interaction. For example, dimensions of accountability surround apparently minor issues such as how quickly we pick up the phone, how we respond to call-waiting tones, or whether we use answering machines as call-screening devices (Hopper 1992). The range of social contexts in which telephone calling and answering take place also

afford the development of a whole range of new, interactionally relevant forms of social identity (→ Social Identity Theory). For example, analysis of calls can reveal a micro-politics of power around what Hopper termed “caller hegemony”; or around the different responsibilities of callers, answerers, and “not-called” answerers (“gatekeepers”; Hutchby 2001).

The advent of *mobile telephony* yields further possibilities for extending this research. Here, technological elements such as caller identification, along with social factors such as the personalization of phone handsets and the de-anchoring of the phone and its user from singular physical locations, lead to changes in the structures of communication, especially in terms of opening exchanges and the organization of topic initiation (Hutchby & Barnett 2005; → Mobility, Technology for).

### **ONLINE INTERACTION: TEXTUAL “TALK” AND TEMPORALITY**

The Internet affords new and distinctive forms of mediated interaction (→ Internet, Technology of). Here newsgroups and Internet “chat” domains have grown up as spaces in which participants can interact, albeit largely through a textual rather than a verbal medium, while being geographically distributed. Studies of online interaction have foregrounded *temporality* as a dimension of additional relevance. Newsgroup interaction tends to be asynchronous, in the sense that participants leave messages that can be retrieved at any time by others (Baym 1996). Internet relay chat (IRC), on the other hand, is quasi-synchronous: participants need to be online at the same time in order to contribute to the discussion, but the technological mediation introduces a temporal lag between turn production and reception, which renders turn-taking problematic. For example, participants in this environment may experience difficulties relating “current” and “prior” or “current” and “next” turns because other turns may intervene as their own is being typed out or distributed via the network server (Garcia & Jacobs 1999).

IRC enables an escape from traditional paradigms of social interaction, which are based on the centrality of presence (even on the telephone, our interactant is “present” at the other end of the line; in broadcasting, personalities are visually or sonically present). One upshot of this relative anonymity is that users can feel freer than in co-present interaction to breach the social boundaries which humans ordinarily place around interaction with strangers (Reid 1991). Nevertheless, online interaction is mediated not only by the technology of Internet servers and computer terminals, but also by a unique hierarchy of participant statuses. While aspects of IRC encourage users to play with the conventional limits of expression, breaking the boundaries of social etiquette, the participants appear to be attempting to form themselves into “communities” with distinctly structured behavioral norms, forms of expression, and the rest (→ Language and the Internet).

### **EXPERT SYSTEMS: ADAPTING TO THE TECHNOLOGY**

Computer technologies such as expert systems and those for supporting cooperative-work-based tasks also operate as media for communication of a certain sort. Such systems, typically deployed in workplace environments, are designed ostensibly to assist

or complement human workers in carrying out specific tasks. But they do not operate in abstraction from human work and communication, and the humans who work with them need to find ways of incorporating into their interactions with each other the demands and constraints that emerge from the design of the systems. At the same time, there are ways in which the technological artifacts themselves can be seen as “participants” in the interaction, at least in the sense that their outputs (such as words or pictures on a screen) can become oriented to as “contributions,” which are the subject of mutual, active, and collaborative sense-making on the part of humans (→ Computer–User Interaction).

When we encounter such technologies we are often invited into a form of dialogue with them (Suchman 1987). For instance, computer screens make suggestions for us, give us instructions, and ask if we really want to do what we have just instructed the system to do. There are two choices here: either we try to make the technology conform to our existing ways of accomplishing actions, or we adapt to the modalities of action and interchange programmed into the technology. Studies of how doctors use their computers when consulting with patients have suggested that the system itself, and its “activities” (whatever is happening on the screen), can become an intrinsic part of the conversation (Greatbatch et al. 1993). The consultation, in other words, becomes modeled according to the technology’s requirements. However, from the opposite angle, studies of how expert systems are implemented in complex decision-making environments such as emergency services dispatch have indicated that humans often end up working around the technological imperatives of the system because their own situated knowledge and interactive flexibility are better fitted to the rapidly changing nature of the environment in which they are working (Whalen 1995).

Lastly, we increasingly communicate “with” certain forms of technology. Although they have not yet reached particularly high levels of conversational sophistication, speech-generating computers and artificial intelligence systems are increasingly encountered in information seeking and other basic service encounters. Designers of more advanced systems are attempting to build computers that could hold “conversations” with humans (Luff et al. 1990), and this prompts the questions of what those conversations will look like, whether they will manifest any significant differences with human–human conversation, and also, significantly, what implicit assumptions about the nature of human interaction will underlie the design of such systems.

# Technology Assessment

Gordon Gow  
University of Alberta

There are numerous approaches to technology assessment but it is essentially a systematic method for exploring technology developments and assessing their potential societal effects. It was typically implemented as a strategy to inform policy decisions within government and industry but now includes a growing body of scholarly research in science and technology studies (Herdman & Jensen 1997; Hill 1997; La Porte 1997). As a research strategy, technology assessment is best viewed as a pragmatic arrangement of theory and method emphasizing one or more concerns: the design and development of an emerging technology; a known technology-related social or environmental problem; or the introduction of a new technology into society (Porter 1980, 51).

## CONSTRUCTIVE TECHNOLOGY ASSESSMENT

One influential approach that attempts to combine all three concerns is known as constructive technology assessment (CTA). This approach was first developed by the Netherlands Organization of Technology Assessment (NOTA), now known as the Rathenau Institute, along two major paths: by introducing public participation in the technology assessment process, and by the funding of several key studies looking at the value of introducing technology assessment in the early design stage of a technology project.

CTA represents an important contrast with the so-called “early warning” approach of technology assessment as it developed in North America during the middle of the

twentieth century. Whereas proponents of early warning technology assessment, such as the United States Office of Technology Assessment (OTA), tended to adopt an *exogenous* model of technology development for their research projects, the CTA approach was conceived within a participatory *endogenous* model of technology development (Eijndhoven 1997). Whereas an exogenous model anticipates a finished technology that enters into and creates effects in a society (Edge 1995), practitioners consider CTA to be a “new design practice” wherein technologies are socially constructed by numerous stakeholders acting within and attempting to influence a social and political context. Technology projects are viewed as highly contingent undertakings open to a range of alternative development paths and an opportunity for “societal learning” (Schot & Rip 1996, 255).

Following the tradition of constructivist science and technology studies, proponents of CTA view technology assessment as an active contribution to the shaping of technology as opposed to an independent program of ex post impact analysis (→ Technology, Social Construction of). In other words, CTA is an approach that studies the design process itself in order to understand the potential effects – both positive and negative – of technology projects well before they become entrenched or “locked-in” to society.

### **THE COLLINGRIDGE DILEMMA**

Any effort to anticipate future effects of a technology project must address what has come to be known as “the Collingridge dilemma.” This term describes the methodological quandary that confounds attempts at technology forecasting and efforts at social shaping. According to Eijndhoven (1997, 279), “the Collingridge Dilemma points to the fact that the early warning function of technology assessment has severe limitations, because either the knowledge or the power are missing to change the direction of technological development, leaving quick adaptation to new technology as the only way society can react.” In other words, the social and environmental effects of a technology are sometimes difficult to anticipate until it is widely deployed. Yet once deployed, it may be impossible to effect substantial change to a technology because of previous investments made in its development and deployment, as well as the network effects it might have created.

It has been suggested that a solution to this dilemma can be found in developing highly flexible technology designs capable of multiple configurations. CTA proponents claim that this is a conceptually flawed strategy because “entrenchment is necessary to implement a technology” (Rip et al. 1995, 7), and argue that we should accept this inevitability as integral to technology design while asserting that development can be positively directed to the extent that social actors understand the implications of and participate in choosing a pathway from among a range of alternatives – one of which might be the outright cancellation of a technology project.

### **STRATEGIES FOR TECHNOLOGY ASSESSMENT**

In terms of implications for public policy, three generic strategies for action have been defined within the CTA approach: technology forcing, strategic niche management, and reflexive deliberation. Technology forcing is described as a demand-side strategy where a social actor with some measure of authority, often a government or regulatory agency,

stipulates desired impacts and directs technology development toward those ends through regulations or other incentives. One example of this strategy in action is the mandatory unbundling of telecommunication networks as part of a government-led market liberalization strategy.

Strategic niche management is a supply-side strategy where industry stakeholders orchestrate product development through setting up a series of experimental settings where designers can learn about user needs and other social aspects of the technology. Aspects of the free and → open source software movement might be considered to fall within the definition of this type of technology assessment strategy. Finally, reflexive deliberation is a strategy that seeks to build relationships between users and developers through consensus conferences or special workshops. Government-sponsored public proceedings on, for example, the reform of radio spectrum management policy might, under certain conditions, be regarded as an example of this type of intervention strategy.

## APPLICATIONS

Since its introduction in the Netherlands, CTA has been adopted by numerous organizations across Europe, including technology assessment groups in Denmark, Germany, and Norway, as well as the Organisation for Economic Co-operation and Development (Schot & Rip 1996, 254). In addition, various European Union programs in research and development have recognized CTA as having contributed to improved technology policy and development (Berloznik & van Langenhove 1998). While CTA has become a recognized approach in much of Europe, in North America its presence is less evident. This may be a result of the OTA dominating the field until the mid-1990s, when it was disbanded. Despite this, it is becoming increasingly apparent that the normative principle of CTA has taken root in a number of selected areas of science and technology policy research in both Canada and the United States (see, for instance, Loka Institute 2004).

Worldwide, there is also a growing body of technology-assessment-based research involving information and communication technologies (ICTs; → Technology and Communication). Early technology-assessment-inspired work on innovation in telecommunications services was undertaken by the Danish Board of Technology Assessment in a series of experiments to examine user demand for early telematics services, such as video calling (Cronberg 1992). Today, the Centre for Studies of Science, Technology, and Society (CSSTS) at the University of Twente manages a research program that draws on CTA to conduct research on projects involving e-government, open source software, privacy and security aspects of ICT in healthcare, and innovation in telemedicine ([www.bbt.utwente.nl/kennisinst/cssts](http://www.bbt.utwente.nl/kennisinst/cssts)).

The concept of “social learning” has been adapted from the technology assessment literature and applied to a study of the *Digital City project* based in Amsterdam to overcome the descriptive limitations of the social shaping approach and to provide “a more prescriptive or normative position” on the role of research in addressing emergent socio-technical practices (Lieshout 2001). In this respect, technology assessment has provided a foundation for action research that attempts “on-the-spot” adjustments of the social shaping process in ongoing ICT projects. Similarly, CTA has been used in research

on the dynamics of telecommunication networks and the role of stakeholder intervention related to disaster management and public safety communication (Gow 2005).

Research on emerging ICTs and their potential environmental, social, and health effects has also referred to principles and methods associated with technology assessment. This work is particularly concerned with *risk management* and the *precautionary principle* in the context of a future scenario involving ambient intelligence (Som 2004; → Ubiquitous Computing). This principle states that if an action like the introduction of a new technology might cause severe or irreversible harm to the public, but there is no consensus in science, the burden of proof falls on those who are in favor of taking the action. The problem of path dependency and the associated Collingridge dilemma, both formulated in relation to CTA, are regarded as core issues in this work.

CTA has been cited within the community informatics literature, in relation to the development of a *community-oriented technology assessment processes model* (McIver 2005). In this context, the normative principles of CTA are brought to bear in developing an approach for community involvement in ICT development, which is intended to offset some of the shortcomings of other technology assessment methods developed within corporate settings and often dominant in ICT policy research. Several essays dealing with the social shaping of information technology have also appeared in a CTA-informed volume on modernity and technology. Notable examples include Lyon's (2003) chapter on surveillance technologies and Slater's (2003) case study of Internet development in Trinidad.

The journal *Poiesis and Praxis* is devoted to studies in technology assessment and includes articles that examine information and communication technologies. Eggermont et al. (2006), for example, adopted a participatory technology assessment method combined with foresight and scenario-building exercises to look at design issues related to the elderly and their use of ICTs. The results of that study are intended to provide policy recommendations for future policy to address aging populations and access and use of future ICTs.

## Technology and Communication

Robin Mansell

London School of Economics and Political Science

As users we will come to rely on our handset as a single device to manage not just communications but much of our lives. It will truly become a “remote control for life,” with massively enhanced capabilities, advanced methods of user interaction and in-built tools . . . The substantial change that end users are going to witness has become possible more because the underlying infrastructure has become stable than because it is rapidly evolving. (Webb 2007, 35)

This quotation offers a technologist's view of the potential of technological advance for new modes of communicative interaction based, in this instance, on innovations in handset technology. In this view, by the early part of the twenty-first century technological innovation in the fields of engineering concerned with the underlying communication infrastructure had stabilized, offering a foundation for current and yet-to-be-imagined applications

(Gilder 2000). This observation echoes many of the technologically deterministic views that are frequently criticized in the humanities and social science literature that considers the relationship between technology and communication.

## **DIMENSIONS IN THE RELATIONSHIP BETWEEN TECHNOLOGY AND COMMUNICATION**

In the humanities and the social sciences it is generally understood that research and theory building in this area must be historically situated. Thus Smythe argued, for example, that technology and its relationship to communication are dynamically interrelated and best understood as having a number of constituents:

one part is bureaucracy (in both the private and public sector) . . . The second part is science which is being taken over increasingly by the third part, capital. The fourth part is tools and machines created by engineers. The fifth part is ideology which provides the raw materials with which the sixth part, propaganda, seeks to mould public opinion to accept the myth. (Smythe 1984, 2)

This definition embraces not only the technical features, but also the *human and social dimensions of the relationship between technology and communication*. The technologies of human communication are those that enable the establishment of communicative relationships virtually by creating a sense of co-presence or when participants in such a relationship are physically present. Analytically, the implications of the relationship between technology and communication for human development might begin at any point in human history, with, for example, the Phoenicians and their development of an alphabet, with the Sumerians and their development of cuneiform writing, or, indeed, with the Egyptians and their development of hieroglyphic writing – all between 3500 and 2900 BCE. Historically, many types of information and communication technologies (ICT) have been used to mediate human communication (Innis 1951; → Media History). The first wooden printing press was invented in China in 305 CE, with newspapers appearing in Europe in 1450 (→ Printing, History of; Newspaper, History of). The first telegraph line was invented in 1793 by Claude Chappe (→ Telegraph, History of), while 1876 saw the patenting of an office copying machine by Thomas Edison and the electric telephone by Alexander Graham Bell. Marconi transmitted the first radio signals across the Atlantic Ocean in 1902 (→ Radio Technology). The → Internet (ARPANET) started in 1969, IBM's personal computer was first sold in 1981, and the world wide web became available in 1994 (see [http://inventors.about.com/library/inventors/bl\\_history\\_of\\_communication.htm](http://inventors.about.com/library/inventors/bl_history_of_communication.htm)).

In the media and communication field there are many perspectives upon which one can draw to highlight the complex historical and current relationships between technology and communication. For instance, the way *politics* influences the relationship between technology and communication may provide the focus for research. Sussman's (1998) *Communication, technology, and politics in the information age* examined the intersections between politics, society, and technology. Alternatively, a sociological approach may encourage a focus on cultural specificities and the ways new technologies become embedded in society. Marvin's study *When old technologies were new* notes that "a recurring theme in the study of literacies past and present is how skill and technique for performing particular

literate practices are transferred from communities of adepts to less skilled communities. What is not so easily transferred is the specific cultural setting” (1988, 14).

Another approach that is common in the literature on the relationship between technology and communication is that of the *futurologist*. In this case emphasis is often given to forecasts about the timing of inventions entering the consumer market. Innovations in ICTs have been forecast over periods as long as 60 years such that, for example, Neild and Pearson (2005) speculate that by the 2030s, learning will be superseded by transparent interfaces to a smart computer, by the 2020s network-based telepathy will be in use, and by 2017 the first bacterial computer will be available. No single disciplinary approach encompasses all the facets of the complex relationships between technology and communication.

In this overview entry, emphasis is given to ICTs that incorporate microelectronics or digital technologies, and an effort is made to embrace a broad spectrum of theoretical perspectives that bear on the relationship between technology and communication.

## **TECHNOLOGY AND COMMUNICATION: ANALYTICAL FRAMEWORKS**

Interest in the emergence of the → information society (Machlup 1962; Porat 1977), in which there is an increasingly intensive relationship between ICTs and the potential for new modes of communication, has grown since initial efforts to document a shift in the wealthy economies from their reliance on manufacturing to services. The spread of the Internet (→ Internet, Technology of) and access to the world wide web, together with the convergence of communication services around digital platforms since the mid-1990s, has intensified that interest. For some, it is an article of faith that ICTs hold the solutions to economic, political, and cultural problems. These people argue that if ICTs make information easily accessible from multiple sources and on multiple platforms, then the information needs of all segments of the population worldwide potentially can be met. Others have argued that the many forms of → digital divides make it unlikely that these technologies will alleviate deeply rooted social and economic problems (→ Access to the Media; Communication Inequality; Golding 2000).

In fact, the relationships between technology and communication (including changes in the production and consumption of ICTs) are embedded in institutionalized *power relations*. This has implications for the way they become implicated in the workplace and in the everyday lives of their users. These power relations are rarely symmetrical or stable, and it is therefore important to examine the dynamics of change empirically to understand their implications for the changing ways in which communicative relationships are mediated by technology (Mansell & Silverstone 1996). Broadly, there are two main conceptual frameworks that inform research in this area: the exogenous and the endogenous frameworks.

### **An Exogenous Framework**

The question as to whether technological innovation in the ICT area is exogenous or endogenous to a social system is central in differentiating between alternative assessments of its implications. One school of thought treats ICTs as if they are objects isolated from

the social, political, and economic environment in which they are produced and consumed (Bell 1973; Drucker 1961). The way in which ICTs come to be integrated within societies is assessed within this framework in terms of whether a particular technology is a progressive, regressive, or neutral force. Sometimes there is an attempt to find causal relationships between the appearance of new ICTs, for example, such as satellite technology, and social change (de Sola Pool 1983).

This approach tends to isolate technology from its *socio-economic context*. Thus, if a technology such as a computerized database is found to have negative effects, the problem can be attributed to the software design. The result is a mythical understanding of technology, which is taken for the purposes of analysis to exist in an external relation to society. This view is sometimes also found in literature informed by legal perspectives (Barrow & Manelli 1969).

It is assumed within this framework that social relations leading to the production and distribution of ICTs act on society in rational or logical ways. Is it the human being or “technology” that directs social change? As ICTs pervade ever more aspects of human endeavor, it is easy to claim that it is technology and not the human being that is “out of control” (Beniger 1989). If it is technology that is the determining factor in social organization, then what is left for the researcher is an observer role. For example, Ellul argues that “our civilization is constructed *by* technique, *for* technique and *is* exclusively technique” (Ellul 1964, 128). Similarly, Bell, who coined the term “information society,” argued that “technology is the instrumental mode of rational action . . . Technology has created a new definition of rationality, a new mode of thought” (1979, 15). Here, the emphasis is on the efficiency and rationality of technology, and social, cultural, political, and economic factors are relegated to secondary positions.

In addition, from this perspective, it may also be assumed that technology has *universally similar effects* regardless of where it is implemented; that technology is self-generating and goal-oriented (Winner 1977). The goals of efficiency and productivity are seen as being embedded in an autonomous technological system where there is little room for human decision-making or agency. Research tends to focus on the activities of technicians, engineers, and scientists to assess how ICTs or new information (or knowledge) are generated, rather than on the interests (economic, political, social, and cultural) that are at stake. In fact, it is institutions, individuals, and groups that are influential in the development of the ICTs.

This exogenous framework tends to be used to *attribute responsibility* for positive or negative economic, cultural, and other effects to each successive wave of ICTs. Researchers become preoccupied with facilitating the promotion and expansion of technology, without critically assessing the way ICTs become woven into the fabric of life – in terms of morality, the economy, culture, or the political. As Williams (1977, 80–81) argued, abstract analytical categories of idealist thought, “almost unnoticed, become substantive descriptions, which then take habitual priority over the whole social process to which, as analytical categories, they were attempting to speak.”

The notion of exogenous or autonomous technology appears throughout the literature on ICTs. It offers the possibility of avoiding critical assessment of the human factors that give rise to opportunities and the disadvantages associated with each new generation of technology. In contrast to Shallis’s (1984) deterministic account of the microelectronics

revolution in *The silicon idol*, Braverman's comment on technological change is pertinent to the investigation of innovations in ICTs and the way they mediate communicative relationships: "The key innovation is not to be found in chemistry, electronics, automatic machinery . . . or any of the products of these science technologies, but rather in the transformation of science itself into capital" (Braverman 1974, 166).

### An Endogenous Framework

When the endogenous characteristics of technology and communication relationships are considered, it is feasible to investigate the specific, material conditions under which technology is produced and consumed within society and to focus on the everyday aspects of its organization. Technology, in this framework, is regarded as *part of the social fabric* in which actors sanction certain forms of change and not others. Common to the work of those contributing to this framework is an emphasis on the structural factors, external and internal to a country or region, that result in unequal distributions of power. Power is usually located in the interwoven alignment of state (administrative and military), private capital, and civil society interests. In this view, the emphasis is often on the way technology mediates human relationships and on the set of limiting constraints that distort benefits that might otherwise accrue to those who are not at the center of economic and political power (Silverstone 2006). Mattelart (1979, 17), in his analysis of the media, for example, calls for an examination of the process of transnationalization that "can only be understood in a complex correlation of national and international or even local and regional forces, crisscrossed by the existence of resistance, adaptation, recuperation, offensives, and mimicry."

An endogenous framework is also present, for example, in Smythe's work on the concept of "*cultural screens*." Cultural screens were defined as those "aspects of a national culture or ideological system which serve to protect its cultural realism against disruptive intrusion" (Smythe 1981, 232). This idea drew researchers' attention to questions about whether it is feasible, given power relations at all levels, to create a space for distinctive cultural development in a technologically mediated world.

Researchers whose work embraces an endogenous framework have emphasized *historical and recurrent patterns of ICTs*. With respect to changes in ICTs and the organization of media and communication markets, Marvin (1980, 18), for example, has emphasized the idea that "the prediction that all development in communications technology will only lead to greater concentrations of media ownership and less and less information diversity is as classic as the alternative prediction that new communications technologies will inaugurate an era of perfect democracy and well-being." With respect to the implications of advanced digital technologies, an analysis of power relations in the wider economy has been shown to be important for understanding whether and how changes in technology are accompanied by particular changes in the way industrial markets are organized (Mansell & Steinmueller 2000).

With the appearance of new social movements mobilized by civil society actors, the endogenous framework accommodates analysis of the opportunities and constraints offered by innovative technologies. Thus, rather than assume that open source software and networks, for example, automatically give rise to newly empowered virtual communities,

researchers critically examine how the rise of networks is implicated in changing *power relationships* (Kubicek & Wagner 2002). In this framework it is feasible to allow for the fact that the embedding of technology within communicative relationships may be either empowering or disempowering and, depending on the level of analysis, to examine whether they might be both simultaneously. Remaining open to this possibility brings the Janus-faced character of technologically mediated communication relationships to the fore.

The entries for this theme in the encyclopedia draw upon work by those with an affinity to both the endogenous and exogenous perspectives. They are organized around the following sub-themes: (1) theorizing technology and communication; (2) technology, communication, and organization; (3) technology, communication, and governance; (4) innovation, technology, and research; and (5) technological foundations.

### THEORIZING TECHNOLOGY AND COMMUNICATION

The specific relationships between technology and communication can be marked at any time in human history. In this entry the focus is mainly on the period from the 1970s to the present, when the term “information society” gained currency across the disciplines of the social sciences and the humanities (Webster 2006). Terminology varies, with some scholars insisting on the “information society” label, while others stress diversity, coining the term “information societies.” Still others prefer the term “knowledge society” or “knowledge societies,” emphasizing the potential of digital technologies to enhance learning and economic development. The literature reflects ongoing disputes about whether the rapid spread of digital technologies constitutes a shift to a new mode of organization of society. Some focus on the growing quantity of information and its implications for the economy, while others give greater emphasis to the ways that these technologies mediate the construction of symbolic meaning, identity, and cultural development. Terms like “network society” (Castells 1996–1998) and “information society” serve as focal points for discussion of the changes associated with intensely technologically mediated societies.

A key concern is the *political implications* of the information society for democracy (→ Communication Technology and Democracy; Activist Media). In this area research is polarized between those who regard developments in ICTs and the media as having the potential to strengthen democracy and those who regard these developments as disruptive of democratic practice. There have been debates about the relationship between communication technology and democracy since the time of the printing press, but the spread of digital technologies and the Internet has raised new questions about alternative models of democratic participation (Cammaerts in press), about the role of the media in formal electoral processes (Scammell 1995), and about whether a “right to communicate” should be enshrined in international law (McIver et al. 2003).

The implications of investing in the production and consumption of ICTs (→ Information and Communication Technology, Economics of; Media Economics) are examined by those working in both the neo-classical and institutional economics traditions. Economic analysis tends to focus on the diffusion of ICTs, that is, on the pathways for the take-up of new technologies and their impacts on firms, specific industries, and the economy as a whole (Greenan et al. 2002). ICTs are classed by economists as general purpose technologies

(GPTs), suggesting that as they become central to the ICT-using sectors of the economy, they are associated with major transformations – paradigmatic shifts – that are reflected in productivity gains across the economy (Freeman 2007). The implications of technological convergence for industrial dynamics and the embedding of digital technologies in local economies, as well as for the increasing contribution of knowledge-based services to economic growth (Boden & Miles 2000), are key areas of research in the field of the economics of innovation and technical change.

Economists sometimes acknowledge that the implications of advances in ICTs cannot be understood fully without recourse to insights from other disciplinary perspectives. Within *sociology*, two approaches have helped to reveal factors influencing the production and consumption of communication technologies: the social construction of technology (→ Technology, Social Construction of; Constructivism) and the → domestication of technologies. The former understands that artifacts result from processes in which outcomes are not prefigured (Bijker et al. 1987), and provides a basis for a critique of technological determinism that is often present in economics approaches. The domestication of technology approach examines the appropriation of older and newer media and ICTs in everyday life, focusing on processes of commodification, imagination, appropriation, objectification, incorporation, and conversion (Silverstone & Hirsch 1992).

In examinations of the relationships between technology, communication, and society, when the diffusion of ICTs is uneven or where the distribution of the gains as a result of investing in them is uneven, this is often referred to as a digital divide. This concept is strongly criticized in some branches of the literature for its oversimplification of the factors that give rise to inequality. Research designed to understand the key determinants of these divides takes the form of → surveys or → case studies focusing on skills and cultural difference and various forms of exclusion and their consequences. Research on → information literacy or → media literacy is concerned with the skills sets needed to interact effectively with ICTs and with digital information, with an important emphasis on critical literacy.

Although standards for literacy are being devised in some countries, agreement has yet to be reached. This has major consequences for economic competitiveness and for fostering inclusive forms of democracy (Livingstone 2004). Research in this area also is concerned with weaknesses in the capacity to process or understand information, and there is a risk that → “information overload” may occur. This term has its roots in the literature on computer-mediated communication (CMC), and it is a problem that indicates the need for high levels of literacy in information management and for the capacity to distinguish relevant and reliable information.

## TECHNOLOGY, COMMUNICATION, AND ORGANIZATION

Although there is no stable definition, the term → “virtual community” generally applies to online interactions that give rise to new forms of relationships and new organizational forms. These communities also offer new platforms for research that seek to map the architecture of networks and to understand new forms of social relations or “communities of practice.” The fields of → human–computer interaction (HCI) and → personal communication by CMC touch on these issues. HCI is the study of how people interact with

computational devices and the design implications of digital media, whereas studies of personal communication via CMC address the same technologies, but generally focus on the perceived positive and negative features of this mode of communication. This is an area particularly in need of empirical study, since the evidence is mixed, as is the case for research on → online media. Here the aims are to examine the directionality of communication, synchronicity, content modularity, interactivity, personalization, and meaning construction, with issues around user-generated content or Web 2.0 applications providing a focal point for research.

New digital means of interacting online have given rise to interest in the *implications of the Internet* for language development (→ Language and the Internet), for the growth of personal online publishing (→ Personal Publishing), and for the development of → open access journals. In the case of language, research is particularly interested in text-based, interactive modes of communication and may focus on “standard” or “netspeak” languages. Empirically it makes use of large datasets that are contextually classified (→ Log-File Analysis) and archived data (→ Archiving of Internet Content). In the case of personal publishing, attempts are made to understand the motivations of publishers and the sustainability of these online initiatives. Open access publishing refers to the practice whereby the owners of a journal grant the right of free access to digital content and to new models suggested by free or open source software development.

These developments have not only supported online networking activities for individuals, they also have given rise to the “*networked organization*” (→ Network Organizations through Communication Technology), characterized by reciprocal and lateral communication ties. Such organizational forms enable virtual teamworking and, increasingly, outsourcing. They also raise issues about the ownership of the creative capabilities that firms need in order to compete effectively. New business organizations and models are also at the core of the development of electronic commerce (→ E-Commerce), the term used to describe Internet-based ways of engaging in economic exchange. Research in this area focuses on pricing strategies, marketing and strategic behavior, consumer behavior, privacy, and trust. In the case of → e-government services, research tends to focus on models, public confidence in services, and whether new forms of interaction are consistent with democratic practice, sometimes described as “digital-era” governance (Dunleavy et al. 2006).

Changes in the economic and political spheres corresponding to changes in the relationship between technology and communication have been accompanied by *cultural developments* associated with opportunities for the development of sexual relationships and pornography online (→ Sex and Pornography Online; Pornography, Media Law on). “Cybersex” appears to hold the promise of sensitization in a virtual reality where the body is invisible. In addition, there are studies of the role of technology in mediating consumer fashion (→ Technology as Fashion), and developments in this area have implications for the structure and organization of markets for consumer goods such as the iPod or the mobile phone as well as for the advertising industry.

## **TECHNOLOGY, COMMUNICATION, AND GOVERNANCE**

Disruptive technological innovations are often tightly coupled with debates about the positive or negative implications for the global order (→ Technology and Globalization;

Globalization Theories). The relationship between *technology and globalization* is immensely complex, with research on ICTs emphasizing links between local and distant places and the sometimes unifying, and at other times fragmenting, consequences. Differences in views about the relationship between technology and communication in this context give rise to discussions about hybridity and the asymmetric, unpredictable links in the global–local system. Within the globalization debate, the governance of ICTs is an issue that influences how these technologies become embedded in society. In analyzing the relationships between technologies and communication, many authors, for example, are concerned with the relationship between globalization, the nation-state, and the deterritorialization of media (→ Globalization of the Media).

The different framings of the relationship between globalization and communication technology find their echoes in research on the *nature of the governance regimes* that are required on a global basis to enable the production and consumption of ICTs and media content locally and globally. For production and consumption to be feasible on a global basis, governance regimes for technology standardization are essential (→ Communication Technology Standards), especially since compatibility standards are needed when interactivity is required (David 1985). The spread of the Internet has made it necessary to find innovative ways of governing the technical means by which computers are able to “find” each other. The governance of Internet → domain names offers an illustration of the way these complex issues are played out on a global scale. The phrase → “code as law” is associated with Lessig’s (2006) work, which argues that the Internet is “regulated” by the values embedded in the software code (→ Communication and Law; Internet Law and Regulation; Internet: International Regulation; Murray & Scott 2002).

Governance issues arise with respect to specific online behaviors as well. For example, when users access computerized systems, there are many questions about whether there should be sanctions for “bad” behavior. Research on → “*hacktivism*” examines this question, where hacking refers to techniques combined with political strategies. From a governance perspective, whether hacktivism is seen as legal or illegal is a question of the values in a given context (Jordan & Taylor 2004). When it comes to the relationships between crime, terrorism, and communication technology (→ Crime and Communication Technology; Terrorism and Communication Technologies; Mediated Terrorism), the issues and the evidence base are strongly contested. In both cases, there are attempts to control crime and terrorism using law enforcement and criminal justice as well as to “design out” crime through technical measures. The evidence base for claims about the potential for “cyberterrorism” is especially weak (Schmid 2004).

## INNOVATION, TECHNOLOGY, AND RESEARCH

New ICTs raise many issues with respect to *ethical conduct* within the humanities and the social sciences (→ Research Ethics: Internet Research; Research Ethics). Guidelines with respect to Internet-related research have been developed nationally and by organizations such as the Association of Internet Researchers (AoIR). Different methods raise concerns about the risks involved to researchers and to those they study. There are also conflicting views of ethical conduct, for example, with respect to online pornography, suicide pacts, or hate speech.

Analysis of the historical online record (→ Online Research) or memory requires an archive of the contents of the world wide web. Although web-harvesting programs have been available since 1995, there are many outstanding questions in this area, such as the representativeness of the results of web crawling and issues of standards, privacy, copyright, and ethical conduct. The results generated by → *Internet ratings systems* (→ Rating Methods) also generate controversy, although the demographic and behavioral data are used by the advertising industry and by the research community. The profiles of users and of digital information can also be discerned through log-file analysis. There has been little analysis in the social sciences of the implications of these systems for markets or for public policy. Another online research tool is → Link Analysis, or the study of hyperlinks between and within websites, giving rise to concerns about the sampling of links and the selection of content.

Methods of researching online content are being considered within the wider context of research strategy and design, and they are continuously reviewed through organizations such as AoIR (<http://aoir.org>) and by contributors to the *Webology* journal and to *First Monday* (<http://firstmonday.dk>).

## TECHNOLOGICAL FOUNDATIONS

In the social sciences and humanities the technological foundations of mediated communication are sometimes neglected, but by the middle of the first decade of the twenty-first century there was a consensus that research should focus on relationships between online and offline activity (Orgad 2007). In essence, the Internet refers to a technological base and a set of standards upon which software applications rely in order to provide users with communication tools. The Internet is a cluster of technological innovations, infrastructures, applications, and social organizations that would not exist without its underlying → communication infrastructure, upon which media and communication services operate. Innovations in ICTs have progressed with improvements stemming both from “technology push” and “demand pull” factors (→ Information and Communication Technology, Development of). Their application has been accompanied by debates about *technological convergence* (→ Digitization and Media Convergence) and about competition between standardized digital platforms.

Although digitization has been found to contribute to the blurring of boundaries between segments of the media and communication industry, this does not always imply media convergence, that is, the convergence of networks or fully integrated and seamless communication between networks, services, and terminals. Since the Internet revolution in the late 1990s the boundaries between these platforms have become blurred, leading to changes in commercial leadership in ICT markets, with many new firms appearing on the scene.

The spread of digital networks, large increases in information-processing power, media convergence, and the growth of Internet-based communication have supported three *key developments* – → search engines; → P2P networking; and → open source software development – that have called into question the sustainability of traditional business models and the legitimacy of information ownership protected through → *copyright* legislation. The use of wireless communication is also enabling the growth of mobile communication, which, in turn, has substantial implications for the mobility of data,

information, and people (→ Mobility, Technology for). Taken together all of these developments set the parameters for what some envisage as an age of → ubiquitous computing. This refers to networking and computing technologies that are small, fast, interconnected, and cheap enough to be embedded in the environment and in everyday objects. Ubiquitous computing research – when it is grounded in the humanities and the social sciences – resonates strongly with the literature on → cyborgs (a term for a biological, usually human, being enhanced by artificial components), especially with respect to debates about ethics and gendered relationships.

With respect to renewed interest in cyborg developments and related developments in the technological sphere, there is also considerable emphasis in the literature on technology and communication on → *technology assessment*. Some approaches to technology assessment embrace a critical examination of the underlying values and norms that become part of the fabric of everyday life. Constructive technology assessment (CTA), developed largely in Europe, is one line of this work, and is complemented by “early warning” assessments, developed mainly in North America. Technology assessment methodologies seek to evaluate the risks associated with new technologies. In the research literature there is controversy over which approaches work best and about the role of power in influencing whether and how the recommendations of these methodologies filter into policymaking and technology designer practice. Technology assessment methodologies, informed by theories drawn from across the social sciences and humanities, continue to be essential to the ongoing investigation of the historical, present, and future relationships between technology and communication within society.

## Technology as Fashion

Michael Bull

University of Sussex

In 1957 Vance Packard complained that the manufacturers of typewriters and telephones had recently begun producing models in a wide range of colors rather than in their traditional black. He critically surmised that the sole motive for this innovation was “to make owners dissatisfied with their plain old black models” (Packard 1957, 72). Packard understood that the introduction of color into the appearance of these technologies added nothing to their functionality, that color was ephemeral and external to the workings of these technologies. The ephemeral was merely “fashionable.” That owners of traditional black models might become dissatisfied with their “old” models was, he thought, attributable to the workings of those in the → advertising industries (→ Advertising; Advertising: Global Industry) who would work their sophistries upon a naïve public.

Packard's understanding of the role of advertising in consumer culture looked forward to → Roland Barthes's *The fashion system* (1983), in which Barthes highlighted the central role played by advertising in the construction of cultural meaning. For him, fashion items are never understood raw, as mere material objects, but are always understood through the mediation of media messages. Without the media, there is no → fashion.

Packard's analysis also looked to the work of Thorstein Veblen, who had produced the earliest analysis of the centrality of fashion in consumer culture in his *Theory of the leisure class* (1994), published originally in 1899. Veblen, like Packard, denied any value to the "aesthetics" or "style" of a product, subordinating these aspects as forms of conspicuous consumption, the *raison d'être* of any fashion item. The central dynamic of fashion culture, according to Veblen, was conspicuous waste. In order for their users to stay ahead of others, new fashion objects would continually be made to distinguish their users from those lower down the social ladder. Fashion embodied display, distinction, and cultural capital (Bourdieu 1986). Veblen's -is a "trickle-down" theory of taste in which the less wealthy envy, imitate, and emulate the rich.

### TELEPHONE AS FASHION

The telephone, originally a product for commercial use and then for the families of the rich, was slowly incorporated into the houses of the middle classes in an increasingly urbanized and disparate population, for whom advertisers proclaimed that "Your Voice is You" (Fischer 1992, 76). Packard's consumers had seen the practical advantages of telephone use in the home. What Packard failed to observe was that the black phone itself had been considered fashionable, not merely as an "object" but in terms of the values of connectivity that it represented. A culture's utopian wishes are often located in its most recent consumer technologies (→ Domestication of Technology). These technologies themselves are barometers or signposts of a culture's unfulfilled desires. As more people succumbed to the aspiration toward connectivity, they were thus seeking to emulate others. The 1950s was a time of "keeping up with the Joneses," with consumers striving to keep abreast of their neighbors. The introduction of colored phones, while not adding to the functionality of the device, reflected upon notions of the "fashionable" home in which all contents were color coordinated. The technology of the phone was thus doubly fashionable.

Understanding the role of social emulation was central to the European sociologist and philosopher Georg Simmel's theory of fashion (Frisby & Featherstone 1997). At its core was the dualism of conformity and individualism; thus, telephone users wished to be like others who possessed a telephone (emulation) yet strove to distinguish themselves from others (by purchasing a colored model). Simmel recognized that fashion itself had become the *zeitgeist* and driving force of modernism, represented by the values of universal change, preferring the new to the old, and "keeping up to date." The elevation of the transitory over the permanent is embodied in the very definition of fashion as a "continuing pattern of change in which certain social forms enjoy a temporary acceptance and respectability only to be replaced by others more abreast of the times." (Blumer 1968, 342). Simmel also recognized that fashion had become universalized; "that it has overstepped the bounds of its original domain, which comprised only externals of dress, and

has acquired an increasing influence over taste, theoretical convictions, and even the moral foundations of life in their changing forms.” (Simmel in Frisby & Featherstone 1997, 189).

### **AUTOMOBILES AS FASHION**

Consumer technologies play an increasing role in the economy of fashion. Packard highlighted the role of telephony as fashion; Barthes extolled the cultural significance of the Citroen DS as the ultimate consumer aesthetic object of an age in which the automobile took pride of place. Automobiles embodied the cultural values of movement and individualism, with drivers no longer constrained by the timetables of others, free to travel wherever they pleased. Makes and models were made for differing social strata, so that the automobile became the equivalent of clothing: the aesthetics of speed represented by makes such as Ferrari were, to follow Veblen’s critique, not functional for everyday driving, while the aesthetics of the middle classes were those embodied by the Citroen DS. The aesthetics of durability and power were meanwhile embodied in the emblematic radiator of the Rolls-Royce, symbolizing for Panofsky an unchanged representation of “art nouveau infused with the spirit of unmitigated romanticism” (Panofsky 1997, 166). Yet automobility itself represented an overarching cultural ideal in which most consumers could share (→ Consumer Culture).

Technology as fashion differs from clothing as fashion inasmuch as there are recognizable measurements of progress within the development of the technologies themselves (→ Technology and Globalization). A Ferrari that lacked speed or acceleration would lack the essential ingredients that made it a Ferrari; equally, in a culture in which the values of miniaturization and mobility are paramount, modern mobile phones are considered both more functional and more aesthetically pleasing than their large and heavy forebears. While fashion in dress, music, and furniture has increasingly looked backward in remodeling itself on the 1960s, 1970s, and 1980s (Carter 2003), today’s technologies are more resistant to the mass take-up of retro-fashions.

### **DEFINING CONSUMER TECHNOLOGIES OF THE TWENTY-FIRST CENTURY: MOBILE PHONE AND IPOD**

Two defining consumer technologies of the twenty-first century are mobile phones and Apple iPods. These technologies represent two differing modes of fashion appropriation. Mobile phones are possessed by the majority of consumers in the industrialized world (→ Mobility, Technology for), while Apple iPods, despite being a mass-produced technology, are endowed with an aura of exclusivity, style, and status (Bull 2006; Levy 2006). The mobile phone represents the antithesis of Veblen’s trickle-down theory in which the many emulate the fashion of the rich and powerful. Fortunati (2005) has argued that mobile phones became fashionable only when they became objects of mass consumption. They are emblematic of a transformation in fashion that, due to global → marketing strategies, is largely simultaneous and democratic in nature. The mobile phone, rather like the automobile, embodies a set of fashionable cultural values, such as “distance, power, status and identity” (Katz 2006, 65), that appeals primarily to the young consumer.

The presentation of the mobile phone to young consumers by advertisers invariably appeals to notions of “youth, modernity and futurism” (Katz 2006, 69), with connectivity being emblematic of contemporary → discourses of being “up to date.” Fortunati found that just over one half of young Italian mobile phone users valued the aesthetics of their phones, often allying themselves to brand-name phones such as Nokia or Sony Ericsson – companies that spend millions annually promoting their phones as fashionable to precisely that target audience (→ Brands). However, the perception of mobile phones as fashion objects is not widely replicated among older users, who perceive their phones primarily as functional objects of communication (Katz 2006).

Among those users who do perceive their phones as fashion objects, some engage in customization of them. In doing so they attempt to transform a mass object of consumption into something more individual. Customization has been perceived as the consumer reappropriating the meaning of the consumer object by individualizing it through personalized ring tones or alternative covers, thereby transcending the standard commodified messages embodied in the object. Nevertheless, Fortunati (2005) found that many teenage users of the mobile phone desired forms of “prepackaged individuality,” choosing from a selection of prepackaged ring tones rather than composing their own, for example. When mobile phones have been marketed as Veblen-type objects of conspicuous consumption, such as the Vertu phone, which comes encrusted in expensive jewelry and costs £13,000, they are used primarily as items of jewelry rather than as mobile phones.

