Product differentiation refers to adding further products that are modifications of existing products in the line. The reason for the popularity of this strategy lies in the possibility to meet each market's specifics. But product differentiation can also bring cannibalization of company-owned products. Therefore, it is important to carefully examine the new product's substitution effects in advance. A third option is product elimination. If products are outdated and are no longer successful on the market, it is best to eliminate them. Through this elimination, companies' gain space on retailers' shelves for new, successful products, though it must be considered whether the eliminated product is complementary to another product in the company's line.

To ensure a company's long-term success, product innovations play a pivotal role. Just recently, Nokia managed to raise its profits by 43 percent worldwide due to new products. A product innovation describes a company's offering that consumers perceive to be a novelty and that differs widely from current products on the market. Before introducing a new product to the market, marketers need to thoroughly plan its communication, pricing, and distribution strategy.

### **ASSESSING CONSUMERS' PRICE ELASTICITY**

The size of a company's profits depends generally on its costs, its turnover, and the prices of its products and services. These three variables are interdependent. If a company sets a

low price, its turnover goes up. As a rule, with higher turnover and higher production volumes, unit costs decrease. High turnover and lower production cost make it possible for companies to sell their products for a low price. But this strategy does not work out for all products and brands (Simon et al. 2006).

To find out what price leads to maximal profits, managers should estimate the demand and costs associated with the alternative prices and choose that price that leads to the highest estimated profits. There are many factors that affect a company's cost and turnover functions; e.g., pricing has an effect on further variables, like competitors and their reactions, the product's and brand's image, as well as consumers' reactions (Urbany et al. 2000). A major criterion that influences consumers' acceptance of prices is their price elasticity. To assess the change in demand due to changes in prices, marketers need to know about consumers' *price sensitivity and price elasticity*, which describe changes in demand due to a 1 percent rise in price.

In the first case, consumers' price elasticity is relatively high, as an increase in price leads to a substantial decline in demand. Regarding the company's profits, an increase in price cannot compensate the drop in sales. In the second case, it is quite the contrary. The same increase in price leads only to a small decrease in demand, as consumers are not very sensitive to changes in price. Therefore, the increase in price is likely to overcompensate the decline in demand, so that the company's profits are liable to rise (Hanssen et al. 1990). Consumers' price elasticity is low if there are hardly any substitutional products available or if consumers are reluctant to buy a different product. The second factor in particular can very well be influenced by companies. Due to customer relationship management and effective brand leadership, consumers' loyalty can be increased and their price sensitivity lowered. Beyond that, brands offer additional benefits that justify higher prices from the consumers' point of view.

But not all consumers are equally sensitive toward price. Even one and the same person perceives price differently dependent on the situation. For instance, people have a lower willingness to pay for beverages in a supermarket than in a restaurant. To seize these differences in price sensitivity, marketers should consider the instrument of price differentiation.

*Price differentiation* refers to selling principally the same products to different consumers or groups of consumers at different prices. The aim of this strategy is to skim as much as possible of the *consumer surplus*, which can be defined as the difference in consumers' willingness to pay and the price actually paid.

As the willingness to pay differs between consumers, consumer surplus can be better skimmed by setting different prices for single consumers or groups of consumers. Pigou (1960) has identified *three different forms of price differentiation*. According to first-order differentiation, prices are set individually for each customer to perfectly skim his or her willingness to pay. Obviously, this strategy is not realizable in consumer markets. But in b2b markets, where a company addresses only a small number of potential buyers, custom-made pricing is possible. Examples of second-order differentiation are airlines and theaters. Passengers decide for themselves whether they want to fly economy, business, or first class; theatergoers choose where they are seated. According to second-order differentiation, consumers decide independently to which price category they belong.

By contrast, third-order differentiation does not enable consumers to choose their category themselves. Segments and the respective prices are pre-arranged by the company. Prevalently, consumers face this third-order price differentiation in cinemas or museums, where students, pupils, and pensioners typically pay lower admission fees. Another criterion for price differentiation is time of day. In some places, prices for telephone services or electricity are lower at night than they are during working hours. In practice, price discrimination often occurs relative to the amount bought by consumers. In this case, the overall sum is not linear to the number of units bought.

Another kind of price differentiation is price bundling, where the price of a bundle of mostly complementary products differs from the overall price of those products bought separately. The aim of this differentiation strategy is to better skim the consumer surplus of heterogeneous customers. Moreover, consumers are easily tempted to buy more than they originally wanted when products are offered in bundles.

To assess consumers' reactions to changes in prices, it is important to analyze their price behavior, which generally comprises four aspects: interest in prices, knowledge of prices, functions of prices, and the evaluation of prices (Diller 2000; Esch et al. 2006).

## **DEVELOPING AN OPTIMAL DISTRIBUTION STRATEGY**

Planning a company's distribution strategy involves all actions and decisions that need to be made to get the product to the customers. Establishing a distribution system takes several years, so it must be thoroughly planned as it cannot be changed abruptly (Esch et al. 2006). Distribution is an instrument of the marketing mix that is often underappreciated. But distribution is more than getting products to potential customers. A well-planned distribution strategy can support a brand's image and evokes certain associations in consumers' minds (Li Lam 2001). For example, luxury goods would no longer be strived for if they were obtainable everywhere. When planning their distribution strategy, marketers must decide on whether to sell their product directly or indirectly to the ultimate consumers, and whether their product should be distributed universally or selectively (Bowersox et al. 1980). Choosing a certain distribution strategy supports a company in addressing specific target groups and consistently communicating the positioning of the brand.

Companies that distribute their goods directly sell their products to the ultimate consumer without interposing any external distributors, like, for example, Avon with its salespeople or Body Shop with its own shops. Indirect distribution, on the other hand, takes place, if a distributor acts as an intermediary between company and ultimate consumer. Different kinds of indirect distribution exist on the market, which differ in the number of intermediaries involved. Supermarkets are often one-tier distribution systems, whereas pharmacies and florists are two-tier systems, consisting of retail and wholesale. A special form of indirect distribution is franchising, where a company's products are distributed by legally and economically independent firms, whose relationship to the producing firm is agreed by contract. The franchiser (e.g., McDonald's or Avis) provides the franchisee with procurement, retailing, and organization concepts against the payment of hires and shares of the franchisee's sales.

One of the major *disadvantages of intermediaries* is the producer's loss of control, i.e., how the products are presented in the stores. As the company does not have direct contact with the users of the product, it becomes harder to get information about their satisfaction with it. On the other hand, by using intermediaries, their distributor's competencies and know-how of selling can be used, so that these tasks can be done more efficiently and more economically. From the consumers' point of view intermediaries lead to more convenience. Stores where products of different brands and firms are sold make it easier for consumers to compare price and quality of the different products. Furthermore, if all brands contacted their potential customers directly, their information overload would be even higher (Coughlan et al. 2001).

Beside the number of tiers of the distribution system, marketers must decide on their selection of intermediaries. Companies can either distribute their goods universally or selectively. By choosing universal distribution, marketers pursue the target of their product being obtainable everywhere. It depends on the retailers whether they list the company's products in their stores. This strategy is used especially for basic and everyday necessities. Furthermore, universal distribution is also favorable for goods with a low purchase risk and products that are often bought spontaneously. For these products it is important that consumers are often confronted with them.

If a producer carefully chooses the intermediaries that fit with their brand and their customers, the company follows a "selective distribution strategy." Selection criteria, among others, are the size and business situation of the retailer, the quantity of units ordered, and the retailer's service quality and promotion activities. For "exclusive distribution" the selection criteria are even stricter. This special case of selective distribution is prevalently paired with exclusive licenses in trading areas. Additionally, the cooperation is closer and conditions are well defined.

By distributing a product only via handpicked retailers, marketers try to ensure that the intermediaries do not oppose the company's or the brand's image. Moreover, although this approach secures the product's presence on the market, it also ensures that it does not have the image of an ordinary, commonplace product.

To meet consumers' benefits effectively and, therefore, to succeed in the market, marketers must not look at the instruments of the marketing mix as isolated tools. Quite the contrary; it is the interaction and orchestration of these instruments that make the company thrive. For instance, strong brands with a unique positioning are often distributed exclusively. In these exclusive stores, these products are available at a premium price. Besides, customers are attended to most attentively. They are offered additional services and are contacted regularly after their purchase. If marketers appropriately align all instruments of the marketing mix, the basis of the product's success in the market is laid out.

## **Marketing: Communication Tools**

*Richard Alan Nelson*

*Louisiana State University*

For the sponsoring organization, the role of marketing communications includes distributing information, promoting image and reputation, creating and stabilizing product and service demand, emphasizing features and benefits, providing competitive differentiation, generating sales leads, ensuring customer retention and loyalty, and motivating staff. To accomplish these and other objectives, there are many marketing communication tools available. They include advertising, direct marketing and relationship marketing, sponsorship, event marketing, sales promotion, public relations, and other, alternative strategies. Contemporary media are the most commonly utilized “vehicles” to get the message out, including print, broadcast, outdoor, digital, direct, online, and other technologies. Historically, markets were largely places one could barter or trade commodities with another individual. Amazingly, Ancient Egypt survived for thousands of years without money, the structure of their society being based on provisions for the workers in return for support of the ruling dynasty and religious temples. Only later did specie or currency come into existence as a commonly accepted and convenient measure of utility or wealth – most evident during the relatively peaceful years of the Roman Empire now called the Pax Romana. European society in post-Roman times largely devolved into feudalism, under which workers were restricted from travel and tied to the land. Industrialism was a significant change because it broke the choke-hold of localism, bringing with it the expansion of the middle class as an important market. Barter still existed, of course, but residents of emerging cities now labored for money rather than products. Those that made or controlled products could sell more distantly, over time creating intermediaries (such as wholesalers, distributors, and retailers). The growth of river and oceanic trade, development of canals, construction of railroads, and other improvements contributed to more capitalistic societies.

The promulgation of literacy, invention of the telegraph, and automation of printing presses for mass production of → newspapers and → magazines (followed by later media such as film, → radio, and → television) also facilitated the evolution of the marketing process. Increased production also meant that manufacturers needed to differentiate their offerings from competitors by literally → branding shipping boxes and commodities. According to David Ogilvy, famous advertising copywriter and ad agency founder, a

brand's personality and reputation are "an amalgam of many things." These include "its name, its packaging, its price, the style of its advertising, and, above all, the nature of the product itself" (Ogilvy 1983, 14). A brand also includes intangibles such as the images, words, and qualities that people associate with the organization or product.

Linked with branding is the rise of advertising agencies in the mid-nineteenth century. Their emergence reflected the need for better promotion as new competitors entered the marketplace, forging a system of collaboration between business and media that continues up to the present (→ Advertising; Advertising, History of).

Public relations developed in the early twentieth century in support of business interests (→ Public Relations). Facing regulation because of the excesses of monopolistic trusts, corporate leaders recognized they needed to communicate their story to an enlarged middle class of educated consumer voters (→ Mediatization of Society). The necessity to persuade as well as inform became the dominant model (→ Advertising as Persuasion; Persuasion). In a business context, most advertising and public relations responsibilities appear on organizational charts under a → marketing or → corporate communication title (→ Organizational Communication).

Marketing as we know it is thus a relatively recent phenomenon. The classic 4-Ps of the marketing mix refer to the product, pricing, place (distribution), and promotion policies that guide an organization's sales effort. Marketing communications falls under the rubric of promotion, or the strategic effort by the seller to build contact with potential and existing customers (→ Strategic Communication). Businesses use promotion as a means of informing customers about product(s) and attracting customers to buy from them.

## **MARKETING COMMUNICATION**

Marketing communication involves the ongoing process of relationship building with target audiences on all matters that affect marketing and business performance. Targeted are those groups of people an organization needs to communicate with in order to meet goals and objectives. In this sense, marketing communication is a continuous dialogue between an institution, its → brand(s), and consumers (→ Consumer Culture).

Market research is a key part of the marketing planning process, which involves a business determining who the users and potential users are, knowing who else has influence over sale of their products and services, and finding out what these groups want and expect. After a creative strategy is crafted, media research subsequently decides which communication vehicles are most appropriate given the available budget, followed by evaluation of their effectiveness (→ Advertisement Campaign Management; Advertising Effectiveness; Advertising Effectiveness, Measurement of; Advertising Frequency and Timing; Advertising Strategies; Media Effects; Media Planning).

A number of marketing communications options are available that help companies build and maintain audience, increase market share and market awareness, acquire new business, and build more fruitful relationships with existing clients. While nonprofit organizations may have different goals, the process is essentially the same. In addition to advertising and public relations, marketing communication tools also include publicity, direct marketing, sponsorships, organizational/corporate communications, personal selling, promotional products, sales promotions, and Internet word-of-mouth or grassroots

marketing efforts. Although in some instances, one medium may be appropriate to reach a niche audience, marketing communications most often involves utilization of a variety of media to disseminate a chosen message (→ Cross-Media Marketing). Making management decisions about how to effectively marshal resources and select the appropriate media mix is not an easy responsibility. Given problems with message clutter and oversaturation, many traditional forms of advertising and promotion (such as broadcast and print) are losing ground to newer media.

Proponents of → integrated marketing communications (IMC) stress that a company's promotional activities should speak with a single voice to increase synergy. In other words, all marketing communications should consistently work together to project a unified brand image across all points of customer contact. This would seem to be common sense. In practice, however, the results of IMC programs have proven mixed.

### **Advertising**

Understanding the content and pervasive influence of advertising in the modern world remains an important task since, for better or worse, advertising is an integral and influential part of our lives. The advertising process encompasses the consumer domains of (1) *industrial technology*, from which issues an endless flow of new products; (2) → *popular culture*, into which are embedded applied psychological appeals and conventions through which socialization occurs; and (3) *the media*, which unify the flow of symbols, images, and motivational messages that audiences choose to “decode” from what they see or hear.

Advertising is a planned communication activity that utilizes controlled messages carried by the media to persuade audiences. Any form of nonpersonal one-way communication about products, ideas, goods, or services paid for by an identified sponsor can be grouped under the advertising umbrella. Typically advertisements are self-contained, although the growth of product placement (in which a brand is incorporated into a broadcast or film storyline) indicates marketers are embracing alternative strategies.

All advertising is subject to → censorship. However, most advertisements aimed at potential buyers – unlike conventional news releases issued by public relations firms – are generally not edited or changed by media gatekeepers; before they reach their intended target audience (→ Gatekeeping). Mass and niche media include *print* – magazines, newspapers, brochures, flyers, outdoor ads, direct mail, Yellow Pages; *broadcast and film* – radio, television, cable, satellite, product placement; *new technologies* – Internet, mobile phone, podcasting; and *other alternative media* – promotional products, skywriting, etc.

Advertising commonly dramatizes companies and their products, building brand image. Psychologically, research indicates that consumers tend to perceive advertised goods as more legitimate. Another key advantage is that advertising typically reaches large, geographically dispersed audiences, often with high frequency (→ Segmentation of the Advertising Audience). Although overall costs are high, advertising rates can be low per exposure.

### **Public Relations (PR)**

Reflecting the fragmented nature of the many components that comprise what is loosely referred to as the practice of “public relations,” there are numerous widely promoted

definitions outlining the operating philosophy and set of techniques used to integrate organizations and the people they depend upon. Among the best is that of Denny Griswold, founder of *Public Relations News*, who stated that public relations is “the management function which evaluates public attitudes, identifies the policies and procedures of an individual or organization with the public interest, and plans and executes a program of action [incorporating communication] to earn public understanding and acceptance” (Griswold & Griswold 1948, cited in Seitel 1995, 7; → Public Relations Planning).

In practice, public relations is most associated with maintaining good relationships with the company’s various publics by obtaining favorable publicity, promoting a good “corporate image,” and effectively minimizing unfavorable rumors, stories, and events. Since public relations appears in many forms (as news reports, sponsored events, etc.), it tends to be highly credible with audiences and reaches many prospects missed via other forms of promotion. Despite being cost-effective (certainly not “free” as many people think), public relations is often the most underused element in the promotional mix (→ Public Relations: Media Influence).

Conceptualizing the process of public relations has led to many theories of public communication. Some researchers stress the role of public relations in determining whether it primarily involves management counseling or technician-oriented communications. The most influential theory in recent years has been the “four management models” approach, first devised by James E. Grunig and Todd Hunt in their book *Managing public relations* (1984) and subsequently elaborated on. Using a systems theory approach, they analyzed the organizational structures and communications strategies most widely used by practitioners to derive the following categories: *one-way press agency model*, emphasizing the generation of favorable publicity in the mass media (→ Media Relations); *one-way public information model*, stressing more journalistic dissemination of relatively objective information through controlled media (brochures, newsletters, direct mail) as well as mass communication vehicles; *two-way asymmetrical or → propaganda model*, involving greater use of social science research so the organization becomes better at persuasion; *two-way symmetrical or conflict resolution model*, engaging in caring, research-based dialogue to establish mutually beneficial partnerships with strategic publics. This last approach is the only one in which the negative implications of manipulation are minimized.

Connected with this four-part outline has been the notion that each model represents an ethical stage in the evolution of public relations, from primitive to advanced. However, scholars recently have begun to dispute this Darwinistic assumption.

## Publicity

Publicity messages are conveyed to the public through the mass media, but unlike advertising are not paid for by the organization. Publicity is a component of public relations linked to press agency – heavy-handed (but shrewd) efforts to promote clients. Often publicists resort to hype (bombastic hoopla and oversell) to promote their clients. Normally, this commercial communication is designed to bring about positive coverage or “ink.” Sometimes, however, backdoor disinformation strategies are utilized to attack opponents and force them into the spotlight of unfavorable publicity.

### **Direct Marketing**

Any communication to carefully targeted individual consumers designed to generate an immediate commercial response is direct marketing (i.e., an order, request for information, or sales visit). Direct communicators want not only to obtain on-the-spot feedback but also to cultivate lasting customer relationships. To do this, they maintain their own databases of current and prospective customers, or rent lists of prospective buyers identified by demographic and psychographic lifestyle profiles from firms specializing in such information (→ Psychology in Communication Processes). All direct-response advertising is structured around three basic elements: (1) the message communicates a definite offer; (2) the recipient is given the information necessary to make a decision; and (3) the ad makes it easy to say “yes” immediately by including one or more response devices (a coupon, free telephone number, preaddressed order form, envelope, bounce-back card, etc.). Infomercials are one of the most popular direct-response television formats (→ Direct-to-Consumer Advertising).

### **Sponsorships**

Event sponsorship in which a business is linked to a popular sporting event is what most people think of when discussing sponsorships. However, the practice is much more widespread. Sponsorships are defined as payment (in fees, goods, or services) in return for the rights to a public association with another organization and/or event (naming rights, onsite banners, cross-advertising, etc.). Cause-related marketing (or cause branding) is another strategic sponsorship approach, connecting a company or brand to a relevant social cause or issue for mutual benefit. When this is done well, the corporations and the social causes they support both emerge with a “win-win” experience (→ Social Marketing). For the company it is a way of reinforcing loyalty, building reputation, enhancing its image of → corporate social responsibility, and increasing market share or sales. For the social cause or issue, having access to corporate resources contributes to prompting public awareness and engendering support. In total, US companies spent an estimated \$1.34 billion on cause-related marketing sponsorships in 2006, a 20.7 percent increase over 2005.

### **Personal Selling**

Most businesses have a sales force whose members make personal presentations to persuade a prospective customer to commit to buying a good, a service, or even an idea. The seller generally interprets brand features in terms of buyer benefits, and the salesperson can be critical when the number of potential customers is limited and the product is technical and/or expensive. The common stereotype of a sales practitioner is that of a pushy, annoying individual. In reality, many customers value direct contact and find salespersons helpful in meeting on-the-job challenges. Rather than being order-takers, most effective salespersons often provide consultative services that establish a relationship, and concentrate on the buyer’s needs. A key advantage of such person-to-person communication is that the receiver is more attentive, with the potential buyer providing immediate feedback through words, expressions, and gestures. Such relationship-

oriented interaction allows for adjustments in the sales approach. Personal selling is a very effective investment for building buyers' preferences, convictions, and actions (including loyalty). However, maintaining a sales force represents a long-term commitment and is thus among the most expensive of the promotional tools.

### **Promotional Products**

Promotional products are now an \$18.8 billion industry in the US. According to the Promotional Products Association International, promotional products comprise an advertising, sales promotion, publicity, and motivational communication medium that displays the sponsoring organization's name, logo, or message on useful articles of merchandise. The imprinted products, called "adcentives" when given away free, or "premiums" when recipients have to make a purchase or contribution before receiving the item, are often personalized to better target those people who are most important to the marketer. Four major business groupings make up the specialty advertising and promotional products industry: suppliers; distributors; direct-selling houses; and trade organizations. There are literally tens of thousands of different types and styles of promotional products. Examples of common promotional products include apparel, writing instruments, calendars, drinkware, and many other items. Popular programs cited most often by industry consultants are business gifts, employee relations, orientation programs, corporate communications, and presence at tradeshow to generate booth traffic. They are also effective for attracting new customers or new accounts, in dealer/distribution programs, co-op programs, nonprofit fundraising, public awareness campaigns, and for promotion of brand awareness and brand loyalty. Other uses include employee incentive programs, new product or service introductions, and marketing research for survey and focus group participants.

There has been a debate on whether promotional products constitute advertising or sales promotion. Actually, such items can be both and more simultaneously. For example, consider the person who occasionally drinks a particular brand of soda and, responding to a sales promotion campaign, receives a T-shirt complete with commercial art message. He or she wears the shirt when out with friends, providing more exposure for the brand. Additionally, according to research in psychology, the consumer's positive attitude toward the brand will be strengthened as a result of publicly wearing the shirt. Regardless of the advertising or sales promotion labels, promotional products have the potential of providing high impact to a tightly targeted market niche. They can also deliver long-term advertising value beyond short-term sales promotion objectives. The key to success in such endeavors is in matching the adcentive-based elements to the interests of the audience segment – that is, targeting true prospects rather than suspects.

### **Sales Promotions**

Sales promotions are defined by the American Marketing Association as those activities other than personal selling, advertising, and publicity that stimulate consumer purchasing. Sales promotions are typically short-term field marketing and merchandising incentives to encourage purchase or sale of a product or service. Examples of point-of-sale and business sales promotion vehicles include contests, coupons, rebates, refund offers,

sweepstakes, etc. One advantage of sales promotions is that they may be targeted at the trade or ultimate consumer. By effectively attracting attention, sales promotions offer strong purchase incentives, stimulate quick response, and boost sagging sales. The downside is that such efforts are short-lived, and have not been proven effective at building long-term brand preferences.

### **Internet Word-of-Mouth and Grassroots Marketing Efforts**

Word-of-mouth has long been recognized as the most effective form of communication. The problem has been how to stimulate branded product conversation. The potentially huge number of viewers who can take action is one attraction of → Internet campaigning. A well-placed link on a popular website, or passed from friend to friend, may generate millions of page “hits” very quickly. The impact of Facebook, YouTube, and other web locations has caught the attention of major marketers. By tapping into these “virtual communities” on the Internet – individuals who share common identification – companies are finding they can mobilize interest through “viral marketing” techniques (→ Internet, Technology of). In a way analogous to the quick progression of an epidemic, viral marketers seek to exploit pre-existing social networks to produce exponential increases in brand awareness. By identifying opinion leaders in a market segment and providing them with special incentives, sponsors are also creating “buzz” within target groups. Marketers typically incorporate edgy humor and a mix of pop culture references to catch the user’s attention and build interest, especially among younger demographics. Music and compelling visual images that are already “part of the conversation” help convey their message. From a grassroots marketing perspective, embracing brand “co-creation” means that marketers invite consumer sub-cultures to help shape a brand’s persona, ideology, use, and persona. The more involved consumers become with a branded product as part of their “grassroots” lifestyle, the greater the likelihood they tell others about their experience (→ Grassroots Media).

Although email marketing has been subject to widespread abuse, it remains a powerful communication tool. Rich email (graphically designed email that is forwardable and trackable) is among the new Internet-based technologies for → e-commerce. Evidence indicates rich email achieves higher receipt and response rates and the tracking information results in useful lead generation. Really simple syndication (RSS) blogging technologies make it easy to create an online journal. More corporations are especially using blogs by their executives, helping personalize the firm and establishing thought leadership in a market. Voice-casting platforms empower business clients to support their sales and marketing campaigns through a personalized audio message that is then narrowcast to thousands of business-to-business phone numbers. Other tools are coming online all the time.

### **FUTURE DEVELOPMENTS**

The accelerating changes we see in communication technologies are evidence of a fundamental shift in society as a whole. Many commentators argue we are at a historical turning point similar to that which marked the introduction of movable type in Europe and the rise of industrialism. No one is yet sure what “globalism” really means in terms of the way we live or how we conduct business. Shifts that give consumers greater control

over messages they pay attention to are definitely changing the notion of the marketplace. Combined with the erosion of older models of how media deliver audiences, these developments are temporarily causing consternation among many marketers who are still groping to find what works. Given past performance, they are likely to be successful.

# Markets of the Media

*Benjamin J. Bates*

*University of Tennessee*

Markets are where media function. They also provide the foundation of economic analyses, providing the context and mechanisms for explaining and predicting media and audience behaviors. Economists define markets broadly as any context in which goods and services are offered and purchased. Markets are thus defined by a set of goods or services, the set of firms and individuals that offer them for trade (supply), and the set of firms and individuals that seek to acquire them (demand, or in media terms, audiences). The context of markets includes their scope (reach) and a variety of structural features, including the particular attributes of media technologies and organizations, their products, and their distribution systems. Law and policy often play a role in defining markets, by influencing or even defining some of those structural features and costs.

Being able to define media markets, and to understand how particular markets function, is critical to understanding, explaining, and predicting media operations. Being able to discern and predict shifts in markets and consider their implications is similarly critical to media survival in an increasingly competitive environment (→ Media Economics).

## MARKETS IN ECONOMICS

### Defining Markets

Markets are at the heart of economic theory and analysis, where supply and demand functions interact to determine market outcomes. Supply functions are defined in terms of the willingness of producers to offer goods at various prices. Similarly, demand functions are defined by the willingness of consumers to purchase products at various prices. A critical first step in looking at markets is to clearly define them. There are various ways to define or characterize economic markets.

Markets can be *defined in terms of the good*, defining supply as those offering the good, demand as those interested in acquiring the good, and the market scope delimited by the ability to actually engage in the exchange. Where goods are highly differentiated, as in many media markets, the market is more appropriately defined by the range of close substitutes. Substitutes are defined as products that consumers see as potential alternatives, and might choose to consume in lieu of the primary good. For example, one could define a market by a specific good, say copies of today's edition of a specific newspaper. Or one could define the market as all newspapers available locally, or in terms of media outlets offering current news, depending on how close a substitute is being considered.

Markets can be *defined geographically*, by the area in which the product is distributed, and made available for acquisition. This can delimit those considered as viable suppliers and consumers for a particular product. For some media, like broadcasting, this can be determined in large part by policy, through licensing and designation of technical standards. For others, like cable, it can be constrained by licensing and the area covered

by the physical distribution networks (→ Cable Television; Radio Broadcasting, Regulation of; Television Broadcasting, Regulation of). For other media, market scope is more flexible, and can be influenced as producers search for audience and the costs of reaching various potential market areas change over time.

Markets can also be somewhat *defined in terms of various barriers to entry*, on both the supply and demand sides (→ Supply and Demand in Media Markets). Conditions may exist where some potential suppliers or demanders are unable to participate in the market, restricting the scope of the particular market. Barriers can exist in the form of high costs of entry, in terms of the lack of access to required skills or complementary products (as with the → digital divide), or through law and policy limitations (such as limiting the availability of required licenses, as in broadcasting, cable, and telephony). In most cases, markets are defined by some combination of product range and geography. In some cases these are heavily influenced by regulatory actions and various entry barriers.

### Market Operations

Once defined, market operations can be addressed. Market operations, and the behaviors of those on the supply and demand sides, are considered largely through the interaction of supply and demand curves. Defining the market delimits whose supply or demand functions get aggregated. At that point, structural factors that may affect valuation (and thus supply and demand curves), or can directly influence the movement of supply or demand curves, need to be considered.

A number of factors can impact on valuation. *Incomplete information* about the product and its potential utility (a common issue with media and information goods) can create uncertainty and reduce perceived value. Law and policy can influence value by adding costs through mandates or taxation, or can reduce them through various forms of subsidy. The presence of substitutes or complements can influence valuation and impact on supply and demand shifts. Substitutes provide alternative outlets for satisfying demand, and can moderate the reaction of demand curves to price changes. Complements refer to other goods whose use and value are linked to the primary product. They include situations where use of one good requires use of others, or where use of one affects the perceived value of others. Changes in one market have ripple effects in supply and demand for complementary goods.

*General market structure* can influence market behaviors by providing differing potentials to influence supply or demand. Four basic types of market structures have been identified: perfect competition, oligopolistic, monopolistic, and monopolistic competition. These structures differ primarily in the degree to which each provides a degree of market power (the ability to influence prices) to suppliers or consumers. A perfectly competitive market is defined as one where an undifferentiated good is offered by a large number of suppliers to a large number of potential consumers, with no barriers to entry. In the absence of market power, market equilibrium determines prices, theoretically at a socially optimum level. Markets are rarely perfect, though, so it is more typical to think in terms of competitive markets, defined as situations where neither potential suppliers nor potential consumers have any meaningful ability to influence supply and/or demand curves (and thus prices) in the long run.

The other three structures vary in terms of the *degree and source of market power*. Market power permits some control over prices in order to extract any consumer surplus in the market. This is generally seen as socially harmful, and has widely resulted in a range of → antitrust regulations that attempt to limit the application of monopoly power. In a *monopolistic market*, there is a single supplier (or purchaser) of the good. Being a single source allows the monopolist a high potential for market power through its ability to control supply or demand. *Oligopolistic structures* exist when a few sources dominate supply or demand. Their contribution to market supply or demand is large enough that their decisions influence (although do not completely determine) market levels, giving them a degree of market power. Oligopolistic structures also facilitate collusion, as the major players know one another and their actions. Collusion can increase the potential for market power. Monopolistic competition occurs when sources of supply or demand can sufficiently differentiate their product to the point where they can carve out a sub-market that exhibits monopolistic or oligopolistic structures. This gives them market power within the sub-market, although it is moderated by the larger market.

Market power is also influenced by the presence of substitutes and complements. The presence of substitutes moderates the ability to benefit from controlling prices, as price shifts lead to greater demand shifts and reduce the ability to capture surplus value. This is the main source of the moderating power of the wider market in monopolistic competition. This can focus on shifting values (consuming a book may impact on the likelihood of seeing a movie based on that book), or when the ability to acquire and use some product is based on having certain other pre-existing skills or products (watching TV requires access to a television set and electrical power).

Still, being able to adequately describe markets and the range of factors that can affect supply, demand, and their interaction over time can provide a foundation for explaining and predicting market behaviors, and the impacts of changes in market factors.

## MARKETS OF THE MEDIA

Media produce products, and interact in markets with those who desire those products. From a media perspective, the main products of interest are the media goods – the → newspapers, → books, movies, and broadcast programming (→ Radio; Television). Media markets were, in that sense, widely identified by those products and the geographic area in which a set of products was made available. The attendant distribution system thus contributed to defining geographic boundaries by constraining the ability to get the offered goods to potential consumers. The scope of many markets emerged as tradeoffs between maximizing potential reach and the costs of producing and distributing media goods and services. Economies of scale play an important role in determining efficient or viable reach, and thus market size. For other media, market definitions were effectively imposed by limits of technological design and standards, or through law and policy. Potential audiences, and thus demand, were identified largely in terms of that geographical area.

### Characteristics of Media Goods and Services

This helped to identify media markets as being largely synonymous with media. In fact, and in practice, identifying markets of the media and using them to examine media

behaviors are much more complicated. Some of the problem emerges from the particular characteristics of media goods and services. First, *media goods and services almost always have complements*. Some require acquisition of specific skills or equipment before they can be consumed. For example, print media require a degree of literacy, and DVDs require both a player and a display device, both of which also require access to, and consumption of, electrical power. Further, consumption of media products takes time, a limited and costly resource (→ Audience; Audience Research). The presence of complements can limit markets, but more critically from the perspective of examining market operations, it means that supply and demand curves are influenced by conditions in the markets for those complementary goods and services.

Media goods and services also tend to be *highly differentiated and innovative*. While helping to continue demand over time, this also means that there tend to be a number of potential substitutes, and a fairly high level of uncertainty about value of specific goods. Media goods also tend to exhibit a *degree of perishability*, where the value of the product declines over time, or with multiple uses. Finally, media products tend to exhibit certain characteristics associated with → public goods, particularly *nonexcludability and nonrivalrous consumption*. Nonexcludability refers to the situation where it is difficult to exclude those who do not pay from consuming the product, and nonrivalrous consumption refers to products where use by one consumer does not greatly affect the ability of others to use it.

In addition, the use of information products can have *impacts outside of the particular market*. When these impacts are not considered in the individual supply and demand functions, they create externalities that can impact on considerations of broader social efficiency. When products exhibit some or all of these characteristics, it can make it difficult for the markets to operate efficiently, and to achieve “optimal” solutions. Aspects of market structure, such as the presence of monopoly power or barriers to entry, can also contribute to sub-optimal solutions. Concerns about media concentration and conglomeration are based on arguments that they tend to increase the potential for exercising monopoly power, resulting in less than socially optimal markets (→ Concentration in Media Systems; Media Conglomerates).

### Market Failures in Media Markets

As media goods and markets tend to exhibit many of these characteristics, media markets are often perceived as exhibiting “market failure.” Market failure in this sense does not indicate that markets do not work; rather, it is an economic concept that suggests that the market may fail to achieve what are considered socially optimum outcomes. This does contribute to concerns about the broader social impact of market operations and whether media markets provide the proper supply and mix of information goods and services. Perceived market failure also provides a rationale for using law and policy to “correct” apparent market failures, even though law and policy often contribute to the factors causing the “failure” (→ Media Policy).

To illustrate, → copyright and intellectual property policy are a reaction to one set of market failures (the public good characteristics; → Intellectual Property Law). The solution, though, is the creation of monopoly rights and the granting of monopoly power to the owner of those rights, which happens to create a different kind of market failure, of possibly greater consequence (Lessig 2004).

Additionally, media confound things by *operating in multiple markets*. Media often can be said to operate in multiple product markets, and media products can often be marketed to different sets of potential consumers. Broadcasters and newspapers, for example, use their basic media good (the paper or signal) as an intermediate good in two very distinctive markets. In the audience market, the firm uses the information content of their good to attract the attention of audiences, who compensate the firm through some combination of their time and attention, and fees paid to access the content. The media firm then takes the audience's time and attention, and offers it to those who seek to communicate with the audience. Different groups may seek access to that audience, and to the extent that the various groups exhibit different demand characteristics, they may constitute separate markets (→ Audience Commodity; Cost and Revenue Structures in the Media). For example, broadcasters and newspapers often differentiate between local and national sales markets for advertisements, while others seek access through provision of press releases and other content. In addition, broadcasters and newspapers also operate in the market for content, producing some, acquiring others through various markets. Finally, media incorporate distribution networks, which in some cases can also be used to distribute other goods and services, providing another potential market.

The audience good and its markets display many of the same basic characteristics of the markets for media goods and services. There is uncertainty in terms of actual audiences reached, substitutions galore in → audience segmentations, and the variety of media options available for those who seek to reach audiences. Motivations for demand may be commercial, or the seeking of social or political influence. In either case, there are clear externalities. While having much of the same potential for market failure, efforts to regulate audience markets in western states have been moderated by concerns about possibly infringing on freedom of information.

*Media markets are complex*, often comprising multiple affiliated markets, and are marked by a broad range of competing influences driven by the presence of substitutes, complements and externalities, market structures, and regulatory policies. This has restricted the ability to fully articulate markets of the media, and thus to be able to understand and predict market behaviors and results. This is likely one reason for the apparent inability of some communication law and policy to achieve their stated goals. If policymakers do not understand the full market, efforts to correct perceived market failures can contribute to further market distortions, aggravating rather than solving conditions. Complexity and uncertainty have also made it more difficult to predict the impacts of changing market conditions, such as can be brought on by new technologies, convergence, increased competition, and so on.

### **EMERGING MARKET ISSUES**

The growing convergence of media markets and the growth of cross-media marketing also contribute to the growing complexity of media markets, expanding the range of substitutes and blurring market boundaries (→ Convergence of Media Systems). Contributing to this is shift in audience focus from media to content, further blurring (or converging) media markets from the demand perspective. The growing complexity, flexibility, and uncertainty of media markets led Lacey (2004) to suggest the embrace of at least a degree of uncertainty through the concept of “fuzzy markets.”

*Technological innovation*, particularly in the fields of digital technology and telecommunications, is starting to transform markets of the media. It is contributing to convergence, reducing old market boundaries and barriers. It is leading to the rise of new media forms and content, and new distribution systems (→ Digitization and Media Convergence; Technology and Communication). It is expanding market boundaries, and reducing distribution costs, creating global markets. In the → Internet, there is the potential for the emergence of a global market that is radically different from traditional media structures, and offers a number of advantages over them. At the very least, this emerging market for media and information goods and services will provide strong competition. The inherent cost structures are such that they have the potential to transform how value is associated with products, and possibly radically transform supply and demand functions, leading to new ways of thinking about market functions.

A final emerging issue comes from *current trends in copyright and intellectual property law*. Current policy focus tends to be on extending rights, and protecting against unauthorized uses through enhanced legal protections and penalties and the use of technological protection measures. Such activities add costs to media products, and can impact on their perceived value, shifting supply and demand functions and distorting markets. In general, the impact is negative, suggesting reduced use of media, which will also impact on audience markets. The cost of technological protection measures can significantly impact on distribution costs, even to the point of affecting economic viability. Current copyright and intellectual property policy is focused on content creators and owners; it needs also to consider the broader impact on markets and society.

## Masculinity and the Media

*John Beynon*

*University of Glamorgan*

The focus of this entry is upon representations of masculinity in one medium only, television, while making it evident that the approach adopted could be applied equally well to newspapers, magazines, radio, and film (→ Television as Popular Culture).

Three broad phases can be identified in the evolution of *televsual masculinities*, a term coined to reflect the breakup of the *stereotypical masculine narrative* over the past three decades (→ Sex Role Stereotypes in the Media). It acknowledges that masculinity is far from monolithic and uniform but is rather composed of a number of “masculinities,” of ways of “doing” masculinity. Another factor that should be borne in mind at the outset is the massive growth today in the amount and variety of television (including the current development of Internet-delivered television) increasingly available to viewers throughout the developed world. What Creeber (2006) aptly terms “tele-visions” are a barometer of social and cultural change, and any assumption that the medium today remains male-dominated (or its representations of masculinity unchanged) should be treated with considerable caution. Finally, reference below is made to many programs that, although originating in the US or Britain, have subsequently been dubbed and exported and have thereby contributed to the emergence of an embryonic global media culture (→ Globalization of the Media).

### PHASE 1: WHEN MEN WERE MEN AND WOMEN WERE WOMEN

From the mid-1950s up to the late 1970s, the depiction of gender on British, European, and American television was highly stereotypical. “Real men” were inevitably presented as dominant, rational, and competent, whereas their antithesis (that is, desirable, compliant, irrational, domesticated women) featured mostly in comedies and soap operas. In fact, male displays of any feminine characteristics were rare and occasions for comedy.

Unsurprisingly, second wave feminists mounted a trenchant critique of television from the mid-1960s on, accusing it of playing a major role in the continuing denigration of women by constantly depicting them as weak and overdependent upon men (→ Sexism in the Media). A dominant *male gaze*, they claimed, pervaded both the production and consumption of television. Yet a little over a decade later, Hearn and Melechi (1992, 231) confidently pointed to television’s key role in “assisting the fragmentation of (traditional) masculinity.”

## PHASE 2: A WEAKENING OF THE MASCULINITY MOLD

Throughout the 1970s, western popular culture gradually eroded the still relatively intact *masculine paradigm*, so much so that it has been described as a decade marked by “a desire to play about with masculinity” (Mort 1996, 203). Television continued as a major vehicle for this throughout the 1980s, as narrow stereotypes were challenged and more dramas with central female protagonists appeared on both sides of the Atlantic, as, for example, in *Juliet Bravo*, *Silent Witness*, *Cagney & Lacey* and *The Gentle Touch*. Male leads increasingly combined toughness with a degree of sensitivity, even vulnerability (as in *Inspector Morse*), while female ones became less reliant on men. The change was particularly noticeable in television advertisements and where masculinity could be most readily reshaped and men lampooned as comically incompetent. Meanwhile, displays of male bonding and *homosocial buddy relationships*, accompanied by a degree of emotional disclosure, grew in popularity on prime-time television, perhaps best epitomized by the US series *Starsky & Hutch*. Elsewhere, in other popular series (like, for example, *thirty something*), male friendships become even closer and ambiguous.

Men, too, were becoming increasingly fashion conscious: *Miami Vice* was a prime example of the male incorporation of the pleasures of appearance and style, albeit without any real diminution of masculine power. MacKinnon (2003, 82) sees 1980s American television as characterized by the conflict between *old and new masculinities*: for example, if the *A-Team* was a post-Vietnam reconstruction of the masculine, *thirty something* promoted a softer and more sensitive (and middle-class) masculinity more appealing to women. At the same time, conventional masculinity was increasingly being held up to ridicule in what Hanke (1998) terms “mock macho sitcoms.”

It is undeniable that by the late 1980s the former mask of cyborgian toughness and emotional reticence had been lowered, if not finally discarded, as *macho masculinity* increasingly began to be viewed more as a handicap than as a strength. During the 1990s, rigid gender stereotypes were further eroded in such series as *Buffy the Vampire Slayer*, *Friends*, *Absolutely Fabulous*, and *Sex in the City*. Moreover, ridiculing pompous men had become an increasingly popular format in situation comedy since the 1960s. In the UK, examples include the character Alf Garnett (*Till Death Us Do Part*), Captain Mainwaring (*Dad's Army*), Del Boy (*Only Fools and Horses*), Basil Fawlty (*Fawlty Towers*), and the latest in line, David Brent (*The Office*). Brent daily bullied and humiliated his workforce, but was really a vain, sexist, egotistical, and ultimately ludicrous figure. In such characters, the veneer of control and authority is soon undermined by their absurd actions and the consequences that follow: in short, they are to be laughed at more than laughed with. Meanwhile, another way of rendering (particularly young) men absurd from the 1990s has been through the depiction of *laddish masculinity* in, for example, *Men Behaving Badly*, *Fantasy Football League*, and *They Think It's All Over*.

As is evident, then, throughout the 1980s and 1990s, television undoubtedly made a significant contribution to the deconstructing and repackaging of masculinity. Indeed, Gauntlett (2002) is of the opinion that modern media have a more complex view of gender and sexuality than ever before. He identifies a number of programs that he feels were particularly influential in transforming gender representations over this period, among them *Ally McBeal*, *Buffy the Vampire Slayer*, *NYPD Blue*, *Friends*, *Frasier*, *ER*,

*Dawson's Creek*, and *The West Wing*. Meanwhile, in the groundbreaking UK police series *Prime Suspect*, a woman (Detective Chief Inspector Jane Tennison) eventually triumphed over the *masculinist culture* in which she worked.

### PHASE 3: POSTMODERN TELEVISION

In the contemporary, postmodern era, there is not only more television than ever before but also a proliferation of programs with less structured formats (→ Postmodernism and Communication). An increasing number of televisual texts resist semantic closure, being less linear and more ambiguous than previously and demonstrating what Creeber (2006) terms “semiotic excess” and “inter-determinacy” (an apt example is the recent US series *Lost*).

If structuralism was inclined to prescribe meaning, poststructural textual analysis stresses the polysemic and open nature of such rich visual and auditory texts (→ Structuralism in Visual Communication). The widening portrayal of gender they convey is, however, more and more driven by a rapacious (and increasingly globalizing) → *celebrity culture* that manufactures dreams and sells “stars,” and in which consumerist imagery is everything (Holmes & Redmond 2006).

### REAL OR COSMETIC CHANGE?

It is quite clear that representations of gender on television have changed considerably over the past 50 years (→ Gender: Representation in the Media) in that a far wider range of masculinities (and femininities) has today replaced the earlier relatively uniform and stereotypical representations of masculinity (and femininity). Indeed, what Connell (1987) describes as “*hegemonic masculinity*” is now held by many to have multiple coexisting, rather than subordinated, versions. However, there are at least two interpretations of the nature of such changes.

The first is that masculinity on television today in the west has been largely stripped of its hegemony and is more open to alternative representations. Gill (2007) is the latest to record the increasing fragmentation and proliferation of masculinities and of their representations. Meanwhile, Gauntlett (2002, 7) argues that television today is “full of information about being a man in the here and now,” mirroring postmodern times in which gender is more unstable than ever before. Similarly, Creeber (2006, 54) sees television attempting to “play around with, subvert, ridicule, investigate, resist and even transcend *traditional male heterosexual ideologies*.” Soaps everywhere (from *Coronation Street* to *EastEnders* to the once ultra-macho Brazilian telenovelas) have widened the array of masculinities they parade before their audience.

The second interpretation is that whatever changes may have taken place are misleading in that all that has really happened is that a new set of stereotypes have been brought into play, and that “underneath what appear to be radically different images of women and men are some very familiar, very traditional themes” (Wood 2003, 262). A good illustration of this in the 1990s is the previously cited British police drama series *Prime Suspect*, where the lead character, DCI Jane Tennison, repeatedly draws upon her feminism to survive the police canteen culture (Creeber 2004). However, in order to earn credibility, she has to adopt many of the attributes of her misogynistic colleagues. Brunson

(1998, 234) argues that as a result *Prime Suspect* still preserves the basic ingredients of the conventional masculine narrative in that Tennison, in order to succeed, is forced to become “fully integrated into the language of the lads.” Likewise, McQueen (2001) maintains that British situation comedy is still largely dominated by men, while Mills (2005, 111) goes even further, claiming that “television humor has been largely co-opted as a male trait.” In similar vein, MacKinnon (2003) argues that surface changes should not blind us to what remains constant, in that representations of men as soft, sensitive, and caring can ultimately function to reinforce male privilege. Another factor to bear in mind is that while the production process may well have resulted in more diverse and open texts, the ethnographic evidence on television reception is that consumption patterns still remain strongly gendered (with men generally opting to watch factual programs, documentaries, sport, and high-action dramas).

Perhaps the ultimate litmus test of how open television is to actual, as opposed to cosmetic, change is how it portrays *gay masculinity* (→ Gay, Lesbian, Bisexual, and Transgender Media Studies; Heterosexism and the Media). Does it adequately reflect the shifts in attitude in the west toward homosexuality over the past three decades? Many argue that television lags behind in that gay men are still crudely stereotyped. An early, groundbreaking camp figure on British television was Mr. Humphries in *Are You Being Served?* His legacy has endured, a notable recent descendant being Dafydd (“the only gay in the village”) in the successful BBC comedy series *Little Britain*. Mills (2005, 126) points out that the gradual growth in gay characters on television “has done nothing to undermine the recurring use of campness as an indicator of homosexuality.”

While comedy is one of the few places on television where homosexuality even has a presence, its representation continues to be limited, with campness still to the fore, so much so that “in British comedy campness is funny, not homosexuality: the latter hardly exists” (Mills 2005, 125). Mills illustrates his argument by reference to two sitcoms, both featuring James Dreyfus. In the first series (*The Thin Blue Line*), an attempt is made to disentangle homosexuality and campness. Constable Goody is heterosexual, but camp, whereas in Dreyfus’s follow-up series (*Gimme, Gimme, Gimme*) he played an openly gay character by drawing heavily upon the camp stereotype. If the former series contradicted (even confused) viewers’ expectations, the latter confirmed them, leading Mills (2005) to conclude that gay characters continue to be caught in a rigid representational trap.

To conclude, it is claimed that increasingly gender-literate television writers and directors are more prepared than ever to experiment with nontraditional and subversive representations of gender. Many would like to see television become more proactively involved in promoting masculinities firmly based on personal qualities and quality relationships rather than upon physical power, action, achievement, and possessions. While Bignell and Lacey (2005, 6) argue that television has the potential to articulate “radical defamiliarizations of familiar sights, sounds, ideas, places and moments,” others would regard this as somewhat utopian and, instead, be more inclined to conclude that as a medium it continues to reflect, rather than instigate, meaningful and enduring social change.

## **Mask**

*Kathy Foley*

*University of California, Santa Cruz*

A mask is a facial representation worn by performers and exists in a continuum with puppetry, which often represents the same characters (Harlequin, Punch, Devil, etc.; → Visual Representation). Emigh (1996, 3, 7) theorizes masks as “transitional objects” that bridge gaps through strategies of play and argues that though in the west the mask is “generally regarded as a cosmetic disguise,” in some non-western areas the mask is “an instrument of revelation, giving form to the ineffable and providing a nexus between the individual and communally defined forces.”

In social, ritual, and theatrical masking, the mask is a “liminal” in Turner’s (1969) sense of the word, doing things the face cannot. Masking normally involves an animal/

humanoid head representing a human, animal, ancestral, divine, or demonic figure. In social use the mask is often seen as hiding the reality of the animator underneath, and this mask is most customary in western usage in the post-Renaissance period. In this mode of thinking the mask is conceived of as a “trick” or “lie.” However, in ritual and theatrical use in Asia, Africa, and Oceania, the mask is often seen as a tool meant to reveal an ideal that the material world masks. It represents a hidden and greater “truth.”

The mask transforms the face, helping the wearer signify grotesque, animalistic behavior or inspiring awe. *Social uses of the mask* invite freedom from everyday decorum. We see masks used in rites of reversal, which may range from the medieval festivals of fools to the modern carnival or Halloween mask. The mask of the devil, animal, ghoul, or clown on the common man eases everyday constraints. Authority is disrupted, sexual and animal behaviors exalted, and death and destruction are put temporarily at bay by the anonymity of the carnival mask. The *Fastnachtspiele* of Germany or the English Whitsunday appearances of horses, phallic clowns, and cross-dressed men are European models. By temporarily reversing social mores these aberrations may reinforce the non-holiday hegemonies of class and culture (→ Cultural Studies). These “safety-valve” uses of the mask may allow the lower-status person (commoner, child, woman) to put on the mask to critique the higher-status one (aristocrat, adult, male). Half masks allow verbal critique. Full masks may invite the mime of sex and mayhem. Mask may also enforce social hierarchy through awe. Male secret societies have sometimes used masks this way. The *duk-duk* dancers of New Guinea were members of secret societies who wore cone-like masks to visit those who defied the mores of the group. Ku Klux Klan hoods seem an American variant of such a masked society (→ Socialization by the Media). In such examples, only the initiated (insider males) can wear the mask; audiences (women, children, outsiders) remain passive observers of the power of the image (→ Media Events and Pseudo-Events).

As *ritual use* the mask is popular in shamanic traditions: altering the performer, it allows the viewer to visualize the spirit, illness, or ancestor for whom the shaman/medium temporarily speaks. The *thovil* exorcist of Sri Lanka dances 18 demons/masks of disease in his healing rites, diagnosing the “devil” which beset the patient. The elaborate costumes of the *teyyam* trancer of India transform the spirit medium, who then is possessed by the god. Representations of ancestral or totem figures allow groups from northwest America; north, south, and southeast Asia; Melanesia; and Africa to commune with animal or spirit worlds, for social cohesion, ceremony, or healing (→ Media and Group Representations). The mask visually “others” the performer, making it useful in ritual performance (→ Rituals in Popular Communication). Even when groups abandon shamanic beliefs, traditional masks linger. Lion dances continue in Buddhist cultures without the exorcising power they once held. Alligator and reptilian figures (*naga*) remain important from India and China through the Pacific. Deer and horned masks are associated with helpful fertility in Scandinavian, Khmer, and southwest American (Yaqui Indian) celebrations. Horned masks with their phallic associations in Christian Europe, however, became linked with devils. Ritual trickster types, which may have color imagery of dark and light or white, appear in both the theatres and village ceremonies of south and southeast Asia. Their iconography and coloring may link to both traditional puppet clowns of Europe and the *commedia dell'arte* (→ Iconography).

The transformative possibility of the mask has made it a *useful theatre device*, allowing an actor to play multiple roles (→ Theatre). The use of masks is strong in theatres that prefer a solo artist. The *dalang* (puppet-master or masker) of Java and Bali is traditionally conceptualized as a solo performer (though in contemporary times multiple performers are the norm). The five major masks of the *topeng Cirebon* of the north coast of Java represent the five directions (the cardinal points and the center), the five ages of man, the five elements (earth, fire, water, air, ether), etc. Voice, movement, character traits, etc., are associated with each mask. Dances allow the individual performer to understand the correlations between the microcosm (*dalang*) and the macrocosm. Though the performances of the present are theatrical rather than ritual, ideas of a solo artist using diverse masks to portray a story remain strong where Hinduism and Buddhism have migrated (→ Religion and Popular Communication). Indonesian *topeng* (mask) theatre, Japanese *noh*, Korean *talchum*, and Thai *khon* are important mask theatres where mask dancers use multiple masks to tell culturally central stories. The mask image, not the physicality of the performer, defines the character. One performer presents many characters via the mask image.

Greek theatre found masks similarly useful, allowing three actors to play multiple roles. The stylized expression could be “read” over the distance of the amphitheater. Grotesque masks were used in Greek and Roman comedy and the *commedia dell’arte* of the fifteenth to seventeenth centuries favored masks for clowns and old men, while the more realistic ladies and lovers were unmasked. The wart-marked, pug-nosed Harlequino and the sharp-nosed, jowl-cheeked merchant Pantalone dominated the stages of Europe before realistic tastes unmasked them in the 1800s. These characters have sparked other explorations of mask work in the acting training of twentieth-century western teachers like Jacques Lecoq (France) and Carlo Mazzone-Clementi (Italy). But a preference for faces correlates with the current western orientation toward secularism and realism. Theatre masks can represent demons, gods, and animals. They are useful for letting us see ourselves as better or worse than in real life, and work well with music, dance, and poetic flights (→ Art as Communication). Masks make the wearer appear bigger and rougher, or thinner and more refined. But when the aesthetic involves individual psychology, everyday speech, and representation of the real world, the actor’s face and not the mask may be more appropriate (→ Entertainment Content and Reality Perception).

## McLuhan, Marshall

Joshua Meyrowitz

University of New Hampshire

Marshall McLuhan is best known for his theories on the impact of media apart from the specific content/messages they convey. McLuhan linked major historical shifts, social trends, and changes in psychological and sensory orientations to the influence of changes in communication media and other technologies (→ Technology and Communication; Media History). McLuhan ridiculed typical concerns about message imitation and persuasion in his most famous pun: “The medium is the message.”

Herbert Marshall McLuhan was born in Edmonton, Alberta in 1911 to a Scottish-Irish Baptist family. He earned degrees at the University of Manitoba and Cambridge University. He converted to Catholicism in 1937. His early training and lifelong passion were in English literature. But in trying to bridge the gap he perceived between himself and his students at his first US teaching job at the University of Wisconsin, he turned his attention to pop culture. His first book, *The mechanical bride* (1951), was on the content of advertising, a message-based approach he later rejected in favor of studying media environments. McLuhan began teaching at the University of Toronto in 1946 and founded the Centre for Culture and Technology there in 1963. He died in Toronto in 1980.

At the University of Toronto, McLuhan was influenced by the work of political economist → Harold Innis, who argued that communication media have a major impact on societies by shaping patterns of information flow. Yet, while Innis was very concerned with issues of media monopolies and political power and control, McLuhan focused more on the ways in which new media experiences lead to perceptual shifts, such as a changing ratio of the senses. Citing Innis’s work in a proposal to the Ford Foundation, McLuhan and anthropologist Edmund Carpenter used part of the resulting grant to publish *Explorations* (1953–1959), an eclectic journal concerned with changes in media.

In 1962, McLuhan published *The Gutenberg galaxy: The making of typographic man*, which describes the ways in which writing, and especially print, transformed oral cultures, encouraging linear thinking, categorization, and individualism. In 1964, he published his best-known book, *Understanding media: The extensions of man*. In it, he focused primarily on the shift from print culture to electronic culture, which he saw as entailing a “retribalization” of society. McLuhan did not envision (or desire) that books and printing would disappear, but he argued that print-encouraged forms of perception and social organization were in dramatic decline. *Understanding media* also defines “media” broadly to include inventions such as clothing, houses, money, and the automobile (→ Media).

McLuhan coined the phrase “the global village” to describe the ways in which electronic media involve people in each other’s experiences across vast distances, leading to new connections, but also to new forms of tension and violence. He explored *media as extensions* of human senses or processes (e.g., the wheel extends the foot, the microphone extends the ear, electronic media extend the nervous system) to describe how we can be transformed by our own creations. He described how different types of content and behavioral styles succeed in different media and how people react differently based on whether a medium is *hot* (high definition) or *cool* (low definition). In talks and articles in the 1970s, McLuhan developed a *tetrad* model (published posthumously as the 1988 book *Laws of the media*, co-authored by his son Eric) to describe a medium’s impact by answering four questions: What processes does the medium enhance? What does it retrieve from a deeper past? What does it reverse into when pushed to its limits? What does it obsolesce?

Late in his career, McLuhan became increasingly interested in the functions of the left and right brain hemispheres and how their differences related to forms of human expression, media, and art. In a tragic irony, a stroke a year before his death left him unable to read, speak, or write.

McLuhan’s skyrocketing fame in the 1960s was accompanied by withering *attacks from critics* that he was a charlatan. McLuhan’s fans saw him as an “oracle of the electronic age,” while his critics saw him as a dangerous denigrator of literacy, rationality, and other hallmarks of western civilization. The praise and condemnation often grew from the same foundations. McLuhan promulgated the notions of “media” and “information” in an era when books and other communication forms (such as radio, movies, and TV) were not generally grouped together as one sort of thing. McLuhan’s employed an unusual “oral,” nonlinear, aphoristic style of writing in presenting what he called “probes” about media, where being absolutely correct concerned him less than being insightfully provocative. Consistent with his theories about the influence of new media on the organization of knowledge, he also ignored the traditional boundaries of academic disciplines, to the delight of some and to the horror of many “experts.”

Citations of McLuhan’s work are filled with mischaracterizations of his theories by both fans and critics, some of whom believe incorrectly that McLuhan was advocating an end to literacy or presenting a utopian thesis of global harmony. McLuhan has been criticized more legitimately for downplaying issues of power, propaganda, and class conflicts. Many scholars have dismissed McLuhan for presenting an overly deterministic model of single-factor and unidirectional causation. But defenders of his work, such as Donna Flayhan and Paul Grosswiler, discern in it an underlying dialectical method.

McLuhan’s reputation declined significantly in the 1970s and 1980s, most of his books went out of print, and his name disappeared from the majority of media textbooks. A major revival of interest in his work occurred following the rise of the world wide web and the recognition of social changes that resemble what McLuhan had predicted. McLuhan is now seen as an early postmodernist theorist and a prime herald of the “information age” and “globalization” (→ Globalization of the Media; Postmodernism and Communication). McLuhan’s reputation is solid as a central figure in a larger interdisciplinary area of research called → Medium Theory.

## **Meaning**

*Klaus Bruhn Jensen*

*University of Copenhagen*

The title of a widely influential 1923 volume, *The meaning of meaning* (Ogden & Richards 1989), suggested the difficulty of capturing the complex connotations of the concept of meaning. The contents of the volume, authored by a linguist and a literary critic, with appendices by anthropologist Bronislaw Malinowski and medical doctor F. G. Crookshank, underscored the interdisciplinary roots and relevance of the concept. Meaning applies to issues of perception, cognition, and interaction across the natural, human, and social sciences. In contemporary communication research, meaning is perhaps most commonly associated with humanistic perspectives on the texts of communication and their interpretation by culturally specific audiences. If → *information* denotes a social scientific conception of those specific differences which communication makes in later events, *meaning* refers to the cumulative and unitary experience that humans derive from participating in processes of communication.

### **THREE CONCEPTIONS OF MEANING**

At least three different notions of meaning have fed into communication research from the history of ideas, paralleling three different understandings of human knowledge (Kjørup 2001, 20–22). First, in the domain of individual experience and existence, meaning implies a *saturated sense of self*. Meaning constitutes an identity, a presence, and an orientation toward other people and projects in the world (→ Identities and Discourse). In ordinary language, one connotation in this regard is “the meaning of life,” as articulated in human consciousness and communication, whether in religious or

secular terms. In different forms of communication research, meaning as experienced has been examined as a psychological, sociological, and aesthetic phenomenon. Notwithstanding suggestions by postmodernist philosophy that human subjectivity has no such center or self-identity (→ Postmodernism and Communication), everyday as well as scholarly practices normally presuppose a meaningful frame or horizon within which individuals understand “how to go on” (Wittgenstein 1958, no. 154).

Second, meaning is the outcome of innumerable communicative exchanges in a culture or collective, manifesting and being sanctioned through *tradition* (→ Culture: Definitions and Concepts). On the one hand, traditions are meaningful insofar as they tap classic or authoritative insights that have proven their relevance and value over time. On the other hand, traditions become meaningful in relation to the current contexts in which they lend themselves to tasks, interactions, and reflections. If the first conception of meaning is expressed in the Delphi oracle’s admonition to “Know thyself,” this second conception focuses attention on how individuals come to know themselves with reference to meanings beyond themselves.

Third, in the modern period, meaning has become an emphatically contested terrain – an object and a source of *reflexivity* (Beck et al. 1994). A terminology of “meaning production,” while sometimes used metaphorically, has also been applied literally to both cognition and communication: subjects produce meanings and, by extension, identities for themselves, and, in communication, they jointly accomplish meaningful social realities. Particularly constructivist strands in communication research, such as symbolic interactionism and cultural studies, have emphasized how everyday meaning production not merely reproduces, but also challenges and changes cultural conventions and social structures. In this perspective, meaning is a constitutive component of modern culture and society as such, and the category through which both can be reimagined, whether in political dialogue, aesthetic expression, or scientific thought-experiments.

### MEANING AS AN OBJECT OF COMMUNICATION RESEARCH

While all three general notions of meaning – individual–mental, collective–cultural, and contingent–constructivist – enter into diverse traditions of communication research across interpersonal, organizational, and systemic levels of analysis, each notion has lent itself to a variety of definitions. In the domain of individual experience, for example, a cognitivist approach would emphasize procedural aspects of how meaning emerges in consciousness (→ Cognitive Science), whereas a phenomenological position rather takes meaning as a preparatory condition of conscious experience (→ Phenomenology). As a manifestation of cultural tradition, meaning may be approached in relatively consensual terms as a shared outlook on the world and as a matter of interpretation between cultures, as in intercultural communication studies, or it may be perceived, as in cultural studies, as a hegemonic position to be contested. And in the perspective of the ongoing structuration of modern society and culture, meaning has been examined as a comparatively stable, if preliminary, meaning *product*, as embodied in discourse, or as a *process* orienting people in contexts of action.

As an analytical object, moreover, meaning has been operationalized in distinctive ways. Figure 1 indicates four ideal-typical ways of examining meaning (Jensen 2002, 30).

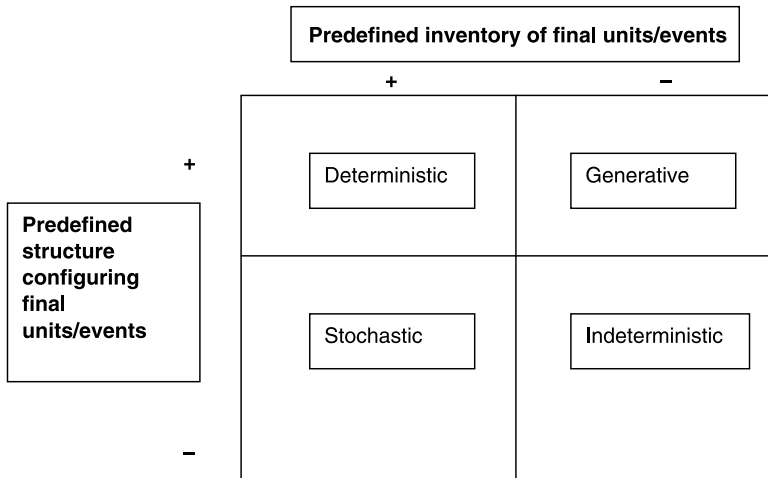

Figure 1 Four ways of examining meaning

The two dimensions of the model address the constituents of meaning and their interrelations, respectively. Meaning arises from the selection and combination of certain elements, even if their characteristics may vary considerably across different forms of expression; for instance, speech, images, and gestures. As a combinatorial structure, the two dimensions give rise to four types or models of meaning. On the one hand, the structure may, or may not, be a fixed matrix configuring the potential outcomes of meaning production. On the other hand, the constituents may, or may not, make up a pre-defined inventory anticipating the units that could possibly result from meaning production. In addition, the terminology of “units/events” allows for empirical research that operationalizes meanings as either vehicles or processes of interchange.

The two main models of meaning in current media and communication research, arguably, are the stochastic and generative types. The *stochastic* type is witnessed in the prototypical social scientific study in survey, experimental, or content-analytical settings, relying on a hypothetico-deductive methodology (→ Critical Rationalism). Given a pre-defined range of content or response units, the question is which of these, and in which configurations, will enter into a particular event space, as measured by an appropriate statistical technique. In other words, the question is when and where – in which discourses and minds – particular meaningful messages manifest themselves.

The *generative* type is associated with humanistic media studies, typically qualitative analyses of media texts, but also of audience reception and, to a degree, the production of media content, for example, in newsrooms or user-generated content on the Internet (→ Qualitative Methodology). These forms of analysis depart from a pre-defined expressive repertoire – what linguistics and literary theory know as a “deep structure,” for example, grammatical categories or standard components of fairy tales. At the “surface” level of concrete sentences or connected discourse, this matrix may produce an almost infinite variety of meanings (→ Structuralism).

Even while few researchers explicitly align themselves with either deterministic or indeterministic conceptions of meaning, such models continue to inform the practice of

research, sometimes unwittingly. Deterministic models tend to underlie work assuming a direct impact of media on audiences (e.g., Postman 1985). And postmodernist theory implies that both the textual content of media and its interpretation by audiences amount to free-floating, indeterministic processes of meaning (e.g., Fish 1979).

### WHERE AND WHEN IS MEANING?

Like information, meaning is often considered as some entity that resides in messages and minds. Rather than asking, “Where is meaning?” – in which spatial location, material vehicle, or psychological domain – it is helpful to ask, “When is meaning?” (Jensen 1991). Just as information theory has refocused attention on the (communicative) difference that (discursive) differences may make in later events, a theory of meaning must address those contexts and practices in which meaning is actualized. In accordance with much twentieth-century philosophy, from Ludwig Wittgenstein to J. L. Austin to Jürgen Habermas, meaning is increasingly associated with action. Whereas meaning may still primarily connote the representation and contemplation of reality, meaning is performative.

A further set of distinctions pertains to the interrelations between meaning and action. First of all, it is important to distinguish between *declarative* and *procedural* aspects of meaning as well as of knowledge (Thurlow 2006) – knowing *that* something is the case, and knowing *how* to engage this something (Ryle 1949). In empirical communication studies of, for example, attitudes, the declaration of a political preference does not equal an orientation toward action, as in voting. Communication is one way of acting, but people do not necessarily enact what they communicate.

In addition, the distinction between *manifest* and *latent* meaning poses notorious difficulties in communication research. The tradition of content analysis was founded on the identification of manifest meanings in media messages (Berelson 1952). Yet one ambition of media studies has been to extract the latent implications of such manifest structures and, next, to establish the uptake of both by audiences. Importantly, latent meanings, while sometimes difficult to ascertain in intersubjectively reliable research designs, are key to diverse cognitive and behavioral consequences of communication. The relationship between manifest and latent meanings has been studied extensively in qualitative communication research, frequently with reference to the concepts of *denotation* and *connotation*, which are conceptual analogies to manifest and latent meaning.

Finally, the scale from *intentional* to *incidental* meaning involves analytical problems regarding the “when” of meaning: when, specifically, does meaning arise in a process involving senders, messages, and receivers? A core notion of meaning, and of communication as such, is the presentation of intentions by humans to other humans, who may recognize such intentions in one or several turns. In social interaction, however, a communicator is rarely able to control any number of incidental (or perhaps latent) meanings that an audience will add or attribute to his or her intentional (usually manifest) meaning. More or less incidental meanings also abound in natural as well as cultural environments, for example in architecture, which is a socially meaningful organization of people and objects in space. In this regard, human bodies as well as

their material environments cannot *not* communicate (Watzlawick et al. 1967). The main challenge of communication research remains one of specifying how humans and their extensions in information technologies serve as media of meaning in communication.

## **Measurement Theory**

*Stephanie Lee Sargent Weaver*

*Emory University*

Thinking about measurement brings to mind an old adage, “If it exists, it is measurable.” However, in research, we tend to go beyond that adage, saying “If it exists, it must be measurable” (Leedy 1997). Most researchers will likely agree that measurement is a pillar of social and behavioral sciences research (Guilford 1954).

## WHAT IS MEASUREMENT?

Given this, what exactly is measurement? The things that come to mind when we think of measurement are rulers, yardsticks, and → scales, to name a few, but in research, measurement takes on a whole new meaning. Leedy (1997, 26) defines measurement as “limiting the data of any phenomenon – substantial or insubstantial – so that those data may be examined mathematically and according to an acceptable qualitative and quantitative standard.” Similarly, Babbie (2001, 199) views measurement as “careful, deliberate observations of the real world for the purpose of describing objects and events in terms of the attributes composing a variable.”

In other words, scientists make a deliberate decision to observe, are equally deliberate about what they will observe, take precautions against erroneous observations, and record their observations carefully as measurements. Ultimately, measurement is the process whereby a thing, concept, or object measured is *compared against a point of limitation*. For example, in the social and behavioral sciences, we frequently compare the results of research against statistical norms such as the normal curve, point of central tendency, and degree of dispersion for quantitative data, and across data sources, methods, and time for qualitative data (Leedy 1997). Measurement, therefore, is a tool by which data is inspected, analyzed, and interpreted so that the researcher may probe to discover or attribute meaning (→ Quantitative Methodology; Qualitative Methodology).

The fundamentals of measurement are quite simple: A researcher assigns numerals to objects, events, or properties according to systematic rules (Kerlinger 1986; Wimmer & Dominick 2003). Examples of measurement are everywhere: we turn on the television and see an advertisement for toothpaste with the slogan “9 out of 10 dentists recommend . . .” Sometimes measurements are numerical or quantitative, such as “students purchased sandwiches from the Sub Shop 2.4 times more than the previous month.” Other times they are qualitative, such as “the motorist expressed annoyance on being told the emergency road service closed at 5 p.m.” (Wimmer & Dominick 2003).

## CONCEPTS OF MEASUREMENT

In measurement, there are three central concepts: numerals, assignment, and rules (Katzer et al. 1998; Kerlinger 1986; Wimmer & Dominick 2003). *Numerals* are symbols such as S, 5, 10, or 100, and have no explicit quantitative meaning. When a numeral has been given quantitative meaning, it becomes a number and can be used in mathematical and statistical computations. *Assignment* is the designation of numerals or numbers to certain objects or events. An example of a simple measurement system would be to assign the numeral 1 to the people who obtain most of their news from television, the numeral 2 to those who get most of their news from a newspaper, and the numeral 3 to those who receive most of their news from the Internet. *Rules* specify the way that numerals or numbers are to be assigned. Rules are the foundation of any measurement system, so if the rules are faulty the measurement system will be faulty too. For some research studies, the rules often seem to be obvious (i.e., a stopwatch and standardized message may be sufficient to measure reading speed). In other research studies the rules may not be

apparent. For example, before a researcher can measure “enjoyment of televised sports” or “attitude toward violence,” he or she must articulate thoughtful measurement techniques.

### MEASUREMENT AND “REALITY” ISOMORPHISM

In addition, measurement systems also strive to be isomorphic to reality. Basically, isomorphism means identity or similarity of form or structure (Kerlinger 1986; Wimmer & Dominick 2003). To strive for isomorphism, researchers must define the sets of objects being measured and the numerical sets from which we assign numerals to those objects, and check that the rules of assignment or correspondence are tied to “reality.” To assess isomorphism to reality, researchers ask the question “Is this set of objects isomorphic to that set of objects?” In the physical sciences, for example, isomorphism is not a problem, because there is usually a direct relationship between the objects being measured and the numbers assigned to them: if an electric current travels through a substance with less resistance than it does through a different substance, it can be concluded that the first substance is a better conductor than the second. Additionally, testing more substances can lead to a ranking of conductors, where the numbers assigned indicate the degrees of conductivity. In this example, the measurement system is isomorphic to reality (Wimmer & Dominick 2003).

In the social sciences, this assessment is not as clear cut or obvious. For example, researchers must ask the question “Do the measurement procedures being used have some rational and empirical correspondence with ‘reality?’” (Kerlinger 1986). The ultimate question that must be asked is “Is the measurement procedure isomorphic to reality?” The only problem is that we rarely discover easily the degree of correspondence to reality of our measurements. Unfortunately, many researchers often do not know whether they are measuring what they are trying to measure. Even so, researchers must find a way to test the isomorphism with reality of the measurement numbers game they play.

### LEVELS OF MEASUREMENT

In 1946, Stevens suggested a hierarchy of levels for the measurement of data that has become a classic of categorization for statisticians and researchers. Stevens suggested four levels, or types, of measurement, which he called (1) nominal, (2) ordinal, (3) interval, and (4) ratio.

The word *nominal* comes from the Latin *nomen* meaning “a name.” Thus, we can measure data by assigning names to them. In other words, by assigning a specific name to a concept or object, we have restricted that thing to the meaning of its name (Leedy 1997). Nominal measurement is the weakest form of measurement and identifies variables whose values have no mathematical interpretation. Examples of nominal-level measurement are gender, ethnicity, occupation, religious affiliation, social security number, license plates, and so on. They must be mutually exclusive (only check one) and exhaustive (everyone can be classified into a category).

In the *ordinal scale* of measurement, we think in terms of the symbols  $>$  (greater than) or  $<$  (less than). The ordinal scale implies that the entity being measured is quantified in terms of being of a higher or lower or a greater or lesser order than a comparative entity. In measuring on the ordinal scale, the relationship is always asymmetrical. For example, something is always greater than, less than, older than, younger than, more intelligent than, more desirable than, more tactful than, etc. (Babbie 2001; Leedy 1997; Wimmer & Dominick 2003). In other words, the numbers assigned to cases specify only the order of the cases, allowing for greater than/less than distinctions. Examples of ordinal-level measurement are a student's academic level, and socio-economic status.

The *interval scale* of measurement is characterized by two features: (1) it has equal units of measurement, and (2) its zero point has been established arbitrarily (Leedy 1997). Thus, it includes the characteristics of the nominal and ordinal scales, and in addition the numbers indicating the values of a variable represent fixed measurement units. In the interval-level measurement there is no absolute or fixed zero point. The most familiar example of interval-level measurement is temperature: in both the Fahrenheit (F) and Celsius (C) scales, each degree is equal to the others and the zero point has been established arbitrarily. For instance, it takes the same amount of heat to warm an object from  $30^{\circ}$  to  $40^{\circ}$  as from  $50^{\circ}$  to  $60^{\circ}$ . Also, since heat does not begin at  $0^{\circ}$  on the Fahrenheit scale,  $60^{\circ}$  is not twice as hot as  $30^{\circ}$ . A common use of interval measurement is in the rating scales employed by many businesses, survey groups, and professional organizations.

The highest level of measurement is the *ratio scale*. Ratio measurement is also the measurement ideal of the research scientist. It possesses the characteristics of the nominal, ordinal, and interval scales, and in addition it has an absolute or natural zero point that has empirical meaning (Leedy 1997). If a measurement is zero on a ratio scale, then we can say that the object in question has none of the property being measured. Since there is an absolute or natural zero point, all arithmetic operations are possible, such as multiplication and division, and the numbers on the scale indicate the actual amounts of the property being measured. For example, if a ratio scale of achievement existed, then we could say that a student with a score of 8 had an achievement level twice as great as a student with a score of 4. Other examples of ratio level measurement include driving speed, weight, hours of coursework completed, age, and the balance in your checking account.

Interestingly, Senders (1958, 51) has summarized the four levels of measurement in the following test for various kinds of data measurement. If you can say that: one object is different from another, you have a nominal scale; one object is bigger or better or more of anything than another, you have an ordinal scale; one object is so many units (degrees, inches) more than another, you have an interval scale; one object is so many times as big or bright or tall or heavy as another, you have a ratio scale.

Taken together, we see that measurement is crucial to any research project. Without good measurement, we have faulty research. Measurement involves the assignment of numerals to objects and concepts according to rules. Then researchers decide the appropriate level of measurement and also assess whether the measurement procedure is isomorphic to reality. To be useful, a measurement must be both valid and reliable. Measurements begin with observations, but these raw materials must often be refined and clarified.

## **Media**

*Klaus Bruhn Jensen*

*University of Copenhagen*

The term media refers broadly to the range of *tools* that humans have used throughout history to communicate with each other about a shared reality. The most common reference is to the set of modern *technologies* – from the printing press to the Internet – which facilitate communication across space, time, and social collectives.

### **HISTORY OF THE MEDIA CONCEPT**

The *Oxford English Dictionary Online* (OED) (accessed January 5, 2006) notes that while classical Latin *medium* referred to some middle entity or state, in postclassical Latin and in British sources from the twelfth century onward, medium and media also came to denote the *means* of doing something. On the one hand, a medium could be understood as a more or less incidental presence, linking natural phenomena of this world and some metaphysical realm. On the other hand, a medium can serve as an intentional instrument of human action in a modern sense. In the latter respect, the OED distinguishes two conceptions – medium as an artistic modality, material, or technique; and medium as a channel of mass communication – both of them from the mid-nineteenth century. This was the period when a general idea of communication took hold (Peters 1999), partly in response to new technological means of communication with important social and

aesthetic implications, from telegraph and telephone, to film, radio and, later, television (→ Communication: History of the Idea). It was not until the 1960s, however, that media came into general use as a term covering diverse technologies and institutions, most commonly in the sense of mass media, communicating from one center to a mass of dispersed and anonymous receivers.

By the mid-twentieth century, medium in the sense of “any physical material (as tape, disk, paper, etc.) used for recording or reproducing data, images, or sound” (OED) also had become common, as represented by digital media with diverse input and output options. In the course of the 1990s and into the twenty-first century, the terminology of *mass media* increasingly was replaced by one of *media*, in everyday as well as research contexts, this time in response to more differentiated digital media. The shift was registered in the naming of one of the main international communication associations – the IAMCR. Founded in 1957, at a time when the “old” mass media, with television at the forefront, were consolidating themselves as social institutions, it originally was known as the International Association for *Mass Communication Research*. As of 1996, it came to be called the International Association for *Media and Communication Research*. In the intervening period since the 1950s, when the field of media and communication research has been taking shape (→ Communication as a Field and Discipline), three main concepts of media have informed theory development and empirical work.

### THREE DISCIPLINARY ROOTS

Each media concept implies a particular understanding of the basic communication model of sender, message, and receiver. The first concept, articulated in *Lasswell's paradigm* (Lasswell 1948) – who says what, in which channel, to whom, with what effect – approached the medium as a neutral conduit for the dissemination of information of all kinds. In order to assess the effects and implications of a given medium, such as a newspaper or a radio station, scholars might focus their attention on the strategies of the sender, the selectivity of the communicated message, the reach of the medium in question, or the susceptibility of the receivers to particular ideas. A great deal of subsequent work has questioned Lasswell's focus on separate stages of communication, as associated with separate forms of media analysis. In fairness, Lasswell further emphasized the function of media as mechanisms of surveillance at a macro-level (→ Lasswell, Harold D.). Media are means of monitoring a society as well as its surroundings with a view to self-protection, self-regulation, and long-term stability. In this regard, media can be understood in social scientific terms as a particular set of *institutions* in society.

The second variant was stated in the *mathematical theory of communication*. Its basis was Claude Shannon's research and development regarding the physical and technological conditions for the transfer of signals in telephone systems. A number of the insights were presented in a joint publication with Warren Weaver (Shannon & Weaver 1949), and it was this volume that influenced a good deal of theory development on media. In fact, Shannon was addressing the material aspects of how to design a communication system. In its popularized form, however, the underlying model of engineering was applied to humans as a description of social interaction. Although such applications have regularly been criticized as metaphorical and imprecise, the model has remained an important part

of the heritage of communication theory. This may be due, in part, to the obvious point that media are concrete vehicles whose affordances and constraints condition their potential role in human communication. The attempt to account for media as *material technologies* with social implications has continued to occupy communication researchers (→ Technology and Communication).

The third concept derives from humanistic perspectives on media as aesthetic means of expression and as carriers of cultural and historical meaning. Rooted in centuries of rhetorical and hermeneutic scholarship, this *discursive media concept* received an influential formulation in Roman Jakobson's (1960) model of communication (→ Discourse). While carrying an outward resemblance to the models of Lasswell and Shannon and Weaver, Jakobson's model grew out of literary theory, highlighting the various communicative functions of different linguistic and aesthetic choices by authors. Jakobson further made a distinction between the *channel* (what he termed *contact* – the material relation, such as book, newspaper, or Internet) and the *code* (the modalities or forms of expression, such as speech, writing, music, moving images, etc.). Compared to both Lasswell and Shannon and Weaver, however, Jakobson stayed entirely within the boundaries of the text or message, calling for an immanent analysis of how communicative functions manifest themselves in concrete textual structures, and bracketing the social contexts and uses of, for instance, literature or advertising. Much humanistic scholarship, accordingly, has approached media as forms of expression that are externalized and available for study in the form of *discourses*.

### AN INTERDISCIPLINARY CONCEPT

Particularly since the 1980s, much media research has been characterized by efforts at combining and integrating these concepts as dimensions within some form of theoretical systematic. A common position is that all three perspectives are necessary, and none of them sufficient, for a scientifically valid and socially relevant field of media studies. Interdisciplinary research and debate has explored not least the relationship between social sciences (media as institutions) and humanities (media as discourses) (for overview, see Jensen 2002b). Until recently, there appears to have been relatively less theory development devoted specifically to the interrelations between media as material technologies and media as institutions and discourses – despite the wealth of research on new media technologies as well as a growing interest in the distinctive affordances of different media technologies and their historical uses. Digitization has provided an impetus for reconsidering how, concretely, the materiality of media shapes, and is shaped by, culture and society (→ Digital Media, History of).

The individual media can be understood as characteristic configurations of the human potential for communication at a given historical time. These configurations are organized along three dimensions – materials, modalities, and institutions – as identified in the three conceptions of a medium.

#### Materials

Media are physical materials which – in a particular cultural shape – enable forms of communication that previously had not been possible. Sound recordings, from the late

1800s, made possible the preservation of parts of the cultural heritage that until then had disappeared into the air. From the 1910s, recorded sound became mobile with the introduction of portable gramophones. And, from 1979, media users wearing a Walkman were able to create soundscapes that were at once mobile and private.

### Modalities

It is through specific forms of expression and experience that media enable human communication – language, music, moving images, etc. These modalities, on the one hand, are grounded biologically in the human senses. On the other hand, modalities have been subject to millennia of differentiation and cultivation. In modern media technologies, the modalities have entered into shifting and evolving genres – from novels and radio serials, to music videos and virtual worlds (→ Modality and Multimodality).

### Institutions

Media, finally, constitute distinctive institutions in society: through media, individuals and collectives can describe and reflect upon themselves as well as the rest of society. Media and other social institutions have jointly reproduced each other under changing technological and cultural circumstances (→ Medium Theory). Print and electronic media extended cultures in space and sustained nation-states over time; nation-states and international treaties regulate the legal limits of public communication and the economic bases of each new medium. Television, for example, was developed as a consumer good for the home, financed by advertising or license fees, even though the material technology might have been framed socially on the model of cinema as a public or community activity.

In comparison with other meaningful cultural artifacts and social arrangements – from interior decorating to business transactions – the media that constitute the objects of analysis in media and communication research, are distinguished by their *programmability*, being uniquely flexible resources for the articulation of information and communicative interaction as part of an ongoing social structuration (Giddens 1984).

Whereas programmability is most commonly associated with the various levels of the digital computer, other communication platforms also lend themselves to combinatorial configurations. First, the *modalities* of media amount to semiotic registers of language, music, images, etc., allowing for an immense repertoire of genres and discourses, and engaging the human senses in selective and culturally conventional ways. Thus, media make possible the rendering of and interaction with worlds past and present, real and imagined. Second, the *technologies* of media provide the material substratum of such representations, not as fixed conduits, but as resources for accomplishing particular social and aesthetic ends. Third, media communicate to, about, and on behalf of social *institutions*, which, again, are shaped and reshaped through communication. As combinatorial systems, media and societies can be said to mutually program each other – a notion that, for example, systems theory has elaborated and formalized (→ Systems Theory). The degrees of freedom that condition this entire process, in three dimensions, help to account for the relative indetermination of the structures and outcomes of

mediated communication, and continue to challenge research on the question of what difference the media make.

### MEDIA OF THREE DEGREES

The coming of digital media has stimulated renewed research interest in the duality of mediated and nonmediated communication. For one thing, ordinary human conversation, while nonmediated by *technologies*, is mediated by aural–oral *modalities*, in addition to body language, broadly speaking. For another thing, computer-mediated communication – email, chat, online gaming – often carries a stronger resemblance to interpersonal than to mass communication. In order to assess the implications of digital media as emerging social and cultural *institutions*, much ongoing work has begun to address the interrelations between different media types (Bolter & Grusin 1999; Manovich 2001; Lievrouw & Livingstone 2002). One explanatory framework would distinguish between media of three degrees (Jensen 2002a).

*Media of the first degree* can be defined as the biologically based, socially formed resources that enable humans to articulate an understanding of reality, for a particular purpose, and to engage in communication about it with others. The central example is verbal language, or speech, as constitutive of oral cultures and subcultures – additional examples include song and other musical expression, dance, drama, painting, and creative arts generally, often relying on mechanical techniques such as musical instruments and artistic or writing utensils as necessary elements. Importantly, such media depend on the presence of the human body in local time–space. While one might identify (spoken) language, or the human voice, as the medium, it is helpful to differentiate between, for instance, speech and song as media with reference to their different modalities, sharing the same material substratum, but commonly addressing different social institutions, contexts, and practices.

*Media of the second degree* come under the classic definition by Walter Benjamin (1936/1977) of the technically reproduced and enhanced forms of representation and interaction which support communication across space and time, irrespective of the presence and number of participants. Whereas Benjamin emphasized photography, film, and radio, media of the second degree range from early modern examples, including the standardized reproduction of religious and political texts by the printing press, to television and video. The common features are, first, one-to-one reproduction, storage, and presentation of a particular content and, second, radically extended possibilities for dissemination across time and space. These technologies had important consequences for major social institutions – from the breakup of the Catholic church to the rise of the nation-state. Also, modalities from media of the first degree were refashioned. In radio talk shows, conversation took on new conventions, just as acting styles were adapted from the theater stage to cinema and television.

It is debatable whether manuscripts, which fix speech, drawing, music, and other human communication in a stable format, should be considered a separate media category, partly in view of their epochal significance. In historical perspective, Meyrowitz (1994, 54) suggested that its comparatively inefficient forms of reproduction and distribution made handwriting a transitional cultural form. For a systematics of media,

and from the perspective of media and communication research as a field, it can be argued that the production of manuscripts, like other media of the first degree, is embodied and local, laborious and error-prone; that their distribution is commonly selective rather than public, within established institutions, as supported by oral commentary; and that the constitutive role of handwriting in the reproduction of cultural tradition and social institutions has been taken over by media of the second degree.

*Media of the third degree* are the digitally processed forms of representation and interaction. Digital technology enables reproduction and recombination of all media of the second degree on a single platform: computers, thus, can be understood as meta-media (Kay & Goldberg 1977/1999). The central current example is the networked personal computer, although this interface, like that of mobile telephones, is likely to change substantially as technologies are adapted further to the human senses, and integrated into both common objects and social arrangements. Whereas classic mass media, such as illustrated magazines and television, combined modalities to a considerable degree, the scale and speed with which digitalization facilitates their incorporation and reconfiguration suggests that digital media may represent a qualitative shift from media of the second degree that is comparable to the shift from first-degree to second-degree media. The media types have not replaced each other – they recirculate the forms and contents of shifting cultural traditions in social contexts (→ Intermediality; Remediation). They do, however, offer distinctive and ascending degrees of programmability in terms of adaptable technologies, differentiated modalities, and institutions transcending time, space, and social collectives.

### THE DOUBLE HERMENEUTICS OF MEDIA

The development both of the concept of media and of media studies indicates that media are understood in historical context. The modern, general concept of communication was, in part, a response to nineteenth-century analog technologies (Peters 1999); current debates about the concept of media may be a response to twentieth-century digital technologies. This interplay of social and conceptual changes has been called a double hermeneutics (Giddens 1984): changing social realities challenge research to deliver new interpretations and explanations – which, in turn, may change society, for example, through the design and regulation of media.

## Media Advocacy in Health Communication

Lori Dorfman

Berkeley Media Studies Group

Media advocacy is the strategic use of mass media to support community organizing and to advance public policy that improves health (→ Health Communication; Strategic Communication). The purpose of media advocacy is to put pressure on policymakers by setting the agenda and shaping debate to include policy solutions in news coverage of health issues. Media advocacy equips people to become active in the political process of making change.

Media advocacy grew from a collaboration of public health groups working on tobacco and alcohol with → public interest and consumer advocates in the 1980s. The public interest and consumer groups brought strategies and tactics that were more common in political campaigns than in public health efforts. The public health perspective provided a solid basis in science and theory for creating change. The result has been an approach that blends science, politics, and advocacy to advance public health goals.

Rather than intervene at the personal level to change behavior, media advocates practice at the political level to change policy. Media advocacy relies on theories and research from fields such as political science, social psychology, and mass communications, such as

agenda setting and framing (→ Agenda-Setting Effects; Framing Effects). This research is applied in the context of community organizing, coalition building, and policy advocacy.

Media advocacy campaigns progress through *four layers of strategy*. First is *overall strategy*, a plan for environmental change. Advocates develop the overall strategy by determining: What is the problem? What is the solution or policy? Who has the power to make the necessary change? Who can be mobilized to put pressure on the primary target(s)? The “target” for media advocacy will be a policymaker or a body (such as a city council) that has decision-making power. This is a different strategy than is used in most health communication campaigns, where the focus is on individual change.

Second, the *media strategy* uses mass media to direct attention to the policies that can reshape systems, institutions, and environments. Many public health communications campaigns are based on the idea that poor health outcomes result from a lack of information or motivation; media strategies are then devised to fill the “information gap” or “motivation gap” (→ Knowledge Gap Effects). Media advocacy focuses on the “power gap,” viewing health problems as arising from people’s lack of power to create change in the broader systems and environments that influence health. Media advocacy strategies are designed to increase community participation in the policy process.

Third, the *message strategy* links public health problems to inequities in social arrangements rather than to flaws in the individual. Media advocates refer to this as “framing for content” because they attempt to create news stories with content reflecting the importance of using policy to improve health environments. Framing for content is a formidable challenge for media advocates because research on the news suggests that public health issues are rarely portrayed in ways that illustrate the underlying causes of problems or their potential policy solutions. Health stories, like other news, often obscure factors outside of individual choice. This is in part because most news is framed episodically, like a portrait, focused on people or events, rather than as a landscape, focused on the context surrounding people and events (→ Framing of the News). About 80 percent of → television news and well over half of newspaper stories are framed this way. Consequently, the news usually reinforces values of individualism and personal responsibility rather than the core value of public health, collective obligation to the social good. This pattern in news is important to media advocates because it means that routinely they will have to reframe news stories from portraits to landscapes so public debate can focus on the policies and institutions that shape the circumstances determining people’s health.

Finally, the *access strategy* aims to garner news and editorial attention. Media advocates refer to this as “framing for access” since they emphasize what is newsworthy about their issue at the moment to attract reporters. Media advocacy uses media relations tactics that practitioners of other communications strategies use: news releases, pitching stories, piggybacking on breaking news, monitoring the media, and creating news. But these practices alone are not media advocacy. Media advocates also use paid → advertising, as their issues are usually too controversial to rely on public service advertising (→ Advocacy Journalism).

Media advocacy continues to be used by tobacco control advocates, most recently in China. Children’s advocates used media advocacy to pressure national policymakers to prevent childhood lead poisoning. Disability rights advocates used media advocacy to

fight for accessible public transportation. In New Zealand, alcohol control advocates used media advocacy to increase support for alcohol policies. In the US, affordable housing advocates used media advocacy to reframe technical policy discussions into stories that reflected their values and the values that resonated with policymakers. Violence prevention advocates used media advocacy to enact policies that reduced morbidity and mortality from firearms. Nutrition advocates have used media advocacy support laws that limit soda and “junk food” in schools. Common to all these media advocacy campaigns is a focus on policies that change the environment in which people live and make their health decisions.

Media advocacy has several *limitations*. Media advocacy requires a clear policy target. If the strategy is not clear and the target has not been well defined, the media advocacy effort will be diffused and ineffective. Since media advocacy is about raising community voices to demand change, it often focuses on policy advocacy, which can require lobbying that public agencies and some nonprofit organizations are prohibited from conducting. The political nature of media advocacy means that some practitioners will not be able to participate in all aspects of a media advocacy campaign. A final limitation is that the reach and promise of media attention – the idea that so many individuals can be reached at once with a single message – can be a distraction from the policy target. Media advocacy should be thought of as a tool in service to policy advocacy and community organizing, not as an approach that stands alone.

Media advocacy, used as a tool to accelerate and amplify community organizing and policy advocacy, directs public and policymaker attention to the policies that can reshape the social and physical environment so that it fosters health.

# Media Campaigns and Perceptions of Reality

*Rajiv N. Rimal*

*Johns Hopkins Bloomberg School of Public Health*

Humans act, at least partly, on the basis of how they think others expect them to act. This means that humans have the capacity to know what others think or expect them to do. Some researchers have argued that understanding what others think is essential to social life and that successful human relationships depend on our ability to read the minds of others (Gavita 2005; → Symbolic Interaction). How good are we, though, at knowing what others think or expect us to do? Data show that there is often a negative correlation between our perceived ability to know what others are thinking and what they are actually thinking (Davis & Kraus 1997). In other words, those who are more confident about their ability to know what others are thinking are, in fact, less accurate, compared to those who are less confident. Accuracy, however, may not be important in this context because what we choose to do usually depends on our perceptions more strongly than on objective reality (→ Media and Perceptions of Reality; Social Perception).

Most communication-based campaigns, at their core, have the central mission to change people's perceptions of reality, whether that reality pertains to something external (such as a political issue, an organization, etc.) or internal (self-concept). For example, political campaigns seek to change people's perceptions about a particular candidate or issue, commercial campaigns strive to alter people's attitudes toward a product, and health campaigns seek to alter people's perceptions about their self-image, ability, or self-worth, just to name a few (→ Advertisement Campaign Management; Election Campaign Communication; Health Campaigns, Communication in). In many instances, the ultimate goal of the campaign may be to change individuals' *behaviors*, but changing people's perceptions with regard to their attitudes or beliefs is thought to be an important pathway for doing so (→ Development Communication Campaigns; Health Campaigns for Development; Population Campaigns).

## SYSTEMATIC MISCONSTRUING OF PERCEPTIONS OF REALITY

Research shows not only that people are often inaccurate in their assessment of others, but also that people's misperceptions follow *systematic* patterns (Fields & Schuman 1976). People make predictable errors when asked to assess where others stand on a particular issue, how much at risk others are to various threats, and how much others are influenced by the media. Many of these patterns have been empirically studied by scholars, and those with particular relevance to media campaigns are summarized below.

Although it has been defined in many ways, → *pluralistic ignorance* was first articulated by Allport (1924) as the tendency of people to overestimate the public support for norms deemed to be socially desirable. In classic studies of this phenomenon in the United States in the 1970s, researchers found, for example, that, although people themselves believed in

racial justice, they also perceived that their peers harbored more racist attitudes than they actually did (O’Gorman 1979). Similarly, people have been found to report greater concern for environmental causes in comparison to their estimates of how much their peers are concerned with the same issues. Pluralistic ignorance has also been found in the context of college students’ perceptions about the prevalence of alcohol consumption among their peers. Most students tend to hold exaggerated beliefs about how much alcohol their peers consume (Perkins & Berkowitz 1986), and they believe that regulations against alcohol will be resisted by others more strongly than by themselves.

The cognitive mechanism underlying the effects of pluralistic ignorance is not fully known, but researchers have asked questions about how people come to internalize the incorrect information about public perceptions. There is some evidence to indicate that the frequency with which people hear about a particular opinion – even if it comes from a single source – tends to increase perceptions about how widely the opinion is held by the larger public (Weaver et al. 2007). This seems to indicate that pluralistic ignorance may be linked with the accessibility of opinion – ones that are cognitively more accessible are thought to be held by many others (→ Attitude Accessibility). If so, it would further seem that, to the extent that an issue garners a great deal of media attention, pluralistic ignorance around that issue would be high.

The → *false consensus effect* and pluralistic ignorance are similar in that both pertain to patterns of misperception; they are different in that the false consensus effect is the tendency to overestimate the extent to which others share or are in support of one’s own attitudes, beliefs, or behaviors (Ross et al. 1977). Furthermore, the greater the relative deviance of the behavior one engages in, the greater the magnitude of the false consensus effect. In other words, paradoxically, individuals’ tendency to misperceive the presence of consensus among their peers is stronger if the behavior in question is practiced less often (that is, less normal). The false consensus effect is also thought to be a special case of social projection, whereby people validate their beliefs by projecting their characteristics onto others (Holmes 1968). Hence, the greater the need to validate the beliefs, the greater the pressure to perceive that others holding similar beliefs are in larger numbers. When beliefs are *actually* held by a great many people, there would be less of a need to validate those beliefs; social pressures would be greater to justify holding on to unpopular beliefs.

Because the false consensus effect is thought to be a motivational drive to restore an internal balance, its impact should be greater among those who are more concerned with projecting a normatively appealing image of themselves. When individuals are less concerned about how they appear to others, they should experience weaker drives to exhibit the false consensus effect. This predicted moderating effect of self-monitoring has, indeed, been empirically supported (Bauman & Geher 2002).

People’s tendency to believe that the media have greater influence on others (i.e., third persons) than on themselves has been termed the → *third-person effect* (Davison 1983). Accordingly, this concept has been implicated in people’s proclivity to institute strict → censorship of media content (especially when it comes to pornography and other deleterious effects on children; → Sex and Pornography as Media Content, Effects of; Violence as Media Content, Effects of; Violence as Media Content, Effects on Children of)

because of their belief that others will not possess the requisite mental faculty to remain unharmed. It is generally believed that third-person effects arise because of an exaggerated perception about effects on others as well as an underestimation of the effects on oneself. Furthermore, there are certain conditions that exacerbate these effects, including the perception that the source of the message is biased or that the content is harmful or negative.

The “*influence of presumed influence*” (Gunther & Storey 2003) is an extension of the third-person effect in that it posits that people modify their behaviors in response to their beliefs that the media have had an impact on others. In other words, because of the third-person effects, people come to believe that others have been influenced by the media, which results in people modifying their interactions with those they believe have been so influenced. Gunther and Storey (2003) first observed this phenomenon as a result of a radio-based intervention in Nepal that targeted health-care workers. Because lay persons were also exposed to the program, the lay persons came to believe that their health-care providers would have been influenced by the program and hence they expected greater service and more professionalism when they interacted with the health-care providers. This form of influence is particularly relevant when the recipients of a media intervention comprise individuals who were not directly targeted by the campaign.

*Optimistic bias* is the tendency to view oneself as being less vulnerable than others to various diseases and risk factors (→ Social Perception: Unrealistic Optimism). We tend to believe that others, in comparison to ourselves, are more susceptible to risks and negative life events. Since Weinstein (1980) first articulated this term, researchers have found the existence of optimistic bias across a variety of health domains, and this finding seems to be robust across cultures. The magnitude of its effects decreases, however, when the target (the average other whose risk is being assessed relative to one’s own) is portrayed as being similar or when the risk factor in question is perceived to be uncontrollable.

## IMPLICATIONS FOR CAMPAIGNS

The systematic way in which people misperceive reality has a number of implications for campaigns seeking to change individuals’ opinions and behaviors. Misperceptions can act as impediments to social change. Theories of normative influences predict that when people (falsely) believe they are in the minority (as in the case of pluralistic ignorance, for example), they are likely to underestimate the social support that they would receive in seeking social change, they would view their own stance as being abnormal, and they would be less willing to take on challenging tasks for fear of sanctions. Similarly, as the false-consensus effect would predict, individuals engaging in certain deviant behaviors may erroneously believe their behaviors are normal (thus obviating the need to change) when, in fact, they are not. Thus, campaigns seeking to bring about social change need to focus on understanding the extent to which their audience members harbor misperceptions about their social reality. This is also the approach adopted by interventions seeking to reduce college students’ alcohol consumption. These campaigns, based on what is known as the “social norms approach,” seek to educate students about the actual level of alcohol consumption on campus, under the assumption that students’ consumption will decrease once they realize that drinking moderately is the norm, not the exception.

The patterns of misperception described here also speak to the frame of reference that people use in making judgments about the need to make changes in their lives. If the frame of reference is well calibrated, the need to change may be well informed. If, however, the frame of reference is biased to support inaction (as when people engaging in high-risk behaviors perceive that their activities are within the norms of acceptable social practice), then there may be few motivations for change. One explanation for the existence of optimistic bias, for example, is that people use others (who are more at risk to a disease) to make assessments about their own relative risk (Rimal & Morrison 2006). Similarly, the third-person effect may exist because individuals judge their invulnerability to media influences in relation to others who, in their minds, are more susceptible. Hence, it seems that media campaigns need to understand which frames of reference people use to make assessments about the appropriateness of their own status. The biases that have been documented in the literature could be attributed to the inaccuracy of individuals' judgments. They could also be attributed to the inappropriate frames of reference that people invoke in making such judgments, and, if so, it seems that interventions need to focus not so much on providing the appropriate source of information.

There is now an extensive body of work that documents the various misperceptions that are brought to bear when individuals are asked to gauge the opinions, beliefs, and behaviors of others. A lot of work has also been done in articulating the conditions that either exacerbate or ameliorate the patterns of these misperceptions. What is now needed is work that specifically seeks to determine how campaigns can reduce these misperceptions so that individuals are able to make decisions based on accurate information about others' attitudes and behaviors. Furthermore, this work needs to be done through controlled studies that take temporal order into account as much of the extant literature is based on cross-sectional data that make it difficult to delineate cause from effect.

## Media Conglomerates

*Daniel Biltreyst*

*Ghent University*

The issue of media conglomeration, or the phenomenon of a vast amount of cultural (media) production being controlled by a relatively small number of corporations, has generated heated debates among communication scholars, policymakers, and industry practitioners. In these debates, the concept of media conglomeration primarily refers to ownership structures within media and communications industries, as well as to the nature and organization of this type of cultural production. The phenomenon of media conglomeration, though, touches upon a much broader set of interrelated issues – ranging from questions on diversity, competition, and control in a tightly oligopolistic market, to concerns over the wider societal implications of a situation where huge conglomerates dominate the global communications system (→ Globalization of the Media).

Drawing upon → public sphere theories, scholars working within a critical research tradition have been asking questions about how far and at what price a communication system can be dominated by a handful of corporations, and how this might affect the diversity of information and argument needed for effective and well-informed citizenship (McChesney 1997; Bagdikian 2004; → Critical Theory). Sharp political economic analyses on how the corporate structure and strategy of media conglomerates tend to homogenize cultural production and restrict critical media content have been opposed by advocates of

the free market (Compaine 2005). Media conglomeration is also an important concept in the academic field of international communication and in debates on media, internationalization, and globalization (Thussu 2000; → International Communication). Because much of today's communications industry is under the control of multinational corporations with cross-media activities in most parts of the world and with their headquarters in the USA, western Europe, Australia, or Japan, the issue of media conglomeration is often associated with older arguments about Americanization, Eurocentrism, or cultural imperialism (Tomlinson 1999; → Americanization of the Media; Cultural Imperialism Theories).

## BACKGROUND

Although an unparalleled series of international acquisitions and buy-outs of media and entertainment companies in the 1980s and 1990s fueled the debate, it is clear that the issue of media conglomeration is not a new phenomenon. During the second half of the nineteenth century, new technologies such as the telegraph, facilitating the transfer of information over a long distance, created the first modern media corporations with an international scope. Telegraph operators, advertising companies, and world news agencies emerged and spread their activities to many parts of the world (→ News Agencies, History of). In the twentieth century, the growth of other new media sectors went hand in hand with vertically integrated and internationally active companies. The film industry, for instance, quickly saw the emergence of oligopolistic structures, first with French companies (Pathé, Gaumont) and later with Hollywood-based majors (Paramount, Warner Bros., etc.), which tried to control most levels of the industry (production, distribution, exhibition), increased their interests in the wider leisure industry (music, radio, etc.), and operated in an international environment. In the postwar period, the filmed entertainment industry saw several waves of mergers and concentration, completely transforming the production, distribution, and exhibition of motion pictures. Mainly from the 1950s onwards, with the advent of television, Hollywood majors diversified their activities and increased their interests in the broader entertainment industry, including the production of television series or the exploitation of theme parks (Wasko 2003, 59). In the mid-1960s, a major wave of takeovers took place, leading to several Hollywood studios being absorbed by ever-larger media and entertainment formations (e.g., Paramount was taken over by Gulf and Western in 1966). In the 1980s, the rapidly expanding global entertainment market led to a new wave of concentration. The availability of new delivery systems, the development of new markets and technologies (e.g., home video, pay-TV), combined with a more liberal regulatory policy (or deregulation), all resulted in a further cycle of mergers. A spectacular flurry of concentration moves emerged, mainly because film and television companies, as well as other players with interests within the audiovisual scene, sought to gain control of the new technologies and the expanding entertainment market. In 1985, for example, Twentieth Century Fox was engulfed by Rupert Murdoch's global entertainment empire News Corporation. In 1989 Sony purchased Columbia for \$3.4 billion. One year later, another Japanese electronics manufacturer, Matsushita, purchased MCA/Universal for \$6.9 billion, while in that same year Warner Communications and Time Inc. merged.

This trend toward greater corporate entities did not stop in the 1990s; more recently, there have been spectacular mergers, such as the creation of *AOL/Time Warner* in 2001,

considered to be the largest entertainment group in the world (→ Time Warner Inc.). This very big, vertically integrated media corporation with total revenues of \$38 billion (in 2005) has a dominant position in the media, communications, and entertainment sectors, ranging from Internet services (mostly under the heading of AOL) to film production, distribution and marketing, publishing, music, and cable and network activities. The group's most well-known subsidiaries are Warner Bros. Pictures, New Line Cinema, AOL, CNN, *Time* magazine, and HBO, but many more brands and companies fall under the umbrella of AOL/Time Warner. Although most of its activities are located in the USA, it is clear that the corporation has worldwide interests, not only for the sales of its products, but also through a structural network of control and ownership of divisions in Europe and elsewhere. At the time of the big merger, AOL/Time Warner was seen as the perfect illustration of the importance of new delivery technologies and the Internet as a driving force behind the media conglomeration tendency. It was also presented as a clear example of synergy potentials, or the tendency whereby different divisions within a media corporation develop cross-promotional activities and use their outlets to sell a common product or a recognizable brand (e.g., the exploitation of New Line Cinema's *Lord of the Rings* through books, gadgets, DVDs, and merchandising within the Time Warner group). The monstrous AOL/Time Warner merger, however, did not work out completely as the corporation's managers and observers had expected. In its first year, AOL/Time Warner faced a big loss, while the market value of AOL (and other Internet companies) decreased. In 2002, the corporation was renamed Time Warner, while many more transactions were made in an attempt to reduce the debt load.

Another dominant US-based media group, often quoted for illustrating corporate trends of cross-media synergy, internationalization, and expansion, is *Viacom*. The Viacom Group, which goes back to CBS, grew heavily through mergers and acquisitions from the 1970s onwards. In 2005, Viacom's empire ranged from cable network and television to interests in the publishing, radio, video, and filmed entertainment industries. Besides the activities under the Paramount label (film library of more than 2,500 titles including *Titanic*, film production, distribution, film theaters, home video), Viacom is mostly associated with cable and television networks such as Showtime, the MTV chain, and CBS, as well as with television and film production companies. In March 2005, it was announced that the media conglomerate had decided to split up into two separately traded public companies. The split, which was inspired by internal rivalry between managers and shareholders and which tried to revitalize Viacom's stagnating stock price, took effect at the end of 2005, leading to the emergence of *CBS Corporation* and (the new) *Viacom*. The latter now comprises high-growth assets, namely the cable networks (MTV in particular) and movie studios (Paramount Pictures and DreamWorks). The other company, CBS Corporation, includes the CBS and UPN broadcast TV networks, the CBS, Paramount, and other television production operations, the Simon & Schuster publishing activities, Paramount amusement parks, as well as activities in radio, digital media, and advertising. The reorganization went further after the split, with the sale of some other assets (e.g., the Paramount parks were sold in 2006).

A third major corporation is the *Walt Disney Company*, often quoted as one of the most synergetic players in the media and entertainment field (→ Disney). Founded in 1923 by

the brothers Walt and Roy Disney, the small independent film production company managed to become a major with interests in many directions. Following a difficult period after Walt Disney's death in 1966, the company struggled to survive, but since the 1980s Disney has been the driving force behind many new successful initiatives (Touchstone Pictures, the Euro Disney resort near Paris), mergers and acquisitions within the field (e.g., Miramax in 1993, Capital Cities/ABC in 1996, Pixar in 2006), and the strategic use of new technologies. The corporation, which is claimed to be valued at \$32 billion, is best known for its activities in (animation) feature film production, distribution, and exhibition (e.g., Miramax, Walt Disney Pictures), record labels (Buena Vista Music Group), an empire of theme/amusement parks and resorts, as well as in cable, television, and radio network activities (ABC, ESPN, the Disney Channel). The corporation's products are heavily marketed and circulated in other forms, such as books and interactive media (Buena Vista Games), as well as a wide range of merchandise.

The world of the big media conglomerates does not only consist of US-based corporations. A clear example is *News Corporation*, controlled by Australian born, but naturalized American Rupert Murdoch and his family (→ News Corporation). News Corporation, whose revenue is estimated at around \$24 billion, has its roots in publishing, the newspaper industry, and television in Australia, but Murdoch soon moved to the UK and the USA. The conglomerate now controls dozens of magazines and newspapers in Australia, the UK (including leading tabloids such as the *Sun*, and the quality paper *The Times*), the USA (e.g., the *New York Post*), and Asia. Murdoch's adventure in the American audiovisual industry started in 1981, when the tycoon purchased half of the Twentieth Century Fox film studio. In 1986 Murdoch launched an attack on the "big three" television networks by creating the Fox Broadcasting Company. Fox Television grew from an independent broadcaster to a much criticized, but successful, network in the USA. The Fox empire now comprises a range of thematic cable network programming in the USA (Fox News, Fox Movie Channel, etc.), where it also controls some of the leading film and television production companies (e.g., Twentieth Century Fox Film Corporation). News Corporation's television interests reach from the USA to Australia, Latin and South America, Asia, the Eurasia region, central and eastern Europe, and the UK (e.g., BSkyB). News Corporation is now one of the three largest international media groups, operating in most sectors and most continents. Besides its television, film, magazine, and newspaper activities, the corporation also has major interests in book publishing (HarperCollins), radio, music, advertising, and the Internet and interactive media.

The list of major media conglomerates also contains some French-based groups, including the *Lagardère Média* company, which is mainly active in the press and book publishing industry (under Hachette Filipacchi Médias), the music industry and record shops (Virgin Megastores in different parts of the world), radio, television, and new media (Table 1). Another major French player with a tumultuous history is *Vivendi*, which is active in publishing, music, television and film, telecommunications, and the Internet, as well as video games. Vivendi, now estimated at nearly \$20 billion, grew out of the French water and energy company CGE. In 1998, CGE was renamed Vivendi and began to invest in the telecommunications sector and the mass media in Europe and

**Table 1** Major media conglomerates (2005, revenues in \$ billion)

	Film and programming	Broadcasting and cable programming	Music	Publishing	Multimedia and Internet	Cable and telecom	Others
Time Warner	11,853	9,054		5,565	8,692	8,484	
Viacom/CBS Corporation	5,055	17,180					1,880
Disney	8,713	11,788		2,511			7,750
News Corporation	5,187	9,230		5,680			862
Lagardère Média		679		3,549			4,366
Vivendi Universal	3,170	4,876	6,801		647	1,545	3,467
Bertelsmann		6,644	3,469	8,724			5,116
Sony	6,857		2,328		6,821		50,906

Source: EAO (2006)

North Africa (e.g., the Canal+ Group). Two years later, Vivendi acquired the Canadian-based Seagram's entertainment division. Through this acquisition, Vivendi came to control some of the most prestigious American media icons such as MCA, Universal Studios, and the Universal theme parks, as well as the PolyGram and Deutsche Grammophon record companies. However, the new *Vivendi Universal* conglomerate discovered that this rough acquisition and diversification strategy was not as rewarding as expected. The company started a strategy to sell nonstrategic assets. In 2004, some 80 percent of the Vivendi Universal entertainment branch was sold to General Electric's NBC, now forming the powerful *NBC Universal* group, which controls a wide array of news and entertainment television networks, film and television companies, theme parks, etc. After slimming down its assets considerably and changing its name again to *Vivendi* in 2006, the French conglomerate is still an important player in the music industry (Universal Music Group), television, and the games and telecommunications industry, while maintaining a 20 percent part of *NBC Universal*.

Another major conglomerate with European roots is the German-based *Bertelsmann*, which started as a book publisher (→ Bertelsmann Corporation). After World War II, Bertelsmann grew into a major German multimedia group with interests in the film, music, newspaper, and magazine industries. In the 1980s, the group started to develop a clear international strategy, acquiring American and other music labels. Ever since, the Bertelsmann group, with its revenue of nearly \$18 billion, has been among the leaders in the world's media and entertainment scene, with major interests in the publishing, music, television, and new media industries. The conglomerate consists of six divisions, including RTL (a powerful network of television channels in Europe),

Gruner + Jahr (the biggest European publisher, with major interests in the USA), Random House (one of the leading publishers of popular books worldwide), Bertelsmann Music Group (BMG, a key player in the music industry), and Direct Group (a network of book clubs and other assets with a global reach).

A final player, exemplifying the corporate strategies of conglomeration, is the media and entertainment division controlled by *Sony* (→ Sony Corporation). This Japanese multinational with a leading position as a hardware manufacturer of electronics, games, videos, computers, and information technology, started to increase its interests in the media and entertainment arena at the end of the 1980s. After the acquisition of CBS Records (transformed into Sony Music Entertainment), it purchased Columbia Pictures in 1989 for \$3.4 billion, using it to build the Sony Pictures Entertainment unit. In recent years Sony has been active in many more mergers and joint ventures, increasing its position in the film, television, and audiovisual scene (interests in the MGM Company) and the music industry (with BMG).

## DISCUSSION

This picture of a continuously changing world of major media conglomerates is far from complete and should pay attention to internal rivalries, as well as alliances and the position taken by other players in the field. The latter includes powerful conglomerates controlling an increasing amount of cultural production within national or even wider boundaries (e.g., the Spanish *PRISA*, Brazilian *Globo*). Referring to the extreme case of *Fininvest*, the holding company built around the former Italian prime minister Silvio Berlusconi, with its established market leadership in sectors ranging from commercial television and advertising to the film and publishing industries, it is clear that the issue of media conglomeration goes further than questions dealing with the structure of the media market. The case of Berlusconi exemplifies wider concerns related to the possible implications of media conglomeration.

A first bundle of wider questions deals with how far a market can be controlled without harming competition in terms of production, dissemination, and consumption of media products or content. Critical voices in the debate argue that the emergence of strong conglomerates with holdings in several media with an international scope reduces the diversity of cultural goods in circulation. From this perspective, conglomeration might have a restricting effect on media content while it tries to offer more variants of the same basic themes and images (Murdock & Golding 2005). Critics argue that media conglomerates seek content that can move fluidly across different media and channels (synergy), while they ignore creative talent and content in favor of commercial viability. Market-oriented media systems make no distinctions between people as consumers and as citizens, while the commodification tendency transforms messages into marketable products and tends to deny the free access and distribution of other content. This critical analysis is countered by arguments claiming that a free market has led to a decreasing oligopoly and the emergence of new players, while consumers enjoy more choice than ever (Compaine 2005). This position refers to the growing amount of television and other media providers since the 1980s, the emergence and the growing use of the Internet as a

source for information and entertainment since the 1990s, as well as the notion of counterculture audiences who do not accept what major media conglomerates offer. The answer to this position is that a key to understanding the media conglomeration phenomenon is that major players in the field continuously try to absorb viable alternatives through mergers in order to extend their scope and consolidate their position.

A second set of questions refers to a higher level of implications, dealing with the role of the media as a central political and societal institution in democracy. Inspired by public sphere theories in relation to the media, critics of media conglomeration notice that the traditional worries about the power of press barons and media moguls in controlling the flow of information and open debate in society, have only increased since the 1980s. The case of Italy, where Berlusconi openly used his media empire to influence the political arena and public debate, is used to underline the fear that the growing power of media conglomerates might restrict information and harm democracy. Opponents claim that the danger to democracy is a myth given the extension of choice and the survival and even emergence of new alternative sources of information. Also, it is argued, managers of major media conglomerates are not “fostering a political ideology or suppressing an ideology through the media properties they program” (Compaine 2005, 46). Referring to the American debate on the role of Murdoch’s Fox Television and the absence of critical information on the Bush administration’s foreign policy, it is clear, however, that this issue remains open for debate.

# Media Content in Interpersonal Communication

*Daniel G. McDonald*

*Ohio State University*

Although today's mixture of theories and approaches combining interpersonal and mass communication is a two-sided one (incorporating researchers with training in both fields), virtually all of the accessible research on media content in interpersonal communication has arisen from researchers primarily trained in the effects tradition of mass communication research, rather than from interpersonal communication researchers studying the content of conversation.

Early in the history of media research, scholars investigating the effects of motion pictures through the Payne Fund studies (Blumer 1933) and even earlier (Phelan 1919) found that there was a great deal of interpersonal discussion about the content before, during, and after viewing (→ Interpersonal Communication; Media Effects). While the primary research objective was to understand how media were affecting individuals, it was clear that there was a social component to the process of media attendance and enjoyment. Over its history, research on media content in interpersonal communication has led to *four major ideas*: (1) interpersonal discussion has an impact on selection of media content, (2) media content provides material for interpersonal discussion, (3) interpersonal communication alters a number of the effects of media by amplifying or dampening them, and (4) interpersonal discussion affects the enjoyment of the media experience.

## SELECTION OF MEDIA CONTENT

Herbert Blumer found evidence for all four of the aspects of interpersonal discussion of media content listed above. Similar results were found for various media research efforts through the 1930s, 1940s, and 1950s. During and after World War II, the notion of → selective exposure became an important one for researchers studying persuasive properties of the media. Notable research in the 1940s and 1950s echoed Blumer in noting the impact of interpersonal discussion of media content on content selection (Riley & Flowerman 1951; Friedson 1953; Zimmerman & Bauer 1956). McCombs (1972) also noted that the interpersonal exchange of information typically precedes media content selection in a political campaign (→ Election Campaign Communication).

Current research on selective exposure has focused more on psychological aspects of the audience member than on interpersonal discussion, either assuming or neglecting the role of interpersonal discussion in the selection process. However, research only tangentially related to selective exposure continues to document the impact of interpersonal discussion in selection of media content (Mohr 1979; McLeod et al. 1982; Nathanson 2001).

### MATERIAL FOR INTERPERSONAL DISCUSSION

While interpersonal communication can serve as a mechanism influencing the choice of media content, media content can also be the topic of discussion before or after a viewing experience. Riley and Riley (1951) provided a label – *social utility* – for the idea that media content served a function in everyday interpersonal interaction. What was watched or listened to in the media could become the topic of conversation later. That label was continued and adopted by → *uses and gratifications* researchers during the 1970s and continues today. In a political campaign context, Chaffee and colleagues noted that voters were more likely to ask for campaign information (brochures) if they expected to talk about the election with friends (Chaffee et al. 1971). They described this as the “communicatory utility” of mass communication content, and saw it as a motivator for media use. While Chaffee (1972) saw this as evidence that media information enables one to talk with others at the level of peers, Bernard Berelson (1949) saw something else. Berelson had recognized the same phenomenon but described it as a “social prestige” factor because reading newspapers enabled people to appear more informed than others in social gatherings. Berelson noted that it was not that the content is good in itself, but that it is good *for* something – to impress those with whom we talk. The term “social prestige” for this idea was also provided by Lazarsfeld and Merton (1948).

Leo Bogart (1955) suggested that media content provided impersonal material that helped develop bonds between people. Dervin and Greenberg (1972) found that television content provided a major topic of conversation for the urban poor, with more than half indicating that they talked about TV content two or more times per week. At that time, Dervin and Greenberg indicated that plenty of data was available related to the frequency of interpersonal interactions about television, but no data was available related to how talk about TV is used in social interactions. Only a handful of relevant studies have been published since that time. Most involve children talking about media, and nearly all of those are analyses of responses to interviewers’ questions rather than observations of interpersonal conversations between children or between children and adults.

### ALTERING THE EFFECTS OF MASS MEDIA

A notable exception to the lack of research studying media content as used in interpersonal interaction can be seen in the literature on → *parental mediation* of children’s viewing and → *co-viewing*. Although early research indicated that the mere presence of others in a viewing situation was enough to alter the effects of TV content on children, by 1982 McLeod and his colleagues had concluded that conversation was required to mediate the effects of TV on children. By the late 1990s, this area of research had led to mixed results in terms of whether adults’ co-viewing leads to positive or negative outcomes for children, although Nathanson concluded that there is increasing evidence that co-viewing suggests to the child that the parent approves of the content, even if that content is violent (Nathanson 2001). If Nathanson is correct, then that interpretation helps to explain a number of both negative and positive effects attributed to co-viewing of TV content (McLeod et al. 1982; Nathanson 2001).

Katz and Lazarsfeld (1955) also focused on the idea that interpersonal communication could dampen or amplify media effects. In their “two-step flow” hypothesis, they noted that an individual’s response to a media campaign cannot be understood without understanding his or her social environment and interpersonal relationships. They suggested that interpersonal communication is the key link in a chain of intervening variables that promised to promote the *convergence of mass communication and social relations*. Research in the intervening years has not been overly kind to the two-step flow analysis. As Chaffee (1972) noted, it is probably more useful to think of the two-step flow as a factor that should not be overlooked than as the powerful hypothesis it claims to be. In his review, Chaffee suggested that the bulk of the evidence indicates that direct flow from the media is the rule for most people, rather than the exception. He notes that, even in the original Katz and Lazarsfeld study, 58 percent of reported opinion changes came about without involving other people. Following from Katz and Lazarsfeld and extending into today, others have noted the effects-altering aspects of interpersonal communication, especially in the area of political communication. Considerable thought has turned to understanding how conversation about political topics alters the effects of media presentations.

As noted above, in the selection of media content for interpersonal discussion, the focus is on the media experience. Interpersonal communication leads to selecting content that will be enjoyable, educational, and stimulating, or that will supply any of a number of gratifications which the communicators share as a motive for attending to the content. In providing material for interpersonal discussion, the focus is on reacting to or anticipating a media experience that produces a shared gratification.

With → *political communication*, however, researchers typically focus on a content that exists independently of the medium or the ongoing discussion – content related to the evaluations of candidates or factual information about candidates’ positions – rather than on discussion of candidates’ appearance in the media (Scheufele 2002; Eveland 2004). Political communication researchers typically focus on the discussion of specific political topics – local government, presidential debates, current events, etc. – rather than specific media topics (actions portrayed, motivations of major actors, etc.), and the frequency of occurrence of interpersonal discussion rather than the gratifications or motivations for such discussion. These are subtle distinctions, but are responsible for major differences because research in political communication is often about decision-making related to the content – i.e., choice of a candidate. Choice in regard to selection of media content might be seen as comparable at first glance, but selection of media content typically does not involve exclusion of other choices, as does political decision-making. Nor does political knowledge necessarily lead to increased prestige in social groups, as those supporting a different candidate can fairly easily discount such knowledge, knowing which candidate the speaker supports.

## ENJOYMENT OF THE MEDIA EXPERIENCE

An unspoken assumption for much of the research on mass communication is that selection and use of media content in interpersonal discussion lead to increased enjoyment of the media experience, either by content that provides increased gratification being selected or by the experience being relived and enhanced through discussion

afterward (→ Emotional Arousal Theory; Enjoyment/Entertainment Seeking). Similarly, an unspoken assumption of much interpersonal discussion research is that enjoyment is the motivating factor. A handful of early studies considered the impact of others on enjoyment of mediated content (e.g., Hylton 1971; Hocking 1982), but only recently has enjoyment as a result of media use (Vorderer et al. 2004) or interpersonal discussion (Step & Finucane 2002) been studied. Within the few recent studies of media enjoyment, some are beginning to focus on the enjoyment that arises from the *social situation of using media in groups* (Denham 2004; Raghunathan & Corfman 2006). However, and somewhat surprisingly, most current studies including both media enjoyment and interpersonal communication tend to assume interpersonal discussion rather than measure it. The Raghunathan and Corfman research stands out as one study focusing on the role of congruent or incongruent comments about media content, and the effect of those comments on enjoyment. Their study generally confirms that positive comments made about ongoing media increase enjoyment of that content, but that it is the perception of shared opinions about the content that enhances enjoyment, while perception of differing opinions detracts from enjoyment.

### FUTURE DIRECTIONS

Although Raghunathan and Corfman's study involved adults' perceptions of TV ads, it ties nicely with Nathanson's (2001) contentions regarding parental mediation. Coming from a long history of media research on the use of media content in interpersonal discussion, much of what was assumed to be the case might be questioned. If nothing else, recent research has demonstrated that our understanding of media effects must take into account the social context of media consumption. Future research on media effects will need to deal not only with the frequency of interaction about content but also with the nature of the conversation if we are to be able to predict the effects of media.

# Media Content and Social Networks

*Dietram A. Scheufele*

*University of Wisconsin-Madison*

In *The people's choice*, → Paul F. Lazarsfeld and his colleagues laid out many of the key issues that disciplines such as communication, political science, and sociology continue to struggle with when modeling the intersection of mass media and social networks (Lazarsfeld et al. 1948). More specifically, they offered two key constructs to explain the interplay of mass-mediated information, → social networks, and political → attitudes that are still relevant today: opinion leadership and political cross-pressures (→ Opinion Leader).

Lazarsfeld and his colleagues saw *opinion leaders* as nodes in social networks who provided critical connections between mass media and citizens. Opinion leaders, they argued, were citizens “who are most concerned about an issue as well as most articulate about it” (Lazarsfeld et al. 1948, 49). Subsequent research has refined the → operationalization and measurement of opinion leaders (e.g., Noelle-Neumann 1985; Weimann 1994). But little has changed about the original interpretation of the construct and of the role that opinion leaders likely play in social networks (Katz 1957). Most importantly, opinion leaders provide a critical link in what Lazarsfeld and his colleagues called the “two-step flow of information” (→ Two-Step Flow of Communication). Specifically, opinion leaders tend to rely less on interpersonal sources for their own information seeking than the average public (→ Interpersonal Communication). Instead, they turn to mass media for new information. And given their position as influentials in the community, they pass along this information to non-opinion leaders who rely less on mass media and more on interpersonal networks.

Subsequent research supported much of Lazarsfeld et al.'s original theorizing in the context of contemporary social structures. Weimann (1994), for instance, found opinion leaders to have higher levels of interest, knowledge, and social recognition than non-leaders. And most recently, Scheufele and Shah (2000) linked opinion leadership directly to life satisfaction, levels of social trust, and engagement in one's community.

According to Lazarsfeld et al. (1948), the two-step flow of information in social networks is especially effective since interpersonal channels (rather than mass-mediated ones) can counter and circumvent initial resistance to information, based on partisan preferences (→ Selective Exposure). More recent research, however, suggests that the likelihood of exposure to attitude-inconsistent information in modern democracies is much higher in news media than in most interpersonal contexts (Mutz & Martin 2001; → Consistency Theories; Cognitive Dissonance Theory). Regardless of where exposure to attitude-inconsistent information takes place, however, the question remains if the resulting *cross-pressures* are a desirable outcome.

Lazarsfeld and his colleagues (1948) suggested that exposure to cross pressures resulted in individuals attempting to avoid politics, which in turn delayed citizens' voting decisions and made them less likely to vote. More recently, Mutz (2002) distinguished two interrelated processes that undermine political engagement among citizens who are exposed to cross pressures. First, individuals who are part of social networks that expose

them to frequent discussions with non-like-minded others steer clear of politics in order not to threaten the harmony of their social relationships. Mutz calls this a “*social accountability*” effect. Second, her study showed that “exposure to those with political views different from one’s own also creates greater ambivalence about political actions, and thus makes it more difficult to take decisive political action” (Mutz 2002, 851). She labels this effect “political ambivalence.”

Scholars like Scheufele et al. (2004), in contrast, have suggested that exposure to attitude-inconsistent information in one’s social networks and the resulting cross pressures are an important and normatively *desirable part of opinion formation*. In particular, they argue that exposure to such information can have important informational and mobilizing benefits. First, frequent exposure to attitude-inconsistent information may lead to greater → political knowledge and learning, simply by exposing citizens to information and viewpoints that they were not aware of before. Second, and more importantly, discussions with other citizens who hold different viewpoints can result in network members having to compromise between different viewpoints, motivating them to re-evaluate those issues where conflict occurs. This exposure to discussion disagreement is therefore likely to produce greater cognitive activity or additional → information seeking, forcing individuals to learn about alternative perspectives, and reflect more carefully on what they already know (Scheufele et al. 2006). In turn, recent findings suggest, citizens who are exposed to more attitude-inconsistent information tend to have greater argument repertoires (Cappella et al. 2002) and be more participatory in politics overall (Scheufele et al. 2004; 2006).

Most recently, some researchers have suggested that citizens may begin to rely on *online forms of communication* to supplement or even replace face-to-face interactions in their social networks (→ Exposure to the Internet; Online Media). In particular, findings by Hardy and Scheufele (2005) showed that mobilizing effects from traditional news media during campaigns were significantly stronger for citizens who participated in online discussions about campaign issues with others than for those who did not (→ Election Campaign Communication). In other words, citizens either used online discussions to help them make sense of information that they had been exposed to in traditional media, or processed information from traditional media more carefully in anticipation of their online discussions with potentially non-like-minded others. Ultimately, the emerging interplay between geographically defined face-to-face networks, online interactions, and traditional mass-mediated information will require a new paradigm for how we think about social-level influences on opinion formation and political participation.

# Media Corporations, Forms of

William M. Kunz

University of Washington Tacoma

Just as there are numerous kinds of media – from electronic to print, local to worldwide – so too are there many different forms of media corporations. There are corporations that are vast multinational conglomerates operating in unrelated industries and spanning the globe (→ Media Conglomerates), and those that focus on a single medium in a solitary market. There are those that are closed or private corporations, owned and controlled within a limited group without shares for sale, and those that are public corporations, with stock traded on the open market. And there are public corporations with dispersed ownership spread across millions of shareholders, and those with a single individual or group with sufficient ownership to exercise control over the business. While there are countless differences between corporations, there are also important characteristics they have in common (→ Media Economics).

Investors and entrepreneurs often form joint stock companies and incorporate them to function as a business, but corporations can also be formed for political, religious, or charitable purposes and can be for-profit or not-for-profit organizations. The modern business corporation emerged in the United States in the 1800s, when most states passed general incorporation acts that granted perpetual life and extended to shareholders limited liability, two defining characteristics of corporations. The late 1800s featured the rise of the large, multi-unit business enterprise, and the acceptance of this structure was evident in 1914 when US president Woodrow Wilson declared that “the antagonism between business and government is over.” Wilson embraced the foundations of what became known as *corporate liberalism*, which accepted the large business corporation as permanent and desirable. The significance of this period is clear, since it was on Wilson’s watch that the US government orchestrated the pooling of broadcast radio patents and the creation of the Radio Corporation of America (RCA).

## ECONOMIC DOMINANCE OF CORPORATIONS

Large corporations are now the fundamental organizing unit of the capitalist economy, although not the most common business enterprise. In 2002, a total of 26.4 million businesses reported to the US Internal Revenue Service, and 21 million or 80.1 percent of those were nonfarm sole proprietorships or partnerships, compared to just 5 million corporations (US Census Bureau 2006). In spite of this imbalance, corporations still generated the bulk of business receipts, accounting for 83.6 percent of \$22.6 trillion in total revenue in the United States in 2002. Graham Murdock (1982) documented how the merger movement that accelerated after the mid-1950s resulted in media firms becoming a part of larger corporations, and this is evident in the US sample. Corporations were even more prominent in the “*Information*” group within the industrial classification system used by the US Census Bureau, which includes the most prominent media sectors. In that group, corporations accounted for 32.3 percent of total firms and 86.9 percent of total revenue.

The forms of corporate ownership in the US provide a framework for discussion, with basic elements evident in other settings. In the US, a corporation is a legal distinction that establishes rights and obligations of individual persons that are separate from those of its shareholders. This is an important difference from other business structures. In a sole proprietorship or partnership, an individual or group of individuals contributes the working capital for business, and risks not just their investment but also their personal assets. In such a legal structure, investors are liable to third parties that are injured by the proprietorship or partnership, so their liabilities are unlimited. That is not the case with corporations. Unless there is fraud or malfeasance, investors in a corporation are exposed to *limited legal responsibilities* and are shielded from the indebtedness and other liabilities of the corporation. A corporation assumes other aspects of personhood, including the ability to own property, sign contracts, and pay taxes. In 1978, the US Supreme Court even extended First Amendment rights to freedom of speech to corporations.

An ownership structure that sits between limited partnerships and corporations is a *limited liability company* (LLC). This business configuration is evident in some of the independent production and distributions companies in the US motion picture business, including the Weinstein Company after Harvey and Bob Weinstein split from Miramax, and DreamWorks SKG and Newmarket Films before they became part of Viacom and → Time Warner Inc., respectively (→ Hollywood). One of the advantages of this ownership structure is that an LLC exists as a separate legal entity, which gives its owners the same liability protection from business debts and claims as with a corporation. There are, however, clear differences between an LLC and a corporation. Flexible profit distribution and flow-through taxation for LLCs mean that profits, losses, and expenses flow through the company to the individual members.

### **PUBLIC VERSUS PRIVATE OWNERSHIP**

A second distinction can be made between public and private corporations. A *public corporation* is one that issues securities, such as common stock, that represent equity in the company. These securities are then traded on the open market. This process enables public corporations to generate capital for investment in new endeavors or continuing operations. The sale of shares can occur in multiple markets. Firms incorporated outside the US can create American Depository Shares that represent securities in their domestic market. Sony Corporation, for example, is incorporated in Japan and shares are sold on the Nikkei stock exchange (→ Sony Corporation), but it is also traded on the New York Stock Exchange (NYSE). The same is true of Spanish-language television giant Grupo Televisa, which is traded on the Mexican stock exchange and the NYSE (→ Mexico: Media System). A privately held corporation can also issue shares that represent a percentage of ownership, but these are not traded on the open market.

Most large media companies are public corporations, but there are exceptions, such as the empires of the Cox family in the US and the Marinho family in Brazil. *Cox Enterprises* is prominent in three different media sectors in the US, with ownership of 17 daily newspapers, and 15 local television stations and cable systems that reached over 6 million basic subscribers in 2005. James M. Cox acquired his first newspaper in Dayton, Ohio, in 1898, but expanded in the 1930s with horizontal integration in the newspaper business

through the purchase of the *Atlanta Journal* and diversification into broadcast radio with the launch of WHIO in Ohio. A century later, the Cox assets remained within the family, with Barbara Cox Anthony and Anne Cox Chambers in control of the corporation.

The roots of the *Marinho empire* are in newspapers, as well. *O Globo* was first published in Rio de Janeiro in 1926, and that fueled diversification into → radio in the 1940s and → television in the 1960s. The latter was the venture that defined the Marinhos, as TV Globo became a dominant force in Brazil. When Roberto Marinho died in 2003 at the age of 98, control of the corporation passed on to his three sons. Organizacoes Globo controlled Brazil's largest broadcast television network, the third-largest newspaper, and a collection of businesses that included cable and pay-TV services, radio networks, record labels, and the Editora Globo publishing house (→ Brazil: Media System).

The largest privately held media corporation in the world is *Bertelsmann AG* (→ Bertelsmann Corporation). Carl Bertelsmann founded the corporation in 1835 with a focus on publishing hymnals and religious materials, but Reinhard Mohn, a fifth-generation descendent, transformed it into a diversified media conglomerate. In the mid-2000s, Bertelsmann owned Random House, the most prominent trade group publisher, 50 percent of Sony BMG Music Entertainment, and controlling interests in magazine publisher Gruner + Jahr and European television broadcaster RTL Group, as well as other companies. After a stock buy-back in 2006, the Bertelsmann foundation controlled 76.9 percent of the corporation, with the Mohn family owning the rest.

## PUBLIC CORPORATIONS IN THE MEDIA BUSINESS

There are various incentives for private corporations to make public stock offerings. The founders of a corporation will often go public to generate cash that can then be used for other purposes. Another reason for a public offering is the desire to generate working capital that can be used for new investments or continuing operations. Such an offering comes with a price, however. For instance, public corporations trading in the US must comply with Securities and Exchange Commission (SEC) laws and policies. These rules include the disclosure of persons or groups that have beneficial ownership of more than five percent of the voting shares of any class of stock. The SEC also mandates that corporations disclose extensive financial information and liabilities. The Sarbanes-Oxley Act of 2002 added teeth to such requirements, since it mandated that corporate executives personally certify that filings are accurate and complete.

The evolution of Cox Enterprises reveals the different sides of the public/private equation. In the 1960s, James M. Cox, Jr established a publicly traded corporation, Cox Broadcasting, which included the firm's broadcast and cable assets, while organizing its newspaper interests in a private corporation, Cox Enterprises. The development of → cable television systems is resource intensive, and the public offering was one route to raise needed capital. In 1985, the Cox family took the broadcast and cable business private and merged it with Cox Enterprises. That structure lasted for a little more than a decade, when Cox Cable merged with the cable systems of Times Mirror in 1995 to create Cox Communications, Inc., a publicly traded company. In 2004, the Cox family completed a cash tender offer and once again took its cable business private.

The public corporation is much more common in the media industries, but there is *no single model*. Some are diversified conglomerates with vast holdings in unrelated industries. In the case of General Electric, NBC Universal was one of six operating segments in 2005, with the Infrastructure and Industrial units combining for close to 50 percent of total revenue compared to just under 10 percent for its media division. Some are diversified conglomerates with holdings in media-related industries. The Time Warner portfolio, at that time, included Internet services and cable systems, filmed entertainment, broadcast and cable networks, and publishing. Other media corporations focus on a pair of related news and information industries, with the newspaper and television holdings of Gannett Co. Inc. and Tribune Co. prime examples. There are still others that focus more or less on a single industry – newspapers and broadcast radio, respectively, in the cases of the McClatchy Co. and Cumulus Media.

### **GOALS AND CONTROL IN DIFFERENT FORMS OF OWNERSHIP**

The organization of media companies as public corporations can be seen as quite problematic, since placating Wall Street and investors mandates a focus on the bottom line. For instance, when General Electric acquired NBC in 1986, chairman Jack Welch bristled at claims that broadcast → television networks were a public trust, believing that the same public trust applied to making an air conditioner as running a broadcast network (Auletta 1992, 19). For Welch, the main obligation was not to the public who owned the airwaves, but to the shareholders who owned General Electric stock. General Electric's conglomerate form also intensifies concerns since it is involved in what Murdock (1982) has called "socially and politically contentious areas" such as nuclear power and military aviation engines. The impact of corporate ownership on media content has been the focal point of extensive research in the communications field (Murdock 1982; Herman & Chomsky 1988; Wasko 1994; Barnouw 1997; McChesney 1997; Hesmondhalgh 2002; Bagdikian 2004; Croteau & Hoynes 2005; → Bias in the News; Commercialization: Impact on Media Content).

### **Concentrated versus Dispersed Ownership**

Public corporations, large and small, must adhere to the same rules and regulations, but there are significant differences in the nature of corporate ownership. The most obvious distinction is between firms with concentrated ownership and those with dispersed ownership. This is an important difference according to the arguments made in regard to the separation of ownership and control in modern corporations. According to one perspective, this separation has severed the ties between the elite families and the means of production and distribution, and has transferred control to a managerial class that represents the capitalist class, but has different interests.

The significance attached to this supposed separation is profound. In 1933, Adolph Berle and Gardiner Means argued in *The modern corporation and private property* that the dissolution of the "old atom of ownership" into two parts, control and beneficial ownership, destroyed the "very foundation" upon which the economic order had rested for three centuries (Berle & Means 1933, 8). The central tenet of an economic order based on

private enterprise was that the self-interest of the property owners was tantamount. The ownership interests of those who control modern corporations in the twentieth century was so minimal, it was argued, that the “return from running the corporation profitably accrue to them in only a very minor degree” (Berle & Means 1933, 8–9).

Such a shift in motivation would be a profound change for communication corporations, given the role assigned to the media in democratic theories of the press and the potential for media outlets to educate (→ News as Discourse; Public Sphere). Berle and Means argued that the rise of groups in control of corporations that were independent of owners placed the “community in a position to demand that the modern corporation serve not alone the owners,” but the society as a whole (Berle & Means 1933, 355–356). They argued that,

Neither the claims of ownership nor those of control can stand against the paramount interests of the community . . . It is conceivable – indeed it seems almost essential if the corporate system is to survive – that the control of the great corporations should develop into a purely neutral technocracy, balancing a variety of claims by various groups in the community and assigning to each a portion of the income stream on the basis of public policy rather than private cupidity.

There are prominent media corporations where stock ownership is dispersed and the separation that Berle and Means envisioned is evident. In the first quarter of 2006, the members of the board of directors and executives of Gannett Co., Inc., the largest newspaper publisher in the US, owned just 2.2 percent of the common stock. The stock ownership of the directors and executives in the Walt Disney Co. was even less, as the same groups controlled less than 1 percent of the common stock (→ Disney). Other large media corporations represented very different ownership structures. The separation of Viacom in 2006 split its various media assets into two corporations, Viacom Inc. and CBS Corporation, but Sumner Redstone retained power over both with beneficial ownership of over 70 percent of the common stock of each through National Amusements, the private corporation that his family controls.

### **Allocative versus Operational Control**

There is another level of control that defines corporations, and that is the difference between allocative and operational control. The separation that Berle and Mean advanced and which Daniel Bell (1960) supported, arguing that there was no longer a power-holding elite with both an “established community of interest and a continuity of interest,” requires such a partition. *Allocative control* resides in the board of directors of a corporation and consists of the power to define the overall goals of the firm and decide how resources are distributed. *Operational control* is wielded within the parameters set at the allocative level. Once such decisions are made, managers determine the most effective use of the resources that the board has allocated and the implementation of policies it has established.

There are media corporations where there is a clear line between allocation and operational control, and some where such a detachment does not exist. General Electric, the parent corporation of NBC Universal, shows the clearest separation. In the first

quarter of 2006, there were 15 members of the board of directors, and just 3 of those were executives within the corporation. The outside directors were strategic choices, including the chief executive officers of two prominent advertising agencies, current or former chairpersons of six Fortune 500 companies, and the former chair of the Armed Services Committee in the US Senate. In another case, the makeup of the board of → News Corporation, the parent of Twentieth Century Fox and Fox Television Network, was quite different. The 14 members of the board included 2 members of the Murdoch family, Rupert and his son Lachlan, and 3 senior executives from within News Corporation or one of its subsidiaries. There were three additional board members who were long-time lieutenants to the elder Murdoch, so he had close ties to 8 of 14 board members. The Murdoch family, moreover, controlled around 30 percent of the News Corporation stock.

### PROCESS OF CONSOLIDATION

While there are various forms of media corporations, more and more prominent media properties are contained within ever fewer conglomerations. In the first edition of *The media monopoly*, published in 1983, Ben Bagdikian concluded that ownership of most of the major media in the United States was consolidated in 50 national and multinational corporations. Two decades later, when *The new media monopoly* was published, that number had dwindled to just five (Bagdikian 2004).

The extent of corporate ownership is evident at each turn. In the mid-1980s, federal regulations in the United States limited a single individual or corporation to the ownership of just seven local television stations and seven AM and seven FM radio stations nationwide. In 2006, Clear Channel Communication owned 1,182 local radio stations, including 8 in 12 different markets, while CBS Corporation owned 39 local television stations, with multiple stations in 10 markets. More generally, although there are cases in which media content is produced by sole proprietorships and partnerships or corporations of modest size, the large corporation is the dominant form of business organization in the mass media.