Apple iPods were the first cultural consumer icon of the twenty-first century (Bull 2006) and appear to represent a marriage between → aesthetics, → design, and functionality. Apple products invariably cost more than competitor machines and are marketed largely on their aesthetic appeal. Postrel (2003, 2) maintains that “in a crowded market place, aesthetics is the only way to make a product stand out.” She argues that aesthetics is functional in itself, that the pleasure that consumers derive from the aesthetic design of their iPods gives added pleasure. Central to the marketing strategy of Apple has been an attempt to create brand identification through design and advertising that makes the use of Apple products “a way of life.” They are marketed and interpreted as representing “imagination, design and innovation.” Klein (2000) argues that Apple no longer sells mere products, but the brand itself, embodying consumer hopes, dreams, and aspirations. Apple consumers in their identification with the product often see themselves as living within an imaginary community of Apple users and will often acknowledge other iPod users in the street. They also see themselves as distinctive, or individual, through their possession of their iPods, which are visually recognizable to others. Apple spends large amounts of money to convey these meanings through global advertising campaigns, but the status of such identification with consumer products is a contested one. Writers such as Postrel associate fashion with diversity, liberal economies, and the individual freedoms fostered by democratic nations, whereas others take a more critical view of the role of global industries in the manufacture of what they perceive as “diligently assembled illusions.” (Ewen 1990, 38) in which consumers resemble “Yale locks, whose difference can be measured in the fraction of millimetres” (Horkheimer and Adorno 1972, 154). In a global economy in which major brands increasingly control production, the ideological construction of freedom of choice, administered through the advertising industry, becomes paramount: “Fashion and information give individuals the illusion of following

the movement of the world. As life is movement, the continual change produced by fashion and information gives postmodern individuals the sensation of being alive” (Fortunati 2005, 44).

## **Technology and Globalization**

*Kwang-Suk Lee*

*University of Texas at Austin*

The term “globalization” and related terms such as global system, global economy, and global culture have been used since the mid-1980s in both the popular and academic literature to describe the “temporal-spatial compression” of the physical world (Harvey 1989). New information and (tele)communication technologies (ICTs) are viewed as

linking distant localities into one globalizing world in a synchronous time zone that goes beyond real territories. The speed and mobility generated by electronic networks becomes indispensable for creating the physical conditions of globalization, tying together the world as a whole (Virilio 1997; → Mobility, Technology for).

Popular futurists have optimistically characterized a globalizing or united world: Fukuyama (1992) depicts globalization as the last triumph of capitalism and its market economy; Friedman (2006) writes of a flattening and fiber-optic global world; while Gates (1999) refers to friction-free capitalism that creates new opportunities for all countries to participate in global competition. Meanwhile, critical scholars see globalization as the result of the industrialized countries' and multinationals' imperialist expansion without colonies (Magdoff 2003). In this view, advanced technologies offer support for absorbing the surplus generated in the so-called "third world," thus undermining its technological, political, economic, and cultural viability. In the mid-nineteenth century, Marx predicted a global move toward unconstrained capitalist expansion, arguing that "all that is solid melts into air" in the face of the bourgeoisie's constant expansion of markets across the surface of the globe (Marx & Engels 1848/1998, 38). In contrast to the optimistic scholars, for the more pessimistic scholars, technology is subordinate to the expansionist economic logic of contemporary capitalism, which penetrates into every corner of human life.

### MULTIDIMENSIONAL GLOBAL SPHERES

Criticism of these optimistic and pessimistic forms of economic reductionism, both of which tend to focus on a shift toward a *united world economy*, arises from the observation that globalization should not be understood as a dynamic that fosters a unified borderless world. This claim gives rise to a "loose structure" thesis, which emphasizes the relative independence of socio-cultural factors when the local is confronted by globalizing forces. From this perspective it is argued that there are fundamental disjunctures between the economy, culture, and politics. As Appadurai (1990) suggests, a globalizing world mediated by ICTs produces a global sphere of "technoscapes," or multiple spheres consisting of the flows of people, technology, money, media content, and ideologies. Sreberny (2005) similarly sees the technology and market logics as components of multidimensional spheres of the global. These analytical categories of mini-globalizing processes have helped to create an awareness of the nonlinear, unpredictable nature of cultural globalization in contrast to the uniformity envisaged by those more concerned with economic globalization. Empirical studies, for instance, have focused on the independent consumption patterns of television audiences that are understood as being strongly affected by cultural proximity created by factors such as local culture, language differences, local market strengths, and other cultural variables (Straubhaar 1991).

These approaches reveal globalization as a web of hybridity or complexity that gives rise to uneven, asymmetric, and unpredictable links in the global-local nexus, suggesting that this nexus is central to the present phase of globalization. They negate perspectives that give rise to what are regarded as unhelpful dualistic and hierarchical framings of the world in terms of the dominant and dominated, colonizer and colonized, and center/periphery relationships. For instance, Urry (2005) divides the global system into *global networks* and *global fluids*. Whereas global networks are predictable, calculable, routinized,

integrated, and standardized (as in global enterprises), global fluids are regarded as being autopoietic, rhizomatic, and decentralized (as in world money, auto-mobility, social movements, the → Internet, anti-globalization movements, and international terrorism; → Terrorism and Communication Technologies). It is the latter that is said to account for global complexity and hybridity. In view of the out-of-control and unpredictable state of global flows, Giddens (2003) describes the present condition of globalization as a “runaway world.”

Castells’ (1996) concept of flows is helpful in understanding patterns of global interconnectedness as a space that is increasingly process oriented and fluid, unlike the earlier place-adhesive understanding of space as something fixed. The space of flows is said to be a more significant factor in economic, political, and symbolic life than the “space of places.” The fluid and liquid space of flows is enabled by the global conduit of electronic networks, which include transcontinental networks such as submarine cables, ship-to-shore wireless networks, broadcast radio and shortwave wireless services, conventional telecommunication networks, and worldwide Internet-enabled business networks. Castells’ perspective considers the complex and liquid flows of technology, information, and culture across borders. In a similar way, Held et al. (1999) highlight the transformative potential of these spatio-temporal attributes, and it is argued that new complex hierarchies are being reconfigured within a new geography of centrality and marginality, which is bounded not so much by national boundaries as by virtual and geometric representations of power (Sassen 2005).

### THE HOMOGENIZING WORLDVIEW

In contrast to those who favor an unbundling of the global multiplicities of different flows and who argue that globalization cannot be understood using a single world-system model, political economists of media and communication suggest that modern technology and the interests of those active in global markets lead to a continuous tendency to integrate the frontiers of the local into a homogenized globalizing world. For these scholars, a deepening crisis of capital accumulation during the period of the recession in the early 1970s was accompanied by a revolution in microelectronics and computer technologies, creating a foundation for capitalist expansion worldwide. As a result of the expansion of global networks and enhanced computing power, since the 1980s the multinational corporations have sought to tie their local subsidiaries, agencies, and overseas factories together (→ Information and Communication Technology, Development of; Information and Communication Technology, Economics of; Network Organizations through Communication Technology). In this sense, the global electronic telecommunication network is said to become the material infrastructure of contemporary global capitalism, allowing the products of immaterial labor to be disseminated throughout the world. Terms such as *cybernetic capitalism* (Robins & Webster 1999), *digital capitalism* (Schiller 1999), *electronic empire* (Hardt & Negri 2000), and *fast capitalism* (Agger 2004) denote the deepening reliance on the virtual dynamics of a global capitalism shaped by technological innovation. These terms suggest a stage of globalization in which the flows of capital, labor, commodities, information, and images achieve a global reach, and in which they can be produced and consumed almost instantaneously.

Scholars working in the political economy tradition view global crises of capitalism as emerging as a result of the microelectronic revolution and networked flows of information, communication, and culture, and as a result of the flows of industrial and financial capital. Research in this tradition has been centrally concerned with the contribution of digital information and communication to the operation of global monopolies and with transborder data flows (Herman & McChesney 1997). Other key research themes that inform studies of *global technocapitalism* include work on the way in which the international activities of transnational media and communication firms evade regulatory barriers to a greater extent than the activities of firms in traditional manufacturing sectors; the dynamics of monopolistic global media systems; cross-border flows of media outputs; and the restructuring of global electronic communication networks.

In this tradition, globalization is associated with technological regimes that signify rapid changes in spatial structures. The process of *spatial rezoning* is said to stratify and concentrate the power of capitalism over physical and virtual geographies. It creates a domain of symbolic re-territorialization and de-territorialization for increasingly complex flows of information and capital through electronic networks. The virtual global space is regarded as an expanding source of capitalist power augmented by a fabric of electronic networks that enables flows of intellectual assets embodied in financial capital, electronic business data, and entertainment content on a planetary scale. From this vantage point, contemporary capitalism is seen as reshuffling local geographies so as to facilitate the national and global expansion of capital by increasing and channeling the mobility of people, money, goods, and information.

In summary, early globalization theses envisaged globalizing forces as giving rise to unifying hierarchical structures. Later theses, associated with scholars who focus on hybridity and complexity in globalization, suggest the unpredictability of globalization and the multiplicity of local contexts that may be free from the domination of global capital. Others argue, however, that signs of hybridity and complexity should be regarded as indications of global capital's ability to absorb local differences, and that media and communication networks play a central role in this process. The differences between more recent contributions to debates about the consequences of globalization turn on whether the global–local nexus is regarded as an intricate web structure and on whether globalizing forces are seen as having the capacities to absorb differences at the local level.

## Technology, Social Construction of

Wiebe E. Bijker

Maastricht University

The social construction of technology (SCOT) is one approach among several constructivist ways of studying science and technology that emerged in the 1980s. Here, “constructivist” means that the truth of scientific facts and the working of technical artifacts are studied as accomplishments; that is, as being constructed, rather than as intrinsic properties of those facts and machines (→ Constructivism).

The phrase *social construction* was first used by Berger and Luckmann (1966) in their “treatise in the sociology of knowledge.” Building on the phenomenological tradition, and particularly on the work of Alfred Schutz, they argue that reality is socially constructed and that these processes of social construction should be the object of the sociology of knowledge. Berger and Luckmann are concerned with the reality of social institutions and their focus is on society at large, rather than on sub-cultures such as

science and technology. Then, scholarship developed around such themes as the social construction of mental illness, deviance, gender, law, and class. In the 1970s the social construction of scientific facts followed (Latour & Woolgar 1979/1986), and in the 1980s the social construction of artifacts (Bijker et al. 1987).

Constructivist studies of science and technology come in a variety of forms, mild and radical (Sismondo 1993). The mild versions merely stress the importance of including the social *context* when describing the development of science and technology; for example Douglas's (1987) history of radio broadcasting. The radical versions argue that the *content* of science and technology is socially constructed. In other words, the truth of scientific statements and the technical working of machines are not derived from nature but are constituted in social processes (→ Communication Theory and Philosophy; Objectivity in Science).

### **THE ORIGIN AND DEVELOPMENT OF THE SOCIAL CONSTRUCTION OF TECHNOLOGY**

An important, though negative, starting point for the social construction of technology was to criticize *technological determinism*, which was taken to comprise two elements: (1) technology develops autonomously, and (2) technology determines to an important degree societal development. This view was seen as an intellectually weak research strategy because it entails a teleological, linear, and one-dimensional view of technological development. It was considered politically debilitating because technological determinism suggests that social and political interventions in the course of technology are impossible, thus making a political debate on technology a futile endeavor. To bolster this critique, it was necessary to show that the working of technology was socially constructed – with the emphasis on *social*. The unit of analysis was the single artifact. This was a choice for the “hardest possible case.” To show that even the working of a bicycle or a lamp was socially constructed seemed a harder task, and thus – when successful – more convincing, than to argue that technology at a higher level of aggregation was socially shaped.

The agenda of demonstrating the social construction of artifacts by detailed analysis at the micro level resulted in a wealth of *case studies*. A few years later, the program was broadened in two ways (Bijker & Law 1992). First, questions were raised at meso and macro levels of aggregation as well. Second, the agenda was broadened to include the issue of technology's impact on society, which had been bracketed for the sake of fighting technological determinism. Concepts developed for this agenda were “technological frame,” and various conceptualizations of the obduracy of technology (→ Framing Effects). The unit of analysis was broadened from the singular technical artifact to the more comprehensive and heterogeneous socio-technical ensemble. The emphasis now was on *construction* rather than on *social*.

Current research in SCOT combines empirical case studies with more general questions about the modernization of society, politicization of technological culture, and management of innovation. It has become increasingly difficult (and unfruitful) to observe the boundaries between the various approaches within the broader social construction of technology: research collaboration and conceptual combinations have

emerged between, for example, the actor-network approach, the social construction of technology (in the narrow sense; SCOT), and gender and technology studies (→ Gender and Discourse). Connections are developing with studies in the social sciences more generally, including politics, economics, and law.

### SCOT AS A HEURISTIC FOR RESEARCH

As a heuristic for studying technology in society, the social construction of technology can be laid out in three consecutive research steps (Bijker 1995). *Key concepts* in the first step are “relevant social group” and “interpretive flexibility.” An artifact is described through the eyes of relevant social groups. Social groups are relevant for describing an artifact, when they explicitly attribute a meaning to that artifact. Thus, *relevant social groups* can be identified by looking for actors who refer to the artifact in the same way. For describing the high-wheeled *ordinary* bicycle in the 1870s such groups were, for example, bicycle producers, young athletic *ordinary* users, women cyclists, and anti-cyclists. Because the description of an artifact through the eyes of different relevant social groups produces different descriptions – and thus different artifacts – the researcher is able to demonstrate the “interpretive flexibility” of the artifact. There is not one artifact, but many. In the case of the *ordinary* bicycle, there was the Unsafe machine (through the eyes of women) and there was the Macho machine (through the eyes of young male *ordinary* users). For women the bicycle was a machine in which your skirt got entangled and from which you frequently made a steep fall; for the “young men of means and nerve” riding the bicycle was a means to impress people (including young ladies!).

In the second step, the researcher follows how *interpretive flexibility* diminishes, because some artifacts gain dominance over the others and meanings converge – and in the end, one artifact results from this process of social construction. Here, the key concept is “stabilization.” It describes the result of the process of social construction, which can take several years while the degree of stabilization slowly increases.

In the third step, the processes of stabilization described in the second step are analyzed and explained by *interpreting* them in a broader theoretical framework: why does a social construction process follow this course, rather than that? The central concept here is “technological frame.” A technological frame structures the interactions among the members of a relevant social group, and shapes their thinking and acting. It is similar to Kuhn’s concept of → paradigm, with one important difference: “technological frame” is a concept to be applied to all kinds of relevant social groups, while “paradigm” was exclusively intended for scientific communities. A technological frame is built up when interaction around an artifact begins. In this way, existing practice guides future practice, though without logical determination. The cyclical movement thus becomes: artifact–technological frame–relevant social group–new artifact–new technological frame–new relevant social group, and so on. Typically, a person will be included in more than one social group, and thus also in more than one technological frame.

This three-step research process amounts to sociological analysis of an artifact to demonstrate its interpretive flexibility; description of the artifact’s social construction; and explanation of this construction process in terms of the technological frames of relevant social groups.

### SCOT AS A THEORY OF TECHNOLOGY IN SOCIETY

The social construction of technology also provides a theoretical perspective on the relation between technology and society, and on their joint development or co-evolution. The development of technology can be explained as a social process in which a variety of relevant social groups participate. This social process does not stop when an artifact leaves the factory, but continues when users give the technology its specific usage and meaning. Laws of physics and economics are not irrelevant, but insufficient to characterize technology's development.

Analogously, the development of social institutions in modern society cannot be fully understood without taking into account the role of technology. The social fabric of society may be kept together by such institutions as church, capital, government, labor, communication, and education; but where would all these be without technology? Social order in modern society can only be explained by reference to technology (Latour 1992). This requires a view of technology's impact on society. This can be done by conceptualizing the hardness or *obduracy of technologies*.

An artifact can be hard in two distinctly different ways. The first form, "closed-in hardness," occurs when the humans involved have a high inclusion in the associated technological frame. For example, students well versed in the use of mobile phones will react differently to a malfunctioning phone than the old-fashioned author of this article (→ Mobility, Technology for). Students may start modifying the network selection, switch the battery, or tinker with the preferences menu. Only after some time will it occur to them that they could also look for a landline phone: they were "closed-in" by the mobile phone technology. The author of this article, when confronted with a non-working cell phone, might try to ring a second time but then soon give up and look for a landline phone or write a letter. He can barely locate the power switch, and experiences the second kind of impact by technology: "closing-out obduracy." He sees no alternative but to leave the technology aside and pick up his fountain pen. In both cases the technology has an impact on these people, but in completely different ways. These two forms of hardness of technology can also be seen on the societal level. The automobile technology, for example, exerts a "closed-in hardness" on the inhabitants of Los Angeles: much differentiation within auto culture, but no alternatives outside it. The standardization of mains power voltage and wall plugs mean a "closing-out obduracy" to most people: accept it by buying the right plug and apparatus, or do not use electricity (→ Communication Technology Standards).

### THE POLITICIZATION OF TECHNOLOGICAL CULTURE

We live in a technological culture: our modern, highly developed society cannot be fully understood without taking into account the role of science and technology. The social construction of technology offers a conceptual framework for discussing the democratization of this technological culture. The social construction of technology approach not only gives an affirmative answer to Winner's (1980) question "Do artifacts have politics?" but it also offers a handle to analyze these politics. Technology is socially (and politically) constructed; society (including politics) is technically built; and technological culture consists of socio-technical ensembles (Bijker 2006).

Studies that elaborate this agenda do not exclusively extend the SCOT framework, but typically draw on social constructivist technology studies in the broad sense. One of the most fruitful bodies of work is the analysis of gender and technology (Wajcman 1991, 2004; Cockburn & Ormrod 1993). Another domain of research focuses on the politicization of → information society and information and communication technologies (see Schmidt and Werle [1988] for a fruitful approach via standardization issues).

The issue of political decision-making about technological projects acquires a special guise under the light of SCOT. If it is accepted that a variety of relevant social groups is involved in the social construction of technologies and that the construction process continues through all phases of an artifact's life cycle, it makes sense to extend the set of groups involved in political deliberation about technological choices. Several countries are experimenting with consensus conferences, public debates, and citizens' juries. One of the key issues is the role of expertise in public debates. The SCOT approach suggests that all relevant social groups have some form of expertise, but that no one form – for example, that of scientists or engineers – has a special and a priori superiority over the others (Bijker 2003, 2004).

## Telecenters

*Royal D. Colle*

*Cornell University*

Telecenters are public places where people can gain access to information technologies and other communication resources (→ Access to the Media; Participatory Communication; Public Access Television). They originated in the mid-1980s in Scandinavian countries as an effort to help people in rural areas become part of the information economy, particularly by making modern office equipment available to them on a shared basis. Although the idea spread through many of the industrialized countries during the next decade, it was the emergence of the computer and digital networks in the 1990s that launched a variety of these public access centers – with a variety of names, such as community technology centers, village information centers, and community learning centers. UNESCO, the World Bank, the International Telecommunications Union, and overseas development agencies such as those of Canada, Switzerland, the UK, and the US gave the telecenter movement significant propulsion as they perceived a link between information and communication technologies (ICTs) and development (→ Development Communication; Information and Communication Technology, Development of; Technology and Communication; UNESCO).

While → radio, film, and → video make up an earlier generation of ICTs, it is the unique benefits of computers and networks that drive the interest of national and international agencies toward telecenters as a tool for development. The most important of those characteristics are access by individuals to many information databases “on demand”; opportunity to participate in → e-government, → e-commerce, e-health, and e-education; and the prospects for individuals, at relatively low cost, to connect with one person or millions of people beyond their communities for personal communication or for mass communication. However, because many people could not own their own computers or could not afford network connections, concern arose among many of society’s leaders about a → *digital divide*. Data on ownership and use of the new information technologies demonstrated a gap between countries and between populations within countries (→ Information and Communication Technology, Economics of).

Telecommunications specialists look to experience with telephone services for terminology to apply to the Internet situation. They use the term “universal service” to describe the one-telephone-to-one-household ownership pattern. The more viable strategy for developing countries is “universal access” – meaning that a telephone should be within a reasonable distance for everyone. Thus, an interim strategy for dealing with the digital divide is universal access – to have computers and network coverage *shared* in public places and accessible to all.

## TYOLOGY

Although *telecenter* is frequently used as a generic label for different kinds of public-access communication centers, three principal types – with variations within each – have emerged. These are:

- *Multipurpose community telecenters.* These telecenters tend to be in the public sector, operated by governmental bodies or nongovernmental organizations (NGOs). Generally, they serve a low-income clientele and have a community development mission. Typically, these telecenters offer a broad range of communication services related to the needs of the community, some of which are free or subsidized by external bodies such as governments or NGOs. Examples include the Community Learning Centers in Ghana and Hungary's *telecottages*. Along with computer and Internet access, services might include desktop publishing, community newspapers, sales or rental of audio and video recordings, and library, training, photocopying, faxing, and telephone services.
- *Cybercafés.* The commercially oriented *cybercafés* that are found in places ranging from Aruba to Vietnam have been an equally energetic movement. They are usually in the private sector and focus more narrowly on providing customers with the use of computers and connections to the → Internet and the world wide web. Often the principal attractions at cybercafés are computer games and email. In some places – for example Senegal and Nigeria – computers and Internet connections are being added to private-sector phone shops. Cybercafé clients tend to be more urban, more educated, and economically better off than the clients of community telecenters.
- *Information access points (IAPs).* IAPs borrow from the cybercafé and telecenter approaches. As they focus on Internet and network services, they emphasize the opportunity for the community to seek information. The most dramatic example is Canada's Community Access Program (CAP), which established almost 10,000 access points in rural and urban areas across the country between 1994 and 2001. Computers and network connections were placed in community centers, libraries, schools, and other public places in order to make Canada "the most interconnected country in the world" (→ Canada: Media System). Canada's success energized other national IAP initiatives such as Mexico's network of Centros Comunitarios Digitales. IAPs play a substantial role in the ITU-led initiative to Connect the World, an effort to connect about one billion people in 800,000 villages – 30 percent of all villages worldwide – that are without any kind of ICT connection except possibly radio broadcasting.

## COOPERATION WITH OTHER INSTITUTIONS

### Schools and Telecenters

While many telecenters are standalone ventures, some initiatives link them with schools. World Links for Development (WorLD) supported the creation of school-based computer and network facilities that would be open to their communities after the close of the school day and on holidays. Using this model, the project established some 800 Community Learning Centers (CLC) across the developing world. In Bindura, Zimbabwe, the dual-use

school and community character of the center was important because the small fees paid by the community for telecenter services helped support the recurrent costs of hardware maintenance, power, supplies, and connectivity of the school's digital system.

### **Radio Broadcasting and Community Multimedia Centers**

Community radio has begun to emerge as a newly discovered medium in parts of the world that have historically had centralized, government-run radio systems. UNESCO, the major supporter of community radio, considers it as a medium "that gives voice to the voiceless . . . a mouthpiece of the marginalized." Building on this approach, in 2001 UNESCO launched a program for the development of Community Multimedia Centers (CMCs), with Kothmale Community Radio in Sri Lanka as the prototype. "Radio browsing" is a feature of this system. Radio browsing encourages people to contact the station to ask for information. The staff research on the Internet and then answer the questions in radio broadcasts. A major UNESCO effort has been to create 50 CMCs in *each* of three African countries – Mali, Mozambique, and Senegal – by the end of 2008.

### **University-Supported Telecenters**

Largely absent from the telecenter movement across the world have been higher education institutions. Although universities in developing nations have started to incorporate information technologies in their teaching, research, and administrative operations, they have paid relatively little attention to using information technologies to support such activities as those associated with rural development. Initiatives supported by such organizations as Canada's International Development Research Centre, the International Food Policy Research Institute, Asia-Pacific Economic Cooperation, the World Bank, and Cornell University and the University of Washington in the United States have started to test the idea that universities can be important supporters of telecenters by providing research-based localized content, helping communities assess their communication and information needs, and involving students as interns and volunteers in a telecenter's day-to-day operations. In these situations, universities have incubated community-based telecenters, nurturing them in their earliest development prior to the telecenters becoming independent community institutions. In this model, pioneered in Tamil Nadu, India and in the northern mountainous area of Vietnam, universities continue to assist telecenters after incubation by adapting scientifically authentic content to local conditions for retailing by telecenters, jointly conducting research on such matters as community information needs, and by involving students as volunteers and interns in the day-to-day operations of telecenters. Similar university-supported telecenters have been designed for eastern Africa, especially to support agricultural development and the welfare of small farmers.

### **CHALLENGES AND PROBLEMS**

Despite the enthusiasm and the support given to the shared access concept by international and national agencies, significant challenges impede more widespread

scaling up of development-oriented telecenters. Foremost among these is the lingering question concerning the relative benefit of putting money into information technologies versus the demands for other kinds of development resources, such as roads, water supplies, and health clinics. This stems, in part, from the perceived lack of convincing data about the impact of the Internet – a skepticism captured in a 2006 book by World Bank expert Charles Kenny. He points out that “As of December 2005 . . . there had not been survey-based, academically rigorous study of economic impact on an Internet access program in any developing country.” While there is no evidence of a cause–effect relationship, the question of relative return on investment may help explain the minor attention given to information technologies in Poverty Reduction Strategy Papers, the policy papers drawn up by developing nations as planning documents for encouraging broad-based growth and easing poverty.

Because access to the Internet is one of the principal attractions of telecenters, the quality of service provided by the Internet influences the potential benefits of a telecenter. Broadband connectivity, which reduces downloading speed as well as the delivery of more complex (often graphically enhanced) web pages, is problematic for many telecenters, particularly those in Africa, because of availability and cost. Wireless connectivity has become one of the solutions, especially for providing network services to remote and hard-to-reach locations, although cost–benefit considerations continue to be an issue. Also, the characteristics of Internet content relate to consumer demand for telecenter services: the relevance of content to local needs, the language of databases and websites, and the style of presentation are among the factors that telecenters need to address to become a community-oriented, demand-driven local institution.

Another challenge that telecenters face is their sustainability. Telecenters obtain operating funds from service fees (for example, for sending email or providing computer training), from public subsidies, and from contributions (including volunteer help). Most begin with donor funds and then struggle to survive when donor funds decline or end. An evaluation of UNESCO’s telecenter program indicated that long-term benefits related to health and economic opportunities are being realized. However, the evaluation notes that the telecenters cannot survive solely on charges paid by individuals. This dilemma could mean that efforts to achieve financial sustainability will drive telecenter managers to target services at community members who *can pay* – to the detriment of those who are poor.

Although attachments to existing entities such as schools and local government bodies are a way toward becoming solvent and institutionalized, telecenters as micro-enterprises may be the most feasible arrangement for widespread diffusion of the telecenter concept. The awarding of the Nobel Peace Prize in 2006 to the Grameen Bank in Bangladesh and to its founder Dr Muhammad Yunus demonstrated that private enterprise such as the women’s Grameen phone businesses could be profitable while helping combat poverty. Some independent telecenters have been innovative in developing income-producing services to support their operations. Among the *telecottages* in Hungary, there are more than 50 different kinds of income-producing services offered to the community. A major source are the contracts that they obtain from government agencies, thus becoming (for a fee) extensions for government services.

A continual challenge for telecenters is making them and their resources available to women. Location in the community, an inhospitable and intimidating telecenter

atmosphere, and lack of training conspire against women's participation in telecenters in many developing countries. Some organizations have taken steps to address the situation. The International Telecommunications Union launched a program to establish a network of at least 100 multipurpose community telecenters in 20 African countries. The telecenters are to be managed by women to enable them to participate actively in the building of information societies and to expand their role in communities through the use of ICTs. In India, as part of a strategy to attract women to participate in telecenter activities in Pondicherry, the Swaminathan Foundation requires that at least one woman be engaged in the management of each center that it supports (→ Development, Gender, and Communication).

## **Telecommunications: Law and Policy**

*Russ Taylor*

*University of Oxford*

The field of telecommunications law, policy, and regulation is a subset of the larger fields of governance and regulation generally, and the regulation of media and communications in society in particular. Telecommunications law and policy generally concern the ownership and control of and access to large-scale electronic networks that connect people and businesses. These networks may be fixed (primarily involving the use of fiber and wires)

or mobile (primarily involving the use of radio frequency spectrum), but that terminology is increasingly becoming antiquated as new technologies create products and services that are more difficult to define.

Telecommunications law and policy generally involve the application of state power through public regulation to secure three objectives: (1) the promotion of competition in the provision of telecommunications services to end users; (2) ensuring that those services are widely available to all sectors of the public, including the poor and those living in rural areas; and (3) aiding citizens and consumers through the often complex choices associated with telecommunications networks in the face of technological change (→ Media Policy).

### RELATIONSHIP OF THE STATE TO TELECOMMUNICATION

The story of telecommunications regulation is, first and foremost, the story of a relatively recent triumph of a set of governance values that (1) reject state ownership and monopolies, and (2) promote competition and consumer choice. These values have been adopted by most national and regional policy organizations, the end-user community, and the telecommunications providers themselves. Further, organizations such as the World Trade Organization (WTO) and the Organization for Economic Cooperation and Development (OECD) have placed reform and better regulation of the telecommunications sector near the heart of their missions. These values are so ingrained in this industry sector that it is now difficult to imagine a nation deciding to nationalize its telecommunications sector or otherwise limit competition in some manner.

In terms of policy orientation, the telecommunications industry is typically subject to regulatory control instead of direct political control. The complexities associated with telecommunications regulation often require sustained expertise that is commonly found in public regulation. In modern societies there is also a tendency to view direct political control over media and communications systems with suspicion. Accordingly, in this sector, policies may be originated at the political level, such as the enactment of legislation to govern the sector, but they are often implemented and enforced by public regulators or civil servants who act within a communications-themed ministry or government department.

The European Union, for example, enacts policies to ensure that national regulatory authorities within the telecommunications sector stand independent from their national governments (as well as stand independent from the business sector). For example, the EU Framework Directive requires, *inter alia*, that EU member states insure the independence, impartiality, and transparency of their national regulatory authorities in the communications sector (→ European Union: Communication Law; Communication Law and Policy: Europe).

Because many observers conclude that formerly separate technologies are converging, so that different media and communications service providers will offer similar services over digital networks, there has been an increased interest in what is known as *converged regulation* (→ Convergence of Media Systems; Digitization and Media Convergence). The notion of converged regulation, while perhaps based on an unproven causal connection between regulatory structure and successful economic or social outcomes for the public,

at least satisfies common sense with the notion that one regulator will be better equipped to deal with converged product offerings than multiple regulators. In practice, this has meant the merger of what were formerly separate media and telecommunications regulators. A notable recent example of this trend is in the UK, which created Ofcom (Office of Communications) from five different legacy regulators in 2003.

It was common throughout the world prior to the 1980s for most telecommunications providers to be *state-owned*, or in certain cases, private firms with monopoly power. In those countries with state ownership, the concept of modernized telecommunications regulation was unheard of: the state informally regulated the conduct of the enterprise directly through its ownership and control. Nevertheless, the situation remained far from ideal because the state-owned telecommunications firms were remarkably inefficient and consumer choice was lacking. State ownership of telecommunications firms is definitely now in disfavor as a policy option. However, the phenomenon continues to exist in isolated circumstances; for example, as of October 2006 Australia continued to own a 51 percent stake in that country's largest telecoms provider, Telstra, and was finalizing its plans for privatization.

### **PRIVATIZATION AND SECURING COMPETITION**

By way of example of how a private firm's monopoly power in telecommunications was addressed through public regulation and policy, one only needs to consider the example of the United States. In 1984, using competition law as the instrument, the US government settled a lawsuit against AT&T and partially broke up AT&T's then-existing monopoly on telecommunications services and equipment. Subsequent regulatory and legal decisions at both the state and federal levels further limited the reach of AT&T's market power and the market power of the so-called regional Bell operating companies that succeeded to AT&T's local networks after the 1984 break-up. Finally, the Telecommunications Act of 1996, as well as legislation intended to promote the → cable television and wireless industries, resulted in the current situation where the goal of US telecommunications regulation is to seek intermodal competition – competition between differing platform owners. Intramodal competition efforts, such as the efforts to promote local loop unbundling and similar network access regimes, have generally failed in the US, at least on a national level (→ Communication Law and Policy: North America; United States of America: Media System).

It may be useful for the reader to imagine a large-scale telecommunications network, constructed and maintained for years by a publicly owned or private monopoly. Attempting to change that situation by fostering a climate where multiple private networks exist and interconnect with each other while still sharing certain key facilities and resources is complicated. The picture becomes even more complicated when one adds in other goals, such as permitting end-users to move from network to network without undue delay or cost. This process has generally been called *telecommunications liberalization*. Finally, at the same time as liberalization measures are taking effect, the telecommunications law and policy often requires or encourages the network to be upgraded for better safety and data transmission purposes. Accordingly, telecommunications regulation abounds in policy complexity.

The United Kingdom is generally credited as the first significant country to privatize the ownership of its state-owned telecommunications firm. In 1984 the UK privatized British Telecommunications by selling a 51 percent stake, and also established an independent telecoms regulator known as the Office of Telecommunications, or OFTEL, a regulator that continued in existence until 2003, when it was replaced by the new UK regulator, Ofcom.

Europe has also been a leader in the development of telecommunications competition and modernization of policy in the sector, albeit in the wider economic and social project of greater European integration. Europe's early efforts to regulate the telecommunications sector and put it on the path to competition and private ownership started before the EU even existed as an entity. Early European measures prohibited member states from preventing competition in the telecommunications sector – both in terms of service and equipment manufacture. Later EU directives – effective from July 2003 – enacted a comprehensive regulatory framework that covers everything from universal service to radio spectrum regulation.

## **REGULATION AT THE GLOBAL LEVEL**

At a global level, the pre-eminent institution of telecommunications regulation is the International Telecommunications Union (ITU). The ITU, which has most of the world's states as members, serves mostly in a coordinating role in two key areas: (1) radio-frequency spectrum, and (2) standardization of telecommunications networks. It is perhaps in the area of radio-frequency spectrum where the ITU has had the most influence, hosting world radio conferences and adopting the ITU radio regulations to which ITU member states adhere. Certain inherently transnational applications that involve radio spectrum usage, such as satellite and maritime communications, have greatly benefited from ITU coordination. The ITU has not played a significant direct role in the process of telecommunications liberalization.

One important milestone in the advent of telecommunications regulation at the global level was that in February 1997, 69 members of the WTO agreed to open their basic telecommunications networks to competition as of January 1998. The number of parties to that landmark agreement has since grown, as has the number of countries that have adhered to the associated WTO Reference Paper that sets forth telecommunications regulatory principles, such as interconnection, universal service, regulatory independence, and fair allocation of scarce resources like radio-frequency spectrum.

## **ACHIEVEMENTS OF REGULATION**

With a few exceptions, the advent of modernized telecommunications regulation is very recent. The question remains, therefore: has public regulation in the sector of telecommunications been successful? One common critique of telecommunications regulation is that – because it ultimately aims at producing the benefits of a competitive marketplace – telecommunications regulation ought to be replaced by the robust application of general competition law. Competition law alone, however, would probably not produce the outcomes associated with the regulation of telecommunications networks. Nor would

competition law have an ongoing institutional mechanism to perform many of the common tasks found in telecommunications regulation, such as the coordination of the usage of radio-frequency spectrum, or the creation of technical standards that enable products and services to be made widely available.

Further, available evidence indicates that a telecommunications regulation approach that is based on the underlying goal of promoting competition where possible furthers the → public interest. The introduction of competition has lowered prices and increased choices for end-users of networks, without sacrificing quality of service or universality. Nonetheless, public regulators certainly make errors, and the history of telecommunications regulation has seen numerous policy interventions that have proved unsuccessful, such as the US attempt to promote competition by requiring telecommunications carriers to open portions of their networks to competitors. Similarly, inter-carrier compensation policies, special taxes, and fees adopted or required by telecommunications regulators all over the world often lead to retail service fees or situations that confuse or victimize consumers. On balance, however, the world's 20-year experiment with privatization and competition in the telecommunications sector has largely been a successful one.

Simply adopting laws and policies that legally permit new entrants to compete in the telecommunications marketplace may be an insufficient policy step if one desires robust competition to develop. This is because large-scale networks are costly to construct (most being developed initially as monopolies or state-owned firms) and – if true end-to-end communications with all members of society are important – there needs to be a method to interconnect networks. Not only is interconnection important, it is also a means to permit end-users to migrate as customers from one network to another, taking both their end-user equipment (e.g. their telephone) with them, and also the means by which the network addresses them (e.g. a telephone number). In other words, in a competitive system the transaction costs for someone to switch to a competing provider should be kept as low as possible. If an end-user must purchase new equipment and change their telephone number, it will impede competition.

Thus, standardization of telecommunications equipment design and network interfaces becomes important. Accordingly, telecommunications regulations often specify what technical standards should apply to devices that interact with the network. This enables a telephone user to move to a different part of the same jurisdiction and still be able to plug their telephone into the same type of wall jack. Telephone number portability functions in a similar manner: it generally enables users to retain their telephone when switching providers, and sometimes even when switching geographic locations.

## **ACCESS TO TELECOMMUNICATIONS**

In recent years, telecommunications law and policy have taken on increasing importance in the overall governance community, because telecommunications networks serve as the means by which people *access the* → *Internet*. Increasing the number of high-speed, so-called broadband, connections between end-users and the Internet (enabling the use of video applications and other bandwidth-intensive uses) has therefore become an important policy issue (→ *Internet, Technology of*). Policymakers are also grappling with the terms and conditions of the relationships between network owners, such as cable

or telephone companies, and Internet application providers, such as Google or Yahoo! (→ Search Engines). The issue, often called network neutrality, is whether network owners should be prohibited from discriminating among the various applications that run over their networks.

The *management of radio-frequency spectrum* by society is a function usually delegated to telecommunications regulators by policymakers. Working in conjunction with frequency allocation plans agreed on an international and often regional level, telecommunications regulators make decisions about (1) the service and technical rules associated with particular frequency bands, and (2) the terms and conditions under which that spectrum is licensed to individual users. Because radio-frequency spectrum is often made available on an exclusive-use basis to end-users, there is often competing demand for the limited number of licenses that governments make available. One method of resolving that demand is to auction the radio spectrum license to the highest bidder. Radio spectrum auctions have proved to be an attractive license assignment mechanism for two reasons. First, the auctions have sometimes turned into significant revenue raisers for the government involved, raising the internal political profile of the telecommunications regulator. Second, and perhaps more important, auctions have demonstrated themselves to be efficient assignment mechanisms because they tend to result in the spectrum license being awarded to the person who values it most highly.

Telecommunications regulators have, however, also realized the public value associated with the unlicensed use of radio spectrum in the so-called spectrum commons. The US innovated the unlicensed use of spectrum through its Part 15 radio regulations. For years, low-power devices – often with consumer implications such as cordless telephones and remote controls – took advantage of regulations by the → Federal Communications Commission (FCC) permitting unlicensed uses in certain frequency bands. The advent of WiFi technologies in the 1990s changed the debate, however. The remarkable success of WiFi – an unlicensed wireless technology – caused proponents of the spectrum commons to lobby for the increased usage of unlicensed spectrum.

One important concern in the regulation of telecommunications is how to ensure that poorer and harder-to-connect members of society have access to telecommunications networks. The series of policies that is designed to address this potential problem is often called *universal service*. Universal service regulations often involve two elements. First, these policies typically declare what types of telecommunications services the policy will legally enable all people – regardless of their economic status – to secure. Second, these policies usually specify a mechanism by which society funds the universal service obligation. The funding mechanism, such as a special tax on communications services, can be explicit, and may require special obligations of the dominant network owner to connect people to its networks under special rate plans.

Universal service obligations and related government programs are designed to ameliorate the so-called → *digital divide*. The digital divide attempts to measure the significance of those numbers of people in society who do not have access to, or understanding of, the digital technologies provided by telecommunications providers, such as Internet access (particularly broadband) and mobile telephony.

Because most telecommunications products and services are ubiquitous in society, a great deal of telecommunications regulation covers consumers' dealings in the marketplace,

such as fair terms and conditions for telecommunications contracts. Consumer-focused intervention also deals with policies relating to how telecommunications networks connect people to public safety providers. For example, policies may be enacted that require or enable telecommunications providers to give certain end-users (e.g. fire and rescue teams) priority during public safety emergencies. Some policies directly target network end-users themselves, making it illegal to disrupt telecommunications networks or use them in an annoying manner, such as telemarketing restrictions, or restrictions on the use of autodialing devices.

One recent area of telecommunications law and policy that deals with consumers is the issue of *consumer privacy*. Telecommunications regulations now commonly describe what are the acceptable uses of customer-specific data by telecommunications carriers with respect to marketing practices, sharing with third parties or affiliates of the carrier, and cooperation with law enforcement organizations. Other forms of telecommunications regulation deal with the fact that networks are physically intrusive in society. Accordingly, regulation may cover, for example, terms and conditions for the emplacement of wireless antenna devices, or the sharing of conduit or utility pole space among service providers.

# Telegraph, History of

Peter Putnis

University of Canberra

The term “telegraph” was used from the late eighteenth century to describe line-of-sight distance communication systems, most notably Claude Chappé’s semaphore network. By 1810, this network linked 29 of France’s largest cities to Paris. Experimental telegraphs utilizing electricity passing over wire for signaling purposes were developed in the early 1800s, though it was the inventions of Cooke and Wheatstone in the UK in the late 1830s which led to their practical application, initially on railways, where, in warning of accidents and stoppages, this form of signaling had the obvious advantage of traveling much faster than any train itself. Around the same time Samuel Morse, in the US, developed his system of using a series of short and long pulses of electric current, generated by turning the current on and off with a Morse key, to represent letters of the alphabet (Morse code). This system came to dominate telegraph communication for the next 100 years.

From the 1850s telegraph networks spread throughout the world with extraordinary speed. While in continental Europe state-owned systems were developed, in the UK and the US private enterprise drove their expansion, though in the UK the domestic telegraph system was nationalized and became part of British Post Office operations following the Telegraph Act of 1868. In the US, while there were initially dozens of telegraph companies, a single company, Western Union (which completed the line between the east and west of America in 1861), came to dominate, eventually becoming America’s first major industrial monopoly.

The *demand for telegrams* initially came from governments, the military, merchants, and newspaper companies (→ Telegraphic News). It is noteworthy that Germany’s extensive network of underground cables constructed in the 1870s was prompted by the political needs of a newly unified Germany. As prices reduced and technology improved, telegrams came to be also used extensively by the general public. The pattern of growth is indicated by the fact that within the UK the number of words transmitted by telegraph increased from 4.2 million in 1874 to 15.7 million in 1899. Outside Europe and the US, the largest telegraphic network in the second half of the nineteenth century was in India, which by 1860 had 18,000 km of telegraph lines spread across the entire subcontinent.

The development of *intercontinental telegraph links* was delayed because of the difficulty of manufacturing insulated submarine cables. The first successful link across the English Channel was established in 1851, while a link across the Mediterranean between France and Algeria was completed in 1854. The first working submarine cable uniting the vast systems of North America and Europe was completed in 1866, while Australia was connected to the UK via India in 1872. South America was linked to the growing international network in 1873, while eastern and southern Africa were connected in 1880. The encircling of the globe by telegraph cable was completed in the early 1900s.

In the late 1890s Marconi demonstrated the viability of wireless telegraphy and in 1901 sent the first wireless message across the Atlantic. As well as providing a service to

shipping, wireless telegraphy's main application was in long-distance communication augmenting existing cable links. It was boosted by the development of shortwave beam systems in the 1920s.

The telegraph was a watershed in communication history and a model for future developments (→ Information and Communication Technology, Development of). From its earliest days, it was recognized as an extremely powerful tool which, it was said, "annihilated time and space." It marked a decisive *separation of communication from transportation* and also allowed communication to control physical processes, such as switching, from a distance. Its introduction, and the advantage it conferred in matters of commerce on those who could access the information it afforded, initiated debate about whether telegraphy should be conducted by governments as a public service or whether it was best left to the private sector. In the upshot, most domestic telegraph systems (that of the US excepted) developed on a public service model, while most international links were established by private enterprise.

The telegraph had a major impact in many realms of activity. It became integral to *military operations*, allowing, through field telegraphs, command at a distance and rapid mobilization of troops. It was credited with preventing a Confederate takeover of Washington during the American Civil War because it enabled a rapid mobilization of Unionist troops in response to this threat. It made world markets a possibility since prices of commodities at geographically separated trade centers could be readily compared. It contributed to the rise of global business, aided imperial expansion, and changed international diplomacy. It also transformed news reporting and distribution, both nationally and internationally, and led to the development of news agencies. Carey (1989) has noted how, in freeing communication from the constraints of geography, the telegraph enlarged the spatial and temporal boundaries of human interaction. Its networks enabled the development of communities of knowledge and action across local and national borders.

As the price of telegrams dropped, the telegraph came to be widely used by the general public. In the UK growth was encouraged by a uniform rate to all parts of the country, which was set at six pence from 1885. However, before too long the telephone (patented in the US in 1876 by Alexander Graham Bell) began to encroach on telegraphic use. In 1914 about 69 million inland telegrams were transmitted in the UK, but by 1970 this had declined to 7.6 million.

# Telegraphic News

*Menahem Blondheim*

*Hebrew University of Jerusalem*

The telegraph enabled rapid, continuous, and simultaneous diffusion of public information across space. Its application to news reporting transformed journalistic practices, institutional arrangements, and audience experiences. The advent of telegraphic news further affected political, socio-economic, and cultural processes internationally.

Introduced in the US in 1844, the telegraph helped sustain the press for nearly a century as the fastest, most alluring and useful news medium (→ Telegraph, History of). Discovering the → news – the provision of timely information on recent events – helped launch major increases in daily circulations beginning in the second quarter of the nineteenth century. Readers found timely news functionally useful for operating in the rapidly changing economic, political, and social world. Fast news also provided emotional gratification, by connecting audiences to major events across time, if not space. Speeding news by telegraph increased the potential usefulness and popularity of newspapers on both accounts. At the same time, news transmission proved the most successful application of the early telegraph and would remain a major source of income and influence for the telegraph industry (→ Newspaper, History of).

This synergy gave rise to an institution mediating between the press and telegraphy: the *news wire service*. Although newspapers at the time were becoming big businesses, their news-gathering operations were organizationally compact, incapable of managing a far-flung system of active news gathering in real time. Nor was the capacity of early telegraph lines sufficient for delivering separate news reports for each newspaper. An operation that specialized in telegraphic news gathering on behalf of many newspapers could economize on telegraphic capacity and tolls, as well as on newspapers' scarce organizational resources (→ News Agencies, History of).

The emergence of wire services also followed a technological rationale. Besides the obvious utility of speeding news from point to point, telegraphy also had the novel capacity of broadcasting. Information from any node on the network could reach all other nodes simultaneously, by integrating the telegraph lines. News gathered at one point could therefore broadcast to every point connected to the network at once. The wire service thus operated as a giant funnel, gathering news from a vast field into its headquarters, processing it, and then broadcasting it to newspaper clients spread over space. The systemic features of both ends of the wire service funnel implied that telegraphic news gathering, like postal or electricity networks, would have monopolistic tendencies. In many countries a single wire service dominated, but the structure varied among geopolitical systems (→ News Agencies).

In the *United States*, once the major trunk lines connected in New York in mid-1846, the city's six leading dailies joined in a cooperative arrangement that became known as the Associated Press (AP). Before long it began selling the telegraphic news it gathered to out-of-town newspapers, and after mid-century the AP dominated a national system of telegraphic news. Once the telegraph began spreading over *Europe*, a variety of telegraphic news-gathering arrangements emerged. In France, a private commercial enterprise

established in 1835, the Havas Agency, added telegraphic news distribution to its translation and advertising services, cooperating closely with government in its wire news operation. The Wolff Bureau in Germany was also a private business, and cross-ownership of telegraph and cable enterprises buttressed its position. Its cooperation with German political and commercial interests was also significant but remained covert. Guiliamo Stefani's agency in Italy was fundamentally a commercial venture, but Paul Usoff in Russia led a telegraphic news-gathering system founded on cooperative elements. In the United Kingdom, the public telegraph companies at first provided news to the provincial press. By the late 1850s Reuters foreign news service augmented the telegraph company reports, and from 1868 it cooperated in the domestic field with the British Press Association.

News gathering by telegraph had far-reaching *implications for the development of the press* and influenced major social processes. Providing a coherent first report, wire news set the agenda for the press (→ Agenda-Setting Effects). The reports, combining news from all over the country and shaped for a national audience, served the cause of national integration. By collating and spreading uniform economic information, wire service news leveled market prices and advanced the integration of national economies. As the most popular kind of news copy, wire reports also influenced journalistic practices and standards, from setting the inverted-pyramid structure for telling news stories to using objective language in reporting (→ Objectivity in Reporting). Read across regions, the wire report spread national languages, discourses, and cultures.

*International news gathering* by telegraph expanded with the laying of trans-oceanic cables in the second half of the nineteenth century, increasing the scope of telegraphic news (→ International News Reporting). Although rapid sharing of economic news across political boundaries rationalized markets, it did not necessarily harmonize international relations. International conflict and war proliferated in the age of the telegraph, illustrating that news briefs from foreign sources could increase friction and hasten belligerence.

Improvements in telegraph user equipment in the 1870s generated a variety of telegraphic indicators and “tickers” for delivering commercial quotations and news headlines direct to subscribers, circumventing the press. By the latter part of the nineteenth century, telephone reporting supplemented telegraphic news gathering, and teleprinters facilitated its distribution. After the turn of the century, news transmissions used radiotelegraphy extensively, with news photographs transmitted alongside text. Radio and television, like newspapers before them, made use of wire reports in their newscasts (→ Radio; Television). By the latter twentieth century, digital transmission replaced telegraphy as the conveyer of fast news in text, voice, and video to media outlets (→ Technology and Communication).

## Telephone Talk

*Kathleen C. Haspel*

*Fairleigh Dickinson University*

Telephone talk has been a central communication practice and site of study since Shannon and Weaver developed their fundamental model of communication at Bell Telephone Laboratories in the 1940s to explain how technological and human channels of communication transmit information (→ Information and Communication Technology, Development of) . As telephone service spread and ushered in the information age in the latter half of the twentieth century, it acquired the status of an important social indicator. Yet little was known of the social use of the telephone until the 1970s (Pool 1977), when sociologist Harvey Sacks recorded and studied telephone conversations for the access they provided to structures of social action (Atkinson & Heritage 1984). With his colleagues Emanuel Schegloff and Gail Jefferson, Sacks developed a method of transcribing and analyzing social interaction within and beyond the context of telephone talk (→ Conversation Analysis). In the 1980s and 1990s, Robert Hopper adapted conversation analysis to studies of telephone talk across relational and cultural contexts. These scholars established libraries of recordings that provide a valuable resource to researchers of language and social interaction worldwide. The practice and study of telephone talk have since grown, so that it is now considered vital to the construction of identities, relationships, cultural practices, and institutional procedures – as well as to information exchange.

### **CANONICAL OPENINGS AND SITUATIONAL VARIATIONS**

Openings of telephone calls have garnered the most attention from researchers because of their uniformity, complexity, and the trajectory they set for ensuing talk. In openings, callers and answerers are seen to establish their identities and relationships, and initiate the agendas that are integral to the achievement of their telephone talk (→ Identities and Discourse). Routine features of telephone openings constitute a “canon” for researchers, who draw inferences from circumstantial, technological, relational, institutional, and cultural (i.e. situational) variations on them. The canonical opening is a pattern of ordered

tasks achieved through four sequences: a *summons–answer sequence* (the ring of the phone and answers to it), an *identification–recognition sequence* (identifying and recognizing parties to the talk, implicitly or explicitly), a *greeting sequence* (forms of “hello,” sometimes combined with inquiries), and a *sequence of initial inquiries*, sometimes called the “*howareyou*” sequence (Schegloff 1986).

Although initially identified in studies of telephone talk in English, the canonical opening and variations on it appear in telephone conversations in Finnish and Swedish (Baker et al. 2005); Arabic, Chinese, French, and Spanish (Hopper 1992); and Danish, German, Greek, Japanese, Korean, and Persian (Luke & Pavlidou 2002). The canonical telephone opening serves as a living prototype against which varieties of text and talk in interaction are compared and explained. Its application to various kinds of telephone talk has shown that telephone calls share a “functional similarity,” in spite of structural and situational variations (ten Have 2002). All calls unfold in two phases of action: one primarily relational and phatic (→ Small Talk and Gossip), and a second that is more topical, task-, and goal-oriented. In the first phase, telecommunicators establish contact and relationships through summons–answer, identification–recognition, greeting, and some inquiry sequences. In the second phase, usually marked by an inquiries sequence, telecommunicators work toward a first topic and/or reason-for-calling.

### ESTABLISHING CONTACT AND RELATIONSHIPS

While telephone companies once prescribed ways of answering telephone calls, telecommunicators have developed their own ways of establishing contact that are tailored to their particular relationships and situations. Research on telephone talk shows that call type, relationship type, and participant actions are closely aligned. How people answer phones varies well beyond versions of “hello,” indicating not only that a channel of communication is open, but that contact has been established between parties who are ready (or not) to take action. Answers to telephone summonses range from directives (e.g., “speak, please” and “go ahead” in Greek) to simple acknowledgments of recipient readiness (Italian *pronto*), to polite invitations or commands to talk (e.g., Czech *prosim*, Spanish *mande*; Sifianou 2002).

Researchers *classify telephone calls* according to the relationship established by telecommunicators through their talk (intimates, acquaintances, or strangers) and characterize the talk as ordinary/interpersonal or institutional according to displayed orientations to reasons-for-calling. Calls among acquaintances typically open in canonical order, while calls between strangers or intimates have reduced and specialized openings. In calls between lay persons and institutional representatives, personalized elements of openings (such as greetings and inquiries) are usually suppressed or replaced with specialized identifications and/or inquiries (e.g., “police desk”; “what is your emergency?”). Yet sales, service, and broadcast callers regularly employ synthetic personalization in their openings to foster interpersonal relations and gain specialized access to the time and interest of called parties.

*Telecommunicator relations* are shaped by their means of contacting one another. Technological variations on telephone openings – hyperpersonalized identifications and summonses in mobile phone calls, standardized answers and elaborate accounts in voice

messages, and depersonalized, disjointed exchanges via voice recognition systems – have relational and power implications because they “afford” variable access to participants in telephone talk (Hutchby 2001). Caller hegemony has changed. Technologically modified telecommunication affords some participants more agency (by enabling them to avoid calls or contact unavailable parties) and others less (by constraining the timing and taking of turns at talk). Expectations of increased availability and reduced privacy fueled by greater telephone access further shape relations between callers and answerers. As the telephone hosts media that broaden access to others – Teletype (TTY) conversation, Internet relay chat (IRC) (→ Internet, Technology of), short and instant messaging services (SMS and IM), and media sharing (photos and videos sent via mobile phones) – telecommunicators acquire the means to achieve perpetual contact, micro-coordinate their activities, and form “fused” relationships (Katz & Aakhus 2002).

### WORKING TOWARD A FIRST TOPIC OR REASON-FOR-CALLING

All telephone talk is driven by reasons-for-calling and requires an investment of temporal, financial, and relational capital. How telecommunicators transition from phatic opening sequences and work toward reasons-for-calling often rests on the design and position of inquiries in the talk. An initial inquiry such as “how are you?” or a request for help can mark a pivotal moment in a call, to which the rest of the conversation is anchored. It is at this moment that telecommunicators move beyond establishing contact and/or relationships (and in some cases, the language or dialect of choice) to get to the matters that occasioned the call. Telephone talk is a means of taking care of business as well as relationships, two avenues of activity that are not mutually exclusive, as evidenced in participants’ efforts to manage both in calls whose primary purpose is supposed to be one or the other (Tracy 1997). Nowhere is this more evident than in calls to help lines (→ Support Talk), and other telephone services that involve the management of human relations and emotions (→ Emotion and Discourse).

*Telecommunicator motivations*, as well as relations, are enacted and managed through inquiry sequences. For example, preliminaries and prefaces to questions asked by news interviewers and talk-show callers of public figures instantiate complex asymmetrical relations between them and may display multiple, even contradictory, motivations (→ Broadcast Talk). Prefatory → discourse markers such as *kedo* (Japanese) or *nuntey* (Korean) used in initial inquiries can make some calls sound “businesslike” long before reasons-for-calling are addressed (Park 2000). Yet the absence of prefatory utterances can mark calls as routine or topic-less, as when calling to “say hi” or “keep in touch.” Some telecommunicators use initial inquiries such as “how are you?” to address relational and institutional concerns simultaneously, as in calls concerning healthcare issues. Ambiguous inquiries such as “how [or what] are you doing?” are used to manage calls-on-hold, calls-in-a-series, and calls dealing with delicate matters. Inquiries like these placed at calls’ openings may communicate considerable or urgent concern. How inquiries are used and what they accomplish ultimately depends on their situated use. Inquiries into location and ongoing activities, for example, may be taken as breaches of etiquette or privacy in landline calls, yet are standard in emergency service calls and common in mobile phone calls.

## BEYOND TELEPHONE TALK

The most widely used communication medium that now links others (radio, television, Internet), the telephone is more situated in the lives, loves, and jobs of communicators than ever before, providing researchers with unprecedented access to communication practices in action. Research on telephone talk has spread with mobile telephone use, from its origins in the US, the UK, and the Netherlands to Finland, Hong Kong, South Korea, Japan, and Taiwan. Yet as telecommunication grows more universal, remote, and standardized, spontaneous telephone talk carries a higher premium for all who participate in it and study it. Telephone talk is now much more than an efficient means of information transmission; it is, as early researchers proposed, a fundamental site of sociality. As a site of study, it offers insights into communication phenomena such as intimacy-at-a-distance, mediated relationships, interpersonal and institutional crisis management, electronic privacy, social networking, emotional labor, the commodification of interpersonal relations, and citizen participation in public spheres.

## TeleSur

Omar Hernández Sotillo

Monterrey Institute of Technology and Higher Education

TeleSur was a → television initiative launched in July 2005 and spearheaded by the government of Venezuela, in cooperation with three other Latin American states – Argentina, Cuba, and Uruguay (→ Argentina: Media System; Cuba: Media System; International Television). The channel was presented by its promoters as “the new television of the south,” with a geopolitical emphasis on the global south reflected in the way they write its very name: *teleSUR*. While there were some undeniably innovative aspects to this project, its central objectives corresponded to old and traditionally unfulfilled political aspirations for Latin American regional integration on the one hand, and for providing alternatives to the hegemonic ideologies of cultural imperialism on the other (→ Cultural Imperialism Theories). This orientation was clearly reflected in one of the channel’s slogans, often seen on the screen in promotional spots between programs: “Seeing each other we get to know each other, knowing each other we get to respect each other, respecting each other we learn to love each other, and loving each other is the first step toward integration.”

As an actual organization, then, TeleSur had a quite short history at the time of writing. However, the specific motivations behind its formation, beyond the rather general political ideals outlined above, may well be traced to the events of April 2002 in Venezuela, when, after massive yet peaceful demonstrations against the government had resulted in a number of deaths, President Hugo Chávez was briefly removed from power. While the main responsibility for his ousting was commonly attributed to opposing sectors within the military, the mainstream commercial media played an important role, first (and clearly),

in galvanizing the growing discontent against Chávez, and second (but not so clearly), in helping to form and publicize the hastily arranged, ill-conceived, and short-lived interim government. A proper discussion of these crucial events in Venezuela's recent history is well beyond the scope of this entry, but there is little doubt that when the President was reinstated after a two-day absence, one of his top priorities was to find ways to check the power of the commercial media system and generate alternatives to them. The passage of the Law for Social Responsibility in Radio and Television in late 2004 (→ Communication Law and Policy: South America), and the strong support lent to the TeleSur project leading to its implementation in 2005, can both be seen as practical consequences resulting from the heightened importance granted by the Venezuelan government to media issues.

In 2007, two other countries joined the TeleSur partnership: Bolivia and Nicaragua (→ Bolivia: Media System). Bolivia held only 5 percent of the shares, contrasting with the 46 percent held by Venezuela. Argentina (20 percent), Cuba (19 percent), and Uruguay (10 percent) completed the list of shareholders, although this last country's official participation underwent a lengthy approval process and still awaited congressional confirmation at the time of writing. Nicaragua's involvement was limited to the provision of a certain amount of content and the transmission of TeleSur's signal both over the air and via cable. Expanding the reach of its signal, in fact, was one of the crucial challenges faced by this regional channel; even in Venezuela, it was initially only available via pay-TV until free-to-air transmissions began in February 2007, and even so the broadcast signal barely reached 30 percent of the country's population at that point in time. During these early stages, TeleSur's signal was also available, though at times partially and for limited periods, through a wide variety of distribution channels. These ranged from modest community stations in Brazil (→ Brazil: Media System) to the satellite service DirecTV in Venezuela. The common denominator in all cases was a relatively low number of even potential viewers. Besides the effort to place its signal on open TV in Latin American countries, which included a Portuguese version of its transmissions for Brazil, another TeleSur strategy for increasing its reach consisted of plans for making the channel available throughout Europe. To that end, it opened offices with news correspondents in Madrid and London in May 2007 (→ Foreign Correspondents).

The difficulty in reaching very large audiences was not only a function of the lack of adequate distribution channels, but had much to do with the attractiveness of the contents offered. While → news and → information naturally constituted the cornerstone of its programming, TeleSur's broadest objective was to become a window into Latin America and its peoples, not just from the outside, but mainly so that they could recognize each other and the richness and diversity of their cultures. Thus, it encouraged its viewers to be producers of content as well, and to submit their reports, documentaries, and fictional works for broadcast (→ Citizens' Media; Citizen Journalism; Access to the Media; Public Access Television). Perhaps the biggest challenge for TeleSur, then, would be how to attract large audiences and thus become a successful alternative to the commercial media outlets it criticized, without reproducing the habitual practices of such mass-oriented media.

## **Televised Debates**

*Carsten Reinemann*

*Johannes Gutenberg University of Mainz*

*Marcus Maurer*

*Johannes Gutenberg University of Mainz*

Televised debates have become a key feature of election campaigns in many countries around the world. Unlike regular campaign media coverage, they provide voters with the chance to directly listen to the candidates and learn about their stands on the issues and their personalities without the filter of the media's news selection. Unlike campaign ads, they provide much more information and give the opposing candidate the chance to counterargue. Therefore, televised debates are often regarded as an especially valuable form of campaign communication (→ Election Campaign Communication). In many countries, televised debates reach a larger audience, generate more media coverage, and stimulate more discussion among citizens than any other single campaign event. In addition, numerous studies in several countries show that televised debates have a variety of effects. Due to their assumed importance, a large body of research has been accumulated investigating various aspects of the debates, especially in the US. However, due to differences in political systems, electoral procedures, the role of the candidates, political cultures, and the debates themselves, these findings should not be uncritically transferred to other countries (→ Political Communication Culture).

### **HISTORY AND FORMATS**

The first televised election debate took place in 1956 in the US when Adlai Stevenson and Estes Kefauver ran for the nomination as presidential candidate for the Democratic party. In 1960, the four debates between John F. Kennedy and Richard Nixon were the first US presidential debates broadcast in television. However, it was not until 1976 that

presidential televised debates were held again. Before that, the incumbents refused to take part in televised debates. Besides the US, televised debates have also been common in many other countries for a longer time. For example, the first televised debate in Sweden took place in the late 1950s, in Canada in 1962, and in Germany in 1969. In contrast to that, even some established democracies, like the UK, have never had televised debates in general elections (Coleman 2000).

Since the 1970s, the spreading of televised debates has become part of the modernization and personalization of election campaigns throughout the world (→ Personalization of Campaigning). At the end of the 1970s, televised debates were common in only 10 countries. By the end of the 1990s, they were a regular part of general elections in at least 35 nations (Plasser & Plasser 2002). It is very likely that their number has increased since then, because there are various countries in which televised debates have been held for the first time in the past few years (e.g., Taiwan, Ukraine, Kyrgyzstan).

Televised debates are not restricted to general presidential or parliamentary elections on a national level. They are also a part of campaigns at the state/regional or local level (e.g., in the US, Germany, and the UK). In addition, there are debates not only between candidates of different parties but also between candidates of the same party trying to win a party's nomination for an office (e.g., in the US *primaries*). Moreover, televised debates are not restricted to presidential democracies (e.g., France) or two-party systems (e.g., the US). They are also a part of campaigns in parliamentary democracies with multiparty systems (e.g., Australia, Canada, India, Israel, and South Africa).

There are considerable differences between and within countries as far as the *number* of debates and their *format* is concerned. For example, debates differ in their length, the participation of journalists and voters, the number of candidates participating, and their rules (e.g., as far as the length of statements, the possibility of direct responses, etc. is concerned). In the US, candidates standing or sitting on a podium were traditionally interviewed by one or more journalists (*joint press conference*). In the 1990s, the so-called *town hall format* was introduced. Here, (undecided) voters discuss with the candidates. In many countries with multiparty systems, debates are not restricted to two candidates but representatives of several parties hold a joint debate moderated by journalists (e.g., India).

In some countries, separate debates are held for the candidates of small and larger parties (e.g., the Netherlands). And in still other nations, candidates of all parties represented in parliament debate in a series of one-on-one discussions (e.g., Austria). The format of a debate is not without consequence. First, several studies investigating debate content indicate that the format of a televised debate influences the actions of the candidates and moderators. For example, in a podium format, candidates seem to be more aggressive and attack-oriented than in town hall formats. Second, format also seems to have an impact upon what viewers learn from a debate and to what extent issues and images play a role in candidate evaluations. For example, the more informal chat format seems to result in more issue than candidate image learning, because the format generates more issue-oriented discussion.

## AUDIENCE OF TELEVISED DEBATES

In many countries, televised debates in general elections generate the largest audience of all single campaign events. Often, they have the largest audience of all TV events in an

election year. For example, 16 million people – about one quarter of the Italian population – watched the debate in the Italian 2006 general election. In the US, about 63 million citizens watched the first debate in 2004 (about 21 percent of the population). However, at least in the US, the audience of the debates has decreased since the first debates in 1960 and 1976. Generally, if a series of debates is held, the first one usually attracts the largest audience. In addition, the size of the audience is influenced by voters' perceptions of how close the race is, by the number of undecided voters, and by the number of TV stations broadcasting the event.

In several countries, more politically interested voters and those who strongly identify with the debaters' parties are more likely to watch. In addition, education, income, and age have been found to be significant predictors of debate watching: more highly educated voters, those with higher income, and older voters are more likely to tune in. In addition, as has been shown at least for the US and Germany, those watching a debate are heavier users of news media. Overall, the structure of debate audiences is quite similar to that of consumers of other campaign media. Still, in absolute numbers the candidates can reach more undecided and uninterested voters via debates than by any other means of campaign communication.

Just as the large audiences suggest, numerous studies show that voters like televised debates. They regard them as a good opportunity to learn about the candidates' personalities and their stands on the issues. In addition, undecided voters hope to get help with their voting decisions. On the other hand, studies have shown that viewers are not always satisfied with the debates. For example, viewers of the 1996 US presidential debates would have preferred longer responses and more rebuttal opportunities, fewer topics, and more questions distinguishing candidates from one another.

## EFFECTS OF TELEVISED DEBATES

### Content and Research Questions

Numerous studies have dealt with various aspects of what happens during a debate using both social science content analysis and classical rhetoric. Researchers have investigated the statements of candidates and moderators or citizens in town hall formats, looking at both verbal and visual message elements. Studies on *verbal content*, for example, have examined the use of arguments, evidence, and humor, the amount of attacks, acclaims, and defenses, language styles, and the degree of clash (analysis of one's own versus the opponent's position or attacks). Most of these studies show that debates are rather issue-oriented and contain less character discussion or attacks on opponents than other forms of campaign communication. This does not necessarily mean, of course, that there is much depth of argument in the debates. In contrast to that, studies on *visual content* have been rather rare. This is quite surprising, bearing in mind the widespread notion that the visual appearance of candidates might be able to decide a debate. Even in the US, the latest comprehensive analysis of visual message components dates back to the 1992 presidential debates.

The largest amount of debate research investigates their *effects*. Most studies focus on immediate effects on perceptions of who won the debate, knowledge about candidates'

issue stands, candidate images, and voting behavior (→ Political Cognitions). A limited number of studies deal with more latent effects on, for example, voters' civic engagement and political alienation. Most effect studies use pre-test/post-test design with (representative) surveys or focus groups. In addition, there is an increasing number of experimental studies and studies using real-time response measurements of viewers' reactions during debates (→ Real-Time Ratings [RTR]). Generally, debates seem to differ in their impact on voters due to differences in the specific campaign contexts, formats, candidates involved, their performances, etc. This means that some debates seem to have strong effects whereas others remain of marginal influence.

### **Verdicts About Who Won**

Post-debate surveys of viewers and large portions of post-debate media coverage focus on the question of who won the debate. In fact, studies have shown that only the perceived winner can benefit from a debate in terms of votes. Therefore, it is important to know how viewers arrive at their immediate post-debate verdicts. Generally, those verdicts are affected by political predispositions, expectations, and the perception of the debate itself. Unfortunately, there are only a few studies that combine measures of all of these factors to explain post-debate verdicts. These studies show that the debate itself can have an impact on the perceptions of the winner that goes beyond the influence of party identification and expectations. The likelihood of positive verdicts can be increased by candidates when they use acclaims and commonplaces in the debate. These often result in positive reactions by viewers. On the other hand, attacks and factual evidence tend to polarize supporters and opponents of the candidates (Reinemann & Maurer 2005).

### **Learning**

Numerous studies have shown that televised debates can enhance viewer's knowledge of candidates' *issue stands*. These effects are mostly the result of verbal elements of the debate. The question in the studies usually is whether participants are able to accurately assign statements or positions to a candidate. However, effects are stronger for less politically interested viewers, early debates have a stronger impact, and viewers seem to learn more about the challenger than about the incumbent. A second learning effect is *agenda setting* (→ Agenda-Setting Effects). Several studies show that those issues extensively discussed in a debate are likely to be of greater importance to debate viewers afterwards. And finally, although this has not been extensively studied, televised debates have also been shown to affect viewers' *perceptions of reality*, e.g., of the economic state of a country (→ Media and Perceptions of Reality; Political Knowledge).

### **Candidate Images**

Another group of studies has shown that debates influence → candidate images, i.e., how personal traits and abilities of the candidates are perceived and how candidates are evaluated. Effects on two types of traits can be differentiated: whereas perceptions of political traits like issue competences or effectiveness seem to be more strongly affected

by verbal message components, perceptions of personal traits like trustworthiness or likeability are more strongly affected by visual elements. Again, the images of less well-known candidates are more likely to be affected than those of better-known candidates (incumbents).

### Priming

Recent studies have begun to look at priming effects of televised debates (→ Priming Theory). They argue that debates can change the relative importance of various cognitive elements that are connected to attitudes about candidates and voting decisions. Priming effects are regarded as the link between “indirect” effects on candidate images and “direct” effects on voting decisions. Debates can have priming effects at *three levels*. First, debates can increase the importance of some personality traits in comparison to others (e.g., trustworthiness vs. rhetorical abilities), changing the overall evaluation of a candidate’s personal qualities. Second, they can enhance the importance of personality traits in comparison to personal issue competences, changing the overall evaluation of a candidate. Third, they can enhance the importance of candidates in comparison to party identification and issue positions, changing voting intentions (→ Issue Voting). A study of the second 2002 German debate showed priming effects at all three levels (Maurer & Reinemann 2003).

### Voting Intentions

At least in the US, presidential debates tend to reinforce the voting intentions of those already committed more than they change them. For the US, the number of partisans changing their voting intentions because of debates has been estimated to be about one to four percent (Jamieson & Adasiewicz 2000, 26). In other countries, much stronger effects have been reported for certain debates (e.g., Australia, Mexico). But even when the number of converted party identifiers remains relatively small, this does not mean that debate effects are minimal. In many western democracies, the number of party identifiers has been declining and effects on independent and undecided voters seem to be much stronger. In addition, a small percentage of converts still might decide an election in close races. On the basis of their extensive review of US debate research, McKinney & Carlin (2004) came to the conclusion that four of the eight presidential races between 1960 and 2000 that featured televised debates were *decisively* influenced by them (→ Political Persuasion).

## DEBATE COVERAGE AND ITS EFFECTS

In several countries, content analyses have shown that televised debates generate more media attention than any other single campaign event. Before the debates, the media mold the expectations of the debate. Immediately afterwards, journalists and experts give their interpretations of it, sometimes relying on instant polls (→ Polls and the Media). In addition, the contestants’ campaigners try to get through with their interpretations (→ Spin Doctor). In the following days, the media do not focus on issues but on the performance of the candidates, the question “who won?” and strategic aspects of the

debate. In addition, they generally accentuate the negative. In some countries, general political leanings of the media are also clearly visible in debate coverage. Post-debate coverage influences perceptions of a debate, even among those who watched it themselves. For example, studies in Germany using panel designs showed that up to one quarter of the viewers of the second debate in 2002 changed their minds about who won the debate in the following days as a result of media coverage. In addition, the media communicate the result of the debate to those who did not watch it themselves.

### FUTURE DIRECTIONS FOR RESEARCH

Despite a large body of research, there still is a need for more studies of televised debates. Among the various aspects that seem to deserve special attention are:

- 1 *International comparisons.* Most of our knowledge on televised debates comes from the US context. Internationally comparative studies could enhance our understanding of the impact of contextual factors like political culture, or the political and the media system. For example, effects of televised debates are likely to be stronger in emerging democracies and more complicated in multiparty systems.
- 2 *Linking debate content and effects.* In most studies, debates are regarded as one single stimulus, and what actually happens in them is largely ignored. In recent years, researchers have come to call for more micro-level investigations of how debates produce their effects and what types of arguments, statements, rhetorical means, and visual message elements resonate with the audience.
- 3 *Stability of effects.* In another promising line of research, scholars have begun to investigate whether immediate post-debate effects last until election day and how debate messages interact with messages in other channels of campaign communication. Disentangling these interactions will give us an even better understanding of the impact of televised debates.

## Television

*Amanda D. Lotz*

*University of Michigan*

Since the advent of the post-World War II era, television has functioned as the quintessential mass medium. Television's status as a central cultural storyteller that offers a widely shared lens on news information, media events, and fictional narratives has allowed it to transcend academic approaches and operate as a crucial object of study for a range of communication traditions.

The medium's origins in radio inform many of its key characteristics, and although the technology of broadcasting provided for it to easily transcend national boundaries, the medium has been dominated by the particularities of nation-based decisions about its funding and regulation. Early experiments with television date to the 1920s and 1930s, but for the most part, the medium did not become widely used until the 1950s.

Television's status as an object studied by multiple fields results from its integration in central political and commercial activities. Many countries around the world began with publicly run television systems that made television an important source of national

culture and provided it with a particular mandate to serve the government or the citizenry. Most of these countries have since allowed the introduction of commercially based private networks that compete with the public system. The US established such a commercial system from the early days of radio. The commercial mandate still allows television a significant role in culture, although it results in a different relationship between television and the state. There is now significant blending of public and private structures for financing television around the globe.

### **PRIMARY APPROACHES**

The study of television has been central in many different communication intellectual traditions. Initially, researchers focused on the medium in terms of its “effects” and its use for propagandistic purposes (→ Media Effects). This scholarship was influenced by cultural concerns central in the study of many different means of communication in the postwar period and the growing consideration of cultural industries as powerful influences in society. Much of this research is particularly concerned with audiences and how television affects them.

A tradition of critical television studies emerged in the 1970s, coterminous with various developments in cultural studies, feminist studies, and critical theory, which perceives the medium in a very different manner. Initially, this research examined television shows much like any other “text.” Detailed textual analysis of television series drawing from critical theory and the analytical tools central to the study of literature and film also became common as theorists identified how television entertainment and news often reproduced the dominant ideology (→ Television News; Television as Popular Culture). Within cultural studies many scholars soon turned their attention to studying audiences, while those trained in film or literary studies tended to continue more textually focused examinations.

Studies developed from within cultural studies conceive of the audience much differently than the earlier (and ongoing) effects tradition. Cultural studies ascribes considerable agency to viewers and theorizes a complicated and more individualized meaning making process, rather than previous approaches, which tended to perceive fairly standard effects of media upon audiences. Considerable debate emerged about whether news and entertainment media reinforce hegemonic structures of power or whether viewers might make redemptive readings and derive pleasure despite the ideological content (→ Cultural Studies).

Political economy scholarship exploring the governmental and commercial links of the television industry developed various theories about the role of institutional factors such as law, policy, and capital in the functioning of public and private television industries. Such scholarship often linked the structural organization of the industry with the texts that were consequently likely to be produced. As the norms of television have changed – such as the addition of private competition in previously public systems or the introduction of nonbroadcast television competitors (cable and satellite) – political economists have attended to likely outcomes and offered policy recommendations aimed at the public good rather than the advance of controlling commercial or governmental powers.

The study of television now includes many different aspects of the technology and its role in culture, and television continues to be considered through a broad range of intellectual traditions spanning the experimental methods of social science, criticism common to humanities, and applied policy, law, and technology studies. Despite the common object of study, these approaches to television differ significantly in their fundamental conception of the medium, and while vibrant intellectual debates exist within each tradition, there is little interaction among those of differing approaches. Regardless of intellectual tradition, the following six critical functions (adapted from Mittell, in press) organize much television scholarship that considers television as an important communicative and cultural agent.

### **Television as Commercial Industry**

At least some aspect of nearly every country's television system has become commercialized. Despite this, commercial television industries rarely operate as a free market (even in the US), but are regulated by governmental bodies in various ways: the nature of its content (limits on nudity or violence); the origin of its content (quotas limiting importation); or the manner of including commercial messages and the types of claims that they can make (→ Television Broadcasting, Regulation of). This commercial base leads television to operate as a "dual market" system as networks produce programs to sell to audiences in order that they might sell those audiences to advertisers. The mandate of commercial systems complicates the democratic goals for a mass medium such as television because of advertisers' inequitable pursuit of various audiences. Commercial goals also lead to the production of programming unlikely to disturb advertisers. Changes to global economies also have led to increasing consideration of television as a crucial part of the information and entertainment economies that are fundamental to postindustrial nations. This function is particularly central to the research of political economists and others engaged in cultural industries studies.

### **Television as an Electronic Public Sphere**

The functioning of television as an electronic public sphere is important to many intellectual traditions and lines of research. Originally, television derived this status as a source of broadly shared information and stories. Television exists as a ubiquitous media form in many places, and for much of its history it offered a limited range of options, which increased the likelihood of a national audience sharing its programs. Whether the case of a popular comedy, the nightly news, or a media event such as the Kennedy assassination or the wedding of Prince Charles and Lady Diana, the breadth of audience reached through television has been fundamental to those concerned about media effects as well as the constitution of culture. The significance of this breadth has been theorized variably, with some arguing that the medium creates a site of negotiation in which those with different perspectives on social issues might come to see competing positions with sympathy, while others have argued that content can only reinforce existing world views. As opposed to other media, such as particular radio formats or niche-targeted magazines, television's operation as a medium that relied upon and was capable of drawing broad

and heterogeneous audiences has been central to its study as a medium. Notably, the expansion in channel options increasingly in place around the globe has decreased the likelihood of television gathering such audiences and continuing to operate in this way – at least in most cases.

### **Television as a Site of Cultural Representation**

If many have assumed television operates as an electronic public sphere, this reach made it an important source of cultural representation. Many have examined how television does, and most often does not, reproduce the “reality” of the societies that view its content. In the 1970s, many such studies considered, for example, the frequency with which women were depicted in television narratives and in what roles relative to their status in society. Other researchers have assessed how television shows depict the solving of problems and the use of violence, among many other topics. The critical television studies that drew from cultural studies and emerged in the 1980s evaluated representation very differently than the preceding tendency to assess depictions in terms of their realism. Following Stuart Hall’s constructionist view of representation, critical television scholars argue that the depictions are constitutive of the viewers’ “reality” rather than there being a “true” meaning that exists outside of representation (Hall 1997). Such analyses consequently examine what reality or beliefs about the world are likely to develop from the stories and representations available on television.

### **Television as a Textual Form**

Other studies focus less upon the ideological nature of the ideas and depictions of television content, and instead attend to television’s particular textual and visual forms. Examinations of fictional texts draw extensively from film theory in establishing particular generic attributes and narrative techniques common to television storytelling. The reliance on serial storytelling is particularly distinct to television relative to other competing artistic forms. These more formal approaches also have been applied to television news, as in examining how the format of newscasts and story conventions reproduce knowledge in specific ways. These approaches examine the formal attributes of a text – whether an entertainment series or a news program – more than the specific content of the text. The visual features and construction of television images also provide important sites of research – often drawing from film theory and studies of visual culture (→ *Television, Visual Characteristics of*).

### **Television as a Part of Everyday Life**

Television also can be considered as a communicative force broader than the programs or content it transmits. Television continues to be a primary focus of leisure time in many countries, and its transmissions are central to daily routines and structure patterns of behavior. Research traditions such as that of uses and gratifications have explored the different reasons why and the varied ways in which people use television, and have found behaviors that far exceed the rapt and attentive viewing that many other considerations of

its content tend to assume (→ Uses and Gratifications). Such studies face new challenges as technological and distribution developments increasingly enable television to surpass its domestic boundaries and function as a portable and mobile technology.

### **Television as a Technology**

Despite the varied communicative and cultural functions of the medium, television also can be considered based upon its technological features (→ Television Technology). Television's aural and visual registers allowed its early distinction from radio, and subsequent enhancements have allowed greater complexity to its images and sound. Much television use has been domestically based because of its particular technological attributes, although new developments now allow users to view live television on their office computers or on mobile phone screens, among other mobile devices. Likewise, many other technologies – such as the remote control, video cassette recorder, and digital video recorder – have enhanced viewers' ability to control the externally determined programming flows that come through the box.

Many new areas of study are emerging as a result of massive adjustments in the medium itself and consequently, how it is used and experienced. These changes often challenge existing assumptions of the medium and require revisiting previous research about the use of television, its texts, and relationship to culture. The massive expansion in channel choice and personal program control, convergence with other media (computers), new portability, and the digital transition are all redefining the medium in a manner that has significant consequences for how it is studied and the assumptions that can be made of it.

# Television Broadcasting, Regulation of

*Roger L. Sadler*

*Western Illinois University*

Historically, TV regulation in various countries has fallen into one of four broad categories. None of these regulatory frameworks exists in its true form in any country, but these categories provide a general framework for how different governments regulate television (→ Media Policy).

*Authoritarian* broadcast regulation is most often seen in countries where there is a strong autocratic government such as a dictatorship or communist regime. The government finances the television system and strictly controls the information and entertainment that is broadcast to the public.

*Paternalistic* broadcast regulation dictates that TV programming content is to be determined by a combination of free marketplace forces and government regulations. In this type of system, the government feels that public demand will not always lead to television programming that is good for the culture. Government recognizes that television can play a pivotal role in helping a country maintain its national heritage and traditions. As a result, government and not the marketplace must have a stronger role in TV regulation to help serve the public interest.

*Permissive* broadcast regulation allows for the marketplace to play a dominant role, with limited regulation from the government. Advertising is the dominant source of funding and thus provides citizens with what is known as “free TV.” In a permissive system, public demand and the marketplace are the primary forces determining the content of programming.

*Pluralistic* broadcast regulation is the “perfect blend” of paternalistic and permissive frameworks, where the government carefully balances the marketplace and the public interest. In the ideal pluralistic setting, television provides programs that not only satisfy the tastes of a diverse public audience but also provide a valuable public service.

## **RATIONALE FOR TV REGULATION AND REGULATORY BODIES**

The US is the world’s model for permissive broadcasting regulation and provides a general model for how other countries view the airwaves (→ United States of America: Media System). The roots of US TV regulation can be found in the American Constitution’s First Amendment: “Congress shall make no law . . . abridging the freedom of speech or of the press” (→ Freedom of Communication). Still, the US model of regulation does not provide for a system free of all government regulation. The Radio Act of 1912 required that all radio operators and transmitters had to be licensed by the federal government. By the 1920s, the airwaves had become cluttered, with radio station signals overlapping, and nearly 1,000 unlicensed radio stations broadcasting across the nation. Such problems led to the Radio Act of 1927. Congress passed the Act to create the Federal Radio Commission (FRC) to oversee the rapidly expanding radio industry. The FRC’s mission was to assign frequencies and to make radio stations serve the public interest with their programming. Most other countries today use similar justifications for government regulation of broadcasting.

Most nations have special bureaus or government agencies that oversee TV broadcasting. For example, in the permissive US, regulatory authority is given to the Federal Communications Commission (FCC). The FCC also oversees telecommunications such as the telephone. However, in the paternalistic UK, the Department for Culture, Media and Sport oversees broadcasting while a separate entity, the Department of Trade and Industry, regulates telecommunications. Communist China tends to be authoritarian in its television regulation, and the central government controls all telecommunications.

The Communications Act of 1934 is the foundation for US broadcasting regulation today. The Communications Act replaced the FRC with the FCC, which was given the power to oversee “all of the channels of interstate and foreign radio transmission,” including the telephone industry. Local and state governments have no jurisdiction in broadcasting regulation. The 1934 Act states that the FCC is not allowed to “interfere with the right of free speech by the means of radio (and TV) communication.” However, the FCC, Congress, and the courts treat this part of the Act with great flexibility.

A foundation principle for the FCC was the concept of the “public airwaves,” a general idea that has been adopted in one form or another by many nations around the world. The government views the airwaves as a public, not a private, resource. In essence, the government considers the airwaves to be like a public street. Private citizens are allowed to use the street, but the street still belongs to the government. Therefore, the government has the right to pass certain laws about the use of the street.

### SERVING THE PUBLIC

In the US, the FCC makes sure stations serve the → “public interest, convenience and necessity.” Other countries have similar mandates for broadcasters. Italy, for example, requires TV stations to “represent the full range of social, cultural, religious and philosophical tendencies” (→ Plurality). The US government argues airwave regulation is necessary because of the *scarcity rationale*. This concept says the public airwaves are a “scarce” resource and need to be regulated and monitored. However, courts in recent years have argued the scarcity rationale may no longer be valid because of the proliferation of other media such as satellite, the Internet, and cable.

The UK government has a paternalistic approach and has traditionally seen TV broadcasting as a public service (→ Public Service Broadcasting: Law and Policy). Therefore, a main mission of the British Broadcasting Corporation (BBC) has been to provide the citizenry with news, information, and education programs (→ BBC World Service). The BBC gets its operating budget from a license fee paid by every household with a TV set. The UK also has three commercial TV networks whose programming is determined more by public taste. At the same time, these commercial networks must still provide time for some “public service” shows. In Australia, the Australian Broadcasting Authority (ABA) makes individual TV stations responsible for serving community interests. Still, the ABA has numerous restrictions. For example, broadcasters are prohibited from airing material that could “incite dissension among ethnic peoples and disrupt national unity.”