## Media Democracy

*Otfried Jarren*

*University of Zurich*

The term “media democracy” insinuates that the media and mediated communication are of central relevance for modern democracies due to their decisive influence on (or consequences for) political institutions (macro level) and political actors (meso level) as well as individual citizens (micro level). Theoretically associated with the media democracy concept is the notion of a “media society.” This idea implies that traditional mass media, as well as the new online media, are pervading all spheres of society and social life and have thus become the central precondition of exchanges and interactions among individuals and organizations of society (→ Mediatization of Society).

The media society can be seen as the result of a process of functional differentiation making the media increasingly independent of their former sponsors which were, in the European tradition, primarily the churches and the political parties. The media now operate according to a specific → media logic and, due to economic necessities, guided by commercial rules in order to maximize their audience shares. Part of this evolutionary process took place following the development of communication technologies (→ Commercialization of the Media). But to a certain degree the process is also influenced by general tendencies of social change.

### CHANGING POLITICAL SYSTEMS

The media democracy concept signifies special aspects of the transformation of politics, in analogy to the notions of “media-centered democracies” (Plasser 2004), “mediated politics” (Bennett & Entman 2001), and the → mediatization of politics (Mazzoleni &

Schulz 1999). These terms imply fundamental political changes, particularly structural transformations of the → political communication system and the → public sphere leading to what Blumler & Kavanagh (1999) have termed “the third age of political communication.” According to Blumler and Kavanagh, in this still emerging age of media abundance political communication is reshaped by an intensified professionalization of political publicity, increased competitive pressures on political actors, diversification of political communication forms, and changes in how audiences receive politics.

The changes attributed to the influence of mass media are leading to *phenomena* such as → media events and pseudo-events, → mediated populism, → mediated terrorism, and → symbolic politics. Governments, parties, and other political groups or organizations, with the aid of → political consultants and → spin doctors, are trying to influence the public issue agenda through professionalized strategic communication (→ Issue Management in Politics; Professionalization of Public Relations). Some forms of public relations activities that are targeting the political elite affect the democratic core of political organizations (Jarren & Donges 2006). Further, as content analyses show, the media’s presentation of politics has become more complex, more negative, and also more sensational and entertaining (→ Content Analysis, Quantitative; Horse Race Coverage; Negativity; Tabloidization). There is concern that, in the long run, this is affecting people’s images of politics, their attitudes toward democratic institutions, and their willingness to participate in politics (→ Political Cynicism; Political Efficacy; Video Malaise).

A key role in these processes is ascribed to → *television as the “lead medium”* in public communication. Television through its visual images is said to have the power to shape and to distort reality (→ Construction of Reality through the News; Media and Perceptions of Reality; Television News, Visual Components of). Moreover, a growing personalization of politics is assumed to result from televised reporting of political events, particularly during election campaigns (→ Personalization of Campaigning). The expansion of commercial television intensified the critical debate about suspected political changes because the commercial programs cover comparatively little institutional politics and instead concentrate on entertainment formats thus abetting → politainment and the entertainization of politics. Like television, most other media are also subject to a creeping commercialization process. Since they are dependent on advertising, sponsoring, and PR material, they have to adapt to economic actors and cater to the interests of specialized target groups. As a consequence of commercialization, the differentiation and fragmentation of the media system continues to accelerate (→ Commercialization: Impact on Media Content).

### **REASONS FOR CHANGES IN THE MEDIA–POLITICS RELATIONSHIP**

Initially the change processes were regarded as *Americanization* tendencies, particularly in western Europe where in the 1980s most countries deregulated their broadcasting markets and introduced commercial radio and television, with a subsequent decline in the importance of public service broadcasting (→ Americanization of the Media; Public Service Broadcasting: Law and Policy). Today, the predominant view is that it would be more useful, rather than talking of Americanization, to understand the changes as a

process of → *modernization* which takes a similar progression in many western democracies (Swanson & Mancini 1996).

In *explaining the changes in the media–politics relationship* several authors assume that the media have become a functional prerequisite for the political system and its actors. Kepplinger, for example, holds that there has been a fundamental power shift at the expense of political institutions and in favor of the mass media. Moreover, because of feedback loops from the media coverage of politics to the political events and issues covered, politics became “mediatized” and to some degree a media construction: “What the media present as politics is partly the consequence of the conditions set by the media” (Kepplinger 2002, 983). Furthermore, because of the media’s focusing on political conflicts and scandals, they evoke a negative image of politics and the “dismantling of politics.” Similarly, Meyer (2002) observes a change from party democracy to media democracy with political institutions increasingly losing credibility. He posits a “colonization of politics” by the media leading to what he calls a “mediocracy.” This line of arguing was earlier highlighted by the seminal publications of Edelman (1964), Nimmo & Combs (1983), and Blumler (1990) which provide rich insights into the transformations of the media–politics relationship; yet these authors do not explicitly use the term “media democracy.”

Most theoretical explanations draw on → systems theories postulating a functional relationship between the political and the media systems. Three different explanatory paradigms may be distinguished: (1) redistribution of powers (the media emerging as the → “Fourth Estate”); (2) domination and dependency (of media over politics or vice versa); (3) interdependency or symbiosis of media and politics.

Whereas the first paradigm implies the presumption of media autonomy, the second is rooted in specific conjectures about power and control, particularly regarding the changing possibilities of both media and politics to maximize influence. The third explanation assumes a mutual interrelationship, in which under varying circumstances, either the media or politics prove the stronger influence. The three paradigms are explicitly or implicitly based on different normative ideas about the specific societal functions of politics and the media and their respective degree of power and autonomy.

In spite of the limited empirical evidence available for these hypotheses about macro phenomena it seems clear that the sole responsibility for the structural transformation and functional differentiation associated with the notion of media democracy cannot be attributed to the media, that is, these changes cannot be seen (only) as effects of the media. As for the micro and meso levels, it seems fruitful to redefine the media–politics relationship again and again empirically, starting from the premise of interdependency.

## **MEDIA DEMOCRACY IN CRITICAL PERSPECTIVE**

Several gloomy implications of the media democracy concept may be contested. For example, speaking of *the* media and thus implying a homogeneous mass media institution is quite unrealistic. Instead, in all modern democracies we find a highly differentiated and specialized media system with a large diversity of content supply. Mass media are still expanding, offering ever greater choices of political information. Moreover, political actors are disseminating information themselves via → Internet and employing new means of

→ strategic communication, for example by appearing in entertaining media formats. These changes may be expected to result in increasing political media use and political learning, at least among some groups of society (→ Political Media Use; Political Knowledge).

Generalizations about media democracy are quite frequently based on singular phenomena in a specific national and historical context, often during election campaigns. Yet → comparative research shows that political systems and media systems differ considerably, with corresponding implications for political actors and processes. It is also apparent that political actors and organizations adapt to the changing media environments and develop institutional arrangements that compensate for a loss of autonomy (Schulz 2004). Moreover, the model of democracy is also changing (as it is, e.g., indicated by the substitution of the “government” concept by “governance”). These changes have not yet been adequately considered in the media democracy discourse.

The consequences of mediatization for institutional structures and processes in politics, particularly at the meso level, deserve greater attention in empirical research and theory development. Institutionalism approaches seem to be particularly promising (Donges 2006). Political actors do not only adapt to environmental changes; they also have an impact on the rules for other actors, which can trigger institutional changes. On this background, it seems useful to start out from a view of → *political communication cultures* as relatively stable social arrangements. That the media are taking over the functions of political institutions, as some authors claim, is not in sight. Even in media democracies collectively binding decisions are made by the actors of the political system. And while it can be established that mass media have an influence on political decisions, other societal groups and actors are also participating in the decision processes.

Although the media democracy concept has been increasingly used in political communication research since the mid-1990s, its analytical usefulness is still contested. The concept is hardly more than a cipher for various phenomena that can be observed empirically and that are – within communication and political science – reflected theoretically. However, it has served to stimulate the discussion about the transformation of the media–politics relationship and its societal consequences and about the normative grounds for political communication in modern democracies.

## Media Democracy Movement

*Robert Jensen*

*University of Texas at Austin*

For a political system to be democratic – for ordinary people to have a meaningful role in the formation of public policy – an active citizenry must have the means to communicate their views about ideas and issues, among themselves and to political leaders. In a period of unprecedented advances in communication technology – more ways for more people to send more information ever more rapidly to others – one might assume that such changes mean more democracy. The post-World War II experience in the United States suggests that such an assumption is unwarranted. The increased capacity for communication does not automatically deepen democracy, and can in fact be an obstacle to attempts to deepen democracy when elite-run economic institutions have a dominant role in the development and deployment of technology, and when other social and cultural forces work to undermine active public involvement.

Hence the paradox: The final decades of the twentieth and first years of the twenty-first centuries have seen an atrophying of meaningful democracy along with the refinement of radio and television broadcasting technology; a dizzying expansion of → cable television and satellite channels (→ Satellite Television); changes in printing technologies to make high-quality publications more affordable; and the creation of the → Internet and a dramatic expansion of its scope and use. Citizens concerned about the inability of existing mass-media institutions to enhance and expand democracy have responded by creating what is often described as the media democracy movement.

### **PARTICIPANTS AND GOALS**

The movement has no central headquarters, single dominant organization, supreme leader, or unified platform. Instead, the term “media democracy movement” typically is used to describe a number of loosely affiliated groups that share a goal of expanding participatory democracy by (1) challenging the dominance of corporately owned media and (2) fostering the growth of independent or alternative media (→ Activist Media; Citizens’ Media).

On occasion, groups from a wide range of political positions in the US – from the conservative National Rifle Association to the liberal National Organization for Women – have come together to support a specific policy proposal, such as resistance to attempts by the → Federal Communications Commission (FCC) to loosen regulations that limit concentration of ownership in broadcasting (→ Television Broadcasting, Regulation of; United States of America: Media System). But in general, the media democracy movement is a liberal, progressive, and/or left formation rooted in some degree of critique of the concentrated power of corporations in capitalism and the way in which those corporations tend to dominate the political process. Among the most prominent US groups in this movement are the Free Press, Center for Digital Democracy, Media Access Project, Center for Media and Democracy, Prometheus Radio Project, Common Cause, Reclaim the Media, and Media Alliance.

These groups share a *central goal*: to slow, stop, and eventually reverse the consolidation of media ownership in the hands of a small number of mega-corporations. These conglomerates have holdings in multiple forms of media, including production companies and distribution outlets. While commercial media have never been ideal vehicles for independent journalism and creative entertainment programming, these trends toward consolidation have tended to lower the quality and critical edge of journalism, while pushing entertainment programs toward a lowest-common-denominator dullness, both in comedy and in drama (→ Media Conglomerates).

### **POLICY PROPOSALS**

Attempts by citizen groups to influence media policy are complicated by the power of the media corporations to intervene in the political process. In addition to the political influence any corporation can wield through campaign contributions from its executives and political action committees, media corporations also can use the threat of negative news coverage to seek to control politicians and influence policy. And by refusing to provide substantive crucial issues about legislation that benefits big media corporations,

these companies can help keep citizens uninformed about the consequences of consolidation, as was the case with the 1996 Telecommunications Act. This law, the most far-reaching modification of policy since 1934, was virtually ignored by mainstream media in the US, and typically treated – when there was coverage – as a business story of interest only to industry insiders (→ Commercialization of the Media).

One clear example of this power of media corporations concerns the proposal labeled “*free airtime*.” Under the fundamental law governing broadcasting, first laid down in the Communications Act of 1934, radio and later TV broadcasters are granted licenses to use the frequencies of the public airwaves at no cost but are instructed to work in the “public interest, convenience, and necessity.” In the 1990s, interest began to build in the idea that to help fulfill that public obligation, broadcast television stations could be required to offer to bona fide political candidates free airtime to articulate their political platforms. This would enhance democracy by lowering the amount of money candidates need to raise to pay for expensive TV commercials, while at the same time elevating the level of → political discourse by giving politicians a more expansive setting for debate and discussion than a short commercial (→ Election Campaign Communication). The National Association of Broadcasters, the industry’s main lobbying group, has opposed the measure, which would reduce their income from the lucrative political ads. Critics have also suggested that broadcasters reflexively reject any notion that their licenses, which are granted free of charge, should come with any such public obligations (→ Media Policy).

Among the *other policy proposals* that are supported by some or all of the groups in the media democracy movement are: the establishment and funding of low-power, noncommercial community radio and television stations; a commitment to localism in commercial broadcasting’s programming, to guarantee that communities have adequate channels for news and public affairs; a reversal of the trend in copyright law, which has been to extend the length of time corporations can claim exclusive rights to material; resistance to the commercialization of the Internet, in an attempt to insure a free flow of information and prevent the emergence of a two-tiered system, in which the profit-generating and subsidized political websites run on cutting-edge networks while noncommercial sites are relegated to slower, and hence less attractive networks; bridging the → “*digital divide*,” making sure that broadband Internet access, and training in the use of the Internet, are available to people in low-income communities; greater restrictions or an outright ban on television advertising aimed at young children; stemming the tide of ever-increasing commercialization of the culture, such as the expansion of product placement in television programs and films, which effectively turns entertainment programs into advertisements; exposing the growing use of sophisticated public relations techniques, such as the production of video news releases produced by companies to promote their services and products, which some television stations air as if they were news produced by the stations’ journalists; and media literacy education, beginning in grade school, to help people understand how to analyze media content, especially the image-based, highly commercialized television programs.

To advance these goals, media democracy groups have focused on critique of the existing media systems; political organizing for legislation to democratize the system; and the creation of alternative media to challenge the dominance of corporate media. The

movement tends toward local, decentralized, grassroots strategies, though there have been national organizing efforts, especially to affect FCC policies. In addition, in the first decade of the twenty-first century there have been national media reform conferences, spearheaded by the Free Press, to attempt to focus the diverse movement on common goals. Those conferences revealed both the broad interest in making media policy a central issue in progressive politics, and the divisions in underlying theory and politics among the groups, with some groups comfortable with a liberal or reformist position, and others pushing for a more radical analysis of fundamental economic and political structures. Divisions also have emerged as groups representing the interests of people of color have challenged the predominantly white movement on diversity issues.

Despite these differences, virtually all the groups and people identified with the media democracy movement reject the notion that market systems in capitalism will serve the needs of a democracy polity. While policy proposals may differ, the growing strength of the movement into the twenty-first century suggests that media policy will continue to be a focus of progressive politics.

## **Media Diplomacy**

*Eytan Gilboa*

*Bar-Ilan University*

Media diplomacy has become a major instrument of foreign policy, and journalists are more frequently and more intensively engaged in diplomatic events and processes. Sometimes they even initiate diplomatic processes. There are several ways in which the media can help or hinder diplomacy. The media functions both as an independent actor and as a tool in the hands of policymakers and journalists. Knowledge about media diplomacy is still very limited, and scholars from the fields of communication, international relations, and diplomatic studies should be encouraged to conduct multidisciplinary research on this topic.

Media coverage of negotiations and summit meetings among leaders transformed traditional, mostly secret, formal, professional diplomacy. The new diplomacy became a dominating ingredient in contemporary international relations due to three interrelated revolutionary changes in mass communication, politics, and international relations. First, the revolution in communication technologies created all-news global networks such as International, BBC World, Sky News, and Al Jazeera (→ Arab Satellite TV News; BBC; CNN; Newscast, 24-Hour), capable of broadcasting, often live, almost every significant development in world events to almost every place on the globe (→ International Communication; International Television). The → Internet has also revolutionized communication among peoples, communities, and organizations around the world. Second, the revolution in politics has generated growing mass participation in political processes and has transformed many societies from autocracy to democracy. Third, the revolution in international relations has transformed the goals and means of foreign policy. Favorable image and reputation around the world achieved through attraction and persuasion (soft power) became more important than territory, access, and raw materials obtained through military and economic measures (hard power). Today, → image and reputation determine the status and influence of states, leaders, and nonstate actors more than military and economic strength (→ Foreign Policy and the Media).

Politicians, diplomats, and scholars have suggested that the convergence of these revolutions created new types of interactions between media and diplomacy, and new terms to describe them, such as → *public diplomacy*, *media diplomacy*, *television diplomacy*, *populist diplomacy*, *instant diplomacy*, *headline diplomacy*, *teleplomacy*, *photoplomacy*, and *telediplomacy*. Several experts have argued that global television news now drives foreign policy, and have even developed a hypothesis, the “CNN effect,” to describe and analyze this phenomenon (Gilboa 2005a). Several of these terms are no more than lingual gimmicks, but they all represent an effort to capture the growing place of the media in diplomacy.

## THEORETICAL APPROACHES

The first scholarly attempts to define and explain media diplomacy were vague and confusing. Karl (1982) equated media diplomacy with open diplomacy – the mere exposure of diplomacy to the media and public opinion – or with public diplomacy – the use of mass media like the → Voice of America to influence → public opinion in a foreign society. For Ramaprasad (1983, 70) and Ebo (1996, 44) media diplomacy is just the role the media plays in diplomacy and foreign policy. Van Dinh (1987, 51–52) equated “television diplomacy” with → propaganda, but most of his examples – the televised ultimatum John F. Kennedy sent to the USSR during the 1962 Cuban missile crisis, Richard Nixon’s visit to China in 1972, and the 1977 visit of Egyptian president Anwar Sadat to Jerusalem – were designed to resolve crises and promote conflict resolution, and were not propaganda.

Ammon (2001) promoted media diplomacy to the status of a new paradigm. He claimed that paradigmatic changes in both communication and diplomacy produced a new paradigm of world politics, which he called “telediplomacy.” He explained that the emergence and expansion of real-time global news coverage caused the shift in

communication, while the “new diplomacy,” mostly characterized by openness, caused the shift in foreign policymaking. The result, telediplomacy, has displaced existing diplomatic methods, and for the first time in human history, under certain conditions, it also drives policy and determines diplomatic outcomes. Ammon went too far because his evidence and case studies do not support his paradigmatic claims.

Several scholars have offered much more specific and sophisticated definitions and approaches. Cohen (1986, 7) suggested that media diplomacy served three policymaking tasks: conducting public diplomacy, sending signals to other governments, and obtaining information about world events. This approach, however, seeks to characterize media diplomacy both as a part of and as somehow distinct from public diplomacy. Rawnsley (1995) distinguished between public diplomacy and media diplomacy: in the first, policymakers use the media to address foreign publics, and in the second they address government officials. Gilboa (2000) distinguished between three uses of the media in diplomacy: *public diplomacy*, where state and nonstate actors use the media and other channels of communication to influence public opinion in foreign societies; *media diplomacy*, where officials use the media to investigate and promote mutual interests, including conflict resolution; and *media-broker diplomacy*, where journalists temporarily assume the role of diplomats and serve as mediators in international negotiations. In this conceptual scheme, media diplomacy refers to uses of the media by leaders to express interest in negotiation, to build confidence, and to mobilize public support for agreements.

## USES OF THE MEDIA

Media diplomacy is pursued through various routine and special media activities, including press conferences, interviews, leaks, visits by heads of state and mediators to rival countries, and spectacular media events organized to usher in a new era (→ Media Events and Pseudo-Events). The media are used for several different purposes in international politics.

### Signaling

In the absence of adequate direct channels of communication, or when one side is unsure about how the other side might react to conditions for negotiations or to proposals for conflict resolution, officials use the media, with or without attribution, to send messages to leaders of rival states and nonstate actors. Using the media without attribution to sources is particularly efficient when policymakers wish to fly a “trial balloon.” They can avoid embarrassment and disassociate themselves from an idea that may receive a negative response. After the 1973 Arab–Israeli war, Henry Kissinger perfected the use of the media for signaling and pressure purposes during his famous and highly successful “shuttle diplomacy.” He often gave senior American diplomatic correspondents aboard his plane background reports, information, and leaks, mostly intended to extract concessions from the negotiating parties and to break deadlocks. Sometimes attitudes towards journalists of the other side send an important signal. Usually, the Syrian leader Hafez al-Assad and his foreign minister Farouq al-Shara barred Israeli journalists from attending their press conferences, but reversed this policy when they were interested in negotiations with Israel (Gilboa 2002).

### Communication

During grave international crises or when all diplomatic channels are severed, the media provide the sole unblocked channel for communication and negotiation between rival actors. During the first phase of the 1979–1981 Iranian hostage crisis, the US communicated with the terrorists holding the hostages exclusively through the media. A similar case occurred in the 1985 hijacking of a TWA jetliner to Beirut. During the crises preceding the 1990–1991 Gulf War and the 2003 war in Iraq, American presidents and the Iraqi leader Saddam Hussein hurled messages back and forth via the global news networks. In 1990, US Secretary of State James Baker delivered the last ultimatum to Hussein through CNN, and not through the US ambassador to Iraq. Baker chose CNN not only to save time but also to persuade the entire international community that the US was exhausting peaceful means to resolve the crisis and was determined to use force only if Hussein ignored the ultimatum.

Leaders use reliable third parties to secretly explore intentions of the other side, but sometimes simultaneously they also use the media to support the secret exchanges and to further indicate that their approach is serious. In the 1990s, the parties to the conflict in Northern Ireland conducted dialogues and exchanged messages through the media because formal negotiations among them were neither possible nor desirable. The media dialogue helped the sides keep the peace process alive and exchange significant messages (Sparre 2001). In recent years, leaders have used global communication more frequently to deliver messages intended to alter an image or to open a new page. They pursue this task through press conferences, interviews, leaks, and attitudes toward journalists of the other side. For example, in January 1998, the newly elected Iranian president Mohammad Khatami chose CNN to send a message to the US.

### Negotiations

Media events represent classic manifestation of media diplomacy. They include summit diplomacy: meetings between protagonist leaders seeking an opening for conflict resolution and possibly even longer-term reconciliation. Media events are broadcast live, organized outside the media, preplanned, and presented with reverence and ceremony (Dayan & Katz 1992). Live coverage of media events interrupts scheduled broadcasting and attracts wide audiences around the world. Media events have trivialized the role of ambassadors but they also help to break diplomatic deadlocks, create a climate conducive to negotiations, and promote favorable conditions for sealing an accord. Leaders can use media events to cultivate public support for a peace process *after* the conclusion of the initial phase but *before* moving on to the next phase (Gilboa 2002). This typically appears in cases where a breakthrough has been achieved, but the sides still have a long way to go before translating principles into a permanent legal peace agreement. Such an intermediary effect can help in mobilizing sufficient public support inside the societies involved for the next phase in the negotiations. The effects of media events gained vivid expression in summit meetings between the US and the Soviet Union during the Cold War and in Arab–Israeli talks. The media, however, may hinder negotiations by applying too much pressure on diplomats to make either too many or insufficient

concessions, by prematurely revealing sensitive information, and by creating unrealistic expectations.

### **Media-Broker Diplomacy**

The communication and information revolution has inspired journalists to assume, directly and indirectly, mediation roles in complicated international conflicts (Gilboa 2005b). Journalists pursue direct intervention when they actively help parties to begin official negotiations. Walter Cronkite of CBS News helped to arrange the historic 1977 visit of Anwar Sadat to Israel. In bridging, journalists facilitate a virtual stage for talks between enemies and attempt to help them realize the value of negotiation to resolve their conflict. Ted Koppel of ABC News frequently performed this role on *Nightline*. Journalists were also engaged in critical secret mediation. John Scali, diplomatic correspondent for ABC News, helped to end peacefully the 1962 Cuban missile crisis through secret talks with a high-ranking Soviet official. Media-broker diplomacy raises professional and ethical issues. Critics argue that journalists should cover events, not create them. Additionally, while serving in diplomatic roles, journalists continue to cover diplomatic events, and they may provide distorted coverage because of personal interest in a successful outcome.

## Media Ecology

Julianne H. Newton

University of Oregon

Media ecology is a multidisciplinary field that studies the evolution, effects, and forms of environments. Media ecology is most often defined as both the study of *media as environments* and the study of *environments* – such as situations or contexts – *as media*. Scholars work within expansive definitions of media, ecology, and technology. Although “medium” is often conceptualized in terms of transportation or a pipeline, the term actually means “environment.” Media therefore include not only communication technologies but also such entities as the brain and body, a lecture hall or galaxy, and languages, symbols, and → codes (→ Information and Communication Technology, Development of). Media ecologists study all types of technology, not just communication technologies, and often use the terms “media” and “technology” interchangeably. “Ecology,” too, encompasses a complex range of meanings for media ecologists, who draw on → systems theory to analyze the co-evolution of the human organism and technologies. In addition, media ecologists are concerned with the general role of technology in society (→ Communication and Social Change: Research Methods).

Media ecology as a field distinguishes itself from communication per se, positing an open, dynamic, interdependent, and living system of forces. When studying human communication systems, media ecologists work from an inclusive perspective, exploring the creation, exchange, mediation, and dissemination of information, as well as the reciprocally influential relationship among means/content of communication and communicators/users (→ Language and Social Interaction). Media ecologists frequently employ a model of four major media environments and concomitant cultures: oral, scribal/manuscript/chirographic, print/typographic, and electronic.

Lance Strate, co-founder and president of the 10-year-old Media Ecology Association (MEA), categorizes media ecology as a field of study, eschewing the concept of discipline or even cross-disciplinary study in favor of inviting overlap among multiple disciplines in search of holistic theoretical approaches and explanations for communication phenomena. For example, media ecologists might ground theory in the traditionally distinct ideas of Aristotle and Plato, science and art, or → journalism and literature (→ Communication as a Field and Discipline). The goal – and indeed the genesis – is complementarity and

simultaneity rather than separate, oppositional categories. Strate stresses that media ecology is “an intellectual tradition, a perspective and a shared sensibility . . . a network of related literature, a series of conversations and arguments that span the centuries” (Strate 2006, 2).

## HISTORY

Neil Postman is credited with coining the term “media ecology” in 1968. However, the history of this expansive approach to studying meaning-making and dissemination is often traced back to ancient times, with particular attention to analyzing contemporary media forms in context with the oral traditions of early humans. Media ecologists point to communication forms external to the body – such as gesture, cave art, speech, and in particular writing – as evolving from and influencing the evolution of communication forms that are internal to the body – such as mental structures, patterning, memory, and creativity (→ Gestures and Kinesics; Evolutionary Theory; Discourse, Cognitive Approaches to). A *foundational hypothesis* is that each form of communication simultaneously evolves from and affects the nature of thought itself and therefore affects message content and perception. This idea is most famously expressed through → Marshall McLuhan’s axiom “The medium is the message.” Asked what happens to content in such an approach, Eric McLuhan responds, “My father was asked that many times. His answer? The user is the content.”

The three foundational theorists in contemporary media ecology are Marshall McLuhan, Walter Ong, and Neil Postman. Although McLuhan’s first book, *The mechanical bride: Folklore of industrial man* (1951), laid the groundwork for future theory through its scrutiny of popular culture as revealed through advertising and other media imagery, his *Understanding media* (1964) expresses a number of influential themes: media extend the body, media transform the user, media transform other media, media transform culture, and the medium is the message. Among the major influences on McLuhan were political economist → Harold Innis and anthropologists Edward T. Hall and Edmund Carpenter.

Walter Ong, who studied with McLuhan, emphasized evolution of media environments and intersections of consciousness, communication, and culture. One of his best-known works, *The presence of the word* (1967), presented his conceptualization of primary orality, or communication before the time of writing, and secondary orality, or communication influenced by writing and subsequently by electronic forms of media. Ong’s *Orality and literacy* (1982), which further explores differences between oral and literate societies in terms of communication and cognition, has been particularly influential.

Neil Postman, who founded and directed the Media Ecology Program at New York University until his death in 2003, has been influential in both scholarly and public arenas. An advocate of the need for schools to preserve print-based literacy as a way to preserve cultural values, he also achieved fame as a media critic. He is known for a number of books, including *The disappearance of childhood* (1982) and *Amusing ourselves to death* (1985), in which he admonishes television and electronic media for their negative effects on culture and language. The Media Ecology Association, led by scholars who began their careers under the tutelage of Postman, meets annually.

A common theme among the works of McLuhan, Ong, and Postman is that the development of writing, and in particular the Greek alphabet, significantly altered how humans think, behave, and make meaning. The scholars asserted the value of written communication over other forms of mass media, crediting “the word” with helping humans develop a sense of individuality and intrapersonal communication. A related theme is the influence of communication systems on social organization and culture. In this vein, notation and writing systems are linked with the origins of civilization, the city and empire. The visuality and linearity of the Greek alphabet, for example, are viewed as primary determinants of western civilization, including laws and systems of government. Media ecology literature frequently refers to the influences of the alphabet and Gutenberg’s printing press on the development of such modern-world concepts as nationalism and individualism. In turn, the pervasiveness of contemporary electronic media now undermines nationalistic boundaries. Another common thread is the idea that we now live in an “acoustic age,” in which media dimensions extend beyond the visual through sound and emotion, fostering multi-sensory experiences.

Other major scholars from disciplines ranging from linguistics to sociology to physics form a nucleus of the literature providing key threads of theory supporting and influencing media ecology scholarship. Frequently referenced are Edward Sapir, George Herbert Mead, Lewis Mumford, Benjamin Whorf, Edward T. Hall, → Erving Goffman, Daniel Boorstin, Jacques Ellul, Eric Havelock, Buckminster Fuller, and Gregory Bateson. Particularly influential is Susanne Langer, whose *Philosophy in a new key* (1942) expanded the concept of symbol to include art, music, and sensory perception. Other thinkers who have influenced the field include Noam Chomsky, Niklas Luhmann, Susan Sontag, Humberto Maturana, Francisco Varela, Ilya Progogine, Isabelle Stengers, Jay David Bolter, Richard Grusin, Robert Logan, Joshua Meyrowitz, James Carey, Denise Schmandt-Besserat, David Altheide, and Kathleen Hayles.

## METHODS

Media ecologists employ cultural history, seeking to discern historical patterns that illuminate the present and offer insight into the future. In *The myth of the machine* (1967), Lewis Mumford explained: “If we do not take the time to review the past we shall not have sufficient insight to understand the present or command the future: for the past never leaves us, and the future is already here” (1967, 13). Additional methods include ethnography; case study; context, textual, aesthetic, philosophical, and critical analysis; and creative literary and artistic forms used as probes to facilitate awareness, understanding, and innovative exploration. Media ecologists occasionally employ traditional quantitative methods, particularly in triangulation with qualitative methods.

One method unique to media ecology scholarship is application of the *tetrad* to interpret and predict media effects on society and culture. Articulated by Marshall McLuhan and Eric McLuhan in *Laws of media: The new science* (1988), which Eric McLuhan completed after his father’s death in 1980, are four laws, or questions: What does a medium enhance or extend? What does it obsolesce or background? What does it retrieve? And what does it reverse into when pushed to the extreme? Eric McLuhan describes the tetrad process as similar to playing a musical chord in which a medium’s effects are experienced synchronally,

dynamically, and through multiple dimensions. Another presentation of the tetrad is found in Marshall McLuhan and Bruce Powers' *The global village: Transformations in world life and media in the twenty-first century* (1989), which Powers completed after his colleague's death. This version illustrates the four laws via a Möbius strip through which media forms and effects continually shift or resonate. Both versions emphasize simultaneity, complementarity, and an endless, nonlinear, dynamic process of transformation. Recent work extends application of the tetrad to the analysis of practices, institutions, and concepts.

## KEY ISSUES

A number of major themes and issues can be identified: (1) Tension between organisms as technologies and organisms as creators of technologies; (2) co-evolution of organisms and technologies, though scholars such as Mumford emphasize development of brain over development of external tools; (3) influence of a medium on content, users, and cultures; transformation through and because of technological use; (4) multidisciplinary, in which art/science, literature/journalism, fiction/fact, popular/elite, internal/external, figure/ground, and visible/invisible reciprocally inform and transform; (5) concern about deterministic aspects of potentially out-of-control technology, particularly in relation to humanistic values and global sustainability; (6) tension between understandings of word and image, oral and written, visual and acoustic, organism and machine; (7) holistic, contextualized views of particular occurrences; (8) emphasis on synchronous and complementary, rather than distinctive and oppositional, processes and influences; (9) inclusive topics of study ranging from autism to artificial intelligence; (10) playful exploration balanced with theoretical commitment to relationships among organisms and ideas; (11) openness to creative approaches and intellectual risk-taking in the interest of discovery.

In his keynote address to the first conference of the Media Ecology Association in 2000, Neil Postman asserted that media ecology “exists to further our insights into how we stand as human beings, how we are doing morally in the journey we are taking.”

## Media Economics

Alan B. Albarran

University of North Texas

Media economics is the application and study of economic theories and concepts to the media industries. Media economics encompasses all forms of media, including traditional media such as print, broadcasting, music, and film, and new media forms such as the Internet. Media economics scholarship is broad and diverse and includes such topics as policy and ownership issues, market concentration, practices and performance of media firms, and political economy of the media. This entry reviews the historical development of media economics, the key theories and paradigms in media economics research, and the contributions of media economics to the broader area of communication science.

### HISTORICAL DEVELOPMENT OF MEDIA ECONOMICS

The development of the field of media economics began with the study of economics itself. The earliest literature on economic thought began to evolve with the study of mercantilism in the sixteenth century in western Europe. *Mercantilists* equated wealth with the accumulation of precious metals like gold and silver. If nations lacked mines, they could acquire products through trade and commerce. This led to political intervention in the market via tariffs and subsidies, elevating commercial interests to national policy and tying economic activity to political interests. The *French physiocrats*, a group of eighteenth-century philosophers, rejected mercantilism in favor of agriculture, and represent one of the first groups to call for a policy of *laissez-faire*, or minimal government involvement in the market. This group was among the first to view the economy as a constant flow of inputs and outputs.

The philosopher *Adam Smith* is credited with providing the first syntheses of economic thought with a large collection of writings that became a seminal work entitled *The wealth of nations*. Smith identified land, labor, and capital as the three most important factors of production and the key contributors to a nation's wealth. Smith referred to the

growing discipline as “political economy,” which became the early name for the study of economics. In addition to Smith, David Ricardo, Thomas Malthus, and John Stuart Mill collectively formed what is known as the classical school of political economy. The work of these authors centered on the interplay of economic forces, the operation of markets, and the cost of production.

The classical school would later be challenged by new ideas: *marginalist* economics and Marxism. While the classical scholars believed that price was determined primarily by the cost of production, marginalists equated prices with demand. The marginalists contributed the basic analytic tools of demand and supply, consumer utility, and the use of mathematics as analytical tools – all forerunners to the development of the area of economics known as microeconomics. Marginalists also argued that, given a free market economy, the factors of production (chiefly land, labor, and capital) were important in understanding the economic system.

The *Marxist school*, built on the works of Karl Marx, identified labor as the source of production. Marx rejected the idea of a market system that allowed capitalists (the owners of factories and machinery) to exploit the working class and deny them a fair share of the goods produced. Marx predicted the eventual fall of capitalism, believing that the disenfranchised labor class would ultimately rebel, overthrow the capitalists, and seize the means of production.

By the beginning of the twentieth century, institutions of higher learning embraced the growing field and dropped the word “political” in favor of the single word “economics,” used to represent courses of study in both North America and Europe. But another more important shift was occurring, as economic research moved from a classical approach to that of neo-classical economics. *Neo-classical economics* differed by its use of both analytical tools and mathematics (primarily calculus) to examine market behavior and price determination. Yet another important contribution of neo-classical economics was its refinement of demand theory, since much of classical economics tended to focus only on the concepts of production and supply. Many principles developed in the neo-classical era became the basis for the broader study of microeconomics.

In the second half of the twentieth century, the study of economics was further enhanced by a number of important contributors. Alfred Marshall emerged as one of the most prolific economic scholars, influencing countless graduate students during his tenure at the University of Cambridge. Marshall is credited with refining many aspects of economic theory, and also made key advances in the study of industry supply, consumer surplus, elasticity of demand, and allocation of resources.

Edward H. Chamberlin, another key scholar, theorized a new form of market structure during this period called *monopolistic competition*. Monopolistic competition centered on the concept of product differentiation, with application to a number of different markets where multiple suppliers offer products that differ slightly from one another. Joan Robinson, one of the few female scholars in the neo-classical era, developed the theory of imperfect competition, which examined price discrimination among monopolists as well as the market for labor. Welfare economics, the examination of how economics can be used to promote better social policy, also came of age during the neo-classical period.

Significant changes in twentieth-century economic thought were further realized with the development of *macroeconomics*. Here the focus shifted to aggregate economics,

which encompasses the entire range of monetary and market principles. Macroeconomics became a catalyst for numerous fiscal policy decisions in both western Europe and the United States during the 1950s and 1960s. John Maynard Keynes, a student of Alfred Marshall and the eventual founder of Keynesian economics, became the best-known scholar of macroeconomics.

Keynes's thinking and research would provide the rationale for the use of government spending and taxation to stabilize the economy. Keynes believed the government should increase spending and decrease taxes when private spending was insufficient and threatened a recession; conversely, government would reduce spending and increase taxes when private spending was too great and threatened inflation. Keynes's focus on the factors that determine total spending remains at the core of modern macroeconomic analysis.

Other scholars who helped influence macroeconomics as an area of study included Irving Fisher (money, price, and statistical analysis), Knut Wicksell (public choice), A. C. Pigou (welfare economics), and Milton Friedman (economic policy and consumption). The study of macroeconomics is now concerned with many topics, including economic growth, employment, aggregate production, consumption, inflation, and political economy. Still other areas of study that coincided with this time period included the development of international economics, improving methods of applied economics, and the adoption of more powerful analytical and statistical tools through another sub-field known as econometrics.

Economic theories and economic thought are constantly changing and evolving. By the 1970s, growing inflation and changes in productivity pushed economics in new directions such as monetarist theories, which re-emphasized growth in the money supply as a determinant of inflation. Rational expectations anticipate government intervention; the theory argues that the market's ability to anticipate government policy actions limits their effectiveness.

The study of supply-side economics revisited a concern expressed in the classical school regarding economic growth as a fundamental prerequisite for improving society's well-being. Supply-side economics emphasizes the need for incentives to increase consumer savings and investment if a nation's economy is to prosper, and the danger of canceling out those incentives through high taxation.

## **DEVELOPMENT OF MEDIA ECONOMICS**

This review of major historical developments in economic thought illustrates the rich diversity of scholarship and theories in the field of economics. As the study of economics became more refined, scholars began to investigate many different markets and industries, applying economic concepts and principles to different fields, including media. The interest in this area would lead to the development of media economics.

The growth of the mass media paved the way for the study of media economics, with some of the earliest research emerging during the 1950s and flourishing through the twenty-first century. The media industries featured all of the elements necessary for studying the economic process. Content providers offering information and entertainment represented suppliers, with consumers and advertisers forming the demand side of the market (→ Supply and Demand in Media Markets). Regulatory and policy agencies (e.g., → Federal Communications Commission [FCC], Federal Trade Commission, and other

entities) affected macroeconomic market conditions, while the relationship among suppliers in various industries created microeconomic market conditions.

Many of the early media economics studies addressed microeconomic concepts, with → newspapers, → radio, and → television the primary industries under examination. Much of this early research is descriptive in nature, reviewing topics like ownership, advertising revenues, the structure of the market, and competition with other media (→ Advertising, Economics of).

*Concentration of ownership* emerged early in the field as a critical topic, and continues today. Concentration of the media impacts both regulatory and social policy, and there is a considerable body of literature on media concentration available on all segments of the media industries. Concentration is synonymous with ownership, another area of concern for media economics research (→ Concentration in Media Systems; Ownership in the Media). Ownership studies also can be examined from a media management perspective, illustrating the interdependence between media management and media economics. Other studies have examined media competition, consumer expenditures and the principle of relative constancy, barriers to entry for new firms, advertiser and ownership demand, and consumer utility.

In 1988, the field of media economics became further established by the debut of the *Journal of Media Economics*. Over time, the *Journal of Media Economics* has emerged as the premier journal for the latest research in the field. In addition to articles in scholarly journals, a number of books and edited volumes have contributed to the development of media economics.

## **THEORETICAL DIMENSIONS OF MEDIA ECONOMICS**

Media economics research utilizes a variety of theoretical approaches. In terms of theoretical development, the field can be broadly classified into three major areas that account for much of the knowledge regarding media economics: microeconomic theories, macroeconomic theories, and political economy, which may also be identified as critical theory (→ Political Economy of the Media). Much of the historical literature base deals with microeconomic trends and issues, which is particularly suited for media economics research as it centers on specific industry and market conditions.

Macroeconomic studies by their very nature take a much broader focus, examining such topics as labor and capital markets, gross domestic product, and policy and regulatory concerns (→ Labor in the Media). In comparison, the literature base utilizing macroeconomic theories is much smaller than the literature drawing on microeconomic theories.

Political economy of the media is itself broad and diverse, emerging as a response to positivist approaches in mainstream economic theory. The mass media became a natural area of inquiry for political economy research, drawing scholars from fields such as political science, sociology, and economics as well as communications. This section of the essay focuses on micro and macroeconomic theories used in media economics research.

### **Microeconomic Theories: The Industrial Organization (IO) Model**

The most widely used framework for the study of media economics is the industrial organization model, developed by a number of neo-classical economists. The model

offers a systematic means of analyzing many of the abstract concepts encountered in the study of a specific market. The industrial organization, or IO, model is built around three main variables: market structure, market conduct, and market performance. As such, the model is also identified as the SCP model, used as a tool for analysis in the study of media markets and industries.

In its simplest form, the IO or SCP model posits that if the structure of the market is known, it allows explanation of the likely conduct and performance among firms. Each of the three areas (structure, conduct, and performance) can be further defined and analyzed by considering the specific variables associated with each part of the model. For example, in regards to market structure, the variables often used for analysis include an examination of the number of sellers and buyers in the market, the degree of product differentiation, the barriers to entry for new competitors, cost and pricing structures, and the degree of vertical and horizontal integration.

The market offers great utility for media economics scholarship. Some scholars have focused on just one part of the model, such as market structure, while others take a holistic approach and analyze all parts of the model. The model recognizes the interdependent relationships that exist between how the market is structured, and the resultant conduct and performance expectations. There has been criticism that media economics scholars rely too heavily on the IO model, and that the IO model does not capture all of the nuances associated with new technologies and the convergence of markets. However, the model still offers great utility to researchers and remains one of the key theoretical foundations in microeconomics research.

### **The Theory of the Firm**

Efforts to refine an understanding of market structure led to the development of what is known as the theory of the firm. The theory of the firm is an expansion of the industrial organization model, with the goal of gaining a more thorough explication of the most common types of market structure: monopoly, oligopoly, monopolistic competition, and perfect competition. Most media markets tend to be dominated by oligopoly and monopolistic competitive structures. Perfect competition is rarely identified in the media industries (one exception being websites), and monopoly tends to be limited to areas like newspapers and cable television.

The appeal of this approach lies in its simple and parsimonious nature. However, the defining of a market structure has become increasingly complicated due to rapid consolidation across the media industries and technological convergence (→ Consolidation of Media Markets). For example, the market for radio can be considered as simply the market for broadcast radio, but it can also encompass a much wider definition that includes high definition (HD) and satellite radio, Internet radio, and even podcasting. Many scholars suggest that market structure cannot clearly be defined using these broad and simplistic labels.

### **Media Concentration**

Another area of theoretical development with significant implications for both public and social policy is *media concentration*. In the United States, antitrust laws are designed to

promote competition and limit concentration, making this a controversial topic of study. Media concentration tends to be examined in one of two ways. Researchers gather existing data on firm or industry revenues to measure the degree of concentration by applying different methodological tools such as concentration ratios, or other indices. The other approach is to track concentration of ownership among the media industries. Regardless of the approach, research has clearly shown there is increasing consolidation across all areas of the media industries with many facets reaching the levels of “highly concentrated” status, indicating that a limited number of firms control the revenues or ownership in a market. Globalization of the media industries has contributed to media concentration, with a global oligopoly of media firms controlling the majority of what people around the world see, hear, or read (→ Globalization of the Media). Media concentration research can be studied at all levels of analysis, from local markets to global markets.

### **Media Competition**

The study of how the media compete with each other has also captured the interest of media economics scholars (→ Competition in Media Systems). Much of this literature draws upon niche theory, which originated in the field of biology and the study of ecosystems. Competition studies typically take one of two forms: competition within an existing industry, or competition across media industries. Various indices are used in this area of research to measure the breadth, overlap, and superiority of one media form over another.

### **Relative Constancy**

The principle of relative constancy sought to understand the relationship of consumer spending to media consumption. This research first appeared in the 1970s, and stressed that on average households spend around 3 percent of their disposable income on media services and products over time. Some later studies on relative constancy were conducted over the next few years, but the topic has not been revisited for some time.

### **Macroeconomic Theories in Media Economics**

There is a much more limited body of literature involving macroeconomic analysis in the field of media economics. Most of the macroeconomic research is related to policy and regulatory analysis, usually conducted at a national level of analysis. Policy studies usually attempt to analyze the impact of regulatory actions and decision-making on existing markets and industries (→ Media Policy; Communication and Law).

Labor and employment trends in particular media industries are another area of study that is often approached from a macroeconomic perspective. Much of this research tends to be centered on the print (newspaper) or broadcast (television and radio) industries (→ Television Broadcasting, Regulation of; Radio Broadcasting, Regulation of).

Another area of focus centers on *advertising revenues and expenditures*. Often these types of studies build on aggregate data from specific countries and regions of the world to determine their economic impact. For example, many studies in this area consistently

show that the bulk of advertising dollars are located in what is known as the triad, the regions of the world representing North America, western Europe, and Japan and the Pacific Rim nations. Due to many trade pacts and the rise of the World Trade Organization (WTO), analysis and tracking of advertising data is of interest to researchers in media economics.

In its early stages, much of the media economics research was labeled as atheoretical. This criticism was justified as many of the early studies lacked any theoretical foundation, but since the 1970s the field has witnessed considerable theoretical growth and development, although there is still room for greater expansion and refinement of theory.

### METHODOLOGIES USED IN MEDIA ECONOMICS RESEARCH

Media economics research embraces many different types of methods to answer research questions and investigate hypotheses. However, most of the existing literature tends to utilize one of four methods: trend studies, financial analysis, econometrics, and case studies.

*Trend studies* are used to compare and contrast data over a time series. In assessing media concentration, scholars typically study concentration indices over time to gauge the impact of policy decisions or other significant actions on media ownership. Most trend studies tend to use annual data as the unit of analysis. Trend studies are helpful due to their descriptive nature and ease of presentation, and aid in analyzing media company and industry performance. Trend studies can be applied to virtually any media industry (→ Survey; Research Methods).

*Financial analysis* is another common tool used in media economics research. Financial analysis can take many different forms and utilize different types of data. The most common data includes information derived from company financial statements, along with the use of financial ratios. In the USA, all publicly traded companies must file financial statements with the Securities and Exchange Commission (SEC). Individual companies distribute annual reports to their shareholders that contain financial statements. The → *Internet* has become a very important source of financial data for researchers, making it much easier to collect and analyze financial data. Financial analysis is much more challenging in research on privately held companies, which are not required to disclose any financial information, as well as companies domiciled outside the US where accounting practices and currency exchange rates vary.

*Econometric analysis*, drawn directly from economics, involves the use of *statistical and mathematical models* to verify and develop economic research questions, hypotheses, and theory. Econometrics is more prevalent in the general economic literature, because most media economics researchers coming from communication or journalism backgrounds lack the mathematical expertise needed for econometric modeling (→ Statistics, Descriptive; Statistics, Explanatory).

*Case studies* represent another extremely useful method in media economics research (→ Case Studies). They are popular for researchers because they embrace different methodological approaches as well as types of data. For example, a case study of a particular company might combine in-depth interviews, financial information, and analysis of company reports over a series of years. Case studies in media economics research tend to be very targeted and focused examinations. They are not limited to just companies and

industries; they can investigate topics such as management styles, marketing and branding strategies, and consumer behavior.

Methods used in media economics research are not limited to these approaches. Researchers can also employ policy analysis to investigate regulatory action on media companies, markets, and industries. Historical research is occasionally represented in the literature, and may be combined with approaches like trend studies.

*Critics of media economics research* contend that too much of the research remains descriptive in nature, and that the variety of methodological approaches is limited. There are also complaints that researchers tend to spend too much time studying only the major companies, and that too much attention has been expended on traditional media industries like television and newspapers, and not enough on new media forms and enterprises.

### **FUTURE DIRECTIONS FOR MEDIA ECONOMICS RESEARCH, THEORY, AND METHODOLOGIES**

There are a number of steps researchers and scholars need to address in their efforts to further develop and shape the field of media economics in terms of research, theory, and methodologies. Each of these areas has equal priority given the rapid pace of change and evolution occurring across the media industries.

#### **Media Economics Research**

One of the most pressing research issues in the field of media economics is reconceptualizing and defining what constitutes a market and expanding our *understanding of the key variable of market structure* (→ Markets of the Media). Media economics research must grapple with the evolving definition of how to define a media market, a critical issue given the convergence and consolidation taking place across the media industries. Markets are no longer defined cleanly. Media companies supply products in many different markets and sub-markets, in competition with other providers. Yet the tendency among policy-makers and researchers is still to treat markets using traditional labels, such as television, newspapers, or motion pictures. This approach fails to recognize the realities of the media marketplace, and can lead to inaccurate assumptions over which firms dominate a particular market. In reality, each of these media is undergoing significant change in terms of how their products are distributed and their content. The trend for many media companies is toward becoming multimedia enterprises. Newspapers have websites that feature video and audio clips (“podcasting”) while television stations offer streaming media and links to partnership newspapers and print products (→ Convergence of Media Systems).

One answer to this dilemma is to consider the functions of a firm rather than focusing on just the final product. If for example, → Disney is considered a company with multiple brands engaged in content creation and distribution, it perhaps offers a clearer interpretation of what the company is about and how it seeks to be a leader in many different markets like network television, program syndication, cable networks, radio, and feature films (→ Distribution; Diversification of Media Markets). Such an approach considers the totality of media operations, and provides researchers with a more accurate picture.

In addition to clarifying and refining key concepts, media economics research must also expand into new arenas. No doubt, studies on television, newspapers, and other traditional media will continue to be conducted, but there are new areas where research is needed. Among the areas where new understanding and investigation are required are online phenomena like blogging and podcasting, as well as exploring new emerging industries like satellite and HD radio, online video distribution, and the use of search engines to deliver media content (→ Blogger).

It is also time to revisit the relation of consumer spending to the media. Knowledge of this area is limited to the principle of relative constancy introduced earlier. Research is needed to build upon this principle, to see if the early patterns identified with consumer spending have been maintained, or to determine to what extent they have changed.

### Media Economics Theory Development

Media economics research has relied heavily upon microeconomic concepts and principles, most of which build on the industrial organization model. While this emphasis has helped to clarify the relationship of various concepts in microeconomic analysis, it has also limited the development of the field. Other economic theories, which have possible application to the media industries, have been ignored, especially those found in macroeconomics. Macroeconomic approaches can be used to strengthen our understanding of areas such as the factors and patterns of global consolidation of media markets. The impact of global consolidation on topics like employment, economic development, and inflation are just three possible topics of interest.

In addition to drawing upon the diversity of existing economic theory, media economics scholars should consider *new theoretical inquiries* that could draw upon multiple methods of investigation. The interplay of business structures, government regulation, new technology, and social policy implications across the media industries offers a unique opportunity for scholars to generate new theories and hypotheses. Researchers must be willing to move away from simply describing specific firms' structure and performance, take some risks, and produce more analytical and investigative analysis.

In addition to the need to understand the concept of the market better is a need to *redefine the theory of the firm*. Media economists have functioned primarily within the three areas most prevalent in the mass media: monopoly, oligopoly, and monopolistic competition. But other types of structures are evolving across the industries. Duopoly, the structure identified with two primary firms, is becoming more common in media markets, such as with satellite radio (between competitors XM and Sirius) and multichannel video (between cable and satellite providers).

In many media industries what we really have is a two-tiered market structure, with a limited oligopoly of firms (from three to seven) controlling between 75 and 90 percent of the revenue/market share, and a number of smaller firms on the other tier competing for the remaining market share. Media industries representing this type of hybrid structure are the motion picture, recording, television network, radio, consumer book publishing, and magazine publishing sectors. Exploration of the variables that describe these new and evolving market structures is badly needed in the field of media economics.

### Improving Methodological Tools

Improvements in developing theory and redefining and conceptualizing the media market and market structure must be realized in conjunction with enhancements in methods and methodological tools. No area deserves attention more than measures used to assess competition and concentration.

Measures to assess competition and concentration have relied primarily upon one of two available tools: descriptive concentration ratios and the Herfindahl-Hirschman Index (HHI), used by the US Department of Justice. Concentration ratios provide a parsimonious way to measure concentration, using either the top four firms or the top eight firms in a market. If the top four firms control at least 50 percent or more of the market revenue, or if the top eight firms control at least 75 percent or more of the revenue, the market is labeled “highly concentrated.” While the measure is useful, it fails to address the possible inequality of market shares. For example, using a four-firm ratio, one could encounter one firm dominating the market with 40 percent of the revenues, while the other three firms hold a combined 10 percent. Such a market would be considered highly concentrated, but there is a clear dominance by the top firm (→ Cost and Revenue Structures in the Media).

The HHI index is more rigorous. It squares the market share for each firm, and then aggregates a total from all the firms. Researchers need data on *every* firm in the market in order to calculate the index. Researchers in the academic sector often lack access to data from all firms, especially privately held companies. Further, calculating the index can be unwieldy.

But more problematic for both these measures is that they are designed only to measure concentration *within* a particular market segment. There are no generally accepted measures available to assess concentration *across* markets yet, although some researchers have attempted to offer some solutions. Time Warner (→ Time Warner Inc.), → News Corporation, → Sony Corporation, Disney, Viacom and other media giants may have a limited market share within individual market segments, but no tools exist to measure their combined influence across markets. With so many multi-product firms engaged simultaneously in many different media markets, measures need to be developed to assess within-industry concentration and competition.

Media economics provides theories and tools to understand the activities and functions of media companies as economic institutions. An understanding of media economics strengthens our overall understanding of the role and function of the media in society. At a theoretical level, media economics complements existing communication theory by adding important dimensions regarding the structure, conduct, and performance of media firms and industries, the interplay of economics, policy and regulation, and audience behaviors and preferences. Media economics research will continue to evolve as it attempts to analyze and evaluate the complex and changing world in which the mass media industries operate.

## **Media Effects**

*Hans Mathias Kepplinger*

*Johannes Gutenberg University of Mainz*

The concept “mass media” is a collective term that stands for a broad variety of print media like → newspapers, → magazines, → books and electronic media like → radio, → television, and the → Internet. The concept “newspaper,” in turn, comprises daily and weekly newspapers, and “magazines” publications like news magazines, fashion magazines, sports magazines, etc. All mass media offer different features – news analysis, → news, → editorials, commercial messages, and so on – and deal with a broad variety of topics – including domestic and foreign politics, economy, arts, sports. Some mass media present only visual information (printed media), some only acoustic information (radio), some primarily moving images (TV, movies), while some present them all (Internet).

The concept of the effects of mass media is also a collective term for the effects of different signals like verbal messages and nonverbal signals (→ Nonverbal Signals, Effects of); of the style of coverage (→ Order of Presentation; Exemplification and Exemplars, Effects of); depicted behavior like violence (→ Violence as Media Content, Effects of), sex and pornography (→ Sex and Pornography as Media Content, Effects of); and of

coverage of different topics like politics, economy, and sports. Therefore, when we discuss the effects of mass media we would be interested in the specific effects, for example, of the news on specific topics, of entertainment programs, of visual images, and so on.

### **TYPES OF EFFECTS**

The mass media can produce a broad spectrum of effects. Among them are physical effects (→ Physical Effects of Media Content), effects on beliefs (knowledge), effects on attitudes and values (→ Attitudes, Values, and Beliefs, Media Effects on), effects on emotions (→ Emotions, Media Effects on), effects on social behavior (→ Social Behavior, Media Effects on), effects on public opinion (→ Public Opinion, Media Effects on), and effects on the reputation of people covered by the media (→ Social Capital, Media Effects on; Reciprocal Effects). These effects may be the consequences of media use, but they may also be a result of interactions with people who have used the media and subsequently been influenced by prior media exposure (→ Opinion Leader; Two-Step Flow of Communication; Media Effects: Direct and Indirect Effects). Alternately, the media may intensify or change existing beliefs, opinions, or attitudes (→ Persuasion). Media effects may also be manifest in the acquisition of knowledge or in the imitation of behavior depicted by the mass media (→ Observational Learning). In some instances, the mass media may also influence the conclusions drawn by the recipients of media messages, which might actually exceed the information presented (→ Priming Theory).

Media effects may be present after just a single contact with an article and may occur within a short period of time. Alternately, observable effects of media exposure may also be the result of ongoing multiple contacts with several related articles and may set in only after a certain lapse of time (→ Cumulative Media Effects). The effects of mass media may erode quickly in some cases, or they may last for a long time (→ Media Effects Duration; Sleeper Effect). Furthermore, media effects are often proportional to the intensity of coverage or the frequency of media exposure. Thus, effects may already be very strong after only a few articles (contacts) or may set in only if the media have reported often on a subject (→ Linear and Nonlinear Models of Causal Analysis).

The effects of mass media may be limited to singular aspects such as beliefs or emotions or there may be interdependencies between various effects. For example, media information may arouse emotions that contribute to an increase in the credibility of consistent information (→ Appraisal Theory). However, because of the multitude of possible causes and effects, general statements on the effects of the media cannot be made. The type and strength of media effects depend on the respective production techniques and consumption conditions.

### **HISTORY OF MEDIA EFFECTS RESEARCH**

The effects of the mass media have been and are still being examined by a considerable number of researchers who have made substantial contributions. Some of them are outstanding and deserve special attention, among them → Albert Bandura, → Steven H. Chaffee, → Leon Festinger, → George Gerbner, → Carl I. Hovland, → Elihu Katz, and → Elisabeth Noelle-Neumann. Following the work of these pioneers, the history of media

effects research is often roughly divided into three phases: the phase of strong media effects (c.1910–1945), that of weak media effects (c.1946–1970), and that of moderate media effects (c.1971 onwards).

The *first (strong effects) phase* is characterized by case studies based on outstanding events. Two of the most notable are the panicky reactions to the Orson Welles radio play *War of the Worlds* (Cantril 1940) and Kate Smith's radio campaign for the sale of war bonds that yielded US\$39 million within 15 hours (Merton 1946). Even after the end of the first phase, strong media effects were documented most thoroughly by Hovland and his colleagues. Their results, however, were relativized because of the limited external validity of their laboratory experiments where there was no possibility of selective exposure and unnaturally high attention levels among subjects.

The *second (weak effects) phase* started with Lazarsfeld et al.'s (1944) study on the 1940 presidential election in the USA. The election was a recurring routine event and the coverage was less spectacular and the effects far less dramatic. The authors offered a range of explanations for what was at the time a surprising result. Most prominently, they introduced the two-step flow of communication model, the influence of opinion leaders, and the role of selective media use (→ Selective Exposure).

The *third (moderate effects) phase* started with McCombs & Shaw's study on "The agenda-setting function of mass media" (1972) and Noelle-Neumann's programmatic article on the "Return to the concept of powerful mass media" (1973). McCombs & Shaw shifted the attention of researchers from media effects on attitudes and opinions to their effects on beliefs. Noelle-Neumann introduced three ground-breaking concepts: the consonance of the media (→ Consonance of Media Content), their cumulative effects, and their influence on the → climate of opinion. These constructs became the basis of the → spiral of silence theory. The theoretical reorientation of the field was accompanied by a growing number of long-term studies based on content analyses of media coverage and representative surveys. Thus the development of media coverage and public opinion could be categorized and statistically analyzed.

From today's point of view, the differences in effects in the three phases were smaller than they have historically appeared. As far as such differences actually existed, they can be explained by the specifics of the events covered as well as by theoretical and methodical innovations in research. In cases of outstanding events, the effects today are at least as strong as the effects that were detected during the first phase of media effects research. For example, two weeks after the attacks of September 11, 2001 on the World Trade Center, American celebrities collected US\$116 million for the victims within two hours by holding a benefit concert that was broadcast on TV and radio. For routine events, the effects correspond approximately to what was actually determined in the second phase of media effects research. That is, in the case of long-term thematization of facts and opinions, the beliefs of a remarkable part of the population follow the media's tenor.

## THEORIES OF MEDIA EFFECTS

The effects of mass media can be described by *models* (→ Stimulus–Response Model; Media Effects Models: Elaborated Models; Models of Communication) and explained by theories (appraisal theory, → Catharsis Theory; Emotional Arousal Theory; Excitation

Transfer Theory; Frustration Aggression Theory; Media System Dependency Theory; Social Judgment Theory). Theories on the effects of the mass media can be roughly categorized into two general types: learning theories and cognitive theories.

Despite numerous similarities between the two theoretical bases, there is one important difference. Specifically, learning theory approaches address the correct reproduction of information, and therefore divergences between beliefs and information provided by media are considered learning deficits that may also be interpreted as a lack of media effects. In contrast, cognitive theories do not necessarily understand deficits as a lack of media effects, but rather as the result of predictable contributions of recipients who process the information provided. Thus, because of this essential difference the two theories are treated separately even though they share certain similarities.

### **Learning Theory Approaches**

#### *General Assumptions*

According to learning theory, learning is based on the association (conditioning) of stimuli and reactions. In the present context, *operant conditioning* is most significant. This describes the accidental co-occurrence of a stimulus and a reaction that is established as a unit if the reaction is rewarded (reinforcement). In the area of media effects the reward could, for example, be the social recognition awarded by friends and peers for knowledge about political incidents a viewer gathered from a news program watched by chance. Presumably, such processes are important motivators for individuals to become more vigorous media consumers.

A variation of learning theory is the *theory of observational learning*, which is relied upon above all to explain the acquisition of aggressive behavior. Accordingly, observers learn patterns of aggressive behavior in mass media that they later apply under certain conditions of action. In most effects studies oriented to learning theories, the key variables – objective contents and subjective understanding, attentiveness and effects, cognitive and emotional aspects of the effect, and others – are not differentiated and recorded separately. This is because, in existing studies available for secondary analyses, the required data are often missing, and measuring them all simultaneously in primary studies would be too difficult and expensive.

#### *Remembering Media Content*

No one can remember all the media reports they have read, heard, or seen. This raises two related questions. First, what percentage of media information on current events is retained? Second, what percentage of knowledge about current events is based on media information? Research has been shown that immediately after watching → television news, viewers remember an average of two to three news stories out of 15. From this and similar results it can be concluded that a single report about an event normally leaves nearly inconsequential effects on the memory. Only repeated reports are effective, and the number of repetitions has to exceed a critical threshold.

From the poor recollection of single reports, it may be assumed that media coverage generally has a small influence on the beliefs a population holds about current events. This assumption, however, is wrong. Evidence has shown that about two-thirds of what

ordinary people know about current events derives from media reports (Früh 1992). The reason for the apparent contradiction is the large number and frequency of media reports on all important events, which therefore structure the dominant beliefs of the population (→ News Processing and Retention; Memory; Memory, Message).

#### *Influence on the Perceived Relevance of Issues*

Media coverage on current affairs has an influence on the public's assessment of the significance of social problems and the urgency for solving those problems (→ Agenda-Setting Effects). The theoretical basis of the agenda-setting hypothesis is the notion that the media have no strong influence on *what* the recipients think, but a considerable influence on what they *think about*. Two main research designs have been established in agenda-setting research. The first constructs a comparison of all issues on the media's agenda with the population's agenda over a short period of time such as a few weeks. The second examines a comparison of the development of media coverage on single issues with the development of the population's beliefs over a longer period of time of several years or more.

The original formulation of the agenda-setting hypothesis includes the unspoken assumption that public opinion follows the ups and downs of the emphasis placed on issues by the media. This assumption, however, does not apply to all cases. For example, the population often remains worried after massive reports on serious disasters even after the coverage has already decreased. In these cases there is no linear relation between the media coverage and public opinion. If correlations that assume linearity between variables are calculated, the results paradoxically demonstrate weak effects. To avoid this error several nonlinear models have been developed.

#### *Influence on Assessment of Risks*

Individuals generally have good judgment concerning the relative frequency of causes of death. They are aware of causes of death that are more likely and those that are less frequent. They typically make two mistakes, however, by overestimating the occurrence of rare fatalities and underestimating the occurrence of frequent causes of death. The concept of *availability heuristic* explains how this is related to media coverage. Since exceptional events have high news value the media report intensively on rare causes of death such as tornados, poisoning, lightning strikes, and so on, but relatively seldom on frequent causes of death including heart attacks, lung cancer, diabetes, and other common life-threatening diseases.

People focus less on the real frequency of causes of death and more on the emphasis in current media coverage. Therefore, the beliefs of the population on chances and risks follow the representation of unlikely but possible damages rather than the development of the actual number and size of damages (→ Risk Communication).

#### *Influence on Beliefs about the Distribution of Opinions and Behaviors*

Media reports contain two types of information on the distribution of opinions and the relative frequency of behaviors. One type common in media coverage is quantitative information, such as used in reporting polls where a certain percentage of respondents share a position. The other type is reports on individuals who represent different behaviors and opinions. The presentation of individuals has a stronger influence on the

beliefs about majority opinions than quantitative statements. If, for example, a report specifically over-represents members of the minority, many recipients consider the minority to be the majority even if the same report contains quantitative statements on the actual majority opinion.

#### *Influence on Suppositions about Effects*

Most people estimate unwanted (negative) media effects to be higher on others (alter) than on themselves (ego). The concept of → third-person effects was introduced by Davison (1983). The occurrence of the effect was confirmed by several surveys and experiments, which also found that the power of third-person effects increases with the social distance between alter and ego. Third-person effects are also enhanced when the sizes of the comparison groups are greater.

The source of the third-person effect may be an overestimation of media effects on other individuals, an underestimation of the effects on oneself, or a combination of both. The third-person effect presumably has important consequences, but these remain relatively unexamined. There are indications that it reduces the disposition to present one's own opinions in public controversies. Also, third-person reasoning has been shown to promote the demand for banning certain media content that is believed to have undesirable effects, such as pornography.

#### *Influence on the Distribution of Knowledge in Society*

In the 1940s it was already well known that there was a connection between education and the use of information presented by the media. In simple terms, more educated individuals make better use of information offered by the media. Nevertheless, social scientists in the 1950s continued to assume that the distribution of the media would improve the knowledge of the population in general. This optimistic assumption was called into question by Tichenor et al. (1970) and their discovery of the knowledge gap (→ Knowledge Gap Effects). This framework identified the growing gap between the knowledge of higher-educated and lower-educated groups that develops over the course of coverage on singular events or issues.

#### *Influence on the Perception of the State of Society*

The cultivation hypothesis developed by Gerbner and his colleagues is based on the assumption that the media – and above all TV – are an important factor of cultural and political socialization (→ Cultivation Theory). Through both information and entertainment TV conveys ideas of the state of society in which people live (→ Entertainment, Effects of). The more frequently and intensely people watch TV, the stronger the influence of its presentation of reality. The influences of information and entertainment presented on TV co-mingle and therefore have to be regarded in conjunction.

On the individual level, intensive use of TV leads to inaccurate beliefs in the frequency of violent acts in society. On the societal level, widespread intensive use has been linked to the homogenization of beliefs and opinions on current issues (→ Mainstreaming). In contrast to the significantly more limited knowledge-gap hypothesis, which examined shorter periods of time and singular issues, the cultivation hypothesis deals with longer periods of time and general beliefs, opinions, and attitudes.

## Cognitive Theory Approaches

### *General Assumptions*

Cognitive theories generally inquire as to how people perceive their environment and themselves, how they interpret it in a reasonable way, and how they experience it emotionally. These theories are centered on human information processing and its triggers, which include media presentations. Beliefs, opinions, attitudes, emotions, and actions are thereby considered interrelated parts of a system. Cognitive theories are based primarily on two assumptions that were first outlined by Fritz Heider in the 1940s, but initially received scant attention in research.

The first assumption, which became the basis of consistency theories was that people do not perceive reality surrounding them as single elements, but as prestructured units (→ Consistency Theories). The second assumption, which later became the foundation of attribution theories is that people intuitively attribute causes to occurrences (→ Attribution Processes). According to cognitive theories, beliefs and opinions are not merely copies of media presentations; in fact, most clearly go beyond the presentations but are based on them. Differences between media presentations and public beliefs do not indicate a lack of effects, but rather signify information processing predictably triggered by media reports.

### *Influence on Schema-Conducted Processing of Information*

Schema theory is based on the assumption that media recipients do not take up individual pieces of information independently of one another and derive meaning from them, but interpret them consistently according to a predetermined schema (→ Schemas and Media Effects). Schema theory was introduced into effects research by Graber (1984). Schema-induced information processing can be controlled by media reports that present events from a certain perspective (→ Framing Effects).

For example, differently framed crime news (possibilities of fighting against crime, suffering of victims, or the responsibility of government, for example) stimulates public interpretations that correspond to the respective frame. Thus, personal schematic information consistent with the frame of news is retained better than information that contradicts it. In addition, readers, listeners, or viewers tend to believe they have received information consistent with the frame even when such information was not actually included in the reports.

### *Influence on the Relevance of Individual Characteristics of Politicians*

Priming theory is based on the assumption that certain emotions, thoughts, and memories can be seen as knots in a network that are more or less closely connected to other parts of the network. Information activates parts of the network and sensitizes them for similar information. Thus, such information that follows will be consumed more attentively and processed more intensively.

The theory was introduced into media effects research by Iyengar and Kinder in 1986 and included several crucial assumptions. Citizen assessments about politicians and voting intentions are based in part on beliefs about politicians' competence. Repeated coverage of issues sensitizes recipients to some issues and makes solutions to the issues seem especially urgent. Thus the presumed ability of politicians to deal with the issues becomes more significant, contributing to a positive or negative image of them. General

opinions as well as voting intentions may therefore change, although judgments about the individual characteristics of politicians may remain constant.

#### *Influence on the Interaction of Cognitions and Emotions*

Appraisal theory (Nerb et al. 1998) combines elements of attribution theory and emotional arousal theory. Appraisal theory operates under conditions where media reports on great damages trigger high attention and evoke great excitement.

Descriptions of events trigger predictable emotions. If the damage is attributed to uncontrollable natural forces, the event evokes sadness, but if it is attributed to a person acting in a controlled way, it evokes anger. The extent of reactions is enforced or diminished by the interaction of emotions and cognitions. Therefore, emotions are not only effects of media coverage but also causes of beliefs and vice versa.

#### *Influence on Public Opinion*

According to Aristotle, people depend on the society of others and therefore fear social isolation (*zoon politikon*). The basic ideas of this notion were introduced into media effects research by Noelle-Neumann (1984), who suggested that people constantly monitor their environment to stay abreast of popular majority opinion in order to avoid social isolation.

Therefore individuals often draw on their interactions with other people and personal observation as well as media presentations. Each of these resources can incidentally stimulate correct or incorrect ideas about the distribution of opinions. Nevertheless, in the long term most people will be influenced more strongly by media presentations than by their personal observations. People who consider themselves in the minority tend to withhold their opinions in public. In so doing, the presumed majority opinion is artificially inflated, which in turn increases the pressure on the actual or alleged minority.

#### *Influence on Opinion Formation in Public Controversies*

The theory of cognitive affective media effects incorporates elements of Rosenberg's (1956) affective cognitive consistency theory and applies them to the analysis of public controversies (Kepplinger et al. 1991). According to the authors of cognitive affective media effects theory, all conflicts comprise events or factors that favor one side or the other (issue ownership). In this sense, the events have an instrumental quality where opponents and unsympathetic media coverage emphasize information that marginalizes competing claims (→ Instrumental Actualization; Negative Campaigning).

Readers, listeners, and viewers prefer information supporting their own view, but are confronted with a considerable amount of contradictory information. The knowledge of information that favors one side, or is against the other side, influences opinions about the opponents. This in turn increases or diminishes the range of legitimate behavior and thereby minimizes the chances of success of the opponents (→ Media as Political Actors; Media Campaigns and Perceptions of Reality; Scandalization in the News).

### **De Facto Effects**

In studies based on learning and cognitive theories, the information provided by mass media is identified and the processing strategies analyzed. This procedure is based on a

significant reduction of the complexity of coverage, since in reality the relevant information is not isolated but presented as part of a mixture of correct and incorrect assertions of facts, presumptions, and opinions. Furthermore, there are many ways in which recipients of mediated reports might be influenced. For example, individuals can develop and form their opinions by perusing statements of opinion from journalists and other sources, but they can also derive their opinions from neutral information. Accordingly, the beliefs and opinions of recipients may be influenced by a broad variety of sources that can hardly be isolated in the flow of media information and that converge to create a more or less consistent picture of reality. Such effects are called “de facto effects,” or the → trap effect.