In *authoritarian systems* such as those of Saudi Arabia or the People’s Republic of China, the airwaves are considered a government entity, and programming critical of the government is prohibited. In 2005, for example, the Chinese government announced it

was prohibiting any new foreign television programs that promoted “western ideology and politics” (→ China: Media System). The government said it would also stop granting licenses to foreign satellite channels and would continue its ban on the private ownership of TV satellite dishes. Chinese TV stations may not form partnerships with foreign companies. One of the major goals of authoritarian regulation is to censor any messages or programming that may be considered “subversive” to the ruling party and its political and cultural ideologies.

Regulatory bodies in most countries are given the power to grant *licenses* to broadcasters and may reject applicants that do not meet government standards. Other regulatory responsibilities often include the allocation of frequencies, the authority to pass rules and regulations, and the power to levy fines on broadcasters that violate rules. In the US, FCC rules may be overturned by the courts or changed through laws passed by Congress. Congress also controls funding for the FCC, which allows Congress to withhold funding to the FCC if law-makers disagree with certain agency policies.

In the US, a person or party may apply for a broadcast license for a new or existing station. The Communications Act states clearly that a broadcasting license is granted “for the use of such channels, but *not the ownership* thereof, by persons for limited periods of time, under licenses granted by Federal authority.” The person/party must be an American citizen or a company with less than 25 percent foreign ownership. Authoritarian systems tend to allow no foreign ownership of broadcast licenses.

### **OWNERSHIP ISSUES: THE CASE OF THE US**

In order to prevent individuals or companies from controlling too many broadcast stations, the FCC has historically instituted ownership rules. These rules limited how many broadcast stations a person could own in a single market or nationwide. In 1940, the FCC began enforcing the duopoly rule, prohibiting one company from owning more than one broadcast station (AM, FM, TV) in any one market. However, the FCC often allowed exceptions to these rules to keep as many stations on the air as possible.

In 1943, the Supreme Court ruled that the FCC had the right to restrict the power of radio networks, limiting the number of stations directly owned by any one network. This ruling would eventually apply to TV networks as well. However, this ruling did not give the FCC the power to interfere with the local operations of network affiliates.

In 1953, the FCC established the 7-7-7 rule, stating that one party could not own more than 7 AM, 7 FM, and 7 TV stations nationwide, with stations in each medium reaching no more than 25 percent of the national audience. The limits were raised to 12-12-12 in 1985 and 20-20-12 in 1994.

The Telecommunications Act of 1996 greatly liberalized broadcast ownership rules. The FCC dropped a prohibition on TV networks owning cable systems but still prohibited the “Big Four” TV networks (CBS, NBC, ABC, and Fox) from merging with each other. The Act also allowed the FCC to liberalize the 25 percent national audience limit for TV, which is still a matter of debate. The FCC may no longer prohibit someone from owning a cable system and a TV station in the same market.

Within the next decade, the FCC issued more liberal ownership rules in such areas as newspaper/broadcast cross-ownership and telephone/cable cross-ownership. The

commission also relaxed TV network rules to allow a Big Four network to start up its own smaller network or to merge with an emerging TV network. Smaller TV networks may also now merge with each other.

## CONTENT REGULATIONS

In the US, the FCC is prohibited from “censoring” TV programming, but courts have upheld certain content regulations that serve the “public interest.” The FCC enforces political broadcasting rules such as Section 315 or the “equal time” rule. If a station gives or sells time to one candidate for public office, the station must also give or sell time to every other legally qualified candidate running for that same office. This rule ensures that broadcasters do not use the power of the airwaves to favor one candidate over another.

Broadcasters are not obligated to provide free airtime to any candidate unless the station has offered free time to an opposing candidate. For the most part, stations are not allowed to censor political ads. Also, in specified time periods before primaries and general elections, stations are required to offer candidates the lowest advertising rates. Section 315 does not apply to news reports, so a candidate’s appearance in a news story does not obligate a station to provide “equal time” to opposing candidates. Stations must also abide by the “reasonable access rule,” providing reasonable amounts of advertising time to federal candidates. Stations must keep public files detailing how they have followed political broadcasting rules and also how they have served the public interest in general.

In some countries, politicians are granted *free airtime before elections*. The rules are varied. In Azerbaijan, political parties with more than 60 candidates get free airtime on state-owned media. Smaller parties say such rules give an unfair advantage to larger established parties. In the US, broadcast debates between candidates are exempt from “equal time” restrictions, thus broadcasters usually choose to have only the major party candidates participate (→ Televised Debates). Candidates from smaller parties say this system is discriminatory, helping to keep the major parties in power.

The FCC more directly regulates content through *indecentcy rules*, punishing broadcasters that air “patently offensive” material relating to “sexual or excretory activities or organs at a time of day when children are likely to be in the audience.”

Current indecency regulation had its genesis in a 1978 Supreme Court case involving the afternoon radio broadcast of comedian George Carlin’s monologue “Filthy words,” in which Carlin frequently repeated seven “dirty words.” The Court ruled that the FCC had the right to fine broadcasters who aired indecent material during daytime and evening hours, saying such regulation was justified in protecting children from indecent material.

According to the FCC, indecent material includes foul language, nudity, and sexual innuendo. In February 2004, the infamous “wardrobe malfunction” occurred during the CBS broadcast of the Super Bowl. During halftime, singer Justin Timberlake tore away a part of singer Janet Jackson’s costume, briefly revealing her bare breast. Congress reacted by passing legislation that greatly increased indecency fines and included possible license revocation for repeat offenders. The FCC later fined CBS \$550,000 for the incident, although the network in 2006 said it would contest the fine.

The “wardrobe malfunction” would not violate government standards in countries such as Japan, Brazil, and Germany, where nudity is considered less objectionable than in

the US. On the opposite end of the spectrum are authoritarian systems like that of China, where indecent or offensive material is strictly prohibited. In 2005, the Chinese government banned prime-time shows with crime or violence in an effort to protect children and to “safeguard national cultural safety.”

In the US, the courts have ruled that the FCC does not have jurisdiction to enforce indecency rules on other media such as satellite services, cable TV, newspaper, the → Internet, and telephone (→ Internet Law and Regulation). That is because these media do not operate on the public airwaves. In Europe, though, regulators tend to make no differentiation between broadcasting and cable and satellite. EU standards state that member countries should avoid broadcasts that are indecent, pornographic, racist, or violent. Shows that are “likely to impair the development of children” are to be scheduled at later hours. However, standards of “decency” are determined by each EU country (→ European Union: Communication Law).

Authoritarian countries tend to extend indecency regulation to the Internet as well. In Saudi Arabia, the Council of Ministers requires anyone using the Internet to avoid “any activities violating the social, cultural, political, media, economic, and religious values of the Kingdom.” Persons must also get permission from the government before sending or receiving coded information. China blocks citizen access to a wide variety of Internet sites deemed by the government to be inappropriate or indecent.

### **CABLE, SATELLITE, AND ADVERTISING REGULATION**

The FCC and the courts approach regulation of cable and satellite with more of a “hands-off” approach, saying that these media do not operate on the “public airwaves” and are therefore exempt from most content regulations. However, *cable and satellite* operators must still abide by political broadcasting rules. Both must also follow “must-carry” rules, requiring them to carry local broadcast stations on their services. The FCC says such protections are necessary for broadcasters because of their roles in serving the public interest. There are similar must-carry rules in the EU, requiring cable systems to carry a variety of broadcast stations (→ Cable Television; Satellite Communication, Regulation of; Satellite Television).

In the US, most cable regulation is done at the local level through franchises, where local governments help determine service standards and whether the cable system must provide “access” channels for local public interest programming. The FCC has the right to fine cable and satellite operators that violate FCC policies.

Many countries have separate government agencies that oversee *advertising on television*. For example, in Denmark, the Radio and Television Advertising Commission reviews citizen complaints about ad content. In the US, the Federal Trade Commission (FTC) punishes false and misleading advertising. Otherwise, most governments avoid content regulation of commercial speech.

One major exception is advertising for tobacco. In 1965, the UK banned all TV ads for cigarettes, but did allow TV ads for cigars and other tobacco products until 1991. The US Congress in 1970 banned cigarette ads on radio and TV, saying such a ban was necessary to protect the public health and to discourage tobacco use. Broadcast ads for smokeless tobacco (chewing tobacco) were banned in 1986. The US continues to allow broadcast ads

for other smoking products such as pipe tobacco and cigars. The 1998 Tobacco Settlement added new restrictions, such as prohibiting cigarette companies from paying to have their brands used by characters in TV shows.

A majority of countries restrict TV ads for cigarettes. In the early 1990s, the European Union (EU) banned all TV cigarette advertising. In July 2005, the EU Tobacco Advertising Directive extended the cigarette ad ban to radio, the Internet, and print media. Japan began banning brand-specific cigarette ads on TV and all other electronic media, including the Internet. However, the law still allows cigarette ads on the electronic media as long as the ads do not show cigarettes or include brand names.

## INTERNATIONAL AND REGIONAL AGENCIES

The International Telecommunication Union (ITU), founded in 1865, is an international body comprised of roughly 200 countries. The ITU's constitution says the organization's mission is to "promote the extension of the benefits of the new telecommunication technologies to all the world's inhabitants." The ITU is a United Nations organization and works to minimize technical interference between broadcast and satellite services in different countries.

There are also agencies that deal with telecommunications issues on a regional basis. Two examples are the Asia-Pacific Broadcasting Union (ABU) and the European Broadcasting Union (EBU). However, membership in such agencies often extends beyond their regions. Roughly 100 countries belong to the ABU, including members from Europe and North America. Like similar regional agencies, the ABU represents its members' interests with other regional agencies as well as with groups like the ITU. Such regional groups also provide technical advice and support to members.

# Television for Development

*Bella Mody*

*University of Colorado at Boulder*

During their colonial occupation, many parts of Asia, Africa, Latin America, and the Caribbean were underdeveloped; forced labor was used in mines, fields, and plantations to supply the factories of Europe. Television has been part of state-led reconstruction attempts for national development since the 1970s, albeit with no explicit policies. After the pressure to privatize and deregulate media in the 1980s, TV for development has increasingly consisted of advertiser-supported → entertainment education.

After the Second North Atlantic War of 1939–1945, the Soviet bloc, the US, and the Bretton Woods institutions (the UN, the World Bank, and the IMF) initiated modernization and development projects in Europe's former colonies (→ Modernization). The Soviet Union promoted its centrally planned economy route to national development that included class struggle. The US and Europe promoted capitalism, class compromise, and modernization. Ignoring the fact that these countries had been set back through western interruption of their indigenous growth path, the modernization approach again focused on the diffusion of western ways, this time through science and technology. By the 1960s, this *social-engineering-of-change project* began to be called "economic development" (or "development" for short, as in the title of this entry). A communication medium like television with audio and visual capability and two sound tracks was considered an extremely promising educational tool for low-literacy populations and a channel for their modernization (→ Educational Communication).

## MODES OF TELEVISION ENTRY

Radio stations spread to developing countries in the 1930s and 1940s (→ Radio for Development). The introduction of television began in the 1950s and was much more complex. The capital and operating costs of television production studios, transmission equipment, and program development were high, not to mention the costs to the consumer of receiver purchase and the need for domestic electricity. The modes of different nations' entry to television varied according to the nature of the state, audience/market size, domestic capital, and national cultural characteristics. These modes of television entry were initiated by domestic private capital for urban entertainment, grants by foreign government (e.g., Japan) to help market expansion, sales promotion by their manufacturers (e.g., Sony), and UN- and foreign-aided demonstrations of television's educational potential.

Competing foreign equipment manufacturers (e.g., Germany and Japan) used *aid-for-trade offers* from their home governments. In Sri Lanka, the Japanese donor offered free staff training and equipment (for production and transmission) in return for the right to monopolize the market for television sets. Local capitalists (television set distributors, ad agencies, etc.) took the initiative for the introduction of television in countries where there was domestic capital and openness to financing by advertising. UNESCO, the Ford Foundation, and bilateral foreign aid agencies promoted demonstrations of the audiovisual

capability of the medium as an educational solution for low-literacy countries (→ UNESCO). In many cases, once the short-term financing ended, the donated equipment and facilities were transformed into a sports and entertainment channel for the middle and upper classes.

### PROGRAMS AND INITIATIVES IN THE 1960S AND 1970S

Among the many educational radio and TV projects supported by national governments, intergovernmental organizations (UN agencies), and non-governmental organizations, the documentation on TV projects in Colombia, El Salvador, Mexico, the Ivory Coast, and Samoa is solid (UNESCO 1967; Mayo et al. 1975; Schramm 1977; McAnany et al. 1983). Beginning in 1964, the Ministry of Education and the broadcasting authority in Colombia sponsored a *primary school TV program* with support from USAID and the Peace Corps. Well-respected US communication researchers John K. Mayo and Jack Lyle got their start in the field by working on the evaluation research directed by Nathan Maccoby and George Comstock of Stanford University's Institute for Communication Research. The US Congress, the Department of the Interior, and the territorial government of American Samoa funded a television project in American Samoa from 1964 to 1972. Directed by Lyle Nelson and → Wilbur Schramm, this television project covered all primary and secondary grades plus preschool and some adult services.

Television was also part of the national Ministry of Education's reform of El Salvador's middle schools from 1969 to 1973, with substantial assistance from USAID and its evaluation sub-contractor Stanford University. Television provided program support for instruction in all major subjects in addition to curriculum reform and training for teachers and supervisors. Beginning in 1971, the *French government* (through UNESCO) funded a primary school TV project with an out-of-school evening adult education component in its former colony the Ivory Coast. The only major educational TV project still functioning after decades is the *Mexican Telesecundaria* (grades 7–9) run by its own Ministry of Education. Rather than an add-on for quality improvement, this essential delivery of middle-school classes via television across the nation provides government-recognized credit for students who cannot attend traditional middle school. USAID financed an evaluation jointly conducted by the Ministry of Education and Stanford University (Mayo et al. 1975). The role of communication in development that is clearly conceptualized, alongside a listing of theory, program, and political failures, in Hornik (1988) fully applies to television projects.

With the introduction of direct-broadcast satellites pioneered by NASA in the early 1970s, development pilot projects of varying lengths were conducted to demonstrate the capability of TV, radio, and telecommunication (→ Satellite Television). In 1971, the University of the South Pacific used audio conferencing to connect its extension centers on both sides of the international dateline in four time zones. The state of Alaska also used NASA's experimental satellite services to facilitate the delivery of rural health-care, leading to the development of a 24-hour medical network connecting every village.

The *mid-1970s* saw a more advanced NASA satellite demonstrate educational applications in Alaska, the Pacific, Appalachia, and India. India's year-long (1975–1976) *Satellite Instructional TV Experiment (SITE)* was studied by over 150 social scientists hired by the government of India as part of NASA's requirement for the year-long loan of four hours

of satellite time. SITE research findings (Mody 1978, 1987) elaborated on the findings of projects elsewhere: more attention should have been paid to the design of educational programs. The emphasis on technology and the neglect of TV programming identified in previous projects repeated itself in SITE too: the total effort involved 3,300 person years of which 2,050 were spent on technology, hardware, or equipment: only 9 percent was dedicated to program development.

Hardware work started 5 years before transmissions started; program development started less than a year before. Nevertheless, children exposed to TV in the classroom showed significant gains in language development; programs led to enquiries for more knowledge, as measured by the greater utilization of libraries in schools where they were available. The adult education evening transmissions resulted in statistically significant gains in the knowledge of preventive health: those who watched more learned more. Small farmers and landless day laborers made up the greater part of the audience for the free community TV, resulting in no gain in general agricultural knowledge (dependent on land-holding sizes and purchasing power for irrigation, fertilizer, and pesticides). Twice as many adult men as women watched in the evenings: women were busy with domestic responsibilities after their day jobs in the fields and reported little interest in program topics. In general, the knowledge gains from free community TV were greater for those with limited access to other sources of information: lower castes among the Hindu majority, low income groups in general, and women.

*In the 1980s*, US foreign aid (USAID) and the then satellite cooperative INTELSAT conducted educational demonstrations of satellite capability. INTELSAT enabled the Chinese Open University to experiment with one-way video and audio applications; Ireland and Jordan to exchange university courses; and hospitals in Latin America and Miami, and Uganda, Kenya, and Canada, to do telemedicine.

### **PRIVATIZATION AND ENTERTAINMENT EDUCATION SINCE THE 1980S**

Until the 1980s, TV was owned and operated in Asia, Africa, and the Caribbean by the state, except for Latin America, which had fallen under US commercial influence after its independence from European colonizers. The few applications of television for development were expensive and state-financed, and hence constituted additional demands on already overstretched state budgets. As developing countries struggled with spiraling oil costs, budget deficits, and a world economic slowdown, the US, western Europe, and Japan pushed them to open up national firms (including state broadcasting monopolies) to private and foreign investment. Simultaneously, domestic lobbies within developing countries were advocating the US model of advertising-based radio and TV ownership so coverage could expand beyond the capital city (→ United States of America: Media System). US film and TV exports increased nearly five times. State-produced symbolic public service TV programs on agriculture, health, and education with small audience sizes disappeared as large-audience entertainment financed by advertisers became more visible, some imported and some domestic.

A new entrant on the post-1980s scene was the “educational entertainment” dramatic serial, which took off from Miguel Sabido’s pioneering “social content communication methodology” that was made famous in successful family planning serial dramas in Mexico

(Singhal et al. 2004). Promoted by David Poindexter of the US Methodist Church's Population Communication International, "entertainment education" serials in radio, TV, and multiple media have addressed AIDS and sexual issues in South Africa (e.g., *Soul City*), India (e.g., the → BBC World Service Trust's collaborative production of *Vijay Detective*), Kenya (e.g., *Heart and Soul, Come With Me*), Tanzania (e.g., *Let's Go with the Times*) and the Philippines (e.g., *Interweaving Lives*). Foreign aid and technical assistance have been provided by the US and European countries.

The balance between audience enhancement and education is delicate: in the case of *We The People* in India, the strong focus on gender equality had to be diluted by episode 13 in light of opposition from audience and advertisers. Thus, even advocates acknowledge that the "educational" component of these admittedly entertaining shows is highly variable, ranging from a few lines of dialogue, to a general do-good theme, to a strongly targeted focus. It has been found that constant audience research is required to monitor whether a negative role model is being misperceived as a heroine for emulation by some.

The instructional design model of the 1960s and 1970s for specific educational audiences, which was so expensive to implement and was infrequently used outside short-lived, aid-financed projects, has given way to another educational model initiated by foreign aid that is more suited to the large-audience needs of an advertiser-financed media system. Entertainment education has actually been credited with helping the state broadcaster to move from state public service ownership to a commercially competitive operator in India.

Television for development in the early 21st century is promoting *modernization via the marketplace*. Audience-specific educational media interventions are limited to community radio initiatives, where they exist.

# Television Networks

*James R. Compton*

*University of Western Ontario*

Television networks are organizations that produce or acquire the rights to TV programs, which are centrally distributed to affiliated stations where they are scheduled at uniform time slots. The distribution of content to geographically dispersed stations can occur using a variety of technical systems, involving traditional over-the-air electromagnetic broadcasting, cable, satellite, and now digital transmission. The history of television networks has been influenced by two principal broadcast network models: the public service broadcasting (PSB) model (→ Public Broadcasting Systems; Public Broadcasting, History of), epitomized in the English speaking world by the British Broadcasting Corporation (→ BBC), and by the for-profit commercial model, associated with television networks in the United States.

In the case of the BBC, and many other public service broadcasters, identical programming is simultaneously distributed to repeater stations, with some regional variation. In the case of for-profit networks in the United States, regional affiliate stations produce local content (e.g., → newscasts) while accepting a portion of their programming via the central distribution of their parent network. In vernacular language the terms *television network*, *television channel*, and *television station* are often interchanged; however, the terms are distinct: a channel is a band of electromagnetic frequencies assigned to individual broadcast stations, which, in turn, may be members of a television network. Most historical accounts of the development of network television have pointed to three interrelated factors: the state, as both owner and regulator of broadcasting networks (→ Ownership in the Media; Television Broadcasting, Regulation of); the introduction of new technologies (→ Television Technology); and the influence of commercial and market forces (→ Markets of the Media).

## HISTORICAL ORIGINS

In the United Kingdom and the United States, television networks were launched by the already established → radio networks (→ United Kingdom: Media System; United States of America: Media System). That is to say, by the BBC in the former country, and by the National Broadcasting Corporation (NBC) and the Columbia Broadcasting System (CBS) in the latter. The one significant exception was the short-lived Dumont Television Network – itself the first licensed television network in the United States started by inventor and television manufacturer Allen B. Dumont. The network operated for 10 years, beginning in 1946, before closing due to financial losses. But television networks' connection to the production and sale of television receiver sets would continue through NBC's parent company the Radio Corporation of America (RCA).

The BBC began the first regular high definition television service in 1936, broadcasting in London. It was put on hold in 1939 due to World War II; but in 1948 the government threw its support behind the idea of a national television network to parallel radio. Construction began in earnest on a series of transmitter stations to link the various regions of the nation. As with radio, the BBC's national television service would be a monopoly.

The public service remit of BBC television carried forward BBC founder Reith's mission to inform, educate, and entertain. Commercial influences were to be resisted in the name of the public interest and to preserve "quality" broadcasting. Funding was secured through a license fee paid by all television users.

A majority of European nations started their own public service TV networks, as did the Australian (→ Australia: Media System), New Zealand, and Canadian (→ Canada: Media System) governments. Invariably, PSB would reflect national and cultural differences. In Germany constitutional authority for broadcasting was granted to individual states, thereby establishing a decentralized PSB model to protect against government control of radio and television networks, as had been the case under Nazi rule (→ Germany: Media System). In Canada the Canadian Broadcasting Corporation (CBC) was given a national mandate to provide a buffer to easily available signals of American TV networks. Television service would be mixed, accepting some → advertising revenue with the balance of funding coming from government stipend. What united all public broadcasters was a commitment to attracting a broad television audience while serving the needs of citizens, not consumers.

"Auntie" BBC, as the service was known, soon faced competition funded by advertising. The postwar years saw a surge in advertising expenditures with a correspondingly increased desire for consumption, after many years of imposed austerity. Advertisers, helped by the work of the J. Walter Thompson agency, argued that television should be part of a renewed consumer economy. The Conservative government of the day agreed and commercial network television came to Britain in 1955 with the launch of Independent Television (ITV). However, in exchange for lucrative access to a scarce analog spectrum, ITV, and also Channels 4 and 5 launched in 1982 and 1997 respectively, were required to meet public service obligations. In the 1990s both Conservative and Labour governments called on the BBC to adopt a more commercial approach.

In the *United States*, educational television started in 1954; by 1965 there were 100 noncommercial stations. The US Congress passed legislation creating the Corporation for Public Broadcasting (CPB) in 1967. Two years later the Public Broadcasting Service (PBS) television network was created, but it has remained plagued by funding problems. The dominant American television networks were privately owned and profit oriented from the start. They became possible in 1951 after AT&T began to lay TV cables, and microwave relays were stretched across the continent.

An important element of the growth of television networks has been the economic efficiencies gained through the transmission of one program to multiple stations along the network. But efficiencies were not simply a product of technology. NBC and CBS inherited their corporate structure from radio, as did the American Broadcasting Company (ABC). The so-called "third network" was created in 1943 after a federal competition probe suggested NBC sell one of its two radio networks: NBC Red and NBC Blue. The Blue network was sold and ABC would eventually join NBC and CBS as one of the "big three" networks. The networks also inherited radio's profit model, which structured their relationship with advertisers. Many of the early program formats on network television, such as live episodic drama, were derived from radio. Programs such as CBS's *Man Against Crime* were produced by advertising agencies. Historian Erik Barnouw has documented how the sponsor of the program, Camel cigarettes, dictated to writers how and under what favorable circumstances their product should appear in the drama: "Cigarettes had

to be smoked gracefully, never puffed nervously” (Barnouw 1970). The networks, worried about the loss of control over production, eventually moved to change the relationship. NBC in particular worked to convince advertisers that sponsored programming was less effective than purchasing insertions within programs, which could be used to make direct sales pitches, as in a magazine. In a related move, NBC created two important live programs – *Today* and *Tonight* – which were produced and controlled by the network. Both programs, one a morning current affairs show, the latter a late-night comedy program, are broadcast today.

In 1956 videotape was introduced, replacing the more expensive film. Programs could now be stored and shown again and again. By the mid-1950s the live episodic series was displaced. Advertising was sold on a cost-per-thousand basis and the currency for those sales was audience-ratings surveys. The model that would structure the business of network television for the next 50 years had been established: audiences would be maximized and sold to national advertisers who bought time within a programming schedule controlled by the networks (→ *Television: Social History*).

## PROGRAMMING

The television industry enjoyed enormous growth in its first decade, creating a real mass audience. The number of US households with at least one television jumped from 34 to 90 percent between 1952 and 1962. Television had become an important part of popular culture, with network programming taking the lead. Networks produced what media sociologist Todd Gitlin has called “recombinant culture” – shows based upon proven formats with easily identifiable characters (Gitlin 1983). Successful genres including the → situation comedy, crime drama, and westerns flourished, making programs such as *I Love Lucy*, *The Untouchables*, and *Gunsmoke* popular and lucrative, especially when they were sold as syndicated reruns. Entertainment dominated, including popular quiz shows such as *The \$64,000 Dollar Question*, which drew large audiences until a payola scandal forced it off the air. Indeed, in 1961 Newton Minnow, the chairman of the → Federal Communications Commission (FCC), would quip that US network television was a “vast wasteland.” But the trend was established. Many of today’s most popular programs, including *Friends*, *Jeopardy*, and *CSI: Crime Scene Investigation*, are extensions of these early program formats.

Entertainment remains a predominant part of network scheduling today, but it was news and current affairs programming that would confer prestige upon TV networks. In Britain, one early moment was the broadcast of Queen Elizabeth’s coronation in 1953. Close to 20 million people are estimated to have watched the program, including a sizable audience from the United States. Some sociologists have argued the broadcast marked the first “media event” (→ *Media Events and Pseudo-Events*), in which a mass audience participates in a live broadcast ritual. In the United States, the first network newscasts were sponsored. NBC’s *Camel News Caravan* took its name from Camel cigarettes. Such dubious associations would eventually be severed, while news budgets expanded and professional work routines of “objective” reporting were established (→ *News Routines; Objectivity in Reporting*). CBS’s *See It Now*, hosted by celebrated newsman Edward R. Murrow, received special praise for its critical coverage of McCarthyism. The nightly

newscast format was regularized following coverage of the assassination of President John F. Kennedy in 1963.

Coverage of live sporting events (→ Sports and the Media, History of) has from the beginning been a tremendous boon to television networks. Popular success was found early on in North America with broadcasts of boxing, wrestling, baseball, and football, while the BBC generated interest in 1954 with its coverage of Roger Bannister's "Miracle Mile," breaking the 4-minute barrier at the Iffley Road track in Oxford. The initially small audiences were more than made up for by low production costs. Sporting events did not need to be created and did not require expensive writers and actors. Today television networks sign multimillion-dollar contracts for the broadcast rights to the World Cup and the Olympics. These global media events attract billions of viewers and the interest of transnational corporate sponsors, who have made global celebrities out of athletes such as footballer David Beckham.

### NETWORKS IN FLUX

By the late 1970s and early 1980s new technologies and regulatory changes had ushered in a new area for network television in the United States. In 1984 the FCC lifted federal regulations over cable operators, giving them greater freedom. Satellite and cable subscription services proliferated (→ Satellite Television; Cable Television). Specialty channels such as Home Box Office (HBO), the Entertainment and Sports Network (ESPN), and the 24-hour Cable News Network (→ CNN; Newscast, 24-Hour) became household names. The established American networks saw their prime-time share shrink as audiences fragmented. By the 1990s there were three new broadcast networks: Fox, United Paramount Network (UPN), and Warner Brothers (WB). Further government deregulation followed. Legislation lifted media ownership restrictions in 1996, accelerating a round of corporate media mergers that began in the mid-1980s. After WB and UPN merged in 2006 to create the CW Television Network (CW), five companies owned and co-owned the remaining five networks and most of the highly subscribed cable channels: → Disney (ABC, ESPN), General Electric (NBC), Viacom (CBS, CW), Time Warner (CNN, HBO, CW; → Time Warner Inc.).

Changes in network regulation, ownership, and technological distribution had important repercussions for programming. For nearly 20 years the big three network newscasts provided a similar rundown of the day's most important events. But when audiences began to fragment in the late 1970s networks laid off reporters and started to produce more dramatic stories with emotional human interest angles. CNN's coverage of the 1991 Gulf War scooped the big three and solidified its reputation as a serious news provider. Five years later, Fox News and MSNBC (co-owned by Microsoft and NBC) would start their own 24-hour cable news channels. Competition on melodramatic stories, such as the so-called "Monicagate" sex scandal involving intern Monica Lewinsky and US President Bill Clinton (→ Scandalization in the News), institutionalized a form of live "rolling news." It was coupled with high-octane talk shows in which a spectacular news story could be repurposed among the networks' programs 24/7.

The pressures of neo-liberal globalization during the 1980s and 1990s together with the global expansion of transnational communication companies, such as the News Corporation's

Star News satellite network, contributed to the extension of these melodramatic forms of news storytelling throughout Latin America, Europe, and Asia. In India, Star partnered with the Zee network while the Indian Broadcasting Network (IBN) collaborated with CNN, creating a hybrid mixture of genres and Hindi language programming (→ Globalization of the Media).

Rising production costs were also giving networks trouble. In wrestling with the problem, networks increased the number of ads run during prime time. They also amortized the fixed first-run costs of news programming through newsmagazines such as NBC's *Dateline* and ABC's *Primetime Live*. Another successful strategy was the introduction of the → reality TV genre, epitomized by such programs as *Survivor*. The originally British TV format was a surprise summer hit for CBS in 2000. Its importance was similar to early sports programming – reality TV did not require expensive writers and actors.

All four major US networks quickly adopted the genre, marking a shift in their business model. Antitrust rules that limited the number of hours of network-produced programming were eliminated in 1995. Networks could now produce their own shows in-house. They were still in the business of selling the attention of affluent audiences to advertisers, but now program content would be integrated into multimedia merchandise tie-ins. Synergistic cross-promotion strategies between network programs and → Internet websites expanded. The direct advertiser sponsorship and product placements that were the norm in such 1950s hits as *I Love Lucy* reappeared in the *Apprentice* and *Survivor*.

## Television News

*Mike Conway*

*Indiana University*

Almost from the moment Vladimir Zworykin, John Logie Baird, Philo Farnsworth, and others started improving German inventor Paul Nipkow’s “spinning disc television” idea in the early twentieth century, the debate began concerning journalism’s role on the small screen. Communication researchers, sociologists, and other scholars were slow to take the medium seriously as an information source, even while people around the world turned to television as their primary source of news. Television news became one of the most popular sources for information in the last four decades of the twentieth century, especially in Europe and the US. By the start of the twenty-first century, satellite technology helped spread news channels in the Middle East, Asia, and other regions of the world, allowing non-western perspectives on world issues to gain a wider audience (→ Satellite Television; CNN; Arab Satellite TV News).

### TYPES OF TELEVISION NEWS

Diffusion of television, and television news to a greater extent, has happened at dramatically different rates around the world (Conway 2006). Broadly speaking, the two most important

factors determining television news content are the method of funding and the political structure of the host countries. Countries that have set up a *tax or user-fee system for funding* broadcast news (e.g., Great Britain, Germany, the Netherlands; → Public Broadcasting Systems) tend to focus more on political and governmental coverage than advertiser-based systems with limited government regulation (e.g., the US, Taiwan, the Philippines), which provide less public affairs coverage and more emphasis on crime, lifestyle, health, entertainment news, and high-decibel, polarizing debates on top issues. But in both scenarios, the pressure is growing stronger to make the coverage more interesting and relevant for the viewers (Holtz-Bacha 1997; Thussu 2003; Deuze 2005; Hendricks Vettehen et al. 2005). Therefore, even traditionally “hard news” news organizations such as the → BBC and Germany’s ARD (→ Germany: Media System) are evolving as they are forced to compete against flashier, faster-paced private news organizations that are gaining market share. The market system pressures therefore affect the publicly funded stations because journalists are worried that if their ratings drop too low, the public will start to question why it must pay for a service provided free on other channels (→ Commercialization: Impact on Media Content; Tabloidization; Soft News).

The *government influence* on television news also plays an important role in content. Controlling governments such as China (→ China: Media System), the former Soviet Union, and North Korea use television news as a mouthpiece for the people in power. Viewers of these services recognize the → propaganda aspects of the broadcasts and treat them more as government channels than independent news sources. Therefore, former communist countries in eastern Europe are having a hard time setting up legitimate public service broadcasting systems because the people grew up with the idea of broadcasting as propaganda (Thompson 2006). In the 1980s, Indian prime minister Rajiv Gandhi attempted to turn his country’s television service, Doordarshan, into a more professional news service. But when the ministers realized they would no longer get their free publicity under the new arrangement, they quickly put an end to the plan (Ninan 1995; → India: Media System). In the Middle East, Al Jazeera has built a reputation on controversial and hard-hitting news coverage, but the 24-hours news network avoids most issues that might upset its host country and financial benefactor, Qatar (→ Gulf States: Media Systems).

### EMERGENCE OF TELEVISION NEWS

Two events happened in November 1963 that put television news firmly into the public, and academic, consciousness in the US. First, President John F. Kennedy was shot and killed in Dallas, Texas. For four days, Americans stared at their TV screens as local and network reporters covered the assassination, the installation of Lyndon B. Johnson as president, the murder of suspect Lee Harvey Oswald, and finally, the Kennedy funeral in Washington. Ninety-six percent of all American households watched the coverage, with the nation in communal mourning because of the common, live link of television. Also that month, for the first time in the Roper annual poll of where people get their news, television beat newspapers as the most popular reported source of news in the country.

Television still has the top ranking for news use in the US and in many countries around the world. The advance of satellite technology at the end of the twentieth century allowed

news channels, including Al Jazeera, to break down geographic borders and increase news viewership in areas such as the Middle East. But that same satellite technology allowed the importing and exporting of non-geographic entertainment programming (*Big Brother*, *Who Wants to Be a Millionaire?*) that was much cheaper to present than locally originated news programming (Moran & Keane 2004; Zayani 2005; → Cost and Revenue Structures in the Media; Economies of Scale in Media Markets).

In addition, during the mid-1960s, television news film from civil rights riots in the US and graphic images from the Vietnam War also focused attention on television (→ Civil Rights Movement and the Media), while → Marshall McLuhan argued that content did not matter, since the medium was the message. Whether or not any of these events were the specific impetus, sociologist and communication scholars started to study television news. Instead of the image of an independent journalist seeking the truth, scholars found a structured organization designed to bring order out of the chaos of potential stories (→ News Routines). Epstein (2000) found NBC's criteria for covering a story depended on newsworthiness (→ News Values), predictability, film value, geographic balance, time considerations, and finally, correspondent preferences. These observations apply to other journalistic platforms, but US television news had the added constraint of limited photography crews and indirect government pressure through Federal Communication Commission regulations (→ Television Broadcasting, Regulation of).

The merging of audio, moving pictures (→ Newsreel), and words as information has proven to be a slippery area of research. Barnhurst and Nerone argue the divide between words and pictures starts in school, continues in newsrooms, and is reflected in scholarship: "The resulting studies of journalism pay scant attention to visual devices and visual communication usually brackets the text" (Barnhurst & Nerone 2001, 10; → Television News, Visual Components of; Television, Visual Characteristics of; Video).

## NEWS CONTENT AND FUNDING

Around the world, television news content depended on the funding source and mission of the service. In England, BBC television mirrored the public service mission of BBC radio (→ BBC World Service) while ITN was a closely monitored commercial station (→ United Kingdom: Media System). In Germany, the main public broadcasting network, ARD, was shaped by the Allies after World War II to ensure that no political party or powerful group could gain control of the media as the Nazis had done while in power. In developing countries, → UNESCO used both radio and television as a way to disseminate important information to people, especially in rural areas. Teleclubs were set up for community viewing to prompt civic involvement in solving basic problems such as unsafe drinking water and environmentally damaging farming practices (→ Development Communication; Telecenters; Radio for Development; Television for Development).

Over the past 40 years, the pressure has been building for television news to compete with entertainment programming for viewers. The US advertiser-based system has led the way, especially since the 1980s, as media corporations have convinced the government to continually loosen regulations on public affairs programming (→ Media Conglomerates).

The concept of losing money on news as a way to keep highly profitable broadcast licenses faded, especially as local television news, and some network news programs – most notably *60 Minutes* – went from loss leaders to profit centers for television stations and networks.

In the US, local television stations turned to outside consultants for guidance on how to increase viewership, which has resulted in local television news becoming the most profitable program for most stations (→ Media Marketing). Critics have skewered the consultant influence in turning local news into a cookie-cutter approach to journalism with an emphasis on anchors, happy talk, weather, and reduced coverage of traditional government and public affairs issues (Powers 1980). Allen (2001), though, argues that consultants have used detailed → survey research to determine what the public actually wants from news, and that the resultant product reflects the needs of the lower to middle class instead of the upper middle to upper class that tend to work in journalism and critique its content (→ Audience Research). US local television news did lead the way in hiring women and minorities, concentrating on people-oriented and lifestyle news, and employing the latest graphic and live coverage technology; all practices later adopted by network and cable news.

### **TELEVISION WAR AND CONFLICT COVERAGE**

Coverage of war and conflict, especially since the advance of satellite and digital technology, has had a dramatic influence on television news around the world (→ Conflict as Media Content). Historians point to anecdotal evidence of violent civil rights protests and Vietnam War footage in the 1950s and 1960s raising the issues' salience with US viewers and even changing some minds. Arlen (1969) dubbed Vietnam “the living-room war” because of television’s ability to bring the horror into the comfort of the American home.

In 1991, the *Cable News Network (CNN)* turned war coverage from a national to an international viewing experience. With its connections around the world, CNN became the only US network broadcasting from Baghdad as the US invaded the country, and also providing the only live coverage of the war for many nations around the world. For many, CNN became the face of US policy. As a result, nations and multinational corporations witnessed the power of satellite technology in spreading a message beyond national borders. As well, the impact of live television, the communal experience which had gripped the US back during the Kennedy assassination coverage, now could be worldwide. The BBC extended its reach, and the STAR-TV group of stations began broadcasting on an international basis, with RTL and other services around the country extending their reach.

In 1996, after the BBC shut down its Arabic channel, *Al Jazeera* was launched in Qatar with funding from the emir of Qatar, who had deposed his father as leader of the country. Al Jazeera was set up partly to provide a forum for critics of other Arab governments, since many of those nations do not allow oppositional viewpoints. The network took its cues from western news channels with an emphasis on conflict, exciting video, heated debate, and extensive live coverage. Al Jazeera immediately made enemies throughout the Middle East, since leaders in many of those nations were not used to open criticism. The

emir of Qatar ignored pleas for censorship and allowed the Al Jazeera staff to pursue stories without intervention.

### CHANGING DYNAMIC FOR WORLD NEWS

Al Jazeera's impact reached beyond the Middle East with the US invasion of Afghanistan. Instead of just the conflict framed from a western point of view, Al Jazeera also broadcast messages from Osama bin Laden and other Al-Qaeda images. The Taliban in Afghanistan recognized the power of the 24-hour news cycle and used Al Jazeera to present its views during the war. During the US invasion of Iraq, Al Jazeera showed graphic, often unedited, video of Iraqi war victims while western news channels focused on the coalition forces advance toward Baghdad. The US government put pressure on Qatar to shut down or muzzle Al Jazeera, with no effect. Zayani credits Al Jazeera with reversing the traditional flow of news: not "from the Occident to the Orient, but the other way around" (Zayani 2005, 31).

In the US, the success of CNN caused Rupert Murdoch to launch a competitor, the *Fox News Channel*, in 1996. Fox's Roger Ailes, a former Republican strategist, hit upon a successful formula of marketing Fox as the moderate alternative to the traditional liberal media (→ Bias in the News). Confrontational hosts such as Bill O'Reilly and Sean Hannity, coverage that favors conservative viewpoints, and effective use of graphics and news productions techniques pushed Fox past CNN in the cable news ratings in the US.

The *power of the images* in television news became apparent during the Iraq War with the toppling of a Saddam Hussein statue in Baghdad. Even though Hussein statues could be found throughout Baghdad, the repetitive airing of this one action (later revealed as a staged event by coalition forces) prompted US cable networks to switch from a battle frame to a victory frame in coverage (Aday et al. 2005).

Satellite technology and globalization (→ Globalization Theories) in the twenty-first century have brought increased attention to the effect of television news expanding from a national to an international experience, with an increasing pressure on broadcast journalists' often oppositional missions of both providing a public service for the viewers and attracting a large enough audience to justify either the advertising revenues or the tax or user fees.

## **Television News, Visual Components of**

*Peter Dahlgren*

*Lund University*

The emergence of television news programs in the late 1940s in the US marked a major historical development in the history of journalism (→ News; Television News; Journalism, History of). Combining the broadcast auditory flow of radio (→ Radio Technology) with the moving images (→ Film Theory) of the movie → newsreels shown in the → cinema, television news was able to provide the public with a new experience in journalism. In the context of American commercial broadcasting, television journalism – more than any previous form of news – was shaped by the economic demands of entertainment and advertising (→ Advertising, Economics of), not least on account of the compelling visual dimension (→ Commercialization: Impact on Media Content). The American model of

television news was quickly exported, and has become the global norm for how it is done. The visual elements are a part of the taken-for-granted professional routines, yet continue to evolve as the genre develops, and they remain of important analytic concern (→ News Routines).

It is the visual dimension that gives television news its unique attributes. In traditional broadcasting, television, like radio, has strict time schedules. Only in very extreme cases can more time be allotted. The public cannot alter the tempo of the program or the sequence of the stories. Unlike radio, television news has moving pictures, which alters the mode of cognitive attention, adding the visual to the aural. Moreover, television news provides a different experiential flow; not only are the images supreme in conveying visual phenomena, the visual elements in themselves generally enhance the affective involvement of the viewer, not least in regard to engagement with people seen on the screen (→ Parasocial Interactions and Relationships; Emotions, Media Effects on).

Certainly with the advent of video recording, and more recently of digital formats – as well as channels with 24-hour news transmission – some of the temporal and scheduling constraints of viewing have been loosened (→ News Production and Technology; Newscast, 24-Hour). While new technologies have in some ways altered the production processes (e.g., reporters today can transmit their materials immediately to the studio via their digital equipment), the visual dimension retains its decisive role in the production of television news, and exercises certain imperatives that continue to define the genre (→ Newscast). Television news has to be “good television” as well as “good journalism,” and on occasion tensions arise between the use of visuals and journalistic values. Stories that may be of journalistic importance may not always readily lend themselves to suitable visuals (e.g., much political negotiation can be of little visual interest), and conversely, dramatic visual footage may be available but may lack a good informative story (e.g., breathtaking images of war may be weak in terms of information).

## DOCUMENTARY REALISM AND OBJECTIVITY

The principles guiding the use – and evaluation – of visuals in television news derive from the documentary tradition, which in simple terms means that the professional goal is to accurately represent reality (Corner 1995). The visual dimension soon became entangled in the ongoing discussions about “objectivity.” “News” does not exist in nature and can never be a simple “reflection” of reality; it always involves the work routines of news organizations (Tuchman 1978). Thus, there are always two basic sets of journalistic decisions to be made: *what* to inform the public about (i.e., selection), and *how* should it be done, in terms of the manner in which a story should be angled or framed (i.e., presentation). The professional goal of appearing to be “objective,” coupled with the cultural expectation that news does not reflect any subjective point of view, led early on to the development of sets of conventions of camera use that have come to be associated with the visual aesthetics of realism (→ Realism in Film and Photography).

The key element of realism is to convey an impression of “natural observation”: the camera strives to function as the surrogate eye of the viewer, and thereby becomes in a sense “invisible,” deflecting awareness from the constructed character of news (→ Visual Representation). The visual is thus experienced as merely rendering the world as it is, in

a documentary manner, untouched by human intervention (→ News Myths). To say that news is constructed is not to suggest that it is “faked” or deliberately misleading. Rather, it merely asserts that all news, as an organizational product, is predicated on human intervention and decisions.

It remains to be seen whether or not this notion of visual objectivity will be eroded as some segments of the viewing audiences become more aware of how television generally gets done. Popular conceptions about “real” versus fictive have become somewhat more sophisticated in the wake of versions of → reality TV, as well as via the growing involvement in amateur and home digital media productions of all kinds. Audiences seem quite aware of – and sensitive to – the “rules” of various television genres of factual programming (Hill 2007), yet the visuals remain compelling in television news as well as in other media genres (see, for example, Messaris 1995).

### GENERIC PICTURES

At one level, all → journalism is engaged in a kind of “translation service”: it must take that which is new and convey it in terms which are recognizable and meaningful. This tension is of course a continuous challenge, in that certain events or developments cannot be truly understood with reference to the familiar. Much of journalism consists of reiterations of the world as it is: familiar kinds of stories with recurring elements. The highly conventionalized use of language and, in broadcast news, modes of speech, also enhances the impression of the everyday, the “normal.” With television news, the repertoire of the visuals is also quite standardized, consisting of many generic ingredients in the camerawork. The → codes that define the genre are quite unmistakable. For journalists as well as audiences, this camerawork is not merely the “containers” that carry information; the particular use of specific shots is part of a well-developed “language” that can convey meaning in an effective manner.

Thus, the typical title sequences that introduce a TV news program usually make use of graphics signifying “the world,” for example abstract illustrations of the globe and collages of images from “all around the world.” Together with the accompanying fanfare music, the aura of pomp, and the brisk professional efficiency conveyed by the news anchor(s) and reporters in the studio (based on their dress, body language, facial expressions, etc.), this sequence tells us the program should command attention (Bignell 2002). It not only “brings” us the world and “covers” it, but also by implication positions itself in an implied all-knowing Olympian manner. After this introduction, the traditional news program usually makes use of a standard set of visuals, usually comprising: the news anchor(s) in the studio, addressing the viewer; studio interviews/discussion with guests; live sequences with reporters on location; pre-recorded materials (with either a reporter visible at the scene, or with just a voice-over). Still images, such as graphs, charts, and photos, are also used (→ News as Discourse).

Within this basic visual framework, there are more specific signifying practices that serve to transmit meaning (→ Semiotics). For example, the semiotics of location include an inventory of familiar images of political power (e.g., shots of a presidential emblem or the Houses of Parliament), familiar icons of major cities, the chaotic violence in the streets of the Middle East, starving refugees in a camp in Africa. Also surrogate “proxy

images” are used for events and actions where genuine documentary pictures are unavailable (Griffin 1992). There are also tacit rules, or codes, which tell us things about the news organization, such as its hierarchy: there is a “chain of command” that filters the information. Thus, a guest interviewed in the studio never looks into the camera, but instead always at the reporter. Only the reporter has the prerogative to address the viewers directly. Similarly, a reporter on location will usually address the studio anchor, if one is present, rather than the viewer.

Further, the visual codes for depicting people are significant. For instance, different kinds of shots structure social distance. Thus, “normal” and “respectful” distance is suggested by a medium close-up, simulating proximity in social situations; a long-shot of many people suggests their relative lack of significance in terms of social power and individuality; while an extreme close-up signifies intimacy or psychological intensity.

The basic genre of TV news is still very recognizable, but it is of course ever evolving. Viewing videotapes of news programs from, say, three decades ago would make some of these developments quite visible. One would notice, for instance, the increase in tempo and sensationalist news values, even in the traditionally more staid network evening news programs in the US. With the increased tempo come more visual cuts and shorter sound bites. Moreover, with → CNN and other 24-hour news services we have witnessed more material with live shots – focused editing is not always as evident as in the traditional news programs with tight schedules.

Beyond cueing the viewers’ understanding, the visuals also serve a powerful legitimizing function (Griffin 1992). Given that the images afford an almost indisputable experience of reality, of truth, in their visual facticity, the implication is that “seeing is believing.” Moving images also imply immediacy, in the sense of being instantaneous – thereby further underscoring the authority of the news organization – but also in the sense of being direct, untouched by personal subjectivity. The difficulty here is of course that the visual “truth” may not always be able to say much about the social, political, economic, cultural, or other factors that have shaped a phenomenon captured by the camera. In seeing images we all too easily assume that we understand the realities they represent.

## **ONGOING DEBATES**

From a learning point of view, the visual dimension has at times been criticized for being ambiguous, allowing many different meanings to emerge. But research (see Graber 2001) suggests that this is really not the case. The verbal dimension helps anchor the visual and facilitate comprehension. Also, given that the visual repertoire within a given national culture is a limited and rather stereotypical one, it is governed by well-established codes. The “preferred” meaning intended by the news organization is usually not ambiguous. Further, the communication of information in TV news watching depends not just on the contents and form of that which is represented in the images, but also on the stimulation of schemas – i.e., the activation of relevant archives of memory and meaning in the viewer. Visuals thus have the potential to aid learning by triggering recall. Discussions continue, however, in regard to how best to coordinate visuals with voice-overs of spoken text. The larger issue of the ideological interpretation of news is another question, however, and is greatly dependent on the predispositions of different groups in the audience.

The theme of affect and emotional involvement in images is at times raised in regard to the informational function of news. The Enlightenment legacy of rational thought is seen in some quarters as threatened by the visual dimension of news – a dimension that is on the increase in media culture generally. The questions are raised whether democracy can survive the growing journalistic use of images, and whether the visuals automatically imply a “dumbing down” of the public. Can television news seriously address its viewers as citizens, or do they inexorably become positioned as spectators and consumers? Such debates continue, with sustained intensity.

## **Television as Popular Culture**

*Toby Miller*

*University of California, Riverside*

“Television” refers to “seeing from afar.” It describes a physical device, a cultural system, and a labor process that brings the two together and embeds them in the daily experience of half the world’s population (→ Television). “Popular” signifies of, by, and for the people, offering transcendence through pleasure, but doing so by referring to the everyday (→ Popular Communication). “Culture” derives from agriculture (→ Culture: Definitions and Concepts). With the emergence of capitalism, it embodied instrumentalism and abjured it, via the industrialization of farming and the cultivation of taste.

These terms have generally been understood through the social sciences and the humanities – truth versus beauty. In the humanities, popular television texts are evaluated by criteria of quality and politics, understood through criticism and history. The social sciences focus on different viewers, investigated ethnographically, experimentally, or statistically. So whereas the humanities articulate differences through symbolic norms (for example, which class has the cultural capital to appreciate high culture), the social sciences articulate differences through social norms (for example, which people play militaristic electronic games). “Popular culture” relates to markets, as does most television. Neo-classical economics assumes that expressions of the desire and capacity to pay for services animate entertainment and hence – when the result is publicly accepted – determine what is “popular.”

### EARLY CONCERNS ABOUT TELEVISION

This background explains why television is the focus of so much theory and research. People have long fantasized about transmitting images and sounds. Richard Whittaker Hubbell published *4000 Years of television* in 1942, and the device has its own patron saint, Clare of Assisi, a teen runaway from the thirteenth century who was canonized in 1958 for imagining a midnight mass broadcast on her wall. In 1935, Rudolf Arnheim predicted TV would bring global peace. But he also warned that “television is a new, hard test of our wisdom.” The emergent medium’s easy access to knowledge would either enrich or impoverish its viewers, manufacturing an informed public, vibrant and active – or an indolent audience, domesticated and passive (Arnheim 1969, 160–163).

Such concerns about TV have never receded. When Edward R. Murrow addressed the US Radio-Television News Directors Association in 1958, he used the description/metaphor that television needed to “illuminate” and “inspire,” or it would be “merely wires and light in a box.” In a famous speech to the National Association of Broadcasters three years later, Newton Minow called US TV a “vast wasteland” (1971). He was urging broadcasters to show that the US was not the mindless consumer world that the Soviets claimed. The networks would thereby live up to their legislative responsibilities to act in the public interest by informing and entertaining. For his part, Alfred Hitchcock said: “Television is like the American toaster, you push the button and the same thing pops up every time” (quoted in Wasko 2005, 10; → Television: Social History).

These concerns come from a longstanding class concern. Ever since the Industrial Revolution, anxieties have existed about urbanized populations vulnerable to *manipulation by images* and demagogues through the popular. This is spectacularly the case with television. The notion of the suddenly enfranchised being bamboozled by the unscrupulously fluent has recurred throughout the modern period. It leads to an emphasis on the number and conduct of television audiences: where they came from, how many there were, and what they did after being there. These audiences are conceived as empirically knowable, via research instruments derived from sociology, demography, psychology, communications, and marketing (→ Research Methods). Such concerns are coupled with a concentration on content. Texts are also conceived as empirically knowable, via research instruments derived from communications, sociology, psychology, and literary criticism.

### KEY TOPICS IN RESEARCH

Television analysts “speak different languages, use different methods,” and pursue “different questions” (Hartley 1999, 18). But broadly speaking, TV has given rise to *three key topics*: ownership and control, texts, and audiences, with the question of the audience, and the knowledge that it has or that it lacks, as the governing discourse. Within these categories lie several other divisions. Approaches to *ownership and control* vary between neo-liberal endorsements of limited regulation by the state, in the interests of guaranteeing market entry for new competitors, and Marxist critiques of the “bourgeois” media’s control of the agenda for discussing society. Approaches to *textuality* vary between hermeneutic endeavors, which unearth the meaning of individual programs and link them to broader social formations and problems, and content-analytic endeavors, which establish patterns across significant numbers of similar texts, rather than close readings of individual ones (→ Text and Intertextuality). And approaches to *audiences* vary between social-psychological attempts to validate correlations between watching TV and social conduct, and culturalist critiques of imported television threatening national culture (→ Audience Research; Exposure to Television).

Just as US communication studies doggedly clings to a binary opposition between qualitative and quantitative approaches, between impression and science, between commitment and truth, so its dominant formation has hewed closely, with an almost febrile desire, to methodological individualism in seeking to explain why people and television interact as they do, looking for links between TV and violence, misogyny, and educational attainment. By contrast, most study of TV elsewhere is more exercised by imported programs’ impact on their countries’ cultural expression, using terminology and methods that address TV as a collective issue, rather than an individual one; a matter of interpretation and politics, more than psychological impact. But there is in fact a link between the two anxieties.

### MODELS OF THE IMPACT OF TELEVISION ON POPULAR CULTURE

Each one assumes audience members risk abjuring either interpersonal responsibility (in the US) or national culture (in the rest of the world). Both models assume that the audience is a “cultural dope . . . acting in compliance with the common culture.” Caricaturing people in this way clouds the actual “common sense rationalities . . . of here and now situations” (Garfinkel 1992, 68). The dope first appears in a *domestic effects model* (DEM). Dominant in the US, and increasingly exported around the world, it is typically applied without consideration of place and is psychological (for the apotheosis, see Surgeon General’s Scientific Advisory Committee on Television and Social Behavior 1971). Entering young minds hypodermically, TV can both enable and imperil learning and drive viewers to violence. The DEM is found in laboratories, clinics, prisons, schools, newspapers, psychology journals, television stations’ research and publicity departments, everyday talk, program-classification regulations, conference papers, parliamentary debates, and state-of-our-youth or state-of-our-civil-society moral panics (→ Violence as Media Content, Effects of).

The second means of constituting “dopes” is a *global effects model* (GEM), primarily utilized in non-US discourse. Whereas the DEM focuses on the → cognition and

→ emotion of individual human subjects, via observation and experimentation, the GEM looks to customs and patriotism. Cultural belonging, not psychic wholeness, is the touchstone of the GEM (→ Globalization Theories). Instead of measuring audience responses to TV electronically or behaviorally (→ People-Meter), as its domestic counterpart does, the GEM interrogates the geopolitical origin of televisual texts and the themes and styles they embody, with particular attention to the putatively nation-building genres of drama, news, sport, and current affairs. GEM adherents hold that local citizens should control TV, because their loyalty can be counted on in the event of war, while in the case of drama, only locally sensitized producers will make narratives that are true to tradition and custom. The model is found in media-imperialism critique, everyday talk, broadcast and telecommunications policy, unions, international organizations, newspapers, heritage, cultural diplomacy, and postindustrial service-sector planning. In its manifestation as textual analysis, it interprets programs in ideological terms.

In contradistinction to the DEM/GEM, a third tendency in communication studies is stimulated by the *cultural-dope critique*. Endorsing the audience as active rather than passive, it constructs two other model audiences: all-powerful consumers (invented and loved by neo-liberal policy-makers; desired and feared by corporations) who use TV like an appliance, choosing what they want from its programming; and all-powerful interpreters (invented and loved by utopic communications and cultural critics; investigated and led by corporations) who use TV to bring pleasure and sense to their lives. Each claims that the television audience makes its own meanings, outwitting institutions of the state, academia, and capital that seek to measure and control it. Ownership patterns do not matter, because the industry is “wildly volatile,” animated entirely by “the unpredictable choice of the audience” (De Vany 2004, 1, 140). The first approach demonstrates a mechanistic application of neo-classical economics. The second varies between social-psychological tests of viewers’ gratifications and a critical ethnography that engages cultural and social questions.

But the DEM and the GEM continue unabated as the major players. From one side, effects researchers Dorothy G. Singer and Jerome L. Singer comment on “the impact on children of their exposure through television and films or, more recently, to computer games and arcade video games that involve vast amounts of violent actions” (2001, xv). From the other side, cultural researcher Néstor García Canclini notes that: “We Latin Americans presumably learned to be citizens through our relationship to Europe; our relationship to the United States will, however, reduce us to consumers” (2001, 1).

Regardless of their political or epistemological quixotries, all such researchers begin with popular culture and television as problems in need of address, whether through critique or adulation. Perhaps future scholars will break away from this rather elderly dance, and consider issues of textual diversity, cultural democracy, TV labor, and the high-technology trashing of electronic waste.

## **Television: Social History**

*Jérôme Bourdon*

*Tel Aviv University*

Television history has developed relatively recently. After pioneering work in the UK (Briggs 1961–1995) and the US (Barnouw 1976), national histories of television (and broadcasting) have been written, mostly in Europe and sometimes beyond (bibliographies can be found at André Lange's history of television website). Historians have focused

mostly on political and institutional history. Television content has long been ignored except for countries (or researchers) rich enough to have access, and this remains a problem except in privileged situations (as in France, where the Institut National de l'Audiovisuel [INA] archives television programs for free access: [www.ina.fr](http://www.ina.fr)).

However, the growth of → cable television has made, somewhat haphazardly, some past programs available. The main missing link in historical work is the → audience, a notion hard to historicize both from a methodological (→ Audience Research) and epistemological viewpoint. Therefore television history has trouble connecting with major debates of the field that focus on audiences. In sum, globalizing mostly national efforts and digging into the past of television viewing remain the major challenges facing television historians. Taking stock of their efforts cannot be done without first attempting to integrate varied national data.

There is a paradox at the heart of television history (Bourdon 2004). Not only has it mostly been written on a national basis, but researchers often insist on national specificity without clarifying its comparative basis – e.g., on the close relation between television and government in France (→ France: Media System), the penetration of political parties into public television in Italy (→ Italy: Media System), the relation between television and the army in militarized societies, etc. The only major attempt at an “international” history is framed mostly as a set of national (at best continental) histories (Smith & Paterson 1998). And yet, the reader of all these works will easily realize that global similarities are no less striking than celebrated differences. This should not be interpreted as technological determinism (→ Technology and Communication). Television has not necessarily forced similar trends, or at least similar debates, on different societies. More probably it has accompanied, and to some extent encouraged, some globalizing trends. “Global,” however, needs heavy qualification (→ Globalization Theories).

## THE ORIGINS: TELEVISION AS NATIONAL TOOL AND ART FORM

Television was framed, from the start, as a *national medium*, which quickly became important for national culture and politics, despite some resistance. The first major media events (Dayan and Katz 1992) had strong national implications, whether a royal (UK, 1953) or imperial (Japan, 1961) marriage, or a major electoral or sports competition located in the country (→ Historic Key Events and the Media). A technological competition to be the first television country began in the 1930s before World War II, starting with the UK and the US. Everywhere, a television station was considered, unofficially, as part of the outfit of a “fully fledged” nation. Witness, after the war, the tremendous efforts made by poor countries such as African nations and India (→ Africa: Media Systems; India: Media System) to set up networks of transmitters for populations that could barely afford television sets. Often the real or imagined threat of transmissions spilling over from neighboring countries (and sometimes from US army stations) accelerated the setting up of stations, while for stronger nations the willingness to export their culture encouraged the development of television. Israel started television in 1968, mainly to counteract the popularity of Arab stations among Arabic-speaking citizens (Jews or Arabs) and also to reach the population of the newly conquered territories (→ Israel: Media System). In the 1950s, France promptly set up a transmitter in the eastern part of the country where

people were exposed to West German television. West German television, in its turn, played an important part in showing the capitalist world to its communist Eastern counterpart. Neighbors of Brazil worried about the popularity of Brazilian telenovelas on their borders.

Beyond the emphasis on the nation, there is another common feature to early television, in the 1950s in the UK and the US, and in the 1960s in much of Europe (including Eastern Europe). Whether commercial or public, many national stations tried to appropriate television not only as a new medium, but as a *new art form*. A hybrid class of creators excluded from → cinema – engineers dreaming of poetry, avant-gardists willing to experiment with technology – entered television to experiment, mostly in drama – especially live drama, with Shakespeare being a “global” favorite, but also in the documentary, where British television culture was the major exponent of the trend (→ Documentary Film; Documentary Film, History of). Although with less encouragement from heads of programming, this was true both in public and in commercial stations.

### **PUBLIC VERSUS COMMERCIAL**

To a certain extent, this contradicts the well-established view that media developed according to very different national traditions. The notion of “media models” (or “theories”) was first proposed (albeit not for TV) by Siebert et al. (1956), and has been re-elaborated several times since (see notably Curran & Park 2002; McQuail 2005). Radically, this will be simplified into two models, which themselves should be sub-classified: public and commercial.

As defined in this article, “public television” applies to stations controlled by the state, whatever the means of this control are. It is financed by general taxes or by a specific tax, the license fee (“invented” for radio by the UK), although advertising is sometimes added to the financing mix. Within this model can be included stations working within public service (as in western Europe; → Public Service Broadcasting: Law and Policy), authoritarian, dictatorial, and (formerly) Soviet frameworks. In all cases, the state directly or indirectly regulates the content of television. Television is not only a question of national sovereignty and identity (as it is everywhere), but also of national culture and education (→ Culture: Definitions and Concepts). In authoritarian, dictatorial systems, it is attached to a ministry of information (as it was also in France until 1974), but everywhere public television emphasizes its educational mission. Feedback from viewers and audience ratings do not really matter (→ Rating Methods). The aims are those that were first set for radio in the → BBC royal charter of 1927, to “inform, educate, and entertain.” Entertainment came third, while it was always first in commercial television. Public television also includes McQuail’s “developmental” model (2005), where television is mobilized to unify new nations (→ Development Communication; Television for Development). Even older European nations had something akin to developmental television, such as postwar Italy, which used television to spread literacy in the national language (notably with a program tellingly called *It Is Never Too Late*).

*Commercial television* is financed by advertisements only, and state control is relatively weaker than in public television. Within the typology used by Siebert et al., there is only one model, the liberal one; according to this, the media are organized on a free-market,

commercial basis, and this is linked to political independence. There is no room for a situation where commercial media are politically controlled, although this has since occurred, and is still occurring, in many countries. Strong commercial television stations are there to maximize the audience and to make money. The big media groups that emerged early in the history of Latin American television, like the Brazilian Globo, launched in 1965 one year after the rise of the military regime that ended only in 1989, knew how to adapt to the military dictatorship of their country quite well (→ Brazil: Media System). Commercial television is related to political independence, which can draw prestige and audiences, especially in situations where commercial television is born out of authoritarian or monopolistic systems. But sometimes independence comes at too high a cost. Witness what happened to oligarch Gusinsky's station NTV in post-Soviet Russia in 2001, when President Vladimir Putin had the state conglomerate Gazprom take over NTV and force the owner into exile (→ Russia: Media System). Present-day semi-commercial Chinese television is by no means politically independent.

### FROM PUBLIC TO COMMERCIAL

The global history of television can then be summed up as follows: in the beginning, the public model was dominant. Commercial television reigned mainly in the United States. Quickly, however, it spread, first south into the Latin American backyard, where educational attempts (notably in Chile) quickly yielded to the ambition of media entrepreneurs supported by US networks. The US also made inroads in countries not formerly colonized by Europe, such as Iran, Thailand, and Japan, or in Anglo-Saxon areas of influence. Commercial television coexisted with public television from the start in Japan (1953) and Australia (1956). In the UK it was born in 1955, whereas most of Europe waited until the deregulation of the 1980s to launch commercial television.

US stations might have been relatively independent vis-à-vis governments and political parties. They can impose their agendas and formats on political life (like the Kennedy–Nixon debates in 1960, which would become a reference for pre-electoral debates in the west and beyond; → Televised Debates). However, television became a tool of imperial commercial policy, supported by the state (Segrave 1998), to export programs, formats, technologies, and even modes of regulation to the rest of the world (→ Americanization of the Media). US executives viewed with surprise the reluctance of Europeans, but quickly (and aggressively) sold their programs in poorer countries with networks officially based on the public model, using strategies like block booking (popular programs had to be bought as parts of a package) or dumping.

Public television was vulnerable: US programs and formats were cheap and attractive, which can be explained both by their competitive commercial character and by their targeting of multicultural audiences of immigrants. By the early 1960s, *I Love Lucy* was popular in parts of South America, Africa, and Japan. Game show formats were adapted in many places, openly and eagerly by British and Australian commercial TV, more discreetly by public European stations, which domesticated popular American recipes – loosely adapting them without paying copyrights at a time when the idea of internationally selling “formats” on the basis of existing copyrights was still in its infancy. In the 1970s, many public television countries talked of promoting a → “New World Information and

Communication Order” (NWICO) to counteract US influence. Their efforts culminated in the publication of the McBride report (*Many voices, one world*, published by → UNESCO in 1980; → International Communication). At the same time, several American series were proving to be successful with audiences around the globe, notably *Dallas* at the end of the decade. *Dallas* was not the first major American export, but its west European triumph came at a time when European public television felt threatened by financial crises and rising costs, increased criticism from social movements demanding more space in the air waves, rising neo-liberalism, and pressures from capitalist groups eager to use the media. Western European television executives then wondered how to produce their own *Dallas* (→ Soap Operas).

### THE MEANING OF DEREGULATION

The deregulation of television affected the whole of western Europe first, but spilled to the south, and also to the east after the fall of the Berlin Wall (→ Television Broadcasting, Regulation of). New commercial stations were born everywhere. Media barons became key figures, openly embracing populism, and sometimes entering politics. The emblematic figure here is the Italian *Silvio Berlusconi*, pioneer of wild deregulation in the late 1970s, head of Italian media conglomerate Mediaset, and Prime Minister in 1994 and from 2001 to 2006. Other media barons took a less direct interest in politics but entered the field of television, globalizing not necessarily culture *per se* but certainly formats, schedules, and ways of working. The (formerly Australian) press baron *Rupert Murdoch* successfully (but after heavy losses) created a fourth American network, Fox, in 1986, and the main British bouquet of channels, British Sky Broadcasting (BSkyB). But smaller markets also have their media barons, wielding much political influence, and controlling major national TV channels (→ News Corporation).

International *format convergence* seems to be the order of the day. This is clear when considering the rise of a new genre, reality television (Holmes & Jermyn 2004). “Reality television” is a blanket term used originally in the US in the 1980s for programs foregrounding ordinary viewers in “real-life” situations, such as *America’s Most Wanted* (itself adapted from a German show). However, it is the rise of European “reality games” which made the genre universal, such as the Dutch *Big Brother*, in 1999. While major flows of export worldwide still run from the US, reality TV offers many examples of European global hits. In those games, contestants expose themselves to the camera in personal, emotional, intimate, stressful situations. They participate in their own elimination from the program (sometimes with the intervention of a jury and/or the audience. They have triggered media panics, but now seem to have settled down, sometimes recycling well-known formats like couple games or talent shows in *American Idol: The Search for a Superstar*, adapted in 2002 from the British format *Pop Idol*. Comparative analysis shows that national cultures domesticate these formats in different ways.

However, this is not simply the victory of a commercial model of television, a media version of Fukuyama’s end of history. Undoubtedly, some professional norms, ways of scheduling, formats (the anchor-person for news), and audience measurement methods (push-button audimeters; → People-Meter) introduced in the 1970s and now adopted in more than 80 countries, still continue to spread. Commercial television has many faces,

however. Its relation to democracy remains problematic, as in many parts of the former Soviet empire, where one could talk of commercial authoritarian television. There are also varied degrees of commercialization (→ Commercialization of the Media). American (including Latin American) television still leads the trends. Public service television, despite persistent criticism, remains different from and more regulated than its commercial competitors, despite being taken to task for aping them: it still schedules more news (at a slower pace) and current affairs. Weak production infrastructures and the persistent exaltation of individual authorship contribute to explaining why most of Europe still struggles to produce long-lasting series and serials; soap operas and telenovelas tend to remain an American monopoly.

### THE END OF TELEVISION?

The “end of television” has been prophesied many times. It refers to the end of national channels as assemblages of clearly identifiable genres in coherent schedules. The schedule is the same on every weekday (breakfast news, talk, games, mid-day news, soaps) while it changes weekly in the evening, with mostly series (national ones in rich countries), variety shows, and talk (especially in poorer markets). Advertising is the only genre which pervades the schedule at all times, with more interruptions in aggressive commercial markets.

Some researchers have argued that *fragmentation* – e.g., in themed cable channels, digital TV and interactivity, video on demand, diffusion of programmes on the Internet or the mobile phone – will destroy this assemblage. They highlight the implications for daily patterns of living, social memory, and even social cohesion. Since the early 1990s, the rise of cable and → satellite television has changed television but not fragmented its audience into specific groups according to taste and culture, as many had predicted. Major channels did lose audiences, but still garnered the majority of viewing time, and some old genres became the matrix of the new themed channels based on fiction (Home Box Office, 1975), news (→ CNN, 1980), children’s programs, sports – in short, old genres, although one should note the addition of musical videos (MTV, 1981) and later → reality TV as the basis for themed channels. Old television also keeps on expanding. It passed the bar of the majority of world households in the late 1980s (with China becoming a television country), and there is still much room for expansion in Africa and parts of Asia (→ Audience Segmentation).

Finally, television culture remains very much national through the content of some genres (information and light entertainments) and their specific stars (hosts, newscasters, etc.), despite some globalizing trends. Although → media conglomerates have shares in different countries, the dream of a global diffusion of the same program cherished in the 1980s has been forsaken. No channel has embodied this dream as vividly as Viacom’s MTV, created in 1981. The idea of a global music youth culture was enticing both to idealists of a universal world and to advertisers of global brands for the young and affluent. After a noisy start, MTV underwent a process of “*renationalization*” and created national (French, Italian, or even British) or continental (Latino) channels with a mix of “international” (Anglo-Saxon) success, and local clips. This example illustrates how a globalization of formats goes hand in hand with constant hybridization.

Most recently, MTV has announced the launch of MTV-K for Korean Americans. This is a symptom of another major change, connected to the rise of global migration movements. The national public is fragmenting, but it seems to be fragmenting along national-diasporic lines. This was heralded by the rise of video in the 1980s, which reached communities of immigrants in the west. Cable channels now allow for a de-territorialization of national cultures, with Turkish immigrants in Germany, Russian immigrants in Israel, or Pakistanis in the UK keeping in touch with their country and culture of origin (→ Ethnicity and Exposure to Communication; Ethnic Media and their Influence).

“Old” channels have shown not only resilience, but the ability to combine with new media (→ Convergence of Media Systems). The relations between television and the → Internet are the best example of this convergence. In reality television, audience participation plays a major part (through the Internet and mobile phone). Official and unofficial sites of such programs are key places for (un)planned exposure of the instant stars’ privacy and biography. Older genres also combine with the Internet, where Internet development has been devoted to constantly updated news in an online environment. On the Internet, the ever-popular US television series grow into a whole sub-culture, not only about celebrity gossip (→ Celebrity Culture), but also alternative screenplays, with international hits like *Lost* (entering its third season in 2006–7) or *24*. The vitality of these programs and their international exposure suggest that (relatively) “old” television still exerts a powerful influence. Undoubtedly, television channels now promote a more instant, more commercial, more individualistic culture than in the past. But this culture remains steadily national and related to major television genres, with reality television as an important addition.

## Television Technology

*Hugh Mackay*

*Open University*

Technological developments have played a major part in shaping the production, broadcasting, and reception of television. Histories of television tend to highlight a sequence of technologies (e.g., the cathode ray tube, fiber optic cable, and remote control) and their inventors (e.g., Nipkow, Baird, and Zworykin). This approach allows us to trace the development of the devices that together constitute television technology, while also identifying the relevant social groups, including scientists, technicians, entrepreneurs, governments, and even home enthusiasts, involved in shaping this emergence and form.

### TECHNOLOGICAL DETERMINISM VERSUS THE SOCIAL SHAPING OF TECHNOLOGY

Scholarly investigations of television technology frequently revolve around the relative significance of the determining or constraining power of the technology, on the one hand, and the social and cultural circumstances from which the technology emerges and within which it is deployed, on the other. To the extent that these relative emphases can be counterpoised against one another, two broad positions can be identified – positions often characterized as forming a debate about technological versus social determinism. Raymond Williams (1921–1988) is the cultural theorist who first outlined the major issues in this debate, notably in his *Television: Technology and cultural form* (1974), but also in his essay ‘Culture and Technology’ (1983).

*Technological determinism*, Williams argued, is the immensely powerful and orthodox view of the relationship of technology to social change. Harder variants of technological

determinism are sometimes criticized for focusing on the “lone inventor,” the engineer who applies scientific knowledge and invents or modifies technology in some sort of neutral, apolitical way. This is seen as ignoring the fact that invention is goal-oriented; that is to say, it is intended to achieve a particular end or purpose. It also ignores the key role of large corporations (e.g., RCA, EMI, and → Sony Corporation) and state governments in backing the development of specific technologies. It is similarly criticized for focusing on technical development as “one-off” instances, whereas the history of television technology shows a recurrent cycle of development, innovation, adoption, take-up, use, and modification.

“Soft” versions of technological determinism see technology as an element in a process of change that is (about to be) occurring anyway – the technology is a symptom of change of some other kind. This is essentially Williams’s approach. In contrast with technological determinism, his account of the development of television restores intent to the process of research and development – television was developed with particular purposes in mind. He points out that a technology depends on other technologies in a system for its effectiveness; that is, specific artifacts are embedded in what sociologists of technology term “socio-technical systems.” For Williams, television technology is more than simply a series of isolated inventions. Its emergence depended on a set of developments in electricity, telegraphy (→ Telegraph, History of), → photography, film (→ Film Genres), and → radio, most of them made with ends other than the transmission and reception of moving images in mind. The components of television were effectively drawn together to realize the transmission and reception of moving images with little prior thought given to prospective institutional structures, forms, or content. In other words, it was a technology looking for a use.

At the same time, Williams maintains that television (like radio before it) reflects or embodies particular societal features, including the unequal distribution of economic and political power. Television was developed to serve the twin processes of mobility and the more self-sufficient family home – which, together, he terms “mobile privatization.” This is the broader context for understanding the particular development of television technology. For Williams, television technology is the outcome, rather than the cause, of culture (→ Culture: Definitions and Concepts). The system of “centralized transmission” and “privatized reception” is not built in to the technology – it was neither inevitable nor immutable, but is what led to licensing and sponsorship or advertising systems. These core aspects of television, as it is understood today, underpin the very notion of broadcasting.

### **THE ORIGINS AND DEVELOPMENT OF TELEVISION TECHNOLOGY**

Williams traces television technology back to Volta’s and Faraday’s work on electricity (in 1800–1831); the electrical telegraph (which was envisioned as a technical system in 1753 and demonstrated in various places in the early nineteenth century); photography (notably the work of Niepce in 1816, Daguerre in 1839, Fox Talbot in London, and George Eastman in the USA); and slide projection by “magic lantern” (which had been practiced since 1736). In other words, television is embedded in a complex system of scientific knowledge, technologies, expertise, organizations, and individuals, and depends on their existence, involvement and compatibility to operate effectively.

Seeing at a distance was imagined in the 1870s, for example by George Carey, who produced drawings for a “selenium camera” that would enable people to see at a distance “by electricity.” Alexander Graham Bell, inventor of the telephone, had plans for a “photophone” which would enable one to see the person one was talking to on the telephone. The physical realization of this vision was linked closely with the development of radio, since television broadcasting involves sounds and words, as well as pictures.

The visions of the late nineteenth century were developed physically in the early decades of the twentieth century, with many of the key features of television invented by the time of World War I. At the technical core of television is the process of scanning an image. Generally, this has been done with a beam of light, traveling from top to bottom and left to right. When the light passes over the image an electrical impulse (of greater or lesser strength) is produced. This is amplified and transmitted by radio waves or along cables. The *cathode ray tube* (CRT) reproduces the image at the receiver. This contains an electron beam facing the screen, which has a uniform coating of a material that emits light when struck by the beam, which is of varying density – depending on the shade of gray dot being transmitted. The complete picture is received 25 times per second, so movement appears unstilted and realistic. In the 1920s and early 1930s television was “low definition”, with 30 lines to the screen. By 1936 the → BBC had developed a system with 405 lines, while more recently most of Europe has standardized on 625 lines and the USA and Japan on 525 lines (→ Communication Technology Standards). Much of this has changed in recent years with the arrival of digital television technology.

In the 1920s and 1930s there were *two paths of experimentation* that were followed in developing television, namely mechanical and electronic scanning. Mechanical television was based on Paul Nipkow’s spinning metal disc patent that he submitted in Berlin in 1883 for an “electronic telescope” to scan and transmit images. This idea was taken up, in particular, by Charles Jenkins in the USA and John Logie Baird in Scotland. The electronic approach (which proved superior) was developed by Alan Campbell-Swinton in the UK and Boris Rosing in the USSR, and later by Vladimir Zworykin (Rosing’s student) and Philo Farnsworth in the USA. Around this time experimental television broadcasting was underway, with demonstrations held, equipment exhibited (e.g. at the at the 1939 New York World Fair), and small numbers of television sets sold – by 1935 there were 2,000 Baird television sets in service in the UK.

Individuals, corporations, and nations competed with one another, so there are numerous *claims of “firsts” in television* in this period – milestones include Logie Baird’s broadcast, initially of stick figures and silhouettes (in 1925) and then with 30 lines of resolution and a refresh rate of five frames a second (in 1926); Charles Jenkins’s licensed station (1928) and broadcast advertisement (1930); the BBC’s public television service (which began in 1932); the German television “service” (1935), which broadcast the Olympics in 1936; and the British Alexandra Palace 240- and 405-line service (1936). Interest from commercial organizations, state governments, and the public, however, remained lukewarm. The Federal Communications Commission (FCC: the regulatory body in the USA) hampered developments there, and there was no pressure group comparable to the amateur “ham” operators who had pressed for radio broadcasting. By the outbreak of war, only 20,000 sets had been sold in the UK. Nowhere had television broadcasting become a mass medium.

The key factor that transformed television from a toy to a mass medium, according to Brian Winston, was the spare capacity in the electronics industry immediately after the end of World War II. During the war there had been a massive expansion of the radio industry in the USA: between 1942 and 1944 expenditure on radio had expanded by about 1,300 percent (→ Radio: Social History). The industry employed 300,000 workers, and television production provided a cushion against unemployment and depression. This exemplifies how television was accommodated by existing bodies, with radio manufacturers and others shifting to television. By and large it was the same corporations and organizations that had been involved in radio that became involved in television. Television was absorbed by existing bodies, rather than creating new ones.

The 1950s was the decade of expansion and, as such, something of a golden age for television. In the UK, by March 1947, 14,560 households had licenses; by the end of 1951 about 1 million; and by June 1953 about 2 million. The coronation of Queen Elizabeth II, viewed by 20 million people, added enormous impetus. In the USA 0.02 percent had a television in 1946, 9 percent in 1950 and 65 percent in 1955 (→ Television: Social History).

Since the arrival of television as a mass medium in the developed world in the late 1950s, there has been a steady stream of *technological developments*. These have occurred in relation to production, distribution (or broadcasting), and consumption (receivers and the ancillary devices that are used with television in the home). As with the CRT television receiver, the origins of most distribution and consumption technologies can be traced back over several decades. An experimental *microwave relay system* was introduced by Western Union between New York and Philadelphia in 1945; by the 1970s this was the main form for carrying television signals, having lower costs than coaxial cables. *Color television* was demonstrated in 1946 (by Peter Goldmark at CBS), though this mechanical system (with a red–blue–green wheel spin in front of the CRT) was later replaced by an electronic system; this became available from the 1960s and by 1972 half of US households had color television.

*Videotape* was introduced to television production in 1956, the VCR for use in the home was introduced by Phillips in 1972, and in 1977 RCA introduced the first VHS format VCR in the USA. Today VCRs are hardly sold at all, having been displaced by DVD recorders and players. The TELSTAR *satellite* was launched in 1961, enabling the first transatlantic reception of a television signal by satellite in 1962 (→ Satellite Television). *Fiber optic cable* was introduced from the 1970s; it is used to transmit digital data, carries tens of thousands of times more data than conventional copper wire, and today forms the core of cable and telephone networks (→ Cable Television). *Remote controls*, which can be traced back to the end of the nineteenth century and were used relatively widely in World War II, were developed for use with domestic television in the 1950s, notably by Robert Adler at Zenith Radio Corporation in 1957.

Accordingly, rather than being a single or fixed technology, television is a set of inter-linked devices and components that are constantly being upgraded and modified, with “new” technologies arriving on the market after lengthy periods of thought, experiment, demonstration, and development. At the time of writing, the “new” technologies are mainly digital in nature.

## DIGITAL TELEVISION

Digital television was introduced in the late 1990s, and analog television is planned to be switched off in the USA by 2009 and in the EU by 2012. Digital television is much cheaper to transmit and allows considerably greater transmission capacity. It thus facilitates more television channels (which in turn is leading to the decline in viewing of public service broadcasting channels and in the power of public service broadcasters), interactivity, various screen formats, higher-quality sound and cinema-like surround sound systems. Flat-screen monitors with the video signal received by cable are replacing CRT televisions with receivers tuned to a station's frequency to receive the images that are being transmitted. Many of these features are coming together and being further enhanced with the arrival of high definition television (HDTV), which provides much higher-resolution pictures, a larger picture, more colors, higher quality sound and a faster refresh rate – so motion will be smoother and clarity greater, especially from near the screen.

There is much debate about whether it will be the personal computer (PC) or television that will become the home entertainment hub of the home in the future. *Convergence* allows → Internet access via many forms of television, and television can be received on many PCs (by broadband downloads or in-built television receivers; → Digitization and Media Convergence). Still and moving images, as well as sound, all use the same digital systems of data representation and transmission. However, there remain fundamental differences between how television and PC technologies are designed, with the former relatively easily operated by a remote control, and the latter being more of a “lean-forward” activity requiring frequent operation of a mouse, in an environment which does not easily accommodate more than one user at a time, and requiring far greater technical knowledge and intervention. In other words, despite technically similar capabilities, the convergence of the PC and television is far from realized.

Whatever the outcome of this contest, the contemporary era is one characterized by particularly rapid changes in television technology. It may be that, with the greater interactive possibilities afforded by digital technologies, the fundamental characteristic of television, that it is broadcast from one to many, may be changing, with users empowered to become producers too. The preconditions for television that Raymond Williams identified, however, remain as significant now as when he was writing – the unequal distribution of power and information; and the need for institutions to provide social cohesion in the context of mobile privatization. Changing notions of “public” and “private,” and with them of family and community, are among the factors that will shape, as they always have done, the development of television technology.

## **Television, Visual Characteristics of**

*John T. Caldwell*

*University of California, Los Angeles*

Television – which literally means “seeing from a distance” – has seldom been discussed by either critics or scholars primarily as a visual medium. Yet from the start, key sectors of the television industry itself were fascinated by the possibilities and potential for televisual representation (→ Visual Representation). In the shadow of more “legitimate” art forms in the twentieth century, and → cinema’s → spectacle-oriented wide screen in particular, television came to be known in largely style-less terms as “the small screen.” But this denigration of television glosses over a great deal of visual complexity and diversity that can be understood within three broad perspectives: the industry, the audience, and scholarship (→ Television; Television: Social History).

First, “the” television industry is not one thing; it is many, each with very different visual imaging practices. Reality television producers, for example (→ Reality TV), employ very different visual strategies to filmed dramas. Second, “the” television → audience, far from being monolithic, splintered into many different forms of visual consumption, decades before digital cable and YouTube. Since the early 1980s, for example, “narrowcast” music videos challenged their niche audience with visual styles far more complex than televised games in sports bars. Finally, scholarship, while largely discounting television’s visual complexity, offered research theories that viewed televisuality on a wide continuum, from the merely instrumental to the sometimes irrelevant. Many scholars who theorized television within either the social sciences or the humanities followed the modernist impulse to find the “specificity” of each communication medium. For television this meant anything but the image: effects, → propaganda, agenda setting, content, and/or psychological gratifications (→ Media Effects; Uses and Gratifications; Agenda-Setting Effects).

Television, in short, became many different things to many different industry sectors and audiences. Any discussion of television’s visuality, therefore, must be specific, and

explained in terms of television's varying historical genres, end uses, and modes of production. This entry describes the development of the visual characteristics of television mainly from the perspective of the US, where the medium gained its social significance earlier than in other countries, which often followed the path taken in the US.

## INDUSTRY AND TELEVISUALITY

Television's maligned visual status may have fitted early prototypes of television, which glimmered with ghostly, amorphous, black-and-white imagery. But this status ill fits both the ways that production personnel and programming departments in the US conceptualized TV in the 1930s and 1940s, and the ways that television eventually began to appear after 1980, in the multichannel age of → cable television and later high definition television (HDTV). Popular critics had their own reasons for ignoring TV's visual dimension in the 1950s and 1960s. Historian Eric Barnouw (1974) celebrated live drama and method acting as defining features of television's "golden age" in the 1950s. This view presupposed that artifice and production technique were merely obstacles in the creation of naturalistic, psychological authenticity. In hour-long live anthology dramas, jostled stage flats, sweating actors, and lighting hot spots didn't lessen television art. They proved that sensitive, nonvisual writers, directors, and actors were "operating without a net" in front of the camera's disinterested mechanical eye.