De facto effects may always be assumed when the formation of opinion follows the media tenor. In these cases, effects of media coverage have to be assumed, despite the fact that they cannot be traced back to single sources and explained by specific theories. Examples of de facto effects include the development of opinions about the state of political parties or about the chances of parties and candidates in election campaigns. Other examples involve opinion development about public officials, such as the American President George Bush or the German Chancellor Helmut Kohl, or about issues like the development of the economy and ecological scandals. In this context, studies on cultivation theory must also be considered.

### DOUBTFUL AXIOMS

Most studies in the effects of mass media are based on three doubtful, mostly unspoken, axioms. These axioms have a considerable influence on the design of effects studies, the relevance of theories for the explanation of media effects, and the interpretation of the social importance of the results of effects research.

The first axiom is: *Events happen, media cover*. According to this axiom, current events on which the media report happen independently of the media. The validity of this axiom, however, is doubtful because a number of events on which the media report are the result of previous coverage. Furthermore, in conflicts and crises, people and organizations on which the media report change their behavior as a result of media coverage. For example, if coverage by influential media is critical, politicians may change their strategy, parties may withdraw parts of their agenda, governments may change their mind about the implementation of changes in laws, or companies may phase out or otherwise modify their products. When the media follow up and report on these decisions, strictly coverage often speaks about the effects of previous coverage. Another reason why the first axiom is untenable is because many of the events on which the media report would not take place or happen in the way they do if the actors did not expect media coverage. This applies to all press conferences, but also to party congresses, sporting events, and other planned media-centric events.

There are three different *types of events* that can be distinguished. First, some events happen independently of the media, such as natural disasters, accidents, or terrorist attacks (genuine events). Second, certain events would happen without media coverage, but their character is modified by media coverage (mediated events). Third, there are events that happen only in order to generate media coverage (staged events), such as press

conferences (→ Media Events and Pseudo-Events). After spectacular events, a large proportion of the press reports is not devoted to the key events that had originally triggered media coverage. Instead, media reports tend to focus on staged and mediated events that are thematically related (Kepplinger & Habermeier 1995), which is partly due to the reciprocal effects of the mass media. That is, the subjects of media reports frequently adapt their behavior to meet the conditions of successful portrayal in media coverage (→ Mediatization of Politics; Mediatization of Society). The subjects of coverage are a comparatively small number of people, most of whom wield considerable influence. Thus, decisions influenced by media reports may affect many more people indirectly.

The second axiom is: *No effect without change*. This suggests that the reinforcement of existing beliefs, opinions, attitudes, and behaviors cannot be regarded as an effect of media coverage. The axiom holds true only under two conditions. First, even if the media did not support the existing beliefs, opinions, attitudes, and behaviors of its audience, these characteristics and attributes would still exist. At most this assumption applies to attitudes and habits, but it is not true of most beliefs and opinions. An example is public assessments of the most important problems facing the nation: if the media report less frequently than they used to on a particular issue, fewer people consider it to be a problem.

The second condition under which the axiom holds true is that the relevant beliefs, opinions, attitudes, and behaviors have developed independently from previous media use. This assumption, however, also applies only in part. One example is the processing of TV news, where there are two kinds of effect. First, where viewers don't know anything about the events or individuals covered, new knowledge and opinions are at least partly the effects of TV coverage. Second, where viewers already know the events or individuals covered and have opinions on them, their knowledge and opinions are mostly based on previous media reports. Thus, it is primarily the mass media that establish the context for the interpretation of the news on current events, which in turn reinforce and supplement the context (Kepplinger & Daschmann 1997).

The exclusive interpretation of reinforcement as evidence for a lack of media effects is a result of a static and thereby unhistorical approach. Such an interpretation does not do justice to the actual role of the media in the development of individuals and societies. In reality, the status quo is often a result of previous media effects. From these theoretical notions one has to conclude that existing beliefs, opinions, attitudes, and behaviors can also be regarded as effects of previous media coverage. Thus, insofar as these beliefs, opinions, attitudes, and behaviors would vanish without ongoing media coverage, reinforcement must be regarded as a central and important effect of media coverage.

The third axiom is: *No effect without contact*. This axiom is acceptable if at least one of the two following conditions is fulfilled: first, existing attitudes and peer bonds largely prevent the reception of dissonant information; second, dissonant information that is received from the mass media will be reinterpreted in such a way as to correspond to existing attitudes. If one or both conditions are fulfilled, the opinions and attitudes of media users are an efficient protection against the transmission of dissonant information to others. In this case, effects implied by the conveyance of information from the media must be attributed to the conveyors. Only then do conveyors work as filters that marginalize the

effects of media on third parties considerably. However, when conveyors or opinion leaders also use and pass on dissonant information, the effects should be attributed at least partly to the media.

There are several reasons why the assumption that people exclusively use consonant media information and exclusively pass on consonant media information to third parties is incompatible with the findings of empirical research. One is that attitudes have only a small influence on the use of most mass media, especially TV newscasts, which are the most important and frequently utilized source of information. Another, related reason is that media recipients do not use negative information about people and organizations that they respect in a selective way. Additionally, the tendency toward the selective use of positive information can be overcome by journalistic means of design. Among these are big or spectacular headlines, long and well-placed articles, and ostentatiously illustrated reports (Donsbach 1991; → Cognitive Dissonance Theory).

For these reasons, the preference for consonant information does not present an impermeable barrier for dissonant information on any level of selection. Even though media effects may be reduced by such preferences, the effects of the mass media are certainly not eliminated. Accordingly, predispositions and selective exposure do not represent an efficient protection against the reception of dissonant information. Therefore, the *no effect without contact* axiom is untenable. Opinion leaders and other interlocutors do not restrain the influences of media reports, but rather extend them in unique ways to those who lack direct contact with the same media coverage.

The model of indirect media effects has consequences for the interpretation of multilevel effects processes. This concerns, first, studies that have shown an influence of interlocutors on the beliefs and opinions of other people. Provided that no theoretical reasons or empirical facts suggest that the interlocutor relied on sources independent of the media, the effects must be assigned to the media. Second, it also concerns studies in the → diffusion of information and innovation and in the change of social values and norms. Opinion forming mass media with a low distribution level may alter the perceptions of minority groups, which may then be adopted by media with high distribution levels and thereby shape the beliefs of the majority. Third, the consequences of the model of indirect media effects concern contemporary studies of the role of the mass media in historical developments. This addresses mainly questions as to whether and how the opinion-forming media shape public opinion, restrict the scope of decision-makers, or predetermine which kind of decisions are deemed legitimate and appropriate.

The model of indirect media effects outlines a basis for discussing the role of the media as a catalyst, amplifier, and moderator of dynamic complex processes that hitherto lay outside the interests of recipient-fixed effect research. At the same time, it points out connections to questions and approaches of other disciplines such as political science (studies in decision-making), sociology (studies in conflicts and crises), and economics (studies in consumer behavior, development of supply and prices). The more general the questions asked, the further removed the causes (i.e., media coverage) become from the effects (e.g., decisions made by politicians as a consequence of media coverage), and the greater the number of intervening variables that have to be taken into account (such as opinion leaders who derive their opinions from the media and might influence decision-makers). The disadvantages of such studies are in the inevitable reduction of the level of

evidence, but what is important is that the advantages include a realistic estimation of the media's role in modern societies.

## Media Effects: Direct and Indirect Effects

Hans Mathias Kepplinger

Johannes Gutenberg University of Mainz

The term “indirect effects” denotes the consequences of direct effects on individuals who are not exposed to media content. According to Seymour-Ure (1974, 22), “a primary [=

direct] effect takes place when the person affected has himself been involved directly in the communication process. A secondary [= indirect] effect takes place when individuals or groups not involved in the communication process are affected by changes in individuals who are.” The concept of indirect effects extends the effect of the mass media beyond the users and to nonusers in two ways. Individuals exposed to media content spread information and opinion provided by the mass media, as far as they transmit them unchanged (→ Opinion Leader). Such individuals may also transform the information and opinion provided by the mass media into action, as far as their action is predictable on the basis of media coverage (→ Priming Theory; Appraisal Theory).

Three types of indirect effects can be distinguished. First, there are *administrative reactions*, i.e., direct effects on a large number of recipients of media content affect the behavior of a small number of decision-makers. For example, the negative tone of coverage about a politician’s plan decreases support for him or her (direct effect), which stimulates the politician to give up the plan (indirect effect). Second, there are *public effects*, i.e., direct effects on a small number of decision-makers who are the subject of media coverage (→ Reciprocal Effects) lead them to make decisions that affect a large number of people. For example, media coverage about the potential side-effects of pharmaceuticals cause the producer to take it off the market (direct effect), which has positive and/or negative consequences for a large number of patients (indirect effects). Third, there are *snowball effects*, i.e., direct effects on a large number of recipients of media content affect a large number of people not exposed to the relevant media content. For example, a new TV show has impressed a large number of viewers (direct effect) who stimulate their friends to watch the next episode (indirect effect).

For several reasons, the concept of indirect effects denies the adequacy of the axiom that there is “no effect without contact.” People’s attitudes have no significant influence on their use of TV news and only a moderate influence on their use of national quality newspapers (Kepplinger et al. 1991). The selective use of media does not exclude the use (Donsbach 1991) and transmission (Deutschmann & Danielson 1960) of dissonant information. Therefore, people exposed to the mass media may play two roles. As far as they transmit exclusively consonant information, they act as *filters*. As far as they transmit dissonant information, they act as *amplifiers* of media effects.

Because of the axiom mentioned above, indirect effects of mass media have not been a major topic of research. Nevertheless, several quantitative and qualitative studies document a broad *variety of indirect effects*. Pre-trial publicity may bias jurors against defendants (direct effect) and thus might disadvantage them (indirect effect; Brusckie & Loges 1999). Intensive coverage of terrorism (Weimann & Winn 1994) may stimulate additional violence (direct effect) and cause additional victims (indirect effect). The dominant tone of media coverage may discourage recipients from speaking out in public (direct effect), which may push others into falling silent (indirect effect; Noelle-Neumann 1993). Media reports indicating a lack of supply may increase demand (direct effect), causing a shortage that harms other people (indirect effect I) and stimulating political activity (indirect effect II; Kepplinger & Roth 1979; → Media Campaigns and Perceptions of Reality). Media coverage of the availability of pornography or violence might stimulate concern about antisocial effects on others (direct effect I; → Third-Person Effects), increase support for censorship (direct effect II); and bring into office politicians planning to change

the law (indirect effect; Shah et al. 1999). Before World War II the pro-German coverage in *The Times* most likely had an impact on the British and German politicians who negotiated the Munich Treaty (direct effect), which had far-reaching consequences for people living in Czechoslovakia (indirect effect; Seymour-Ure 1974; Holbert & Stephenson 2003).

Direct effects of media reports can be identified using → survey or observational data (→ Observation; Research Methods). One can relatively easily identify direct effects of media reports. By comparison, indirect effects – i.e., the consequences for the behavior of subjects who are influenced by media coverage – are more difficult to identify and more difficult still to link to media coverage directly. First, one has to establish a direct effect upon the relevant subjects. In doing so, one has to take into consideration the decisions that have been taken and those that have been avoided because of the mass media. Second, one has to demonstrate that the event under investigation is in fact a consequence of a direct effect. Here, the concepts of necessary and sufficient causes of effects are useful. In many cases, the media might be a necessary but not a sufficient cause of indirect effects (Seymour-Ure 1974; → Mediatization of Politics).

# Media Effects Duration

*Dolf Zillmann*

*University of Alabama*

In view of the preponderance of published research on the effects of the communication media, it is astounding, if not disconcerting, how little attention has been given to the systematic examination of the duration of these effects, and, as a result, how little is known about their duration. Such apparent neglect does not necessarily reflect lack of interest, however, but derives from principal and practical challenges associated with the assessment of the duration of media effects.

Among the principal difficulties are, first, the time discrepancy between cause and effect, and, second, extrinsic influences during the time course of the effect. The *time discrepancy* results from imprecision in the termination of causal stimulation and the onset of the frequently delayed effect measurement. Such imprecision has mostly plagued the assessment of quasi-immediate and potentially short-lived effects. *Extrinsic influences*, in contrast, have mainly complicated and often compromised the assessment of media effects of potentially long duration. The effect-duration measurement requires that extrinsic influences be assessed alongside the course of presumed media effects, such that the effects of these influences can be extracted. However, extrinsic influences are often accepted as unavoidable consequences of an ecologically valid environment in which media effects of any duration manifest themselves (→ Media Effects Models: Elaborated Models).

Another principal consideration is that the repeated assessment necessary to establish the duration of media effects may modify these very effects. Such likely distortion accrues to all obtrusively obtained assessments, as they create cognizance of the effects being measured.

The practical issues with the measurement of effect duration are primarily economic. Repeated taking of measures obviously requires a greater investment of resources, both labor and funds, than does a single effect measure. The likely attrition of respondents over repeated assessments is a further impediment.

The various indicated aspects of duration measurement are exemplified in the following research demonstrations.

## **DURATION OF SHORT-LIVED EFFECTS (SECONDS, MINUTES)**

Media research abounds with demonstrations of immediate and potentially short-lived effects of various kinds. A process known as priming is most frequently invoked to explain these effects (Jo & Berkowitz 1994). Briefly, an episode of media content is construed as a *prime* that activates particular neural networks and, as long as the activation persists, influences subsequent prime-related thoughts and actions. Following exposure to scenes of violence, for instance, the prime is expected to facilitate ensuing anger and aggression mainly because it activates related constructs. The research on such contingencies of prime and subsequent behavior has generally failed, however, to ascertain the time course of either prime activation or contingent behavior. As a result, the

duration of immediate media effects has remained a matter of conjecture (→ Priming Theory).

Although systematic assessments of the duration of priming effects are lacking, it is widely held that these effects are short-lived, perhaps spanning minutes. But it has also been suggested that the flow of media and alternative environmental stimuli defines a chain of primes, the effect of the last presented one superseding that of all prior ones. In this conceptualization, the effects created by particular primes may be limited to seconds. The resolution of this issue obviously awaits detailed duration measurements.

Theories of emotional reactivity gave more attention to effect duration. For instance, → excitation transfer theory projects that excitation, however induced, decays slowly, and, as long as residues persist, intensifies subsequent affective experiences and behaviors. As the enduring excitatory residues are the mediators of the effects, duration measurements became crucial.

An early investigation explored the enhancement of music appreciation (Cantor & Zillmann 1973). After pre-arousal by exposure to films, respondents listened to musical selections. Transfer facilitation was observed up to 5 minutes. After that period, residues had decayed and facilitation was no longer in evidence.

Another excitation transfer study determined the duration of aggression facilitation after exposure to differently arousing films (Zillmann et al. 1974). Following a highly arousing erotic film, but not a less arousing violent film, transfer effects were observed for up to 11 minutes.

Other investigations examined the *distractive effects* of stark emotional reactions, such as elicited by exposure to news footage of a suicide. Three counterbalanced reports about issues of general interest, each 90 seconds long, followed a distressing report. Information acquisition was greatly impaired for the first and second of these reports, but not for the third. The effect of emotional distraction thus lasted for 3 minutes (Mundorf et al. 1990). A follow-up, methodologically parallel, study examined the impairment of information acquisition from commercials and offered the same conclusions about effect duration (→ News Processing and Retention).

Recent technological developments in computer-assisted data collection have made more systematic assessments of effect duration possible. In selective exposure research, for instance, automated procedures have been devised to measure exposure in second or minute intervals (→ Real Time Ratings [RTR]).

In an exploration of the *effects of moods on the choice of music*, respondents were placed into good or bad moods and then allowed to listen to music (Knobloch & Zillmann 2002). Unbeknown to the listeners, their choices were automatically recorded at minute intervals over a period of 10 minutes. It was observed that persons in a bad mood, compared to those in a good mood, decided more quickly on their preferred music and then stayed with their choice of energetic, joyful music for the rest of the recorded period.

An investigation of the *effects of headline framing* on reading of the associated articles used the same fully automated procedure (Zillmann et al. 2004). The framed headings, displayed in the overview of an electronic newspaper, were factual or indicated human conflict, misfortune, agony, or economic circumstances. After initial sampling across frames for about 4 minutes, respondents' choices became focused and stabilized. The

reading of articles whose leads suggested conflict and agony dominated the reading of articles with other leads for the remaining 6 minutes.

Given the indicated new means of assessing the duration of effects automatically and without the creation of cognizance of research objectives, progress in effect-duration measurement seems finally at hand.

### **INTERMEDIATE DURATION OF EFFECTS (HOURS, DAYS, WEEKS)**

Some research on the *effects of media violence and pornography* employed a design of repeated exposure and delayed effect assessment. Respondents were exposed to material in consecutive daily sessions throughout a week, and effects were ascertained days or weeks after exposure. Delays were used to ensure that measured effects were not short-lived ones immediately after the last exposure (→ Cumulative Media Effects). Repeated exposure to media violence was found to exert effects 1 day after exposure, strengthening aggressiveness and increasing hostile behavior (Zillmann & Weaver 1999; → Violence as Media Content, Effects of).

The measured effects of repeated exposure to pornography, at times one exposure session throughout a month, extended to 1 through 8 weeks (Zillmann 1989). After 1 week, various perceptual and dispositional consequences were in evidence. After 2 weeks, shifting erotic preferences were observed. A habituation decline of physical aspects of sexual arousal persisted up to 8 weeks (Howard et al. 1971; → Sex and Pornography as Media Content, Effects of).

Research on the perceptual and judgmental *effects of single exposure to news reports* has ascertained effects over periods from 1 to 3 weeks. Reports that differently framed the economic and environmental consequences of livestock farming, for instance, were found capable of altering perceptions of the issue immediately after exposure (Tewksbury et al. 2000). A repeated assessment after 3 weeks indicated a weak residual effect (→ Framing Effects).

The perception of issues presented in the news was also examined in terms of exemplification theory (Zillmann & Brosius 2000). Respondents were exposed to reports, and their assessments of the issues were recorded either immediately or after a delay of 2 or 3 weeks. None of the assessments was ever repeated (→ Exemplification and Exemplars, Effects of).

One investigation employed a factual report on small-farm economics that featured either a representative distribution of interviews with successful and failing farmers or involved only farmers in financial difficulties. The immediate measurement of issue perception showed that the one-sided exemplification produced a particularly bleak view of family farming. The 2-week delayed measurement yielded the same result, indicating that the created perceptions were stable over at least such a period (→ Sleeper Effect). A parallel study explored the *effects of pictorial exemplars*. Instead of textual exemplars, photographs of successful or failing farmers were interspersed in the report. The effects were ascertained immediately versus 10 days later. The effects were again stable over time.

Using the same basic design, an investigation of *risk perception* concerning carjackings involved a factual report that highlighted different consequences for victims. Victims were

presented either as having come to minor harm, as having suffered considerable bodily injury, or as having been killed. The immediate measurement showed that the respondents' apprehensions about the crime of carjacking increased with the severity of injury suffered by the exemplars of the news report. The 1-week delayed measurement revealed that the apprehensions not only persisted but had actually increased (→ Risk Communication; Risk Perceptions).

Again using the same design, an investigation of *health concerns* indicated prolonged and potentially growing effects. Exposure to a program explicating the risks of skin cancer involved either threatening or rather innocuous images of the cancer's visible manifestations. Immediately after exposure, the difference in imagery failed to produce appreciably different effects on risk perceptions, presumably because the effect of the imagery was overpowered by the immediacy of the textual message. In contrast, 2 weeks after exposure the threatening imagery showed a stronger, increased effect on the respondents' assessment of the threat of this cancer to others and to themselves. Whereas much of the text's influence had apparently been lost, the recalled imagery could at later times dominate the message's influence (→ Health Communication). To safeguard against possible extrinsic influences during the delay period, issues were chosen that, during data collection, were not on the media agenda. Additionally, pre-tests ensured that respondents had little, if any, knowledge of the selected issues.

The duration of most of the described effects may be substantially longer than reported. In the absence of further delayed assessments, this remains conjecture, however.

### **DURATION OF LONG-TERM EFFECTS (MONTHS, YEARS)**

Research on health-promoting messages often ascertains effects in repeated assessments over extended periods.

An investigation into the effects of different *appeals in a campaign* aimed at improving sun-protective behavior, for instance, found that particularly direct and unmitigated language fostered more compliant behavior than alternative means of expression (Buller et al. 2000). This effect was not only observed immediately after message reception, but also 6 months later.

In another study, aimed at increasing fruit and vegetable consumption, messages were tailored or not tailored to the respondents' personal situation (Heimendinger et al. 2005). Interviews were conducted after 5 and 12 months. Compared to an untailored appeal, tailored messages, especially multiply applied ones, proved longitudinally more effective in improving dietary behavior.

Concerning long-term effects of exposure to *media violence*, a 1-year study was conducted with nursery-school children (Singer & Singer 1981). The children's viewing habits and their aggressive behavior were recorded during several selected periods and compared in cross-lagged fashion. In some of these periods, earlier viewing was correlated with later aggression, but earlier aggression was also correlated with later viewing. The pattern thus suggested reciprocal influences.

The ultimate longitudinal investigation on these effects spanned 22 years (Huesmann & Eron 1986). Both the preference for violent media content and the aggressive behavior of 8-year-olds was assessed. A 10-year follow-up was applied to many of these children.

Cross-lagged analysis revealed a significant correlation between boys' earlier violence viewing and later aggression. The reverse correlation between earlier aggression and later violence viewing proved negligible, however. This finding was interpreted as suggesting that exposure to violence eventually causes violent behavior. The final follow-up explored effects after 22 years. A cross-lagged analysis again showed the indicated pattern. At the age of 30, aggressive men seemed to have succumbed to the influence of 22 years of watching violent television programs.

Later research, conducted in different countries and cultures, spanned 4 years and yielded further corroborating evidence (Huesmann & Eron 1986). A 3-year research project with school children and adolescents aged 7 through 16 failed, however, to lend unequivocal support to the causal interpretation of violence watching and aggressive behavior (Milavsky et al. 1982). Regression analysis revealed that, although numerous aspects of the examined relationship were positive, they were of negligible magnitude. A causal relation between the extended consumption of media violence and aggressive behavior could consequently not be considered substantiated, and the debate over the impact of media violence continues despite the considerable investment in longitudinal assessments (Cook et al. 1983).

## Media Effects, History of

Frank Esser

University of Zurich

The established history of media effects research is characterized by a series of phases marked by fundamental paradigm shifts (see McQuail 1977, 72–74; 2005, 457–462; Lowery & DeFleur 1983, 22–29; Severin & Tankard 2001, 262–268; Baran & Davis 2006, 8–17). Each of these phases is associated with particular concepts, researchers, studies, and historical circumstances that influenced ideological development regarding media effects (→ Communication as a Field and Discipline).

### THE FOUR PHASES OF MEDIA EFFECTS PARADIGMS

The *first phase*, from World War I to the end of the 1930s, was characterized by the assumption that the effects of the media on the population would be exceedingly strong. The media were credited with an almost limitless omnipotence in their ability to shape opinion and belief, to change life habits, and to mold audience behavior more or less according to the will of their controllers (McQuail 2005, 458). The power of media messages over unsuspecting audiences was described in drastic terms: the mass media supposedly fired messages like dangerous bullets, or shot messages into the audience like strong drugs pushed through hypodermic needles. These descriptions gave rise to the “*hypodermic-needle concept*” (Berlo 1960, 27), the “*magic bullet theory*” (Schramm 1973, 243), and the

“transmission belt theory” (DeFleur & Ball-Rokeach 1982, 161). Instinct psychology and the theory of mass society were interpreted to show that people in urbanized and industrialized society were rootless, alienated, and inherently susceptible to manipulation. As a result, they were defenseless against and at the mercy of the capricious stimuli of the media – particularly as early ideas maintained that the mass media were run primarily by people and organizations that were deliberately trying to exert a targeted influence upon recipients (→ Stimulus–Response Model).

The *second phase* of the standard history lasted approximately from the end of the 1930s to the end of the 1960s and was distinguished by the assumption that the media were largely not influential. The research group of → Paul F. Lazarsfeld ushered in the deconstruction of the bullet theory. The results of their empirical, social-scientific election study, *The people’s choice* (1944), moved interest away from what the media did to people and toward what people did with the media. Rather than seeing a society of fragmented individuals receiving all-powerful messages from the mass media, the view shifted to one of a society of individuals who interacted within groups and thus limited the effects of media messages. Early on, Lazarsfeld et al. (1944) defined all three key concepts that Joseph T. Klapper (1960) later united and used as the basis of his *limited effects theory*. These three concepts also characterized the second phase of effects research. They state that: (1) people use → selective exposure and selective perception to protect themselves from media influences, accepting almost exclusively only such information as corresponds to their previously established attitudes (→ Selective Perception and Selective Retention); (2) → opinion leaders initiate a → two-step flow of communication by absorbing ideas and arguments from the mass media and then communicating these – transformed – ideas to less active individuals; (3) social group formation enhances the role that → interpersonal communication plays in protecting an individual member from a change of opinion, as members do not wish to lose membership in their relational group (→ Katz, Elihu).

The *third phase*, from the end of the 1960s through the end of the 1970s, was characterized by the *rediscovery of strong media effects*. According to standard media effects history, an essay by → Elisabeth Noelle-Neumann entitled “Return to the concept of powerful mass media” (1973) may be considered to have set the program for the movement into the third phase (see Severin & Tankard 2001, 264; McQuail 2005, 460). A number of highly regarded studies showed that it was possible for the media to overcome some selectivity processes in a television-saturated environment. Near the end of the 1940s Herbert Hyman and Paul Sheatsly (1947) published a study in *Public Opinion Quarterly* entitled “Some reasons why information campaigns fail”; then, a quarter of a century later, Harold Mendelsohn (1973) used the same forum to proclaim the exact opposite: “Some reasons why information campaigns can succeed.” Three distinct features are attributed to this phase: more sophisticated methods of analysis (→ Research Methods), more specific hypotheses, and more highly differentiated theoretical approaches. Thus, survey data and content analysis data could be combined long-term with the help of time-series analyses or panel design studies (→ Survey; Content Analysis, Quantitative). In addition, effects research since that time has been less focused on crude changes in attitude or behavior, and more interested in subtle changes in our *perception* of the world.

The *fourth phase* of the standard media effects history extends through to the present time and is characterized by “*negotiated*” or “*transactional*” effects (McQuail 2005, 461). Now the central premise maintains that the media exert their greatest influence when they become involved in the process of constructing sense and meaning. Typical theories connected with this new approach are social → constructivism, → cultivation theory, framing (→ Framing Effects), and → information processing theories. McQuail considers research in this vein to be driven by two insights:

First, media “construct” social formations and even history itself by framing images of reality (in fiction as well as news) in predictable and patterned ways. Second, people in audiences construct for themselves their own view of social reality and their place in it, in interaction with the symbolic constructions offered by the media. The approach allows both for the power of media and for the power of people to choose, with a terrain of continuous negotiation in between, as it were. (McQuail 2005, 461)

### CHALLENGES TO THE FOUR-PHASES MODEL

The oversimplified account of the received view of media effects history has been criticized harshly in recent times. Lang and Lang (1993, 93) called the alleged sequence of phases unrealistic “paradoxes” that feigned contradictions that had never existed. Instead, they maintained that “a considerable continuity” had been prevalent in the research community over the decades (Lang & Lang 1981, 662). Even proponents of the phase model felt forced to play down its heuristic value as time progressed (see McQuail 2005, 460). It seems that the model was able to establish itself so firmly because it offered a clear summary of a complex developmental process. However, current thought considers it evident that, in every period, studies could be identified that indicated limited or powerful effects – depending on what → operationalizations, conceptualizations, definitions, measurements, designs, and variables were used (→ Measurement Theory; Media Effects, Strength of).

Likewise, careful reanalyses of research literature from the first phase of effects studies show that “few, if any, reputable social scientists in the pre-World War II era . . . worked with what was later described as the hypodermic needle model” (Lang & Lang 1981, 655). Even the empirical findings from the second phase, upon closer inspection, show no justification for an overall verdict of media impotence (Lang & Lang 1981, 659). Instead, numerous studies from that time indicating the presence of media effects can be identified. Due to the prevailing opinions of the time, however, no notice was taken of these findings. Two main factors explain the successful run enjoyed by the “*minimal effects myth*”: first, there was an exaggerated concentration of a limited range of effect types (especially short-term attitude change during election campaigns); second, there was a one-sided and inappropriate interpretation of the results of three key studies, which further secondary literature adopted without additional review.

In the first of these key studies, Lazarsfeld et al.’s *The people’s choice* (1944), the data in no way unequivocally supported both central investigative findings – the importance of interpersonal communication (“two-step flow”) and of reinforcement instead of chance (“minimal effects”). In spite of the fact that 61 percent of the interviewees named newspaper (23 percent) and radio (38 percent) as their “most important sources” of

information during the election, the authors alleged that it is not the media but *people* who can move other people (although less than one fourth cited a personal source as important). Moreover, in spite of the fact that 8 percent of those questioned did indeed alter their voting decision because of media influences, the authors interpreted this as evidence for a lack of effect (see Chaffee & Hochheimer 1985, 273, 279). Not only is 8 percent a considerable change, it should also be noted that the authors were concerned only with voting intention and ignored other possible political effects where media impact might have been even greater (→ Election Campaign Communication).

In the second key study, *Personal influence* (1955) by Katz and Lazarsfeld, an inappropriate claim was made to the effect that all previous effects research had been based on the following framework: “that of the omnipotent media, on the one hand, sending forth the message, and the atomized masses, on the other, waiting to receive it – and nothing in between” (1955, 20). In retrospect, Katz (1987, S35) admitted that early empirical communications research seems not to have based its efforts on the idea outlined in 1955, which propounded an omnipotent media and the stimulus–response model arising from this assumption. Nevertheless, Katz and Lazarsfeld’s book created a mythos that has definitively influenced the history of this field even up to today (see Delia 1987, 65–66).

### BIASED PERCEPTIONS OF MEDIA EFFECTS

From Klapper’s synopsis *The effects of mass communication* (1960), the third key work of that era, secondary literature adopted primarily those conclusions that pointed to minimal effects, failing to subject these inferences to review. However, Klapper did also clearly define conditions under which the media could develop strong effects. Even so, since he provided only very few pieces of evidence and examples for these in his one-sided presentation, they made no impression on the readers of the time or on later generations of research (see Perse 2001, 25). In addition, Klapper worked as director of social research for CBS, one of the largest media corporations in the United States (→ Television Networks), and media companies were uninterested in evidence supporting the strength of the media. Quite the contrary: they were interested in evidence proving the insignificance of media effects and used Klapper’s book to argue against regulation (Perse 2001, 28).

The apparent change of mind leading to the rediscovery of strong effects may also be better explained by factors outside of, rather than within, the research world. The rapid spread of television during the 1960s and 1970s lent a political dimension to the field of effects research (→ Television: Social History). Influential commercial and political forces increasingly accused the media of failing to respect these entities’ interests and, consequently, of distortion. Such allegations drew heightened public attention to the effectiveness of the media.

Today, a growing number of scholars agree that the established standard history of the field is misleading because it tends to ignore those findings that do not fit neatly into the stage-by-stage scenario. Many authors (e.g., Lang & Lang 1981; Chaffee & Hochheimer 1985; McLeod et al. 1991; Wartella 1996; Bryant & Thompson 2002) have thus concluded that the development of mass media effects research did not move in pendulum swings from “all-powerful” to “limited” to “rediscovered powerful” to “negotiated” effects. Bryant and Thompson (2002, 42, 58) argue that the body of media effects research from

the beginning showed overwhelming evidence for significant effects. Thus, the sum total of all these considerations yields the conclusion that the history of media effects research still waits to be written (see Wartella 1996, 179).

## Media Effects Models: Elaborated Models

*Elizabeth M. Perse*

*University of Delaware*

The study of media effects has driven mass communication research for most of the twentieth and twenty-first centuries. Scholars have developed, tested, and supported various theories of → media effects. The key to this research is uncovering the explanation for the way mass media exposure translates into effects. Over the history of our field, the study of media effects has been driven by generalized views about how media effects occur. These general views serve the field as models, or simplified representations of the media effects process. Different models about media effects place different weight on either media content or the audience in providing the central explanation of media effects. Moreover, different models focus on different variables as central to understanding media effects (→ Media Effects, History of).

The *first model* of media effects emerged in the early twentieth century. This model was grounded in sociological views of the mass society and psychological interests in stimulus–response models. This first model has been termed the “hypodermic needle” or direct effects model, because mass communication was seen as an effective stimulus to evoke predictable responses from isolated and helpless audiences.

A *second model* developed around 1940. This model, limited effects, reflected researchers’ beliefs that media’s dominant effect was reinforcement. According to this model, because of the audience’s tendency toward → selective exposure, attention, perception, and recall (→ Selective Attention; Selective Perception and Selective Retention), most media messages were filtered and rejected unless they supported pre-existing beliefs and attitudes (e.g., Hovland et al. 1949; Katz & Lazarsfeld 1955).

A *third model* grew out of the rapid adoption of television in the 1960s (→ Television: Social History). Television viewing grew steadily and content analyses revealed that there were few thematic differences in the content of the three dominant channels. Scholars began to believe that television could overcome selectivity processes. That is, exposure to television insured exposure to particular themes and images. This model is characterized as a return to the era of powerful effects.

The widespread adoption of → cable television, remote control devices, and the broadband world wide web (→ Internet) have shifted media use away from a static, time- and-space-bound delivery mode to one that allows the audience to select what media to

use whenever they choose. Now, media researchers accept that audiences can be powerful and dominant in the media effects process. Effects, however, are not viewed as limited. Instead, they are enhanced when media content intersects with audiences' interests and personal characteristics.

## FOUR GENERAL MODELS OF MEDIA EFFECTS

Our field is now marked by four dominant models of media effects: direct effects, conditional effects, cumulative effects, and cognitive automatic effects.

### Direct Effects

The direct effects model focuses on the impact of media content variables to stimulate fairly automatic and predictable responses in the audience. The audience is viewed as reacting involuntarily and automatically to certain features of media content. This model is not to be confused with the outdated hypodermic needle model of the early part of the twentieth century. People are not necessarily viewed as helpless, as in the early years of the hypodermic needle model, but they are seen as unable to resist the attentional "pulls" of some aspects of media content. The direct effects model focuses research attention on aspects of media content that impact audiences' → perceptions and feelings (→ Emotion).

Most research focuses on the impact of *structural features of media content* that stimulate automatic responses, such as the orienting response (involuntary attention), visual attention to the screen, sounds that stimulate attention and evoke automatic responses, and media content that evokes fear. Other research has focused on aspects of media content that increase automatic arousal (→ Excitation and Arousal), or physiological energizing responses. Still other research considers how the degree of realism depicted in the media can lead to audience effects.

Theoretical approaches that fall under this model of media effects include the → limited capacity model of message processing (e.g., Lang 2000), which focuses on structural and content aspects of media that elicit automatic motivational and cognitive responses; salience theory, which focuses on how location and placement of promotional messages affect attention (e.g., Eastman & Newton 1998); research on attention to and memory for "bad" news (e.g., Newhagen & Reeves 1992); and research on "presence" (e.g., Lee 2004), which focuses on how the sensory and personal realism of media content can evoke a sense of "being in" an environment or "being with" another (→ Information Processing).

### Conditional Effects

The conditional effects model places emphasis on the audience as the location of understanding media effects. Like the limit effects model of the mid-twentieth century, this model focuses on *audience selectivity* (selective exposure, attention, perception, and recall), social influence, and individual differences. This model differs from the limited effects model in that it recognizes that media effects are common, but conditional on aspects of the audience. That is, audience characteristics can determine whether and how

media content will have an impact. Media effects are not uniform; different people can be affected quite differently by the same media content.

This model is *audience-centered*, so important variables all relate to aspects of the audience. Traditional variables, such as demographics and social categories (e.g., sex, age, education), are important because they represent common frames of reference, common experiences, and common interests of similar groups of people that can facilitate or moderate media effects (→ Audience). Social relationship variables (e.g., group membership, audience makeup) are useful in this model because they represent the social connections and interpersonal interactions that can facilitate or mediate media effects. Individual difference variables (e.g., personality, prior experiences, mood) allow researchers to uncover how unique attributes and experiences can be conditional forces in media effects (→ Mood Management). Theories of media effects that fall under this model include knowledge gap (Tichenor et al. 1970, in its focus on socio-economic status; → Knowledge Gap Effects), social learning theory (e.g., Bandura 2002, in its focus on observer attributes; → Observational Learning), and → uses-and-gratifications approaches to media effects (e.g., Rubin 2002).

### **Cumulative Effects**

The cumulative effects model focuses on *consonance and repetition* of some themes, images, and frames across media content that override the ability of the audience to avoid exposure (→ Consonance of Media Content; Framing Effects). This model grows out of the third model in the history of media effects research, which recognized the power of television to overcome selective exposure. Cumulative effects are not based on a single exposure; instead effects emerge over time, on the basis of repeated exposure to consistent messages across channels or across media. Effects are typically cognitive; i.e., cumulative exposure leads people to develop beliefs based on the content they consume. These beliefs mirror media content.

Media content's presentation is central to this model. Cumulative effects are based on consistently presented images, themes, and frames that are presented over time and across media channels. Two theories exemplify the cumulative effects model. *Agenda setting* (e.g., McCombs & Shaw 1972; → Agenda-Setting Effects) holds that news media have the power to set the audience agenda because of the consistency of news coverage across different channels. Cultivation (e.g., Gerbner & Gross 1976) is based on the evidence of content analysis that some of television's content presents a world quite different from the real one. As a result, heavy viewers of television begin to believe that the real world is similar to the television world. This model's assumption that some media content is so ubiquitous that it cannot be avoided needs to be tested in new media environments of increased channels and media outlets and the greater content control afforded audiences.

### **Cognitive Automatic Effects**

This model applies the notion of *priming* to the media effects process (→ Priming Theory). Priming refers to the activation of mental concepts as a result of exposure to media content. This model recognizes that much media use grows out of desires for relaxation and entertainment, which suggest that the audience is less mentally active

during exposure. The less active audience tends to engage in more automatic and effortless mental processing. Media content can serve as a potent prime to activate thoughts that affect interpretation and reaction to related environmental stimuli. The *cognitive automatic model* encompasses the several theoretical approaches used to explain priming effects: spreading activation, schema activation, and mental models (Roskos-Ewoldsen et al. 2002) as well as heuristic or peripheral processing (Petty et al. 2002; → Elaboration Likelihood Model). This model has been used to explain short-term effects of media violence, effects of a media agenda on presidential approval ratings, short-term effects of stereotypical media content, and cultivation effects.

Variables important to this model are ones that increase the priming potential of media content. In general, more salient content is likely to prime. Salience is reflected in prominence, intensity, movement, repetition, realism, and emotion. Salient audio and visual content can both prime automatic processing. Audience variables are less important to this model, because the audience is viewed as less cognitively active.

## Media Effects, Strength of

*Elizabeth M. Perse*

*University of Delaware*

Twenty-first-century mass communication scholars rarely question the existence of media effects. Research has presented significant and consistent evidence that the mass media have noticeable and meaningful effects. Evidence comes not only from the accumulation of the body of different studies, but from the various meta-analyses that organize various research studies and combine their findings to assess the direction and strength of media effects. In general, research finds that media effects are modest, small to moderate in size. Conclusions about the strength of media effects, however, must be tempered by considerations of → research methodology (laboratory compared to more natural settings), the effects of different types of media content (pro-social compared to antisocial; → Media Production and Content), and the effects of routine compared to unusual content (→ Media Effects; Media Effects, History of).

### THE STRENGTH OF MEDIA EFFECTS

*Meta-analysis* is the primary method for determining the strength of media effects. Meta-analysis is a research technique that locates published and unpublished studies about different media effects. Then, the results from those studies are combined and averaged to ascertain the overall size of effects, across a range of studies conducted by many different researchers at different times, in different places, and with different samples (→ Meta-Analysis). The strength of this approach is its cumulative character; combining a range of studies allows not only for conclusions about strength of impact, but also for researchers to begin to be able to generalize about the types of people affected and to identify the different variables that might enhance or mitigate media effects.

Meta-analyses reveal that media effects can best be described as small to moderate. Two statistical measures are typically used to describe the strength of media effects. Pearson's correlation ( $r$ ) ranges from  $-1.00$  to  $1.00$ , where values closest to either end point are the most substantial. Values close to  $0.0$  mean that there is no connection between media exposure and the effect. A second measure,  $d$ , is a measure of the difference, in standard

deviations, between the control group and the experimental group. Larger values for  $d$  indicate larger effects ( $\rightarrow$  Statistics, Explanatory).

In some cases, media's impact is fairly strong. Recent meta-analyses (see Preiss et al. 2007), for example, show that the  $\rightarrow$  *agenda-setting effect* is among the largest of our field. Overall, across 90 studies, the relationship between the media and audience agendas is  $r = 0.53$ .

Various meta-analyses have identified moderate effects of *media violence* ( $\rightarrow$  Violence as Media Content, Effects of). In 1986, exposure to television violence accounted for about 0.3 of a standard deviation ( $d = 0.30$ ) in negative effects. Updated meta-analyses find that impact has grown a bit larger. In 1994, scholars found that the effect size of television violence was  $d = 0.65$  ( $r = 0.31$ ). Replication of meta-analyses of the effects of media violence on observed aggressive behavior also reveal a small increase in effect sizes. A 1991 meta-analysis located an effect size of  $d = 0.27$ ; the updated 2007 meta-analysis found an effect size of  $d = 0.35$ .

Other media effects are a bit smaller. The negative effects of *pornography* range from  $r = 0.11$  to  $r = 0.22$  ( $\rightarrow$  Sex and Pornography as Media Content, Effects of). The connection between playing video games and aggression is  $r = 0.15$ . The effects of stereotyped media content and sex-role stereotyping range from  $r = 0.11$  to  $r = 0.31$  across surveys and experiments as well as studies conducted in the US and other countries.

Media content has *pro-social effects*. Pro-social messages targeted toward children have a moderate effect:  $r = 0.23$ . Media campaigns designed to encourage people to adopt healthy behaviors and practices have stronger impacts ( $r = 0.12$ ) than those encouraging cessation of unhealthy behaviors ( $r = 0.05$ ).

## INTERPRETING THE EVIDENCE

The statistical evidence for media effects is modest, considering the amount of *time spent with various media*. Here is a context for interpreting the size of media effects. Meta-analyses in other fields have found that the effect of gender on height is  $d = 1.20$ ; the effect of one year of elementary school on reading ability is  $d = 1.00$ ; tutoring on math skills is  $d = 0.60$ ; drug therapy on psychotics is  $d = 0.40$  (Hearold 1986). For  $r$ , squaring the value allows us to see how much of the variance between two variables is accounted for. So, meta-analyses show that exposure to pro-social messages accounts for 5.3 percent of the variance in pro-social actions in children.

There is evidence the *strength of media effects varies*. Effects of media violence are larger in laboratories ( $d = 0.80$ ) than in the real world ( $d = .35$  in natural experiments and  $d = 0.38$  in surveys). The control and precision of the laboratory experiment magnifies the effects of exposure to media content. There is also evidence that effects of pro-social media content are larger than those of antisocial media content. Moreover, effects can be stronger when encouraging adoptions (such as seat belt use, fruit and vegetable consumption) than when promoting behavior cessation (e.g., smoking, alcohol use;  $\rightarrow$  Observational Learning). Clearly, media have a larger impact on socially encouraged attitudes and behaviors and those that are easier to enact. There is also evidence to suggest that unusual media messages are likely to have a greater impact than routine ones. Research on Magic Johnson's 1991 announcement that he was HIV-positive had much larger effects

on knowledge about HIV and AIDS, attitudes toward HIV-positive people, and desire for more information about HIV than more routine messages (→ Exemplification and Exemplars, Effects of). Salient, or atypical messages, are likely to have greater impact.

The effects of mass communication might be small to moderate, but they are certainly quite meaningful because of the size of the audience and the importance of the outcomes. While the effects of media health campaigns, for example, are smaller than the effects of clinical interventions ( $r = 0.09$  compared to  $r = 0.27$ ), media campaigns are more cost-effective and reach far more people (→ Health Communication). The small effects found for media health campaigns cannot be dismissed, because even small effects sizes mean that large numbers of people have been influenced. Those who conduct research on television violence estimate that eliminating television violence could reduce aggression in society by small but significant amounts. Small effects of mass communication translate into large groups of people being affected.

### PROBLEMS IN INTERPRETING EVIDENCE OF MEDIA EFFECTS

Despite the presumption of media effects and the evidence drawn from meta-analyses, there are still some *areas of disagreement regarding media effects*. The most substantial media effects are found in laboratory experiments (→ Experiment, Laboratory). There is a good deal of value in conducting laboratory experiments because researchers can control the type and amount of media exposure and assess time order, or causation. The control of laboratory settings, though, is also a weakness. Exposure to media content in a laboratory setting is unnatural and cannot account for selective exposure. Experimental participants might be shown television content (e.g., violence or sexual content) that they would never seek out on their own. Much media content is consumed in the presence of friends and families, who are not able to exert influence in laboratory settings (→ Media Effects: Direct and Indirect Effects). Moreover, the dependent measures used in laboratories are often quite artificial. Hitting Bobo dolls or pushing buttons to “shock” people don’t translate to real-life actions. Hovland (1959) also points out that experiments typically focus on short-term effects, measured fairly soon after exposure to media content. The nature of experimental control cannot assess the endurance of effects after the experimental session (→ Media Effects Duration).

Laboratory experiments can also introduce *experimenter effects*, or effects that are due to the actions of the experimenter, rather than the experimental stimulus. When an experimenter presents content to research participants, they might assume that the experimenter approves of the content, even if it is violent, sexual, or stereotypical. As Hovland (1959) noted about persuasion research, messages presented in a laboratory are likely to have stronger effects because of the credibility of the experimenter. Participants might also assume that the various actions presented to them in a laboratory, even if they are inappropriate or undesirable, are also sanctioned by the experimenter. Finally, Hovland explains that researchers often select media content designed to magnify differences between experimental and control conditions. These extreme selections are often atypical of media content seen in the real world. Rosenthal (1979) estimated that various experimental effects range from  $d = 0.23$  to  $d = 1.78$ . So, experimental effects could account for much of the media impact of laboratory settings.

## ARE MEDIA EFFECTS STRONGER THAN EVIDENCE SUGGESTS?

Despite concerns about the problems with laboratory research, most scholars agree that media effects are substantial and meaningful. There are several reasons to believe that research underestimates media effects because of methodological imprecision and conflicting theoretical forces.

Outside of the laboratory, *measures of media exposure are imprecise* and subject to a good deal of measurement error (Webster & Wakshlag 1985; → Readership Research; Rating Methods). Media use is typically a private activity and often inattentive. Assessing media exposure by asking people to estimate how much time they spend is fraught with inaccuracy. Even observations of media use cannot assess level of attentiveness. Media effects might be stronger if researchers could access accurate measures of attentive media use.

For ethical reasons, researchers often *limit dependent variables* to those that cannot harm research participants (→ Research Ethics). So, studies rarely give participants opportunities to enact behaviors that might reflect media impact. Instead, researchers assess attitudes, perceptions, and reactions to hypothetical situations (→ Attitudes, Values, and Beliefs, Media Effects on). These “diluted” measures might not be the most valid and accurate ways to assess the impact of the mass media.

Most theories of media effects assume a linear relationship between media exposure and impact, that is, as exposure to media increases, so will the likelihood of the effects of that content. Nonlinear processes are often not explored. Some media effects processes might be curvilinear, that is, effects might increase to only a certain point (→ Linear and Nonlinear Models of Causal Analysis). Or, there might be a threshold process, so that media content has no impact until a threshold level of exposure is reached. Greenberg (1988) proposed a *drench hypothesis* of media effects. Instead of media content having a “drip, drip” cumulative effect, Greenberg suggests that some media images are so powerful that they command attention and have strong effects.

The main reason, however, that media effects appear limited is that it is *impossible to isolate media’s impact* in most developed societies. It is nearly impossible to find someone who has not been exposed to mass media. And, even those people who don’t watch much television or read newspapers or surf the world wide web interact regularly with others who do. Media’s influence can go beyond direct exposure to the media; it is filtered through other social contact.

# **Media Equation Theory**

*Kwan Min Lee*

*University of Southern California*

The term “media equation” means that → media equal real life. It implies that people (→ Audience) process technology-mediated experiences in the same way as they would do nonmediated experiences, because an “individual’s interactions with computers, television, and new media are fundamentally social and natural, just like interaction in real life” (Reeves & Nass 1996, 5). In 1996, Reeves and Nass first introduced this theory, and carefully summarized their previous media equation studies in the seminal book *The media equation*. Since the publication of this book, Nass, Reeves, and their colleagues have expanded the domain of the theory from traditional communication settings to radically different areas, from e-commerce to human–robot interaction.

## **TWO THEMES**

In general, media equation studies can be categorized as having one of two themes: (1) audience responses to physical features of traditional media (→ Audience Research), and (2) user responses to social characteristics of computers and software agents (→ Human–Computer Interaction; Computer–User Interaction; Avatars and Agents). Reeves and his colleagues have usually worked on the first issue, whereas Nass and his lab members have focused on the latter issue under the research paradigm of “Computers Are Social Actors (CASA).”

### **Audience Responses to Physical Features of Traditional Media**

Media equation studies on audience responses to physical features of traditional media can be categorized into two parts: media and → emotion; and media and form.

With regard to *media and emotion*, Reeves and his colleagues provide convincing results that the emotional valence (good vs bad) of media stimuli has the same effect on the brain as real-life stimuli in terms of electroencephalogram (EEG) activities. In addition, they found that negative events on the screen (→ Negativity) are disliked yet remembered more, just as negative real-life events are processed in human brains. In terms of arousal (→ Excitation and Arousal; Emotional Arousal Theory), they found that arousing media events are remembered more on both short-term and long-term bases in the same way that arousing events in real life are remembered better (→ Memory).

Studies on *media and form* have focused on audience responses to five physical characteristics of media forms: size; fidelity; synchrony; motion; and scene changes. With regard to audience responses to image *size*, the studies found that big objects on the screen yield more arousal, better memory (descriptive, not image recognition), and more positive social responses (e.g., social attraction, credibility) than smaller ones even when the content is identical (→ Visual Communication; Cinematography). These results confirm general human attention to and preference for big objects in real life. In contrast to audience responses to image sizes, the *visual fidelity* of a scene does not bring significant differences in arousal, attitudes, and memory. These results indicate that both virtual and real-life objects are visually processed in the same way in which objects and environments are mainly processed through the peripheral vision field, rather than the foveal vision field. With regard to the *synchrony* factor, Reeves and his colleagues found that asynchrony between audio and video signals generates negative evaluation of speakers on screen, in the same way people distrust speakers with inconsistent verbal and nonverbal cues. Finally, *motion* and *scene changes* on screen cause strong visual orienting responses from audience just as moving objects in real life do (Reeves et al. 1985). As a result, objects shown after the movement on screen are remembered better.

### **User Responses to Social Characteristics of Computers**

In the CASA research paradigm, Nass and his colleagues have studied user responses to social characteristics of computers and software agents (→ Interactivity, Concept of). Contrary to the commonsense view that people's interaction with computers or machines is not social, Nass and colleagues theorize that individuals consistently apply social interaction and categorization rules to computers (although users acknowledge that it is absurd to do so). As a result, the paradigm proposes, computers become social actors to their users. This research paradigm is based on the idea that when confronted with a machine that has anthropomorphic cues related to fundamental human characteristics, individuals automatically respond socially, are swayed by the fake human characteristics, and do not process the fact that the machine is not a human. Primary cues that appear to be important are words for output, interactivity, filling of roles traditionally held by humans, and voice (Nass & Moon 2000). These kinds of cues automatically invoke → schemas associated with human–human interaction, without the need to psychologically construct a relevant human. The first-generation CASA studies reported in *The media equation* (Reeves & Nass 1996) focused on user responses to three major social characteristics of computers: manners; personality; and social roles. With regard to user responses to the social manners of computers, Nass and colleagues found that users evaluate

computers positively when the computers behave politely, flatter them, and criticize themselves (as opposed to blaming others), in the same way that people like other people who are polite, flattering, and/or self-criticizing. With regard to the personality of computers, the researchers found that users can successfully identify the personality of computers or software agents. Moreover, users apply complicated personality-based social rules, such as the similarity-attraction and the consistency-attraction rules, when they interact with computers (or agents) manifesting a particular personality. Plus, users like a computer adjusting its personality to imitate the personality of the users. With regard to the social roles of computers, they found that users easily identify the gender, voice identity, and ingroup-ness of computers that they are interacting with. On the basis of the identified social roles of computers, users apply various social rules (e.g., gender stereotyping; ingroup favoritism) in their interaction with the computers.

The second-generation CASA studies expanded the domain of research to → e-commerce, voice user interfaces, and human–robot interaction. In the area of e-commerce, Moon at Harvard Business School found that customizing the message style of a computer according to user personality can increase the computer’s social influences on users (Moon 2002). She also reports that consumer self-disclosure in e-commerce sites can be enhanced by having a computer disclose itself first, because people unconsciously reciprocate computers (Moon 2000). Since *The media equation*, Nass and his colleagues have focused on the issue of voice user interfaces. The impressive line of evidence on social responses to computers in the context of voice user interfaces is well documented in *Wired for speech* (Nass & Brave 2005). Most notably, the researchers found that even with conscious knowledge of the nature of synthetic voice, humans keep responding to the synthetic voice as if it were a real human voice and apply various social rules (e.g., multiple source effect, personality identification, racial and gender → stereotypes, consistency preference) to the synthetic voice. Finally, Lee and his students at USC Annenberg School for Communication combined two research traditions – social → presence and CASA – in the study of human interaction with artifacts, and investigated human interaction with robots. They found that people feel high social presence and respond socially to a robot when it manifests compelling personality (Lee et al. 2006) and long-term artificial cognitive development (Lee et al. 2005).

### WHY THE MEDIA EQUATION OCCURS

The impressive amount of empirical findings on media equation phenomena calls for a fundamental question: “What makes human minds *not* notice the virtuality of mediated and/or artificial stimuli?” (See Lee 2004 for a detailed explication of the concept of virtuality.)

The main reason is that human brains evolved in a world in which all perceived objects were real physical objects and only humans possessed human-like shapes and human-like characteristics such as language, rapid interaction, emotion, personality, and so on. Therefore, to human minds, anything that seemed to be real was real and any object that seemed to possess human characteristics such as language was a real human. When people use media such as television and computer, people usually do not overcome the evolutionary limitation of accepting everything on the media at its face value. As a result,

people respond to simulations of social actors and natural objects as if they were in fact social and natural. Another fundamental reason for the media equation phenomenon is that humans have a strong tendency to promptly accept any incoming stimuli as if true, unless there is strong counterevidence (Gerrig 1993). Throughout human evolution, prompt reactions to situations have been much more critical for survival than accurate yet delayed judgments; inaccurate and unnecessary reactions to situations result in the waste of energy, whereas accurate yet delayed reactions could cause death or serious harm (Mantovani 1995). Consequently, mediated and/or artificial objects are processed as if real first, before coming under careful scrutiny. Put together, the media equation theory has successfully demonstrated how hardwired information-processing mechanisms in our Stone-Age brains continuously influence our responses to modern media and computer technologies.

# Media Events and Pseudo-Events

*Helmut Scherer*

*Hanover University of Music and Drama*

The terms “pseudo-event” and “media event” refer to the phenomenon that in modern societies many events are created with the sole aim of getting media coverage, or rather that events are staged in a way that lends itself to media coverage.

Boorstin (1961) created the term “pseudo-event”. He sees pseudo-events as “synthetic news.” They do not occur spontaneously but are planned mainly for the purpose of getting media coverage. Most pseudo-events are basically strategic communication and public relations exercises (→ Advertising; Marketing; Public Relations). Press conferences are a typical example of pseudo-events. Boorstin distinguishes pseudo-events from spontaneous events. Spontaneous (or “genuine”) events are never, or hardly ever, influenced by the mass media. However, while the media do not in any way influence the structure of genuine events, such events may nevertheless be newsworthy and highly relevant for media reporting. Ecological disasters or crime are typical examples of genuine events.

Pseudo-events are staged to attract media attention. A media-friendly design is therefore one of the most important aspects of pseudo-event planning. As a result, pseudo-events differ from genuine events in several respects. Pseudo-events are expected or announced in advance so that the media can prepare for reporting. The timing and duration of a pseudo-event follows the rhythm of mass media coverage. The pseudo-event basically has to be designed according to the media’s selection criteria. As the event itself often lacks newsworthiness, it has to be artificially enhanced to make it more interesting (→ News Values; Media Logic). This can be done by involving celebrities or by adding dramatic effects to the announcement or presentation of the event.

Pseudo-events serve a purpose. They aim at promoting specific interests and needs. Lobbies try to attract attention to their interests or bring about a certain atmosphere through staging such events. In this way political candidates during election campaigns often arrange pseudo-events to convey a feeling of confidence in winning to their supporters. Campaign speeches and televised debates are typical examples of pseudo-events. For the media this raises the question of what the underlying purpose of these events is. The manner in which the media report on the intended effect in their coverage depends mainly on the importance attached to such events. Routine coverage is more likely to contain no comment on the aims of the event. However, when the event is of more importance then it is quite likely that the media will not only cover the event but also engage in a “meta-coverage” of its purposes and the reasons behind it.

Pseudo-events are not the only events that are staged with an eye to getting media coverage. It is often the case that events that would occur independently of the mass media are heavily influenced by the desired media coverage. Big sports events, political party conventions, and big trade fairs are examples of these media-driven events. Dayan and Katz (1996) differentiate between “media events” and “news events.” *News events* are events that cannot be foreseen but are nevertheless reported live and are extremely

newsworthy. The September 11, 2001, terrorist attack in Manhattan, for example, was a typical news event. It was unforeseeable, but the media was reporting live within a very short time (→ Mediated Terrorism).

*Media events* are very newsworthy as well, but typically have a ceremonious character. They are subject to media-related staging, to a *mise-en-scène* by the media for the viewers, to the telling of a story. The main purpose is to facilitate virtual participation in the events on screen. A media event in itself has a high social relevance and a festive character. The media intensify this festive character and through live coverage make it available to a wide audience around the world. Events such as political summit meetings, the Academy Awards in Hollywood, or the Olympic Games are typical media events. They are predictable for the media and are staged to gain the highest possible media interest. A characteristic of such events is the ceremonial flair gained by rituals such as signing political treaties, hoisting up national flags and singing national anthems, or introducing award winners with the renowned phrase “And the Oscar goes to . . .” Media events are increasingly used for managing international political relations (→ Media Diplomacy).

The concepts of pseudo-events and media events imply a presumption about mass media effects on society (→ Media Effects). The mere fact that media exist and might report certain events already changes these events and thus affects our social reality (→ Reciprocal Effects). This is the case if political or other actors embroider events and make them more attractive for the media in order to get better media coverage. Moreover, many events are created for the sole purpose of attracting media attention. Thus the media themselves, just by offering the possibility of publicizing events, set in motion processes resulting in social changes. Although pseudo-events and media events are designed to reach a wide audience, the social effects they are producing are not conditional on the audience’s media contact or reception of media messages.

# Media and Group Representations

*Dana Mastro*

*University of Arizona*

Research examining the influence of media exposure on audience members has long revealed that both the frequency and the nature of messages play a role in determining the outcomes of exposure. Consequently, documenting the manner in which different groups are represented in the media (alongside the rate of these depictions) is critical to understanding the possible implications for consumers, as exposure may be associated with the formation and application of group-based cognitions (→ Attitudes, Values, and Beliefs, Media Effects on; Media and Perceptions of Reality).

## GROUP REPRESENTATIONS IN TELEVISION

Despite the proliferation of new media alternatives, television continues to dominate among audience members of virtually all ages and races. Indeed, Nielsen (2006) reported that daily household television viewing in the US had reached a record high of 8 hours and 14 minutes per day, with daily prime-time viewing additionally increasing to 1 hour and 54 minutes. Who, then, are viewers likely to encounter when tuning in to the wide variety of television offerings, and what features are associated with these representations?

Content analyses of current US prime-time television depictions of *African-Americans* indicate that they are presented at a rate exceeding their proportion of the population of the US (at approximately 12 percent) (→ Content Analysis, Quantitative). On average, African-Americans constitute approximately 14 percent of characters appearing on prime-time television (Mastro & Behm-Morawitz 2005). Research suggests that African-Americans can be found nearly exclusively in sitcoms or crime dramas. In dramas, they appear most often in mixed-race casts whereas in sitcoms they are most often found in casts comprised principally of African-Americans (Children Now 2004).

A sketch of the typical African-American seen on prime-time television depicts a regular cast member who is a middle-class male law enforcer or professional, in his thirties, discussing topics related to work (Children Now 2004; Mastro & Behm-Morawitz 2005). In addition to demonstrating average levels of both job authority and social influence, African-American characters are among the least aggressive on prime time (Mastro & Greenberg 2000). They also are rated more hot-tempered, more provocatively dressed, and less professionally attired than their white peers on television.

The picture of *Latinos* on contemporary US prime-time television is less favorable. Latinos are grossly underrepresented when compared with real-world demographics, representing only 4 percent of the prime-time population compared with 13 percent of the US population (Mastro & Behm-Morawitz 2005). Like African-Americans, Latino characters are confined primarily to sitcoms and crime dramas (Children Now 2004). They appear most often as family members, conversing frequently about crime-related topics. Generally speaking, Latinos are depicted as younger, lower in job authority, more provocatively dressed, lazier, less articulate, and less intelligent than their peers on

television. Alongside African-Americans, Latinos are deemed the most hot-tempered characters in prime time. Moreover, when compared with other female characters on TV, Latinos are rated the lowest in work ethic and highest in verbal aggression.

The near invisibility of *Asian-Americans* and *Native Americans* in contemporary prime-time television often excludes them from quantitative assessments. In terms of numeric representation, Asian-Americans make up 1.5 percent of the characters on prime time (and 4 percent of the US population) and are depicted primarily in minor and nonrecurring roles (Children Now 2004). Native Americans represent less than 1 percent of the characters seen on prime time and approximately 1 percent of the population of the US (Mastro & Behm-Morawitz 2005). Their infrequent roles often are based in a historical context (Merskin 1998). Similarly, 0.2 percent of newspaper articles and 0.2 percent of films portray Native Americans (Fryberg 2003). When they are represented in the media, they are characterized in limited roles as spiritual, as warriors, and as a social problem.

Little more than the mere quantity of characters is known when it comes to images of *Arabs/Middle Easterners* and *Indians/Pakistanis* in prime-time television (Children Now 2004). Arabs/Middle Easterners represent 0.05 percent of prime-time television characters. Nearly half of these characters (46 percent) are portrayed as criminals. Indians/Pakistanis make up 0.04 percent of the television population. In terms of the nature of these roles, they have yet to be documented.

Research assessing the representation of *age groups* in prime-time television dramas and sitcoms reveals variations in the number and nature of portrayals based on the age of the character (→ Age Identity and Communication). In terms of numeric representation, Harwood and Anderson's (2002) results indicate that characters between the ages of 0 and 9 make up only 1.9 percent of the prime-time population. Those ranging from ages 10 to 19 constitute 9.7 percent of TV roles. Characters aged 20–34 comprise nearly 40 percent of roles seen on television. Those falling between the ages of 35 and 44 represent approximately 27 percent of actors. Adults in the age range 45–64 make up 18.7 percent of the world on prime time. Finally, those over 65 constitute 2.8 percent of the prime-time population. When these figures are compared with US census data, several discrepancies emerge. Adolescents and children, particularly younger children, are severely under-represented. The same is true of seniors, who are seen at rates well below that of their proportion of society. On the other hand, characters ranging in age from 20 through the early 40s are depicted at levels far exceeding that of the US population.

In terms of the features associated with these different age groups, Harwood and Anderson's (2002) findings reveal that the favorability of portrayals declines with age. In other words, more positive images are linked with younger characters. This decrease in positive evaluations appears to be a function of diminishing perceptions of attractiveness as the characters age.

In the main, images of *racial/ethnic minority children* on prime-time television are uncommon. Only about 3 percent of the characters portrayed on prime time are children, and among these approximately 77.5 percent are white, 15.5 percent are African-American, 3 percent are Latino, 2 percent are Asian-American, and less than 1 percent are Native American (Children Now 2001, 2004). Beyond the sheer number of portrayals, little more has been documented regarding the portrayal of children on prime-time television.

Although *women* outnumber men in the US population, on prime-time television nearly two-thirds of the characters are male (Children Now 2004; → Women in the Media, Images of). In terms of the features associated with men and women, Glascock (2001) notes that female characters are more likely to be depicted as married and parents than are male characters. The type and status of occupations also varies based on the gender of the character. Women are less likely than men to be depicted as bosses and are seen in a smaller variety of roles than men. In particular, although both men and women are often portrayed as police officers, men are also frequently depicted as professionals such as judges, doctors, etc. Alternatively, women are seen in service roles such as secretaries and waitresses, as well as in traditionally female roles such as nurses.

Looking at the features of males and females on prime-time television reveals that, on average, women are younger than men, dressed more provocatively, and are more affectionate. Men, however, are more physically aggressive than their female counterparts on TV, particularly in dramas.

Images of *gays and lesbians* on contemporary prime-time television are infrequent, comprising slightly more than 1 percent of the prime-time television population (Children Now 2001). When depicted, these characters are most often white and are generally male. Typically, gay and lesbian characters are seen in situation comedies. On these shows they are mostly recurring characters (appearing in either primary or secondary roles). When seen in dramas, gay and lesbian characters are commonly found in one-time, nonrecurring roles.

Characters with disabilities are exceedingly rare on prime-time television (Children Now 2001). Only about 1 percent of all prime-time characters are portrayed with some type of disability. When these images do emerge, they are evenly divided between recurring and nonrecurring roles. Among these, over half of the disabled characters are white and the preponderance is male.

## **GROUP REPRESENTATIONS IN ADVERTISING**

Consistent with findings on representations of race on prime-time television, content analyses of minority portrayals in television → advertising reveal that many of these groups also are underrepresented compared with the US population (Greenberg et al. 2002). Mastro and Stern's (2003) investigation of *racial/ethnic depictions* in prime-time commercials found that whites make up approximately 83 percent of the characters seen in television ads, African-Americans 12 percent, Asian-Americans 2 percent, Latinos 1 percent, and Native Americans 0.4 percent. Although the sheer number of minority portrayals is low, these groups fare better when examining the proportion of ads in which minorities appear. Taylor and Stern (1997) noted that although whites are depicted in nearly all television commercials (98 percent), African-Americans are found in 32 percent of television ads, Latinos in 9 percent, and Asian-Americans in 8 percent.

The types of commercials in which different racial/ethnic groups appear have been found to vary. African-Americans are depicted most often in food/beverage commercials as well as in ads for financial services. Comparatively, whites are seen in a variety of

commercials, most frequently those for cosmetics, technology, and food. Asian-Americans are primarily found in ads for retailers (Taylor & Stern 1997) and technology (Mastro & Stern 2003). Latinos are represented most often in banking/finance ads, and ads for soaps/deodorants. The infrequent Native American images in television commercials are found in ads for macro-retailers and automotives (Taylor & Stern 1997; Mastro & Stern 2003).

The roles associated with different characters also appear to differ based on the race of the character. Asian men are seen most frequently at work whereas Asian women are ordinarily outdoors. Latino men are found both at work and outdoors, with Latino women mainly shown outdoors. Both black men and women are most often featured at work. In contrast, white men and women are most often depicted at home (Taylor & Stern 1997; Mastro & Stern 2003).

Assessments of the manner in which different racial/ethnic groups are portrayed in commercials additionally exist. Content analytic research indicates that racial/ethnic minorities appear most commonly in minor or background roles as well as in group settings (Taylor & Stern 1997) and are less often seen in roles as parents or spouses (Coltrane & Messineo 2000). White characters in commercials also are far more likely to give orders than African-Americans, Latinos, or Asians (Coltrane & Messineo 2000; Mastro & Stern 2003). In addition, Coltrane and Messineo's (2000) research finds that African-American characters, males in particular, are more likely than whites to behave in an aggressive manner. Mastro & Stern (2003) obtained parallel results looking at African-American females. Their findings also reveal that Latinos are depicted in a more sexualized manner than their counterparts on commercials, engaging in sexual glances, displaying alluring behavior, and wearing provocative attire.

## GROUP REPRESENTATIONS IN TELEVISION NEWS

Television news coverage portraying racial/ethnic minorities has been largely unfavorable and unrepresentative compared with real-world indicators, particularly for African-Americans. Although *racial/ethnic minorities* and whites appear with relatively equal frequency in news stories unrelated to crime, minorities are nearly twice as likely as whites to appear when the news topic is linked to crime. In these stories, African-Americans are typically characterized as threatening and unkempt, and are frequently shown in restraints.

In particular, when assessing portrayals of race on television news, content analysis findings show that African-Americans and Latinos are depicted as perpetrators at a higher rate than whites. Comparing these rates of representation with real-world crime reports reveals that African-Americans are over-represented as perpetrators on television news, Latinos are underrepresented, and whites are presented either at a rate comparable to that in the real world or are underrepresented (Dixon & Linz 2000a, b). In addition, 91 percent of police officers shown on television news are white and only 3 percent are African-American (Dixon et al. 2003). These figures are discrepant from US Department of Labor statistics, which identify 80 percent of officers in the US to be white and 17 percent to be African-American.

African-Americans and Latinos are also seen as victims on television news less frequently than whites. When these television victimization rates are compared with

real-world crime reports, the results show that whites are substantially more likely to be portrayed as victims of homicide on TV than in the real world, whereas Latinos are less likely to be depicted as victims on TV than to be homicide victims in real life (Dixon & Linz 2000b). The rate of African-American victimization on television is nearly equivalent to that of the real world.

### TELEVISION NEWSMAKERS

Numeric disparities also are evident in the racial and ethnic breakdown of on-air television newsmakers and those working off-air. In 2005, it was reported that the overall proportion of the racial/ethnic minority TV news workforce (21 percent) as well as the percentage of minority TV news directors (12.5 percent) had dropped slightly from previous years (Papper 2005). Although the proportion of African-Americans in the broadcast news workforce has remained relatively stable in recent years (at 10 percent), the percentages of Asian-Americans (2 percent), Latinos (9 percent), and Native Americans (0.3 percent) are down. Among news directors, the percentage of African-Americans has risen modestly (from 3.2 percent to 3.9 percent) over recent years whereas the number of Asian-Americans has remained constant (at 1.3 percent). The number of Latino and Native American broadcast news directors has dropped recently (at 6 percent and 1.0 percent, respectively). In addition, the vast majority of TV news general managers are white (93 percent).

Among on-air appearances, whites account for 77 percent of newsmakers and African-Americans 22 percent – with Asian-Americans and Latinos combined at 1 percent (Gant & Dimmick 2000). Moreover, white newsmakers appear as experts/professionals significantly more often than African-Americans.

Taken together, these data indicate that in terms of the quantity of African-American depictions on entertainment television and in advertising, this group has achieved equivalence when compared with their proportion of the real-world population. The same cannot be said, however, for other racial/ethnic minorities and social groups. Simply put, these groups scarcely exist on television. When attention is directed at the manner in which different groups are portrayed in the media, the picture becomes even less promising. Although African-Americans in fictional programming appear, to a degree, to be represented in more favorable roles (at least when compared to decades past) this is in stark contrast to their depiction in the news, where their images are largely unfavorable and unrepresentative compared with real-world indicators. Portrayals of the remaining groups are difficult to classify systematically, given their scarcity. When considering the significance of media representation in terms of designating group status, strength, and social standing, these disparities are indeed consequential, and warrant greater research attention.

## Media History

Stuart Allan

Bournemouth University

Media history as a concept in its own right possesses a relatively recent lineage. In the early decades of the twentieth century, when references to “the media” – newspapers,

magazines, cinema, radio, and the like – were entering popular parlance, university academics tended to be rather skeptical about whether these institutions were important enough to warrant scholarly attention. Historians, in particular, were inclined to be dismissive. Matters would gradually improve over the course of the century, due to a number of factors (several of which will be identified below). Even today, however, media history continues to occupy a contested terrain between the principal disciplines informing its development, namely media studies (broadly inclusive of communication, cultural, and journalism studies) and history.

Pertinent scholarship is more likely to be found in schools of journalism than in history departments. Media history, when defined narrowly within the terms of press history, benefits from the perceived centrality of the news media to the governance of modern societies (→ Journalism, History of). At the same time, though, much of this research has been criticized for relying upon conceptions of history where the press is regarded as advancing unwaveringly in the cause of freedom over the centuries. In order to overcome the limitations of this “Whig interpretation” of journalism history, as it has been described, media historians have begun to diversify their sources and methods. Moreover, some are striving to look beyond the views of the powerful and privileged so as to recover and interpret the experiences of those who have been traditionally defined as “marginal, deviant and rebellious” where the making of media history is concerned (Carey 1985; see also Williams 1998; Gorman and McLean 2003; Chapman 2005).