Hollywood's telefilms, however, which came to dominate and displace live drama in the mid-1950s in the US, were produced on 35 mm film (→ Hollywood). Golden-age critics characterized telefilms as mindless, lowest-common-denominator factory products from studio assembly lines. This judgment made the writer – not the image-maker – king during this period for scholars and critics. Popular mythology at the time – even from Hollywood – seemed to support this artistic hierarchy and write-off of TV's artistry. Despite Jack Warner's much-quoted prohibition that no TVs should appear on-screen or on the lot, all of the studios had some interest in developing television, and some were systematically involved in making television a central part of their business plans. Radio-Keith-Orpheum (RKO), one of the "big five" Hollywood studios, sold its film library to television; Paramount launched theatrical television and pay-per-view; → Disney created a weekly synergy between its studio films, television, and the network ABC (→ Television Networks); producer David O. Selznick brought wide-screen spectacle to event-status television; and Warner Bros offered its underused studio, back lots, and labor to satisfy programmers' ravenous appetite to fill network and local schedules each night.

The "three-camera," live, studio mode of production favored by critics spread internationally, in part because real-time "editing" (switching), fewer lighting set-ups, and a singular production site were more economic (→ Video). Many genres that employed this mode (news reading, telenovelas, game shows) offered few on-camera visual complexities. Yet a second, related mode of production, "*electronic news gathering*" (ENG), used smaller and lighter crews and increasingly portable equipment to gather late-breaking reality images and transmit them back to the three-camera control room. ENG work, while rapidly cut and catastrophe-focused, works visually, not because of its high resolution, illusionism, or formal beauty, but because of its fragmentary, frenetic, voyeuristic kick. Pressure to include arresting imagery drives TV news coverage, even to the point of

creating proxy footage and manufactured illustrations for events not recorded (Griffin 1992). Today, 24/7 cable news has updated both three-camera and ENG by embellishing them using digital graphics, text crawls, and multi-screens. If three-camera started as rote style-less news reading, it has ended as stylistically excessive, videographic, and cluttered.

*Single-camera, film-style, location production*, by contrast, has served as a workhorse mode of production since the early years of telefilm. In Europe and the US, many series opted for film style, given prime-time drama's higher budgets and higher stylistic expectations. For years, shows shot on film negative offered far higher resolution, richer contrast and tonality, and more subtle color rendition than shows shot with video cameras. Yet the emergence of HDTV since the late 1990s has meant that the actual capture device (film or chip) is less important than the cinematic look achieved. Many contemporary film critics have naïvely "discovered" that television – à la *The Sopranos*, *Lost*, and *24* – are as stylistically provocative and sophisticated as many high-budget studio films (→ Soap Operas; Television Technology).

Yet these same critics ignore the fact that dramatic television has offered viewers high-level cinematic experiences throughout its history. The A-list film directors that pushed network television boundaries in the US include: John Cassavettes, John Frankenheimer, Paddy Cheyevsky, Michael Mann, Steven Spielberg, Oliver Stone, Spike Lee, and Robert Altman, to name but a few. The portable, *cinéma vérité*-based improvisational television work of Cassavettes in the 1960s, for example, is a direct precursor to many contemporary "improvisational-looking" genres, from reality television to the faux-documentary quality of frantic "real-time" shows like *24* and *The Shield* (both shot continuously with two mobile hand-held film cameras and edited like documentaries). If dense digital graphics and computer-generated images (CGI) have converted even three-camera and ENG into stylistic showcases, then commercials and music videos (where many prime-time cinematographers, directors, and editors got their training) helped teach television how to integrate and synthesize cinematic and videographic impulses as a standard look across many channels.

While high-production-value series of this ilk still pervade prime-time, new *digital technologies*, starting in the 1990s, have uncorked an excessively diverse range of video forms and televisual genres, each with their own aesthetic implications. These newer formats, which move beyond the two traditional modes (three-camera and film style), can best be understood in terms of the changing audiences and consumers, and television's increasingly mobile users (→ Digital Imagery).

## AUDIENCES AND TELEVISUALITY

Broadcast television was developed as part of an integrated nationalistic agenda of postwar consumerism and economic expansion, one that rationalized TV squarely within the context of suburban homes and neighborhoods. This domestic setting impacted on the visual approaches that producers adopted and the kinds of visual perception that audiences were able to participate in. While Paramount studios worked hard and failed to make television a large-screen theatrical experience in the late 1940s, electronic manufacturers like RCA/NBC and DuMont in the US succeeded in making television simultaneously an entertainment activity, a desirable new kind of furniture, and a symbol of social status. Sponsors speculated that daytime viewers would be "distracted" housewives, performing

household tasks with the television on. Producers therefore created dialogue-driven shows that did not require intensive observation to be understood. Thus, the image in daytime soaps receded under the weight of highly redundant dialogue that allowed preoccupied viewers to periodically “glance” at the screen (→ Exposure to Television; Audience Research; Media Use by Social Variable).

Producers imagined prime time differently, as a collective family activity undertaken with the room lights on. These shows should be entertaining, even if family members chatted throughout a broadcast. Advertisers in the 1940s and 1950s also directly imported from radio broadcasting another factor that devalued the visual: “direct address” audio narration that hyped products on-screen by overtly asking viewers to consider them. In these ways the early viewer was addressed as a distracted, calculating, and “*multitasking*” viewer. At least in these verbal, multitasking contexts, TV positioned itself in opposition to the darkened, solitary cinema viewer who was willing to suspend disbelief in order to imagine on-screen worlds as real. Marketed as a “window on the world,” TV eschewed illusion, while cinema posed as a “screen” allowing viewers escape from the world.

TV’s initial “de-visualization” – by broadcasters from radio, product sponsors, set manufacturers, and real estate developers – represented only one of TV’s historical strands. Telefilm and commercials would soon bring Hollywood competencies to program production. These influences included expressive and noir-ish lighting, location shooting, wide-screen genres, and film-style storytelling. The latest stage in viewing this television-into-cinema trajectory lies in the widespread design and construction of wide-screen “home theaters” in viewers’ living spaces. Digital television (DTV) and HDTV make this transition possible. The diversity of DTV forms makes it difficult to theorize TV cleanly without considering how home TV multitasking overlaps with home cinematic experiences (at least for consumers affluent enough to afford the new digital products and systems). The ability of high definition viewers to actually see all of this on-screen digital detail also has a direct impact on the ways that production groups now strategize, visually design, block scenes, and direct the action for new HDTV and DVD frames (Caldwell 2008).

With the advent of cable and the VCR in the 1970s, the → Internet in the 1990s, online downloading, video mobile phones, iPods, and mobcasting (distributing video segments over mobile phones and hand-held devices) in the 2000s, TV soon reckoned with what industry and audiences engaged as television’s “second,” “third,” and “fourth screens.” Audience research began to show that these *multiple screens* were not mutually exclusive (→ Nielsen Ratings). In fact, viewers frequently use various combinations of screens at the same time, and younger viewers choose multi-screen multitasking far more than older generations. This complicated simultaneous viewing across multiple platforms makes the audience’s visual experience very different (more fragmented, frenetic, and mobile). It also forces TV programmers to develop more complicated strategies for “content migration” and “multipurposing.” The most effective of these strategies must address several increasingly important factors: the scale, location, and mobility of viewing.

## SCHOLARS AND TELEVISUALITY

The first two frameworks considered here – the industry and the audience – show just how slippery it is to theorize about the visual specificity or definitive tendencies of television.

Scholars can research TV as broadcast, cable-cast, home cinema, DVR'd, downloaded, uploaded, YouTubed, hand-held, collected, mashed, or remixed. Each of these activities entails and exploits different aesthetic limitations, and new social rituals for viewing that directly affect the perceptual and cognitive demands of television's visual experience. This includes gatherings in which groups view entire seasons – only on DVD – through every consecutive episode during a single, sleepless sitting. Others theorize TV's new second, third, and fourth screens; where, for example, producers attempt to jam 35 mm film images from the series *Lost* shot on Panavision into the tiny coarse screens of a mobile phone, or into the stuttering quick-time images of screen-cluttered computer downloads. Such phenomena mean that scholars need to keep going back to television as a historically changing source – both at sites of production and consumption – to test and challenge their theories and assumptions about television's visual communication.

Given its challenging history, some media theorists have framed television in ways that allow us to understand its image-making. Other research, however, seems to have glossed over the complicated technological, production, and viewing developments outlined above. Some early media theorists, for example, by approaching media as propaganda or as having strong effects, inevitably presupposed televised images as deceptions that produced other more significant realities that researchers could examine more substantively (→ Attitudes, Values, and Beliefs, Media Effects on). Some forced important distinctions between constantly developing new media technologies – and the forms of image-making “essential” to each – into locked-down taxonomies and one-size-fits-all formulations.

For → Marshall McLuhan (1964), television's “cool,” low-resolution appearance meant that audiences were conscious not of a show's style, but of a common “all-at-once” viewing experience, shared simultaneously with many others (→ Medium Theory). The global networking of viewers was more important than the screen content or television style. Content analysis researchers also gave some attention to the screen that viewers actually looked at. But content analysis boiled television's communication experience down into isolatable, scripted actions of one sort or another while showing little interest in how stylistic, formal, and narrative engagement in television's visual experience might also create important affective, cognitive, and behavioral effects (→ Emotions, Media Effects on; Content Analysis, Quantitative). Media research tied to broad social processes and “liminal” national rituals (Katz & Dayan 1992), in turn, continued to underscore not TV's visual or formal dimensions, but rather singular events being widely watched in real time through a national TV window.

If McLuhan represented a promising but ultimately limited view of television's visual dimension (because of his technological determinism and tendency to overgeneralize the effects of each medium), then his British contemporary Raymond Williams (1974) offered some of the most important early formulations of television capable of accounting for current digital production and consumption practices. Specifically, Williams argued that scholars must examine not just the history of a communication technology, but the history of the social uses of technology as well. For television this meant examining the medium's most fundamental impact, something he termed “mobile privatized consumption.” Later theorists (Negroponte 1995; Levy 1997; and the magazine *Wired* in general) followed McLuhan's lead in celebrating new media in the 1990s as the result of a new sense of vast digital “networking” – precipitated by engagement with the

wired global Internet rather than with a local visual screen. Williams's more nuanced view of social usage and media mobility (→ Mobility, Technology for) seems a far more accurate description of contemporary uses of television in the age of hand-held video and convergence (→ Convergence of Media Systems).

While social scientists tended to avoid the image, or focus on its use and effects, a new generation of television critical studies scholars (→ Critical Theory) began to seriously engage with the *aesthetics of television*, starting in the late 1970s and 1980s. Yet even these studies started with the assumption that television was largely a narrative phenomenon. While early books in this vein mapped out television as a complex art form involving sophisticated narrative and genre strategies (Newcomb 1974, 1976; Allen 1987), later editions by the same authors show a gradually increasing consciousness of and research into television's visual dimension (Newcomb 2000, 2006; Allen 1992). This shift toward visual aesthetics was due in part to an emerging interest in theories of postmodernism, which took as one focus the pervasive logic of late capitalist societies, which now define themselves through consumer imagery and visual simulation (Jameson 1983).

Cultural studies methodologies (→ Cultural Studies) began to inflect much of this new work on television in the humanities in the late 1980s and 1990s. Yet oddly, this new scholarship tended to place cultural studies in dialectical opposition to aesthetics (Fiske 1987), or simply ignored the possibility that scholars could study culture from the ground up by researching imagery. Both of these tactics again served to devalue the visual dimension in television, in order to excavate its suspect ideologies. Scholars soon demonstrated how this skepticism about the visual in media scholarship was merely the latest manifestation of a recurring, longstanding suspicion and critique of the visual that has defined and animated European philosophy and western intellectual activity for centuries (Jay 1993; Caldwell 1995).

Unlike film studies, communication research never developed visual aesthetics as a central methodology in the field (→ Communication as a Field and Discipline). One exception that proves this rule is the work of production educators like Herb Zettl (1990), whose textbooks elaborated the visual grammar of television for successive generations of production students in communication studies. Visual studies of television are slowly emerging as important ways to understand the medium. This new interest in the visual comes from several important sources: the development of visual communication as a research tradition in its own right (Worth, 1981; → Visual Communication); new primary, archival research in television's industrial history; studies of visual activities in TV → fandoms (Jenkins 1992); and studies of the impact of digital convergence on television aesthetics (Caldwell 2003, 2004). In these ways, even as television has developed great visual diversity in the three broad areas examined above, scholars also now pursue systematic visual research from the varying perspectives of industry, production, audiences, and consumption. These multiple approaches enable scholars to understand how television's visual characteristics differ, depending on whether the viewer/user is: inattentively viewing cable news at the airport; intently screening high definition DVDs in the home theater; downloading series television off the Internet while surfing the net; or watching visual fragments of World Cup matches on a mobile phone while commuting. In these ways television's wide range of evolving visual characteristics can never be usefully separated from television's production, delivery, and use.

# Telework

Annika Hylmö

Independent Consultant

Researchers examining new and emerging work forms not following the traditional “9-to-5 schedule” often explore the impact of opportunities for employees to work remotely by teleworking or telecommuting (Nilles 1977). Teleworking may be defined as any form of work that substitutes information technology for work-related travel, so that work travels to the employee instead of the reverse (Hylmö 2006). While working remotely has been a part of organizations for generations (for example, making cloth for entrepreneurs in the textile industry), the 1970s oil crisis, coupled with increased technological capabilities, spurred interest in large-scale teleworking. Teleworking was especially encouraged during the 1990s as a way for employees to balance work with other commitments, thus enhancing overall quality of life. In the United States, the practice resurged following the September 11, 2001, attacks on the World Trade Center, as many people wanted to decrease their commutes and work closer to home.

Telecommuting and telework function as alternative work forms offering organizations and individuals an opportunity to transition to virtual organizing by using technology to transfer information to workers as opposed to employees traveling to work. In general, telecommuters work outside the principal office – for example, at a client’s office, at home, or at a telecommuting center – on only an occasional basis, while teleworkers, or virtual workers, complete their tasks “anytime, anyplace” and work remotely on an ongoing basis (Hill et al. 2003).

Teleworking employees establish different relationships to their colleagues compared to co-located workers, as they are not available for the immediate face-to-face interactions and meetings that are normative in many organizations. Individuals working off-site often appear available to family members, neighbors, and friends for tasks and assistance unrelated to their work. Combined with experiences of loneliness and loss of professional identity, teleworking challenges the ways that employees communicate with each other as well as in non-work-related contexts (Brocklehurst 2001).

Researchers have used several *theoretical frameworks* to explore telecommuting as a communicative phenomenon. Structurationists (→ Structuration Theory) have shown that teleworkers who are part of successful virtual teams may adapt their communication media use and adoption depending on the group’s geographic dispersion (Timmerman & Scott 2006). Network theorists (→ Communication Networks) have explored teleworkers’ levels of identification with their teams and organizations (→ Organizational Identification), finding that role conflicts and isolation may lead to decreased experiences of connectedness with colleagues (Vega & Brennan 2000).

Teleworking offers *opportunities for creative organizing* while potentially fragmenting and breaking apart traditional workplaces and company cultures (Hylmö & Buzzanell 2002). The opportunity to take advantage of teleworking opportunities may position some companies as leaders in employee relations, but may also lead to divisions between teleworkers and non-teleworkers. These distinctions may be reinforced by other factors,

including the reasons for seeking out alternative work forms. Individuals who telework while transitioning into retirement likely interact differently with colleagues than those who still view themselves as on the career track.

Critical theorists raise concerns about the need for teleworkers to *sustain images of productivity*, working longer hours than their in-house peers out of concern that they appear committed to the employing organization (→ Critical Theory; Organizational Communication: Critical Approaches). Telework challenges organizations by contesting what constitutes work, working, and legitimate locations for professional work (Hylmö 2006). In-house employees feel awkward contacting teleworkers operating out of their home offices by phone, while teleworkers laud their ability to communicate with colleagues and clients anytime, anyplace. Despite limited empirical evidence (Bailey & Kurland 2002), teleworkers argue that they are more productive and available to important stakeholders by being flexible in their workday.

Critical and feminist approaches examine how teleworking *challenges traditional distinctions between public and private realms* (Shumate & Fulk 2004). Scholars argue that teleworking threatens boundaries between “home” and “work” as the home comes under the surveillance of employers seeking to control workers (Broadfoot 2001; Brocklehurst 2001). The home no longer provides a refuge from the workplace when paid labor spills over into private life. Role spillover may be particularly challenging for women, as traditional gendered divisions of family labor remain. As a result, many teleworkers seek to reify traditional boundaries between home and work by maintaining separate offices or strict work hours during which they enact only a professional persona.

Teleworking continues to provide opportunities for future communication research, including organizational implications at multiple levels, the impact of demographic factors, and international comparisons as teleworking becomes integral to multinational corporations’ ability to remain competitive in the global marketplace.

# Terrorism and Communication Technologies

Prasun Sonwalkar

*University of the West of England*

Communication and communication technologies are intrinsic to the idea of terrorism as formulated and understood from the nineteenth century onwards (→ Technology and Communication). The discourse of terrorism has come to be symbiotically linked to communication technologies as state and nonstate actors across the globe use and exploit technological advances to further their causes. Schmid and de Graaf (1982, 9) observed that, “without communication there can be no terrorism,” while for Wilkinson (2001, 177), “when one says ‘terrorism’ in a democratic society, one also says ‘media.’”

In an increasingly globalized world, most people make sense of happenings in distant places through the news media, which are now able to communicate events across continents live (→ Media Effects). Groups and individuals branded by states as terrorists use communication technologies at two levels: to orchestrate events and ensure that news about them is communicated through television, press, radio, Internet, etc. for maximum effect on governments and the public; and they use technologies such as presses, photocopiers, satellite phones, video, email, chatrooms, websites, blogs, encryption software, etc. to coordinate, plan, and execute acts of political violence (→ Blogger; Electronic Mail). As Brazilian ex-communist Carlos Marighella stipulated in his *Minimanual of the urban guerrilla*, “modern mass media, simply by announcing what the revolutionaries are doing, are important instruments of propaganda . . . However, their existence does not dispense fighters from setting up their own secret presses and having their own copying machines . . . The war of nerves – or the psychological war – is a fighting technique based on the direct or indirect use of the mass media” (in Nacos 2002, 15; → War Propaganda).

## CONTESTED TERRAIN

The *definition of terrorism* itself has been controversial, with as many researchers formulating as many definitions. It has profoundly negative connotations. There is no

universally accepted definition of the term mainly because it is vulnerable to vastly different interpretation by state and nonstate actors. The conundrum is best exemplified by the dictum of “one man’s terrorist is another’s freedom fighter.” The same act of violence can be evaluated as either despicable or justifiable means to political ends, “as either the evil deed of ruthless terrorists or the justifiable act of freedom fighters and/or warriors of god” (Nacos 2002, 16; → Political Communication).

The value-loaded term has come to be applied to nonstate actors who use violence to attract attention or further the cause that they deem worth fighting for. Acts of violence perpetrated by states are usually not classified as acts of terror. However, it was not always so. In its original definition in the eighteenth century, terrorism meant acts of violence by the rulers (from above); for example, the violence during the Reign of Terror in the wake of the French Revolution, when terrorism meant the mass guillotining of aristocracy and other real and perceived enemies of the state. During the nineteenth century, the idea of terrorism was expanded to include acts of violence, such as assassinations, by anarchists (from below). In the twentieth century, terrorism came to mean mostly political violence perpetrated by nonstate actors, which include autonomous or state-sponsored groups and individuals (Hoffman 1998).

Researchers, however, agree on the *key role played by communication technologies*. Ted Koppel, ABC anchor, observed that, “Without television, terrorism becomes rather like the philosopher’s hypothetical tree falling in the forest: no one hears it fall and therefore it has no reason for being” (in Weimann & Winn 1994, 51). The importance of communication in a terrorist’s design led Nacos (2002) to suggest the idea of “mass-mediated terrorism,” which refers to politically motivated deeds perpetrated by groups or individuals for the sake of communicating messages to a larger audience. Such a communication-oriented view does not include “state terrorism,” or acts of violence perpetrated by states against noncombatants. This is because governments do not want to publicize such incidents while publicity is a key objective of nonstate actors; for them, political violence is committed with the intention to publicize the deed, to gain publicity and thereby public and government attention (→ Public Journalism).

As Laqueur observed (1976, 104), “The success of a terrorist operation depends almost entirely on the amount of publicity it receives,” which stresses the importance of communication technologies in the process of communicating acts of violence. The technologies constitute the cornerstone that links the three elements of a terrorist strategy: the terrorist, the target of the terrorist (victims), and the actual target of the acts of violence: the government or the public. The idea is often to evoke reactions from the government and instill apprehension or fear in the public.

Terrorist activity is immensely *newsworthy* as it satisfies several → news values such as → negativity, timeliness, and scale. Nonstate actors indulging in violence satisfy the news media’s need for spectacle and entertainment to increase circulation or ratings. Such nonstate actors and the news media feed off each other – acts of violence are often choreographed to coincide with journalistic routines and production schedules to ensure maximum coverage (→ Violence as Media Content). Researchers use the metaphor of *theatre* to describe the ways in which modern terrorism can be understood in terms of the production requirements of theatrical engagements (Catton 1978; Weimann & Winn 1994). In such “theatres” of conflict, there is an intense contest for news space between

nonstate actors indulging in acts of violence and the government, each seeking to ensure that their versions of reality get maximum play. Both state and nonstate actors use communication technologies to achieve contending propaganda objectives.

## COMMUNICATING TERROR

Al-Qaeda using video tapes to communicate messages by Osama bin Laden through the Al Jazeera television channel (and many others) is the most recent and visible example of the ways in which nonstate actors dubbed as terrorist groups deploy communication technologies effectively to propagate their perspectives (→ Arab Satellite TV News). An early example of the link between terrorism and communication technology is the late-nineteenth-century discovery of dynamite in 1866 and the rotary press, perfected in 1881 (→ Printing, History of). Schmid and de Graaf (1982, 9) observed that, “The two inventions soon started to interact.” The San Francisco-based anarchist paper *Truth* declared at the time, “*Truth* is two cents a copy, dynamite is forty cents a pound. Buy them both, read one, use the other.”

Before communication technologies such as the press became key elements of everyday life, the *maximum audience* that could be reached was limited to the range of the human voice. According to Weimann and Winn (1994), nineteenth-century European anarchists faced the problem of communicating their ideas to the general public. Their pamphlets had limited distribution. The anarchists turned to the “propaganda of the deed,” which meant using acts of violence to secure coverage from the national and international press as well as encourage word-of-mouth communication. Nineteenth-century Italian anarchists Malatesta and Cafiero are said to be among the first to understand and exploit the symbiotic relationship between the news media and acts of terror. Around the same time in Russia, Peter Kropotkin stated, “By actions which compel general attention, the new idea seeps into people’s minds and wins converts. One such act may, in a few days, make more propaganda than a thousand pamphlets” (in Weimann & Winn 1994, 53).

Inventions and advances in technology in the nineteenth century and their potential were quickly seized upon. Leon Czolgosz, the anarchist who killed US president William McKinley in 1901, explained his deed thus: “For a man should not claim so much attention, while others receive none” (in Schmid & de Graaf 1982, 10). Another anarchist, Lucheni, who collected news clippings and murdered the Austrian Empress Elisabeth, said he had longed to kill “somebody important so it gets into the papers.”

For early anarchists and latter-day nonstate actors dubbed as terrorist groups, every new communication technology invented increased the potential for effective propaganda as well as better coordination and execution of acts of violence. The national press and international news agencies could carry news of violent deeds to remote regions and countries, thereby providing free and fast communication networks to nonstate actors. The assassination of Abraham Lincoln in 1865 took weeks to be known widely, but when John F. Kennedy was shot in 1963, more than 70 percent of Americans had heard of it within half an hour. The potential for propaganda further increased exponentially with the invention of and advances in radio, film, and television; the world wide web and its many networks of communication such as chatrooms, ICQs, blogs, and email; mobile phone technology and satellite phones (→ Satellite Television); and convergence

technologies that combine text, audio, and video elements. Satellite phones and the → Internet made it easy for journalists to cover acts of violence in different parts of the globe.

The most significant technological change has been the emergence and widespread diffusion of *television broadcasting* (→ Broadcast Journalism; Television News). According to Schmid and de Graaf (1982, 17), “what the rotary press did for the nineteenth-century terrorists, television is doing for contemporary terrorists.” The inclusive nature of the medium – one does not have to be literate to consume it – and its capability to transmit images across continents to millions of viewers, live, provided a new tool to nonstate actors indulging in violence. The medium not only ensured that acts of violence could be covered live, but that the leading nonstate actors could also counter official versions in the cut and thrust of politics in the aftermath. Bin Laden’s selective video appearances made as much news in the western media as outside the west, ensuring that western perspectives in international communications did not go unchallenged. Modern-day terrorists exploit traditional mass media as well as new media technology.

Schmid and de Graaf (1982, 14, 15) observed that, “while in the nineteenth century the deed had to be specific that it would, as it were, speak for itself, developments in communication technology have since allowed for an ever-increasing *distance between victim and message*. Yet in its substance terrorism has not changed fundamentally in the hundred years that separate the beginnings of anarchist terrorism from contemporary terrorism.” Thus, millions of viewers across the globe watched in rapt attention as the second plane ploughed into the World Trade Center on September 11 – the victims were not only those present in the twin towers, but the target included millions of people across the globe.

The 1990 Kosovo military conflict between the Belgrade regime and NATO is seen as the first *Internet war*. Since then, the Internet itself has become a site of terrorism and warfare between contending ideologies and groups, most notably Islamist. According to Khatib (2003, 389), the Internet is used by Islamic fundamentalist groups as a “portable homeland” that allows them to strengthen their global ties and communicate with one another, and also to communicate with the connected world at large. It is important to note that in official and news discourse, the term “Islamic fundamentalism” is often conflated to mean “Islamic terrorism.”

The new information and communication technologies (ICTs) allow a new dimension to nonstate actors who are keen to further their ideologies and causes. The new ICTs allow them diffusion of command and control, which was not available to their predecessors in the nineteenth century, while new opportunities for communication allow them to target the information stores, processes, and communications of their rivals (Whine 1999). The developments in communication technologies facilitate what has been called *netwar*, which refers to offensive acts carried out by often geographically separate, diverse, interconnected nonstate actors. Called *cyberterrorism*, the latest convergence between nonstate actors and communication technologies involves hackers (cyberterrorists) who cripple websites, data systems, and networks of rival groups and/or governments. Nacos (2002) observed that such groups have high-tech specialists in their midst and protect their Internet activities from intelligence and law enforcement agencies in the countries they target.

Whine (1999) listed several benefits ICTs bestow upon nonstate actors: they allow interconnectivity (Hezbollah's website publishes a daily diary of terrorist attacks and urges anybody with an opinion about its anti-Israel activities to get in touch); they enable covert communication; they are cheap to operate; they act as force-multipliers and enable reach and influence that was previously confined to well-organized, state-funded terrorist organizations; and they enable nonstate actors to target audiences that traditional media deny them.

# Test Theory

*Roland Mangold*

*Stuttgart Media University*

In psychology, psychometric tests are standardized data collection methods. To provide significant and interpretable results in an empirical study, a test must meet specific requirements that are laid down by test theory. Only if these preconditions are given can reliable and valid conclusions be drawn with respect to the “real” value of a person’s trait or state under measurement. For standardized tests the raw score obtained during administration is transformed into a test score (e.g., an IQ or an anxiety score), which represents the intensity or strength of the trait/state to be measured on the level of an interval scale (→ Scales).

Classical test theory is influenced by → measurement theory in physics. It is based on the assumption that every test value obtained consists of a “true” value (i.e., the “real” intensity of the person’s trait or state) as well as an additional error value. The error part of measured values should be minimized or at least known in size. For that, classic test theory is based on the assumption that error values are balanced out during repeated testing, that the error value is independent of the strength or intensity of the personal state or trait (the “real” value), and that for separate test administrations error values are independent of each other.

The goodness of a test is indicated by three different criteria. A test is *objective* if different testers obtain identical results with respect to application, data analysis, and interpretation. Ideally, the objectivity coefficient of test is as high as 1.0. Objectivity during application can be increased by providing a standardized instruction. Objectivity of data analysis mainly depends on item construction: objectivity is higher if a person can choose answers from a set of alternatives (i.e., multiple choice items). Objectivity of interpretation is high if conclusions can be drawn directly from a person’s test score to the trait/state to be measured.

*Reliability* is an indicator of the exactness of measurement. A lower → reliability corresponds to higher error values during testing. For tests a reliability value greater than 0.80 should be aimed at. Reliability can be qualified in three different ways. First, the test can be applied twice. The correlation between the values of the first and second measurements is an indicator of retest stability (→ Correlation Analysis). Second, reliability also can be determined by administering two parallel versions of a test and computing the correlation coefficient between them. For that an additional pool of homogeneous test items is required. Third, reliability can be estimated by computing internal consistency. For that, the number of test items is divided into two halves (by chance or by odd and even item numbers). Reliability then is indicated by the correlation between both test halves. A better estimation of internal consistency is provided by the Kuder–Richardson formula or the formula for Cronbach’s alpha. Whereas internal consistency always should be as high as possible, a high stability value is only reasonable for traits that are invariant over time. With respect to (variable) states, the parallel test methods are to be preferred.

A *validity* score indicates to what extent a test measures the aspect it is expected to measure. Criterion validity is based on the correlation between test scores and an external criterion that represents the trait or state as closely as possible. For example, if a test is constructed to measure viewers' preferences for film genres, subjects can be asked to record all programs they have seen on TV in a media diary. Preferences that subjects have specified by answering questions in a test can then be related to diary data. However, it is not always possible unambiguously to define a criterion for the trait under investigation. For example, there is no single criterion for human intelligence. In that case, measurement with an intelligence test will be integrated in a network of other variables being related to intelligence (e.g., other intelligence test, grades, judgments of teachers, problem-solving behavior, etc.). Within this network of interdependencies, the construct of intelligence can be validated (i.e., construct validity or internal validity).

*Item response theory* is different from classic test theory because it is not based on the distinction between "true" and error values. Instead, a personal trait to be measured is conceived of as being a "latent dimension." The strength of this latent dimension with a certain probability is indicated by scoring test items. Item difficulty and the person's ability both determine the probability that a specific test item will be solved by the person: the easier an item and the more able a person, the higher the probability that this person will solve the item. Based on Rasch's (1980) logistic model, item difficulty and personal ability can be determined independently of each other. For that, in contrast to classic test theory, the assumptions underlying a test can be tested empirically.

Computing coefficients for reliability or validity is not reasonable within the model of item response theory, as here accuracy of measurement and the person's ability are not independent of each other. Within the item response approach, tests may be developed for personal traits or states that have been intensively studied in other research and where the items for measurement can be formulated precisely (Bortz 1984, 143). However, for developing new methods for the assessment of personal variables, a test in the framework of classic test theory is to be preferred, which in addition saves time and effort.

# Text Analysis, Computer-Aided

Wolfgang Schweiger

Dresden University of Technology

The basic medium of interpersonal and mass communication is text (→ Text and Intertextuality). Analyzing text helps in understanding the meanings of mass media messages and their potential effects, observing strategies and developments of rhetoric, identifying rules and structures of social communication, etc. Thus text analysis, comprising all kinds of qualitative and quantitative techniques of media content, discourse, and linguistic analysis, is an indispensable methodological field for all social sciences (→ Content Analysis, Qualitative; Content Analysis, Quantitative; Discourse Analysis; Linguistics). But as communicators' encoding of → meaning and ideas (semantics) in text (syntax) does not always follow a straight logic and is heavily influenced by social and cultural context (→ Linguistic Pragmatics), the analysis of large text corpuses is a complicated and laborious endeavor. Therefore, from the beginning of computer science, scholars have tried to develop automated tools for understanding, abstracting, and classifying texts.

Compared to the promise of artificial intelligence research in the 1960s and 1970s, today's facilities for computer-aided text analysis are disappointing. Nonetheless, there is virtually no text analysis without computer support, once one basic premise is met: the text corpus under analysis has to be available in a digital format – as a full text, as a collection of relevant portions of the text (title, author, medium, lead text, date of publication, etc.), or in an indexed fashion (containing additional meta-data like an abstract or keywords, etc.). We can differentiate between computer-based and computer-supported methods of text analysis. While computer-based methods are run completely by computer programs and thus can be automated, computer-supported methods enable or facilitate only selected parts of data collection or analysis and require additional manual operations.

The *fields of application* of computer-aided text analysis are manifold and cannot be fully outlined in this article. Some examples can give a first impression.

In *mass communication studies*, content analyses of print media are usually accomplished by human coders. Nonetheless, *retrieving relevant articles* (i.e., articles dealing with the issue under analysis) from online databases (full text, by keyword or title search, or using other meta-data) drastically reduces the amount of time spent browsing volumes of newspapers or magazines, which in earlier days had to be done manually. There are two drawbacks: first, the retrieval of non-text elements such as photographs, sound files, or movies is limited; second, the identification of relevant articles is restricted to articles containing pre-defined terms, whereas relevant articles using other words (representing the identical meaning) are not found.

A completely computer-based variant of content analysis simply counts *word frequencies* in mass media content as a macro-indicator of the media agenda, i.e., the increasing or decreasing coverage of specific issues or actors over time (see the agenda-setting study by Funkhouser 1973; → Agenda-Setting Effects).

Although providing only limited methodological → validity, standard search engines like Google, specialized search services like Google News, or self-programmed web

spiders or crawlers can be applied for *data-mining* on the → Internet, i.e., retrieving relevant websites or web pages which can be automatically or manually analyzed afterwards.

*Linguistic text-mining tools* classify text documents by measuring the vocabulary used (dictionary) or the style of language (e.g., sentence length, the share of nouns and verbs) and conducting → cluster analyses with the material. Such tools can be used for discourse and linguistic analyses of email, chat, or discussion forum communication; they can also help to identify unknown authors of historical texts by comparing them with other texts by known authors.

More sophisticated linguistic technologies can identify the *semantic meaning* of lexical words (disambiguation) by analyzing their context (e.g., the General Inquirer, a classic software package for text analysis developed by Philip Stone in the early sixties at the Massachusetts Institute of Technology; Stone et al. 1966). There are several tools under development that can identify or classify text corpuses at a semantic level and which can summarize or abstract large text corpuses. For simple English texts, the results are quite acceptable; but for more complex texts or texts in other languages, these tools are still unsatisfactory.

Finally, there is a broad variety of computer programs supporting the basic steps of *qualitative text analysis* (segmenting texts, paraphrasing and classifying propositions, indexing text examples) by elaborate commentary and tagging tools.

Undoubtedly, the Internet is the most important data source for computer-aided text analysis. And it is steadily changing. Some of today's trends present *significant challenges for the analysis of online content*.

Many online documents *change rapidly*, sometimes within seconds (e.g., Internet news sites, discussion forums, emails). This makes online coding almost impossible and requires that data collection is conducted within a restricted period of time. It is almost impossible to identify the *content* of a particular website without referring to the time of retrieval.

On the web, there is a development from static and text-based documents (HTML) to *dynamic media environments* (Flash, Java, mp3, mpeg). Recently, most websites provided distinct and constant units of analysis, which could be saved to file for later (re-)examination and scrutinized with established techniques of text analysis (computer-aided and manual). Today, more and more websites offer animated or audiovisual content, with the boundaries of units of analysis becoming more blurred (→ Online Research).

The most crucial challenge is *interactivity*: in interactive environments, there is no fixed text corpus (→ Interactivity, Concept of). Instead, the content is automatically arranged and constructed according to user input. This means that the researcher cannot gather and analyze a given and unchangeable portion of text, but he or she has to define an inter-subjectively transparent strategy for content retrieval. Methodologically put: the text analysis of interactive material inevitably requires active data *production* instead of data *collection*, which challenges the validity and → reliability of research.

## **Text and Intertextuality**

*Klaus Bruhn Jensen*

*University of Copenhagen*

Texts are vehicles of meaning in human expression and communication. Growing out of centuries of literary, → hermeneutic, and other humanistic scholarship, the concept was originally reserved for written and other verbal messages. From the 1960s onwards, however, *texts* came to denote all meaningful entities, including images, everyday interaction, and cultural → artifacts generally (→ Modality and Multimodality), as examined through increasingly interdisciplinary approaches in communication and related fields.

### **TEXTS AS COMMUNICATION**

Deriving from classical Latin *texo* (to weave, to construct) and *textum* (fabric as well as speech and writing), the concept of text directs attention toward the process in which ideas and insights are given concrete shape and offered in communication to others. Compared to the concept of a *message*, which is commonly said to contain and transmit → information, and which is sometimes used interchangeably with text, this latter concept emphasizes that meaning is only articulated in the meeting of form and content, aesthetics, and propositions. Importantly, the → meaning of a given text is considered open to questioning and interpretation both by contemporary audiences and by posterity.

The complexity of textual meaning helps to account for the preferred methodologies of the humanities, probing the subtleties and nuances of the individual text for what is being communicated. In a medieval worldview, the Bible provided an analogy to the Book of Nature as a means of insight into the Great Chain of Being (Lovejoy 1936). Since both “books” articulated divine intent, they required scrupulous attention to potentially significant details, as overseen and enforced by church and state authorities (→ Book). In

a modern perspective, meaning could still be said to reside *within* texts with socially binding implications. Legal contracts as well as entire cultures and sub-cultures are constituted through texts, and their reinterpretation may anticipate fundamental religious or political change.

Texts lend themselves to the immanent analysis of meaning for practical as well as contemplative purposes (→ Aesthetics). As the arts assumed their modern shape as separate social and aesthetic practices in the course of the eighteenth century, the act of interpretation came to be defined programmatically by Immanuel Kant in his *Critique of judgment* (1790) as the disinterested contemplation of the beautiful, the true, and the good. Artworks could and should be appreciated for their inherent logic, rather than any ulterior purpose. The understanding of texts as singular sources of insight fed into idiographic, individualizing, and qualitative approaches to the study of culture and society (→ Idiographic vs Nomothetic Science). Like artworks and historical events, media texts can be examined for their inherent significance.

### TEXTS IN COMMUNICATION

Studies of texts *as communication* traditionally have asked: *where is meaning* – in which content elements and formal structures? Increasingly, communication research has come to explore how texts enter into communication, asking: *when is meaning* – for whom, and in which contexts (Jensen 1991)?

With reference to this last question, qualitative textual analysis, first of all, makes a distinction between the *story* and the *discourse* of a text (Chatman 1989). While the story is the series of events, the *what* of the text, discourse is the *how* or actual organization and representation of these events, typically in a narrative, which can be implemented in many different ways, for example, to create suspense. Literary and film theory, further, has emphasized the spectator's active participation in the creation of textual meaning (→ Film Theory). Drawing on Russian formalism (Erlich 1955), Bordwell (1985) reintroduced *syuzhet* to refer to explicit narrative information about events, whereas *fabula* denotes the audience's reconstruction of the connections between events. Thus, whereas authors, directors, and other producers offer meaning as a potential in various media and modalities, it remains for readers, viewers, and other audiences to actualize specific meanings. Beyond film and literary theory, qualitative media reception studies in particular have explored empirically how audiences decode textual meaning, depending on social and cultural backgrounds and contexts (→ Interactivity in Reception).

Textual communication in the broadest sense is addressed in content and → discourse analysis, which examine how concrete texts are shaped by, and in turn shape, their social settings (→ Content Analysis, Qualitative). The concept of → discourse, moreover, has been employed to refer to historically shifting dominant worldviews. In this regard, structuralist and poststructuralist theories of society, e.g., in the work of Louis Althusser and Michel Foucault, have suggested that the construction and distribution of knowledge through texts, media, and other social institutions may be understood as an exercise of power (→ Structuralism). In an even wider sense, texts can be considered the stuff that social reality is made of: social contexts have been studied literally as texts, for instance, within anthropology and → cultural studies.

## INTERTEXTUALITY

The inclusive notion of texts has been elaborated with reference to the concept of intertextuality. The seminal contribution was made by the Russian literary scholar Mikhail Bakhtin and his circle in the early decades of the twentieth century (Bakhtin 1981). Bakhtin's most basic concept – dialogism (→ Dialogic Perspectives) – was translated by Kristeva (1984) as intertextuality, and underscores the fact that individual signs only acquire their meaning in relation to other signs, past as well as present. Texts are not stable containers of meaning; instead, texts should be taken as the momentary manifestations of textuality, articulating a cultural heritage and historical tradition. The point is that all human acts of communication enter into structures and configurations that follow distinctive cultural patterns. A culture might be considered an almost infinitely complex instance of intertextuality.

The methodological question of how to examine intertextual structures and the social processes shaping them has tended to divide researchers. The majority of studies derive from literary and film studies, and have centered on, for instance, novels, films, or television series as relatively self-contained entities – texts *as communication* – with explicit or, more commonly, implicit references to previous artworks, symbols, themes, or genres. Genette (1982/1997) has been an influential representative of this position, referring to what he calls *transtextuality*; for example, *metatextual* relations hinting at the origins of certain textual constituents and *paratextual* relations between a novel and its explanatory cover text (→ Fiction).

Conceiving intertextuality as an operational way of approaching texts *in communication*, as well, Fiske (1987) distinguished between two dimensions of intertextuality. *Horizontal* intertextuality covers the transfer and accumulation of particular meanings over historical time, as preserved in the metaphors, characters, and styles of traditional arts as well as popular media. *Vertical* intertextuality, in comparison, operates during a more delimited time period, but extends across several media and social contexts. To specify this synchronic perspective, Fiske identified three categories of texts. Primary texts are carriers of significant insight in their own right. (In the horizontal perspective, the primary texts are the center of attention.) If the primary text, for example, is a new feature movie, the secondary texts will consist of studio publicity, reviews, and criticism. And the tertiary texts are produced by audiences who engage in conversation with each other, before, during, and after attending the movie.

In combination, the two axes of intertextuality amount to a model of how meaning is produced and circulated in society, reinserting the concept of texts into the agenda of communication studies (Fig. 1). At the same time, Fiske's (1987) terminology still privileged media texts as the primary sources of meaning in communication. A few major contributions have applied the intertextual perspective to popular cultural phenomena such as James Bond (Bennett & Woollacott 1987) and Batman (Pearson & Uricchio 1990), with further attention to, for instance, their place in popular memory. Also the *flow* of broadcasting has lent itself to studies of how viewers (and listeners) select and combine discursive elements from multiple channels into an intertextual configuration (for overview, see Jensen 1994).

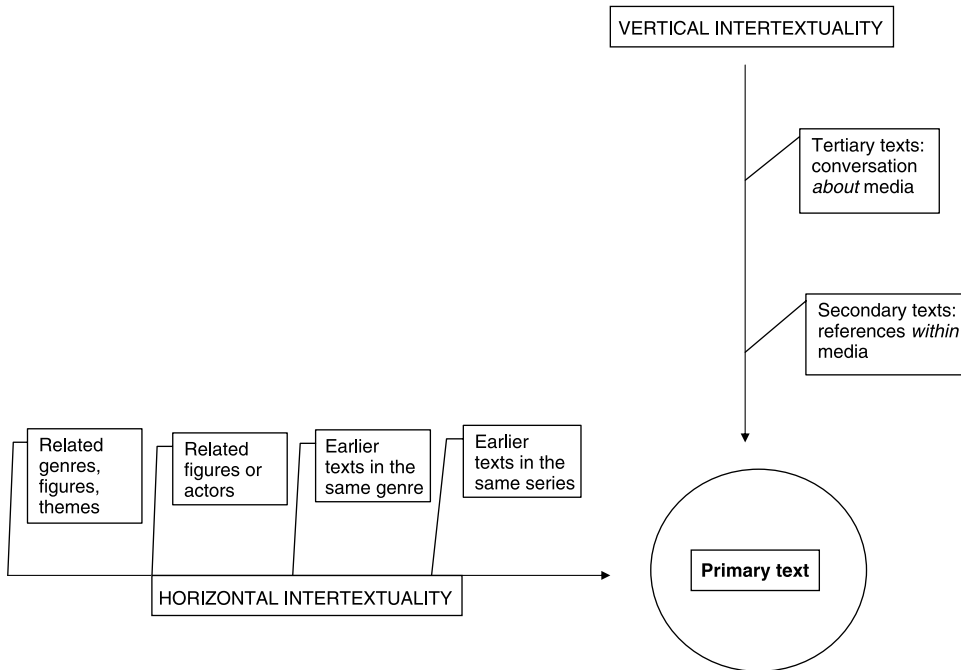

Figure 1 The two axes of intertextuality

## HYPertextUALITY

The rise of digital media and of more differentiated forms of communication has given the theoretical concept of intertextuality renewed importance, also for empirical studies of media use (Bolter 1991; Aarseth 1997). So-called *hyperlinks*, connecting message elements in computer-mediated communication, may be understood as instrumental or operationalized forms of intertextuality – a means of making explicit, retrievable, modifiable, and communicable what might have remained a more or less random association in the minds of recipients (→ Human–Computer Interaction). Hypertexts (or their constituent parts) can be linked for easy access or for purposes of indexing. Similarly, hypermedia join, for instance, video sequences with verbal explanations, to be selected and activated by learners and other groups of users.