Definitions of media history stretching beyond the press have frequently encountered resistance from those who regard the entertainment media as too inconsequential to public life to justify investigation. Serious reservations have been expressed by some historians about the very legitimacy of media history as a “proper” academic subject when it encompasses ostensibly trivial, ephemeral media items (advertisements, comics, graffiti, soap operas, paperback fiction, music videos, computer games, and the like) within its purview. Others have challenged this perspective, insisting that such value judgments be avoided so as to engage with the whole spectrum of emergent media in all of their complexity.

## **DEFINING MEDIA HISTORY**

Depending on how one chooses to define “the media,” a case can be made that media history properly begins in the earliest days of human social life and communication. For researchers interested in the emergence of media in oral or pre-literate communities thousands of years ago, for example, the insights of archaeologists and anthropologists have proven invaluable. The advent of reading and writing is of particular significance, enabling the dissemination of “news” or information at a distance, and thereby helping to sustain a shared sense of social order (Innis 1986; Stephens 1998; → Innis, Harold). Studies have examined the emergence and use of various media facilitating communication, ranging from “pictographs” written on clay tablets, to papyrus, paper, and eventually the movable type of the printing press (Eisenstein 1979; Fang 1997; → Printing, History of).

For many media historians, it is the connection between emergent media of communication and the creation of democratic society that is particularly fascinating. In this

context, Anderson's (1983) analysis of the rise of print as commodity in western Europe illuminates the emergence of nationality – “the personal and cultural feeling of belonging to a nation” – toward the end of the eighteenth century. In conceiving of the nation as an “imagined community,” he points out that it is possible to “think the nation” to the extent that certain media products are available to “re-present” its characteristics. He singles out for attention in this regard the fictional novel and the → newspaper, arguing that the corresponding print languages helped to engender national consciousness in important ways (→ Book; Newspaper, Antecedents of).

Complementing this line of inquiry into how print enriched the ability of people to relate to themselves and to others in new ways have been efforts to understand how these media shaped the formation of → public opinion. Here researchers have found the notion of a → “public sphere,” as theorized by → Jürgen Habermas (1989), to be useful, especially when investigating how spaces for public discussion and debate were initiated and sustained. Habermas identifies a range of institutions facilitating this process, with special attention devoted to coffee houses and the newspaper press (→ Coffee Houses as Public Sphere; Newspaper, History of). This normative conception of individuals participating in reasoned dialogue and debate about the conduct of social life, and thereby compelling “authority to legitimate itself before public opinion” (Habermas 1989, 25), highlights a range of intriguing issues for exploration (see also Starr 2004; Zaret 2000).

For media historians, the broad historical sweep of Habermas's treatment has served as a conceptual backdrop for more narrowly focused inquiries. Related studies have highlighted the ways in which various media forms and practices helped to give shape to new kinds of public sociability. Such studies include examinations of advertising, art, music, street literature, exhibitions in → museums and galleries, as well as reading and language societies, lending libraries, and the postal system, among other concerns (→ Art as Communication; Postal Service, History of).

Media historians continue to rehearse contrary views on the extent to which the normative ideals of a public sphere have been realized in actual terms, a debate which continues to percolate. Nevertheless, there is general agreement that a consideration of the relative freedoms espoused by these ideals throw into sharp relief many of the factors that have acted to constrain public discussion over time. Most successful in this regard have been the efforts of journalism historians, many of whom – from the nineteenth century onwards – have helped to formalize the more influential conceptual and methodological frameworks broadly indicative of modern media history. Even here, though, various problems have beset the craft, several of which have come to the fore in recent years.

“The study of journalism history remains something of an embarrassment,” Carey (1974) wrote in an essay titled “The problem of journalism history,” widely regarded as a classic appraisal of the field in the mid-1970s. Even efforts to justify its ambitious objectives, he remarked, have to acknowledge a doubt about the value of its contribution thus far. “Each generation of journalism historians has been dissatisfied with the nature of our knowledge and the forms of our presentation,” he continued, before making the point that “the existing critiques of journalism history are superficial: they fail to get at a deeper set of historiographical problems” (1974, 86, 87). In his view, historians have

chosen to define their craft too modestly, thereby narrowing the range of questions examined (and claims derived from their analysis) to an unnecessarily restrictive degree. This tendency, in turn, has made it more difficult to refute other, related types of criticisms, namely that journalism history “is dull and unimaginative, excessively trivial in the problems chosen for study, oppressively chronological, divorced from the major current of contemporary historiography, and needlessly preoccupied with the production of biographies of editors and publishers” (1974, 87). In conceding that there is some truth in these charges, Carey issues a call for the guiding assumptions of history writing to be examined anew (see also Briggs & Burke 2005; Czitrom 1982; Solomon & McChesney 1993; Uricchio 2004; Winston 2005).

Matters have improved considerably in this regard since the time of Carey’s intervention, although answers to several of the questions he raises have proven stubbornly elusive. In a British context, Curran (2002) echoes these concerns, maintaining that media history continues to suffer from its marginalized status in relation to the dominant paradigms of media research. “It is now the neglected grandparent of media studies,” he observes: “isolated, ignored, rarely visited by her offspring” (2002, 3). Media historians “labour in the shadows,” with much of the research they produce being overlooked in favor of studies engaged with seemingly more pressing concerns. This neglect is regrettable, not least because media history “sheds light on the central role of mass communications in the making of modern society” (2002, 3). In so doing, it provides a range of alternative ways of thinking about the nature of that relationship, helping to render explicit issues that would otherwise remain difficult to discern from a contemporary perspective.

### **COMPETING NARRATIVES OF MEDIA HISTORY**

In seeking to make the case for a revitalized conception of media history, Curran charts a series of competing narratives that, taken together, usefully elucidate certain core themes. Specifically, seven narratives are identified – liberal, feminist, populist, libertarian, anthropological, radical, and technological determinist – each of which highlights its preferred reading of media history consistent with its vantage point. In the course of briefly outlining the principal features of these narratives, additional studies will be referenced so as to provide an even wider survey of relevant research in media history.

#### **Liberal Media History**

Easily the most pronounced of the seven is the liberal narrative, the tenets of which revolve around the presupposition that the media have played a central role in the democratization of the political process unfolding over the last three centuries. Two key arguments are especially important here, Curran suggests.

First, the media – long pitched in a struggle with government to be free – have successfully secured their independence. Much scholarly attention has been devoted to the liberty of the press in this regard, with a range of studies focusing on efforts to regulate media content in different national contexts. Examples identified by Curran include challenges to the political agenda espoused by the British Board of Film Censors

(BBFC) which, from 1912 onwards, aimed to manage issues of censorship with regard to what was shown in cinemas. What began as a “voluntary” system of self-regulation evolved into a “tyrannical system of ideological control” endorsed by the state. “During the interwar period,” he writes, “the BBFC banned films criticizing the monarchy, government, church, police, judiciary and friend foreign countries” (2002, 4). Related studies of broadcasting in this context have similarly underscored the extent to which certain rights and freedoms have been wrested from the state.

The second key argument builds on this first one, namely by contending that free media empower people in a manner that promotes the democratic project. The media are seen to provide the information necessary for citizens to engage with public affairs, subject authority to critical scrutiny, represent public opinion to government, and – especially in the case of public service broadcasting – encourage social communication, and thus cohesion, among different groups in society (→ *Public Broadcasting, History of*). In essence, then, this liberal tradition relates media history “as a story of progress in which the media became free, switched their allegiance from government to the people, and served democracy” (Curran 2002, 7).

### **Feminist Media History**

The feminist narrative, Curran suggests, “views the development of the media in terms of a chequered, incomplete but nonetheless ground-breaking movement towards the liberation of women” (2002, 14). Research in this area, most of it conducted in recent decades, takes as its central concern the ways in which the media have connected with the social revolution promoting women’s advances in public life. In this regard, the ways in which patriarchal values are embedded in popular culture, for example, have been privileged for critique.

Pertinent investigations include those of women’s magazines published between the eighteenth century and 1918, where a certain ideal of domestic femininity was articulated, such that patriarchal ideology was effectively conflated with social morality (→ *Magazine, History of*). This ideal, Curran writes, “became part of the discourse of class, in which femininity was associated with refinement, delicacy and elegant domesticity, while lack of femininity was identified with work-calloused hands, roughness, coarseness, lewdness, the ‘male’ world of paid work” (2002, 10). Further examples of media representations under feminist or gender-sensitive scrutiny include advertisements, women’s and girls’ magazines, romantic fiction, newspapers, popular films, and television programs, among others.

Accordingly, research in this area has not only spoken to silences in conventional media history in important ways, it has also created spaces for feminist media historians to contribute to academic debates previously defined in predominantly male terms.

### **Populist Media History**

The populist narrative has emerged even more recently than its feminist counterpart. Interestingly, Curran characterizes it as possessing a “villain and a hero” at its center. “The ‘villain’ is the Victorian intelligentsia, and their heirs, who sought to foist their cultural tastes on the people,” while the “‘hero’ is the market which made the media more responsive

to popular demand” (2002, 14). These tensions, played out in a variety of cultural contexts, correspond with the decline of social deference, and with it the erosion of the values of hierarchy in favor of an increased social egalitarianism. The media, as a result, become more responsive to popular demand, in effect being transformed into major sources of popular pleasure.

The rise of the market as a democratizing force, a central theme celebrated by advocates of this narrative, is described as having a profound influence in opening up the cultural experiences of the few to the many. “The response of the cultural elite to the rise of mass culture is thus portrayed as either taking refuge in obscure intellectualism or enlisting the power of the state to impose elite preferences on the people,” Curran writes. “Much of populist history is devoted to revealing gleefully how this latter strategy came unstuck” (2002: 17). Relevant studies have investigated, among other topics, the emergence of the public library system, the rise of “new journalism” from the 1880s onwards, the populist pressures brought to bear on elitist conceptions of radio and television broadcasting, or the ways in which cinema responded to the rise of social democratic values (→ *New Journalism, Nineteenth-Century; Radio Networks; Television Networks; Documentary Film, History of*).

This narrative, in portraying the media as evolving from paternalism to consumerism, similarly highlights the ways in which they connect with the everyday lives of their audiences. “Above all,” Curran observes, “this tradition offers a rather compelling account of how each new medium – film, radio, gramophone and television – was the object of widespread wonder and excitement, became absorbed into the rituals of family and social life, and was the staple of everyday conversation” (2002, 22; → *Radio: Social History; Television: Social History*).

### **Libertarian Media History**

The libertarian narrative revolves around a clash between the liberal or “modern” tradition of tolerance and moral pluralism on the one hand, and moral traditionalism (often expressed in religious terms) on the other. The media’s development is described by the libertarian narrative as a “Manichean struggle” between these respective traditions. Periodic “culture wars” bring these contending traditions to the fore, a struggle “often contested in relation to symbolic ‘out’ groups: members of youth cultures, from 1920s flappers to 1970s punk and moral ‘deviants,’ from sexual minorities to unmarried mothers. These battles marked out where the outer perimeter of the ‘acceptable’ lay” (2002, 24).

Pearson’s (1983) cultural history of hooliganism is illustrative, showing as it does that from “the outcry against ‘street arabs’ in the 1840s and ‘garrotters’ in the 1860s right through to the denunciations of ‘Teddy Boys’ in the 1950s and ‘muggers,’ in the 1970s, these cyclical outbursts bore little relationship to the changing rate of crime.” Time and again, Curran adds, “they identified the same sinister processes at work: moral deterioration among the young, malign foreign influence and the ill-effects of the media (whether this be the Victorian music hall, the Edwardian comic 1920s film, or television)” (2002, 23).

Historical accounts of these and related moral crises have succeeded in revealing, in turn, the ways in which the moral regulation of the media has been caught up in this

larger conflict between liberals and traditionalists. In addition to opposing definitions of public morality, those of taste, permissiveness, obscenity, among others, have similarly figured prominently in varied instances of media prejudice and discrimination on the basis of age, class, gender, ethnicity, and sexuality (→ Women's Movement and the Media; Civil Rights Movement and the Media).

### **Anthropological Media History**

The anthropological narrative takes as its theoretical point of departure Anderson's (1983) conception of the nation as an "imagined political community" (as discussed above). In conceiving of the nation in this way – and thereby attending to the interweaving of narrative strands revolving around different languages, religions, histories, traditions, and identities – the importance of the media is underscored, not least with regard to their role in forging collective terms of social identification.

Examples discussed by Curran range from print-based media in the eighteenth century – promoting "the view that Britain was a freedom-loving, constitutional, Protestant country in contrast to the tyrannical, Catholic nations of Europe" – to the imperialistic pretensions of British virtue promulgated in → BBC radio broadcasts to the Commonwealth, and beyond. In the case of British cinema during its "golden age" (1930–1970), for instance, a framework of shared national experience (and thereby common talking points) encouraged cinema-goers to visualize the country within these terms. "It portrayed the nation in terms of geographically defined archetypes – canny Scots, lyrical Welsh, plain-spoken northerners, dodgy but loveable cockneys, simple West Country people – that made the nation seem both knowable as a community and also a familiar object of affection" (Curran 2002, 29–30).

In tracing the changing nature of national identity, advocates of this perspective on media history have sought to explicate its constructed nature, that is, the ways in which ideologies of nationalism facilitate the projection of unity out of diversity.

### **Radical Media History**

In marked contrast to the five narratives discussed thus far, all of which exhibit varying degrees of optimism about the progressive nature of social change, stands the more pessimistic account of the radical narrative. Habermas's (1989) assessment of the ascension and decline of the public sphere, as noted above, is an exemplar of this latter tradition.

"The early part of Habermas's history is loved by liberals," Curran writes, "while the latter part is relished by radicals. This is because Habermas offers an impeccably liberal history, with an unhappy ending derived from the Frankfurt school" (2002, 44). A radical treatment of the public sphere model, it follows, places its emphasis not on the rise of new spaces for "rational-critical debate" (with their attendant forms of exclusion, including those based on gender discrimination), but rather on its decline from the 1850s onwards. The "forward march of the people," advocates of this narrative contend, gradually came to a halt soon after, with certain crucial gains effectively reversed. In this light, the so-called "free" media, a central tenet of the Whiggish orientation of much media history writing (see above), are shown to be increasingly subject to elite control.

Studies of twentieth-century media have focused on topics such as the emergence of → propaganda, → public relations, the alternative, underground, or dissident press, and media events, including elections, sports, and royal occasions (Williams 1998), so as to show how systems of control have converged, much to the detriment of free expression (→ Underground Press; Historic Key Events and the Media; Elections and Media, History of). This radical tradition underscores the contention, therefore, that “the media came broadly to support the social order as a consequence of controls exerted through the market, state and elite cultural power” (Curran 2002, 39; see also Solomon & McChesney 1993).

### **Technological Determinist Media History**

The seventh and final narrative in this schematic is typified as the technological determinist tradition. Its “sprawling literature,” Curran maintains, can be condensed into four key arguments.

First, the advent of new means of communication – ranging from hieroglyphics carved in stone to, say, wireless telegraphy – alters dimensions of space and time, thereby influencing the larger organization of society. Second, there is a corresponding change in the nature of human senses and perception. Third, the structure of interpersonal relations is altered by the evolution of the media, creating different forms of social identification. And, fourth, new types of media disturb pre-existing flows of communication and influence, thereby impacting on (possibly subverting) established authority relations.

Over recent years, the influence of the technological determinist account on media history has proven to be considerable, with some advocates – citing theoreticians such as → McLuhan (1962) in support – believing that it renders more traditional forms of history writing redundant. This approach belies a number of weaknesses, including a tendency to overstate the influence of communications in relation to other determining influences. “This either takes the form of simplistic mono-causal explanations or, more often, mono-track interpretations which monitor only the effects of communications technology,” Curran contends. Moreover, this tradition “tends to view communications technology as an autonomous cause of change,” that is, as possessing “some inner technological logic,” rather than accounting for the ways in which the invention, development and application of new communications technology are shaped by the wider context of society (2002, 53). This is not to deny that it can generate important insights nonetheless, such as with regard to histories of the → Internet.

These seven narratives, taken together, facilitate efforts to map the broad contours of much media history research and writing. Each of these narratives has its relative strengths and limitations: none is above criticism, while each has something significant to contribute. Future work in the area, he believes, will repay efforts to find ways to interweave these narrative strands together, for it is through their synthesis that the excessive over-specialization of media history can best be overcome. “Instead of telling a story of things getting better or worse,” Curran observes, a commitment to synthesis “offers a more contingent view of ebb and flow, opening and closure, advances in some areas and reverses in others. The contextualization of media history dissolves linear narratives – whether of progress or regress” (2002, 51).

## RESEARCHING MEDIA HISTORY

The importance of media history may appear to be self-evident. More often than not the merits of a historical approach are justified with reference to familiar sayings, such as: “Those who cannot learn from history are doomed to repeat it.” This admonition, and variations of it, reminds us that a study of the past better equips us for engaging with the future. For media historians, the rationale for their craft is often expressed as a commitment to interdisciplinarity so as to situate the evolution of media forms, practices, institutions, and audiences within broader processes of societal change. “The history of the media,” writes Nerone (1993), “cannot be understood apart from the history of the social and cultural contexts within which media developments occurred; the proper unit of study is not the individual medium, but the whole set of media within a particular ecology.” It follows, he adds, that “the history of the media should be written as social history: as the history of societies” (1993, 39).

Briggs and Burke (2005) concur, pointing out that the “immediate intentions, strategies and tactics of communicators need at every point in the story to be related to the context in which they are operating – along with the messages that they are communicating.” That said, they acknowledge that it is always difficult to identify, even with the benefit of hindsight, “the long-term effects, especially the unintended and sometimes surprising consequences of the use of one means of communication rather than another one” (2005, 5). Compounding this difficulty, of course, is the recognition that media processes can be ephemeral, and thereby elusive in conceptual and methodological terms. In any case, their very normality, that is, the extent to which they are simply taken for granted as a part of everyday life, means that efforts to de-normalize them face considerable challenges.

Media historians, it follows, must strive to be sufficiently self-reflexive about their chosen strategies when gathering source material and interpreting evidence, especially where questions related to “effects” or causation are being addressed. Pertinent in this regard is the status of electronic media, for example, which may pose particular problems for the historian seeking to establish relations of significance. Not only are the actual texts under scrutiny – e.g., an early radio play or television broadcast – unlikely to be amenable to more traditional, print-based methods, but issues with regard to such logistical considerations as access, physical → artifacts (microphones, receiver sets, and the like), and format-compatibility (changes in formats can make playback difficult) may surface. In addition, an investigation into a creative production environment will necessitate a different type of evidential basis being secured. “In many cases,” as Godfrey (2006) observes, “media records may be compared and substantiated against existing production records, such as scripts, rough drafts, site maps, organizational outlines, production notes, oral histories, and written materials utilized in creating a program or series.” It is precisely this type of documentation, he adds, that enables the media historian to discern the array of factors giving shape to the program, and to help interpret their relative importance. “Peeling away the layers of production reveals those illustrative historical facts and enhances analytic understanding of the creative process itself” (2006, 14).

At the same time, media historians recognize the ways in which such programs can simultaneously provide valuable insights into their audiences. “From this body of evidence,” Benjamin (2006) writes, “researchers can deduce attitudes, assumptions, and

values of both (creators and their audiences) from past programming.” She proceeds to point out that “listening to an audiotape or viewing a videotape of a speech, for example, provides a more accurate experience than reading a printed copy. Voice inflection, body posturing, and other nuances add rich texture to the speech” (2006, 44). For these and related qualities to be analyzed, new methods are being crafted to address the specificities of electronic media in historical terms.

The advent of digital technologies is already engendering similar types of issues for media historians (→ Digital Media, History of). Thrown into sharp relief are certain assumptions about how intellectual work proceeds, many of which are derivative of print-based culture (Stephens 1998). Print, the Victorian historian Lord Acton wrote in 1895, “gave assurance that the work of the Renaissance would last, that what was written would be accessible to all, that such an occultation of knowledge and ideas as had depressed the Middle Ages would never recur, that not an idea would be lost” (cited in Briggs & Burke 2005, 16). This presupposition no longer holds true in a digital age, where media history scholarship increasingly entails finding alternative ways to manage, interpret, and preserve the extensive array of materials available across different storage systems.

The sheer volume and range of these materials, coupled with continuing innovation in hardware and software (the obsolescence of technology rendering some types of data difficult to retrieve), can make for challenging decisions about how to maintain libraries, archives, databases, and other repositories of information (→ Archiving of Internet Content). New questions are being posed in this regard by electronic records, including items such as emails, voicemail messages, word-processing documents, Internet websites, message boards, blogs, and the like, all of which are highly perishable (→ Electronic Mail).

These questions have been anticipated, at least to some extent, by media history research concerned with still → photography since the early 1990s, when analogue formats began to give way to digital ones. Digitization can make the verification of photographic records very difficult (Wardrip-Fruin & Montfort 2003). A variety of digital editing tools enable the easy manipulation of a digital photographic file’s pixels, in marked contrast with the relative immutability of analogue records (where alteration is usually detectable). Seamless edits may include, for example, the removal of a person or object from a photograph, or more subtle effects at the level of framing, shading, or hue – all accomplished with a click of the computer mouse. For the media historian, then, new tests of authenticity need to be determined for visual (and aural) evidence (Beadle 2006).

Precisely how media history research will evolve invites thoughtful consideration. Current efforts to build on the foundations set down by the press histories of the nineteenth century are making progress, not only by enriching these traditions, but also by pursuing new directions that recast familiar assumptions – sometimes in unexpected ways. The types of criticisms of “standard” media history identified by Carey (1996), namely that its arguments were based on “nothing more than speculation, conjecture, anecdotal evidence, and ideological ax grinding” (and where conclusions were not “theoretically or empirically grounded; none was supported by systematic research”), no longer aptly characterize the field (1996, 15–16). Indeed, it is reasonable to suggest, on the basis of the range and depth of the research surveyed above, that there is every indication that media history will continue to develop in ever more methodologically

rigorous – and intellectually exciting – directions. Still, while there are grounds for optimism, much work remains to be done.

## Media Literacy

*Sonia Livingstone*

*London School of Economics and Political Science*

*Shenja van der Graaf*

*London School of Economics and Political Science*

Media literacy has been defined as “the ability to access, analyze, evaluate and create messages across a variety of contexts” (Christ & Potter 1998, 7). This definition, produced by the USA’s 1992 National Leadership Conference on Media Literacy, is widely accepted, although many alternative and competing conceptions also exist. As the subject of academic research, educational initiatives and communication policy (Potter 2004), media literacy research reflects enduring tensions between critical scholars (→ Critical Theory) and policymakers, educationalists and technologists, defenders of high culture and defenders of public morals. Associated with media literacy is a variety of related concepts – advertising literacy, Internet literacy, film literacy, visual literacy, → health literacy etc. – these reflecting the range of media forms that demand, or assume, knowledge about media on the part of the → audience or → public.

### **MEDIA LITERACY AMONG CHILDREN**

The relationship between children’s age and the development of media literacy is well established. Drawing on Piaget’s theory of cognitive development (Valkenburg 2000), reviews of empirical research on how children of different ages understand media content (usually television programs and advertisements) tell a fairly consistent story. Notwithstanding some concerns regarding the cross-cultural validity and normative assumptions of a “stage”-based theory of development, this research generally maps stages in the development of media literacy onto Piaget’s pre-operational stage (ages 2–7), concrete operational stage (ages 7–12), and formal operational stage (age 12+) of cognitive development.

It seems that before about 3 years old, children see not only life but also → television as William James’s famous “blooming, buzzing confusion” – a potpourri of colors, music, movement, faces, and repetition – though there is beginning to be more research on very

young infants' understanding of media. Before about 5 years old, children tend to regard television as a window on the world, though they begin to distinguish television from reality. Nor do they understand that → advertising is persuasive rather than informational, though they are already sensitive to gender cues in television content.

Between about 7 and 11 years old, children are in a transitional phase as regards media literacy. By about 7 or 8 years old, children have begun to distinguish genres of programs; they tend to find the realism of the → news more frightening than → cartoons; they have begun to recognize the persuasive intent of advertisements. After around 8 years old, children are generally competent in “putting the narrative together” – making inferences about sequencing, causality and morality in narrative, for example. Further, they show a growing interest in production, being critical of content, making more subtle comparisons between television and reality (recognizing that content can be fabricated and yet still make “real” claims about the world if the portrayal is “possible”; Dorr 1986; → Fantasy–Reality Distinction).

By 10 or 11 years of age, children enjoy critiquing the acting, decor, and narrative aspects of television content, increasingly drawing on their own social knowledge to judge the realism of television content. Lastly, from about 12 years old, children's critical judgments are of growing sophistication: they show awareness of bias and → stereotypes; they make subtle aesthetic judgments (→ Aesthetics), being aware of different styles of → realism; and they have a stronger understanding of the purpose of advertising and → branding, often becoming skeptical or distrustful of advertising (van Evra 1998).

## **MEDIA LITERACY AMONG ADULTS**

Media literacy research and initiatives have focused more on children than on adults, and the theory of children's development of media literacy is more developed than that for adults. For children, there are developed media education programs that specify age-appropriate skills, progression across levels, and methods for evaluating the delivery of a formal curriculum according to age-graded levels of achievement. Yet media literacy is important across the life-span (→ Communication Skills across the Life-Span). One challenge is how to reach people, to promote media literacy, if they are not in the formal education system. Another is how to measure media literacy and evaluate the success of media literacy initiatives. Further, theories of media literacy say little about standards and progression, and despite the existence of a media education curriculum for children, formal expectations regarding adult media literacy are rarely formulated (by contrast with targets set for print literacy in many nations).

## **POLICY RELEVANCE: MEDIA EDUCATION AND MEDIA REGULATION**

Policy initiatives in relation to media literacy fall into two categories. In the field of education, there have long been attempts to establish media literacy as a required part of the school curriculum, arguing that, while reading and writing (i.e., print literacy) have long been accepted as central to education, the ability to understand and communicate in the realm of audiovisual and, more recently, computer-based or online literacies must also be recognized as important.

In addition to the resource limitations that limit the success of these efforts, the contested philosophy behind media literacy has also impeded educational initiatives worldwide. Educators differ regarding their valuation of media content: put simply, is media literacy best understood as a means of inoculating children against the potential harms of the media or as a means of enhancing their appreciation of the literary merits of the media (Buckingham 1998; Hobbs 1998)?

The second category of policy initiative concerns media and communication regulation (→ Communication and Law). In the UK, for example, section 11 of the 2003 Communications Act requires the regulator, Ofcom, to “promote media literacy” among the UK population, and in order to implement this, the regulator has drawn on academic work to define media literacy as “the ability to access, understand and create communications in a variety of contexts.” The Council of Europe similarly encourages media literacy training for children to enable the benefits of the changing media and communication environment and to reduce the risks of harmful content and contact (→ European Union: Communication Law). In this context, media literacy represents a tool to empower the public to manage the increasingly complex media and information environment and, arguably, permits the legitimate deregulation of the media content industry.

### **THE VALUE AND PURPOSES OF MEDIA LITERACY**

Media literacy research depends partly on the discipline of those who study it. Those more influenced by the arts and humanities see media literacy as a route to enhancing the public’s appreciation of, and ability to contribute creatively to, the best that the cultural and audiovisual arts have to offer. The focus is on pleasure and interpretation, creativity and diversity, originality and quality. By contrast, the social science approach sees media literacy as a form of defense against the normative messages of the big media corporations, whose commercialized, stereotyped, unimaginative, and parochial worldview dominates mass culture in capitalist societies. The focus is therefore on → uses and gratifications, influences and → cultivation effects, and everyday cognitive and social mediations of mass culture (Livingstone et al. in press).

As media and communication technologies increasingly mediate many spheres of activity, not just leisure and entertainment but also work, civic participation, education, and community, there is growing consensus that media literacy is important for (1) democracy, participation, and active citizenship: in a democratic society, a media-literate individual is more able to gain an informed opinion on matters of the day, and to be able to express their opinion individually and collectively in public, civic, and political domains, while a media-literate society would thus support a sophisticated, critical, and inclusive public sphere; (2) the knowledge economy, competitiveness, and choice: in a market economy increasingly based on information, often in a complex and mediated form, a media-literate individual is likely to have more to offer and so achieve at a higher level in the workplace, and a media-literate society would be innovative and competitive, sustaining a rich array of choices for the consumer; and (3) lifelong learning, cultural expression, and personal fulfillment: since our highly reflexive, heavily mediated symbolic environment informs and frames the choices, values, and knowledge that give significance to everyday life, media literacy contributes to the critical and expressive

skills that support a full and meaningful life, and to an informed, creative, and ethical society.

These goals may seem uncontentious. However, significant differences of opinion persist, for example, over whether media literacy should be conceived as an individual accomplishment or a social and cultural practice, how much emphasis should be placed on critiquing the media, and whether media literacy is better achieved through education or citizenship initiatives. For some purposes, a cognitive approach that prioritizes the acquisition of clearly defined skills is preferable, being most easily promoted, implemented, and evaluated. Others, those drawing on a long history of cultural critique of the uses and misuses of print literacy, would take a more macro-social position, arguing that literacy concerns the historically and culturally conditioned relationship among three processes, no one of which is sufficient alone: (1) the symbolic and material representation of knowledge, culture, and values; (2) the diffusion of interpretive skills and abilities across a (stratified) population; and (3) the institutional, and especially the state, management of the power that access to and skilled use of knowledge brings to those who are “literate” (Luke 1989).

### **THE CHANGING NATURE OF MEDIA LITERACY**

Thus far, most media literacy research has been conducted on broadcast media, and as yet very little exists for new media (e.g., → Internet, digital television, mobile communications). The priority now is to develop a subtle and detailed account of how people understand, trust, and critically evaluate information and communication contents delivered on new platforms, and disseminated and regulated in unfamiliar ways, that can match the analysis already developed for audience’s understanding of (mass, broadcast) television content.

By contrast with the related term → “information literacy,” the media literacy tradition generally stresses the understanding, comprehension, critique, and creation of media materials, whereas the information literacy tradition places more emphasis on the access, identification, location, evaluation, and use of information materials. One reason is that the media literacy agenda was developed at a time when, in developed countries at least, access was not seen as a significant problem or source of inequality, but media ownership and content have been regarded more critically – hence the importance to this tradition of critical literacy. As the media and communication environment diversifies, issues of access and inequality merit increased attention.

By contrast with print literacy research, which has always balanced the study of reading with the study of writing, media literacy research has paid more attention to questions of access, selection, and understanding than it has to the creation of content, since opportunities to create broadcast or printed content have been severely limited for ordinary people. In the changing media and communication environment, opportunities to create content are transformed. It is important, therefore, that all dimensions of the definition of media literacy – access, understand, and create – are valued, for otherwise research risks positioning the audience as recipient rather than, as is increasingly possible, also producer. Producing content may be conceived fairly minimally – e.g., visiting chatrooms – or more ambitiously, in a manner generally not possible for audiovisual

media, precisely because in relation to the Internet the limitations on volume and accessibility of content, and on the tools to produce content, are modest. The world wide web includes many sites constructed by ordinary members of the public, both as individuals and as part of their local or community roles. Consequently, questions of equality and exclusion, and of authority and quality, are all on the agenda for future media literacy research.

## **Media Logic**

*Gianpietro Mazzoleni*

*University of Milan*

Altheide and Snow (1979) were the first to use the term “media logic” to identify the specific frame of reference of the production of media culture in general and of the news in particular. They define media logic as a way of seeing and interpreting social affairs.

Elements of this form of communication include the various media and the formats used by them. Formats consist, in part, in how material is organized, the style in which it is presented, the focus or emphasis, and the grammar of media communication (Altheide & Snow 1991). The underlying idea is that of a dominant form, a representation of reality, and content definitions to which media producers conform (→ Media and Perceptions of Reality). By identifying these “formats” it is possible to better understand what lies behind the process of media production. According to Altheide (1985), formats are also relevant to issues of the social influence of the media, for they affect the perception of reality acquired from the media.

The production processes of media raw materials normally imply a certain extent of standardization, reflecting the goals, traditions, and routines of a given media organizations and an adaptation to the demands of the audiences. Media organizations maintain a set of specifications, which may be economic, technological, and cultural, to assure that content produced and distributed responds to efficiency criteria. The term “media logic” captures the whole of such processes that eventually shape and frame media content.

The mass media institutions, either public or private, have their own specific nature that distinguishes them from other institutions that produce culture (→ Culture: Definitions and Concepts). Public media outlets implement a logic that reflects the statutes of these institutions that cater to the general interest. Private-run media respond chiefly to industrial and commercial imperatives and implement logics that reflect corporate goals and audience tastes and expectations. From this stems a mixed approach by media organizations to political events. For example, *public service broadcast media* are more likely to give space to a plurality of voices and to represent a plurality of views (→ Public Service Broadcasting: Law and Policy). However, at the same time, they cannot avoid packaging political news in appealing formats or yielding to a certain degree of sensationalism, amplifying certain personal traits of political leaders, or making some editorial inroads into the political arena. “Infotainment” programs run by public broadcasting organizations around the world are just one example of this response to “media logics.”

The *commercial news media* have no obligation to present a pluralist and fair treatment of politics, and typically privilege the “populist” dimensions and features in the production processes of political stories. Furthermore, commercial media usually seek the sensational in the news-gathering process, and events lacking spectacular or uncommon features tend to be ignored (→ Sensationalism; Tabloidization). They rather adopt a style of political narrative that emphasizes personalities and penalizes ideas, oversimplify complex issues, focus on confrontation rather than on compromise, and show preference for what has been called the “game schema” or the “horse race” aspects of political life and election campaigns.

The concept of “media logic” is also closely linked to the issues of *bias* and *frames* in media content (→ Bias in the News; Framing of the News) insofar as industrial, cultural, or political pressures contribute to mold the specific character of the product placed on the market. In fact, this concept – often overlapping with that of commercial logic – has been particularly useful to illustrate and explain the process of “news production.” The classical routines of news gathering, selection, and presentation are geared to implement this (commercial) logic in the construction of reality worked out by the news industry.

Journalists are driven by organizational and industrial goals and implement the professional values, norms, and practices of the news organization. Certain issues, topics, and events are “manufactured into news” if they fit the news value system. Novelty, drama, personalization, human interest, timeliness, and conflict are the familiar components of the newsworthiness of an event (→ News Routines; News Factors). Competition for ratings and for advertising resources has increased news professionals’ craving for sensational events, scandals, crime, and sex stories.

In the political communication domain, media logic has been contrasted with “political logic” (Mazzoleni 1987), and seen as an engine of the “*mediatization*” of politics (Mazzoleni & Schulz 1999; → Mediatization of Politics). Politics performed publicly has increasingly adapted to the canons of media discourse; successful politicians have to be media-genic and media savvy; personalized leadership has become more important than parties (and ideologies); election campaigns tend to be media-driven and spectacular; and voters get their image of politics and politicians from the media representation, which responds primarily to media logic. These trends are indicators also of an objective power of the media to shape political reality that politics and politicians can hardly resist.

## **Media Management**

*Lucy Küng*

*Jönköping University*

The core task of media management is to build a bridge between the general theoretical disciplines of management and the specificities of the media industry. Media management is, however, neither a clearly defined nor a cohesive field but rather a loose agglomeration of work by researchers from various scientific fields. The syllabi from the

rash of media management courses that have sprung up over the past decade all over the world exhibit very few commonalities, and an enormously diverse range of theories, topics, and core readings. Notable is that very few of these courses stem from management or business schools. The majority come from mass communications and journalism or economics institutions (Küng 2007).

In contrast to media economics, which since its emergence in the 1970s has acquired an established set of theoretical approaches and an extensive body of literature, media management is still embryonic; the *International Journal of Media Management* was established only in 1998, the *Journal of Media Business* in 2004, the European Media Management Association (EMMA) in 2003, and the International Media Management Academic Forum in 2004 (→ Media Economics).

### SCOPE OF THE FIELD

As Albarran and colleagues have observed, the field of media management “crosses interdisciplinary lines, theoretical domains, and political systems” (2005, 3). This, combined with its newness, has given rise to a fragmented body of literature, one that covers all the major dimensions of management theory – strategy, finance, marketing, operations, technology, human resources, and so on – but falls short of constituting a robust basis for understanding the practice of management in the media sector. It is therefore not possible to provide a clear overview of the scope of media management. But a number of strands can be discerned. In the main, these reflect the “host” disciplines of the scholars responsible.

To date, the major contribution to the field has been from *media economists*. While there is much overlap between media management and media economics, the former tends to focus on the activities of individual media organizations while media economics tends to work at an aggregate level – usually sector or market – with a focus on industry structures and the deployment of resources, particularly financial ones, to meet the needs of → audiences, advertisers, and society (→ Advertising). A number of media economists have strayed purposefully into the field of media management. Here, they have focused on issues related to strategy formulation and implementation by large media organizations, most often applying rationalist models from the industrial organization (IO) school, and looking particularly at the antecedents and/or consequences of change in the sector and alignment between firms’ environment, structure, and performance (→ Concentration in Media Systems; Convergence of Media Systems).

The work of *political economists* and scholars in *communication* has supplied understanding of the broader strategic environment of the media industry (→ Political Economy of the Media). These scholars combine economics, politics, and sociology perspectives to analyze the structure of the media industries, and regulatory and policy issues, looking particularly at the economic determinants, ownership structures, and political allegiances (→ Media Conglomerates). Typical examples would be Tom Burns’ seminal study of the BBC (1977), Michael Tracey’s study of how political, technological, and economic forces have undermined public service broadcasting (1998; → Public Service Broadcasting: Law and Policy), or Jeremy Tunstall and Colin Palmer’s study of media moguls (1991).

*Marketing theory*, itself a substantial constituent part of management theory, has been applied with increasing frequency to the media in recent years (→ Markets of the Media). Branding is a particularly prominent issue, as media organizations seek to find ways to make their products stand out from an increasingly competitive field (→ Branding; Brands). A more pragmatic set of economically influenced insights on trends, practices, and defining characteristics of the media industry comes from *analysts and consultants* who have worked in the industries. These include texts such as Michael J. Wolf's *Entertainment economy* (1999) and Harold Vogel's *Entertainment industry economics* (2007).

### HISTORICAL DEVELOPMENT

From a historical perspective, study of media management reflects changes in the strategic environment of the media industry. The 1980s and 1990s were characterized by liberalization, deregulation, and globalization, and scholars responded by focusing particularly on issues of industry structure, the growth of the conglomerates, and transnational management in the sector (→ Globalization of the Media).

Toward the end of the 1990s, a first and second tier of global media conglomerates became established. These were multiproduct, divisional entities that presented a more complex management task, and scholars began to focus on the specific challenges they presented, applying tools such as the resource-based view (RBV; Chan-Olmsted 2006), theories of organizational culture (Küng 2000), and multiproduct business models (Picard 2002a, b).

The turn of the millennium saw dramatic developments in the media industry's underlying technologies. This gave rise to a flurry of research looking at the emerging digitally based distribution architectures and their ramifications for the public and the established media industry (Shapiro & Varian 1999; Evans & Wurster 2000).

### CURRENT RESEARCH EMPHASES

Management is an applied discipline and current research foci are driven by developments in the industry (→ Applied Communication Research). This, when combined with the diverse backgrounds of researchers in the field, means that current research strands flow in many different directions. In terms of media management, three topics are prominent currently.

The first is *creativity*. Creativity has always been central to the media industry – cultural goods can rarely be standardized on a long-term basis and this, combined with the fickle nature of customer demand, means there is an incessant need for novelty. However, technological advances have increased the number of media products available to consumers and led to the emergence of entirely new product categories. This has increased both competition and need for creativity, since the higher the levels of ongoing creativity, the greater the potential for competitive advantage (→ Digitization and Media Convergence).

A second area of research looks at *new content forms* and their implications. While the largest players in the industry are focusing on blockbuster products that can be reformulated

for many different platforms and marketed globally, some of the most energetic growth in the sector is coming from contradictory trends. The first is niche products. Technology now allows specialized content to be matched with specialist audience niches, and consumers are showing a preference for targeted products over generalized ones (→ Audience Segmentation). This is giving rise to a process of “demassification,” where the appeal of “mass” products is dwindling and that of niche products growing. The second is the growth in user-created social-network-spawned media. A vast amount of information is now being created, stored, and shared by users, often in social networking sites that combine personalized content with a participatory context. This type of content represents both a growth opportunity and a challenge for established industry players.

The media industry is, however, not just about content. It is also deeply and symbiotically *linked with technology*. It was born out of technology and adjusting to technological change has been a consistent and longstanding challenge. However, while technological advance has always been present, the volume and velocity of the changes now under way have created a peculiarly challenging environment (→ Technology and Communication). The third research stream analyses these changes and explores their ramifications for the industry and audiences.

## METHODOLOGICAL ISSUES

The field of management in and of itself represents a number of intrinsic challenges to researchers. First, there is the *problem of breadth*. The body of scholarship relating to matters of management is an enormously dispersed body of literature. Second, there is the *problem of pluralism*. Over recent decades, a profusion of new concepts, approaches, and schools has developed, leaving the field more and more fragmented, differentiated, and complex. Third, there is the *problem of compartmentalism* – or incommensurability.

The various concepts and theories within the field are not only diverse but contradictory and inconsistent, and do not lend themselves to the creation of a solid, coherent foundation for media management. If we add to this the fact that the media industries themselves are far from monolithic, representing a diverse set of industries, operating in all kinds of geographic segments, and catering to many different types of audiences, considerable conceptual and contextual breadth of expertise is required by the researcher.

## FUTURE DIRECTIONS IN RESEARCH AND THEORY

As said, the field of media management is new and unformed. There have been relatively few attempts to apply mainstream management theory to the media industry in a rigorous way. Much basic groundwork remains to be done in the shape of systematic application of management concepts to the industry, highlighting the specificities of the sector and concepts of particular relevance.

In terms of strategy, many insights have come from application from the *rational school*. This will certainly continue: issues such as strategic positioning, competitive dynamics, and diversification strategies are not likely to lose relevance. But with the increasing dynamism and complexity of the media industry’s environment, it is increasingly difficult to make the necessary assumptions to carry out such research. Therefore, a wider

set of tools needs to be adopted, specifically concepts that link the environment, strategy, and the organization. Many of these can be found in adaptive and interpretative areas of management theory.

As its name suggests, the *adaptive school* is concerned with strategic change. It seeks to understand the systems and processes by which an organization responds to changes in the environment. Particularly relevant to the media sector are concepts concerning the interplay between technological change and organizations.

The *interpretative school of strategy* focuses on the less obvious elements of organizations that influence strategic outcomes, namely the deeper, “hidden” aspects such as mindset and belief systems, values, motivation, and emotions. These elements are often sidelined by researchers because they are subjective and/or unconscious phenomena that are difficult to access and interpret. However, they are particularly important in media organizations, partly because the individuals who choose to work in the sector are often motivated to do so because of their own “higher order” needs, and partly because of the tremendous influence that the media industries exert over our lives and societies. There is ample evidence of the relevance of concepts from this school: for example, culture is an important factor in established firms’ ability to respond to new technology, and mental models can lead incumbents to reject such technologies, as evidenced by the music majors’ responses to the Internet.

Applying such models will require a *broadening of research methodologies*, specifically the use of contextualist, constructivist, processual, and pluralist approaches. A contextualist orientation includes the organization’s internal and external environments in the widest sense, and particularly social and historical influences (regulatory and technological ones are well covered) in the research frame. A constructivist perspective is necessary because organizational realities do not exist independently of their observers: environments, organizations, and strategies are constructed rather than natural objects (→ Constructivism). Processual approaches do not assume a linear relationship between formulation and implementation, but rather seek to understand strategic processes, including the multiplicity of nonrational elements that can affect them. Finally, pluralism is necessary because both the industry and the changes taking place in it are complex phenomena. Multi-lens analysis can accommodate the untidy, idiosyncratic, and dynamic inter-relatedness of organizations and their strategic activities.

## Media Marketing

Mark R. Phillips, Jr.

University of Oregon

In an age of rapid technological innovation it would seem counterintuitive to assume that marketing and advertising techniques would remain stagnant; to survive and prosper, as in all aspects of business, marketers need to adapt their strategies and activities and advertisers need to evolve in terms of style, content, and media application (→ Marketing; Advertising). Media, both as a self-perpetuating entity and as a facilitator of others' marketing goals needs to respond to changes in environment and strategic perspective. Indeed, media are currently witnessing great flux in marketing approaches. Marketers are being forced to rethink traditional paradigms and re-evaluate fundamental tenets right down to the bedrock definitions including markets, what constitutes an “ad,” and what is meant by “media.”

### MEDIA MARKETING DEFINED

Media are entities used for communicating; they physically transmit information over space and time. They link sender to receiver. Mass media are venues whereby a sender can transmit to many receivers simultaneously (DeFleur & Dennis 1994).

Traditionally media have been divided into two categories, electronic and non-electronic. Historically electronic media were → radio and → television; non-electronic media included → newspapers, → magazines, direct mail, business papers, and outdoor (billboards, murals, etc.). Using electronic/non-electronic as a way to discriminate among various media is still largely valid but within these categories we have witnessed great change. In the non-electronic sector we have seen the rise of national newspapers as a supplement to local newspapers and the ownership of local papers increasingly by national and international → media conglomerates with a concomitant effect on both → news and advertising content (→ Global Media, History of; Globalization of the Media). General interest magazines have by and large given way to a plethora of magazines that much more narrowly target specific audiences. Outdoor advertising, which essentially was billboards, has morphed into a new category – *out of home*, which includes not only billboards and murals but advertising on the sides of buses and taxi cabs, ads in public venues (airports, sports arenas, shopping malls, etc.), and many other applications. Major changes in electronic media include the conglomeration of local radio, the proliferation of → cable television, an increase in the usage of product placement in television and motion pictures, and the rise of the → Internet.

Marketing as a concept has been variously defined both narrowly and broadly. It has been defined in terms of activities – product conception, pricing, promotion and distribution strategies. Marketing has also been defined in terms of orientation – product orientation, sales orientation, or market orientation (Enis 1974).

When considering the *nexus of media and marketing*, marketing can be defined as all those activities aimed at facilitating and expediting exchanges between entities (Pride & Ferrell 1980). Media, from a marketing perspective, are the intermediaries through which exchanges between entities are facilitated, i.e., media provide a means for producers and sellers to communicate with consumers, both actual and potential. Obviously, the principal, or at least most palpable, way that media facilitate exchange is by running the advertisements of third parties. However, media also engender a favorable culture for marketers via news stories and entertainment programs. It has long been argued that the media in its forms and content encourage and proliferate a consumer culture. Finally, media, particularly electronic media, spend a significant amount of effort in self-promotion. Programming promos, logos on TV screens, “news” stories, event sponsorship, virtual ads during programming, etc., all serve to promote programs, stations, and networks.

As media accommodates marketers and modifies its own marketing strategies the media will necessarily change, *mutatis mutandis*. Due to a confluence of events we may, in fact, be on the cusp of such a mutation. The factors currently driving this polygenism are an increased emphasis on market segmentation and technological innovation and a general proliferation in both media and advertising (→ Marketing: Communication Tools).

## MARKET SEGMENTATION

The practice of market segmentation, dividing the potential audience into relatively homogeneous sub-groups, is neither a new or a revolutionary development. Audiences have long been segmented based on various factors, and strategies have been formulated

to appeal to these varied segments (→ Audience Segmentation; Segmentation of the Advertising Audience). What is different about today's segmentation efforts is the unprecedented ability of marketers to gather information about consumers and the profusion of media outlets in large part designed to appeal to specific market segments. The media is in the process of reorganizing itself to reflect this emphasis on segmentation. While the number of newspapers, largely a general interest medium, is contracting, radio stations are growing in number, the number of special interest publications have grown significantly since the 1970s, and cable television networks have proliferated.

Special interest magazines targeting specific user groups and radio stations with their differing content certainly exhibit the ethos of segmentation but cable television is particularly representative of both the desire to segment and the growth of segmentation strategy. Where once the television market was dominated by a few over-the-air broadcast networks, cable has grown by leaps and bounds. There are now shopping networks, home and garden networks, home improvement networks; networks for women, for history buffs, for those interested in science, weather, travel, fitness, religion, food, government, the legal system, and even jewelry; entertainment networks devoted to comedy, sports, and various genres such as animation, science fiction, and westerns. The mantra of all these media outlets is the viewer demographic. Who is watching? What do they purchase? And how can we appeal to them?

## TECHNOLOGICAL INNOVATION

Digital technology offers virtually infinite opportunities for marketers to promote products. Television stations and networks digitally impose their company logo or call letters in a corner of the screen continually. Promos (words and pictures) routinely scroll across the bottom of the screen announcing upcoming programs and events. Corporate sponsors' logos are digitally displayed on the screen during entertainment programs and sporting events. These "ads" can be changed many times over the course of the programs and games.

*Product placement* has adopted digital technology to create what has been termed virtual product placement. Traditional product placement requires actually displaying or using the physical product in a scene. Virtual product placement digitally inserts the product in the scene after the fact. Not only does this allow for more products to be placed, but it also allows for multiple placements during the lifetime of the entertainment. For example, a feature film contracts with Coca-Cola to have its product placed in the film during theater exhibition. The producer then contracts with another soft drink manufacturer, e.g., Pepsi, to have their product placed during the movie's release on pay cable. The Coke can is digitally erased and a Pepsi can inserted. Similar digital alterations can occur when the film appears on cable, over-the-air, DVD, etc. The same process can be utilized on television for first-run and syndication (→ Digital Imagery).

A second technological innovation that is fueling the increasing emphasis on product placement in television is the digital video recorder (DVR). Increasingly television viewers are not required to watch program offerings at times dictated by broadcasters, rather they can record and watch desired programs when it is convenient. A consequence of this time-shifting behavior is that viewers of recorded programs routinely zap, or fast

forward, through commercial breaks. Ergo, to reach viewers marketers must resort to other methods such as product placement or digital banners that appear during programming.

## **PROLIFERATION**

As advertising demand grows media adapt by exploring new and different ways to present ads within existing media and by creating new media forms to accommodate the demands of marketers. Advertisements are everywhere: chalked on sidewalks, on shopping carts in stores, in airports, on buses and taxis and all manner of public transportation, on closed circuit televisions in public spaces, in public restrooms, etc., not to mention all manner of outdoor signs and billboards.

The Internet, while not created as an advertising medium, has quickly adopted the advertising perspective. It is currently the fastest-growing medium in terms of percentage of advertising volume. In other words, of all money invested in advertising the Internet is increasing its share of total volume more than any other medium. As previously stated the number of radio stations is growing as the industry attempts to further segment the listening audience. Similarly it seems inevitable that cable television will continue to expand its reach. In addition marketers continue to search for other media to utilize. The growth of mobile phones has created one such opportunity. Mobile phone advertising, banner ads running across the bottom of phone screens, is increasing exponentially. It is estimated that by 2011 annual mobile phone advertising will exceed US\$11 billion worldwide (→ Mobility, Technology for).

Product placement continues to expand. In addition to television and motion pictures there have been examples of product placement in video games, in novels, and in popular songs. The DVR has not only spurred the growth of product placement on television but is also causing discussion of expanding the technique in a practice referred to as product integration. Product integration involves sponsorship of an entire program whereby the advertiser controls the content of the program if not actually produces the show. This is, of course, not strictly new. In the early days of radio and television programming was often produced by advertisers who controlled the content of the programs. However, bringing this practice back will controvert the paradigm that has existed for over 40 years where networks create the programming and sell advertisers commercial time.

## **FUTURE DIRECTIONS IN MEDIA MARKETING**

Media marketing involves a bipartite construct where on the one hand the media markets itself – to consumers (audiences) and to marketers of other businesses as a viable intermediary – and on the other hand serves to facilitate the marketing efforts of advertisers. The goals of these two sides of the media marketing equation do not always converge. Programs that generate large audiences may not always be attractive to advertisers (e.g., shock radio) and advertising clutter may discourage viewership.

If the architectural bromide “Form follows function” pertains, it should be expected that media will organize itself to accommodate marketers. Recent developments in terms of segmented media offerings (cable TV, radio, targeted magazines) seem to give credence

to this point of view. However, at what point will media compromise their own existence by acceding to marketing prerogatives? For example, will rampant product placement or product integration compromise programming quality? Will shows become little more than infomercials and will this result in reduced consumption of media? The Internet promises to be instructive as it struggles to evolve. Certainly it is attractive to users and offers value as an intermediary to marketers. It holds the promise of what might be called the ultimate segmentation strategy – tailored appeals to individual consumers. But how the Internet will ultimately be organized and who will control content will certainly involve a struggle between individual, business, and government interests (→ Markets of the Media).

Some media do not rely on advertising for funding. Magazines that support themselves solely through subscriptions or state-supported radio or television networks serve as examples. To the extent that these media do not have to make themselves attractive as advertising intermediaries they avoid some of the issues cited above. However, whether supported in whole or in part by advertising (corporate sponsorship often muddies the clear delineation between advertising- and non-advertising-supported media) the issues of market segmentation, technological innovation, and media proliferation still pertain. Even if media need not deliver audiences to advertisers they still need audiences to claim relevance (→ Cost and Revenue Structures in the Media).

Media marketing is in a state of flux. Both content and delivery are mutating. Mobile phones, which have been transformed from an instrument of personal communication to a mass medium generating billions of dollars of advertising revenue in a very short time, illustrate the stakes involved and the rapidity with which the media environment is changing.

# Media Messages and Family Communication

*Christine Bachen*

*Santa Clara University*

Media use is a central leisure-time activity for many families worldwide. Given the considerable time investment of family members in media use collectively and individually, and the fact that the family is the context in which young people are first exposed to media, it is important to study how family dynamics shape the use of media and the ways in which media messages are understood (→ Exposure to Communication Content). A related question is how communication within the family is influenced by the presence of media in the home (→ Media Effects).

While → television and → radio are the most pervasive media in households worldwide, in economically developed countries the home is the site for increasing numbers of televisions, radio, audio, and → video playback devices, computers, the → Internet, and video-game systems (→ Video Games). Media management is recognized as an important task of contemporary parenting, albeit with a wide-ranging set of practices within and across cultures (see Livingstone & Bovill 2001 for a comparison of media environments for children across 12 European countries).

## **MEDIA-RELATED PRACTICES IN THE HOME**

Research on media and families has identified several key media-related practices initiated by parents in the home: “restrictive mediation” (or rule making), “social co-viewing” (or, more broadly, co-use of a medium), and “active mediation” (or the role that parents play as mediators or interpreters of media content for children through active discussion). Most of this research emerges from American studies on the medium of television, but more recently, Nikken and Jansz (2006) point to the applicability of these three forms of interaction to other media such as video games.

*Restrictive mediation* – parental control over children’s media use through the establishment of rules about time spent with media or permissible media content – is a common practice with children under 7 years old. While parents of children of all ages voice concerns about sexual content (→ Sex and Pornography as Media Content, Effects of), violence (→ Violence as Media Content, Effects on Children of), and adult language in television, video games, and music, the majority of parents with children aged 8 years and older do not enforce rules related to content or time spent with media (Roberts et al. 2005). Restrictive mediation is associated with parental fears about the ill-effects of media (Nathanson 2001).

Use of media by parents and children together is more typical with younger children, and when parents have positive attitudes about a given medium and are frequent users themselves (→ Co-Viewing). Recent trends, however, point to declining co-use of media due to the development of technologies that are more adapted to individual use and the increase in the type and numbers of media present in the home. These factors, added to

the social changes that lead children to spend more time indoors and to exert more control over their lifestyles and activities, have resulted in increasing numbers of children with their own media systems in their bedrooms, a trend that is associated with increased solitary media use (Livingstone 2001; → Media Use by Children). The diminishing opportunities for parents and children to share media experiences together are of concern because they suggest missed occasions for discussion and interaction (→ Mediating Factors), even though most research finds limited parent–child communication about media experiences (Austin 2001).

*Active mediation* has been shown to have several positive outcomes for children. It leads to greater learning of concepts from media, enhances or reinforces information presented, can mitigate internalization of fears and worries and the modeling of antisocial behavior (→ Fear Induction through Media Content in Children), and helps children form accurate judgments about the realism or accuracy of media information (van Evra 2004; → Media and Perceptions of Reality). Active mediation has been associated with parental concerns about the potential impact of media whether it be perceived to be positive or negative (Nikken & Jansz 2006).

While the typical emphasis in family and media research has been on the actions initiated by parents vis-à-vis their children, other relationships among family members are also of scholarly interest, including the ways in which children's media preferences and use affects parents' media use, the use of media among siblings, and the role media play in the functioning of the family as a system in general (→ Media Use across the Life-Span).

## THEORETICAL CONCEPTS

Communication scholars have examined how more general communication styles within families affect media-use patterns, including how media are regulated and how content is discussed and interpreted. McLeod and Chaffee (1973) developed a widely used model of → *family communication patterns* that related to media use in the family. The research revealed two communicative styles within families: socio-orientation (an emphasis on avoidance of controversy and conformity among family members) and concept-orientation (an emphasis on openness to exploring ideas and accepting controversy or differences of opinion). While the conceptualization and measurement of these communicative styles have evolved over time, research has found that more concept-oriented families tend to view television more critically and engage in discussions that both affirm and negate media messages, while socio-oriented families tend to watch more television in general, and draw attention to television messages that affirm their values (Austin 2001).

*Family systems theory* offers another framework to explain how media are used within the family context. This approach takes a holistic view of the family, putting the emphasis on studying the family as the primary unit of analysis rather than studying the behaviors of family members separately. Media use is seen as an extension of the norms, values, and beliefs that define the family system (Jordan 2002). Media research from a family systems perspective includes examinations of how media fit in with the structure of families (e.g., how families organize themselves temporally and spatially within the home), interaction patterns (e.g., how media use facilitates or inhibits communication), and the roles that members

of the family assume in relation to one another (e.g., mother's role as family manager extending to media). Family systems theory, while underutilized, is seen as an important direction for media and family studies because it moves away from a more linear, causal model of how families use media to a more interdependent and complex conceptualization of the family unit and the role played by media in the home (Bryant & Bryant 2006).

The study of *roles* – the recurrent patterns of behaviors of family members – in the home has also been undertaken within a more critical or → cultural studies framework of communication research, with a focus on how media may help maintain or change power relationships. David Morley's (1986) research on British families drew upon this approach, and his in-depth → interviews with family members revealed how traditional gender roles played out in mothers' and fathers' use of television. Specifically, fathers exercised their privilege as breadwinners to come home and control their leisure environment, making more decisions about the content of what was watched on television and viewing with more attention. Mothers, on the other hand, tended to watch television as a more social act, accompanied by other household activities or conversation. In addition to gender, media may help reinforce or change other roles within the family (Bachen 2007). Of particular interest with newer media such as computers and the Internet are role reversals, whereby teens assume the role of the "expert" with parents taking the role of "learner." As work-related media (computers, Internet, fax, mobile phones) erode the boundaries between work and home, the home becomes a contested site where the roles of parent, spouse, and worker are increasingly challenging to negotiate.

## Media and Perceptions of Reality

Lindsay H. Hoffman

University of Delaware

Carroll J. Glynn

Ohio State University

Communication scholars, psychologists, sociologists, and other social scientists have long been interested in how individuals interpret the real world around them. Although some of the information we receive in our daily lives is first-hand, much of what we know about our communities, states, countries, and the world comes to us through second-hand sources. Perceptions of reality, rather than actual observations of reality, guide human beliefs, attitudes, and behaviors. These perceptions often are solidified into normative versions of what “ought” to be. Because there are often concrete expectations of reality in one’s mind, the effects from this perceived view of the world can be just as real as effects of actually experiencing that reality. Importantly, social perceptions arise through processes of communication, resulting in a social world that appears comparable to the physical world that surrounds us. *Misperceptions* of reality can produce a distorted version of the real world, and it is these misperceptions that have been the focus of much attention in public opinion and communication research.

### UNDERSTANDING SOCIAL REALITY PERCEPTIONS AND EFFECTS

Perceptions of reality, or social reality, can be conceptualized as an individual’s conception of the world (Hawkins & Pingree 1982). What intrigues many social scientists is the exploration of the specifics of these → perceptions and the ways in which they are developed. As Lewin suggested, reality is not an absolute; it differs depending on an individual’s social surroundings and perceptions of those surroundings (Lewin & Grabbe 1945). Social

perception has been considered from both individual- and social-level perspectives. Scholars investigating perceptions at the individual level rely heavily on the works of John Dewey, Charles Horton Cooley, and George Herbert Mead, while those considering the social level draw from Paul F. Lazarsfeld, Elihu Katz, and Theodore M. Newcomb.

The individual-level conception of social reality – or, as McLeod and Chaffee (1972), refer to it, *social* reality – derives from Cooley's, and later Mead's, conceptualization of society: an affair of consciousness that is necessarily social (Mead 1930). This definition suggests that others exist in one's mind as imaginations, and it is only in these imaginations that others have an effect on the individual. Cooley (1902) referred to these imaginations as the "solid facts" of society. Dewey's work concerning social perception emphasized the importance of bringing the social world into studies of human behavior and cognition. He suggested that instincts, such as fear and sexual desire, are necessary but not sufficient explanations for human behavior. Any instinctual impulse, he argued, is potentially influenced by its social surroundings.

Importantly, these early scholarly works defined communication as a central mechanism through which humans exist and develop (→ Communication: Definitions and Concepts). In this sense, the mind itself arises through communication (Mead 1930). Because individuals are not capable of experiencing all reality through direct observation or physical experience, they must rely on communication with others or experience this "reality" through the mass media. Since individuals' communication experiences differ, their "cognitive maps" (McLeod & Chaffee 1972) also will differ (→ Cognition). In this way, individuals view their own social reality as self-evident and factual. As a result, researchers cannot easily identify which components of one's social reality are based upon direct observation and which are based upon social learning.

The second perspective of social *reality* (McLeod & Chaffee 1972) defines the social system as the unit of analysis. Scholars exploring social *reality* from a social-system perspective focus on understanding commonly held perceptions shared in society. They often base their exploration on individuals' perceptions of what others think, or whether an individual believes that an opinion or attitude is shared by others. When individuals perceive that others share their own views of the world, the opinion or attitude can become "real" in that particular group, community, or society. Katz and Lazarsfeld (1955) suggested that individuals obtain information from their social environment, observe whether others agree with that information, and then assume that is the "reality" (→ Information Processing; Stereotypes).

Research on social *reality* has tended to focus on degrees of consensus or agreement among members of a system. This literature often draws from work in social psychology on normative sanctions (Newcomb et al. 1965). These sanctions are rules that specify which individuals are supposed to act in which ways in a society. How individuals are to be rewarded or punished depends on whether they abide by those sanctions. Current research in this area is driven by two main theses: (1) the behavior of individuals is affected systematically by various forms of social influence, and (2) this influence is embedded within a particular context. What differentiates this approach from the focus on *social* reality is the emphasis on groups and situations rather than individuals.

Because the media, in particular, provide individuals with indirect representations of reality, communication scholars have been particularly interested in how individuals

**Table 1** Causal mechanisms of the perceptions and misperceptions of social reality

	Individual explanations		Individual–other explanations		Social explanations

develop cognitions of social reality based upon their use of and attention to the media. As noted earlier, much of the information we receive comes from other people and the mass media. McLeod and Chaffee (1972) noted that these sources seem no less valid than direct observation because a large proportion of this information is shared by others around us. In this sense, individuals find themselves thinking that everyone ought to see things the way they do, a normative sharing of “oughtness” that defines social reality.

There are a number of *effects* associated with perceptions of social reality. One category of effects draws heavily from those effects outlined in the social psychology literature, without reference to the media in particular. These phenomena describe perceptions and misperceptions of some generalized other. The second category, outlined later, focuses on media effects in particular. Finally, the mechanisms driving these effects are described and outlined in Table 1.

### GENERAL PERCEPTION EFFECTS

Several phenomena describing perceptions (and misperceptions) of social reality have been outlined in the literature. These effects are pluralistic ignorance, overestimate of consensus, false consensus, silent majority or false idiosyncrasy effect, disowning projection, conservative and liberal biases, looking-glass perception, and social projection.

The term → *pluralistic ignorance* is often used as an umbrella to describe all misperceptions of others' opinions (Fields & Schumann 1976; O'Gorman & Garry 1976; Eveland 2002). Research in this area is primarily concerned with the factors that lead to

individuals being more or less accurate about reality, focusing on the discrepancy between individual perceptions and actual reality. Pluralistic ignorance is most likely to occur when people have differing opinions on a divisive issue, but also results from individual factors such as fear of embarrassment, social desirability, or social inhibition. The primary assumption underlying this and other misperceptions is that individuals have a “quasi-statistical sense,” which suggests that people infer public opinion from their own intuitive sense of their environment, even without access to specific public opinion information (Noelle-Neumann 1993; → Noelle-Neumann, Elisabeth).

*Consensus* is the core concept of several social reality phenomena. Consensus occurs when homogeneous opinions exist across a group of individuals. Complete consensus on an issue exists where there is reciprocal understanding among the members of a group concerning some issue. Importantly, this concept makes no provision for individual perceptions of agreement; it simply describes a state of affairs. In and of itself, consensus does not refer to social reality. However, some research has extended this concept and suggested that an *overestimate of consensus* occurs when individuals perceive greater consensus on their own opinion than exists in reality. In this way, overestimation of consensus is “absolute” because it is objectively false (Eveland 2002).

The concept of → *false consensus*, originally developed by Ross et al. (1977), describes the perception among group members about others in their group or those to whom they have similar attributes. Specifically, this concept refers to the individual tendency to see one’s own behaviors and opinions as normal and those of others as deviant or inappropriate. This phenomenon is best described as the exaggeration of the prominence of one’s own opinions. It differs from overestimation of consensus in that it is a misperception that is relative to others, rather than a misperception of reality. Hypothesis tests have consistently demonstrated this effect to be highly statistically significant with a moderate effect size (Mullen et al. 1985).

The *silent majority* or *false idiosyncrasy effect* is a specific instance in which the majority group perceives its position as the minority. This phenomenon occurs when some individuals support a position on an issue vocally and prominently, while those opposed to the issue – even if they are in the majority – remain silent. The result is that the vocal position is incorrectly perceived as the predominant one, while the silent position is incorrectly perceived as the minority. As such, the misperception is an outcome of an overestimation of the pervasiveness of the vocal opinion (Korte 1972).

The → *disowning projection* refers to the tendency toward attributing selfish motives, evil intent, or ignorance to others and denying these characteristics of oneself (Cameron 1947). This is comparable to the social desirability effect in survey research: individuals may perceive there is a “right” answer to a question and therefore attribute “wrong” behaviors, attitudes, or opinions to others.

*Conservative and liberal biases* have also been documented in public opinion literature (e.g., Fields & Schumann 1976). However, Glynn et al. (1995) argue that, depending upon which phenomenon is being tested, these ideological biases could be described as false consensus or pluralistic ignorance. Moreover, these biases serve more as descriptive patterns occurring in the data, rather than concepts in and of themselves.

The *looking-glass perception* occurs when people see others as holding the same view as they themselves hold. The looking-glass perception is different from the false consensus

effect because a divisive issue is not a precondition for the phenomenon to occur. Moreover, the perception is not by definition inaccurate but could be an accurate reflection of reality. Importantly, this phenomenon occurs quite separately from any actual distribution of opinions or attitudes in reality. The looking-glass perception is likely to arise for noncontroversial issues when people do not care much about the issue or even if there is almost universal agreement (Glynn et al. 1995).

*Social projection* is generally defined as the psychological phenomenon that drives each of these inaccurate perceptions. Broadly, this concept refers to individuals' reference to self-reactions in order to describe others. Some research has suggested that social projection can actually increase individuals' accuracy about others' views, which counters findings on the false-consensus effect. That is, *more* projection, rather than less, can lead individuals to have more accurate perceptions of the social environment around them (Jones 2004). The phenomenon is quite robust and generates moderate to large effect sizes (Mullen et al. 1985; Robbins & Krueger 2005).

## **MEDIA-SPECIFIC PERCEPTION EFFECTS**

Although each of the effects described above can result from perceptions or misperceptions of media content, they do not refer to the media in any consistent way. In fact, some of the effects predate mass media as we now know it. As a result, a second way of understanding perceptions of social reality has developed in response to the advent of media and mass communication research. Eveland (2002) divides these media-specific perceptions of social reality into two categories. The first covers perceptions of media content or impact, while the second maintains perceptions of social reality as the effect, but defines mass media as the primary causal mechanism.

### **Perceptions of Media Content or Impact**

This category of media-specific perception effects focuses on individuals' perceptions about media content or its influence on others. The third-person effect and impersonal influence emphasize that individuals do indeed have perceptions about media's impact on others. Those phenomena specific to media content (the hostile media phenomenon and persuasive press inference) focus on individuals' perceptions that the media are biased or slanted in some direction.

The → *third-person effect* predicts that individuals exposed to a persuasive message will perceive greater effects on others than on themselves. The term was coined by Davison (1981), who based the proposition on personal experiences with journalists who were convinced that editorials had an effect on others' attitudes, but not on people like themselves. The effect has since been delineated into two components: perceptual and behavioral. The former describes the perception alone; the latter builds on the perceptual component and suggests that the biased third-person perceptions will result in some behavioral action. The most commonly studied behavioral outcomes are support for censorship and willingness to speak out.

*Impersonal influence* describes the influence derived from anonymous others' attitudes, experiences, and beliefs (Mutz 1998). From this perspective, media do not need to be

universally consonant or even personally persuasive in order to impact individuals' perceptions of media influence (→ Consonance of Media Content). The underlying assumption of this phenomenon is that the number of indirect associations among individuals has increased while direct associations have decreased. Moreover, there has been a tendency among the general public, as well as policymakers, to attribute much power to the media, which results in real consequences, even if the media's influence has been overrated. As with the third-person effect, impersonal influence includes both the perceptual component and a behavioral component. This behavioral component is enhanced by the indirect nature of individuals' interaction with the political world. The outcome of impersonal influence is perceptions of collective conditions obtained through the media that in turn influence individuals' own attitudes and behaviors.

The → *hostile media phenomenon* suggests that partisans see news media coverage of controversial events as portraying a biased slant, even in news coverage that most nonpartisans label as unbiased. An underlying assumption of this phenomenon is that media coverage is essentially unbiased (→ Bias in the News). However, the seminal work on the hostile media phenomenon relied upon highly involved partisan subjects (Vallone et al. 1985). Not all scholars agree on the assumptions proposed by Vallone et al. (1985), and Gunther and Chia (2001) have suggested that the "relative hostile media phenomenon" is a broader conceptualization that does not require neutral news coverage or highly involved partisans.

The *persuasive press inference* hypothesis draws from the hostile media phenomenon and third-person effect and places the effects into one process. Specifically, this theory assumes that individuals (1) scan the media environment for issues of interest, (2) form impressions about the valence of media coverage, (3) infer that the news resembles what they have personally observed, (4) conclude that this media coverage influences others, and (5) perceive public opinion as corresponding to the perceived news slant (Gunther 1998). As a result of this process, people overestimate the impact of news coverage on public opinion and because of this misperception, estimates of public opinion are inaccurate. Perceived news slant, which draws from the hostile-bias phenomenon, acts as a mediating variable in the process (Gunther & Chia 2001). Although the media have indirect influence in this process, Gunther argues that these perceptions can ultimately have a self-fulfilling effect because individuals assume that the media influence those around them (Gunther 1998; Gunther & Storey 2003).

### **Perceptions of Social Reality with Media as the Primary Causal Mechanism**

Other research on perceptions of social reality has emphasized mass media as the primary causal mechanism explaining perceptions of social reality. Impersonal impact, spiral of silence, and cultivation are the principal theories associated with this category.

Because few people have direct personal experience with politics, mediated information has the ability to influence individuals' perceptions of social reality at the collective level. That is, media enhance the salience of social-level judgments in addition to influencing perceptions of public opinion. This is called *impersonal impact* (→ Social Perception: Impersonal Impact). This phenomenon historically resided in social psychology, where Tyler and Cook (1984) distinguished between two levels of judgment: personal (beliefs

about one's own conditions and risks) and societal (beliefs about conditions of the larger community). A prominent finding in related research is that the media affect societal-level judgments rather than personal ones. Research has suggested that these effects are conditional, with media impact operating differently for various issues and individuals.

The → *spiral of silence* theory is perhaps the most popular – and critiqued – theory on perceptions of public opinion (→ Climate of Opinion). At the heart of this theory is the idea that because the climate of opinion is always vacillating, individuals are always uncertain about the opinions around them. Thus, people turn to the media to understand the climate of opinion. However, Noelle-Neumann argues that the media present biased viewpoints in a uniform way. The result of this biased news media content is that individuals perceive a majority perspective, and this perception either promotes or prevents them from speaking out. The perception of public support for a position increases individuals' confidence in the legitimacy and strength of that position. In turn, this perception fuels their comfort in expressing that position in a public setting. The opposite effect occurs if individuals perceive themselves to be in the minority, judging a position as receiving little public support and legitimacy. Noelle-Neumann draws heavily from research in social psychology – particularly that of Solomon Asch – to support her hypothesis that people will conform to group pressure.

*Cultivation* implies that, over time, people are influenced by the content on television so that their perceptions of reality come to reflect those presented on television (→ Cultivation Effects). Cultivation research is rooted in the work of George Gerbner and colleagues, whose Cultural Indicators project has generated both public and academic debate (Gerbner & Gross 1976; Gerbner et al. 1978). This theory purports that media content, which has been systematically studied for decades, displays distorted estimates of social reality. Among these distortions are the rates of crime and violence; estimates about personal risk of crime and violence; estimates of like risks from lightning, flooding, and terror attacks; estimates about the number of people who serve as police officers or lawyers; and estimates of the number of elderly, among other distortions.

Cultivation effects are commonly delineated into first-order and second-order effects (Hawkins & Pingree 1982). First-order effects refer to the correlations between television viewing and distorted estimates of social reality. Second-order effects refer to individuals' perceptions of a mean and scary world as a result of these distortions. First-order effects have found much support, while second-order effects remain in doubt. Research has also demonstrated a weak relationship between first-order and second-order effects, suggesting that the social relevance of first-order effects is still unclear (→ Media Effects: Direct and Indirect Effects).

Two modifications have been made to the original cultivation theory. First is the concept of “mainstreaming.” This concept suggests that individuals' own experiences can moderate the cultivation effect. In particular, those whose experiences are more discrepant from television's representation of the world are more susceptible to cultivation effects. The second modification is the moderating effect of “resonance.” Resonance predicts an interaction between television viewing and individual experience, such that those whose life experiences are *more* congruent with the television world are most susceptible to cultivation effects. In this sense, mainstreaming and resonance can be viewed as competing hypotheses that occur when certain conditions are fulfilled (Shrum & Bischak 2001).

## **CAUSAL MECHANISMS FOR SOCIAL REALITY PERCEPTIONS AND MISPERCEPTIONS**

The previous section and extant literature suggest that the impersonal impact, spiral of silence, and cultivation hypotheses label the media as a primary mechanism for affecting individual perceptions of social reality. However, the perception effects described here can be attributed to one or more other causal mechanisms, including individual cognitions and motivations, social harmony and public expression norms, and social context, as well as the media. Each of these six mechanisms can be categorized under three broader categories: individual, individual–other, and social explanations. By linking each of the social reality perceptions with their corresponding causal mechanisms, one can better understand how these perceptions operate in a mass-mediated world. Importantly, these explanations are not mutually exclusive; that is, one or more mechanisms might be at work for each concept, theory, or approach. Table 1 outlines the social reality perception effects and the individual, individual–other, or social explanations that can be applied to each.

### **Individual Explanations**

This category of causal mechanisms includes individual motivations and cognitions that lead to perceptions or misperceptions of social and media reality. Nearly all of the theories, concepts, and approaches outlined here can be attributed to either motivational or cognitive mechanisms, or both (see Table 1).

#### *Motivational Mechanisms*

Some individuals may be motivated to interpret their surroundings in a biased way because of a need for social support and validation, or a desire for self-enhancement. One example of this motivational mechanism is the phenomenon of social projection. When a need for social connectedness is made salient, individuals might interpret their surroundings in a biased way.

In other cases, individuals might be driven to see themselves as either unique from others or sharing common views, depending on the context. Prentice and Miller (1993) label this phenomenon “impression management” and suggest it is a self-serving bias that drives individuals to misperceive their surroundings. In this way, some people are motivated to maintain control over their environment (the *effectance motivation*). Additionally, people are often motivated to believe that unfortunate events are more likely to happen to others rather than to themselves (*unrealistic optimism*). Finally, *ego defensiveness* is a motivation that protects one’s self-concept from counterattitudinal or threatening messages. All of these motivations serve as important causal mechanisms in the third-person effect.

The false consensus effect also is based primarily on motivational mechanisms. For instance, individuals may be motivated to see similarity between themselves and what they perceive as an attractive or desirable group or person. In this case, individuals are driven by a desire for self-enhancement. Additionally, individuals with stronger needs to justify or support their own views or behavior may display false consensus because of a need for social support and validation.

The impersonal influence hypothesis can be explained by several mechanisms, but research has suggested that a primary mechanism is the “bandwagon motivation” (Mutz

1998). This occurs when individuals are motivated to affiliate with a winning team or candidate in order to enhance their own public image in the eyes of others. The third-person effect can also be explained in part by motivations.

Motivational explanations can also be applied to those theories that claim media as the primary causal mechanism. For instance, Noelle-Neumann cites *fear of isolation*, or a motivation not to be in the minority, as a driving force behind the spiral of silence. The underlying assumption of this mechanism is that people keep their opinions silent when they feel marginalized. Taylor (1982) and Hayes et al. (2005), however, have provided alternative motivational mechanisms to this fear of isolation. Taylor suggested that individuals examine the incentives and *benefits of speaking out* in certain circumstances, while Hayes and colleagues found that the *willingness to self-censor* can predict willingness to speak out.

Importantly, motivational mechanisms are not necessarily conscious or intentional. For example, one study suggests that individuals who are more prone to feelings of fear are subconsciously motivated to overestimate the prevalence of fear among their peers in order to feel more comfortable (Suls & Wan 1987).

### *Cognitive Mechanisms*

Cognitive mechanisms are perhaps the most common explanations for social reality and media perceptions. Outcomes described in this category tend to rely on the rich literature in information processing. One possible mechanism in this category of cognitive explanations is the *accessibility bias*, or the tendency to derive estimates of others' views based upon that information that is most accessible in one's memory. Social projection has often been explained by this accessibility bias, in addition to motivational mechanisms (see Table 1).

A related mechanism is the *availability heuristic*, which describes the tendency to use the ease with which something is recalled as a representation of that thing's probability (Mullen et al. 1985; → Availability, Cognitive). This heuristic might explain false-consensus effects when experimental subjects are asked to consider opposing points of view (as is the case in many experiments testing these effects). Additionally, unintentional selective exposure, attention, and retention can be defined as cognitive explanations for perceptions of social reality. For instance, individuals are likely to expose themselves to information that is agreeable to their position, attend to it, and recall it later, explaining the false-consensus effect (Sherman et al. 1984).

The hostile media phenomenon and third-person effect are each in part based on cognitive mechanisms. For instance, partisans on different sides of an issue might process the same media content, but in very different ways. They might recall information that was most hostile to their own opinions, explaining the hostile media phenomenon in some cases (→ Selective Perception and Selective Retention). A cognitive explanation for third-person effects draws from *attribution theory*, suggesting that people have an innate – albeit naive – need to explain their social world. In turn, when it comes to the media, individuals adhere to a simple “magic bullet” explanation of media effects, assuming that others are easily influenced by media content.

The third-person effect also is explained by cognitive “errors.” The actor–observer attributional error occurs when individuals underestimate the extent to which others

account for situational factors, and overestimate their own attention to these factors. In this way, people see themselves as more cognizant of media influence and others as easily manipulated. A second cognitive error explanation of the third-person effect is that people project negative effects onto others in order to avoid the discomfort caused by admitting that such content affects themselves. This explanation suggests that although individuals may perceive themselves as also susceptible to media effects, they push these concerns out of mind by attributing them to others.

The persuasive press inference also can be explained by individual cognitions. Research suggests that people are likely to think that their own sample of news media coverage is similar to what others see. This cognitive mechanism is based upon the law of small numbers bias, in which such a sample of news content is considered similar to the population. Additionally, impersonal influence draws from cognitive explanations. Specifically, the “cognitive response mechanism” proposes that individuals might shift their attitudes upon learning the opinions of others, because knowing these opinions encourages them to think about arguments that might explain those opinions.

Cognitive mechanisms also apply to those theories that claim media as a primary causal mechanism. For example, some scholars have proposed that cognitive mechanisms may be better explanations for cultivation effects – particularly for heavy viewers of television. Hawkins and Pingree (1982) suggested that people actively learn facts from television and in turn construct judgments about the real world based on these facts (→ Observational Learning). Alternatively, Shrum and O’Guinn (1993) asserted that relevant information is more accessible and, as a result, overestimates of frequency or probability can be explained by the accessibility bias. The outcome of such heuristic processing is that media play a larger role in judgments about social phenomena with which subjects have less direct experience.

### **Individual–Other Explanations**

Some individuals might be motivated to perceive social reality in certain ways that benefit their social interactions with others, or they might feel pressure to publicly misrepresent their opinions in order to comply with the pressures and norms of social interactions (→ Interpersonal Communication; Language and Social Interaction). These mechanisms can be defined as social harmony and public expression mechanisms (see Table 1).

#### *Social Harmony Mechanism*

Because conflict is not palatable to many people, there may exist motivation to see others’ positions on issues as more like their own in order to avoid argument or dissonance. Although this explanation can be considered a motivation, it specifically pertains to the anticipated future interaction with others. Therefore it is categorized separately from the above-mentioned *individual* motivations.

One example of the social harmony mechanism at work applies to both the false-consensus effect and the spiral of silence. The divisiveness of some issues might influence whether individuals choose to speak their opinions in social interactions. In such an instance, the motivation to maintain accord with others in the future might overrule truthful expression of opinions. Similarly, if individuals expect to interact with other

people in the near future, they may be motivated to view others as more like themselves so that the interaction is more agreeable.

#### *Public Expression Mechanisms*

Misperceptions of social reality at the individual–other level also can arise from either intentional or unintentional misrepresentation of one’s opinions in public. Prentice and Miller (1993) proposed two explanations to address both intentional and unintentional misrepresentations. The *differential interpretation hypothesis* describes a conscious decision to publicly misrepresent one’s opinion. The *differential encoding hypothesis* does not assume intentional misrepresentation, but suggests that some individuals suffer from an “illusion of transparency,” mistakenly believing that their own and others’ opinions are accurately expressed publicly.

One example of this mechanism applies to the impersonal-influence hypothesis and third-person effect (see Table 1). For instance, an individual voter might desire to influence the outcome of an election through strategic or tactical influence. This voter might assume that the media have greater influence on others than on himself or herself. In turn, the voter might publicly express preference for one candidate over another in order to counter that media influence. Such misleading public expression can clearly lead to misperceptions of social reality.

### **Social Explanations**

The social explanations described below and outlined in Table 1 are based upon what McLeod and Chaffee (1972) referred to as social *reality*. That is, a context or situation serves as the causal mechanism underlying individual perceptions of social reality.

The *social context of the issue* – or the distribution of opinions on either side of a public debate – can serve to create misperceptions of social reality. If an issue is particularly divisive, for example, individuals are prone to the false-consensus effect because they see one side as more similar to themselves and the other side as deviant or uncommon. Alternatively, if the issue is not particularly divisive and there is general agreement, one might be prone to the looking-glass perception and exclude alternative perspectives on the issue.

The literature on mass communication and perceptions of social reality has given increased attention to *media as causal mechanisms*. One way to define media as a causal mechanism comes from the spiral of silence theory, which purports that the news media present viewpoints that are consistently biased toward the majority. Noelle-Neumann (1993) suggests that because these biased media messages are consonant, cumulative, and ubiquitous, they have widespread impact on those in the minority. According to the theory, mass media serve as agents of social control through which information about societal norms is conveyed. It is noteworthy that this media mechanism is not based on any specific content, but on a general assumption about media favorability toward the majority.

An additional way of defining media as a causal mechanism is through an understanding of journalistic content and professional norms. The news media apply different journalistic approaches to presenting information about opinion distributions and social reality in general. For example, content analyses have found that social reality is represented in the media through base-rate information, exemplification, or a combination

of both (→ Content Analysis, Quantitative). Base-rate information is the use of statistics and factual information to describe public opinion or social reality. Exemplification, or the use of “exemplars,” relies on personal examples and interviews. Although base-rate information tends to be more accurate in that it represents a larger portion of the population, news audiences attend to and recall social reality perceptions more often from exemplars (→ Exemplification and Exemplars, Effects of). This suggests that the content of media predicts when and how the media influence perceptions of public opinion, and is consistent with the predictions in the persuasive press inference. This mechanism is also closely tied with cognitive mechanisms, in that exemplars are said to have superior accessibility, and thus greater impacts on perceptions of social reality.

A final way of defining this media mechanism is specific to cultivation. In cultivation studies, television content has been found to overestimate the amount of crime and violence that exists in the real world. Television content also misrepresents the proportions of blacks, Hispanics, and Asian-Americans, and the elderly. As a result, specific media content – rather than the consonant, cumulative, and ubiquitous media of the spiral of silence theory – influences perceptions of social reality over time.

### **IMPLICATIONS OF SOCIAL REALITY PERCEPTIONS FOR COMMUNICATION RESEARCH: BEHAVIORAL OUTCOMES**

Although many scholars will contend that perceptions are in and of themselves important outcome variables, others have suggested that a link between these perceptions and individual behavior is necessary in order to establish the social relevance of such research. In this vein, several areas of research have established behavioral effects that result from social reality perceptions.

First, the third-person effect has received much support not only in its perceptual component, but also in its behavioral component. Specifically, research has found that misperceptions of media influence are related to greater support for censorship (Eveland 2002). Second, studies of pluralistic ignorance have demonstrated that misperceptions of social reality are associated with individual behavior. For example, Prentice and Miller (1993) found that misperceptions of alcohol use on a college campus positively predicted drinking behavior. This effect has been replicated with other risky behaviors such as tobacco use and marijuana use, as well as risk judgments. Third, perceptions of opinion climates are related to opinion expression, as hypothesized by the spiral of silence, although support for this relationship is weak. These perceptions have also been related to forms of political participation.

### **RECONSTRUCTING SOCIAL REALITY**

It is important to note that social reality is not a finite reification. Instead, it is a dynamic construct that can change over time and across individuals. McLeod and Chaffee (1972) outlined several ways in which social reality can be reconstructed.

Individuals are able, and likely, to move from one social reality to another at some point in their lifetime. This shift can occur when there are systematic changes in an individual’s social reality, such as a change in his or her reference groups. Such changes

also can take place at critical junctures in the life course – college, marriage, children, for example – that encourage the individual to rethink or actually modify their social reality. These changes might be likely to occur in crisis situations, when individuals are more motivated to communicate effectively and seek out unambiguous information. Changes in the structure of an individual's communication patterns also can reconstruct one's social reality. When people communicate with different or unusual others, or pay attention to different media sources, their perceptions of social reality are likely to change.

It appears that social reality is best conceptualized as a dynamic process with both perceptual and behavioral outcomes that is influenced on an individual level by motivations and cognitions; on an individual–other level by social harmony and public expression motivations; and on a social level by social context and media mechanisms. While research on perceptual outcomes remains highly supported, research on behavioral outcomes, as well as the mechanisms and moderating factors that produce those outcomes, require further research.

## Media Performance

Denis McQuail

University of Amsterdam

The term *media performance* has a broad reference to the assessment of mass media according to a range of evaluative criteria and primarily employing “objective” methods. In practice most attention has been given to the *product* of mass media, its *content* as sent and received (→ Media Production and Content). The criteria applied are mainly derived either from professional goals and standards or from considerations of the → public interest as specified in certain evaluative concepts (→ Standards of News). The methods are mainly those of the social sciences, aiming to be systematic, reliable, and leading to some degree of generalization (→ Research Methods). We are thus speaking of a particular field of media research with several different aims and purposes (→ Communication as a Field and Discipline). Apart from general description, these purposes include the wish to improve the media in some way, to support a line of criticism of media, to explain variations in quality of performance, and to identify causal factors.

### ORIGINS AND HISTORY

Although the origin of the term *media performance*, as used here, is uncertain, it was employed for many years to classify topics of articles (mainly content analyses of news; → Content Analysis, Quantitative) in *Journalism Quarterly*, the official publication of the American Association for Education in Journalism (AAEJ). This positions media performance in close relation to → journalism education and journalism criticism (→ Journalism). James Lemert’s book *Criticizing the media* (1989) is a key work in establishing an identity for media performance research. It is essentially a plea for *empirical criticism*, deploying various concepts of quality of media structure and performance. Lemert distinguished empirical criticism from three other theoretical schools: a Marxist-oriented critique; cultural/critical studies; and social-responsibility-oriented criticism (→ Communication Theory and Philosophy). He also advised against exclusiveness and recommended cooperation between theory and empirical inquiry. His own suggested topics for inquiry included the effects of chain ownership on editorial independence and activity, the coverage of environmental problems, news coverage of rape, and the consequences of

relying on official sources. Each of these could result in recommendations for improvement, reflecting a positivistic inclination, although not necessarily a preference for “administrative” over critical research approaches.

It is not easy to draw *boundaries around performance research*, since many other kinds of research can help in assessing performance. This applies to: ratings (→ Rating Methods) and → readership research; economic and market evaluations of particular media and their products; and criticism in the form of reviewing of other media or the very large literature that has emerged dealing (mainly) with the many alleged social, cultural, political, moral, and aesthetic failings of mass media. Despite this approximate boundary, for certain purposes of media performance assessment both economic and audience data can be relevant and even “subjective” forms of evaluation can be taken into account. Generally, the field of media performance has expanded and diversified in method, especially where attention is given to the full range of output of a (national) media system (or a general television network), as has been the case in the tradition of cultivation analysis (Signorielli & Morgan 1990; → Cultivation Effects).

The earliest phase of media performance research was, as noted, shaped by a concern to improve the professional quality of journalism, with primary reference to various ideas about news objectivity (→ Objectivity in Reporting; Bias in the News). The main criteria applied were those of accuracy and completeness in reporting relevant facts, reflection in news of the external “reality” being reported, lack of personal or political bias in the news report, and avoidance of → sensationalism in tone and presentation. The more complex topic of editorial or journalistic independence was also covered, as well as certain media ethical issues (→ Ethics of Media Content).

From the late 1960s onwards, media performance research was more influenced by external social and political criticism than internal professional criteria, following the rise of radical and antiwar movements in North America and Europe. The rise of → television news to a central position in the media system by the 1970s was also a factor, not only because of its reach and believed impact but also because of high public expectations of neutrality, truthfulness, and informative power. Much effort was made on both sides of the Atlantic to assess the balance of attention in news between various competing actors, political parties, and points of view, with strong suspicion of hidden ideological and manipulative motives and equally strong denials. This trend in research was associated with the intensification of efforts to create and manage news by competing economic or political interest groups and also with a critique of monopoly tendencies in media (→ Concentration in Media Systems). For the most part, this research was done by way of content analysis (e.g., Efron 1971; Westerstahl 1980; Glasgow Media Group 1976), but there was also a significant growth during the 1970s in studies of news organizational practices that shed light on the shaping of news (e.g., Tuchman 1978) and thus indirectly on “media performance.”

An important advance in media performance research was the program directed at measuring media quality under the auspices of the *Japanese Broadcasting Corporation (NHK)* (see Ishikawa 1996). This program worked with a framework of three different levels at which problems of media quality can be identified: the whole media system; the channel (or equivalent); the content (e.g., program). It also identified four different perspectives from which media could be viewed and evaluated: of the state, of the society,

of the audience, and of media professionals. This framework can encompass many criteria and find a way of integrating different kinds of evidence. For the first time, perhaps, systematic account was taken of the views of professionals about qualities that might escape social scientific methods (→ Quality of the News). At about this time, Shoemaker and Reese published their first edition of *Mediating the message* (1991), which systematically examined influences on the production of news content, drawing on empirical research examples. The main relevant causal factors for news performance (quality) were identified as stemming from the personal characteristics of journalists, the organizational routines of news-making, external economic and institutional influences, or ideology and power distributions in society.

### FOCUS AND THEMES OF RESEARCH

One of the main roots of critical research, as noted by Lemert, lies in ideas about the social responsibility of media to society, first given expression by the American Commission on Freedom of the Press (Hutchins 1947) and then taken up in postwar Europe, where both press and broadcasting were made subject to public criticism, inquiry, and policymaking on grounds of their claimed social obligations (→ Journalism: Normative Theories). This is the background to another effort to erect a framework for research, McQuail's *Media performance* (1992), which assembled a number of basic criteria of media performance from theory and practice held to be "in the public interest" and reviewed relevant methods and examples of performance research.

Other perennial topics for media evaluation inspired by → critical theory of one sort or another have included: the representation of women and of gender roles in the media; the portrayal of ethnic and other minorities; the distribution of attention in foreign news to places and countries outside the circle of rich and developed, mainly western, countries; the reporting of insurgent *terrorism and war*. The case of terrorism raised rather complex issues, with competing journalistic norms of freedom and responsibility (→ Mediated Terrorism). The case of war reporting is not so different, since there is great pressure from government and military to insure favorable coverage and deny any propaganda success to the enemy (→ Conflict as Media Content). Inevitably, also, the independence of journalists is compromised. These issues have taken research beyond the scope of news journalism and often into the territory of fiction and entertainment.

Media performance research has at times been inspired by acute public concern about its potentially harmful effects (→ Media Effects). For instance, it played a part in inquiries into the causes of crime and violence (Baker & Ball 1969), into urban rioting in the United States in the 1960s (Kerner 1968), into pornography (Einsiedel 1988; → Violence as Media Content, Effects of; Sex and Pornography as Media Content, Effects of). Most recently there has been heightened concern about the availability of pornography on the Internet, especially where it involves children. In many of these cases, there are conflicting norms for identifying quality.

An abiding focus of performance research is to be found in the field of → *political communication*, dating back at least to the study of the 1940 US presidential election (Lazarsfeld et al. 1944). A core element in election research has been the measurement of time and space allotted to different candidates, parties, or issues, according to criteria of

amount and direction (e.g., Hofstetter 1976). More recently, performance research has been stimulated by the complaint that the mass media are failing the democratic political system by not providing information of substance, by presenting politics in a negative light, and by diverting citizens from active participation (Capella & Jamieson 1997; → Negativity; Video Malaise).

## RESEARCH METHODS AND PROBLEMS

The extension of evaluative attention from printed newspapers to television and non-news content has long called for new thinking and new methods, especially methods for dealing with audiovisual content. Researchers had already encountered difficulty in dealing with news photographs and other images, whose precise meaning cannot be either known or interpreted with any certainty (→ Photojournalism). In assessing print news content, the assumption had usually been that the meaning of words in natural languages is knowable and thus interpreted by its audience as intended by news writers. Readers were also assumed to be familiar with conventions of presentation (space and headlines, etc.) that are guides to interpretation (→ Content Analysis, Qualitative).

Even so, there are considerable obstacles to inferring “meaning” or “learning” that have undermined the claim to objectivity of assessment research. There have also been practical problems of accessing television news after the event (gradually eased by better recording methods) and of devising reliable coding frames for multimedia messages. Theoretical developments in → linguistics, → discourse analysis, and semiology posed fundamental challenges to the very notion of assigning fixed meanings to media content, almost vitiating the whole enterprise. Despite these difficulties, a variety of strategies and research approaches have been developed to achieve some practical results. These developments include: the invention of software for qualitative analysis of content; the specification of recurrent visual codes in news; new ways of assessing the direction of evaluation of content, based on knowledge of language; the application of the notion of “framing” (and also of “schemata” as employed by journalists and audiences) to understanding the intention and direction of news content; the use of ethnographic methods to record variations in the pattern of audience interpretation. All this has tended to make media performance evaluation more possible, but also more costly.

## CRITERIA OF EVALUATION

Although media performance can be evaluated according to many different standards, depending on circumstances and expectations, in practice there is a fairly limited set of criteria that recur, most of them indicated above. They emerge from diverse sources, but especially from one or other of the following: media professionals themselves; government, law and policy (→ Communication and Law); → public opinion; various interest groups and institutions affected by the media; the public as audience; various social critics and moral guardians. The most commonly encountered evaluative concepts to be found in the field include the following: *objectivity*, with its component elements as described above; *diversity*, which is a key value in most pluralistic democracies and underlies expectations that media will pay attention, or give access and expression, to a range of

persons, groups, ideas, and events that are broadly reflective of the social, cultural, and political environment in which they operate (→ Plurality); *cultural quality*, with reference to accepted aesthetic or ethical standards or the prevailing tastes and interests of the public (→ Ethics in Journalism); *freedom*, which here means mainly the independence of media as reflected in a willingness to speak out, to be critical or original, without deference to the power of government, business interests, or (in some cases) the media's owners.

It should be stressed that such higher-level concepts are not applied directly but by way of a variety of more precise indicators related to these concepts. There are, of course, many negative criteria that are either the observed absence (or reversal) of the standards mentioned or relate to undesirable effects.

### THE FUTURE OF MEDIA PERFORMANCE RESEARCH

The last decade or two of media and social transformation have been typically characterized by a reduction in external control of mass media and also by a great expansion of existing and new media, with attendant commercial pressures. The greater reliance on media self-regulation has increased the salience of media performance evaluation, sometimes as a substitute for public policy. The criteria of "good performance" have not, however, changed greatly and the same research apparatus can still serve, but there are significant new challenges. These arise most obviously from the enormous volume of supply transmitted by the → Internet (and other new means). Such content is also often multimedia in character and may not conform to established genres and the conventions of presentation of traditional media. It is difficult to sample, to generalize about, and to codify, making the methods developed for mass communication inappropriate. New indicators of performance are called for. Crude forms of assessment of Internet flow are already appearing, but the task of performance assessment has barely begun.

## Media Planning

*Edith Smit*

*University of Amsterdam*

*Marjolein Moorman*

*University of Amsterdam*

*Peter Neijens*

*University of Amsterdam*

Media are a crucial part of any advertising campaign. Selecting the most effective media gets the advertising message across to the intended target group. Media are also the most expensive part of advertising campaigns. In a typical media campaign, the media costs account for 80–85 percent of the advertising budget (Kelley & Juggenheimer 2003). In deciding how to allocate the advertising media budget, we have to ask several questions: How many people of the target group do we want to reach? How many times do we want to reach them? Within what time frame do we want to make contact? Which contexts are most suitable to get our message across? These questions refer to four key topics in media planning: reach, frequency, timing, and context (→ Advertisement Campaign Management; Advertising Strategies).

### REACH

The question of how many people an advertiser wants to reach forms the basis currency in media planning. Reach is defined as “the number of target audience individuals

exposed to the advertising or promotion, in an advertising cycle” (Rossiter & Percy 1998, 447). Reach is a form of audience accumulation and a measure of how many different audience members were exposed at least once to one or more media vehicles over a period of time (Sissors & Bumba 1991, 73). Reach can also be expressed as a percentage of the target audience, provided that the base number of target audience individuals is clearly specified (→ Audience; Audience Research; Audience Commodity).

The number of contacts – being three individuals having contact with one issue, or one individual having contact with three issues – increases when more magazines (or other media) are scheduled. This is called *gross reach, or gross rating points (GRP)*. The GRPs of a media schedule are the sum of the percentage of contacts of each advertising cycle. One GRP means that the advertisement or commercial reaches 1 percent of the target audience; 10 GRPs means that the insertion reaches 10 percent; and so on (Rossiter & Percy 1998, 447). GRPs are an estimate of the total number of exposure opportunities (OTS) per 100 target audience members in an advertising cycle, without regard to whether the individuals receiving these OTS were the same or different people. The net reach in a medium plan is the number of persons that are exposed at least one time. In other words, the gross reach minus the overlap.

In most industrialized countries, → “people-meters” are used for television ratings, → surveys are used to determine the number of readers of → newspapers, → magazines, mail, and outdoor advertising (→ Exposure to Television; Nielsen Ratings). Diaries are used to estimate the number of listeners to radio stations. Surveys give insights into the reach of mailbox and outdoor advertising (for an overview of these methods see Kent 1994). Media planners use these figures to select the best media for their campaigns.

However, reach figures for various media are *difficult to compare*. Data for print media, for example, indicate the number of people reading the various titles, not the number of people who have seen an advertisement in that title. Television data, on the other hand, refer to the number of people watching specific content, such as television commercials. Comparing data for print and for television, therefore, is like comparing apples and oranges. Furthermore, note that “reach” figures do not tell us how advertisements are processed, and the effect they have on brand attitude and behavior.

## FREQUENCY

How often should people be reached with a message? Decisions with respect to frequency of exposure are important because media costs are high and campaigners want to avoid wasting money due to a too-low frequency (no effects reached) or too-high frequency (unnecessary costs). Most theories assume that repeating the message is useful because it adds to the effects of the campaign. However, after a certain number of repetitions the effects decline, or can even become negative. What frequency is best?

One of the most influential theories on the optimum number of exposures is the *three-hit theory* of Herbert Krugman (1972). According to Krugman, a cognitive reaction dominates the response of the audience during the first confrontation with a commercial. The receiver asks himself: “What is it? What is it all about?” During the second confrontation, an evaluative reaction dominates: “What is in it for me?” The third

confrontation is the real reminder. The viewer knows what it is all about and can take action. However, according to Krugman, it is possible that a commercial brings the receiver to his second response (“What is in it for me?”) after, for example, the twenty-third confrontation, in other words, in this example the twenty-third confrontation is psychologically perceived as the second one.

Based on a literature review, Michael Naples (1979) wrote, on the authority of the American Association of National Advertisers (ANA), that one confrontation with an advertisement would have little or no effect, except in extraordinary circumstances while two confrontations (within a purchase interval) are effective. The optimal frequency would be at least three confrontations within a purchase interval.

John Philip Jones (1995a; 1995b) concluded that a successful campaign is effective from the first confrontation. In other words, the response curve has no threshold. He also concludes that the first confrontation will have the greatest effect and that the next confrontations will have less effect (diminishing returns). Jones analyzed Nielsen-panel data which record buying behavior and looked at short-term effects of established brands in the fast-moving consumer goods (FMCG) sector. His conclusions are thus valid only for these cases.

Twenty years later, Colin McDonald (1996) wrote a follow-up of Naples’s review and reached other conclusions. He subscribed to Jones’s ideas with respect to the short-term effects of advertising for established brands. However, he concluded that new messages, for new → brands, do show a threshold. Furthermore, the shape of the response curve depends, according to McDonald, on a number of factors: in other words, there is not one rule for optimal frequency. The following factors have an influence: share of voice, activities of competitors, market share and status of the brand, quality of the advertisement, time until the purchase, target group, and type of product (→ Advertising Effectiveness).

## TIMING

Within what time frame do I want to make contact? The most important decision in answering this question about the timing of the message is the choice between “bursting” (large media exposure over a short period) on the one hand and “dripping” (spreading small media exposure over time) on the other hand (Zielske & Henry 1980). Heflin and Haygood (1985) concluded that media schemes with an average concentration showed the best results. They explained the bad results of the high-intensity schemes by the fact that concentrations irritate and satiate the audience. The bad results of the very low-intensity schemes were explained by the “forget effect.”

Ligthart (1999) concluded that combining burst and dripping worked best for the brands he studied. According to him, the answer to the question “bursting or dripping?” is dependent on a number of factors. First, if a large audience can be reached quickly, a burst is to be preferred. Second, the greater the forget effect, the more effective dripping becomes. A final factor is the budget: when the budget is substantial, an effective combination of burst and dripping (“maintenance”) is possible (Ligthart 1999, 56). The forget effect is strong when many competitors are advertising, when the ad stock is low, or when the quality of the commercial is low. Ligthart’s findings contradict those of Jones who stated: “we should redeploy media funds towards continuous advertising at relatively

low pressure, in preference to concentrated bursts with gaps in between” (Jones 1995b, 29; → Advertising Frequency and Timing).

## CONTEXT

In order to answer the question “Which contexts are most suitable to get my message across?” it is necessary to first mark out what context is about. Advertising context is a multifarious concept, consisting of many elements that may influence advertising effectiveness. A division can be made between context characteristics related to the receiver of the advertisement and those related to the vehicle carrying the advertisement: the medium context.

The *receiver context* can be described as the situational circumstances in which a person is exposed to an advertisement (Pieters & Van Raaij 1992). This includes the person’s physical environment (e.g., at home, at the kitchen table), the social environment (e.g., in the company of three family members), the time frame (e.g., during breakfast), and the mental state a person is in prior to exposure to the medium content (e.g., an early morning mood). Although it has been shown that each of these aspects can influence advertising effectiveness substantively, receiver context aspects are less relevant for media planning because planners have little or no ways of influencing them.

Of course this is different for the *medium context*. The medium context concerns the environment of the ad provided by the vehicle carrying it, such as a television program, an issue of a magazine, or an Internet site. A distinction can be made here between editorial context and commercial context. Studies on commercial context have predominantly concentrated on the effect of the amount and nature of other commercial messages in the environment of an ad, referred to as clutter and competitive clutter. It has been shown that, as the number of ads in the environment of the target ad (referred to as clutter) increases, the effectiveness of the target ad decreases, especially when the other ads are directly competitive (referred to as competitive clutter) (Kent 1993; 1995).

Part of the medium context is the *editorial context*. Studies on editorial context have predominantly concentrated on the question on whether the same source delivering the same message to the same audience on separate occasions might produce different effects depending on the differing programming or editorial contexts in which the message appears (Norris & Colman 1992). In particular, context-induced psychological responses, such as involvement elicited by a documentary, happiness caused by a sitcom, or sadness generated by a drama series, are considered to have an important impact on advertising processing (DePelsmacker et al. 2002; Moorman et al. 2001; 2002; 2005).

At the heart of all theoretical explanations regarding the influence of context-induced psychological responses on advertising processing lies the assumption that mental reactions toward the editorial context do not cease when the editorial content is interrupted by advertisements, but that these reactions “carry over” to the advertisements. These carried-over reactions, in turn, influence advertising processing. For example, it has frequently been found that advertisements placed in editorial contexts that induce positive feelings are evaluated more positively. Furthermore, it has been shown that context-induced involvement has an influence on attention for advertisements and memory for advertisements. However, it is still a subject of debate whether this effect is positive or negative.

# Media Policy

*Philip M. Napoli*

*Fordham University*

Media policy involves policymaking – and the associated policy research – directed at a wide range of substantive issues and technological contexts, and employing a diverse array of theoretical and methodological perspectives. It is important to note, however, that in the communications field there are a large number of somewhat indistinct policy arenas that overlap with the media policy field, each employing distinctive terminologies and each reflecting somewhat different (and in some cases, broader) areas of emphasis. These affiliated policy arenas range from telecommunications policy (→ Telecommunications: Law and Policy) to communications policy to information policy to cultural policy.

## MAPPING THE FIELD OF MEDIA POLICY

While it is beyond the scope of this entry to define all of these concepts and to articulate their points of intersection with and distinction from media policy, it is important to recognize that the field of media policy rests within a broader policymaking milieu that includes substantive areas such as regulation and policy related to telecommunications infrastructures, information access, and cultural expression (McQuail 1992). And, perhaps most important, it is necessary to recognize that the boundaries separating these concepts are not always clear and are, in fact, becoming increasingly porous as the digitization, convergence (→ Convergence of Media Systems), and globalization of communications technologies (→ Globalization of the Media) blur traditional technological and regulatory distinctions.

The term “media,” however, remains prominent in this converged policymaking environment. Critics of the term tend to insist on associating it only with traditional “mass media” and thus argue for its diminished relevance in a technological environment in which it frequently has been argued that traditional mass media are in decline. Such a narrow interpretation neglects the centrality of “mediation” to a wide range of communications processes, regardless of the specific technology at issue or communication dynamic involved (i.e., interpersonal versus mass communication). Thus, newer communications technologies such as hand-held devices and the → Internet all fit within the parameters of media policy given the centrality of specific mediating technologies. Similarly, the boundaries of media policy extend beyond the electronic media (though they tend to be the most heavily regulated), into the realms of print media, recorded music, and motion pictures. In these ways, the field of media policy certainly intersects quite frequently with other related policy arenas such as telecommunications and cultural policy.

As should be clear in any case, the meaningful boundary lines of media policy are not determined by particular communications technologies or dynamics. Rather, it is more appropriate to define the field in terms of its emphasis on particular substantive communicative concerns. This perspective is well reflected in Braman’s (2004, 179) definition of media policy, in which she defines the field as specifically dealing with issues of “freedom of expression and participatory decision making regarding the fundamental structures of

society” (→ Freedom of the Press, Concept of; Media Democracy). As this definition suggests, media policy is firmly grounded in both the political and the cultural dimensions of communicative processes (McQuail 1992). This definitional focus for media policy will become increasingly clear as the contours of the field and its theoretical underpinnings are outlined here.

Reflecting the wide-ranging concerns that fit within the definitional focus of media policy, it is perhaps to be expected that the field is characterized by a tremendous degree of *methodological diversity*. Historical research has examined the interplay of various stakeholder groups across a wide range of media policy issues in an effort to inform contemporary policy deliberations (e.g., Horwitz 1989; McChesney 1993). Effects research has informed longstanding policy debates such as the issue of the regulation of violent or indecent content and the development of educational content for children (→ Violence as Media Content, Effects of). Audience behavior research has addressed the dynamics of media consumption in ways intended to inform policymaking related to both established and new technologies (e.g., Hindman 2007; Webster 2005). Content analyses have explored the relationship between the structure of media organizations and media markets and the nature of the content provided in an effort to inform policy issues related to ownership regulation, content regulation, and license allocations (e.g., Hamilton 2000a; → Content Analysis, Quantitative; Content Analysis, Qualitative).

All of these methodological approaches build upon a body of economic-grounded and legally grounded analyses that continue to provide the analytical core of media policymaking, despite persistent criticisms that such emphases on the part of policymakers neglect the full range of political and cultural concerns that are at the core of media policy (Baker 2001; Stucke & Grunes 2001). Indeed, if there is one enduring trend in terms of the interaction between the communications field and media policy, it is that the field as a whole has been largely dissatisfied with the extent to which it is able to shape and inform policy debates.

This dynamic reflects a broader tension that long has characterized media policymaking – that between economic policy objectives (such as competition, consumer satisfaction, and efficiency) and political/cultural policy objectives (such as fostering a diversity of viewpoints, as well as a media system that serves the needs and interests of local communities; Entman & Wildman 1992). To the extent that economic policy objectives have, over the past three decades, become an increased priority for media policymakers (van Cuilenburg & McQuail 2003), it is perhaps not surprising that the communications field has experienced some marginalization from the policymaking process, given that the field’s expertise lies more in the political/cultural, rather than the economic, realm (→ Communication as Field and Discipline; Applied Communication Research). Yet when we explore the field of media policy and its major theoretical underpinnings, the centrality of political/cultural policy objectives becomes immediately clear, such that questions about the appropriateness of contemporary policy emphasis inevitably arise (Napoli 2001).

## **THEORETICAL FOUNDATIONS OF MEDIA POLICY**

Media policy is framed, first and foremost, by a number of guiding normative theoretical constructs, all of which are subject to divergent interpretations. These constructs provide

the theoretical underpinnings for the development of baseline criteria for assessing the performance of media systems and for crafting policies that enhance the system's performance (see McQuail 1992). Across different national contexts, the specific criteria are likely to vary somewhat, or the terminology may be somewhat different, but the core principles outlined here can be seen as the fundamental building blocks of effective media policy, and, consequently, as central criteria that inform and guide media policy research.

### Free Speech

As was noted above, free speech is one of the core components of contemporary definitions of media policy. In US contexts, the free speech principle arises from the First Amendment guarantee of freedom of speech, with analogs to be found in various international contexts (see, e.g., Youm 2002). In some international contexts, where a government-granted right to speak freely is not always as explicitly articulated, we have seen in recent years a free speech movement grounded in the notion of a → “right to communicate.” Regardless of the specific national context, in most cases the centrality of free speech as a media policy principle arises from notions of the core function that mediated communication serves in the democratic process. That is, free speech is presumed to guarantee the free flow and widespread dissemination of ideas and viewpoints that are essential to creating a well-informed citizenry capable of accurately ascertaining their best interests and voting accordingly (Fiss 1996). In these regards, the role of free speech in media policy-making is tightly intertwined with the role of the media in the democratic process (Sunstein 1995).

Media policymaking is, somewhat paradoxically, both empowered and constrained by the free speech principle. The empowerment is derived from the fact that many media policies are motivated, at least in part, by a commitment to enhancing the speech opportunities available to the citizenry. Thus, for instance, policy efforts directed at maximizing broadband deployment are premised, at least in part, on bolstering the extent to which individual rights to communicate are maximized. Similarly, efforts to diversify media ownership (→ Ownership in the Media) are premised in large part on maintaining a wide distribution of the uniquely influential speech opportunities associated with the ownership of media outlets (see Baker 2007). The constraints are derived from the fact that many media policies – even those directed at enhancing the speech opportunities available to the citizenry as a whole – can simultaneously impinge upon the speech rights of particular individuals or groups. Thus, for instance, the same efforts to diversify media ownership on behalf of enhancing free speech can be seen as impinging on the individual speech rights of those owners of media outlets seeking to obtain additional outlets and bring their voice to markets or communities that they have yet to reach (Napoli 2001).

This somewhat paradoxical situation illustrates what is perhaps the *central tension associated with the role of free speech* (be it in terms of the First Amendment or of a broader right to communicate) in media policymaking – the issue of the appropriate distribution of this speech right on the part of policymakers. That is, to what extent should speech rights be oriented around the rights of the individual speaker rather than around the rights of the collectivity of speakers and listeners (see Napoli 2001)? This

tension is particularly well illustrated by the current state of broadcast regulation in the United States, where regulation of the industry traditionally has been grounded, in part, in the notion that the speech rights of the listeners or viewers are as important as – if not more important than – the speech rights of the speakers, given the unique technological and institutional contexts in which broadcasting operates (see Barron 1967). That is, to the extent that broadcasters utilize a scarce public resource – the broadcast spectrum (many scholars have criticized the validity of the “scarcity rationale”; see Coase 1959) – that is allocated by the federal government at no meaningful cost to the recipient, then those broadcasters forfeit some of their First Amendment rights in the name of serving the rights of the citizenry to be well-informed and to have access to a diverse array of sources and viewpoints – key elements of a vibrant speech environment in which the right to receive information is placed on comparable footing to the right to speak (→ United States of America: Media System; Television Broadcasting, Regulation of).

It is on grounds such as these that a wide range of *content regulations*, ranging from limitations on indecency to affirmative content requirements such as children’s programming, balanced programming (→ Balance), and preferential access to political candidates, have been based (→ Morality and Taste in Media Content). For the most part, such requirements would not be able to withstand First Amendment scrutiny in other technological contexts – a fact that illustrates the important point that, traditionally, the scope of the protection of speech rights has been dependent, at least in part, on the characteristics of the particular technology via which communication is taking place (see Pool 1983).

The approach to free speech reflected in the US broadcast regulation model clearly emphasizes a “*collective*” *approach to speech rights* over a more traditional “individualist” approach, with the government regulating individual speakers with (presumably) an eye toward magnifying the collective free speech benefits of the citizenry as a whole. Such an approach clearly conflicts with more traditional approaches to the notion of free speech to the extent that individual rights become subservient to the collective good – and it is this clash of often conflicting priorities in the allocation of speech rights that is at the core of the role of free speech as a guiding media policy principle.

### **The Public Interest**

The concept of the → public interest has a long and contentious history in media policy-making (see Napoli 2001). The inherent ambiguity of the term is, no doubt, the primary reason for its contentiousness. To the extent to which the public interest serves as the primary benchmark against which most media policies are assessed, it is not surprising that this normative principle long has been contested territory. The concept of the public interest represents the standard that most media policymakers often are expected to adhere to in their decision-making. That is, policy decisions should not reflect or cater to the interests of individual interest groups, but rather should reflect a broader awareness of the policy outcomes that would best serve the populace as a whole.

As McQuail (1992) illustrates, the concept of the public interest can have embedded within it a wide range of specific normative criteria, ranging from diversity, competition, and pluralism to access and objectivity (→ Plurality; Access to the Media; Objectivity

in Reporting). The specific criteria with which the public interest concept is invested will of course vary across nations (e.g., Hitchens 2006; McQuail 1992). These criteria also have varied over time (see Aufderheide 1999; van Cuilenburg & McQuail 2003), as regulatory philosophies and structural and technological conditions have changed. The criteria can also vary at any given time across different stakeholder groups, which of course contributes to the concept becoming highly contested territory within individual policy debates.

But what is perhaps most important to recognize is that the public interest concept traditionally has served as a normative guidepost not only for policymakers in their decision-making, but also, to a certain degree, for media organizations in their decision-making, to the extent that the political and cultural dimensions of media industry performance generally require attention to concerns beyond revenues, profits, and efficiencies (see Napoli 2001). Thus, the public interest concept perhaps represents the most direct mechanism via which policymakers, media critics, and researchers assess and pass judgment upon the performance of individual media markets or entire media systems, and upon which advocacy for change is most frequently premised.

### **The Marketplace of Ideas**

The notion of a well-functioning marketplace of ideas – and the appropriate role of policy in promoting and protecting such a marketplace – is perhaps where the tensions between the economic and the political/cultural rationales for media policymaking have been the most pronounced, as it is also the guiding metaphor out of which both analytical perspectives toward media policy have largely originated. Thus, like each of the core theoretical constructs for media policy discussed thus far, the marketplace of ideas also is subject to multiple, potentially conflicting, interpretations. But certainly, the metaphor contains within it a rather comprehensive conceptualization of the scope of media policy as both a professional practice and a field of academic inquiry.

Policy scholars grounded in economics naturally interpret the marketplace of ideas metaphor in a way that emphasizes the “invisible hand” and that prioritizes a reliance on marketplace incentives over government interventions to achieve desired social outcomes, but also in a way that generally cedes tremendous authority to the marketplace for determining desired social outcomes (see, e.g., Owen 1975). This analytical perspective has been expressed perhaps most famously in the articulation by Mark Fowler, chairman of the Reagan-era US → Federal Communications Commission (FCC), of a “marketplace” approach to broadcast regulation in which “the public’s interest . . . defines the public interest” (Fowler & Brenner 1982, 4). Of course, such an analytical perspective naturally leads to strong opposition to government regulation of media markets in favor of large-scale deregulation.

It is worth noting, however, that in recent years in the US there has been something of a retreat from this rather extreme perspective, even from among those who have traditionally adopted a primarily economic stance toward media policy issues (see, e.g., Stucke & Grunes 2001). Deregulatory arguments today are now more often couched in First Amendment theory or in assessments of the media marketplace that emphasize the growing importance of new media technologies, the diminished significance of the traditional regulated media, and, consequently, the irrelevance of contemporary efforts to

continue regulating what is perceived as an increasingly shrinking and struggling component of the overall media system (see Baker 2007).

Political/cultural approaches to the metaphor of the marketplace of ideas have, as one might expect, a very different theoretical grounding, drawing not from economic theory but rather from democratic theory, particularly the work of John Milton and John Stuart Mill, who articulated *notions of truth* as being achieved via the free competition of ideas and the greater social good as being served via the wide dissemination of ideas and viewpoints (Schwarzlose 1989; → Truth and Media Content). From a media policy standpoint, of particular importance is the application of this perspective to the democratic process, where emphasis traditionally has been placed on the centrality of the competition between diverse and antagonistic viewpoints to an informed citizenry and effective self-governance (e.g., Meiklejohn 1972).

Media policy, from this perspective, therefore needs to prioritize the extent to which the media system serves the informational needs of the citizenry and facilitates the effective functioning of the democratic process. Out of this interpretive approach grow emphases on diversity, pluralism, and localism as key elements of a robust marketplace of ideas (see Hitchens 2006; van der Wurff 2005).

### KEY ISSUE AREAS FOR CONTEMPORARY MEDIA POLICY

The theoretical constructs outlined above inform three broad substantive areas of concern for media policymaking. These substantive areas are intended to be inclusive of the range of policy issues and concerns that characterize the media policy field. These substantive areas are: (1) content, (2) structure, and (3) infrastructure. *Content* can be thought of as policymaking directed primarily at directly influencing the nature of the content provided by media outlets. *Structure* refers to policymaking directed primarily at influencing the structural elements of media markets, such as competitive conditions, ownership patterns, and related dimensions of the characteristics of content providers. *Infrastructure* refers to the distribution technologies and networks by which content is disseminated.

Each of these issue areas is described in greater detail below; however, it is important to emphasize at the outset that these substantive areas are not wholly distinct. Issues of infrastructure policy bear on issues of content (Yoo 2005), as do issues of structure (van der Wurff 2005). For instance, policies directed at the operation of communication networks can indirectly impact the nature of the content that is produced (Yoo 2005). Structural policies, in fact, frequently have been implemented with the intention of indirectly impacting content (and thereby circumventing possible First Amendment/free speech impediments to more direct efforts to affect content; see Napoli 2001).

#### Content

Content-related policy concerns generally seek to either protect the citizenry from potential harms associated with particular types of media content, or to benefit the citizenry via the imposition of affirmative requirements on content providers to offer certain types of content deemed to be socially valuable.

Protective policies typically have focused on *content deemed to be potentially harmful* (particularly to children) or at least potentially offensive to the sensibilities of the typical media consumer. Thus, for instance, there is a long tradition of content regulation in broadcasting that focuses primarily on constraining indecent language and sexuality. Media violence (→ Violence as Media Content) also has been a longstanding concern in the media policymaking arena (Hamilton 2000b). Policymakers have been concerned about the effects of violent content – particularly on children – across a wide array of media, ranging from comic books to motion pictures to (perhaps most prominently) television and (most recently) the Internet. Given these concerns, media effects research examining the possible relationship between the consumption of violent media content and violent behavior has maintained a position of prominence in media policymaking circles throughout each wave of technological development. This has led to efforts such as V-Chip legislation, which requires that television manufacturers place a device in new televisions that facilitate viewer or parental blocking of both indecent and violent programming.

V-Chip policies are reflective of more indirect (and often industry-initiated; → Self-Regulation of the Media) approaches to content regulation that have characterized non-broadcast media (where First Amendment protections generally are stronger) such as → video games, recorded music, and motion pictures (→ Cinema), where ratings systems have been put into place to facilitate restricting children's access to certain types of content and minimizing accidental exposure to such content by audience members who might find the content offensive. More direct forms of content restrictions tend to remain confined to terrestrial broadcasting, though efforts to impose a more broadcast-oriented content regulation model have been attempted in the online context (→ Internet Law and Regulation), and policymakers have initiated preliminary inquiries into extending such an approach to other media such as → cable television and satellite broadcasting (Congressional Research Service 2005; → Satellite Television). Whether such efforts could ever survive First Amendment scrutiny is doubtful. And, of course, the global nature of the Internet offers tremendous challenges to any nation seeking to impose such content restrictions in the online realm.

Another important form of “protective” policies relating to media content involves *national restrictions on the importation and exhibition of foreign content*. Such policies typically are grounded both in cultural concerns related to preserving and promoting domestic cultural values, traditions, and expressive opportunities in the face of an increasingly globalized media marketplace, and in economic concerns related to protecting and promoting domestic media industries from foreign competitors. Limitations on television programmers' ability to air foreign-produced content can be found across a wide array of nations, ranging from Canada, Australia, and France to China, Malaysia, and Singapore. Similar restrictions can be found in many nations pertaining to motion picture importation and theatrical exhibition.

Turning to affirmative content requirements, policymakers also frequently have seen fit to require media outlets to *provide certain types of content* – typically content judged to enhance the political, intellectual, or cultural development of the citizenry. In the US, such requirements have been in decline over the past three decades (Napoli 2001), though affirmative requirements for broadcasters related to educational children's

programming remain, as do requirements for cable and satellite systems to devote certain amounts of channel capacity to local, noncommercial, and educational content providers. Similar content requirements (often focusing on issues of children's programming and localism) can be found in other nations. In Australia, for instance, certain broadcast licensees must provide explicit quantities of educational children's programming and of programming dealing with material of local significance (→ Educational Media Content).

Obviously, whether the context involves restrictions on what type of content can be provided or requirements regarding the provision of certain types of content, such government involvement in the content arena represents the most aggressive and potentially the most invasive and problematic mechanism available to media policymakers, as such approaches can be seen as running counter to the free expression principle at the core of media policy.

### **Structure**

Structural policy concerns focus primarily on issues related to the ownership patterns and structure of media systems. That is, policymakers across a wide array of national contexts have approached the regulation of the ownership and structure of media outlets as a primary mechanism for preserving and promoting the various normative principles that reside at the core of media policy. Thus, diversifying the ownership of media outlets and restricting foreign ownership have been seen as an important means of maintaining a robust, pluralistic marketplace of ideas in which principles of free speech and a media system that best serves the public interest can be realized. Questions of the effectiveness and appropriateness of such policy approaches have, however, become increasingly prominent in recent years, as technological change, the blurring of traditional industry distinctions, and the globalization of media markets all have contributed to a reassessment of the appropriate approach to structural regulation of the media.

In the US, for instance, there has been, in recent years, an ongoing debate over policies pertaining to *local and national ownership limits* for media outlets. Ownership policy has become particularly contentious, perhaps because of the extent to which the issue straddles the economic and socio-political terrains of media policy. That is, ownership policy directly engages traditional economic policy concerns such as competition and efficiency to the extent to which such policies impact competitive conditions in media markets, and the extent to which media owners can take advantage of potential economies of scale associated with the ownership of greater numbers of media outlets (→ Concentration in Media Systems). Ownership policy also directly engages socio-political policy concerns related to the diversity of sources of information available to the citizenry, the extent to which media outlets are locally owned and oriented, and, perhaps most important, the extent to which the speech opportunities associated with the ownership of media outlets are widely versus narrowly disseminated. The extent to which the media ownership issue resides firmly in the camps of the two traditionally distinct analytical perspectives that have been brought to bear on media policy (Entman & Wildman 1992) is, no doubt, the primary reason for the fact that this policy issue has become highly politicized, highly contentious, and, ultimately, very difficult to resolve.

Other national contexts where the issue of media ownership has been particularly pronounced include Italy, where the election of the nation's most powerful media owner, Silvio Berlusconi, to the office of prime minister raised a wide range of questions regarding the relationship between media ownership and the political process, and the appropriate policy responses to managing this relationship (see Doyle 2002). Australia and the UK, like the US, have been immersed in contentious debates regarding the reform of media ownership policies, and, as in the US, the trend appears to be one of a gradual relaxation of these rules (Hitchens 2006).

Another important structural dimension of media policy involves the *commercial versus noncommercial orientation of outlets* serving individual media markets. In Europe, in particular, there has existed a strong tradition of public service television and radio (→ Public Service Broadcasting: Law and Policy), though over the years most European media markets have – via the efforts of policymakers – become increasingly privatized, and, by association, increasingly commercialized (Hitchens 2006). Similar processes have taken hold in other parts of the world as well. It is important to recognize that concerns regarding privatization and commercialization, and the appropriate policy responses, extend into the new media realm as well (Mueller 2002).

### Infrastructure

Infrastructure, in this case, refers to the transmission mechanisms for media content. In some instances, these infrastructures have historically been under governmental control, in which case the allocation of access to the particular infrastructure becomes a fundamental policy issue. Thus, for instance, *spectrum policy* has been – and continues to be – a core concern in the media policy arena. Early spectrum policy concerns involved establishing the key components of a regulatory apparatus, as well as the mechanisms for license allocation (Hazlett 1990; McChesney 1993). In recent years, the nature of spectrum policy concerns has changed dramatically, reflecting the increased flexibility of spectrum uses brought about by the process of digitization, as well as a stronger governmental commitment to privatization of the spectrum. This privatization process has itself become a major source of policy debate, as have issues related to licensed versus unlicensed spectrum uses, and to spectrum usage priorities that are most efficient and that best serve the public interest.

In other instances, policymakers have seen fit to institute policies in an effort to *spur the growth of certain infrastructures* (→ Communication Infrastructure). Most recently there has been substantial attention devoted to the issue of the broadband infrastructure and possible mechanisms for accelerating its build-out and, perhaps most important, insuring that the infrastructure reaches – and is reasonably accessible to – sectors of the citizenry facing significant barriers to access. Such concerns reflect a longstanding policy tradition of concern for widespread access to key elements of the information infrastructure, whether it be in terms of universal service policies for telephone service or Internet access (→ Digital Divide), or of insuring the allocation of broadcast licenses to even the smallest of communities (see Napoli 2001). Widespread access to the various infrastructure components of the media system has been, and remains, a core media policy issue.

## CONTEMPORARY CHALLENGES FOR MEDIA POLICY

Media policymaking must navigate an *increasingly complex technological environment*, with new media technologies not only introducing new forms and sources of content into the media mix, but also providing new mechanisms for the delivery of traditional media content. In such an environment, effectively defining media markets becomes increasingly difficult, as does maintaining an accurate sense of the roles and functions of the different media in the lives of the citizenry. For instance, policymakers must come to grips with how the migration to increasingly interactive media platforms, and the associated increased prominence of user-generated content, might impact policy approaches to media (Benkler 2006). To the extent that we are witnessing technology-driven “deinstitutionalization” of the media, the question arises as to how this process should be reflected in media policies, which traditionally have been directed at large-scale media institutions and formulated with such institutions in mind.

These increased analytical challenges facing policymakers (and policy researchers) are accompanied by changing dynamics regarding the placement of the *burden of proof in the assessment of individual policies*. That is, individual policies are coming under increased scrutiny by policymakers, stakeholder groups, and the courts, in terms of the extent to which they legitimately achieve the objectives that motivated their introduction. No longer is much deference granted to the predictive judgments of policy professionals. Rather, contemporary media policymaking involves increasingly ambitious efforts to systematically assess the impact of individual policies, as well as to test the underlying assumptions upon which individual policies may be based.

Such developments, of course, point to an *increasingly influential role for research* in the media policymaking arena – particularly in relation to the stakeholder battles (e.g., between industry groups and public interest/advocacy organizations) that remain a prominent component of media policymaking. But such developments also raise the question of whether the full range of policy impacts always will be discernible by available empirical methods, and if not, whether policies reflecting values that perhaps should be considered self-evident potentially suffer in the face of increasingly evidence-based policymaking. The implications of such questions are magnified by contemporary dynamics involving the role of research in policymaking that suggest that a fairly narrow spectrum of research perspectives contributes to policymaking (Mody et al. 2005), and that resource imbalances among the various stakeholder groups can further skew the nature of the research that ultimately impacts policy decision-making (Napoli & Seaton in press).

## Media as Political Actors

*Thomas E. Patterson*

*Harvard University*

Political advocacy is not journalists' main concern. They are chiefly in the business of gathering and disseminating the daily news, and they define themselves more by their professionalism than by their partisanship (→ Journalists' Role Perceptions). According to McQuail (1994, 145), "The height of [journalists'] professional skill is the exercise of a practical craft, which delivers the required institutional product, characterized by a high degree of objectivity, key marks of which are obsessive facticity and neutrality of attitude" (→ Professionalization of Journalism; Quality of the News; Standards of News).

Even the political frames that journalists apply to political coverage do not routinely center on the interests at stake in politics. Political conflict and gamesmanship are among journalists' preferred frames (→ Conflict as Media Content; Framing of the News; Horse Race Coverage). In many democracies, questions of policy, rather than being at the center of the news, are often a backdrop to the struggle for political advantage.

It is a mistake, however, to dismiss partisan advocacy as an insignificant component of modern journalism. Many of the national dailies in Europe and elsewhere are associated

with a particular party or ideology. Of course, they differ in important ways from old-time partisan newspapers. Financed by circulation and advertising revenues rather than government or party subsidies, their news is professionally produced. Nevertheless, the vitality of these newspapers flows from their partisan leanings and the loyalty of their partisan readers. Nor are broadcast organizations completely outside the fray of partisanship. In Germany, Italy, and Korea, to cite a few examples, broadcasting at times has been structured in ways that allow partisanship to enter into news decisions.

Colin Seymour-Ure (1974) proposed the concept of “press–party parallelism” as a way of expressing the relationship between news organizations and political parties. In their recent work, Hallin and Mancini (2004) describe a tighter link between press and party in Mediterranean countries than in northern and central European countries, which, in turn, have a more → partisan press than do English-speaking countries (→ Party–Press–Parallelism).

Even where ties between news organizations and parties are weak or nonexistent, journalists themselves may promote partisan agendas through their news decisions. Allegations of “hidden” bias have surfaced in many countries, partly because surveys have found that most journalists lean toward the left politically (→ Bias in the News). Although studies have not produced uniform results, the weight of the research evidence points to the existence of this form of bias. Kepplinger et al. (1991) found, for example, that journalists’ partisan leanings affect their choices about which issues and positions to highlight. They use the term → “instrumental actualization” to describe this pattern. Patterson and Donsbach’s (1996) five-country survey found in each country that journalists’ partisanship was statistically related to their responses to hypothetical news decisions. The authors conclude, however, that partisan bias is a much smaller influence on news decisions than are journalism norms and conventions (→ Political News).

In some instances, news journalists and organizations serve to legitimize the views of those in power, regardless of party. Bennett (1990) found that the news is “indexed” to elite debate rather than to public opinion. Unless there is substantial disagreement among political authorities, news coverage is likely to highlight the official position only. In such instances, as Entman (2003) notes, the news media act nearly as a propaganda wing of the government.

On the other hand, the absence of an elite consensus widens the range of voices, including nongovernmental voices, brought into the news. Elite disputes also unleash criticisms by journalists of those in power. Major studies of US, UK, German, and Swedish news have found that attack journalism is on the rise. When governing authorities are at odds, journalists’ deference to those in power often gives way to criticisms of leaders of both sides. Their motives, methods, and effectiveness are questioned. Based on their Swedish study, Westerståhl and Johansson (1986) see this development as a “news ideology” premised on the assumption that politicians are self-serving and rooted in the notion that journalists are professionals whose responsibilities include keeping watch on those in power (→ News Ideologies). The effect, as the research of Cappella and Jamieson (1997) suggests, is to weaken the public’s support of political leaders and institutions.

In one area, the politics of the media is one-sided. Given their dependence on advertising revenue, mainstream news outlets tread lightly when it comes to business

exposes. The news, as Hamilton (2004) remarks, is an “information good,” a thing to be sold to advertisers and audiences. Although major corporate scandals get news coverage when they break, news organizations do not invest heavily in investigating private-sector actions (→ Investigative Reporting). News organizations and journalists do not so much promote corporate power as they ignore it, allowing business leaders wide leeway in their dealings, thus helping to maintain a distinction between marketplace power and governing power.

## **Media Production and Content**

*Stephen D. Reese*

*University of Texas at Austin*

Research in the sub-field of media production and content seeks to describe and explain the symbolic world of the media with reference to a variety of contributing societal, institutional, organizational, and normative factors. It draws boundaries around a large and diverse body of research efforts, predominantly social science, but also including more interpretive cultural analysis. If much of the communication field has concerned itself with the effects of media, and the process by which they are produced (→ Media

Effects; Exposure to Communication Content), this more recently emerging area has treated the media map of the world itself as problematic, something to be understood and predicted through an awareness of underlying forces. These forces provide the context of “media production,” which is examined for its systematic ties to “content.” Understanding these “messages” that constitute the symbolic environment is an ambitious task, given the multitude of factors influencing the media. But locating these questions within such a conceptual framework has begun to allow the field of communication to devote the same sustained research to the creation, control, and shape of the mediated environment as it has to the effects on audiences of that environment. The same research tools used so extensively to examine media effects can be turned on those media and their links with the culture of other organizations and institutions (→ Research Methods).

### MAPPING THE FIELD OF RESEARCH

Of course, in such a contentious domain, examining what “is” takes place within the context of what “should be” or what “could be.” The highly normative and politicized questions of media operation, bias, and control have moved to the center of the public arena, with an increasing number of media-literate citizens developing and promoting their own views (→ Media Literacy). Thus, these scholarly research questions are closely related to press criticism that circulates among activists, policy elites, and media professionals themselves. Questions of empirical social science are guided by political, legal, and ethical concerns to yield results with direct implications for social policy (→ Communication and Law; Media Policy). Systematic scholarly research helps at least to provide a solid factual basis for the contending interests.

The *Glasgow Media Group* is a model in many ways for this style of research, diligently collecting since the mid-1970s media transcripts and broadcasts, carefully examining their messages regarding issues of labor, war, and other controversies, and linking them to media and social structures (Glasgow Media Group 1976, 1980). Although such research has become more commonplace, government and media professionals reacted at the time with strong criticism, sensitive to the claim that they played a role in shaping the news. Such scholarly work has helped make the point that media content can be structured and framed in ways that support certain interests, without any one person or group intending or conspiring to do so. This area of the field takes seriously the proposal advanced by Thompson (1990) that in order to understand media in modern culture, we must examine media in specific social-historical contexts, consider the relevant cultural objects, and then interpret how they are connected (→ Content Analysis, Qualitative; Content Analysis, Quantitative).

This research area is also often broadly referred to as “*media sociology*” (reviewed in Berkowitz 1997; Schudson 2001, 2003). Certainly, many of the participant observation ethnographies of newsrooms and other media are so labeled, particularly given their use of traditional sociological fieldwork methods (e.g., Tuchman 1978; Gans 1979; Fishman 1980; → Ethnography of Communication). But the area also encompasses the more psychological studies of individual media workers, and how their personal traits affect their decisions (e.g., Weaver & Wilhoit 2006; → Journalism; News Workers). Many media critics lodge the blame for press bias (→ Bias in the News) squarely with individual

journalists, or find fault with the entertainment industry because of “out-of-touch” Hollywood producers. But the most important explanation for these communication products lies in structural bias, not individual prejudice.

Indeed, as the production of communication messages has become a huge financial enterprise, it is now a natural step to begin applying the same explanatory models we would use to understand other industrial production. Although media organizations – including those supported by the state – employ many creative professionals, the work of those individuals is routinized and structured to yield a predictable product (Bantz et al. 1981). Even the news, which should by definition be the unexpected, must be controlled, anticipated, and packaged to allow the organization to manage its task effectively: in Tuchman’s (1978) phrase, “routinizing the unexpected” (→ News Routines). Outside of the US fieldwork tradition, media sociology has been used in other international contexts – particularly Europe and Latin America – to refer to the entire context of media production and performance, the entire social structural context (McNair 2006). That is the sense in which it is used here.

### **ANALYZING THE BASIS OF MEDIA POWER**

In an influential article critical of the media sociology of the time, Gitlin (1978) took the field to task for overemphasizing the short-run, marketing-oriented, attitudinal, and behavioral responses of the media audiences (→ Attitudes, Values, and Beliefs, Media Effects on). The result of this relatively micro-, individual level definition of influence was to conceptually render the media powerless (and thus not a social problem of great concern), with audiences relatively resistant to persuasion (→ Media Effects, Strength of; Media Effects, History of). Casting the media effect of “reinforcement” as a profound one rather than an indication of impotence, Gitlin argued, opened up important terrain for research: what effects do the very presence and structure itself of media have for what gets defined as normal and legitimate? This version of media power is perhaps best exemplified by Herman and Chomsky (2002) in their propaganda model writings, in which they argue that media content is the result of a number of filters, such as → advertising, ownership, sourcing of news to elites (→ Ownership in the Media; News Sources). These filters yield only that material serviceable to the status quo and create a double standard of portrayal for “us” versus our “enemies.” The questions in the area of media production and content, then, take a perspective somewhere between the two extremes. Media are neither unproblematic and benign, a mere forum for messages from which the audience can choose, nor are they simply tools of the corporate state for producing serviceable propaganda. Media have their own logic and must be examined within the context of their own relative autonomy (→ Media Logic).

*Historically*, studies proliferated in the early post-World War II communication field, continuing to the present, describing various features of news and media content, but often these have been largely unconnected and lacking a consistent conceptual framework (e.g., Tamborini et al. 2000). Beginning in the 1950s Warren Breed (1955) and David Manning White (1950) were among the first scholars to examine the influences on content in a more direct way, with their examinations of social control in the newsroom and the story selections of an editor, described as the news “gatekeeper” (→ Gatekeeping).

But others did not follow their lead in communication until much later, a peculiar thing considering the subversive insight that news is, in White's terms, "what the gatekeeper says it is," and bearing in mind Breed's finding that organizational policy was used to screen out certain happenings from getting into the newspaper.

Reese and Ballinger (2001) took a closer look at these forerunner studies and their reception by other scholars to explain why they did not generate more follow-up research. The reason, they suggested, lay in how the findings were interpreted within the field at that time: the gatekeepers were deemed to be representatives of the larger culture, and news policies were assumed to help identify as news those events of interest to the community – rendering the production and control issues unthreatening to the public interest and, as a result, of less interest to researchers. Eventually, however, these questions returned to the fore, particularly given growing public skepticism about the performance of media and awareness of their corporate and technological constraints (→ Communication as a Field and Discipline).

The traditional mass communication field was associated with → surveys and controlled experiments (→ Experiment, Laboratory), isolating an effect of interest within the audience, whereas the media production and content domain is much more diverse and ranges across many levels of analysis and research traditions, making it more difficult for any coherent overall "theory" to emerge. Not all questions of media content and control can be reduced to such straightforward linear relationships as those between message and receiver (→ Linear and Nonlinear Models of Causal Analysis). Many such questions are qualitative, interpretive, and naturally resistant to being described in more quantitative, variable-analytic terminology. But at least conceptualizing them together helps us to assemble previously disparate strands of research and serves to connect, within a consistent style of explanation, the audience-and-effects side of the field with the shaping and control of content. From the intuitively appealing idea of media agenda-setting, for example, it is an easy rhetorical step to ask "what sets the media's agenda?" (→ Agenda-Setting Effects). Just by asking such a question within the framework of communication research gives it a certain legitimacy (see Reese 1991).

## LEVELS OF ANALYSIS

In understanding how the symbolic environment is shaped, or "constructed," it is useful to have a way to classify the many kinds of forces at work. The *hierarchy of influences model* describes the multiple levels of influences that impinge on media simultaneously and suggests how influence at one level may interact with that at another (Shoemaker & Reese 1996). Within the realm of newsmaking, for example, the personal bias of individual journalists may affect their reporting (→ Instrumental Actualization), but journalists of a particular leaning often self-select into organizations because of their pre-existing policies, history, and organizational culture. The news organization and its employees, in turn, must function within other institutional relationships and ideological boundaries set by the larger society. Thus, the individual functions within a web of organizational and ideological constraints. This model organizes various theoretical perspectives on the shaping of media content, including the suggested categories of Gans (1979) and Gitlin (1980), set out below.

*Content is influenced by media workers' socialization and attitudes.* This is a communicator-centered approach, emphasizing the psychological factors impinging on an individual's work: professional, personal, and political.

*Content is influenced by media organizations and routines.* This approach argues that content emerges directly from the nature of how media work is organized. The organizational routines within which an individual operates form a structure, constraining action while also enabling it.

*Content is influenced by other social institutions and forces.* This approach finds the major impact on content located external to organizations and the communicator: economic, political, and cultural forces. Audience pressures can be found in the "market" explanation of "giving the public what it wants" (→ Media Economics; Media Events and Pseudo-Events; Spin Doctor).

*Content is a function of ideological positions and maintains the status quo.* The so-called hegemony approach defines the major influence on media content as the pressures to support the status quo, i.e., to support the interests of those in power in society (→ News Ideologies).

Refining these perspectives, the hierarchy of influences model sets out *five levels of influence*: individual, routines, organizational, extra-media (institutional), and ideological (socio-cultural). As a guide to research, it helps explicate key concepts on which research is based and unpacks those multiple levels of meaning (Reese 2001). Particularly for journalism, such a model helps to untangle many of the criticisms of press performance (→ Quality of the News), identifies their implicit normative and theoretical assumptions, and suggests appropriate kinds of evidence. For example, conservative media critics have located the source of bias with the individual journalist, calling for more balance in hiring practices and regularly scolding specific news anchors. Left-leaning critics, on the other hand, find fault more with the structure and ownership of the commercial media system, arguing for more public control and protections from the corruption of big advertisers. The irony is that journalists give respectability to attacks from their right flank, which even if targeting them as individuals at least attribute to them the professional latitude to create bias in the first place. By relegating journalists to mere tools of a larger corporate system, the left critique is less professionally satisfying. Both critiques can be more easily understood when we know from which level they are mainly conceived.

With this rough outline of the field in mind, the entries that are associated with it can be sorted into some key categories. They describe research exploring the media–reality connection and the specific shape of the media map. This leads to a set of normative questions concerning what that map *ought* to look like (→ Media Performance). Beyond those questions, in turn, are those entries concerning how that map is produced in practice – and in the various kinds of media, with their different professional routines and organizational dimensions. Many researchers come to these questions with a particular medium of interest: whether television, radio, or the most recent technological innovation. Others are concerned with a particular practice or genre of content that cuts across media forms, such as crime, violence, tabloid news, soap operas, or news. In either case, the media forms and their practices are closely interrelated.