While some work on hyperstructures has tended to overestimate their potential for social innovation or political liberation (e.g., Landow 1997), the concepts of hypertextuality and intertextuality hold significant potential for future theory development as well as for concrete analyses of technologically mediated communication. On the one hand, hypertextuality facilitates distinctive kinds of → navigation and intervention by users within more flexible systems of communication (→ Interactivity, Concept of). On the other hand, users of hypertext systems still engage in a process of interpretation, as informed by intertextual clues and implicit links, which is broadly similar to audiences' encounters with images and verbal texts in print and previous electronic media. Building

on the classic concept of texts, communication research may retain both a sensitivity to meaning as complex and contextual, and an openness to the shifting technological and institutional conditions of human communication.

## **Theatre**

*Marvin Carlson*

*City University of New York*

The term theatre refers to that art form based on mimetic activity. It differs from the closely related performance arts of → cinema and → television by its requirement that the enactment be physically present to its observers, which gives it an important specificity of occasion or event. Despite its traditional close connection to the dramatic text, the play script, and the importance of both the spoken word and other auditory

effects, the theatre has generally relied strongly on visual effects, not only involving the physical bodies of the performers, but also the supplementary arts of scenic and lighting design, costume, and makeup (→ Visuals, Cognitive Processing of; Visual Representation).

As the art which most closely imitates the ongoing processes of human society and culture, theatre has been involved in the depiction of almost every aspect of these processes – religious, historical, intellectual, emotional, political. It has been utilized to express the deepest emotional and spiritual intuitions of humanity as well as the lightest and most casual passing fancies. It has served to advance new, sometimes revolutionary, ideas and also to confirm and celebrate well-established traditional ones. Its effectiveness in such matters has caused it to be the most closely watched and regulated of all the arts by civic and religious authorities.

There is a traditional distinction in English between *theatre* and *drama*, according to which drama refers to the written text that has traditionally served as the basis for theatre's live enactment. The proper relationship between the two has been a subject of controversy at least since the romantic period, when critics such as Charles Lamb (1775–1835) and Goethe (1749–1832) raised concerns that the visual power of the theatre was a potential distraction from the literary power of the written text. Modern semiotic theory has considered the play on stage a different text entirely, often referred to as the spectacle text, and controversy continues about the relative priority and autonomy of these two contiguous “texts” (→ Semiotics). The primacy of the written text, generally accepted without question for most of western theatre history, was challenged by many theorists and practitioners during the twentieth century. Toward the end of the century, performance theorists, drawing upon insights developed in the social sciences, urged that theatre study and production move away even more radically from their traditional association with drama and be considered less in relation to literature than to the human activity of performance.

## HISTORY OF THE THEATRE

### Early History

Performance exists in all cultures, but theatre in its traditional western form, as the physical embodiment of a pre-existing written text, is not nearly so widespread (→ Communication Modes: Western). Its first appearance was in classical *Greece*, in the fifth century BCE. From there it spread to Rome, disappearing with the collapse of the empire. Scholars disagree on whether some elements of this tradition remained alive through subsequent centuries, but the theatre did not reappear as a significant element in western culture until the late medieval period. From the *Renaissance* onward, however, it became one of the major art forms and cultural expressions in Europe. Shakespeare in England, Goethe and Schiller in Germany, and Racine and Molière in France are regarded not only as leading creators of the theatre and drama of those countries but also as the dominant figures in the cultural pantheon of their respective nations.

In *Asia*, with the possible exception of Japan, theatre, although widely found, has not been so central a form of cultural expression as it has been in the west, and elsewhere in the world it has generally only developed in relatively modern times, and often in close

association with nineteenth-century colonialism. Its earliest known appearance outside of Europe was in India, where Sanskrit theatre was created between the fourth and eighth centuries, but without resulting in an ongoing tradition similar to that in Europe. Toward the end of this period, theatre was also recorded in China, possibly inspired by that of India, and from China it spread into Korea and Japan. The classical Japanese theatre, Noh, did not appear until the fourteenth century, and the more popular Kabuki not until three hundred years later.

### **From the Renaissance to the Eighteenth Century**

During the Renaissance the theatre, broadly based in classical and medieval times, began to be fragmented into different forms for different levels of society. For the general populace, theatre had a close association to the *entertainment tradition* of the wandering performers of the Middle Ages, and was composed of such offerings as folk farces and the beginning of the *commedia dell'arte* – a highly popular form of largely improvised comedy built around stock characters, some wearing traditional masks. Although these sometimes offered rather elaborate visual spectacle, they were for the most part quite simple, since the resources of the companies were small and the ease of travel important.

The situation was quite different in the theatre fare being developed by the *aristocracy* – court entertainments employing music, dance, and lavish spectacle, partially for entertainment but primarily as a display of the sponsor's wealth and power. Not surprisingly, the *opera*, traditionally the dramatic form most associated not only with music but also with visual display, has been for much of its history also primarily an aristocratic entertainment. The art of scenic design developed rapidly with this encouragement, and some of the leading artists of the Renaissance and the subsequent *baroque period* did some of their most virtuosic work for theatrical production. New developments in painting, most notably the discovery and application of perspective, moved quickly from the painter's canvas to the stage (→ Perspective, Pictorial). Although magnificent entertainments were sometimes held in public spaces for a dazzled populace, the most common location was in elaborately decorated private theatres constructed within princely residences, and open only to their guests.

By the end of the sixteenth century, the popular street theatres and the aristocratic private theatres were supplemented in several parts of Europe by the *first permanent commercial theatres*, catering to a range of social classes, but tending to draw the major part of their audience from the emerging bourgeois population of merchants and tradespeople. These theatres took a variety of forms – structures open to the air in Spain and England, interior spaces more like the standard theatres of later centuries in France. Despite their commercial orientation, these theatres often sought the patronage of some powerful aristocrat, even the king, partly for financial support, but equally importantly for protection from civic or religious authorities, who often regarded these popular gathering places as potential sites of disorder and immorality.

The company protected by the king in Paris enjoyed another major benefit, a monopoly on theatrical activity in that city. During the seventeenth century this protection was codified into the establishment of an official national theatre, the

*Comédie-Française*. During this and the next century, France served as a cultural and political model for much of Europe, and the idea of national theatres spread rapidly.

### From the Eighteenth Century to the Present

During the eighteenth century the monopolies supposedly held by many of the national theatres eroded, and the arrangement more typical of the nineteenth century began to appear. The most lavish, and usually best-situated, theatre of the city was the *opera house*, sometimes supported by the state, sometimes by private funds, but as significant culturally as a place for the upper classes to gather and display themselves as for any artistic function. Major theatres other than the opera houses were particularly favored by the growing middle-class audiences, while the lower classes, if they attended theatre at all, favored the more accessible, more congenial, and less expensive music halls, melodrama houses, and similar entertainments.

During the course of the nineteenth century a fairly consistent repertoire and public came to be associated with each particular theatre or theatres – opera and ballet, comic opera, classic revivals, new serious and comic works, and the great variety of popular forms such as melodrama, vaudeville, minstrelsy, and burletta. Although visual spectacle was most obvious at the two ends of the theatre's social spectrum – in the aristocratic opera and ballet, and in the popular melodrama and burletta – an increasing interest in historical detail and advances in technology affected every theatre of this period. The early nineteenth century even saw a vogue for theatres like the dioramas and panoramas devoted entirely to visual spectacle, involving little or no text (→ Spectacle).

This relatively stable range of theatrical organizations was disrupted toward the end of the nineteenth century when a generation of major experimental dramatists, led by Ibsen and Strindberg, introduced a kind of drama that the system could not readily accommodate, being not well enough established for the national theatres, and too radical in form and content for either the middle- or lower-class commercial theatres, where it faced the double enemy of censorship and audience incomprehension or hostility.

To solve this problem, a new sort of theatre appeared, which became central to the theatrical culture of the next century. This was the *experimental or art theatre*, and in a century where art was dominated by the ideas of innovation and the avant-garde, this sort of theatre became the favored site for the launching of innovative works or whole new movements (→ Art as Communication). Sometimes such theatres were created as annexes of national theatres, but more often they have been independent ventures, frequently located in sections of cities associated with artistic and bohemian culture.

### SOCIETAL POSITION OF THE THEATRE

Theatre is traditionally an urban art, often highly *centralized*. In some countries, most notably in England and France, the capital city has dominated national theatre since the Renaissance and in those countries a major effort was made in the late twentieth century to decentralize the theatre. Germany and Italy, probably because of the relatively late political unification, both entered the modern era with a decentralized theatre system already in place. The United States has not followed the theatrical organizational model

of any European country. Except for the brief experiment of the Federal Theatre in the 1930s, American theatre has received little official government recognition or support, and a national theatre in the European style has been often proposed, but has never appeared. This, along with the great size of the country, has worked as a counterforce to the concentration of theatre activity in any one city, despite the continuing dominance, for much of American theatre history, of New York City. Community theatres, regional theatres, and university theatres make up a significant part of this country's theatrical culture.

The arrival of the cinema and subsequently of television and of digital technology has offered major *challenges to the theatre*, especially in one of its most important traditional roles, as popular entertainment. A similar major challenge had previously appeared in the late nineteenth century with the rise of the novel, and then, as now, doubts were expressed about the future of theatre. Despite their popularity, however, these newer arts lack the essential element of the theatre experience – its physical presence. The power of the relationship between living spectator and living performer has proven so durable across many cultures and many historical periods that theater in some form seems likely to remain an important element in the expression and transmission of human culture.

This does not mean, however, that the theatre has remained resistant to the possibilities of the new media. On the contrary, those types of theatre that have traditionally been strongly interested in visual display, the opera and the musical theatre on one hand, and many parts of the wide spectrum of experimental performance on the other, have in recent years made the innovative blending of live action with video, film, and digital technology one of the most exciting areas of contemporary theatrical production (→ Digital Imagery). The new technologies, far from replacing the theatre, have, like the coming of modern mechanics and electricity, provided inspiration for a new generation of theatre artists to develop the theatre's expressive potential in ways that these new tools now make possible.

## Third-Person Effects

*Hans-Bernd Brosius*

*Ludwig Maximilian University of Munich*

*Inga Huck*

*Ludwig Maximilian University of Munich*

The third-person effect was introduced into communication research by W. Phillips Davison in 1983. The term conceptualizes his impression that people overestimate the impact that mass media content has on others – so-called “third persons”:

In its broadest formulation, this hypothesis predicts that people will tend to overestimate the influence that mass communications have on the attitudes and behavior of others. (Davison 1983, 3)

People not only overestimate media impact on others, but they also deny that the mass media have an impact on themselves. This does not mean that media are actually more influential on others than on oneself, or even that the media are influential at all. The crucial point is the difference in the perceived or presumed media effect on others and on oneself (→ Media Effects; Media Effects, Strength of). The third-person effect is a purely perceptual phenomenon (→ Media and Perceptions of Reality; Social Perception). It is sometimes also called third-person perception.

### **CONCEPTUAL ADDITIONS**

Davison's basic assumption has already been confirmed by a series of more than 100 empirical studies. Only two studies failed to do so (→ Perceived Reality: Meta-Analyses). Although the idea initially seemed to be quite simple, its empirical study led to further questions, such as (1) how general the phenomenon is, (2) what conditions increase or decrease the size of the it, and (3) what psychological or cognitive phenomena might cause it.

#### **Perceptual and Behavioral Components**

In addition to the already mentioned perceptual component, the third-person effect includes a behavioral component. According to Davison (1983, 3) the behavioral component asserts that the difference between self-perception and the perception of others may also have consequences for affected persons' behavior, particularly of those in a leading position:

the impact that they expect this communication to have on others may lead them to take some action. Any effect that the communication achieves may thus be due not to the reaction of the ostensible audience but rather to the behavior of those who anticipate, or think they perceive, some reaction on the part of others.

For example, a politician, from his or her point of view, may overestimate the influence of a negatively biased media report and, as a consequence, decide to retire, although the actual response on the negative report may have been marginal. The following research overview will show to what extent both components of the third-person effect have been confirmed empirically.

#### **The Reverse Third-Person Effect**

When asking about the perceived impact of mass media on others and on oneself in general, the third-person effect turns out to be quite robust. However, under certain conditions the respondent's self-perception and perception of others are identical. Sometimes the effect of the mass media on oneself is even estimated as being higher than the effect on others. This is referred to in the literature as the "reverse" third-person effect

or as the “first-person effect.” A reversal of the presumed media influence often can be observed in combination with media content that apparently has a positive impact on recipients. While, for instance, cigarette ads produce a third-person effect, anti-smoking campaigns produce a reverse third-person effect; that is to say, people will assume they will be affected more than others. It obviously depends on the (lack of) desirability of being influenced by a specific media content whether a third-person effect or a reverse third-person effect is found.

## **STUDIES ON THE THIRD-PERSON EFFECT**

We found more than 100 empirical studies in our recent literature review of all articles related to the third-person effect in international communication journals (Quiring et al. 2007). The perceptual component of the third-person effect has been examined on a very broad basis since it was first identified by Davison (1983). In addition, there are numerous unpublished conference papers and theses. Particularly since the early 1990s, a number of communication scientists, social psychologists, and pollsters have engaged in third-person effect research. Besides moderator variables and causes of the third-person effect, the possible consequences of such perceptions, particularly the behavioral component, have moved more and more into the center of attention (Perloff 1999, 355 f.).

### **Third-Person Effects and the Type of Media Message**

The perceived influence of mass media has been addressed within various thematic contexts. Some of the authors studying third-person effects concentrated on effects of print or television advertisements, among them political ads, ads presenting common consumer goods or luxury articles, and public service announcements (→ Advertising; Advertising Effectiveness; Political Advertising). Other studies referred to the presumed negative impact of violent or pornographic media content (→ Violence as Media Content, Effects of; Sex and Pornography as Media Content, Effects of). Some others have surveyed the perception of media influence in general or have used real media contents, such as special TV shows, as stimuli. Most of the authors limit their examination to a certain kind of mass media. Nevertheless, seen as a whole, all common mass media genres – including the Internet and even rap music – have been covered. Apart from this thematic diversity, the studies can also be differentiated according to whether the researchers manipulated the crucial media message and whether they did or did not present this media content to the participants.

### **Results on the Perceptual Component of the Third-Person Effect**

#### *The Third-Person Effect: An Artifact?*

In most of the early investigations, → survey instruments placed the question concerning others’ perceptions first, immediately followed by the question concerning self-perception. The notion that the order of questions (primacy or recency) could be responsible for the occurrence of the third-person effect inspired some authors to include the question sequence as an experimental factor. However, the results of these studies

proved that the third-person effect occurred independently of the sequence of questions. Another possibility also was considered: the third-person effect may have been produced because questions concerning self-perception and others' perception were asked in one and the same questionnaire. To test this possibility, a number of respondents were asked to state only their first-person or their third-person perception (David et al. 2004). However, the difference in perception was still observable on the aggregate level. These results indicate that the third-person effect is indeed based on perceptual differences between self and others.

#### *Distance and Perceived Others' Attributes*

As well as the third-person effect in general, the following specific relationship can be taken for granted: when being asked to estimate media effects on others, the more distant or different these others are from oneself, the larger the third-person effect becomes. In particular, the third-person effect is smaller when "others" are described as "neighbors" compared to the description "people in one's country." This distance to others has been specifically varied in the questionnaire by many authors. Apart from social distance, psychological, geographical, and political distance were considered. In most of the studies, the researchers themselves pre-determined the scope of distance. Nevertheless, an increasing perceived distance has also led to larger differences between self-perception and perception of others. The third-person effect also is influenced by the perceived intensity of the third person's exposure to the related media message. For example, respondents who ascribe to others frequent contact with violent or misogynistic songs assume that those others are more strongly influenced. Likewise, if others are perceived to have a lower standard of education than oneself, the third-person effect becomes larger. This observation could possibly be explained by the perception of a sizable cognitive distance between self and others.

#### *Desirability of the Effects*

When media effects are described as positive and personally or socially desirable, the third-person effect not only decreases in size, but it can also develop into a reverse third-person effect. In this regard, desirable media effects are often found in connection with public service announcements such as those against drinking and driving, for the use of seatbelts, etc. The desirability of media effects has been manipulated in (quasi-)experimental designs through the choice of specific media contents or question wording. When, for instance, media influences are not referred to as "being influenced" (undesirable) in the questionnaire but as "being stimulated" (desirable), the third-person effect decreases. Usually, the desirability of effects is postulated in advance by researchers of the third-person effect. But the described interrelation also is evident when the respondents make their own statements on the desirability of media effects.

#### *The Respondents' Attributes and Demographics*

Davison (1983, 9) assumed that the respondent's perceived own knowledge on a relevant topic could play a role in third-person effect research. This assumption has been confirmed by various analyses: people who consider themselves knowledgeable on a certain issue feel invulnerable in regard to media reporting on this issue, resulting in a higher third-person

effect. However, the moderating effect of (political) knowledge is related to the subjective estimation of one's own knowledge. When actual issue knowledge is measured, the relationship disappears. Besides perceived knowledge, age, high education, and low media usage lead to a greater third-person effect.

### **Results on the Behavioral Component of the Third-Person Effect**

Relatively few studies have focused on the behavioral consequences of the perceived difference between oneself and others. Although the relationship between either self-perception or perception of others on the one hand and behavioral intentions on the other has been addressed and analyzed rather often, the behavioral consequences of the third-person effect have only been examined in 25 of the studies at hand. These studies have three main weaknesses. First, the results are not quite consistent: 15 studies confirmed the direct influence of the third-person effect on the respondents' behavior; 10 failed to do so. Unfortunately, examination of these studies' parameters did not help to identify specific conditions that might explain the occurrence or absence of behavioral consequences of the third-person effect. Second, the explanatory power of these results is very limited: rather than real behavior, behavioral intentions are addressed, mostly the disposition to regulate or censor apparent negative media content (→ Censorship). Third, intervening variables concerning the behavioral component have rarely been investigated.

### **THEORETICAL EXPLANATION OF THE THIRD-PERSON EFFECT**

Despite the stability of the phenomenon and its comparatively simple testing procedure, it is still relatively unclear what causes might underlie the third-person effect. Various explanatory models have already been discussed without finding a plausible and empirically confirmed theory of the origin and classification of the effect.

#### **Optimistic Bias**

The concept of optimistic bias (also known as "unrealistic optimism" or "biased optimism"; → Social Perception: Unrealistic Optimism) describes how people have a more positive picture of themselves than of others. Among other implications, this is manifested in a distorted expectation for the future: while people attribute negative experiences like diseases, accidents, or unemployment to others more often than to themselves, they think they will more likely have positive experiences; they face the future with optimism (Weinstein 1980). The structural affinity to the third-person effect is obvious. Both phenomena are based upon a difference between self-perception and perception of others. Considering that media impact in general is perceived to be negative and therefore ascribed to others rather than to oneself, one could regard the third-person effect as a special case of optimistic bias. This means that the connection between the concepts consists in the desirability of being influenced by mass media. As mentioned above, lesser socially or personally desirable media content leads to a greater third-person effect. Admitting that such messages have an impact on oneself means a loss of one's own autonomy in thinking and acting. As a consequence, one can classify them as a danger or

risk. Such a “threat” by the media can be regarded as a negative event in terms of the optimistic bias hypothesis. The optimistic bias hypothesis could offer an explanation for people assuming greater effects on others than on themselves. However, this connection has so far not been confirmed empirically. Actually, a recent study shows a zero correlation between third-person effect and optimistic bias (Quiring et al. 2007).

### **Self-Enhancement**

Explaining the third-person effect through people’s tendency toward self-enhancement also pertains to the desirability of media contents. The concept claims that people sustain and communicate a picture of themselves that is as positive as possible (→ Impression Management; Self-Presentation). A positive picture of oneself corresponds with assessing oneself as immune to undesired media effects but as open toward (socially) desirable effects. The results of experimental studies seem to support this assumption: lower self-esteem and missing opportunities for self-affirmation lead to a larger third-person effect.

### **Impersonal Impact**

According to Tyler and Cook (1984), human judgments can be based on a societal level and on a personal level. Judgments on a societal level are formed relying on interpersonal communication or information transmitted by the mass media, particularly when the object of judgment is beyond personal experiences. Personal judgments, on the other hand, are based on primary experiences. Discrepancies can occur between the two judgment levels when thinking about the same problem: while people are prone to think they will never suffer from cancer themselves, they may think this event is very probable for others (→ Social Perception: Impersonal Impact). Recalling different background information when forming personal and societal judgments may be responsible for the third-person effect. It appears that mass media are credited with having great impact on the societal level, while the individual denies that the media have any influence on him or her. To support the explanation of the third-person effect by means of the impersonal impact, one can refer to the results on the third persons’ distance, which moderates the discrepancy between perceived media effects on oneself and others. The more distant those others are from oneself, the more likely it is that judgments are built on the societal level.

### **Hostile Media Phenomenon**

The → hostile media phenomenon describes a generalized negative attitude toward mass media (Vallone et al. 1985). People believe that media reports are biased against their own opinion, even if content analyses failed to show any bias at all. The authors found that pro-Israeli and pro-Palestinian students both believed that mass media reported against their own position. It was also observed that the respondents expected such media reports to have a great impact on other recipients, who were formerly neutral regarding the specific conflict. They could be convinced of the subjectively wrong side by the “hostile” media. It can thus be expected that respondents’ third-person effect becomes larger, the

more they accuse the mass media of being biased. Again, this connection has not been sufficiently confirmed empirically.

### **Attribution Theory**

Attribution theory has also been considered as a potential explanation of the third-person effect in some studies. This theory refers to the fact that people always seek to rationalize *ex post* their own and others' behavior by looking for causes. In doing so, people trace back their own (undesirable) actions to the particular situation or to the circumstances. In contrast, the behavior of others is often associated with stable personality traits. The tendency to underestimate situation-based influences (external factors) on the behavior of others and to overestimate their personal characteristics (internal factors) is also known as the "fundamental attribution error" (→ Attribution Processes). Relating this fallacy to the third-person effect would mean that – for oneself – one considers factors that may lessen the influence of a media message (such as the appearance and the credibility of the communicator, as well as the specific usage situation). The impact on others, on the other hand, is solely deduced from their exposure to the message. This causes the personal view that one is less vulnerable than others to those contents.

### **THE EFFECTS OF PRESUMED MEDIA EFFECTS**

Not reality itself, but rather its perception and interpretation determine how people act. This simple principle can be very well applied to the third-person effect and is generally known as the Thomas theorem: "If men define situations as real, they are real in their consequences" (Thomas & Thomas 1928, 572). For human behavior, it is thus not so important how much we or others are actually influenced by the mass media; more important is how much we (collectively) believe we are affected by the media. This appraisal may well affect real behavior, or at least behavioral intentions. This provides a subject for study: one may analyze under what conditions and in what areas (other than the much-researched area of censorship of media contents) the third-person effect encourages or prevents certain actions. For instance, the installation of monitoring cameras in public places could be endorsed if one presumes that media violence exerts much more negative influence on one's fellow humans than on oneself. Another example would be over-purchasing a certain food under the assumption that it might possibly become scarce just because of a negative media report and its presumed influence on others. There is probably a great number of similar possible connections between the third-person effect and societal or political behavior. Further third-person effect research should concentrate on situations in which the perceptual phenomenon gains behavioral relevance.

## **Time-Series Analysis**

*Bertram Scheufele*

*University of Jena*

Time-series analysis is a statistical procedure for describing the characteristics of one time series (e.g., a trend) or predicting the future development of one time series (forecasting), but it can also be used to analyze the impact of an event on a single time series (intervention analysis) and to analyze the correlations between two or more different time series (cross-correlations, transfer-function analysis). The first two applications are usually called the univariate perspective of time-series analysis; the second two are known as the multivariate perspective of time-series analysis.

### **TYPES OF TIME-SERIES ANALYSIS**

The univariate perspective can be compared to descriptive statistical analyses of one variable and its values for all elements of a sample distribution (→ Statistics, Descriptive). Yet with time-series analysis the values of a certain variable are organized consecutively, i.e., in a time order. For example, one can ask 365 people ( $n = 365$ ) about the time they spend watching television and get one value for each person, i.e., 365 different values

altogether. Or one can ask just one person about the time he or she spends watching television on 365 consecutive days ( $t = 365$ ). Again, one gets 365 values, but these are in a sequence and refer to one person ( $n = 1$ ). The multivariate perspective of time-series analysis can be compared to calculating correlations – with two variables – or to regression analysis – with more than two variables – as known from descriptive statistics. Yet in time-series analysis all variables are time series. So, a correlation refers to a first sequence of values of variable  $X_t$  being temporally related to a second sequence of values of variable  $Z_t$ .

Besides this classification according to statistical procedures, time-series analysis has to be categorized according to designs and methods. With respect to design, time-series analysis can be described as a special form of longitudinal design ( $\rightarrow$  Longitudinal Analysis). As in the television-viewing example, asking 365 persons at one point of time would be a cross-sectional study. But when asking one person on 365 consecutive days, one measures longitudinally. With respect to methods, a time series can be obtained by applying a  $\rightarrow$  survey, a content analysis ( $\rightarrow$  Content Analysis, Quantitative), or an  $\rightarrow$  observation. This can be illustrated by some examples, which also help to explain the term “time series” and related concepts. Data in a time series are ordered sequentially. For instance, one can conduct a content analysis and count the number of newspaper articles about foreign affairs on each day. If there is one article on the first day ( $t_1; z_1 = 1$ ), three on the second ( $t_2; z_2 = 3$ ), four on the third ( $t_3; z_3 = 4$ ), and two on the fourth ( $t_4; z_4 = 2$ ), one obtains the time series “daily number of articles on foreign affairs,” which has the value sequence  $\{1, 3, 4, 2, \dots\}$ . This time series  $Z_t = \{z_1, z_2, z_3, \dots, z_n\}$  measures or represents daily values of the variable  $Z$ . If the time span between the observations is longer – say, a month – then one obtains a monthly time series. The span between points of time is called the time lag. The time span, e.g., between  $t_1$  and  $t_1$  is lag 0, while the time span, e.g., between  $t_4$  and  $t_5$  is lag +1 and that between  $t_{18}$  and  $t_{17}$  is lag –1. The length of a time series is represented by the number of data points, i.e., time points. If one asks a person  $Z$  on 100 consecutive days about his or her media use, for instance, the daily time series “media use of person  $Z$ ” has length  $T = 100$ , so the time series  $Z_t$  has 100 data points.

### ARIMA MODELS IN UNIVARIATE TIME-SERIES ANALYSIS

In social sciences, both describing and forecasting a singular time series usually refer to so-called ARIMA models, introduced by George E. Box and Gwilym M. Jenkins. Thus, this type of time-series analysis is also called the Box–Jenkins method. The term ARIMA stands for three different stochastic processes: AR is the abbreviation for autoregressive processes, I for integrated processes, and MA for moving-average processes. Other processes, such as the Wiener process or Markov chains, are not included in the Box–Jenkins method since most time series in social sciences can be described by autoregressive, integrated, and moving-average processes or models quite sufficiently.

The idea of *describing* a time series with an ARIMA model can be illustrated by the example of a single person’s emotional state. Person  $Z$  may be in a good mood on some days and in a bad mood on others. Thus, his or her emotional state develops in the form of a daily time series  $Z_t$ . It is quite likely that the moods on consecutive days are not totally independent of each other. For instance, person  $Z$ ’s mood on a current day ( $t_0$ ) may depend on his or her mood yesterday ( $t_{-1}$ ). In this case, one would say that the time series

$Z_t$  is autocorrelated with a first-order autoregression (AR = 1). If not only  $Z_{t-1}$  has an impact on the present-day mood, but also the moods from the day before yesterday ( $Z_{t-2}$ ), then there is also a second-order autoregressive element (AR = 2) in the time series  $Z_t$ . A model for this time series would be denoted by ARIMA (2,0,0). Autoregressions can be compared to conventional  $\rightarrow$  regression analysis. The only difference is that in time-series analysis the predictor is not another variable  $Z$  but the time series itself in a so-called lagged form. For instance, one predictor for  $Z_t$  may be  $Z_{t-1}$ , another predictor may be  $Z_{t-2}$ , and so on. In terms of the above-mentioned example, the current mood of person  $Z$  ( $Z_t$ ) can be explained by his or her mood on previous days ( $Z_{t-n}$ ).

If there were one integrated element in a time series, the shortcut would be ARIMA (0,1,0). This model can mostly be considered the logical equivalent to an autoregressive model. Next to autoregressive and integrated elements, an empirical time series can have moving-average characteristics, which can be described by MA models. With the example of a person's mood development, moving averages represent random influences on a time series. For instance, a current mood may be due to some event that cannot be predicted. The sequence of such random events is called white noise, which is a special form of a random walk and is denoted by  $a_t$ . But not just current random events, but also random events from yesterday – written as  $a_{t-1}$  – can have an impact on a time series  $Z_t$ . This is called a first-order moving average (MA = 1). With a delay of more than one lag (e.g., lag -2), one obtains a second-order moving average (MA = 2). The models for these two random impacts are abbreviated using ARIMA (0,0,1) and ARIMA (0,0,2). The crucial difference between autoregressive elements and moving-average elements in an empirical time series is the quality of the past impact. Autoregression stands for the impact of past values  $Z_{t-1}$  or  $Z_{t-2} \dots Z_{t-n}$  while moving average represents the impact of past random events  $a_{t-1}$  or  $a_{t-2} \dots a_{t-n}$ .

Times series in social sciences can be described by these three models of stochastic processes. This is comparable to regression analysis. A regression model or regression line is a model of the correlation of two variables  $X$  and  $Y$ . Similarly, a stochastic process, e.g., an autoregressive process, can be conceived as a model for the inherent momentum of an empirical time series  $Z_t$ . Usually a time series  $Z_t$  has elements or characteristics of not just one, but two or three, of these stochastic processes. For instance, a time series  $Z_t$  that can be described by an ARIMA (1,0,1) model has characteristics of a first-order autoregressive as well as of a first-order moving average process.

The general form of an ARIMA model is written as ARIMA ( $p, d, q$ ), where  $p$ ,  $d$ , and  $q$  represent the order, i.e., number of autoregressive, integrated, and moving-average elements of the empirical time series. After having described an empirical time series by an ARIMA model, one obtains the residuals  $a_t$ . As in regression analysis, the residuals should be kept to a minimum. The equation  $a_t = Z_t - \text{ARIMA}(p, d, q)$  expresses the fact that the empirical observations – the time series – and the expected values – the ARIMA model for the time series – should match “perfectly” in the sense of residuals being a random walk, i.e., a white noise process. In other words, the residuals  $a_t$  should be a sequence of totally uncorrelated random events.

Describing a time series by an ARIMA model is quite similar to the second form of univariate time-series analysis, namely *forecasting*. Here, the empirical values of a time series are used for predicting future, but yet unknown values of the time series. One

application may be the prediction of unemployment. Both ARIMA modeling and forecasting afford a time series length of at least 30 data points – the more, the better. And in both cases one should also look out for seasonal components. For instance, unemployment time series often have spring or winter peaks, which can be described by seasonal ARIMA models.

## MULTIVARIATE METHODS

Among the multivariate methods in time-series analysis, are intervention analysis, cross-correlation, and transfer-function analysis. In *intervention analysis*, one examines the impact of an event on a singular time series  $Z_t$ . For instance, September 11 certainly had an impact on the amount of articles about terrorism, which can be modeled as a time series. Following the attacks, coverage on terrorism increased tremendously and was constantly on a higher level than before. In intervention analysis the event itself is modeled like a time series ( $I_t$ ), but in the form of a dummy code. For instance, 0 (“no event”) is assigned to all data points before the event and 1 (“event”) is assigned to all other data points. Then a correlation is calculated for the event series  $I_t$  (e.g., September 11) and the time series  $Z_t$  (e.g., number of articles on terrorism).

In *cross-correlation*, one does not examine the impact of an event, but the influence, e.g., of an assumed independent time series  $X_t$  on an assumed dependent time series  $Z_t$ . In the first step, one usually estimates the ARIMA model for each time series separately. In the second step, one calculates so-called cross-correlations for the residuals obtained by the first step. Cross-correlations can be compared to conventional correlations ( $\rightarrow$  Correlation Analysis). Yet one does not only calculate “synchronous” correlations between the two time series residuals (lag 0), but also “diachronous” correlations (lag  $\pm 1$ ,  $\pm 2 \dots$ ). This requires three steps. First, one correlates the residuals of  $Z_t$  with the lagged residuals of  $X_t$ , i.e., with  $X_{t-1}$ ,  $X_{t-2}$ , and so on. Second, one correlates the residuals of  $X_t$  with the lagged residuals of  $Z_t$ , i.e., with  $Z_{t-1}$ ,  $Z_{t-2}$ , and so on. Finally, one calculates synchronous correlations. With this procedure one detects the causal logic between  $X_t$  and  $Z_t$ . A significant correlation between  $X_{t-2}$  and  $Z_t$ , for instance, indicates that  $Z_t$  is certainly not the predictor of  $X_t$ , but  $X_t$  is likely to be the predictor of  $Z_t$ . Furthermore, one can see that this impact has a delay of two lags (e.g., of two days).

In *transfer-function analysis*, not just one time series ( $X_t$ ), but several time series (e.g.,  $X_p$ ,  $Y_t$ ) serve as predictors for an assumed dependent time series ( $Z_t$ ). Here, an overall model represents the causal logic and time relations between all variables (e.g.,  $X_p$ ,  $Y_t$ , and  $Z_t$ ). Thus, a transfer-function analysis resembles a multiple regression analysis in many ways.

## Time Warner Inc.

*Mara Einstein*

*City University of New York*

Time Warner is the world's leading multimedia conglomerate (→ Media Conglomerates), with operations in filmed entertainment, broadcast and → cable television, → Internet services and print media. The company generated more than \$43 billion in revenues in 2005.

Time Warner was built through a series of → mergers over more than 80 years. Time, Inc. began in 1922 as a publishing company for *Time* magazine, which first appeared in 1923 (→ News Magazine, History of). Over the years, the company would create additional titles such as *Fortune*, *Life*, *Sports Illustrated*, and *Money* magazines. In 1965, Time entered the cable distribution business; it launched Home Box Office (HBO), a premium cable program network, in 1972 (→ United States of America: Media System).

Warner Brothers, a producer of filmed entertainment, was founded in 1923. It was home to the first talking picture, *The Jazz Singer*, and the production home for the animation studio Looney Tunes. Warner Bros also became a major producer of recorded music, with Atlantic Records, Elektra Records, and Reprise Records among its many labels (→ Music Industry). As → television became popular in American homes, Warner Bros began producing programming for this medium, and it remains one of the leading producers of broadcast prime time as well as syndicated programming. Warner Bros entered the cable television business in 1973.

In 1989, Time merged with Warner Communications and the combined company was renamed Time Warner in 1990. This merger created the first vertically integrated media behemoth, mixing the publishing and cable system expertise of Time with the filmed entertainment – both motion picture and television – and cable networks of Warner Communications. The company continued to create new magazines and cable networks after the merger, but achieved its most significant growth in 1996 when it acquired the Turner Broadcasting System, home of several major cable networks, including → CNN.

Taking the industry by surprise, America On Line (AOL) and Time Warner announced merger plans in 2000, with AOL being the lead company. This merger was proclaimed by some to be the death knell for traditional media. Another bellwether of the decline in

traditional media came when AOL Time Warner sold off the Warner Music division in 2003. However, the changing fortunes of the Internet space, and AOL in particular, were evident as early as that same year, when the company removed AOL from its moniker and became simply Time Warner.

As of 2007, Time Warner had five broad product areas: filmed entertainment, television networks, cable systems, interactive services, and publishing. These were contained within seven umbrella corporate brands: AOL, HBO, New Line Cinema, Time Inc., Time Warner Cable, Turner Broadcasting System, and Warner Bros Entertainment.

Filmed entertainment included the production and distribution of theatrical motion pictures (→ Cinema), television shows, and animated programming, as well as the distribution of syndicated television properties. Warner Bros Entertainment Group included, among many other companies, Warner Bros Pictures, Warner Bros Television Group, Warner Bros Animation (Looney Tunes and Hanna-Barbera), and the CW Network. New Line, made up of New Line Cinema and Fine Line Features, was the corporation's independent production and distribution arm. Both of these divisions produced and distributed motion pictures as well as television programming, for both major networks and cable outlets. Prime-time programming included *Without a Trace* and *Smallville*, while syndicated hits included *Friends*, *The Ellen Degeneres Show*, and *The Tyra Banks Show*. Movie hits from 2005 included *Harry Potter and the Goblet of Fire*, *Charlie and the Chocolate Factory*, and *Batman Begins*. Releases for 2006 were less successful and included box office bombs *Poseidon* and *Ant Bully*.

The network area included broadcast, basic cable, and premium cable services. It was made up of the Turner Broadcasting System, HBO, and the CW Network. Turner Broadcasting consisted of cable networks including CNN and Headline News, TBS, TNT, Turner Classic Movies (TCM), and the Cartoon Network. Most of these had international counterparts, such as Cartoon Network Latin America and TCM Europe. HBO was the most widely distributed pay-cable service and had approximately 40 million subscribers in the US. Originally created as a purveyor of commercial-free movies, HBO became a leader in prime-time television programming, with shows such as *Sex and the City*, *The Sopranos*, and *The Wire*, which also became successful syndicated products. Cinemax, a second-tier movie channel, was also part of HBO. The CW was a 50–50 joint venture with CBS. This network was launched in late 2006 with a combination of programming from the former UPN and the WB networks.

Time Warner Cable was the second largest US cable provider in the United States behind Comcast. Time Warner served more than 13 million subscribers in 2007 (National Cable and Telecommunications Association). The company had 7 million digital subscribers, and 6.4 million received high-speed Internet access through the company. While the company began to roll out digital phone service, this made no rapid inroads as a significant business. In addition to providing cable service, Time Warner operated 24-hour local news channels in New York, North Carolina, and Texas (→ Newscast, 24-Hour).

AOL was the largest Internet access provider in the United States with more than 19 million subscribers, down from 30 million in 2001 (Holahan 2006). According to the company's website, AOL planned to reposition itself as a global web services company in response to consumers choosing broadband services over AOL's dial-up service. To that end, the company would offer AOL mail and AOL software to anyone with broadband

access. The intention was to take advantage of the continuing growth in online advertising. Other changes included providing innovative programming such as *Gold Rush!* – a 7-week interactive event produced in conjunction with Mark Burnett Productions. In addition to AOL, the company owned a number of well-known online properties including MapQuest, Moviefone and TMZ.com, an entertainment industry insider site which Time Warner planned to turn into a syndicated television program.

Time, Inc. was the leading publisher of consumer magazines and home to more than 150 titles worldwide. *Time*, *People*, *Sports Illustrated*, *Entertainment Weekly*, *In Style*, *Fortune*, *Money*, and *Cooking Light* were just some of the brand names published by this company.

According to Hoover's, Time Warner had surmounted the debacle of the merger with AOL. While AOL subscriptions declined, the company's restructuring and the divestiture of the music and book businesses appeared to have created a more focused institution.

## **Tourism Industry**

*Kevin Meethan*

*University of Plymouth*

The term “tourism industry” covers a wide range of services, activities, and commodities, bound together in a complex network of relationships that involves the temporary migration of people for leisure purposes. There has always been an element of the global within tourism. Since the first worldwide figures were gathered in the early 1950s, tourism has continued to grow year on year. In common with many other forms of economic activity, the increasing reach and spread of tourism has gathered pace since the 1990s to the extent that it is now firmly embedded as an established and important sector in many economies of the world, and consequently has had considerable socio-economic and cultural impacts on localities.

One of the basic building blocks of → modernity was the nation-state, which by and large framed a distinct economic and social realm that defined a particular way of life, a distinct cultural constellation. Under the present conditions of globalization (→ Globalization Theories), where money, commodities, and people move more rapidly than they have ever done before, economic and cultural relations are being reordered. Among other elements, globalization involves increasing connectivity both horizontally, across space, and vertically, within local economic and cultural realms. As a consequence both economic and cultural boundaries are more permeable and fluid than they have been in the recent past, to the extent that parts of the third world have been brought into the economic core, while at the same time segments of the first world, such as redundant industrial areas, have been relegated to peripheral status. Tourism also exemplifies these developments, since it involves the global flow of people to specific tourist locales, and the embedding of global economic networks in those locales, as well as offering the opportunity for regions and localities to remake themselves as arenas of consumption.

### **ECONOMIC SPECIFICS OF TOURISM**

Tourism is, however, *distinct from other forms of production and consumption* in a number of significant ways. First, the tourist destination is conceptually and spatially marked as distinct from the realm of work and home. Second, this distinction itself relies on the commodification of place, people, and culture, which together create sites of leisure consumption, or tourist space. As a tourist, one becomes involved, even if only superficially, in the worlds and lives of others. Third, linked as it is to specificity of place, the tourist product itself is not movable. It is people rather than goods that are imported and exported. As a tourist one is mobile and transient, and engages in the conspicuous consumption of time and in some cases hedonistic excess. Fourth, tourism also cuts across a number of sectoral boundaries, as it involves a bundle of services and commodities, such as insurance and currency exchange, transportation, accommodation, food, and entertainment. The purchase and consumption of these goods and services can be seen as a circuit that runs from point of origin via mode of transit to the destination, then a return to the point of origin. Both the production chains and the consumption of goods and services involved in tourism are cyclical and also spread across space and time.

The *differentiation between work and leisure spaces* can be seen as a consequence of modernity, in which the dominant Fordist mode of mass production was matched by a Fordist mode of mass leisure consumption. While today's form of tourism has changed, the basic pattern outlined above was originally established with the development of modernity and urban industrialization in the mid-to-late nineteenth century, with the creation of resorts that tended to cater for national markets. Tourism was also seasonal, peaking in the summer months and almost nonexistent at other times of the year. In the latter part of the twentieth century, the advent of mass air travel gave rise to charter flight tourism and the creation of mass resorts in places such as the Mediterranean and the Caribbean, which catered respectively for European and North American markets, and thus saw the growing internationalization of mass tourism.

However, Fordist production and consumption has been eroded and partly replaced by a shift into post-Fordist modes of niche consumption and a consequent *diversification of*

*tourism*. In part this is a consequence of the reordering of global economic relations with the near-universal adoption of deregulated markets and neo-liberal economic policies. As many cities and regions in the developed economies began to lose their traditional industrial base, there was a need to find alternative forms of employment. One of the ways in which this was achieved was the revaluation and regeneration of urban space. This not only encouraged inward investment, but also opened up opportunities for new forms of tourism such as the short city break and leisure shopping. As a consequence, the distinction which had previously existed between work and leisure spaces was replaced by more complex and diverse patterns.