## THE SYMBOLIC ENVIRONMENT

The compelling *point of departure for this sub-field* is the idea that media content provides a map of the world that differs from the way that world really is, making the research task one of explaining those discrepancies. Concepts such as “accuracy,” “balance,” and “bias” all imply some assessment of the success with which media adequately portray the subjects at issue. Elements of “truth” and “credibility” further underscore the benchmarking of media against some external standard of reality. Because of its social importance to the political system, news and public affairs content has been given special emphasis in this regard and raises a host of normative issues. Concepts, such as “neutrality,” signal the desirability that media not intrude into what would otherwise be freely expressed “reality” within a community (→ Neutrality). In political science, for example, some studies (e.g., Patterson 1993) implicitly assume that media professionals should not interfere with the ability of political actors to communicate with the electorate (→ Political Communication; Political Journalists). If, contrary to this neutrality, these professionals intrude to shape the symbolic environment, then we may question along what lines they do so. Is there enough information provided for citizens to act effectively in a democracy? Are they given content that is degrading to the culture? Are media portrayals for good or ill with respect to the overall health of the society?

Historically, there have been different expectations for news and entertainment, but the current mix of news, entertainment, and reality shows blurs these normative categories. Nevertheless, similar questions can be asked and examined across the entire array of media content. Although by definition not seeking to correspond directly with an object in reality, fictional accounts speak to larger truths, the human condition, archetypes grounded in reality – even if they are not bound by the same expectations we have of nonfiction, news accounts, and other documentary media portrayals (→ Fictional Media Content). Both forms constitute a map of the social world, and they possess certain regularities and typical features that can be empirically described. These media forms both speak to what matters, who is important, and where the action is. They both tell stories to the culture, with the fictional being no less “truthful” just because it did not actually “happen.” That is why, conceptually, this area of the field often speaks to a larger media symbolic environment, using similar language and models to describe how a picture of the world, a “manufactured reality,” is created across the media spectrum.

The problematic issue of media content has become not only a basic scholarly premise but an article of faith among the many media watchdog groups that monitor press performance – and who fault those media for not adequately representing the “reality” they have in mind. In both scholarly and popular discussions of media content, particularly news content, there is a tendency to ask how “objectively” it reflects reality. The “*mirror*” hypothesis – the expectation that media reflect social reality with little distortion – is no longer taken seriously, although this lack of distortion may be vigorously defended in self-serving attempts by media professionals to argue the accuracy of their work, in holding up a “mirror to society.” Historically, the neutral, objective journalist model favored in the US gave implicit support to this idea, although it now seems rather quaint and self-evidently untrue. In a more subtle version, media are rendered neutral or “objective,” by reflecting the self-regulating and balancing compromises between those

who sell information to the media and those who buy it (→ Objectivity in Reporting; Extra-Media Data). A concise statement of a related view was expressed in the British context by the Committee of Inquiry on the Future of Broadcasting in 1977 (although the same view is still to be heard from defensive media executives there and elsewhere): “What protects the public against manipulation of news reporting is not the centralisation of editorial decisions. It is the variety of news outlets and of editorial judgments, both in broadcasting and in the press, which is maintained in the nation” (Annan 1977, 17.30; → Journalism: Normative Theories).

### THE MEDIA–REALITY RELATIONSHIP

To better understand the different research approaches in this field, it is helpful to grasp some key philosophical ideas concerning the media–reality relationship. The idea itself of a “reality” out there with which to compare media is problematic, and different research styles take such an epistemological issue as a point of departure. An empirical approach assumes that media representations have their correspondence to objects in the real world. The notion of bias itself, used by many press watchdog groups, suggests that media deviate in some measurable way from a desirable standard that can be independently known (Hackett 1984; → Postmodernism and Communication). Traditional measures have involved assessing the relative balance of news accounts, including the time and space devoted to different candidates in electoral races. This assumes that the ideal pattern is evenly split between (in the US context) the two major parties, with any deviation a function of political bias. Research has often designated some other reality benchmark to determine how media accounts deviate from it (e.g., violent crime is over-represented in news and media accounts, compared to its actual statistical occurrence; → Violence as Media Content).

Viewed another way, media content is fundamentally a *construction* (→ Constructivism), and, as such, can never find its analog in some external benchmark, a “mirror” of reality. Media-constructed reality has taken its place alongside other social constructions, whether mental illness, criminality, sexuality, gender, race, and other identities no longer considered self-evidently “natural.” If content is a construction, understanding its special quality requires understanding of the construction process (→ Construction of Reality through the News). That assigns greater importance to the research in this sub-field, which takes as its basic premise that the media necessarily exert their own unique shaping power to the symbolic environment, a shaping that is open to explanation using various theoretical perspectives. The constructionist perspective assumes that “reality” is made in the process of our attempts to apprehend it, cannot be separated apart from those efforts. Journalists, for example, “see” things because their “news net” is set up to allow them to be seen (Tuchman 1978; Fishman 1980). Expressed another way, news does not reside somewhere in the environment waiting to be discovered; news does not become news until sources promote “occurrences” into “events” (Molotch & Lester 1974).

A number of concepts imply the relationship media do or ought to have with reality. *Studies of bias*, as mentioned, have targeted news media for deviating from some appropriate standard, whether some evenly balanced distribution of partisan attention or reflection of the demographic distribution of various ethnic and racial groups. Coverage

of electoral politics in the US has typically been found to hew close to a balanced approach, at least with regard to time and attention, especially given the tight watch the political parties keep over it (D'Alessio & Allen 2000). Media are not monolithic, of course; newspapers, for example, vary in their stance on issues, including such polarizing subjects as the Israeli/Palestinian question (Zelizer et al. 2002), and bias does intrude in more subtle ways. Fictional portrayals, particularly on television, have also been examined to determine if they privilege, exclude, or stereotype certain groups. The cultural indicators studies of → Gerbner and colleagues, for example, have involved extensive research into prime-time television to show what behaviors and groups are over- or underrepresented – all with implicit external benchmarks (Gerbner et al. 1978; → Cultivation Theory; Cultivation Effects).

### **PATTERNS OF MEDIATED “REALITIES”**

Gerbner and other scholars have been influential in articulating a coherent map of the world that cuts across specific programs and networks. As a result, it is possible to make a number of generalizations about the shape of the overall media *symbolic environment*.

In general, media accounts – whether news or entertainment – do give more prominent attention to *groups with greatest privilege*: whites, men, urban dwellers, and professionals. In his often-cited work on national news, Gans (1979) refers to these as the “knowns.” They are known for being known, and their fame underscores the appropriateness of their further visibility. When less powerful groups, the “unknowns,” enter the symbolic arena, they do so via deviant behavior, whereas the “knowns” are present by the mere routine performance of their official duties. Thus, media police the boundaries of the culture with a dialectic interplay between the normal and the abnormal (e.g., Hall et al. 1978; Ericson et al. 1987). In his cultural indicators project, Gerbner and colleagues focused on prime-time television to show who is allowed to exert their will over others, with violence being the symbolic act of power. Men, for example, are shown more often as the perpetrators of violence and women the victims (Gerbner et al. 1994). In news accounts, Entman (1990) shows that blacks are more often portrayed in a negative context. Compared to whites charged with similar crimes, they are more likely to be shown in the grasp of the police, unidentified, unmoving in the visual image – all suggesting a less “human” image. Thus, representations through media are deeply rooted in the prevailing social order (→ Media and Group Representations; Stereotyping and the Media; Crime Reporting).

Beyond this “benchmarking”-type research, analysis has turned to *how stories are framed*, or structured, based on certain organizing principles guiding journalists. The framing approach to content is more likely to take a constructionist view – everything is framed in some aspect. Framing more usefully expands upon the bias concept to emphasize the organizing principles underlying media representations that work to bring coherence to media accounts, both in the minds of media professionals and, as a result, in the audience exposed to such frames (→ Framing of the News; Framing Effects). Moving toward framing and away from bias directs attention away from some impossible goal of perfect representation and toward the more complex shared cultural understandings that media professionals develop as a function of their work and share with others in society (→ News as Discourse).

On a practical level, regardless of philosophical perspective, researchers find it useful to compare “media reality” with “social reality” – that is, that view of the world that is socially derived, what society knows about itself. And to the extent that media reality differs in systematic ways from these other forms of social self-knowledge, we can draw important conclusions about the structures underpinning these differences. Research is concerned with the systematic patterns of those mediated realities, and the extent to which they have real consequences for citizens and media consumers (→ Perceived Reality: Meta-Analyses).

### **NORMATIVE ISSUES FOR THE MEDIA MAP**

Given their important societal role, the performance of media has been a central normative issue within this field. In a democratic society, the media are expected to be accountable, relatively free of undue intrusion from the state, and provide an opportunity for various members and groups to be reflected fairly (→ Accountability of the Media). In much of the developed world, this accountability is closely tied to market forces. Media products must find markets, consumers willing to pay directly through subscriptions or indirectly via their attention to advertising (→ Commercialization: Impact on Media Content). Internal normative guidelines are also upheld by professional and ethical imperatives followed by practitioners. External to the media, the state acts on behalf of citizens to regulate media and oversee them, as in the case of state-run or publicly owned media. In terms of Habermas’s (1989) → public sphere, the media serve as a surrogate for that idealized place where discourse on public issues can occur on the basis of reason without being unduly influenced by either the state or the market. Thus, it concerns us if only those with economic resources are allowed to have a voice, or only those who already occupy positions of state authority. The evidence used to support claims should be clearly available, transparent, and uncorrupted by conflicts of interest. The extent to which media contribute to this ideal functioning of the public sphere is a normatively guided question for research. The tools of social science are engaged, along with the more humanities-based methods of media criticism and legal and ethical analysis.

The North American tradition of objective journalism and commercial media has located the responsibility primarily within the media themselves (Hallin 1996). In exchange for relative freedom from government intrusion, they are expected to be socially responsible, fair, and unbiased in news accounts, and the professionals within those media are expected to adhere to guidelines for taste, morality, and avoid undue sensationalism. With the *proliferation of media* through satellite, Internet, and other technologies, the key gatekeepers are no longer so easy to identify among a handful of important media organizations (→ Satellite Communication, Global; Internet; Internet News). In that respect, performance and accountability issues are more challenging for scholars given the wide array of content. It was easier in the past to describe the media map, taking as a surrogate measure, for example, the front page of the *New York Times* or the prime-time programs on the three traditional US television networks. “Taste” and responsibility issues are still relevant mainly for those broadcasters who are still obliged to please the government oversight agencies (→ Morality and Taste in Media Content).

Fining a broadcaster for an inadvertent display of a performer’s breast during a US Superbowl broadcast seems quaint now considering the graphic sex and violent content

easily available over the Internet. Although what are thought of as “the media” operate largely within large organizations, the rise of the *blogosphere and other Internet-based zones of communication* have, it is argued, strengthened the public sphere and the discourse that flows outside of large institutional structures (→ Blogger; Citizen Journalism). It has also increased the capacity for public monitoring of media decision-making, cross-checking news reports, and the overall transparency of the media production process. The ability of ordinary citizens to express their own critique of media performance adds to the ability to hold violators of important norms of truthfulness and fairness up for public scrutiny (Reese et al. 2007).

Other research takes a more external perspective on media performance, considering whether the media system itself is *functioning to the benefit of society*. While the commercial media are taken for granted in the US as the natural way of supporting media content, state-funded public media are more highly regarded in Europe and elsewhere. The relative merits of these systems have been a topic of concern. A critical perspective emphasizes the extent to which the media reinforce the definitions of the powerful, marginalizing and rendering invisible those voices that threaten the status quo. In spite of the seemingly vast array of television channels and publications, research into the political economy of media has examined the extent to which ownership of these outlets is still concentrated in a handful of corporations (Bagdikian 2000; → Political Economy of the Media).

### **MEDIA EXPLANATORY FACTORS**

On a “routines” level, research has often considered the general problems associated with producing a certain kind of message, such as news. For example, in order to solve the problem of “what is news,” journalists have found it useful to assume news is what officials say it is (Sigal 1973), even as technology allows for more event-driven news (Livingston & Bennett 2003). Understandings of these general tendencies are based largely on the media sociology carried out in the US and the UK, with a significant body of research in Germany, especially concerning → news values (→ News Factors). Given the wide variation among media round the world, however, generalizations about production and content must be made with caution.

Now that more → comparative research has begun to emerge, it is easier to distinguish between those practices common across countries and those peculiar to one or the other. Esser (1999), for example, compared newspapers in the UK and Germany on the basis of their → “tabloidization,” the tendency to lower journalistic standards in favor of sex, scandal, and sensationalism (→ Scandalization in the News; Sensationalism). British papers are more prone to tabloidization given their greater competitive environment, weaker legal protections for personal privacy, and lesser support for journalistic standards. Rather than claim that one country has a tabloid press and another does not, this kind of comparative research helps find general features of media production, ascertains the extent to which they are found in certain settings, and explains why they differ from place to place.

Although there are broad generalizations to be made concerning the symbolic map of the media, there are also important *differences across the various media*. These more

“organizational” issues involve the technological imperatives, audience considerations, economic and other dictates, as well as the regulatory environment that they each face. Each medium, whether radio, television, newspapers, or magazines, has its own unique problems to solve in providing a product to a reader, viewer, or listener. Each has its own historical and technological evolution within the host society. As the newest entry to the media environment, the Internet subsumes within it all of the previous media: audio, visual, and verbal. Its business model, qualities of scope, relative speed, and reach impose their own stamp on the nature of Internet news, entertainment, and other content.

### INTERNATIONAL AND COMPARATIVE ISSUES

Media production and content presents challenges in attempting to summarize research internationally, given the great variety of media operations and cultural norms. The highest level of the hierarchy of influences model, the ideological or socio-cultural, considers how the media function within a society, by virtue of there being a certain kind of system – which necessarily binds them to the prevailing social order usually associated with nation-states. These considerations often require a more interpretive analysis given the difficulty in statistically manipulating the presence or absence of a certain kind of system. Such an ideological analysis may consider how the media reinforce the definitions of the powerful, with this dynamic being common to a variety of national contexts, even if manifesting itself in different ways. Definitions of the situation are naturalized within news texts (Hall et al. 1978), which can be linked to media production practices that support them. More empirical comparisons can be made of comparable cases, treated differently by news accounts because of ideological state interests, as Entman (1991) showed in differing news coverage of the shooting down of airliners by the Soviets and the US.

A *macro-level of analysis* directs attention to cross-national comparisons of media production, where important patterns can be found. Shoemaker and Cohen (2006), for example, have successfully shown that news has a number of common patterns across nations, rooted, as they argue, in socio-biological needs. As media seek global markets, certain stories and programs travel more easily than others (Herman & McChesney 1997), and as news is coordinated across national boundaries, certain stories are consistently preferred for practical reasons (Cohen et al. 1996).

News has a certain consistent set of topics and actors featured across a variety of countries, even if these are filtered through specific national cultures (→ International News Reporting). *Global changes* in media ownership, new ways of carrying out gatekeeping across national boundaries, and emerging shared norms of professionalism all give greater emphasis to this perspective (→ Globalization Theories). Given the international reach of the current media, “global events” are increasingly the subject of research (→ Globalization of the Media). When globally significant events take place, such as the handover of Hong Kong from the British to the Chinese, they are nevertheless filtered through the national prisms of various news organizations (Lee et al. 2002) or locations where the world’s journalists converge to cover the same event or institution. So, under the continuing processes of globalization, this area of research faces the challenge of identifying the universal aspects of media and social representation, the enduring particularities of individual national contexts, and the increasing interactions between these levels.

# Media Relations

*Larsåke Larsson*

*Örebro University*

News media are the dominant way in which organizations of society disseminate information and persuasion to the general public (→ News). Networking, relationship building, and producing works to be published in the media are daily work for most public relations (PR) practitioners. The relation between the PR industry and the news media is therefore of interest for research in both → public relations and → journalism (→ Corporate Reputation; Trust of Publics).

The relation between the groups can be studied from at least two starting points. One is functional and instrumental, with the aim of improving the knowledge and skill of PR practitioners on how to deal with the press, and is often taught in handbooks. The other is research in social and political science, together with cultural and rhetorical studies, with the purpose of depicting and explaining the relation as well as discussing its implications for society and democracy (→ Cultural Studies; Rhetorical Studies; Rhetorical Theory of Public Relations).

Several researchers argue that a media focus has, in fact, grown in importance to the PR industry, especially pertaining to those active on the scene of policy shaping in the broader sense. Manning (2001) argues that media work has become a more central part of political activity in recent years, in line with Blumler's earlier findings that publicity advisers, PR experts, and campaign consultants "immerse journalists in what appears to be an increasingly manipulative opinion environment" (Blumler 1990, 104; → Issue Management; Political Communication; Political Marketing). Other researchers notice an increased interest from commercial groups in strategically mobilizing communicative power and attaining media space (→ Determination Theory in Public Relations; Public Relations: Media Influence).

## THEORETICAL CONCEPTS

Though the concept of PR is built on relationship development, this perspective has only recently become central to PR research, which has mostly preferred an organizational and management perspective. Ferguson (1984) proposed that relationships should be the unit for the study of PR and the best way to conceptualize it. Some researchers have formulated models for public relationships management – models exploring relations with all types of publics and stakeholders, not only the media (Broom et al. 2000; Ledingham & Bruning 2000; Jahansoozi 2006; → Stakeholder Theory).

One can easily see two levels of relationships, organizational and interpersonal relations (→ Interpersonal Communication; Organizational Communication). In the first case, organizations interact, as when a company sends a press release in its name to the media. In most cases and in everyday practice, the relations are likely to be mostly found at the interpersonal level, where, for example, a PR practitioner makes contact with a journalist or editor to promote a new idea. In the developing PR theory, media relations can best be

understood through research in interpersonal or relational communication (Wood 2000). Ledingham and Bruning (2000) present another typology with three types of relationships: interpersonal, professional, and community relations.

Most relations between the two groups result from actions taken by different interest groups with the aim of influencing the media to publish certain promotional items as news. Theories and concepts relevant to this fact are therefore interesting when studying and analyzing the PR–media relationship.

*Agenda-building theory* was developed by Cobb and Elder in 1972, but became the foundation of *agenda-setting theory* the same year (McCombs & Shaw 1972; → Agenda Building; Agenda-Setting Effects). While the agenda-setting theory refers to the question of how the media direct public awareness and debate, agenda-building theory discusses the question of where the agenda really is initiated – whether it is constructed by the media or earlier, by actors as political and organizational leaders. Weaver and Elliot (1985) formulated this question in more concrete words by asking who sets the agenda for the media, meaning that “it is not quite accurate to speak of the press ‘setting’ agendas if it is mainly passing on priorities set by other actors and institutions in society” (Weaver & Elliot 1985, 87). Recently, McCombs (2004) incorporated this thinking into his theory, when he discussed a third agenda level, other agendas (besides the media and public agendas), advanced by organizations, political campaigners, and PR professionals. Media agenda has become a dependent variable instead of the earlier independent variable (McCombs 2004, 98). Other researchers argue that the agenda is being set in a dynamic process where interest groups, actors, the media, and the public influence and are influenced by each other.

The influence toward the media from different interest groups and PR agents appears in many different shapes in daily life. It involves anything from traditional → press conferences and press releases to various ways of more or less successful long-term agenda-setting-related activities. Among other things, strategies for controlling the news agenda are based on producing and serving the media with material that promotes the instrumental purposes of the senders’ interests. This type of media influence and strategies for controlling the news agenda are today often referred to by the concept *news management* (Pfetsch 1998).

Meanwhile, news material from sources outside the media may also be seen as a contribution to journalistic work and as a way of cutting editorial costs (→ News Sources). Observations in line with that point of view have made way for the theory of *information subsidy*, meaning “efforts by policy actors to increase the consumption of persuasive messages by reducing their costs,” in the words of Gandy (1992, 142).

## DEVELOPMENT

Several reasons can be traced for the fact that the relations between the PR industry and the media and between PR actors and journalists are rather poorly researched, except for studies with the purpose of education on “how to do” the PR profession best. One reason is that PR is a relatively new research field, and another, as mentioned above, is that the research has addressed organizational and managerial questions.

However, the media have in many studies been analyzed in relation to other objects and phenomenon. There is, for example, extensive research about the relation between the media and institutional representatives such as politicians and authority leaders.

In recent years, studies of the relations between PR and the media have been published, most of them by European researchers and some of them with a societal/political and critical perspective (→ Organizational Communication: Critical Approaches).

## **MEASUREMENT AND FINDINGS**

Researchers in the field of PR have applied several different methods in the study of the relations between PR and their publics. Surveys have been constructed to measure relations with publics by featuring openness, trust, involvement, investment, commitment, satisfaction, and mutual control. Other studies have been conducted through personal interviews with PR practitioners and journalists, often together with document analysis. Studies of the results and effects of relationship have applied content analysis to determine what the media have published; sometimes studies compare what the PR industry and other sources have delivered to the media and what the media publish (→ Content Analysis, Quantitative; Content Analysis, Qualitative).

Even though the PR–media relation is an underdeveloped research area, studies show that the two groups often establish close relations in order to fulfill a mutual interest (Davis 2002; Larsson 2005). The reason is to be found in the need for both parts in their occupational behavior and task fulfillment – the demand to get promotion and instrumental information published on the one (organizational) hand, and the need to get news material to fill the news pages and programs on the other. A traditional exchange theory can thus be seen to explain the relation phenomenon, as well as a negotiating theory. The two parts are mutually dependent.

The situation is similar to what research has found about the relation between the media and institutional representatives such as politicians and government leaders (Sigal 1973; Gans 1979; Ericson et al. 1989). Here the relation is described as symbiotic, with Gans' metaphor "it takes two to tango" as the most well-known illustration. Some even talk about a love–hate relationship (Hess 1981).

The political sphere and official institutions are those organizations giving most attendance to the news desks and getting most publicity, in line with the media's obligation to inform in a democratic society. Several studies show at the same time that it is more difficult for the business and private company sector to achieve publicity as news in the media, except for business and trade media. On the other hand, some researchers claim that business in recent times has increased not only its ambitions but also succeeded in getting more publicity. One reason, discussed in a Swedish study, is that this sector seeks to give its promotional material a broader political and cultural approach and character, rather than being single-product launching and marketing (so editors accept it more easily without classing it as "text advertising"), as for example when a medicine company and its PR consultants inform about how to cure a disease instead of presenting a new medicine. This study also reveals at least two differences compared to the politicians/institutional–media relation. One is that the contact and relation building between the PR industry and the media is more one-sided, with the former as the active part. The other is that the relation is to a much lesser degree characterized by direct personal contact and is executed more via mail and telephone contacts (Larsson 2005, 2006).

Several studies have shown that a reasonably large proportion of published articles originates from *external sources* – in fact, most of the studies conducted show that more than half of the published articles studied stem from material originating from outside sources (for an overview, see Cameron et al. 1997).

The theory of information subsidy has, according to several scholars, increased its relevance to everyday journalism reality as a consequence of the financial and personnel cutbacks many news organizations have undergone lately (→ Cost and Revenue Structures in the Media). Some analysts claim that this type of contact and exchange has forced journalism to become increasingly dependent on, and more easily affected by, outside influences – a transformation of the professional conduct that has resulted in a more alienated journalism (Blumler & Gurevitch 1995; Bennett & Manheim 2001). According to Davis (2002), the cutbacks are one explanation of the fact that PR practitioners have come to strongly influence today's news agenda. He argues that the material they present has become extremely successful in passing itself off as "real news," and thereby, to a great extent, PR people have "worked to erode the autonomy of journalists at the micro level" (Davis 2002, 172). Other researchers follow this line:

what passes for news of politics is often an inextricable mixture of messages from different sources. Advertising, PR, reports of opinion polls, and propaganda become mixed up in the news product along with facts and editorial opinions . . . It certainly tends to undermine any simple faith in the reliability and independence of news. (McQuail et al. 1998, 253)

The view of media professionals as manipulated by representatives of the PR industry leads to questions about the media's position as a fourth estate (→ Spin Doctor; Spin and Double-Speak). The media's role as a public function in this regard might be discussed as a consequence of the activities conducted by, among others, PR practitioners: "the liberal description of the fourth estate media, based on an image of independent autonomous journalists seeking out news, has been severely undermined" (Davis 2002, 173). In accordance, Street reasons that "journalists are the lapdogs of partial interests, not the watchdogs of the public interest" (Street 2001, 146). Contrary to this view, McNair (2000) argues that editorial staff are fully capable of evaluating and disregarding material sent to them by the PR industry. The academic debate about the implications for society of the relationship between the PR industry and the media will certainly continue.

# Media System Dependency Theory

*Sandra J. Ball-Rokeach*

*University of Southern California*

As early as 1974, Ball-Rokeach presented the first in a series of papers that would unfold the concepts and assumptions of media system dependency (MSD) theory (Ball-Rokeach 1974). The paper was titled “The information perspective.” Its basic premise was that media effects flow from the information resources of the media system that are implicated in the everyday life requirements of people (micro), groups or organizations (meso), and other social systems (macro) to act meaningfully in ambiguous or threatening social environments. Thus, this paper launches the argument that the media system is best viewed as an information system whose powers vis-à-vis effects rest on the scarcity or exclusivity of their information resources – the creation/gathering, processing, and dissemination of information. Media information spans classical news and entertainment genres.

## THE CONTEXT OF MSD THEORY FORMATION

At the time of the initial formulation of MSD theory, the media system was relatively stable and bounded (→ Communication and Media Studies, History since 1968). The prevailing → media effects thesis (Katz & Blumler 1974) was that people are pretty much in charge of the gratifications they seek and find through their media uses (→ Uses and Gratifications; Media Effects, History of). MSD theory emerged, in part, as a felt difficulty with the proposition that the media per se had, at best, weak effects. Rather than trying to posit a powerful media effects alternative, such as was being developed in Gerbner’s → cultivation theory (Gerbner et al. 1980), MSD theory emerged to reframe the effects question to ask: “Under what societal and individual conditions do/don’t media have substantial effects?” The work was informed by other scholars’ attempts (especially those of Gerbner, Rosengren, and Wright) to move the discussion away from the largely social-psychological or micro-level of analysis – where selectivity processes and interpersonal influence were said to operate to conserve audiences’ established beliefs and behavior (→ Selective Exposure; Selective Perception and Selective Retention; Two-Step Flow of Communication). The aim was to develop a multilevel approach that might have greater phenomenological correspondence with people’s everyday experiences of media effects in periods of rapid social change and conflict (see Ball-Rokeach 1998).

## MAJOR CONCEPTUAL COMPONENTS: THE EARLY YEARS OF MSD THEORY

A point of departure was that media effects could not be accounted for in terms of the characteristics of the audience and/or the characteristics of the message, but required a multilevel ecological theory to capture an effects process wherein individuals and media are situated in their larger social environs (→ Models of Communication). The media production system operates in an environment where it has dependency relationships

with other social systems, and these relations not only affect the media's behavior but also contour the relationships individuals can develop with the media (Ball-Rokeach 1985). For example, media systems in the United States (→ United States of America: Media System) emerged initially in the context of a relationship with the political system such that the goals that individuals could attain via MSD relations were largely limited to things political. Over time the scope of media production expanded, through new dependency relationships formed with economic, religious, educational, recreational, health, and other systems, such that individuals could pursue like goals through MSD relations.

The dependency relation thus exists at multiple levels of analysis. In essence, it reflects the extent to which resources controlled by one entity (the media) have to be accessed by another party (other social systems, organizations, individuals) to attain fundamental goals. Thus follows the notion that effects are by-products of dependency relations more than they are by-products of clever persuasion or the characteristics of audience members. These dependencies arise when individuals, organizations, or other systems consider media information resources – the gathering/creating, processing, and dissemination of information both in → news and in entertainment genres (→ Entertainment, Effects of) – to be essential or preferable to alternative modes of achieving their goals. Of course systems, institutions, and organizations control resources that the media system and its constituent organization must access to attain their goals; that is, dependency relationships at these levels of analysis are two-way, varying from asymmetric (one party needs the resources of the other more than the other way around) to symmetric. They are also situated in a dynamic environment where the struggles for control of scarce resources, diffusion of new technologies, changing political economies, etc. effect change in the structure of MSD relations.

By taking an ecological approach, the theory places the emphasis upon the characteristics of the dependency relationship. It is not, for example, that individuals are dependent per se, but that they have a dependency relationship with the media that affects the likelihood of media effects. Most of the empirical testing of MSD theory focuses upon the media–audience (macro-to-micro) relation (see Meshkin 1999 for a review). That relation is conceived to be asymmetric and invariable in structure; that is, media resources are implicated in individuals' goals of understanding (themselves and their social environs), orientation (acting and interacting), and play (solitary and social) more than the resources of most individuals are implicated in media goal attainment. The media–audience-member dependency relation is variable with respect to intensity and scope. Intensity is conceptually defined in terms of how exclusive media information resources are and empirically assessed in terms of perceived helpfulness in goal attainment. Resource scope in the media–individual dependency relation is usually invariant – largely limited to the dissemination resource – as most individuals, in contrast to many organizations, do not try to control media information-gathering/creating and information-processing resources. Referent scope refers to the number of media forms (→ Television; Newspaper) implicated in a particular case. Goal scope is the most frequently addressed scope dimension and refers to the breadth of goals implicated in individuals' MSD relations.

Another major component of the theory is the view of individuals as embedded not only in interpersonal networks that tend to conserve shared beliefs and behavior, but also in a larger context, often marked by ambiguity, threat, conflict, and change, that tends to

open the door to media effects. The origins of the structure, intensity, and scope of individuals' MSD relations are thus grounded in their social as well as their interpersonal and personal environs (Ball-Rokeach 1985). Those environs are dynamic, i.e., changing over situation and time. Put briefly, the more problematic people's social environs, the more likely it is that the media information system will be a, if not the, major resource in people's efforts to understand and act meaningfully in those environs (→ Attending to the Mass Media). The prime condition for media effects, then, is when there are problematic social environs that prompt asymmetric, intense, and broad-goal-scope MSD relations. It is in this sense that media effects are conceived to be an outcome of the nature of media–audience–society relations (Ball-Rokeach & De Fleur 1976).

While the nature of the social environs is a key determinant of individuals' MSD relations, it is not the only determinant. There is substantial variation in how people respond or adapt to the same social environs. Under conditions of ambiguity, for example, some will actively seek to resolve the ambiguity, while others may seek to escape or withdraw (Ball-Rokeach 1974). In this case, the more active are also the more likely to experience media effects, because the media system is usually positioned as the best or most accessible information system through which ambiguity may be addressed. These active problem solvers, thus, would have more intense and probably broader-goal-scope MSD relations. How active an individual is at any one point in time and place will depend on major sources of individual variation. Most important are variations in goals or priorities that implicate media, variations in structural location or the degree to which people have access to alternative information systems (e.g., experts), and variation in interpersonal network discursive agendas.

### **MAJOR CONCEPTUAL COMPONENTS: ELABORATION OF MSD THEORY**

As MSD theory developed over the years, the macro-/micro-focus was expanded with increased attention to intervening meso-level forces; specifically, the interpersonal network (→ Interpersonal Communication; Social Networks). While interpersonal discussion of media topics had been incorporated into the theory early on (e.g., Ball-Rokeach et al. 1984), it was later incorporated in a somewhat different way. Instead of the more usual effects-buffer role, interpersonal discourse on media topics was conceived as a variable that could lessen or intensify media effects. The reasons for this unpredictability were made more explicit in subsequent work (Ball-Rokeach 1998), where the interpersonal network was conceived as also having dependency relations with the media for much the same reasons as had been argued for individuals. For example, when the social environs are ambiguous due to rapid social change, the network must also access the best information resources available to make sense of the members' shared environment. Established beliefs affect information processing, but because they may not be sufficient for understanding, the door may be open to new or altered beliefs. The discourse agenda of interpersonal networks of friends, co-workers, neighbors, and the like is likely to include topics that are a product of MSD relations. It was at this point in the development of MSD theory that Ball-Rokeach incorporated agenda-setting processes (→ Agenda-Setting Effects) into her MSD model of media effects.

More than 30 years after the initial foray into MSD theory, the theory is still employed and elaborated in empirical research. Most studies examine the intensity of individual

MSD relations, but there are also case studies of macro-level issues, such as the evolution of MSD relations under conditions of social change (see Meshkin 1999). However, major changes in media production resources suggested the need for fundamental elaboration of the theory to take into account the less bounded and more chaotic media landscape of the twenty-first century. Obvious examples include the implications of going from three dominant television networks to hundreds of television channels, the emergence and blending of the → Internet with traditional media, the explosion of ethnic media (→ Ethnic Media and their Influence; Ethnic Journalism), and the multimedia and increasingly centralized ownership structure (→ Media Conglomerates; Ownership in the Media).

### **FROM A MEDIA TO A COMMUNICATION ECOLOGY THEORY**

In response to these changes, MSD theory has become even more ecological, moving away from a conception of the bounded media system to a communication ecology where traditional media, new media, ethnic media, the media of community institutions, and interpersonal discourse operate in the context of each other. They become information system alternatives for people to select according to which one or which combination of alternatives best serves particular goals. Another major change has been to drop the term “dependency” and replace it with the term “connectedness.” While “dependency” had a sound theoretical basis in Emerson’s notion that power is the flipside of dependency, the term all too often connoted a dependent personality. Especially when considering the more complex communication ecology, it is helpful to speak of people, groups, and organizations as having connections with alternative information production systems.

The expanded version of MSD theory has been incorporated into communication infrastructure theory (CIT; see Kim & Ball-Rokeach 2006). Some researchers continue to use the earlier version of MSD theory when they are examining the effects of a particular media form(s) and this is appropriate. As any good ecological theory should, MSD theory has evolved over time to adapt to changing environments, including insights and knowledge introduced by other theorists and researchers, especially Elihu Katz, Jack McLeod, and Lewis Friedland. At present the primary effects addressed by CIT are civic engagement, health literacy and disparities, the important roles played by ethnic media in diverse urban communities, the connections between virtual and place-based communities, and the effects of communication environments on the strength of neighborhood storytelling networks (→ Storytelling and Narration).

## **Media Use and Child Development**

*Patti M. Valkenburg*

*University of Amsterdam*

Traditionally, research into the effects of television has assumed that children are passive recipients on whom television has a powerful influence. Since the mid-1970s, however, media effects research has increasingly recognized the child viewer as an active and motivated explorer, rather than a passive receiver (→ Media Effects; Media Effects, History of). Recent research suggests that children are critical evaluators of what they see in the media. Even very young children have been shown to actively screen media offerings for attractiveness and understandability and make an effort to interpret television images in their own terms (→ Audience; Audience Segmentation; Media Use by Children; Media Use across the Life-Span).

### **THE RESEARCH AREA**

Media use and child development are mutually related: not only does children’s media use influence their development, but children’s developmental level also determines their media uses and preferences. According to research that has been conducted thus far, developmental level is one of the most important predictors of children’s media uses and preferences. This entry will focus on the question of how children’s developmental level influences their

media use and preference. The question of how children's media use influences their child development will be discussed in other entries (→ Educational Television, Children's Responses to; Computer Games and Child Development; Fantasy–Reality Distinction).

In the past decades, several media-effects researchers have suggested that the *concept of optimal level of stimulation* might be central to understanding young children's media uses and preferences (e.g., Anderson & Puzles Lorch 1983). These authors assume that children prefer to look at stimuli that they can at least partially incorporate into their existing comprehension schemas, and that they show less preference for extremely simple or extremely complex stimuli. This moderate-discrepancy hypothesis predicts that at any given age, a moderate level of stimulus complexity is preferred and that this level increases as the child matures.

The *moderate-discrepancy hypothesis* predicts an inverted-U-shaped relationship between program comprehensibility and content preference: Children's attention to media should be highest for content that departs only slightly from what they know or are capable of (Anderson & Puzles Lorch 1983). The moderate-discrepancy hypothesis offers a viable explanation of why the media uses and preferences of children in various age groups differ so greatly. After all, the perceived simplicity and complexity of media content change dramatically as children mature. Media content that is only moderately discrepant and therefore attractive to 4 year olds may be overly simple and thus unattractive to 10 year olds. The next section explains some typical developmental characteristics of preschool and young elementary school children and argues how these characteristics might affect their uses and preferences for media content. In the section after that, I will do the same for children in middle childhood.

### EARLY CHILDHOOD: AGES 2 TO 7

Around 2 years of age, most children watch television on a daily basis, and from this age their attention to program content increases dramatically. A study by Anderson and colleagues (1986) demonstrated that 1-year-old children have their eyes on the screen for only 12 percent of the time a television is on, whereas for 5 year olds this figure is 70 percent (which seems to be the maximum, because the average time that older children have their eyes on the screen also fluctuates around 70 percent).

The rapid increase in attention to television programs between 1 and 5 years of age reflects the proportionally rapid increase in children's understanding of television content. From 2 years on, children start to develop a genuine interest in the storyline of media productions. In an observation study by Valkenburg (2004) among toddlers and young preschoolers, almost half of the children asked the → co-viewing researcher questions while viewing in order to improve their understanding of the program's content. This asking of questions started at around the age of 2.5 years.

For preschoolers and young elementary school children, there is an unclear *demarcation between fantasy and reality*. Virtually anything is possible in this child's imagination: A sponge can become a rock, bears can talk, and the wind can pick the child up and take him or her away. Research by Morrison and Gardner (1978) has demonstrated that between the ages of 3 and 10 years, children gradually become more accurate in distinguishing fantasy from reality on television. At first, children believe that everything on television is real. Jaglom and Gardner (1981), for instance, observed that 2–3 year olds ran to get a

paper towel to clean up an egg they saw break on television. In addition, most 4 year olds who participated in a study by Sue Howard (1998) were convinced that Big Bird and Bugs Bunny were real.

Children's failure to distinguish fantasy and reality can affect their preferences for media content in important ways. First, because fantasy and → cartoon characters are perceived as real, they can be just as engaging as real-life characters for young children. Second, some special effects or stunts, such as a character vanishing in a puff of smoke, can have a great impact. Because young children cannot put these events in perspective by understanding that they are cinematic tricks, they are more strongly affected by them.

Another quality of preschoolers' thinking is their tendency to center attention on an individual, striking feature of an object or image, to the exclusion of other, less striking features. Piaget (1954) has referred to this tendency as "*centration*" or "*perceptual boundedness*." A study reported in Acuff (1997) is illustrative of this tendency of young children. In this study, girls were presented with three dolls. Two of the dolls were very expensive, had beautiful and realistic faces, and came with sophisticated mechanical effects. The third doll was cheaply made, but this doll had a big, red sequined heart on her dress. To the surprise of the researchers, the majority of the girls preferred the cheap doll with the sequined heart. This choice is typical of children in this age group. When judging a product or media content, they focus their attention on one striking characteristic, and they therefore have little eye for detail. Their descriptions of television characters tend to fix on single, physical attributes, without integrating them into an overall picture. Young children pay less attention to what characters are doing or saying, and pay most attention to simple, brightly colored visuals and colorful, uncomplicated, nonthreatening characters (Valkenburg 2004).

Children seem to have an innate *tendency to respond to language*. They enjoy listening to songs, rhymes, and music. In a study by Cupitt and colleagues (1998), almost half of the mothers of 2.5 year olds reported that their child had imitated music, rhymes, or songs from television. This study also showed that nearly all of the 2.5 year olds had interacted with television programs while watching, for instance by singing, dancing, or clapping hands. It is no surprise, therefore, that songs, rhymes, and music are often used successfully in educational and entertainment programs for young children.

Because of their immature cognitive capacity, children in this age group need more time than adults to *interpret and make sense* of information and television images. This is the reason why young preschoolers often respond best to programs with a slow pace and with lots of repetition, for example *Barney and Friends* or *Mr. Rogers' Neighborhood*. For the same reason, young preschoolers often prefer familiar contexts and visuals, and objects and animals that they can label, such as a cat, a dog, or a horse. According to Lemish (1987), they like to watch programs that show babies and young children, and they adore nonthreatening real or animated animals, such as kind birds, friendly dinosaurs, and babyish creatures like the Teletubbies.

By the time they are 4–6 years old, children begin to develop a preference for more fast-paced programs. By that age, they become more responsive to verbally oriented shows, with more sophisticated forms of humor, like *The Simpsons*. And they often find slower-paced programs with friendly characters boring or childish. At that time, they begin to prefer more adventurous themes located in foreign countries or in outer space, and more complicated characters.

## MIDDLE CHILDHOOD: AGES 8 THROUGH 12

In contrast to preschoolers, the fantasies of 8–12 year olds more often entail realistic and plausible themes. In this period, children develop a sincere, sometimes even exaggerated, *interest in real-world phenomena*. They can be highly critical of television programs and commercials that lack realism. According to Mielke (1983), children in middle childhood continue to like animals, but they are mainly interested in real-life animals. Because most fantasy characters have been demystified, children in this age group tend to become attached to real-life heroes, such as sports heroes, movie stars, and action heroes.

With the developing ability to “decenter,” children come to *appreciate details*. As explained earlier, a preschooler may focus on only one striking detail of a toy – a doll’s clothing, for example. For the 8–12-year-old child, many characteristics of a toy may be carefully observed, from the face and body to details of the doll’s clothing to how it moves. At this age, children become progressively critical of television programs of low quality, such as those that are poorly produced or repetitious. They are no longer content with simple, salient characteristics, such as a colorful cartoon character. Unlike younger children, who are greatly impressed by special effects and characters with special powers, older children seem to agree that special effects by themselves are not enough.

During middle childhood *peer interactions* become increasingly sophisticated (→ Friendship and Peer Interaction). Because children in this age group develop such a strong sense of commitment and loyalty to the norms of their peer group, they are increasingly sensitive to the thoughts, opinions, judgments, and evaluations of other children, and become very sensitive to what’s “cool” and what’s “in.” They therefore become alert to how to behave in public and how to avoid being ridiculed with respect to what they wear, or prefer to watch on television. For example, older children feel the need to firmly demonstrate their aversion to programs designed for younger children or for shows that feature characters younger than they are.

Current media theories assume that children purposely select and expose themselves to media content to satisfy specific needs. These theories also assume that any effect of media content on children is enhanced or mitigated by how the child perceives it. Research has shown, for example, that the effect of television violence on aggressive behavior is mediated by the extent to which a child likes to watch violent programs (→ Violence as Media Content, Effects on Children of). To understand media effects on children, then, it is crucial to gain insight into children’s uses of and preferences for media content. This entry has discussed how age affects children’s media uses and preferences. Future research should focus on how other child characteristics, such as personality characteristics and emotional development, may affect children’s media preferences and selective exposure to television content.

## **Media Use by Children**

*Marina Krcmar*

*Wake Forest University*

Media play an important role in the lives of adolescents and children. Especially as they age, today's children and adolescents are very frequently connected to each other by means of some medium such as email, instant messenger, mobile phones, and beepers. However, when other media such as → television, the → Internet, → video games, and music (→ Popular Music) are added to the list of → interpersonal communication devices, children and adolescents are not merely perpetually linked but perpetually plugged in. In the US, for example, approximately 25–33 percent of adolescents use multiple media “most of the time.” Therefore, the amount of media to which children are exposed may be increasing even faster than the sheer hours spent with media (→ Media Use and Child Development). This trend seems to be occurring in both the US and in Europe (Valkenburg & Peter 2007); little evidence exists that children and adolescents in less affluent countries are as media-saturated.

As Andreason (2001) has pointed out, the continual convergence of media technology, such as accessing television programs from a computer screen or using a mobile phone to retrieve email messages, makes defining categories of media somewhat complicated

(→ Technology and Communication). Therefore, researchers interested in children's media use sometimes refer to computers, television, videos, and DVD use simply as "screen time." In a given day, 61 percent of children under 1 year old spend time with television or videos and DVDs. By the time children are 2–3 years old, 88 percent spend time in front of a screen daily (Kaiser Family Foundation 2006). Among older children, as they gain facility with media and parent controls decline, media use increases. Screen time for 8–10 year olds averages 5 hours per day; 11–14 year olds spend approximately 5½ hours with a screen and 15–18 year olds slightly less (Kaiser Family Foundation 2005). These patterns are relatively consistent in the US and in Europe (Valkenburg & Janssen 1999).

### TELEVISION USE

Television still occupies the largest proportion of time spent with media for children in every age group. With a greater than 90 percent saturation rate in countries ranging from Finland to Jordan to Tunisia (World in Figures 2006), many children live in a home with a television, making it easily accessible for children of most income levels, especially in North America and Europe. Based on research conducted in the US, children below the age of 1 watch approximately an hour of television daily, whereas children aged 2–6 watch approximately 1½ hours (Kaiser Family Foundation 2006). Children aged 8–14 watch approximately 3 hours; however, by the time children hit 15, viewing decreases to approximately 2½ hours of television per day (Kaiser Family Foundation 2005).

Demographic variables other than the age of the child also seem to affect the amount of time spent watching television. For example, parents with higher levels of *education* tend to have children who watch less television. In addition, black children watch somewhat more television (approximately 4 hours per day) than either Latino children (approximately 3½ hours) or white children (approximately 2¾ hours). Ultimately, however, the strongest predictor of children's television use seems to be parents' own use of the medium (Kaiser Family Foundation 2005). Parents who watch more television consequently have children who watch more (→ Exposure to Television; Media Use by Social Variable; Attention).

In terms of *content preferences*, approximately half of the children aged between 1 and 6 watch both educational and entertainment children's programs (→ Educational Media Content; Enjoyment/Entertainment Seeking). Among preschoolers, approximately 15 percent watch adult shows at least some of the time. However, as children enter middle childhood, 39 percent of the 8–10 year olds watch adult shows such as → situation comedies. As they begin to watch more adult programs, they watch fewer educational programs, with 47 percent of the 8–10 year olds watching educational programs but only 21 percent of the 11–14 year olds doing so. Instead, older children seem to prefer reality shows, dramas, and movies (→ Reality TV; Drama in Media Content). Moreover, older children in particular appear to shift at least some of their screen time to computers (Kaiser Family Foundation 2005).

The greatest difference in content preference appears to be between boys and girls, rather than between European and American children. For example, boys in both the Netherlands and the US prefer programs that contain action and violence; whereas girls in both the Netherlands and the US prefer programs that they deem comprehensible (Valkenburg & Janssen 1999). In fact, the most notable finding in their cross-cultural

study was that US and Dutch children were remarkably similar in their likes and dislikes regarding entertainment programs.

## COMPUTER USE

Although children's computer use is on the rise, there remains considerable variation in computer ownership worldwide. For example, Switzerland has the highest rate of ownership, with 71 computers for every 100 persons, 66 for every 100 in the US, and only 20 per 100 in Spain. Rates in Africa and some parts of Asia are unknown, although thought to be significantly lower (World in Figures 2006).

Among children, approximately 75 percent of the US children *under the age of 6* have a computer in the home, with approximately 30 percent having high-speed Internet access (Kaiser Family Foundation 2006). There is limited information available about what these very young children do with their computer time; however, the available evidence suggests that many preschoolers visit websites for children; whereas some also spend time on the computer playing games (→ Computer Games and Child Development). It appears that it is not until children are somewhat older that they use computers to communicate with their friends, do homework, and listen to music (→ Age Identity and Communication; Electronic Mail).

Children between the *ages of 8–10* spend approximately 40 minutes per day on a computer and half of that time is spent playing computer games (Kaiser Family Foundation 2005). They also visit websites, but the time spent in other activities such as chat and email is negligible (< 3 minutes). As they age, the time spent on a computer increases and most of that increase results from increased time communicating via a computer. For example, 11–14 year olds spend an average of an hour a day on a computer, and although they still play almost 20 minutes of computer games, they now spend approximately 30 minutes communicating using email, chat, or instant messenger; whereas 5–18 year olds spend nearly 30 minutes using instant messenger, another 10 minutes in chatrooms or using email, and almost 20 minutes visiting various websites (Kaiser Family Foundation 2005).

*Gender differences* exist as well. Boys play more computer games (22 minutes per day to girls' 15 minutes), whereas girls spend more time visiting websites (16 minutes to boys' 12 minutes; → Girl Culture). Girls are also more likely than boys to spend time using computers to communicate (Kaiser Family Foundation 2005).

There are also differences between *children in various countries*. For example, although Internet access and use is on the rise across Europe, children in the US have somewhat higher access rates (Valkenburg & Soeters 2001) than children in the Netherlands. In addition, differences exist within Europe regarding parents' attitudes towards computer and Internet use for their children. Some 81 percent of German parents think that the most positive impact of the Internet for their children has been its effect on children's eventual ability to enter the job market; parents in the UK (73 percent) are more likely to state that the Internet has had a favorable effect on their children's homework. Lastly, parents in France (71 percent) are more likely to value the impact of the Internet on their children's interest in hobbies.

In both the US and in Europe, both computer access and Internet access are positively associated with parental income (Livingstone & Bovill 1999). Consistent with this trend,

children in less affluent countries, such as Rwanda, Libya, and Nigeria have consistently lagged far behind in their access to computers and the Internet. As a result, programs such as OLPC (one laptop per child), a nonprofit, UN-backed organization, have delivered millions of cheap wind-up computers to these countries to bring information technology to communities with no electricity (*The Times* 2007).

### CONSOLE AND HAND-HELD VIDEO GAME USE

In the US, only 11 percent of children under the age of 6 play *video games* on an average day and those children play for slightly less than an hour (Kaiser Family Foundation 2006). However, by the time children reach 8–10 years of age, 59 percent play some video game daily. Following a pattern similar to their television exposure, video game play then begins to decrease in late childhood. By the time children are 15–18, only 39 percent play a video game daily, although when computer games are included, a total of 65 percent of the 8–10 year olds and 49 percent of the 15–18 year olds play some type on interactive game (Kaiser Family Foundation 2005).

Children also differ in their console and hand-held game play by sex, by race, and by education of the parent. For example, more boys than girls play console or hand-held video games every day (63 vs 40 percent). Furthermore, boys tend to prefer action games whereas girls prefer fantasy or puzzle games (Buchman & Funk 1996). African-American children spend significantly more time playing video games (1 hour 26 minutes) than Hispanic children (1 hour 10 minutes) and than white children (1 hour 3 minutes). Differences also exist based on the education of the parent. Interestingly, children whose parents attended but did not complete college spend significantly less time playing video games than children of parents who either completed high school or who obtained college degrees (Kaiser Family Foundation 2005).

### USE OF OTHER MEDIA

Although *mobile phone* use is on the rise worldwide (World in Figures 2006), the majority of the research looks at adults or simply overall use. However, a recent study conducted in New Zealand suggests that children's use of mobile phones is also increasing (Census at School 2005). The largest increase was for 9 year olds who were the youngest children surveyed. Among this age group, the number of children who owned their own mobile phone increased by 120 percent since 2003. Among 14 year olds, 84 percent own their own mobile phones. Although parents may give their children mobile phones to use in an emergency, it seems unlikely that use is limited to that. The primary complaint parents have about their children's mobile phone use is large mobile phone bills.

Children as young as 1 year old spend time *listening to music* on the radio, on CDs, tapes, and MP3 players. In fact, 0–1 year olds spend slightly more time (1 hour 4 minutes) listening to music than 2–3 year olds (1 hour) and than 4–6 year olds (53 minutes; Kaiser Family Foundation 2006). 8–10 year olds spend almost an hour (59 minutes) daily, and that length of time increases as children enter their teen years. 11–14 year olds listen to 1 hour 42 minutes daily and 15–18 year olds 2 hours 24 minutes daily (Kaiser Family Foundation 2005).

## **Media Use, International Comparison of**

*Patrick Rössler*

*University of Erfurt*

Mass media content is created for audience consumption. Without at least a small audience, the communication process remains unilateral and incomplete. Despite its relevance for media production, regulation, and → marketing, data on media use is systematically collected only in a few (mostly western) countries of the world. Hence the

international comparison of media use patterns remains fragmentary. Evidence provided by global research agencies is often difficult to interpret because a standardized definition of *media use* is lacking. In some cases, data on the distribution of media offerings (e.g., circulation figures) replaces genuine data on media use because the latter is not recorded. With usage patterns changing over time, this overview focuses on the description of valid sources rather than presenting research results that might soon be outdated. Nevertheless, the picture drawn for purposes of exemplification refers to the data available as of 2006 (→ Exposure to Communication Content).

## FACTORS INFLUENCING MEDIA USE

Globalization of the media as a core issue in academic discourse includes the assumption that even remote areas of civilization are characterized by a substantial amount of media use. However, individual usage patterns always develop within a framework of societal boundaries. Usage patterns depend on several factors that influence the conditions under which media can be used at all, and apply differently to nations worldwide.

Among these is, first, the *system of government*. Constitutions of nations in the western hemisphere enshrine freedom of speech (→ Freedom of the Press, Concept of; Freedom of Communication; Freedom of Information). Other political systems hold a different perception of media regulation, including → censorship or access barriers, while their cultural or religious background may enhance the tendency to self-censorship among communicators. This may limit the range of media available for use. *Communication style* in a society affects media use. Cultures (→ Culture: Definitions and Concepts) are characterized by different rules and social conventions regarding how media are used, which media are used and for what purpose. For example, religious practices may inhibit media use in certain situations. Also, societies based on mutual respect and courtesy may force their members to use media appropriately. Media use depends also on → access to the media, which have different prerequisites for proper distribution (*infrastructure for distribution*). Newspapers and magazines require physical transport and so roads, boats, airplanes; audiovisual media require technical equipment such as broadcasting stations or satellite transmission.

Beyond technical considerations, access is constrained by individual predispositions, particularly by *individual prosperity*. Print media as well as pay-TV stations and → Internet providers charge their customers for media use. The amount people are able (and willing) to spend for media varies with individual living conditions. Media use is pointless when users are unable to understand the meaning of the offerings (→ *media literacy*). When illiteracy is widespread in a society, media based on written text will not be very popular compared to audiovisual media relying on the power of the image or the spoken word. Beyond the mere decoding of the content, making sense of it becomes an issue as well: understanding media coverage requires a fundamental knowledge among potential audience members for a meaningful interpretation of messages.

*Digitalization and mobility* also play a role (→ Digital Media, History of). Media use always occurs in a particular situation with its own spatial arrangement. If using a certain medium requires a special device (like a TV set or a computer) the opportunity for its use is limited by how much time and which times those devices are available or accessible for. Wireless devices such as mobile phones exploit the digital revolution and provide

ubiquitous but expensive access to sources. At the same time, online database technologies allow for individual consumption of content according to one's own schedule.

The analysis of media access and media use in different countries should *avoid two misinterpretations*. The first is that the diffusion of "new" media inevitably follows a linear process that ultimately leads to a saturated audience. From this point of view, regions with a lower distribution wrongly may be perceived as laggards compared to more advanced regions. The second misunderstanding refers to the assumption that the use of a certain medium has the same meaning or influence in different cultures. Moreover, the use of a certain medium and its meaning develop in a process of appropriation and domestication (Morley & Silverstone 1990).

### USE OF DIFFERENT TYPES OF MEDIA

Despite an increasing media convergence ("media meshing"; see European Interactive Advertising Association 2006), media use patterns can still be described following a segmentation of media types. Moreover, the data available are organized accordingly; the countries mentioned in this section serve as examples, as the list of potential instances is long. Detailed information on nation-specific media use patterns can be found in Johnston's (2003–) *Encyclopedia of international media and communications* and in "The world factbook" in the category on "communications" (CIA 2006).

#### Television Use

Infrastructural preconditions for TV access as well as program supply differ substantially between different parts of the world. Data on the role of television in more than 35 countries (based on local surveys) is collected by the annual *international key facts* study (IP International Marketing Committee 2005).

In western democracies such as the US or European nations (see Interview-NSS 2006), but also in technically more developed parts of Asia (Japan, South Korea, and even China), 95 percent and more of households are equipped with a TV set. On the other hand, India (44 percent) and South Africa (68 percent) are examples of the larger group of countries in which television-equipped households are much less prevalent (data for 2002). Television diffusion may even vary between different areas within the same country, notably rural and urban environments. An important factor is marked by the technical basis of TV distribution – by networks or cable or satellite channels. While the latter allow for the reception of a broad variety of channels in several languages, terrestrial broadcasting is usually limited to a smaller range of channels (→ Television Networks; Cable Television; Satellite Television). Another difference is marked by the availability of additional pay-TV programs within a system.

On the basis of time devoted to TV use, the leading role of television as a dominant mass medium is confirmed for most countries. Average time spent in front of the screen exceeds 4 hours in some cases (e.g., Macedonia, US, Poland, Italy), with a large proportion of national mean values ranging between 3 and 4 hours (including Japan, China (Beijing), Germany, and most other EU countries). In poorer and densely populated areas such as parts of India and Southeast Asia, average viewing time may drop to 2 hours and below,

but the same is true for the highly developed South Korean audience. In the Arab world, too, TV has taken the role of the most relevant and most influential medium in society. Satellite television has introduced liberal entertainment programs and, with *Al Jazeera*, a leading outlet for political information, according to surveys in these countries. The USA holds the pole position with adults viewing TV for 297 minutes per day on average. US digital TV reception exceeds 85 percent of all households nationwide, while 70 percent of the population can choose from 100 channels (→ Exposure to Television).

### Radio Use

With its ubiquitous availability and its limited technological requirements, radio has established its role as an unobtrusive companion in the daily life of a global media audience. Daily coverage reaches more than 80 percent in many countries, with a listening time that often exceeds that of television (see IP International Marketing Committee 2002). The popularity of radio is closely tied to its subsidiary use characteristic: Demanding only limited attention, radio programs can easily be listened to while pursuing other activities, even in the workplace or in a car. As a consequence, a substantial part of radio use takes place outside people's homes and while doing other things. Mobility has always been an important factor of radio use.

Beyond this general description, national differences in usage patterns should not be neglected. Taking *Europe* as an example, use in the workplace peaks in Finland while the share of radio consumption in the private home reaches almost 90 percent in Belgium, against the worldwide trend toward out-of-home use. Other differences refer to the daily routines of listeners, with radio serving as a complement to TV use. In some countries, radio use peaks early in the morning, followed by a steady drop-off during the day and almost negligible figures in the evening when TV prime time begins (e.g., in the UK or in Germany).

While the general level of radio use is equally high throughout Europe, dissimilarities can be observed in other regions of the world. Looking at *Asia*, access still is an issue, with 15 percent or less of inhabitants owning a receiver in, e.g., Myanmar, Cambodia, or Laos. It should be mentioned that in some areas it is still common to attach speakers to high trees or poles to play music and to read out newspaper articles in order to provide a radio-like program. Although in Japan and South Korea, there is an available receiver for every person, the actual use figures rank only third after TV and the Internet (e.g., Japan: 94 minutes per day in 2004). In the Arab world, radio is rated higher due to the strong oral traditions in these cultures. Recently, religious content has become increasingly important, with listeners being confronted now with prayers outside the mosque, and, as a sideline, female users accumulating religious knowledge, which contributes to strengthening women's civil rights to a certain degree (→ Exposure to Radio).

### Newspaper and Magazine Use

The use of daily → *newspapers* is related to audience literacy and thus varies heavily among nations. At one end of the range, in countries such as Cameroon, only one newspaper copy is available for 1,000 inhabitants on average, but nevertheless intense sharing means those papers reach 19 percent of the population (data for 2000). At the other end, in

Scandinavian countries, Sri Lanka, Singapore, and the UK almost 90 percent of the population look into a newspaper at least once a day. Furthermore, the informational basis for these figures differs substantially. For example, Norway's high reach is caused by 23 different newspapers available per 1 million inhabitants, while the same number of Japanese and Chinese readers has only one newspaper on average to choose from. Few newspapers in these countries show an extremely high circulation (World Association of Newspapers 2005).

The *global downward trend* of newspaper use has continued unchanged in recent years, although for newspaper use statistics the insight is particularly true that figures may tell a different story according to what is considered to be a newspaper (see also Schneider & Schütz 2004 in detail). The tradition of subscribing to a newspaper is not common in every media system, although the permanence of a newspaper delivered to one's home increases the probability of newspaper use, as well as daily routines including newspaper use (such as the morning breakfast, commuting periods, or work breaks). For rural areas in Africa, reliable distribution is a major obstacle, combined with widespread illiteracy, lingual fragmentation, and poverty. Therefore newspaper use is limited almost exclusively to larger cities. A completely different situation can be found in Latin America, where the press has always played an important role in political conflict.

Related to the newspaper market is the field of → *magazines*, though differing in that there is a positive trend in audience interest and China is the world leader in production (8,135 different titles in 1999). In all regions of the world, the number of magazine titles is steadily increasing, while the total number of copies sold, indicating users' interest, remains rather stable, reducing the audience of a single outlet permanently (Distripres 2006). Thus, more than any other, the field of special interest magazines is dominated by the production of similar formats in different languages for similar target groups in different countries (see below; → Picture Magazines; Exposure to Print Media).

## **Internet Use**

Since the mid-1990s, the Internet in general and the world wide web in particular have attracted an increasing audience worldwide (UCLA Center for Communication Policy 2003). Closely tied to an efficient technical infrastructure, dynamics have been more intense in developed countries. Penetration rates (2005) peak where 75 percent and more of the population report that they have used the Internet within the last week, such as in Scandinavian countries, the Netherlands, South Korea, or the US (Eurostat 2006, 186). Due to the technical requirements, Internet use in developing countries in Africa and Asia is still considerably lower, with mobile technologies opening an option to overcome the dependency on cost-intensive landline cables.

Although the share of Internet users among the population is low in China and India, they already contribute substantially to the estimated more than one billion users worldwide. Given the high population growth rates especially in China, it is expected that English as the lingua franca of the Internet will soon be complemented by Chinese. Recent technical innovations and the emergence of the so-called "Internet 2.0" have changed usage patterns dramatically: Individual blogging of content (→ Blogger), peer-to-peer exchange of data, and interactive gaming (→ Computer Games and Reality

Perception) have intensified the traffic on the global net and, at the same time, increased the hardware and software standards (European Interactive Advertising Association 2006).

Individual use patterns differ according to the places where access is available – in countries with low diffusion rates, public access points (e.g., Internet cafés) are more important than in countries with a high penetration rate, where the personal home is the dominant access point (→ Digital Divide). Still, the workplace and/or educational institutions (schools, universities) are important access providers, and they are also used for private purposes. Data from the Nielsen Internet Panel (including 11 countries) suggest that in late 2006, the average Internet user had 34 private Internet sessions with about 30 hours of Internet use in total, which equals a 1-hour-session per day (→ Exposure to the Internet).

### **Use of Mobile Communication Devices**

In 2004, more than 1.7 billion mobile phones (→ Telephone Talk) were distributed worldwide, most of them in Asia (41 percent) and Europe (33 percent). The availability of prepaid phone-cards contributed substantially to the diffusion of mobile devices. Penetration is highest in European countries, where each person owns (on average) more than one mobile phone. Due to technical constraints and a different billing system, penetration is lower in the US and in Australia (International Telecommunications Union 2006). For this type of media, it is highly relevant to distinguish between distribution of devices and their actual use: In Norway, for instance, 102.4 mobile phone contracts were registered among 100 inhabitants, but still more than 10 percent of the population does not use mobile phones at all. On the other hand, studies from Tanzania suggest that more than 85 percent of the population actually use mobile phones by sharing them, while only five contracts can be found among 100 persons.

In the case of *mobile phones*, the term “use” covers a whole range of different activities. Calling and answering the phone represent only a small portion of activities. In 2004, sending and receiving text messages cumulated to more than 35 billion within three months. Other multimedia functions include Internet access, photography, making short films, playing music or video games, and of course sending and exchanging data files (Kearney 2005). In fact, current mobile devices have become portable microcomputers that accelerate the process of convergence between different media application. Moreover, the distinction between mass media and individual communication gets increasingly blurred, and the same is true for public and private use of media applications (→ Mobility, Technology for).

### **CROSS-NATIONAL MEDIA FORMATS**

With regard to media content, international use can also be generated by cross-national distribution of the same or similar products. On the level of entire channels, transnational television is a common phenomenon in Europe. Beyond simple cross-border broadcasting, which seems unavoidable for territorial reasons, several channels expressly address a transnational audience. According to Chalaby (2005), such channels can be classified as

(1) ethnic, (2) multi-territory, (3) pan-European, and (4) networks. The example of Al Jazeera mentioned above illustrates the relevance of satellite TV for making content accessible to cross-national audiences (→ Arab Satellite TV News). Although few studies are available, this type of content is ideal for an international comparison of media use.

Furthermore, economic globalization (→ Globalization Theories) also *implies trading with successful media products and formats*. Two different business practices are dominant in this field and can best be explained for the TV market: First, producers simply sell their program to a channel in another country, where it is dubbed, subtitled, or broadcast without modification. The global distribution of serialized fiction programs (predominantly from the US) such as *Dallas* or *Dynasty*, or more recently *Emergency Room* and *CSI*, follows this strategy.

Second, national broadcasters *buy the idea* of a specific format and adapt it to their national audience with major or minor changes. This concept is pursued in the case of, e.g., *Big Brother* or *Who Wants to Be a Millionaire?*, and more generally in the field of nonfiction entertainment. Nevertheless, the plots of successful telenovelas or → soap operas are also sold and copied worldwide. The result remains the same: a global audience (which might reach a size of 110 million people watching the different local versions of the *Idols*-shows) confronted with a roughly similar media offering (→ Globalization of the Media; Americanization of the Media).

### COMPARATIVE ACADEMIC RESEARCH ON MEDIA USE

Most of the empirical evidence presented earlier was collected by market research agencies interested in commercially relevant data on the success of media offerings. Academic institutions have contributed only marginally to the level of knowledge in the field, as cross-national research is costly and national grants are often only allowed if funding from different countries is available.

According to the standards of scientific argumentation, international comparisons of media use should be developed against the background of a theoretical approach including or explaining media use as a factor. For example, the “digital divide hypothesis” proposes, among other things, national differences in the use of online media with an emphasis on the dynamics of the process (Norris 2001). However, access figures should not be confused with use and usage patterns, which depend heavily on the media literacy of users.

Comparative empirical studies are mostly limited to the audience analysis of one media application in some selected countries. For example, Jensen (1998) compiled evidence on TV news viewing in seven states: Belarus, Denmark, India, Israel, Italy, Mexico, and the USA. Obviously, substantiating the selection is crucial for the significance of the results: as the sample is not random, but each country stands for a larger set of nations, one could argue that often *international* research on media use in fact is *cross-cultural*, with nations as indicators for the culture they represent.

# Media Use across the Life-Span

*Margot van der Goot*

*Radboud University Nijmegen*

*Johannes W. J. Beentjes*

*Radboud University Nijmegen*

A common finding in media research is that age groups differ in the amount and functions of their media use. Communication scholars have pointed out two possible explanations for such differences. First, there are life-cycle or maturational explanations: media use is supposed to change across the life-span in response to an individual's development. Second, there are generational explanations: people who are born in a certain period are supposed to adopt particular patterns of media use. For example, research shows that older people spend more time watching television than do younger age groups. It may be that older people watch more television than when they were younger because their situation and needs have changed. Alternatively, older people may watch more television than younger people because television is more important to their generation than it is to younger generations.

Theoretical considerations have focused on age. Empirical research shows relations between media use and age. However, researchers writing on life-cycle explanations have argued that this "chronological age" has its limitations as a concept, because it is not the factor that explains the changes in media use across the life-span. In the example: older people watch more television than when they were younger not because their age has changed but because their situation and needs have changed. Therefore, researchers came up with alternative concepts, such as *life-span position* and *contextual age*, that are more insightful regarding developments across the life-span. In generational explanations, the concept of "formative years" is important. Generations are supposed to acquire a strong attachment to the media that they use during these socializing years. For example, the generation growing up in the 1990s (sometimes referred to as generation y or the net generation) witnessed the introduction and popularization of information technologies such as the → Internet, email, and mobile phones (→ Electronic Mail; Mobility, Technology for) in their younger years; this may lead to a continuing strong affection for these media during later stages of their lives.

There are methodological problems in trying to disentangle these life-cycle and generational influences on media use. Fortunately, cohort analyses have been conducted that provide some insight into these coexisting influences ("cohort" is the methodological term for people who are born in a certain period; → Longitudinal Analysis). These theoretical and methodological issues regarding media use across the life-span will be discussed below. Information on research that focuses in more depth on media use at a particular stage of life can be found in other entries (→ Media Use and Child Development; Media Use by Children).

## THEORETICAL CONCEPTS

The basic notion in life-cycle explanations is that media use is related to biological, cognitive, and social development across the life-span. The general idea is that when

people pass through the stages of life they experience changes and therefore their media use changes as well. Several authors (e.g., Dimmick et al. 1979; Rosengren & Windahl 1989) have described this process using the → uses and gratifications paradigm. Central to these descriptions is that *developmental events and processes create needs as well as resources* (such as physical or material resources). Subsequently these needs and resources bring about certain types of media use. For instance, several developments can take place in old age: many older people retire and experience physical aging, and some are confronted with losses in their social networks. These developments may lead to new needs, such as the need for activities to pass the newly available time or the need for company. Changes in resources are also apparent. These changing needs and resources may lead to new patterns of television use, for example spending more time viewing or using television more for company than before (van der Goot et al. 2006).

This developmental perspective implies that it is not chronological age that explains changes in media use. The term “life-span position” (Dimmick et al. 1979) has been used to indicate that it is more insightful to think about the relation of media use to life stages such as childhood than to study the relation of media use and age. This raises the question of how to measure people’s position in the life-span. Rubin and Rubin argued (e.g., A. M. Rubin & Rubin 1986) that it would be better not to use age, but to assess indicators of life position directly. Therefore they developed the concept of *contextual age*. This construct includes six dimensions relevant to defining aspects of people’s situation: physical health, interpersonal interaction, mobility, life satisfaction, social activity, and economic security. A young person and an older person have the same contextual age if they score the same on these variables. However, chronological age is still commonly included in audience research. It is considered to be a marker variable, an indicator of the stages of life.

The main assumption in generational explanations is that the circumstances under which a generation grows up determine to a large extent this generation’s behavior later in life. Scholars argue that experiences during socialization or during adolescence, the so-called *formative years*, leave long-lasting impressions on values and attitudes, and continue to influence behavior at later stages of life (Peiser 1999). Generations are supposed to be different from each other because they have grown up in different societal, political, and economic circumstances. Similarly, scholars have argued that generations are different with regard to media use. Generations may adopt specific patterns of media use when they are young and remain faithful to those throughout the life-span (Mares & Woodard 2006). In other words, generations that are young when a particular medium becomes popular may have a stronger attachment to that medium than do previous or later generations.

Several *generations* have been identified in the twentieth century, with regard to America and to a lesser extent other western countries. The names and birth years are debated, but this identification approximately concerns the following: the pre-war generations (born before World War II); the baby-boomers (born between 1946 and 1964); generation X (born between 1965 and 1976); and generation Y (born between 1977 and 2001). Moreover, generations have been defined in terms of the media they grew up with. So far, a television generation and a net generation have been distinguished. The television generation consists of those people that were young during the introduction and spread of television. A definition in terms of years of birth should be country-specific depending on the diffusion of television. In the United States those born in 1950 or later are supposed to be

**Figure 1** Percentage internet users by age group  
*Source: Eurobarometer 56.0 (2001)*

the television generation; in a study in Germany the television generation was operationalized as the people who were born after 1965 (Peiser 1999). The television generation is supposed to have a stronger affection for television and to be less inclined to read than previous generations. The term “net generation” is used for the generation growing up with information technology, most importantly the Internet. This generation has been defined as the people born between 1977 and 1997 (Tapscott 1998). So in America the television generation partly coincides with the baby-boom generation, whereas “generation Y” and “net generation” are different names for roughly the same generation.

## EMPIRICAL RESEARCH

Ideally, research would provide a picture of the changes in media use across the life-span and the ways in which this media use is influenced by people’s formative years. To gain insight into these life-span and generational influences on media use, it is necessary to have information about the media use of several generations from their childhood to old age. However, this involves methodological problems that will be discussed below. Subsequently, research will be discussed that sheds some light on media use across the life-span. Cohort analyses have been conducted with regard to time spent on television watching, and motives for viewing have been studied in relation to age. Content preferences across the life-span are discussed in other entries (→ Advertising: Responses across the Life-Span; Attention to Media Content across the Life-Span; News Processing across the Life-Span). Research on Internet use will be discussed briefly below, because so far this research leans toward generational explanations (→ Internet Use across the Life-Span).

Most empirical research is cross-sectional, which means that it consists of data collected at one point in time. *Cross-sectional research* shows differences between age groups, but the problem is that older age groups represent both people in old age and older cohorts. This problem can be illustrated with the cross-sectional finding that younger age groups use the Internet more than do older age groups (see Fig. 1). The group aged 15 to 24 years refers to people in their late adolescence and early adulthood, but in Figure 1 it also refers to the group of people born between 1977 and 1986. This means that it is not possible to determine whether this age group uses the Internet more because they are at this stage of life, or because they were born in those years. In methodological terms: it is impossible

to determine whether the differences are caused by life-cycle (age) effects or cohort effects.