### THE GLOBALIZATION OF TOURISM

Parallel to such changes in the developed economies was the globalization of tourism. The increase in long-haul flights in the latter part of the twentieth century meant that tourism began to expand beyond the confines of the developed states and regions, especially in South-East Asia, although the trajectory of resort development was somewhat different to that in the west. Unlike other forms of development, tourism requires relatively low capital investment, continues to increase its potential exponentially as an invisible export and foreign currency earner, and is thus a relatively low cost way to balance payments. However, tourism is also vulnerable to short-term economic fluctuations and heightened perceptions of risk, such as those due to terrorist activity or political instability.

One of the features of contemporary globalization is the *growth and influence of multinational corporations* (MNCs). Both their number and importance have increased significantly since the 1970s, most notably in terms of finance capital, and especially during the deregulatory wave of the 1980s. However, as distinct from some other economic sectors, the influence of MNCs is not as great as may be thought, and extends mainly to three sub-sectors: airlines, hotel chains, and to a lesser extent, travel agents and tour operators. In air travel, we find a trend towards strategic alliances among a number of different carriers. Using a system of code-sharing, onward and connecting flights can be booked as a single ticket. Airlines may also offer other services such as hotel booking and car hire. Such developments are only possible through the advent of sophisticated ICT systems, which also allow individuals to create their own itineraries through online booking. Such developments undermine the traditional role of the tour operators and travel agents, and are of great benefit to airlines and hotel chains. It is at this level that we see the emergence of global standards of service that consumers increasingly expect.

However, such alliances and franchise arrangements are not entirely the result of a deregulated global economy. Both national and regional policies will also have some effect in shaping the form and development of tourist space and the flows of both investment capital and people, since a major incentive for governments to pursue tourism development policies is the lure of foreign exchange earnings. Despite globalization, the state has clearly not withered away. Rather its role can be crucial in mediating and directing the political economy. MNCs may exert considerable economic leverage, more so perhaps in relation to the less developed economies, but they are not doing so in a totally unfettered marketplace.

The main issue in terms of the *global political economy* is the degree to which the state either pursues interventionist policies, or deregulates and opens up development to the

play of market forces, even if these are mediated at a number of spatial and administrative levels. The net result is that competition for tourist spend is now played out in a global arena, and culture, in the wider anthropological sense of the word, is the means through which places market themselves for tourist spend. In order to attract tourists, destinations need to be marked out as distinct, and this often involves policy and marketing strategy development at a number of institutional levels, from the national state to the region and the locality.

### CULTURE AND SYMBOLISM

Both policies and marketing strategies, working within the confines of the global economy, assign symbolic value to selected attributes of place. Through such processes cultures are essentialized and commoditized as representations for the global market place (→ Culture: Definitions and Concepts; Culture Industries). These representations of people, place, and culture assume an exchange value as objects of consumption along with the other material goods and commodities consumed in the tourist circuit.

*Global* → *marketing* inevitably impinges on the lives of people in tourist destinations. Tourism can provide employment and income in areas that previously, for example, had been dominated by agricultural patterns of production. Development requires land, and the building of hotels and infrastructure may displace local inhabitants. The gender division of labor within local societies may also change as new employment and entrepreneurial opportunities are opened up to locals. On a more negative note, we also need to take account of the exploitative relationships that may develop between locals and tourists, most notably perhaps in sex tourism. This is a phenomenon most commonly associated with developing nations, where the disparity of wealth between hosts and guests gives rise to widespread prostitution, which in turn develops into the tourist attraction itself.

The possibility that the bulk of profits will flow overseas rather than feed into the local economy is an ever-present problem, albeit one neither confined to the tourism sector nor to the less developed economies; it is an aspect of globalization itself. For example, profits may well flow from the western economies to those of the east, as they may flow in the other direction.

Tourists not only bring with them money, but also particular *expectations of the destination and its people*, as well as culturally specific norms and ways of acting that can, in some cases, go against local norms and expectations of acceptable behavior. Many criticisms of tourism are based on the notion that it exports “western” values and ways of life that impinge on more vulnerable societies in the less developed world (→ Americanization of the Media). While changes to local social and economic patterns are an inevitable consequence of tourism development, however we judge them, the flow and pattern of tourism itself has also been changing. Many of the less developed or newly emerging economies now have growing domestic tourism markets, as well as contributing to the net flow of overseas tourists. Some smaller nations, though, for example the island states of Micronesia and the Caribbean, will be more dependent on tourism. Even in the developed economies some cities and regions are also more reliant on tourism spend than they have been in the past. In other words, the new order of globalization appears to cut across and redefine the old pattern of geographical and cultural fixities, to the extent that

binary models of center versus periphery or → modernization versus underdevelopment cannot deal with the complex contemporary situation (→ Cultural Imperialism Theories).

This can be seen in the often-voiced assumption that both globalization and tourism will lead to the *homogenization of cultures* to the detriment of more localized forms of cultural identity and expression. So far the evidence is rather mixed, even contradictory. For example, it is often assumed, particularly in relation to developing countries and culturally peripheral regions, that contact with tourism creates markets for handicrafts, and the intrusion of market mechanisms inevitably leads to the production of tourist goods that are inauthentic representations of local cultures. However, such arguments and their variants rely on an outmoded and static model of culture, and ignore both internal and external dynamics of cultural change. Nonetheless, in certain sub-sectors of the tourism industry, such as travel and accommodation for instance, there are global standards of service provision by which individual providers are judged. At the same time, certain aspects of a destination may well be valued precisely because they are perceived to be “free” of global influences.

The contemporary tourism industry comprises a complex circuit of production and consumption that extends across spatial and cultural boundaries. The dominant Fordist model of production and consumption, exemplified by the mass holiday resort, has, in common with other spheres of consumption, gradually but not entirely been superseded by a more fragmented and niched market. As a globalized phenomenon, it encompasses both the macro and global with the micro and local levels of specific places and destinations.

# Tourism and Popular Culture

Arthur Asa Berger

San Francisco State University

Tourism is now the largest industry in the world, and as such, it has increasingly become of interest to scholars in a number of academic disciplines, such as anthropology, sociology, psychology, → semiotics, communication and → marketing. It is also the subject of analyses using interdisciplinary approaches, such as leisure studies, feminist studies (→ Feminist and Gender Studies), and → cultural studies. Tourism studies have moved from being a relatively marginal aspect of the academy to one of considerable importance, and there are now departments devoted to studying tourism and many scholarly journals devoted to the subject.

Tourism scholars pay a great deal of attention to marketing and to different kinds of tourists and what they are seeking when they travel. The tendency is to focus on sociological topics involving tourism demographics and statistical portraits of tourists. There is also an anthropological approach to tourism that considers it as a cultural phenomenon. In recent years, a broader approach, involving a number of disciplines, has become important and one finds now, for example, psychoanalytic–semiotic studies of tourism being made. A good example of the semiotic analysis of a “foreign” culture is → Roland Barthes’s *Empire of signs* (1982).

## TOURISM AS A SOCIAL PHENOMENON

Several years ago, more than 800 million people made trips out of their home country to another country, and while some of those trips might have involved traveling to a neighboring country or one nearby, a huge number of people traveled to distant lands. Traveling abroad is nothing new, of course. For as long as we have recorded history, people have wandered over the face of the earth, in search of food, lost cultures and civilizations, and adventure, or on religious pilgrimages – trying to escape from the routines of their everyday lives in search of that which is different or exotic. But the scope of international tourism is unprecedented and calls for serious investigation.

At one time, foreign travel was reserved for elites who had the time and money to be able to take the “grand tour” and see the world. In recent decades, as a result of the development of relatively inexpensive means of travel, such as airplanes, and new modes of tourism, such as cruise lines and package tours, more and more people are traveling further and further and tourism has become a mass market phenomenon.

The term “tourism” comes from the Greek word *ornos*, which means circle. Tourism is generally understood to mean traveling, for pleasure, to distant lands and then returning to one’s home city, making, in effect, a circle. The World Tourism Organization defines tourism as follows: “It comprises the activities of personal traveling to and staying in places outside their usual environment for not more than one consecutive year for leisure, business and other purposes not related to the exercise of an activity remunerated from within the place visited” (website).

This definition is much too broad and does not consider other important aspects of tourism, such as the notion that it is voluntary, is done for pleasure and amusement, is part of our consumer culture, and involves tourists returning to their point of origin after their travels. Sometimes it is difficult to differentiate between tourism and business travel, for a person who is traveling somewhere on business, which is the main reason for the trip, may spend some time as a tourist, and tourists may occasionally conduct some business while on their trips. For our purposes, tourism and travel will be considered as the same thing.

### **TOURISM AS PART OF POPULAR COMMUNICATION**

Tourism may now be seen as part of our → consumer culture and, because it is so widespread, as a kind of mass culture or popular culture. As such, it is the subject of various kinds of → popular communication. One finds advertisements for cruises, foreign tours, and flights to exotic destinations in our → magazines and → newspapers and on the → Internet. In most newspapers there are special sections in the Sunday editions that deal with travel – both foreign and domestic. There are a number of American magazines, such as *National Geographic Traveler* and *Travel + Leisure*, that are of interest to tourists, and similar magazines exist in most countries.

There are an enormous number of websites dealing with every aspect of tourism, from finding flights to booking cruises and tours. In addition, there are sites where travelers can send back reports about their visits to various cities or countries. For example, on the Frommer's website one can find hundreds of discussions on sites devoted to particular cities and countries. People planning visits to a certain city or country can ask questions and receive answers from others, and many people write involved descriptions of their adventures. There are radio and television shows devoted to travel, and there is a very large travel guide publishing industry.

When tourists visit other places, especially foreign lands, one of the things they do is shop for souvenirs and local products, so tourism is intimately connected with the everyday lives and popular culture of people in sites that are visited. In addition to shopping, tourists visit places to enjoy the food and entertainments found in them, since tourists are in search of that which is different (→ Culture: Definitions and Concepts).

This search for what is different can range from visiting countries where the differences are not great to countries where they are very great. Thus, for example, a person from the United States who visits western European countries would find different cultures (and a person from western Europe would find the United States different), but the difference would not be as great as visiting a country such as India, where there are enormous differences in language, food, religion, architecture, and dress.

### **THEORETICAL CONCEPTS**

We can suggest that there are polar opposites – the everyday and the exotic. The everyday, at one extreme, represents one's own culture. In the middle there is the "different," which represents cultures that are different from ours but not in radical ways. And the exotic represents cultures that are distant from ours in almost every way. If we take the United States as representing the everyday pole, we can see that England, France, Italy, and other

western European countries are different in many respects, but not radically different from America – especially in their popular culture. Thailand, Bali, and India, would represent the other pole, the exotic, where most aspects of everyday life are very different to life in America (Berger 2004, 33).

When people travel, they tend to spend much of their time involved with the popular culture and everyday life of the places they visit. Statistics reveal that shopping is the number one activity that tourists engage in when traveling. Popular culture can be defined for our purposes as all that which is not elite culture (opera, classical music, great works of art, and so on). An important aspect of popular culture involves media and what has been described as mass-mediated culture. Many tourists do sample elite culture when they are in distant lands – they may go to an opera, visit museums, or attend concerts – but much of their time is spent shopping, sightseeing, visiting places of touristic interest with good photo opportunities, enjoying popular entertainments, and dining where they can sample the local cuisine (→ Popular Culture).

The growth of the Internet and the development of mass media mean that the exotic is becoming more and more familiar, and many people can now see when they watch television or go to films how people in other cultures live. Television programs on travel and films that take place in exotic countries have led to many countries becoming “hot” popular tourist destinations. One important matter for tourism scholars to investigate is the impact of tourism and first world mass-mediated culture on third world foreign cultures. Is first world popular culture destroying popular culture in third world lands, or have they learned how to adapt it to their own needs? Much of the discussion of “cultural imperialism” (→ Cultural Imperialism Theories) is theoretical in nature and the subject of continual controversy and debate.

Some theorists, such as Claude Lévi-Strauss, suggest the world is becoming a “monoculture.” The implication of this notion is that as the world fills up with *Starbucks* and fast food outlets, that which is distinctive in foreign lands, whether different or exotic, will diminish or disappear. This is an important question for tourism scholars, for if tourists are in search of that which is different (and authentically different), there will be no reason to travel if the world becomes a monoculture. Tourism scholars face the problem of determining to what degree cultures are losing their identities, or, if not, how they are dealing with the impact of mass media and mass tourism. There is also the question of what impact tourists have on the places they visit. Many scholars have been interested in the effect mass tourism has had on Bali, for example, and there is a good deal of debate about whether tourism has been good or bad for Bali.

Related to this matter is the question of authenticity and the development of what might be called “tourist traps,” namely faked or imitated cultural practices. There is also the broader question of the importance of simulations in life and the impact that simulations are having on tourism and on everyday life everywhere.

Scholars studying the impact of tourism and popular or mass-mediated culture on other lands need to be familiar with the popular and everyday life of the cultures being studied, and find ways of assessing how cultures change and the degree to which they change. These are methodological problems of considerable importance – problems that call for a multidisciplinary perspective and a broader approach to tourism studies than tends to be the norm now.

## **Trademarks in the Media**

*Kim Bartel Sheehan*

*University of Oregon*

Trademarks are symbols used by companies to identify their products and services. These symbols then serve to distinguish a product or service from those of another company (when a service is trademarked, the resulting mark is legally referred to as a “servicemark”). Trademarks can consist of a word, a phrase, a design, a sound, a color, a product configuration, a group of letters or numbers, or any combination of these. The trademark for the NBC television network, for example, consists of the letters “NBC” and a stylized peacock; the trademark for the Playboy empire consists of the word “Playboy” and the famous bunny symbol.

The terms “trademark” and → “brand” are often used interchangeably, and both are considered intellectual property (→ Intellectual Property Law). In the US, trademarks can be registered with the US patent and trademark office. Brands can be registered as trademarks, and include the symbol of an “r” in a circle when this has occurred. If the symbol “tm” is used, it is likely that the brand has applied for registration but has not yet received it.

### **FUNCTION OF TRADEMARKS**

Trademarks play important roles for all companies, including media companies. They minimize consumer confusion regarding the source (or origin) of a product or service.

Trademarks also allow companies to set and enforce high quality standards for those licensing trademarked products and services. Additionally, trademarks prevent other organizations from using a similar trademark on competing products and services. Finally, as consumers become familiar with trademarks and the products or services they represent, trademarks can acquire a secondary meaning, as an indicator of product or service quality.

Thus, these trademarks help consumers select one product or service over another. For this reason, trademarks can be valuable business assets (Tucker & Casabona 2006). For *media companies*, trademarks are arguably even more important than trademarks for products. Media companies invest considerable resources in developing name and trademark recognition, and the reputation associated with such names and trademarks (→ Corporate and Organizational Identity; Corporate Reputation). For media companies, an image or a brand cannot be created overnight; it needs a consistent delivery of a specific type of content in order to become valuable to consumers (→ Branding). The trademark, then, symbolizes this value.

Media companies (such as → Time Warner Inc.) and specific media outlets, such as the → CNN cable network, *Playboy* magazine, and the *New York Times* newspaper, rely on the content that they create to attract audiences (and subsequently advertisers). The audiences create an → image of the media company based on the content provided by the company, and then the company's trademark stands to symbolize that image. The image represents a perceived value to media audiences. *CNN* and the *New York Times*, for example, stand for credible and quality journalism (→ Quality Press), while *Time Warner* and *Playboy* represent certain types of entertainment values. If such values are compromised, the audiences may seek other media outlets, and the media companies would lose not only viewers and listeners but also advertising revenue (→ Advertising).

Trademarks contain a specific *monetary value* for all trademark holders, and trademarks can be valued as part of the assets of a media company. In the US, trademark registration can be sold if it is accompanied by the sale of an underlying asset. When a company that produces trademarked goods is sold, then, the trademark registration will be sold with it. Additionally, a trademark could be sold to someone who purchases a machine specifically made to create a product that bears the trademark. Outside the US, a trademark may often be sold with or without the underlying asset.

## TRADEMARKS AND REGULATION

### Violation of Trademarks

*Trademark infringement* occurs when a non-owner uses an identical or substantially similar trademark that is already being used by an existing party. Infringement exists when the trademark is used to the extent that it is likely that consumers will become confused, mistaken, or deceived about the source of the product. In assessing infringement claims, courts examine the closeness of the appearance, sound, and meaning of the conflicting marks; the similarity of the goods on which the marks are used; the channels of commerce in which the marks are sold; and the sophistication of the relevant purchasers of the goods.

*Trademark dilution* is defined as “the lessening of the capacity of a famous mark to identify and distinguish goods and services, regardless of the presence or absence of (1) competition between the owner of the famous mark and other parties, or (2) likelihood of confusion, mistake, or deception” (Federal Trademark Dilution Act 1995). There are two types of dilution: tarnishment and blurring.

*Trademark tarnishment* occurs if a non-owner uses the mark without permission to promote poor products or services, or illegal or offensive activities. For example, using a Walt → Disney trademark on a website filled with pornography could be claimed to tarnish the reputation of Disney. Tarnishment is not always actionable from a legal perspective; specifically, not when the use would be considered either noncommercial or a parody. The effects of such tarnishment can have negative effects on brands, brand value, and brand equity. Blurring is the gradual decline in the identity or perception of the uniqueness of the trademark or the brand in the minds of consumers.

### **Cybersquatting**

Trademark protection also extends to the Internet (→ Internet Law and Regulation). The Anticybersquatting Consumer Protection Act (ACPA) (1999) is designed to protect consumers and businesses by giving trademark owners legal remedies against defendants, also known as “cybersquatters.” These cybersquatters obtain domain names “in bad faith” that are identical or confusingly similar to a trademark or service mark. The Act also allows for a “safe harbor provision.” A cybersquatter is not in violation of the act if he or she can establish that he or she believed that the use of the domain name was a legally fair use, and if the court concludes that this belief was reasonable. Often, these cybersquatters hope to profit by the eventual sale of the domain name to the company who owns the trademark. Media companies have recently had their trademark protections abused by cybersquatters who register domain names that simulate well-known media company trademark names for the purpose of commercially exploiting the domain name.

The result of such cybersquatting is that the media companies that own the trademarks are unable to clearly distinguish themselves from others. As a result, audiences cannot rely on trademarks as source identifiers, and thus the credibility of a news or entertainment source is undermined. For example, ccnews.com is an Internet domain name that for a while directed web users to a Chinese-language news website. Certainly the domain name created confusion or misdirection in the minds of consumers, many of whom erroneously believed that the site was sponsored by CNN, when instead it was sponsored by a company called Maya Online Broadband Network. The United States District Court ruled that CNN had established all of the essential elements of a trademark infringement claim in this case.

### **Fan Sites on the Internet**

The Internet has enabled fans of programs created by media companies to set up dispersed communities based around popular programs (→ Fandom). For example, during the height of popularity of the Fox Network’s television show *The X Files*, over 900 fan websites were in existence. More recently, children have created hundreds of Harry

Potter tribute sites, using trademarks of Warner Bros, the studio that released the Harry Potter films. In both these cases, the sites contained “fan fiction,” stories about the characters created by visitors to the sites and fans of *The X Files* and Harry Potter.

Concerned with the possibility of audience confusion regarding the source of the content, the Fox Network legal department tried to close down the sites that infringed on the trademarks of both the Fox Network and the program, but the mere volume of sites made it difficult for the network to police. Warner Bros instigated suits against the children with the Harry Potter sites. Not surprisingly, such actions have resulted in backlashes toward the company from loyal fans, who responded angrily to Warner Brothers’ lawsuits. In these cases, it is difficult for corporations to determine when to provide goodwill and enjoy the publicity for their content, and when to be concerned about trademark infringement and the confusion caused regarding the veracity of content. Confusion is not the only concern. Many cybersquatters use the media name in order to direct consumers to inappropriate content. For example, a website with the name *Batman-1.com* (one of Time Warner’s media properties) directed visiting online users to a pornographic website, which would dilute the entertainment value associated with the Time Warner and Batman trademarks.

Trademarks in the media may be simple words and images, yet they represent so much more to media companies. Many media companies lobby on a regular basis for increased trademark protection in the online arena.

# Transactional Models

Carsten Wunsch

University of Leipzig

Representation and explanation of complex communication phenomena are goals of communication research and theory building. To reach these goals, communication science uses simplified representations, also known as scientific models. Scientific models describe, in simplified form, the order of elements in a system and their relations to each other. These relations can be described as temporal, spatial, causal, correlative, interactive, or transactional. A model of our solar system, for example, describes the spatial arrangement of the planets. The Lasswell formula describes the central protagonists of the communication process (communicators, recipients, media, etc.) and their temporal and causal relations in a communication model (→ Lasswell, Harold D.; *Models of Communication*).

A transactional relation can best be described in contrast to causal relations. In a causal relationship the two elements “cause” and “effect” can be clearly distinguished from each other. The cause always occurs before the effect. Such a causal consideration is not theoretically correct in every model. In some cases, a relation can also be described as a transaction. Here, the strict analytical separation between cause and effect is eliminated. An element changes itself at the moment at which it causes something, or, in the language of causal logic, when the effect influences the cause before it has appeared. In this way, an element simultaneously represents both cause and effect.

Suggestions for transactional modeling first came from Dewey and Bentley (1949). Bauer (1963) introduced this concept in the field of communication science. Transactional models are used in descriptions of social and individual phenomena. In the social case, processes between individuals or social subsystems are described, and in the individual case, processes within individuals are described. Schönbach and Früh (1984) suggest the terms “inter-transaction” and “intra-transaction” to distinguish the two.

*Inter-transactions* occur in the process of communication between different communication partners. These can be single individuals or social subsystems. Most of these models describe communication in a form known from Mead’s (1934) theory of symbolic interactionism (→ *Symbolic Interaction*). Knowledge of the effect of the communication is the basis for a successful communication. Communication between two individuals is based on the fact that one person has an idea of the effects and reactions of his or her remarks on the other person, and that this person, utilizing this idea, adapts his or her communication. When the remarks of the first person elicit the reactions of the other person, but it is exactly these reactions that are involved as anticipations in the generation of the remarks, then cause and effect are no longer separable in this model. In this case, one can describe the relationship between the remark of the first person and the reactions of the other person as transactional.

However, this does not apply solely to → interpersonal communication but also to communication via mass media. In the field of → public relations or → advertising, the contents of communication are professionally optimized to achieve an intended effect. In the process of the journalist’s selection of a message (→ *News Values*), this anticipatory

effect also plays an important role. It is a part of a general picture of their audience that journalists construct during the course of their work (e.g., in the form of → news factors).

*Intra-transactions* are used for the description of individual psychological processes. Perception and comprehension are explained transactionally by analogy with Neisser's (1976) perception cycle (→ Perception; Comprehension). His concept describes the comprehension of a text (e.g., a news item) as the interplay between the incoming information (data-driven) and an available schema (concept-driven). Such a → schema represents a → memory structure in a simplified form. Initially, the nature of the incoming information determines which schemas are used for comprehension. However, at the same time, comprehension of this information depends on the schemas retrieved and employed. The decoding of the information (data-driven processes) and the choice of schemas required for this (concept-driven processes) can be sorted neither temporally nor causally. Therefore, the relationship between the two aspects of the perception cycle is best described as a transaction.

An important application area of this basic transactional view of communication can be seen in the modeling of → media effects. Both intra- and inter-transactions are involved in the effect of media on individuals. On the one hand, the transactional perception process described above is a prerequisite for an effect, since only perceived information can, in general, have effects on the audience (→ Schemas and Media Effects). A commercial, for example, will only convey a positive product image when the recipient cognitively maps the positive product attributes implied in the commercial in such a schema-escorted comprehension process.

In communication science, this aspect of a transactional effect model has been successfully used in the description of the effect of violent television content (Sander 1997; → Violence as Media Content, Effects of). Furthermore, the relations described as inter-transactions are also important for the modeling of processes of effect. In the context of persuasive communication, e.g., advertising and public relations, trust and credibility are examples of such transactional concepts (e.g., Woodward 2000): a recipient develops a set of ideas about the communicators and their credibility. This trust guides the reception of the message, but a sense of the credibility of the communicators develops only from the reception (→ Credibility Effects; Credibility of Content).

One conclusion drawn from such a transactional modeling of media effects is that the notion of effect is not adequate, either in the form of a → stimulus–response model with a powerful communicator, or in the form of a purely recipient-oriented model with an active, critical audience that determines the effects it chooses to allow and those it chooses to reject. Media effects arise from a transactional interplay of communicators and their intentions, of media messages and the recipients, and of their intentions and schemas (→ Media Effects Models: Elaborated Models).

# Transcribing and Transcription

*Felicia Roberts*

*Purdue University*

Transcribing is the process of representing, in written form, some stretch of lived activity. The resulting transcription provides a document that is easily perused and examined, and in a variety of institutional settings it serves as the official record of the actual proceedings. Such governmental and commercial transcripts are generally perceived as impersonal or unbiased renderings and are intended primarily as references to activity. In communication research, however, it is understood that transcribing is an *analytic process*, since, in actuality, a transcriber is always selecting and distilling the complexities of speech and action. Or, in the case of rendering original handwritten documents, the researcher loses the artistry of the hand that produced the original document. Transcripts are, therefore, abstract versions of verbal, vocal, bodily, and spatial activities; they embody the transcriber’s stance toward the aims of recording and studying a communication event.

### ORIGIN AND FUNCTION

While researchers who study naturally occurring interaction can agree on the need to represent the participants’ talk and action as carefully as possible, choices of what and how to transcribe are driven by philosophical, theoretical, and methodological orientations to the materials being handled (Ochs 1979). For example, if the researcher is concerned primarily with the thematic content of a narrative – with what is being described or what

the general purpose of the narrative seems to be – then transcribing the verbal content may be sufficient for constructing an argument about that aspect of the discourse. If, however, the researcher is concerned with how a narrative unfolds as an interactive achievement, then the contributions (vocal and nonvocal) of co-present speakers will be necessary as well.

Although the representation of actual events in graphemic and pictorial form can be traced back millennia, the use of transcription for communication research is a relatively modern phenomenon. A variety of systems have developed for the purpose of representing spoken languages. The publication of an international phonetic alphabet (IPA) in 1888 was the first major step in allowing researchers to share materials across language groups without recourse to native orthographic systems. However, the IPA requires a level of phonetic training that is not necessarily relevant for all types of communication research. Therefore, orthographic representation of spoken language is the most widely accepted approach in the field. Furthermore, with the advent of analog and digital recording, researchers rarely try to transcribe human communication directly onto paper; the research process generally begins with electronic recordings, which are then transcribed.

In producing a transcript for analysis, researchers rely on their auditory and visual perceptual skills to render from recordings some stretch of lived interaction. As noted, this is a selective process, based on beliefs about the nature of communication and the aims of the study. Researchers make choices about the kinds of detail they will attend to in interaction and the way in which they will organize those details on the page. Whatever researchers' orientations to their materials may be, all persons engaged in the transcription process confront the paradox that communication is both simultaneous and sequential; participants in interaction move simultaneously through time such that, while some aspects of their activity may co-occur, other aspects follow sequentially. Researchers attempt to capture this layering of simultaneity and linearity by the way that transcripts are structured on the two-dimensional page. Although both the vertical and the horizontal dimensions can represent the passage of time, the horizontal is generally reserved for an individual speaker's contribution (biased in a left to right reading format) while the vertical (top to bottom) will represent the change of speakers over time. Conjoining these levels is accomplished with a variety of symbols to show when overlapping or simultaneous talk (or action) occurs.

### EXAMPLE

In the following (adapted from Roberts & Robinson 2004, 397–407), the beginning of the overlap is captured with the left bracket ([]). Other symbols that capture paralinguistic features are presented in Table 1.

#### Example Transcript

Mara: Have you been there yet?  
 Tina: Yeah. It's really nice.=Like I [go:  
 Mara: [It's like a hotel.

**Table 1** Some transcription symbols and what they indicate

Symbol	Meaning
Question mark (?)	Rising intonation
Period (.)	Falling intonation
Equal sign (=)	Talk that is quickly latched
Colon (:)	Sound that is stretched out

A particularly daunting task for the person transcribing is managing “the recurrent interpenetration of verbal and visual communication” (Duranti 1997, 146). A variety of approaches have been developed for transcribing the coordinated vocal and nonvocal activities of interactants. Some conceive of the transcript as a musical score; others use parallel columns; still others integrate the visual and spatial information parenthetically into the verbal stream or in the lines just below the representation of the verbal stream. The approach used is dependent on the researchers’ interests, their analysis of what is relevant to the participants, and the constraints of the media they are using to format their transcription.

## TRANSCRIPTION METHODS

For transcribing linguistic aspects of interaction, several approaches have developed in the decades since the advent of recording technologies. Although approaches to transcribing talk vary considerably in their details, they can be divided into two *general categories*: those that privilege supra-segmental aspects of language (such as intonation and accent units, or perceptions of rhythmic synchrony) and those that privilege speaker transition and the sequential features of talk-in-interaction. This latter category is the foundation of most contemporary transcription systems since all discourse, whether monologic or multiparty, proceeds through time and therefore develops sequentially. In the case of multiparty conversation, speaker transition will also always be relevant.

The sequentially grounded form of transcription relies, explicitly or implicitly, on a model of conversation (empirically derived) that accounts for the construction and allocation of turns (Sacks et al. 1974). In this approach to segmenting discourse, the core organizing principle is conceived of as speaker transition, with silences providing the fulcrum that moves the transcript forward. In a system for transcription initially developed by Gail Jefferson (Sacks et al. 1974), the representation of both segmental features (sounds/words) and supra-segmental features of talk (such as lengthening, loudness, and other aspects of voice quality) are included, but the transcript is not organized around these supra-segmental features. The range and nature of details in this “Jeffersonian” tradition (e.g., from tokens of laughter to micro-pauses) has allowed research on conversation to move from analysis of surface-level semantic content to the analysis of underlying mechanics and structures of coordinated action. Some of these discoveries might not have been otherwise recoverable from transcription of words alone.

Transcription systems that are intentionally designed around supra-segmental features are often crafted on the basis of a sequential understanding of activities, but they bring an additional interest in the music or rhythm of the speech and its relationship to communication. One prominent approach addresses intonation and action units (also known as “tone groups” or “tone units”). These are conceived of as “units of considerable cognitive significance” (Chafe 1993, 33), which fall under one prosodic contour. In this approach, the tonal unit has a functional significance that may transcend syntactic and semantic boundaries. Such units are discerned by the transcriber’s perception of cues such as phrase-final lengthening, phrase-initial pitch resetting, inter- or intra-utterance pauses, and so on; generally these cues are objectively available in the acoustic signal. Another elaborated, though less widely used, approach is one that captures the rhythmic synchrony in human communication. Here, rhythm is not something objectively measurable in the acoustic information, but is perceived by the transcriber from patterns of acoustic cues. Therefore, “rhythmic transcriptions require the special skill of analytic hearing – a property they share with narrow phonetic transcriptions” (Auer et al. 1999, 35).

### RELIABILITY

Because the process of transcription is essentially one of perception, selection, and representation, questions can arise over the → reliability of transcription practices. Researchers engaged in projects that require transcription must continually work in conjunction with the recorded data to ensure a close relationship between the recordings and the renderings. In addition, researchers often rely on a consensus process, comparing and contrasting their transcriptions with the help of colleagues. This ensures some level of agreement across the perceptions of multiple listeners. Finally, structured assessments of reliability are possible, which can ensure that transcribers are sufficiently converging on the perception and representation of phenomena. This provides some confidence in both the transcription process and its product (Roberts & Robinson 2004).

Although no transcript is ever truly “finished” (in the sense that refinements or new angles of interest can emerge), at some point the researcher makes the transcript accessible to a wider audience for presentation of findings in public meetings or in publications. This “final step” sometimes leads to simplification of the transcript for general consumption or, for those working in languages not known to their audience, the transcription becomes more complex due to the need for translation. Translation poses an additional challenge in that the transcribed activity is now an additional level removed from the original recording. Researchers can provide just the translation, or present the original and the translation in parallel columns, or, in the interest of providing the greatest access to the participants’ actual talk, one common practice is to provide, in three parallel horizontal lines, first a transcription of the original talk (usually in romanized script), then a word-by-word translation underneath, including the identification of grammatical morphemes, and finally a third line which provides an idiomatic translation into the language of the presentation. Following is an example of talk transcribed by Moerman (1988, 125) for a study of Lue-Thai interaction. The Lue-Thai orthography has been simplified here for ease of presentation:

Villager:           xaw   ju    kunthep a       ju    ti    naj    hu    ni  
 Direct translation: They   to be   Bangkok Qprt   to be   CNJ   where   don't   know PRT  
 Idiomatic:            Maybe they were from Bangkok. I don't know where they were from.

Qprt = question particle; CNJ = conjunction; PRT = unanalyzed sentential particle.

In the future, there is always the possibility that machines will be able to handle the conversion from acoustic signal to typewritten transcript. The value of such technology will be debated and its use will vary according to the analytic orientations of the researchers. Perhaps more promising, and useful for presenting and sharing findings, is the proliferation of sophisticated presentation software as well as the possibility of including electronic media (copies of audio/video recordings) in serialized print publications (e.g., *Journal of Communication*, vol. 52, 2002). More widespread is the incorporation of URL addresses to link print readers to audiovisual media through the Internet. Having access to researchers' recordings of lived events allows audiences to experience the data, and keeps the transcript closely linked to that data.

# Transnational Civil Society

*John D. H. Downing*

*Southern Illinois University*

“Civil society” has been through a series of definitions since it first came into use in the 18th century. Locke, Hegel, Marx, and Gramsci all used the term; but for Locke it meant organized human civilization as contrasted with the animal kingdom’s turbulence, for Marx it meant the economic process, and the other two writers assigned it still other meanings. In Soviet bloc countries in the final years of the bloc’s disintegration, and in Latin America in the same period during the gradual disappearance of military dictatorships, “civil society” was a term of hope often used by advocates of democratic governance to denote the hopeful shoots of democratic process they saw emerging in front of their eyes, that they felt were ushering in the dissolution of dictatorial rule.

## CHANGING DEFINITIONS OF “CIVIL SOCIETY”

Beginning in the 1980s and growing in the 1990s, the term became almost iconic within movements for global social justice, basically denoting projects and initiatives undertaken by, and furthering, grassroots political interests. These might be to develop anti-racist and civil rights strategies, to address the AIDS crisis, to promote sustainable environmental policies, to empower women, to promote peace, to strengthen responsive labor organization, and a variety of other issues, all of them quite often interlinked. In particular, it signified citizens’ actions against the globalized neo-liberal economic policies summarized in the term “the Washington consensus” and by the policies and priorities of global finance corporations, the International Monetary Fund (IMF), the World Bank, the World Trade Organization (WTO), and a series of other international bodies (→ Globalization Theories).

In other words, the term had become one that denoted *ongoing movement*, not simply a static category of society. “Civil society” thus only came to life as a category, at this juncture, when it was in action. By contrast, for many mainstream news media during those years and since, the preferred term was quite often “the protesters,” rendering them marginal and on the verge, for sure, of being simply an irritating nuisance, supposedly often having no clue why they were demonstrating. They were not at all, from this viewpoint, the visible groundswell of a growing tide of informed public opinion. The terminology choice directly mirrored the clash of political visions.

However, the very vagueness of the term “civil society” created a rather pressing need to pin it down to practical specifics. One major response to that need was the *emergence of nongovernmental organizations* (NGOs) as the tangible expression of “civil society.” Indeed NGOs often became defined as the very substance of the concept. This had its drawbacks, given the extraordinary proliferation of NGOs across the planet; as well as having a bewildering diversity of focus and location, their agendas were often not merely diverse but diametrically at odds with each other.

For instance, NGOs could be proponents of abortion rights or evangelists for their denial; they could be US foundations sporting budgets of billions of dollars or an entirely

income-free community radio station in the Andes (→ Community Media). To define them by what they were not (namely, directly dependent on government) was also inaccurate in quite a number of cases, in that they were not seldom recipients of, or conduits for, state funding, at least in significant part, and thus hardly nongovernmental. They also served in some contexts as recruiting pools for public administration. Finally, while far from all were ideological warriors for a reactionary religious body's social agenda or for a neo-colonialist policy, it would be empirically misguided to presume they were one and all selflessly devoted to social justice and cultural enlightenment.

### MAKING CIVIL SOCIETY TRANSNATIONAL

Tacking the adjective “transnational” on to “civil society” is hardly surprising in a period in which discussions of globalization and its implications have become so commonplace, and in which international peace activism, environmental activism, labor activism, and solidarity activism have continued to play an important role in world politics. Given the term's evident tendency to vagueness, though, what is the effect of doing so? Four instances will serve to provide some response to the question. One is a much-cited book by Margaret Keck and Kathryn Sikkink, *Activists beyond borders* (1998); the second is a special edition of the *Courrier de la Planète* on global civil society (2001); the other two are book-length treatments of the topic by Mary Kaldor (2003) and John Keane (2003).

The Keck and Sikkink study was not only an important contribution, but quite quickly and widely recognized as such. Their distinct preference (1998, 32–34) is for the term “transnational” civil society over “global” civil society. Their rationale is brief, but appears to pivot on the implicitly overly deterministic sense in which they read the term “globalization,” suggesting a process automatically generated by a mixture of economic, transport, and communication changes. For them, in order to analyze transnational advocacy networks focused on human rights, environmental issues, and violence against women – their core topics – it is sociologically and philosophically pivotal to retain a strong sense of both agency and indeterminacy. In their frame, then, *transnational* civil society is a “fragmented and contested arena” whose politics are all about how certain groups emerge and get to be given an official seal of approval. They do not, however, explain why or how their own distinction between the terms “global” and “transnational” is other than idiosyncratic, or reflects any widely argued positions elsewhere.

Nonetheless, their contribution through a term such as “transnational civil society” enables us to acknowledge the growing role of transnational advocacy networks in international political relations, and that international relations are no longer simply the preserve of states. It can also draw our attention to the *roles of activist networks* in providing opportunities to negotiate issues internationally between, for example, gender or ecological activists in the global north and the global south, in order to reframe priorities in ways that address critical concerns in different regions of the planet. What is signally missing from their analysis, however, is any attention to the roles of media within the advocacy networks on which they focus. The communication process seems, by default, to be taking place automatically within these networks. This is, as will be seen, a common failing.

The contributors to the special issue of *Courrier de la Planète* focused on defining or shaping the term “global civil society”; NGOs; the role of the World Bank and the WTO;

the UN; and aspects of the World Social Forum meeting in Porto Alegre, Brazil. Jan Aart Scholte (*Courrier* 2001) defines global civil society as one in which civic organizations “are engaged with cross-border issues, utilize transnational communication formats, have a global organization, and/or privilege cross-border solidarity as their goal.” He readily acknowledges that few such organizations display all four features. He also underscores that criminal, racist, ultra-nationalist, and fundamentalist forces engage in cross-border communication and organization, so that global civil society is not virtuous by nature. He further admits that at present an Anglophone digitocracy dominates even the constructive dimensions of global civil society. Compared to the resources of states and corporations, he laments, civil society has minimal staffing, finance, equipment, and symbolic capital. Nonetheless, he argues, its emergence is a potential sign of hope.

Maxime Haubert (2001) denies that the term “civil society” has any current value at all, given that military strategists, the World Bank, and global social justice activists all use it, but for very disparate goals. He argues it should be confined to history of philosophy textbooks. François Houtart (2001), a Jesuit priest prominent in the global social justice movement, puts forward a normative position, that “global civil society” should denote (1) a coalition of groups, with multifaceted strategies, to create alternatives to the present world structure; (2) their readiness to engage with utopian visions; (3) their engagement with every form of social existence, from the global to the individual; (4) their involvement with the formal political process as well as movement politics; and (5) acknowledging, but not essentializing, cultural differences.

Mary Kaldor, a long-time peace studies scholar-activist, also recognizes the term’s imprecision. She attacks what she sees as the reductive use of “civil society” to equal NGOs, and proposes instead that there is a long-term process underway, not toward unitary planetary government, but rather toward “multi-lateralist law-making states” whose global meetings offer “the possibility of participation and deliberation at global levels” (Kaldor 2003, 110, 141; → Francophonie; International Communication Agencies; Internet: International Regulation; New World Information and Communication Order [NWICO]; UNESCO). Anne-Marie Slaughter, Dean of the Woodrow Wilson School of Public and International Affairs, has provided a landmark study fleshing these processes out as regards emerging global networks of regulators, legislators, and judges (Slaughter 2004).

Political scientist John Keane vigorously echoes critiques of the term’s frequent imprecision and also its equation to NGOs. His own definition of global civil society is that it “has no collective voice . . . is full of networks, flows, disjunctions, frictions . . . only its constituent individuals, group initiatives, organizations and networks act and interact. Global publics consequently heighten the sense that global civil society is an unfinished, permanently threatened project” (2003, 172).

Yet once again, while his and the others’ definitions are helpful in portraying *the scope, the fluidity and the contradictoriness of activities* to be included under the heading of global/transnational civil society, they never or only briefly engage with the media communication process as central to these activities. Keane addresses this critical issue briefly (2003, 162, 166–174), and provides a short discussion (173–174) concerning the importance of “global public spheres” in holding global organizations of all kinds to account, but no specification of what these “spheres” consist of, or where they inhabit. Furthermore, his discussion of media is practically only of conventional mainstream media.

## TRANSNATIONAL CIVIL SOCIETY AND MEDIA COMMUNICATION

The analyses cited here are virtually all by distinguished political scientists. Within international policy discussions of transnational civil society, at the time of writing the political science discipline tends to dominate. It is unfortunate then to be compelled to register the superficiality of these scholars' engagement with mainstream and social movement media issues and problems. These are, nonetheless, central to the question of transnational civil society and so should never be taken for granted as unproblematic (→ Social Movement Media, Transnational; Activist Media; *Le Monde Diplomatique*). There is a large and constantly growing research literature on social movement media of which these writers appear unaware (e.g. Rodríguez 2001; Couldry & Curran 2003; Opel & Pompper 2004; Kidd et al. 2008).

For example, mainstream media often frame transnational civil society processes in ways that social movement activists feel distort their goals and practices (→ Framing Effects). Whether global environmentalists, labor activists, feminists, information policy activists, or human rights activists, their frequent complaint is that mainstream media typically ignore them, trivialize them, define them as semi-informed idiots, or even criminalize them in over-response to occasional attacks on property by some demonstrators.

Activists generally feel compelled to react to those dominant frames by public actions and statements, but especially by creating their own information spaces and strategies in alternative media. Alternative media activists, quite often closer to the ground than prominent professional journalists, may often "scoop" the latter on emerging stories, but may also find mainstream journalists contributing to their publications under pseudonyms, because they know their editors would refuse to take their copy. Moreover, some social justice organizations develop effective public relations strategies for feeding mainstream media with stories in formats the editors will accept. All in all, the clash of media framings of transnational civil society activism, whether Greenpeace or AIDS awareness or human rights campaigns, is a crucial dimension of the question.

So too is the utilization of the → Internet and wireless telephony for debate, information, and mobilization (→ Independent Media Centers Network). This has become a remarkable phenomenon over the past decade and looks set to be a permanent feature of the global landscape (Granjon 2001; Downing & Brooten, 2007). However, the potential for joint research in this area by communication scholars and political scientists remains to be fulfilled.