In cross-sectional research, scholars can only try to come up with theoretical arguments for life-cycle or cohort effects. Are there reasons to assume that this age group of 15 to 24 years uses the Internet more because it fits better with the needs and situations of adolescents than with the needs of people at later stages of life? Such life-span explanations would mean that part of this group would stop using the Internet later in their lives, because later in life it would be less suitable to their needs. Alternatively, it could be argued that this age group of 15 to 24 years uses the Internet more than do older groups because they are part of the generation that has grown up with the Internet, whereas the older groups are part of generations that did not grow up with this technology. This generational explanation would mean that a large share of this age group would continue to use the Internet when they grow older.

Because cross-sectional research cannot disentangle life-cycle and cohort effects, other methods, such as *cohort analysis*, have been designed. To conduct a cohort analysis, data have to be available for several cohorts at a variety of life stages. It is necessary to have cross-sectional surveys with comparable variables on media use, and that have been carried out at different times of measurement. These data are hard to find, and therefore only a few cohort analyses on media use have been conducted (e.g. Danowski & Ruchinskas 1983; Peiser 1999; Mares & Woodard 2006). Moreover, scholars will have to wait many more years to be able to witness how media use develops across the life-span for the baby-boomers and for generations X and Y. The baby-boomers will turn 65 from 2011 onward, and it will be interesting to see how their media use will change when they retire.

The cohort analysis by Mares and Woodard (2006) provides some insight into the development of the amount of television viewing across the life-span. The researchers used six measurement times (1978, 1982, 1986, 1990, 1994, and 1998) from the General Social Survey in which respondents were asked how many hours they watched television on an average day. Mares and Woodard found that throughout the life-span there are differences in viewing that are not explained by cohort effects. Even after controlling for cohort, period, sex, and education levels, there appeared to be an effect of age on the amount of viewing. Viewing was moderate among 15 to 28 year olds, declined throughout the late twenties, thirties, and forties, and gradually increased again in the fifties, and viewers aged over 60 watched more than younger age groups. Moreover, many cross-sectional surveys since the 1950s have found that older people watch more television than younger people. Therefore, scholars have emphasized life-cycle explanations in the case of time spent on television watching.

Mares and Woodard tested such life-cycle explanations for the finding that older people watch more television than younger people. It appeared that some older people watch more television than younger people because they do not have to go to work. To a lesser extent, some older adults watch more television than younger adults because of poorer health. Mares and Woodard stress that these descriptions apply only to some older people, because of the variability among older viewers. Older people turned out to be even more heterogeneous than younger age groups. Viewing levels were varied in early adulthood, became relatively stable in middle adulthood, and became more variable again as viewers got older (→ Exposure to Television).

Also, this cohort analysis yields some support for the concept of a television generation. Cohorts born just after the turn of the century (before 1905) watched the least television across the six measurement times. Later cohorts watched more, especially those born between the late 1940s through the 1960s. More recent cohorts showed something of a decline. This means that the cohorts that were in their childhood and teens during the introduction and popularization of television seem to have the strongest attachment to this medium.

The *relation between motives for television viewing and age* has been studied in some cross-sectional studies (e.g. Ostman & Jeffers 1983; Gunter 1998; Mundorf & Brownell 1990). Ostman and Jeffers formulated hypotheses on how motives for viewing would vary with the age of viewers. In this survey (N = 140, age 18 to 87), three motives for using television were positively related to age (to learn things; to overcome loneliness; to find something to talk about), whereas two motives were negatively related with age (to forget; to pass time when bored). Also, Rubin and Rubin (e.g., R. B. Rubin & Rubin 1982) conducted several surveys among adult and older samples in which they included their contextual age variables and variables on television viewing motives, program preferences, and viewing behaviors. These studies showed correlations between aspects of contextual age and aspects of television use. However, the research available so far does not present a clear picture of how motives for television viewing change across the life-span.

The Internet was introduced in the 1990s. From its introduction until now, many cross-sectional surveys have shown that older people have less access to the Internet and use it for a narrower array of activities than do younger people (e.g. Loges & Jung 2001). The concept of the → *digital divide* (→ Exposure to the Internet) has been used to indicate the gap between groups that are ahead in using new technologies and groups that lag behind. Within western societies, age is one of the factors associated with this gap. Most scholars lean toward generational explanations: the current generation of younger people will continue to use this technology when they grow older and therefore the age divide will probably disappear with time. On the other hand, other authors (Loges & Jung 2001) are cautious in ascribing the divide to a generational effect. They suggest that older people in 2040 may be similar to older people now. Therefore, differences between the Internet use of old and young people may survive.

## Media Use by Social Variable

Helmut Scherer

Hanover University of Music and Drama

It is a phenomenon that can be observed in all industrialized societies that media use is connected with demographic factors. As a rule, people from different social backgrounds also use the media differently. On the other hand, people from similar social backgrounds also show similarities in their use of the media. Thus, there is a significant difference between the way women and men, older and younger people, and people with higher or lower levels of education use the media. Similarly, people from different ethnic groups differ in their use of the media. Another factor that is closely linked to media use is opinion leadership.

There are some *examples* of the influence of socio-demographic factors that can be observed in almost all industrialized countries. Men and people with a low income, for instance, spend more time watching → television, while people with a higher standard of education tend to read → newspapers. The importance of age for media use is particularly well documented (van der Goot et al. 2006). Analyses conducted in the USA by the General Social Survey and in 12 European countries by the European Social Survey basically show similar results for the use of television. With the exception of Romania, people from the age of 60 (in the USA) or 65 (in Europe) use television more frequently than all other age

groups. On the other hand, older people use the → Internet far less frequently than younger people (Loges & Jung 2001).

## THEORETICAL MODELS

From the point of view of the communication sciences, the mere description of socio-demographic variables of media use is unsatisfactory. The question that needs to be asked is what we *really* know once we have established, say, that women give preference to different types of media than men. We cannot part from the assumption that gender has a direct influence on media use. Women do not show a specific behavior in their use of the media due to the mere biological fact that they are women, but because their sex is linked to other factors. The question we are facing is therefore not a biological but rather a sociological one; it is a question of gender, not a question of sex. An example given by Westerik et al. (2005) shows that pertinent analyses can be very complex. They observed that women start watching television earlier in the day than men. This, however, is mainly due to the traditional role allocation. Women spend more time at home and therefore can watch television more often. If this is taken into account, analyses will show that in similar circumstances – that is, when they are at home – men also start watching television earlier.

This example shows that socio-demographic variables are indicators for specific social situations and that the relation between them and media use is a complex one. An analysis of how social variables affect media use requires a theoretical analysis of the factors that motivate people to use the media in the first place and allow people to use media. If these factors are related to specific social situations they can explain the relationship between socio-demography and media use. Based on these considerations, we can distinguish some characteristics of social situations that are relevant to media use: needs, media images, resources, competence and skills, values, and expectations related to social roles.

The exact nature of the relation is a contentious issue. One approach is the *deterministic model*, i.e., that media use results from the social situation with a certain inevitability. In a different approach, media use is not interpreted as the result of a social situation but rather as *part of a way of life*. Modern sociological approaches are based on the assumption that social stratification can no longer be seen as the main structural characteristic of postindustrial societies. A variety of different life plans and ways of life has taken the place of a clearly recognizable social structure. This process is usually described as individualization. In fact, a new social order is developing that on the one hand allows the individual more freedom of choice, but on the other hand also forces the individual to make a choice and, thus, creates a need for guidance.

This social order can be described on the basis of aesthetic schemas of everyday life. Due to an improved standard of living, striving for the satisfaction of material needs has given way to the wish for an aesthetically satisfactory way of life, for a beautiful life. Not surviving, but living a fulfilled life has become the most important issue. The main characteristic of a so-called experience society (*Erlebnisgesellschaft*) is that experience orientation is its basic collective motivation (Schulze 1992). Individuals are offered more and more options in their everyday life. The choices they make are usually not factual but aesthetic or a matter of taste (→ Aesthetics). Everyday activities are seen as a sign and

expression of personal taste and style. This lifestyle is at the same time a means of distinction and a means of integration. It affects different aspects of life. It is reflected in the choice of clothes as well as leisure activities, the consumption of culture, and also in media use. Groups that share the same aesthetic everyday life schema can be identified empirically and distinguished from other groups that share a different schema. Aesthetic everyday life schemas are collective codes of experience. They limit the infinite number of possible aesthetic everyday life behaviors, including media use, and can be identified by members of the collective.

Thus, new groups, i.e., new social structures, develop and options multiply in such a way that individuals have to choose and combine them to “compose” their lives. Eventually milieus emerge that can be identified and differentiated according to their aesthetic everyday life schemas (Schulze 1992). However, as Bourdieu (1984) has shown, it is an illusion that lifestyles can be freely chosen. In fact, lifestyles are dependent on variables of social stratification. According to Bourdieu (1984), social structure is based on three sorts of capital: the economic, the social, and the cultural capitals. Social classes are formed according to the availability of these and can be differentiated according to their cultural customs and expressions of taste, and therefore also according to their media use.

## EXPLANATORY FACTORS

### Needs

The → uses and gratifications approach is a standard theory of media use (Blumler & Katz 1974). This theory is based on the assumption that the media are used for the satisfaction of needs and therefore compete with other sources of gratification. It is assumed that users are aware of their motivation and relate specific media contents to their perceived individual needs. In other words, the users themselves decide for what purposes they use the media. Rosengren (1974) differentiates between the terms “need” and “problem.” Problems result from the interaction of individuals, situational needs from the structure of society (Rosengren 1974, 270f.). A problem can therefore be described as a special kind of need that is dependent on the factors mentioned above. The term “need” refers to needs in general as part of human nature, whereas the term “problem” refers to the different forms of specific individual and situational needs. This makes clear that the occurrence of needs is related to social situations.

The *need for* → *escapism* occurs more often in situations that are perceived as stressful. There is, for instance, an obvious connection between a person’s need to relax and their workload. It can be assumed that the less control a person has of their work and the more alienated from their work they feel, the more they will turn to the media to satisfy compensatory needs. Some authors assume that older people have less need to relax or seek distraction because they are retired and do not suffer from work-related stress any more (van der Goot et al. 2005). Similarly, the different use of the Internet by older and younger people can be explained by their different needs (→ Internet Use across the Life-Span). Older people use the Internet with a small set of motives. Young people, on the other hand, use the Internet for social interaction, which for older people is less important. Older

people go through “a process of disengagement” (Loges & Jung 2001, 540). While younger people see this as useless isolation, it is quite possibly just a normal process for the elderly.

Jeffres (2000) describes the interdependence of *ethnic integration* and ethnic media use. Members of ethnic minorities use ethnic media more intensively if they are deeply rooted in their ethnicity. This leads to a strengthening of their ethnic identity. It can be assumed that in a minority situation the need to strengthen the ethnic identity will be pronounced and that this is the reason for ethnic media use. “Ethnic media appear to act as vehicles that help ethnics to retain attachment to their culture over time” (Jeffres 2000, 522; → Ethnicity and Exposure to Communication).

### Media Images

Apart from needs, *expectations of the media* play an important role in the uses and gratifications approach. People turn to the media expecting them to be able to provide the gratification they are looking for; that is, on the basis of media images. If there is a specific need and the expectation that the media can meet this need, we will find a motive for media use.

Age, or rather the fact that a user belongs to a specific generation, can play an important role here. Specific age groups share specific expectations of the quality of the media. This expectation that the media will be able to meet certain needs is acquired; that is, it results from the individual’s media biography. It is influenced by key events in the media as well as dominant media contents during biographically relevant periods of life (Dimmick et al. 1979).

### Resources

Human behavior, also in regard to media use, cannot be understood only from the underlying motivation. We also need to take into consideration what possibilities an individual has to act and what restrictions they are subject to. In respect to media use, this means that a potential media user is not completely free to use the media but is restricted by a possibly limited offer, and by laws and other normative regulations (→ Communication and Law). The most important restriction is the cost that is connected with certain actions. Media use is regarded as a low-cost situation (→ Media Economics). Nonetheless, in specific situations, media use can be limited by lack of available relevant resources. In the communication sciences cost–benefit analysis has played a role particularly in the analysis of information obtainment (Downs 1957; Atkin 1973). Here, costs for information obtainment include monetary costs as well as time and cognitive effort (Atkin 1985).

Resources are *external possibilities to act*. They are not personal characteristics of the individual, but the individual can make use of them. Usually resources can be used up and tapped again. Their influence on media use is twofold. On the one hand, the potential media user must have access to necessary resources to be able to afford media use. With regard to the resource of time, for instance, this can be problematic for many potential users. But also material resources often present a problem. It is currently being discussed whether large parts of the world population are excluded from the use of new media technology due to lack of material resources (→ Digital Divide). On the other hand,

available resources dictate what other possibilities there are to meet specific needs besides media use. The connection between resources and socio-demographic variables is obvious. Factors like employment and income determine time and financial resources. There is an evident connection between income and use of daily papers. Higher income leads to more frequent use of daily papers. This also remains true when the influence of education is taken into account (Lauf 2001). It seems that a certain income is required to be able to afford a daily newspaper.

### **Competence and Skills**

Competence and skills are, as opposed to resources, internal possibilities to act. They form part of the individual's personality. As a rule, competence and skills can be acquired or neglected, but they cannot be used up. There is a rather simple connection between competence and skills and media use: a user must be able to read to use a newspaper, or must be an experienced and skilled reader to be able to read more demanding literature. The ability to read, however, is closely linked to age and level of education, i.e., to demographic factors. Nussbaum et al. (2002) assume that the development of communicative competence is a lifelong process. One of the reasons for the – lately weakening – connection between the level of education and newspaper use probably is that people with a higher standard of education are more competent readers (→ Exposure to Print Media).

### **Values**

Blumler (1985, 50) stresses the influence social values have on media use. The expected effect of media use has to be looked upon favorably by the user. It does not suffice to expect to be entertained and amused by the media; entertainment itself must be seen as something valuable (→ Enjoyment/Entertainment Seeking). Therefore, every decision to use the media is a value judgment. Moreover, specific media contents or manner of presentation can clash with the moral values of potential users.

It is reasonable to assume that some users may expect some gratification from pornography in the media but reject it on moral grounds. Different social groups can have different sets of values. Social milieus often share homogeneous moral concepts that differ from those of other milieus. Age is also an important variable. Different cohorts have experienced a different socialization and have been formed by different biographies, resulting in different moral values. Different ethnic groups in modern multicultural societies in most cases have distinct sets of values.

### **Age, Gender Roles, and Expectations**

Different demographic variables are connected with different social roles. We use the term “gender” to describe the fact that sex is not merely a biological, but more importantly a social fact, as it allocates different roles to men and women. Old age and youth are also in a certain sense social roles. Social roles lead to expectations regarding behavior. Society defines what the socially accepted behavior is for an older or younger person, a man or a woman. Dimmick et al. (1979) suggest that media gratification is

influenced by expectations regarding socially accepted behavior of people in a specific “life span position.” Such expectations can also influence media use.

Video games, for instance, are better suited to meet a boy’s need for inclusion and affection than a girl’s. The need for inclusion and affection is equally strong in both sexes. However, it is socially less acceptable for girls to play action games and therefore using these games is not as satisfactory for them as it is for boys (Lucas & Sherry 2004; → Video Games).

### **A Special Case: Opinion Leaders**

Opinion leadership is distinct from socio-demographic factors like age, gender, and education. While these, as shown above, describe a specific social situation, opinion leadership describes a social position in a given social context (→ Opinion Leader). Lazarsfeld et al. (1944), who discovered this phenomenon, parted from the assumption that opinion leadership exists in all social classes and that it is therefore independent of demographic factors like education and income. Research, however, shows that there is a positive correlation between opinion leadership and socio-demographic variables. This might be due to a measurement error. It is possible that opinion leadership measurement is more accurate in higher social classes, but is inadequate to assess opinion leadership in the lower classes.

Opinion leaders use the media differently. They use the information media more frequently and more intensively than others. However, the relation between opinion leadership and media use is a special one. Media use is constitutive to the exercise of opinion leadership. Opinion leadership appears to be not the condition for media use but its cause. In this aspect it also differs from demographic variables. Using the media does not change a person’s sex or age or the fact that a person belongs to a certain generation. Under certain circumstances media users can become richer or more educated through media use.

This entry argues that demographic variables are useful to describe mass media audiences, but without a theoretical framework those variables do not work as explanatory concepts. Demographic variables are indicators for specific social situations. These situations differentiate in regard to values, resources, competences, media images, needs, and social expectations. These are the actual explanatory factors at work behind the demographic variables.

## Mediated Populism

Gianpietro Mazzoleni

University of Milan

Populism, a notoriously ambiguous concept, is a political ideology emphasizing the central role of the “ordinary people” in the political process. Populist leaders “see themselves as true democrats, voicing popular grievances and opinions systematically ignored by governments [and] mainstream parties” (Canovan 1999, 2–3). “Mediated populism” means

the outcome of the close connection between media-originated dynamics and the rise of populist sentiments, and eventually of populist movements.

Comparative research points out the existence of a sort of complicity between the news media and political populism. The increasing commercialization of the news industry has further intensified the media's natural search for mass audiences, and their craving for → sensationalism, scandal, and conflict (→ Commercialization of the Media). This inclination of the media has been also identified as "media populism." In various countries the media – "by engaging with people's moods, catering to their entertainment needs and harping on negative stories that might spread social and political malaise" (Stewart et al. 2003) – have objectively created widespread sentiments and opinion climates on controversial issues like immigration, unemployment, and crime that have been promptly exploited by populist movements (→ Populism and Responsiveness). The question of whether, and to what extent, this complicity is intentional on the part of the media is open to different interpretations, which may vary along with political cultures.

The great diversity of news media makes it difficult to draw broad generalizations. In most of the cases that have been studied, several news media have displayed what Entman (1989) defines as "production bias," the inevitable slant embedded in all news-making processes (→ Bias in the News). This has meant a largely accidental convergence between the media's corporate ends and the political action engaged by populist leaders, movements, and parties. The rise of certain populist forces has been facilitated by the sheer implementation of → news routines. Nevertheless, in a number of other cases, some news outlets have openly and intentionally voiced people's discontent and malaise with the purpose of mobilizing and generating electoral support for populist politicians.

In general, the available evidence shows that tabloid media – which respond primarily to commercial imperatives (→ Tabloid Press) – are more keen to lend direct and indirect support to populist sentiments and claims, by engaging in sympathetic coverage of populist leaders and their rhetoric (→ Rhetorical Studies), whereas the elite media (with significant exceptions) – which tend to be mouthpieces of the ruling classes and paladins of the status quo – usually display overt antagonism and treat negatively populist politicians and their political action. In the latter case, beside the production bias, an "evaluation bias" can be seen at work, which reflects the views of the establishment.

On their part, populist leaders and parties engage in intense relations with the media, resorting to different strategies to court the media and/or to secure their media attention (→ Mediatization of Politics). These strategies comprise playing the underdog (that is, exploiting to their advantage the unfriendly coverage of certain media outlets); using professional expertise; addressing and rallying crowds using abrasive speech; looking for free media publicity, which is easily obtained by bullying against the government and raising blazing issues; staging newsworthy, controversial events; and putting pressure on journalists and editors.

Mediated populism takes different shapes depending on the stage of development of the populist phenomena. Research has envisaged a four-stage life cycle (Stewart et al. 2003). In the *ground-laying phase*, the media may be engaged in providing a dramatic portrayal of the country's illnesses, denouncing corruption in government, highlighting immigration-linked crime stories, and the like. This media coverage in the long run is likely to diffuse social malaise and to trigger popular anger and political disaffection. This

domestic political climate represents the ideal milieu for the rise of political figures voicing social discontent and for the dissemination of the populist message. This was clearly the case of Austria's Jörg Haider, whose success was to a significant extent buttressed by the "newsroom populism" (Plasser & Ulram 2003) of the tabloid newspapers, which fuelled a favorable opinion climate. In the *insurgent phase*, populist movements attempt to enlarge and consolidate their popular and electoral support by exploiting more intensely the communication resources that media make available (unintentionally or not). This is a stage when populist leaders – often media-savvy figures – seek to secure media attention by displaying a wide variety of communication tactics. Italy's Northern League's neo-Celtic liturgies, Haider's remarks on the Nazis, and The Netherlands' Pim Fortuyn's outspoken statements on Islam are the type of newsworthy realities that the media covet and cover, thus granting populist actors an enormous and free publicity. The *established phase* is the stage when the movement obtains full legitimization in the country's political system, with seats in parliaments and even in cabinets. This often means loss of newsworthiness for the leaders and their stances, as they take on more ordinary political roles in the political arena, with the consequent lessening of media attention. Some movements have experienced also a *decline phase*, like Ross Perot's Reform Party USA, and Pauline Hanson's One Nation Party in Australia. The attitude and behavior of the media vary widely in this phase. Their spotlights might be suddenly switched on by the political fall of formerly transgressive (and at times "media darlings") populist leaders. The murder of Pim Fortuyn in the 2002 election campaign was followed by a short-lived electoral success. However, his movement lacked his personal charisma and media savvy, and eventually did not survive, among other things, the fall of media interest.

# Mediated Social Interaction

*Eun-Ju Lee*

*University of California, Davis*

Mediated social interaction refers to the interaction between two or more individuals, normally separated in time and/or space, enabled by various communication technologies. Mediated social interaction may take many different forms, depending on how many people are involved in message construction and reception (e.g., one-to-one vs one-to-many); whether participating individuals are required to be present at the time of message transfer (e.g., synchronous vs asynchronous); what kinds of modalities are being used (e.g., text vs full motion video); and so forth.

Technology-mediated communication has been with us for many years. However, it is the proliferation of personal computers and the Internet that has spawned considerable research on mediated social interaction. Not only has computer-based communication created unprecedented opportunities to form, develop, and maintain interpersonal relationships, but it has also altered the ways in which people collaborate in work groups. Thus, the following sections are devoted to computer-mediated communication (CMC), and especially how it differs from face-to-face (FtF) interaction in terms of communication processes and outcomes.

## KEY CHARACTERISTICS OF COMPUTER-MEDIATED COMMUNICATION

Although recent technological advancements support a wide array of communication modalities beyond the exchange of simple texts, the most common form of CMC is still text-based. Thus, compared to FtF interaction, CMC typically lacks social context cues, ranging from nonverbal cues (e.g., facial expressions and gestures) to paraverbal cues (e.g., volume and pitch) to interpersonal cues (e.g., age, physical appearance; → Nonverbal Signals, Effects of; Nonverbal Communication and Culture). According to social presence theory (Walther & Parks 2002), when deprived of visual and auditory cues, people become less aware of their interaction partners and perceive them to be less sociable, warm, and friendly. In this view, reduced social presence renders CMC less effective and appropriate than FtF for socio-emotional communication.

Second, cue deficiency fosters perceived *anonymity*. With their identities hidden, people tend to feel freer from social constraints and become less concerned about → impression management than in FtF encounters. Thus, anonymity might promote uninhibited behaviors, such as strong and inflammatory expressions (i.e., flaming). At the same time, anonymity can serve to democratize communication by liberating individuals from power differences manifested through various status cues (Joinson 1998). For example, an opinion deviate or a low-status individual might find it more comfortable publicly expressing his or her unpopular opinion anonymously, an opinion which might have been suppressed in FtF discussions.

Lastly, CMC does not require participating individuals to be co-present in the immediate environment. Rather, many variants of CMC, such as email, listserv, and

newsgroups, support asynchronous interactions, allowing people from remote locations to send, read, and respond to a message at their convenience. Freed from geographical and temporal constraints, the boundary of an individual's social network has been substantially expanded.

### **SELF-PRESENTATION AND PERSON PERCEPTION**

Studies have reported that people engage in greater spontaneous self-disclosure in CMC. Several explanations exist for why people reveal more about themselves during mediated communication. First, anonymity reduces perceived risks in disclosing potentially embarrassing aspects of self. Thus, those who have stigmatized identities (e.g., non-mainstream sexual preferences or political views) can find similar others more easily in chatrooms and online newsgroups and share their experience. Second, physical separation and the lack of sensory cues lead people to focus more on their inner feelings and thoughts (private self-awareness), while lowering concerns about public evaluations (public self-awareness). Supporting this view, research found that individuals' currently possessed, but not usually expressed traits ("true self") became more accessible in their mind after CMC than after FtF interaction, and these traits were better acknowledged by CMC partners (Bargh & McKenna 2004).

Not only do people speak more about themselves, but they also speak better of themselves in the cue-limited environment. Although people usually present more of their ideal-self qualities to strangers than to their friends or co-workers, text-based CMC allows greater room for strategic self-presentation by eliminating a number of distractions, such as environmental stimuli, simultaneous cues from the partner, and their own physical back-channeling. Consequently, people can concentrate on message construction, making sure that their messages reflect preferred characteristics they wish to present. This selective self-presentation fosters overly positive perceptions and exaggerated interpersonal ("hyperpersonal") expectations. Indeed, after semester-long interactions with remote partners, those who saw their partners' photos formed less positive impressions than did those who communicated without photos (Walther & Parks 2002). In addition, not knowing that they actually interacted with the same person twice, people reported greater liking for their partner after CMC than after FtF interaction (Bargh & McKenna 2004).

One benefit of text-only interaction is the potential nullification of social stereotypes. Because these are often linked to physically salient features, such as gender and race, visual anonymity might suppress social stereotypes. Despite the absence of physical indicators, however, some social category cues seem to remain in text-only CMC. For example, mirroring gender-linked language differences observed in FtF interaction, men's postings to newsgroups showed self-promotion, sarcasm, insults, and strong assertions, whereas women's messages revealed supportiveness and personal orientation. Likewise, female-only discussion groups displayed more self-disclosure, personal opinions, and coalition language than did male-only or mixed-gender groups, and women relied more on graphic accents to express emotions (e.g., smiley faces) than men (Thomson & Murachver 2001; → Language and the Internet). Another implicit gender identity cue is gender-specific knowledge or interest. When judging the target's gender in anonymous

CMC, people relied mostly on the conversation topic and interaction content. Moreover, even when avatars (graphical representations of a person in virtual space) were randomly assigned, in the absence of legitimate gender cues, participants inferred their partner's gender from these arbitrary characters (Lee in press).

Once the interaction partner's category membership is revealed, the information restrictions of the medium can amplify the category's influence (Lee in press). For example, when the interviewee's race was known, people rated Asian-American women as more introverted than African-American women after an email interview, although no such difference was found in telephone interviews. Apparently, to compensate for the interpersonal information filtered out in text-only communication, people turned to social stereotypes and filled in the missing information. Similarly, when gender stereotypes were activated, people exhibited stereotype-congruent behavior only when they were unable to individuate one another; when they exchanged brief biographical information with other group members, the activation of gender stereotypes had no significant effect. Taken together, these results indicate that the limited channel capacity can promote self-stereotyping, as well as category-based person perception (Postmes et al. 1999).

### **GROUP PERFORMANCE AND NORMATIVE INFLUENCE**

In work groups, CMC has the potential to address problems common to FtF discussions: evaluation apprehension and production blocking. By allowing anonymous and simultaneous input from participating individuals, group support systems can lower concerns about negative reactions and prevent a particular member from dominating the floor. Supporting this idea, electronic brainstorming was found to be more effective for idea generation, especially when the group size was large. When group decision-making is concerned, however, a meta-analysis (Baltes et al. 2002) showed that FtF groups generally outperformed their CMC counterparts; that is, FtF groups made higher-quality decisions, took less time to reach a consensus, and yielded greater member satisfaction. Moreover, the advantages of FtF groups were more pronounced when there was a time limit and when the group size was large. Interestingly, anonymity had opposite effects on subjective and objective measures of performance, such that it decreased member satisfaction, but improved the decision quality of CMC groups (→ Meeting Technologies).

Some studies, however, have challenged the notion that anonymity weakens normative concerns in CMC. According to the social identity model of deindividuation effects (SIDE), when there is a common group identity, the lack of individuating information ("deindividuation") can reinforce group-oriented behaviors (Spears et al. 2001). That is, in the absence of interpersonal information that highlights individual differences within the group, people come to perceive themselves and their interaction partners as representatives of a group. Thus, they are more likely to conform to group norms and exhibit ethnocentrism. In fact, when group members were primed with certain social behaviors (i.e., efficiency vs pro-social norms), anonymous groups made prime-consistent decisions in the following discussion, whereas identifiable groups did not. Likewise, people preferred an ingroup (same university) member to an outgroup (different university) member for future collaboration only when no individuating cues were available (Tanis &

Postmes 2003). Collectively, these findings suggest that normative group influence still operates in mediated interaction and can become even stronger with a salient group identity.

### **DIRECTIONS FOR FUTURE RESEARCH**

To understand how CMC affects the ways in which people communicate, make sense of others, and collaborate, researchers have compared CMC with FtF interaction, treating the latter as a gold standard. An implicit assumption underlying this approach is that certain features of the communication channel (e.g., anonymity) influence individuals' perceptions and behaviors in a rather uniform manner, representing technological determinism (→ McLuhan, Marshall). However, as social information processing theory posits, people are capable of adapting to the restrictions of the medium (Walther & Parks 2002). Specifically, users have devised various graphical accents to express their feelings (emoticons) as substitutes for nonverbal cues missing in CMC. In addition, to compensate for the limited opportunities to observe others unobtrusively or to gain information about the target from a third party, CMC participants relied more upon interactive strategies than their FtF counterparts, asking more personal questions (→ Uncertainty Reduction Theory). Consequently, although it might take longer, CMC users can eventually develop as intimate interpersonal relationships as those based on FtF contacts (→ Online Relationships).

Recent studies also demonstrated that different individuals use the same medium differently to different effects. For example, CMC reduced interpersonal influence by temporarily heightening the self-focus, but such an effect was found only for those who chronically experience a high level of private self-awareness. Moreover, when the task posed interpersonal risk (e.g., asking for a date), individuals with low self-esteem had a stronger preference for email over FtF communication than those with high self-esteem. Therefore, to understand better the psychological and social effects of CMC, it seems crucial to investigate how individuals' dispositions moderate the uses and effects of the medium (Lee in press).

Due to the paucity of longitudinal studies, little is known about long-term effects of repeated engagement in CMC. For example, the SIDE model predicted and found that deindividuation amplifies the effects of group identity, but it remains unclear what will happen as people get to know each other better over time. It may be important to examine how prolonged CMC experience alters the nature of non-mediated interaction. Although some researchers have studied how online interaction influences the frequency and amount of offline interaction, it is not known how the communication procedures and conventions associated with CMC might influence the way people carry on FtF interactions, an area which awaits more research.

## **Mediated Terrorism**

*Gianpietro Mazzoleni*

*University of Milan*

Following the September 11, 2001 massive attacks on the United States, the issue of political terrorism has assumed a priority stance in the political agenda of several countries. Once fairly disregarded by scholarly research and analysis, the phenomenon has gained wide attention since the events of that day and those that took place in Iraq, as well as in Bali, Madrid, Beslan, and London. All of these tragic events had in common huge coverage by the media, which amplified the psychological impact on public opinion in the respective nations and worldwide. Extensive and emotion-stirring media coverage is a common feature of modern terrorist events. It has been observed in relation to other breeds of terrorism, such as the IRA in Ireland and the UK, ETA in Spain, the Red Brigades in Italy and the Rote Armee Fraktion in Germany, the Kurdish extremists in Turkey, and domestic US terrorism (the Oklahoma bombing), and others.

Terrorism, whatever definition is given, has been closely associated with communication and → propaganda, to the point that there cannot be envisaged any terrorism without some kind of media-conveyed visibility. The primary goal of terrorist organizations

is, in fact, to “send a message,” usually to target governments, the victims being the instruments to pursue the goal. This message may take the form of violent acts, often with bloodshed, but also of personal threats to political leaders, blackmailing of public authorities, and verbal attacks on political or corporate policies. According to Schmid and de Graaf (1982) “terrorism [itself] can best be understood as a violent communication strategy” (→ Strategic Communication).

In the global village, the mass media and the new media play a pivotal role in the terrorist scheme. Thanks to the new communication technologies, today’s terrorism has undergone an epochal change: it is “less centralized, less structured, and less organized, yet far more dangerous than the terrorism of the late twentieth century” (Weimann 2006, 5). Terrorists can count on global media networks to seize the worldwide public arena. In particular, the most notorious terrorist organization, Al-Qaeda, has demonstrated a shrewd exploitation of media outlets and the → Internet, securing a global impact for its “message.”

The goals of terrorist groups of securing vast publicity for their actions can be defied only in part by the counteractions of government authorities, which might impose bans on the diffusion of violent or subversive messages, and even → censorship on printed and broadcast news, but cannot regulate the Internet, which remains the most resourceful communication means of postmodern terrorism (→ Violence as Media Content).

By means of the Internet, political terrorism succeeds in attaining several *strategic purposes*. First, the Internet serves the practical purpose of planning and coordination and to ensure networking and circulation of key information. Through the Internet, affiliated, semi-independent cells, often “sleeping” ones, scattered around the world are able to maintain contact with one another and to plan common actions. Second, it ensures cheap publicity and diffusion of ideological and motivational messages. All sorts of groups, movements, causes, and parties can resort to the Internet to post their propaganda. Third, it makes fundraising easy and safe: terrorist websites can provide bank account numbers where donations can be wired, with information about donating by credit card and forms to initiate monthly donations via automatic withdrawal from the donor’s bank account. Fourth, its worldwide reach provides receptive audiences among which to recruit new followers and activists. Fifth, it can be used to wage psychological warfare, amplified by the mainstream media organizations that draw on Internet materials (videos, pictures, documents) to feed their news outlets. Finally, search engines and similar technologies have made isolated information quickly and easily retrievable by terrorists, who can attack vulnerable public infrastructures via the web.

Beside the Internet, the traditional media may also become instrumental to terrorism in several ways. One question that has often been debated among public opinion worldwide is whether there occurs a sort of inevitable “complicity” between the news media and terrorists, especially in political contexts, such as liberal democracies, where censorship is not tolerated by the media. The widely accepted news selection practices and rules, such as “bad news is good news,” tend to privilege the uncommon and the dramatic. Terrorist attacks, like disasters, perfectly fit the news value criteria of newsworthiness such as sensationalism and negativism – the more violent and spectacular, the better (→ News Values). With the increasing commercialization of the news profession, terrorist incidents may fit more than ever the infotainment mold that the media industry

increasingly prefers, by offering the sorts of villains and heroes on which the entertainment industry itself thrives in its search for box-office hits (Nacos 2002).

This raises in many cases excruciating *dilemmas* on the part of the free media, battling between the professional imperative of covering what makes the news and the resolution to defend democratic institutions and social peace. Despite the efforts especially of mainstream media to avoid supporting terrorists even indirectly, it appears inevitable that information and communication outlets, from the traditional mass media to the online media, offer groups and individuals with violent agendas and messages of hate extensive and inexpensive opportunities to spread their message and to accomplish their search for political legitimization and popular support. Today the information that is not delivered by one medium is inescapably and immediately provided by another. The Arabic television station Al Jazeera and the Internet have often served as disseminating channels for news, announcements, videos, and other materials produced by terrorist organizations which other outlets around the world had intentionally decided to ignore (→ Arab Satellite TV News). Nowadays terrorists may not have access to weapons of mass destruction but clearly can command a large array of arms of mass communication.

## **Mediating Factors**

*Christiane Eilders*

*University of Augsburg*

Mediating factors are the psychological and social conditions in the communication process that moderate the effects of persuasive mass communication. The concept was

first introduced by Joseph T. Klapper in his influential book *The effects of mass communication* (1960). Sifting through empirical studies available in the late 1950s, Klapper identified five mediating factors that explain why media messages tend to reinforce rather than change existing attitudes. The consideration of moderating variables in media effects research marks a shift from the hypodermic needle or → stimulus–response model to the stimulus–organism–response model.

### INTELLECTUAL CONTEXT

Klapper developed the concept of mediating factors in his review of the state of the art in media effects research. According to the empirical evidence minor change, short of conversion, occurs far less frequently than *reinforcement*, and conversion is particularly rare. Klapper (1960) concluded that “mass communication ordinarily does not serve as a necessary and sufficient cause of audience effects, but rather functions among and through a nexus of mediating factors and influences.” Mediating factors were thus conceptualized as integral elements of this nexus that typically contribute to reinforcement rather than change or conversion of existing attitudes.

Klapper supported his claims with empirical evidence from a wide range of studies on attitude change covering two decades of research activity. Two studies, conducted by → Paul F. Lazarsfeld (his academic teacher at the Columbia University) and his colleagues received particular attention and have ever since served as main evidence for the reinforcement thesis. The first study (Lazarsfeld et al. 1948) investigated the role of the media during the election campaign of 1940. Employing a panel technique, the research team found 5 percent of the respondents to definitely have been converted. They crossed party lines regarding their voting intentions. More than half of the respondents, however, after being exposed to several months of persuasive campaign messages, were found to have reinforced their previous attitudes. The second study (Berelson et al. 1954) examined the media’s role in the decision-making process of the residents of Elmira, NY in the 1948 campaign. Again, a panel design was employed, and the study found that 8 percent of the respondents had been converted.

### THEORETICAL CONCEPT

Trying to explain why persuasive communication is more likely to reinforce than to change attitudes, Klapper focused on the factors external to the communication itself. He claimed that *five factors mediate the mass media’s influence*. The mediating factors are: (1) predispositions and related processes of → selective exposure, perception and retention (→ Selective Perception and Selective Retention); (2) groups and their norms; (3) interpersonal dissemination of communication content; (4) opinion leadership (→ Opinion Leader; Two-Step Flow of Communication); and (5) the nature of mass media in a free enterprise society. Drawing upon empirical findings, Klapper discussed how these factors might interfere with the process of media effects. Particular attention is directed on the findings regarding the predisposition of recipients.

*Selection:* People tend to expose themselves to content according to their existing attitudes and to avoid content inconsistent with their attitudes (selective exposure).

Furthermore, even if they do use media content not consistent with their attitudes, they might find alternative cognitive processing strategies for inconsistent content (selective perception) or tend to forget it more easily (selective retention). It represents a threat to their existing opinions. New issues, however, present a better chance for direct media effects since no predispositions have yet been developed (Lazarsfeld et al. 1948).

*Groups:* Rather than being atomized, individuals forming the mass society people are embedded into social groups whose norms shape their opinions and behavior (Katz and Lazarsfeld 1955). The norms of groups to which an individual belongs or wants to belong have proved to be particularly resistant to change. Intragroup discussion appears to intensify or reinforce these attitudes and inhibit opinion change.

*Interpersonal communication:* Much of what is disseminated through the mass media does not reach the respondents directly but is transmitted by other media users (→ Media Effects: Direct and Indirect Effects). Since interpersonal communication about a certain topic is more likely to happen between individuals with shared opinions on that topic, it tends to have a reinforcing effect. This supplements the reinforcing quality of persuasive communication because it represents a secondary selection of attitude-consistent media messages.

*Opinion leadership:* Opinion leaders can be described as particularly representative members of a group. They stand for the group's relevance assignments and attitudes. They are characterized by heavy media use. Mass communication is frequently mediated by the opinion leaders. They selectively transmit the media messages to the followers, interpret them in accordance to group norms and thereby reinforce the norms held by the group (Lazarsfeld et al. 1948).

*Nature of mass media in free enterprise societies:* In their attempt to maximize their audience, commercially competitive media try to refer to universally shared norms. Thus content that contradicts dominant social and political values is unlikely to be disseminated by media in free enterprise societies. The content is thus unthreatening to the audience members and supports existing opinions rather than promotes change. Even though this argument relates to fiction rather than political campaigns, it can be applied to information as well.

Klapper emphasized that the specific mediation through these factors all work in the direction of reinforcement. He pointed out that all five mediating factors are characteristics of normal communication situations, even though they might not always be active in the communication process. In his review of empirical evidence Klapper also found incidents of modifications of opinion, especially in laboratory studies, which were considered as minor change. He observed that minor change was not as affected by mediating factors as conversion because fluctuations of opinion do not constitute a psychological threat for the individual. He also conceded that at times and under specific conditions the mass media might provoke change. Several such conditions were discussed. Persuasive communication might promote attitude change if the selective process lacks perfection due to conflicting predispositions, cross pressures in the reference group of an individual, or if individuals chose a new reference group (→ Group Decision-Making, Functional Theory of). Whether or not persuasive communication leads to change also depends on the degree of *ego involvement* of the attitudes. Ego-involved attitudes are attitudes that are particularly relevant for the individual. They were found to be particularly resistant to change. Direct media effects might also be observed in the case of

attitudes regarding new issues where attitudes have not yet been developed (→ Involvement with Media Content).

## IMPLICATIONS FOR THE DEVELOPMENT OF MEDIA EFFECTS RESEARCH

Klapper's work had far-reaching *consequences for the further development of media effects research* in several ways. First, the formerly dominant stimulus–response model or hypodermic needle model of media effects was replaced by the stimulus–organism–response model. The consideration of mediating factors in communication research thus marks a crucial shift in the media effects paradigm (→ Media Effects, History of). Second, the widespread assumption of strong media effects had to be modified with regard to the specific conditions under which media may or may not have effects. The reinforcement thesis became the dominating thesis regarding media effects.

Yet, Klapper's work has hindered rather than promoted research and theoretical discourse on media effects. Although Klapper had not explicitly or implicitly ruled out media effects entirely – but only specified the conditions under which media produce either reinforcement or change – his publication was frequently taken as discouragement of further studies on media effects. Scholarly attention tended to shift away from effects research in general, and from effects on attitudes in particular. It increasingly focused on media use and cognitive effects. This shift in attention, however, threatens to underestimate the power mass media may develop under particular conditions.

By and large Klapper is to be credited for two things in particular. He drew attention to the role of predispositions and the related mechanisms of selective exposure, and he emphasized the role of interpersonal communication and the idea of opinion leadership as two crucial dimensions in the communication process. Although media effects models have become increasingly complex, incorporating a vast number of variables, these two mediating factors have remained key concepts in media effects research. It may be expected that future research will contribute to a further specification of the exact way mediating factors moderate the effects of mass communication.

# Mediatization of Organizations Theory

*Piet Verhoeven*

*University of Amsterdam*

Almost everything the general public knows of corporations and other organizations is mediated by the mass media. This is especially the case regarding strategic decisions, policymaking, and managerial behaviors. Consequently, the mass media seem to be used by organizations as key publics for → public relations in building trust, especially since people tend to trust the media more than they do corporations or political parties (→ Corporate Reputation; Trust of Publics). *Eurobarometer 61* (European Commission 2004) shows that 71 percent of the European public trusts the radio (up from 63 percent in 2001), 61 percent trust television (up from 56 percent in 2001), and 56 percent trust newspapers (up from 40 percent in 2001).

Despite booming public relations efforts in all European countries (Van Ruler & Verčič 2005), 60 percent (in 2004, up from 57 percent in 2003) of the public in the European Union countries said that they do not trust big corporations. Only political parties ranked lower in this *Eurobarometer* (European Commission 2004). In the USA, trust in the news media is lower; Gallup polls show that only about 50 percent (in 2003) of the American public has confidence in the news media, down from about 70 percent in the 1970s. In 2004 only 30 percent of the American public said they had trust in newspapers and television news. Although these numbers are lower than in Europe, US trust in the media is still ahead of trust in big corporations, and American organizations also see the mass media as a key public, subsidizing journalists with all kinds of information (Geary 2005; → Credibility of Content).

## ORGANIZATIONS AND THE MEDIA

The use of public relations subsidies by journalists seems to be enormous. The term “public relations subsidy” is used to describe the activities public relations and public information professionals undertake to provide journalists with information for free. In exchange for this service journalists are expected to make the given information public and thereby legitimize its content (Prenger & Van Vree 2004; Sallot & Johnson 2006). Hallahan (1999) talks about 50 percent of the news coming from these information subsidies; Merten (2004) even speaks of 80 percent. “The relationship between sources and journalists resembles a dance,” as Gans had already said in 1979 on the basis of his empirical studies of the news, “for sources seek access to journalists and journalists seek access to sources. Although it takes two to tango, either sources or journalists can lead, but more often than not, sources do the leading” (Gans 2004, 116).

It is, however, also clear that journalists do not act merely as a pipeline to publics, as many public relations authors as well as professionals tend to believe (Van Ruler 2003). That is why Bentele (2005) talks about the reconstruction of the organizational news by journalists into a final portrayal of the organization. In other words, there seems to be a *complex relationship between organizations and mass media*. In public relations literature,

building trust is nowadays seen as a key issue in the field, replacing issues like supplying information and image building or creation (e.g., Grunig 2001; Bentele 2005). The press plays an important role in this process of building trust, and the interdependence of organizations, the mass media, and the → public sphere has been called a “*ménage à trois*” by Van Ruler (2004). In public relations literature, the complex relationship between organizations, the press, and the public sphere has not yet been described or conceptualized in detail. To conceptualize this *ménage à trois*, the theoretical concepts of mediaization and mediatization can be helpful.

### **MEDIAZATION OF CULTURE**

The concept of mediaization describes the influence of media and of media organizations on the cultural transformations associated with the rise of modern societies (Thompson 1995). This mediaization of culture is seen as a process of cultural change, mainly explained by the increasing number of the mass media and their omnipresence in (post)modern societies. A lot of interaction in today’s society is mediated by some kind of media (→ Culture: Definitions and Concepts).

In the last decades of the twentieth century, mediaization extended, especially within the media field. Thompson (1995, 110–111) writes that “it has become common for media messages to be taken up by other media organizations and incorporated into new media messages . . . There is a relatively high degree of self referentiality within the media, in the sense that media messages commonly refer to other media messages or to events reported in the media.” Because of this “extended mediaization,” the mass media’s role as an intermediary between actors in society, facilitating communication, is diminishing, and some say the media are actively creating a reality of their own: a media reality. The concept of extended mediaization resonates with other theories and notions about the mass media such as media logic, media worlds (Altheide & Snow 1979, 1991) and media hypes (Vasterman 2004).

### **MEDIATIZATION OF INSTITUTIONS**

Some say that mediaization as described above is not only a cultural change but has also led to a change within the institutions of the modern society (e.g. Altheide & Snow 1979; Altheide 2004). Following German sociologist Max Weber, who described how the rationalization of institutions was preceded by the rationalization of culture in the eighteenth and nineteenth centuries, the mediaization of culture in the twentieth century might lead to a mediatization of the institutions of (post)modern society. The economic sector could be one of the first sectors of society where such a change is visible, because of the quest of private and public organizations for customers, profits, trust, and legitimacy. The concept of mediatization (see Kaase 1998; Mazzoleni & Schulz 1999; Kepplinger 2002; Schulz 2004; Schrott 2005) might therefore be useful to understand how organizations are coping with the mediaization of culture and their portrayal in the mass media. The question is how organizations cope with media logic and how media logic influences organization logic (Van Ruler 2004) and vice versa.

The term “mediatization” can be used to describe the *penetration of mass media and their logic into other social systems*, e.g., organizations in society (Mazzoleni & Schulz 1999; Kepplinger 2002; → Media Logic). Schulz (2004) has said that mediatization is not only the accommodation of media logic by actors and organizations in society. He suggested explicating mediatization further “with reference to basic performances and function of the medium in communication processes” (Schulz 2004, 98) in order to make the concept applicable to not only the traditional mass media, but also the new media and the role they play in society. Schrott (2005) has taken the concept of mediatization a step further again and proposed an analytical concept of mediatization for empirical research in the political field. Here mediatization is understood as an institutionalization process by which media logic is established as a pattern of orientation and interpretation within political institutions. These patterns of orientation are seen as implicit regulation systems, which overlay or even complement political or economic or scientific regulation systems (Schrott 2005).

Schrott (2005) proposes to operationally define *mediatization in five dimensions of institutionalization*. These five dimensions are (1) causes of and criteria for conforming to media rules and media logic; (2) the context in which these causes and criteria evolve into orientation frames for actors; (3) sanctions and control in order to enforce conformism to media logic; (4) the externalization of contingencies, so that only those problems will be dealt with that can be solved with media logic; and (5) concurrence with regulation patterns other than media logic for interpretive power.

Schrott proposes “a non-normative and therefore neutral definition” (2005, 17) of mediatization as an analytical model for mass communication research in a wide range of empirical contexts, for example in the fields of politics and science. This concept of mediatization also seems promising for the analysis of mediatization processes in the economic field, raising the empirical question of how organizations cope with their portrayal in the mass media and how this influences their patterns of orientation and interpretation as an institution.

## Mediatization of Politics

Gianpietro Mazzoleni

University of Milan

Mediatization of politics is a complex process that is closely linked to the presence of a → media logic in society and in the political sphere. It is distinguished from the idea of “mediation,” a natural, preordained mission of mass media to convey meaning from

communicators to their target audiences. To define politics as “mediated” is a simple truism, in that communication and mass media are necessary prerequisites to the functioning of political systems (Mazzoleni & Schulz 1999). Some scholars, such as Deutsch (1963), even hold that politics *is* communication. Certainly, politics and the way it is performed and communicated have been widely affected by the rise of mass media between the nineteenth and the twentieth centuries. Such media-driven influence in the political environment is the core of the concept of mediatization. The media have become indispensable actors within the political domain. They have gained a central position in most political routines, such as election campaigns, government communication, public diplomacy and image building, and national and international celebrations.

The centrality of the media in the political arena is a peculiarity of modern democracies, which are strongly characterized by interconnecting forms of mass communication (→ Media Democracy). The media’s rise to a pivotal place in the political processes has caused significant changes and developments in politics as a whole, to the extent that politics is often considered by political communication scholars as media dependent. The concept of dependence, however, is not supported by solid empirical evidence. The interdependence of media and politics seems to constitute a better pattern to represent the actual nature of the relationships between them. The media are nevertheless frequently credited with exercising overwhelming influence on political events, persons, issues, and opinions, and, at the same time, politicians are aware of the media’s attention rules, production routines, and selection criteria, and adapt their communication behavior to media requirements.

## EFFECTS OF MEDIATIZATION

Research has pointed out several effects of mediatization, among which are the capacity of the media to set the agenda of the political debate, the spectacularization and personalization of political communication, the fragmentation of political discourse, and the “winnowing” effect.

### Agenda Setting

The mass media, especially the information outlets, are acknowledged to have significant power to *structure and frame political reality* by determining what is relevant for public discussion, by raising issues, and by providing criticism (→ Agenda-Setting Effects). By pointing their spotlights on certain political events and by investigative reporting, the news media are in a position to drive the public debate, influence the campaign agenda, and prompt political figures to focus and take stances on the issues raised. This power is exalted or mitigated by the nature of the political milieu in a given national context. For example, in political systems that grant large autonomy to the media, political communicators are less successful in neutralizing the agenda shaping of the media. However, in political milieus where media–politics relations are characterized by close interdependence, the political agenda is more likely to be the joint output of the interaction of both actors (Semetko et al. 1991).

### Spectacularization and Personalization of Politics

The spectacularization of politics is an effect especially linked to the influential presence of television on the political scene. The “grammar” of television language has increasingly changed the patterns of political communication (→ Political Communication Culture). By becoming the target of an incessant dramatization on the part of commercial media, political activity has been driven to adjust its traditional forms of communication to the new canons of a media-centered environment (Mazzoleni 1987). This fact has entailed a recasting of the symbolic and expressive devices of political representation. In addressing citizens and voters, political communicators no longer rely on the mediation of militants. They can no longer “use the rhetoric of mobilization of supporters, but the rhetoric of seduction of the masses” (Lecomte & Denni 1990). In other words, the most significant effect of the mediatization/spectacularization of politics is somewhat equal to a “genetic mutation” of → political discourse. No politician can communicate successfully without molding his or her message to suit the most preferred and most popular language schemes of the mass media, especially those of entertainment, showbiz, and advertising. By dramatizing politics, the news media “take advantage of the popular propensity to believe in things as they seem rather than as they are,” and jointly with politicians who have swiftly embraced the imperatives of mediated communication, the media contrive to “construct politics as spectacle” (Nimmo & Combs 1990).

A necessary condition of spectacularization is the tendency of mass media, especially those that are commercially oriented, like the tabloids (→ Tabloid Press) and their equivalent in broadcast media, to personalize political information by focusing on who and how, rather than on issues, context, structure, and interpretation. “Average news consumers prefer to read about other people, not about abstract groups or remote bureaucracies and government agencies. To cater to these preferences, news stories, especially those that appear on television, are routinely framed from the point of view of central actors . . . Inevitably, stories about groups are transformed into stories about group leaders” (Davis 1990). Political players on the contemporary post-ideology political stage seem to respond enthusiastically to this media-driven tendency. They adjust willingly to media personalization, responding to the demands of visibility, look, and image (→ Personalization of Campaigning). Television is once more the *deus ex machina* of this adaptation: “Political figures cannot help subjecting themselves to the rules of TV popularity, obliged as they are to be either stars or nullities . . . Television is indeed the medium that resorts more to personalisation and relies a lot on rivalry among politicians” (Mouchon 1989).

A side-effect of personalization is what could be termed the “leaderization” of politics. In certain political milieus political leadership is strongly personalized, either for institutional reasons (as in a presidential system such as that of the US) or induced by the influence of the mass media. Political leaders extend their personal charisma (or idiosyncrasies) to the whole political process, setting themselves against collective actors such as parties or any shared expression of authority. The natural preference of the media for personalized political discourse provides a powerful support to the process of the strengthening of leadership in modern politics, and also in contexts where collective, impersonal, party-centered political action is the traditional pattern.

The media exert a further strong influence on political messages when these messages are carried on the mass communication channels. During this process, political debate fragments into “pills and clips.” “Audiovisual communication tends to propose a political speech which is fleeting, fluid, instantaneous, privileging verbal tricks rather than discursive strategy, in like manner of jingles-ads” (Courtine 1993). The well-known practice of sound bites favors the coverage and reporting of short and preferably catchy sentences at the expense of information on perhaps more substantial topics and issues in the domestic political debate. Like personalized framing of stories, sound-bite communication makes politicians into the accomplices, whether willing or unwilling, of media producers. In doing so, politicians attempt to adjust to the velocity of contemporary broadcast news, squeezing up their speech and thus increasing their chance of being covered by the media.

### **Fragmentation of Politics**

This sort of fragmentation of political discourse, triggered mostly by highly commercialized broadcast news media, has different national intensities, according to the strength of local newsmaking traditions. For example, in a number of European countries, such as France, Germany, and Italy, the news media still allocate a great deal of space to the complex dialectics between the many political contenders, and European politicians still exhibit a preference for articulated and somewhat lengthy declarations. Even if political discourse in these countries still enjoys significant attention in the media, there are several signals of an “Americanization” in the news coverage, thanks to the proliferation of channels and the sharp increase in competition between them for the conquest of audiences (→ Americanization of the Media).

### **Effects on Recruitment of Political Personnel**

A final effect of the mediatization of politics is the selection (“winnowing”) of political elites through the imposition of media-driven requisites and coverage formats upon political communication as a whole (Matthews 1978). There is also some indication of a progressive weakening of party organizations in many western democracies. For example, there has been a transfer of methods for recruiting political personnel (leaders, activists, candidates, mayors, etc.) from party machines to external agents – mostly communication experts, spin doctors, and media professionals – that implement tactics and follow criteria that collide with those of traditional professional politics.

The actual selection of political personnel and candidates is to a certain extent affected by the degree of media attention. Leaders chosen in this manner respond to the media’s predilection for telegenic, controversial, and possibly colorful personalities. Politicians who are natural newsmakers are assured of significant public visibility, while the media ignore those who are not “media-genic” talents. “Those who eventually succeed in election contests are no more local notables, but ‘mediatic personages,’ individuals who master better than others communication techniques; . . . a new breed of communication specialists takes the place of militants and of apparatchiks” (Manin 1995).

Vis-à-vis the rapid diffusion of online media, Schulz (2004) questions whether the traditional patterns of mediatization of politics will disappear to leave room for new ways

of interdependence between the new media and political players. In fact, the new communication environment created by the → Internet and other new media is likely to challenge the media logic that characterized the era of mass communication, and consequently its clutch on political communications. Schulz's argument is that there is not yet an end of mediatization as we have known it to date: "Since the new media do not displace the old media, the mediatization effects of the latter endure in the new media environment." In addition, the new media bring along *new patterns of mediatization*. Clearly, the new media logic will affect politics and political discourse, but the adaptation process will be mutual, not simply on the part of the political players, thanks to interactivity, a feature that conventional media do not possess.

# Mediatization of Society

*Gianpietro Mazzoleni*

*University of Milan*

From a very general point of view, “mediatization of society” is a concept that indicates the extension of the influence of the media (considered both as a cultural technology and as an organization) into all spheres of society and social life. In this broad sense, the way the media influence social life is linked to the larger process of culturalization, that is, the process by which culture – considered as the complex of signs, symbols, meanings, and values circulating within and between societies – has become increasingly central to the operation of all social institutions (→ Culture: Definitions and Concepts).

Thus, “mediatization of society” can be roughly considered as a process involving all the spheres of society, from the structure of the family to the aging process, from gender relationships to power, from the political apparatus to the economic structures, from everyday life to globalization processes. Moreover, it is a concept that examines the ways in which the media, which are vehicles of various types of messages (by which → meaning is exchanged and negotiated), and society have made themselves mutually indispensable and unavoidably interrelated.

## **MEDIA AND CHANGES IN SOCIAL LIFE**

Arguing that the media have a significant role in all the spheres of society and social life means stressing the importance of the media system in the transformation processes of society itself. According to Schulz (2004) four main processes of change represent different aspects of mediatization. At the first level, the media are considered to *extend* the natural limits of human communication capacities; in this sense the media are “extensions of man,” according to → McLuhan’s famous expression, providing means of communication that bridge spatial and temporal distances. At a further level, the media tend to *substitute* social activities and institutions, thus changing their characteristics (suffice it to remember the changes in private communication brought by phone and email). Third, the media *amalgamate* with different non-media activities. This is an important feature of the media–society complex, as since media-centered and non-media-centered everyday activities mingle with one another and media use becomes a normal aspect of social life, the media’s definition of reality becomes part of the social definition of reality. Finally, all sectors of society (including social actors in their everyday life) tend to *accommodate* to the way the media operate, produce texts, and provide vehicles for meanings. In short, several sectors of society must take into account the → media logic of electronic media (above all television), thus following the logic and the formats that are typical of media language and organizational practices, such as the ways the contents are organized and put together, the styles they are presented in, and the grammar (syntax, semantics, and pragmatics) of mass media communication.

*Media logic* has played an important role in the processes that shape the nature of the changes brought by mediatization. Media logic is the combination of several

technological, organizational, and cultural elements. The most important element is commercial logic, which involves the commercialization of both the media institutions (→ Commercialization of the Media) and society as a whole, followed by such elements as industrial logic (the media are an important industry), technological logic (referring to the importance of technologies in producing and reproducing contents), and cultural logic. We can find the logics of the mediatization processes particularly at the commercial and technological levels.

The *commercial level*, in both its economic and industrial dimensions, refers to the processes of standardization of mass media products and contents, which is accompanied by a continuous self-reinforcement of the media system and a growing circularity of media messages, ending in a series of “feedback loops” from the media coverage to the events covered (Kepplinger 2002; → Consonance of Media Content; Media Production and Content). Thus, from standardized production, which makes media contents almost ubiquitously available at relatively low costs, we arrive at a general dependence on mass media products, explained by such theories or hypotheses as the → media system dependency theory (Ball-Rokeach & DeFleur 1976), → agenda-setting effects, the priming effect (→ Priming Theory), or → cultivation theory.

The *technological level* has much to do with the fact that the media are technologies of communication that embody the ways messages are constructed, presented, and circulated, which also affect the ways they are interpreted by their audiences (→ Information and Communication Technology, Development of). This is at the core of → “medium theory,” according to which every single medium embodies a “bias” that affects the message itself (this is the meaning of McLuhan’s famous statement “the medium is the message”). Authors like Meyrowitz (1985) have extended this process not only to effects on the audiences’ patterns of consciousness, but also to changes in the patterns of the social actors’ everyday interaction rituals, thus providing a theory of social behavior that represents an important connection between social interactionism à la Goffman and “medium theory” à la McLuhan. Moreover, these technological constraints lead to mediation theory, where, again, media logic is at stake: the media’s technological characteristics contribute to the shaping of media messages and contents according to a specific “logic” that involves specific production routines and content formats. According to these technological (and commercial) characteristics, the media encode and format their contents in a way that reinforces specific patterns of human perception and information processing.

### **MEDIATIZATION /IN SOCIETY**

In brief, the concept of “mediatization of society” indicates an extension of the influence of the media into all societal spheres. Therefore, it is important to see what are the (main) domains that are influenced by the media system (remembering that the media system is both a cultural technology and an economic organization). In broad and general terms, all the main societal domains are affected by the connection between media and society: sex/gender and generational relationships, deviance, control and surveillance, religious and ritual dimensions, power relationships, urban environment and city life, localization and globalization processes, and so on.

As far as gender relationships are concerned, Meyrowitz (1985) argues that in contemporary western society men are becoming more woman-like and women more man-like. The so-called “private sphere” of men is becoming less private and more open to the gaze and knowledge of women – and vice versa. Meyrowitz sees this movement toward a unisex lifestyle as influenced by the advent of media images that the two genders had previously kept separate (→ Gender: Representation in the Media). The author claims that the same is true for generational relationships: due to the media, younger people gain access to the so-called “adult world,” thus gaining more information than ever in the history of childhood (→ Age Identity and Communication; Media and Perceptions of Reality).

As far as *deviance* is concerned, an important dimension that highlights the processes of interplay between forces of social reaction and control, the media, and certain forms of deviant activity is that of “moral panic,” while the processes of control and surveillance are more and more “mediatized” thanks to the new information and communication technologies. The concept of “war” itself is undergoing a mediatization process, from “media diplomacy” to “infowar.” The concept of “*mediatization of war*” refers not only to the relationship between war, media system, and political and military system, but also to the use of media languages and codes to define and frame war. In fact, the information technologies play a leading role in the development of the forms of contemporary conflicts. The war cycle is fulfilled within an IT logic, from remote sensing (a satellite surveying the territory) to “photo finishing” (the photos after the raid; → Conflict as Media Content).

Even the *religious and ritual aspects of society* are undergoing a continuing process of mediatization. If the “mediatization of religion” is a topic raised by McLuhan, who pointed out the importance of electronic and technological devices for changes in the Roman Catholic liturgy, the mediatization of the ritual dimension is demonstrated by Dayan and Katz (1992) and by their definition of media events. By “media event” Dayan and Katz mean an event that is broadcast “live” and is “remote” from its audiences, and that is a real event occurring at the society’s “center,” not set up by the media themselves. The effect of the media event is to enhance the symbolic importance of social ceremonies, while at the same time reaffirming the social bond through the media process.

If → *mediatization of politics* has been much studied and analyzed (Mazzoleni 1987; Mazzoleni & Schulz 1999), and it is now clear that political actors have to adapt to the rules of the media system in order to increase their publicity (at the price of a loss of autonomy), other spheres of society are undergoing a growing process of mediatization. It is the case in *sport*, where it is evident that sport and the media, two separate institutions, have come to be intimately involved over the past decades, with economic, political, and professional forces united in the making of media sport culture (→ Sports and the Media, History of). Other societal domains where we can detect a growing mediatization are those of urban life, with the rise of the “digital cities” of the “network society” (Castells 1996), or in architecture itself: as Colomina (1994) argues, while conventional criticism portrays modern architecture as a high artistic practice in opposition to mass media products, the mass media are the true site within which architecture is produced, as architectural discourse is the intersection of a number of systems of representation (such as drawings, models, photographs, books, films, and advertisements) that presuppose a new sense of space, one defined by mass mediated images rather than walls.

Lastly, the mediatization of society is evident in the processes of *globalization* (→ Globalization Theories) and cultural identities, where the mass media have become a proliferating resource for the production and the reproduction of identities.

## **Medium Theory**

*Joshua Meyrowitz*

*University of New Hampshire*

Medium theory stands apart from more generic “media theory” in its exploration of the influences of communication technologies in addition to, and distinct from, the specific content (messages) they convey. Medium theorists argue that media are not simply channels for transmitting information between two or more environments, but are themselves distinct social-psychological settings or environments that encourage certain types of interaction and discourage others (→ Media). Medium theory analyzes differences among communication environments.

Medium theory focuses on the characteristics of each medium (or of each *type* of medium) that make it physically, socially, and psychologically different from other media. Thus, medium theorists study how television differs from radio, but also how electronic media (including TV and radio) differ from print media (such as books, magazines, and newspapers). Medium theory also examines how communications through a particular medium or type of medium compare and contrast with face-to-face interaction. The singular “medium” is used in the name of the theory to highlight the focus on the particular characteristics of each medium.

### CHARACTERISTICS OF MEDIA

In comparing and contrasting modes of communication, medium theorists explore the influences of such characteristics as the *type of sensory information* the medium can and cannot transmit (e.g., visual, aural, tactile, etc.; → Modality and Multimodality); whether the medium is *uni-sensory or multi-sensory*; the nature of the medium-conveyed *form*, or forms, of information within each sense (e.g., picture vs. written word as distinct types of visuals, or Morse-code clicks vs. voice as distinct types of sound); the *speed and degree of immediacy* of communication through the medium; whether the medium affords *unidirectional vs. bidirectional vs. multidirectional* communication; whether interaction through the medium is *simultaneous or sequential* (as in the difference between telephones and CB radio); the *physical requirements for using the medium* (e.g., whether one has to stay in a certain location or look in a certain direction to attend to the medium); the *degree of control the user has over reception and transmission* (such as when readers choose their own pace and order of reading articles in a newspaper vs. the fixed speed and sequence of a news broadcast); the *scope and nature of dissemination* (e.g., how many people in how many different locations can attend to the same message at the same moment); and the relative *ease or difficulty of learning to use the medium* to code and decode messages (including whether one tends to learn to use the medium all at once or in stages over time).

Medium theorists see such characteristics as fostering unique uses for each medium and different responses to the same content when experienced through different media. Medium theorists have described, for example, how the Bible in restricted-access *manuscript* form served to support the medieval church’s monopoly over the word of God and access to salvation, while the Bible in widely available *print* form became a tool of Martin Luther’s sixteenth-century Protestant Reformation, which weakened the power of the Catholic church. Another classic medium theory example is how US radio audiences and television audiences in 1960 apparently responded very differently to the same set of events, the Nixon–Kennedy debates. Although no one thought to carry out a definitive medium research project during the debates, it was widely observed at the time that radio listeners tended to think that Nixon (with his ministerial voice and superior verbal debating skills) had won, while TV watchers (with access to images of a haggard, sweating, lip-licking, and eye-darting Nixon, contrasted with a tanned and composed Kennedy) were much more likely to think that Kennedy had won (→ Televised Debates).

## MICRO VS. MACRO MEDIUM THEORY

Medium theory operates on at least two levels: the micro (individual situation) and the macro (cultural). On the micro level, the key issue is how the medium selected by a person or group for a specific purpose influences a particular situation or interaction. On the macro level, the primary medium theory question is how the addition of a new medium to a society's existing matrix of media may alter social interactions, thinking patterns, social roles, social institutions, and social structure in general.

Micro- and macro-level medium theory questions are interconnected. On the micro level, a medium analyst might ask how the presence of a camera and/or microphone affects the specific behavior of a particular politician. On the macro level, a medium theorist might ask how electronic media alter political styles in general, shift the criteria used to judge candidates (thereby altering the range of viable candidates), and change the public's overall perception of politicians and world leaders. The dramatic increase in state, corporate, and citizen surveillance technologies in public and private settings in recent years raises similar micro and macro questions about the average person's behaviors. On the micro level, we might ask how behavior in a particular situation is affected by the presence of a camera and/or microphone, while on the macro level we could ask how general conceptions of private and public spheres and "appropriate" behavior are being reshaped by ubiquitous visual and aural monitoring and replay.

The most interesting – and most controversial – medium theory deals with the macro level. *Macro-level medium theory* is typically the most different from analyses of media content. One of the most popular media questions over the late twentieth and early twenty-first centuries has been a content-related one: do children imitate what they see on TV, such as TV violence? Medium studies, in contrast, explore such factors as the influence of structural changes in the boundaries of experience rather than the imitative and persuasive impact of media messages. The role-system form of medium theory suggests that changes in media alter the balance of what different types of people know about, and compare to, each other. Because young children are rarely able to read adult books, for example, books for parents about what to tell and not tell children tend to reinforce parental power. Yet a television show with the same content, a medium theorist would argue, undermines parental authority because thousands of young pre-literate and partially literate children are able to listen in, learning about the very topics that are being recommended for restriction from them, and learning the biggest secret of all – the "secret of secrecy" – the fact that adults conspire over what to tell and not tell children (Meyrowitz 1985, 226–267). Medium theory would argue that child–adult roles and interactions are thereby transformed, changing not just children, but what we, as a culture, mean by childhood and adulthood (→ Developmental Communication).

Similar contrasts exist between content-related questions and medium questions regarding gender and minority roles. Content questions about television, for example, might focus on the imitative and persuasive power of sexist and racist role portrayals in the medium, while medium questions would more likely look at the different ways in which various media restrict or expand the experiential worlds of women and minorities. Medium theorists would point out, for example, that the dire content-based prediction

that young girls growing up watching sexist TV would embrace limited roles for themselves has been falsified by the dramatic call on the part of women who grew up in the television era to integrate into what were once considered the “male spheres” of culture: business, sports, medicine, law, and the military – spheres that were exposed to, and demystified for, young girls and homebound women in television households (→ Media and Perceptions of Reality).

By exploring the potential impact of the characteristics of various media on the macro level, medium theorists have also developed arguments about how different dominant media tend to encourage different modes of thinking (e.g., print encouraging abstract, linear thinking vs. television encouraging concrete, nonlinear thinking); different human sensory balances; different relationships between physical location and experience; different layouts of houses, stores, offices, and cities; different forms of individual and collective memory; different perceptions of war; different conceptions of self vs. other (e.g., localism vs. nationalism vs. globalism or a multilayered sense of identity); different conceptions of privacy and of public etiquette; changes in relative social statuses; and different value systems (including shifting assessments of the relative merits of various media of communication).

### THE HISTORY OF MEDIUM THEORY

The term “medium theory” was coined in the 1980s (Meyrowitz 1985, 16) to give a unifying label to the work of a number of mid-twentieth-century scholars in a variety of fields (including history, anthropology, political economy, philosophy, religion, the classics, and communication), who were exploring how the different characteristics of different media encourage unique forms of interaction. The roots of medium theory, however, go back much further. Indeed, throughout history, each major development of a new medium has stimulated a new form of medium theory (→ Media History). In ancient Greece, Socrates complained that writing differed from oral dialogue in several key ways. Written texts, he argued, were incapable of answering questions put to them, reached audiences for which they were not intended, and weakened the memories of those who relied on them. Ironically, Socrates’ critiques of writing are well known today only because his student Plato recorded them in his written dialogues. Plato continued the medium theory tradition, but with a reversal of value judgments about at least some modes of orality versus text: Plato was enthusiastic about writing but wanted to banish the oral poets from his Republic.

In the fifteenth century, Johannes Gutenberg touted the ways in which his own invention of movable type differed in method and potential effects from the work of the scribes. And in the sixteenth century, Martin Luther and his followers consciously exploited the revolutionary potential of print via the first mass-mediated publicity campaign.

The rise of the film era in the early twentieth century encouraged film theorist Rudolf Arnheim to defend film as a potential art form (rather than a simple mechanical reproduction of reality). He proposed a form of medium theory that he called *materialtheorie*, which suggested that artistic and scientific descriptions of reality were shaped as much by the peculiarities of the chosen medium of representation as by the reality being portrayed.

As the influence of electronic media grew in the 1940s and 1950s, political economist → Harold A. Innis dramatically advanced the development of medium theory with two densely written books that extend the principles of economic monopolies to the study of information monopolies, *Empire and communications* (1950) and *The bias of communication* (1951). Innis rewrote the history of civilization, from early Mesopotamia and Egypt to the British Empire and the Nazis, as the history of communication media and their influences.

The increasing dominance of television in the 1960s set the stage for the most famous and controversial medium theorist, → Marshall McLuhan, who burst on the popular-culture scene with his second medium theory book, *Understanding media*, published in 1964. McLuhan, who was influenced by Innis's work, attracted the wrath of the literati and many scholars, not only by suggesting that television and other electronic media were having a major (and not necessarily negative) impact on the culture as they diminished the social significance of literacy, but also by presenting his ideas in nonlinear, aphoristic form, with little respect for what he saw as print-encouraged disciplinary boundaries and scholarly style. McLuhan defined media broadly to include not only print, the telegraph, movies, telephone, radio, TV, and computers, but all technologies, including clocks, motor cars, and weapons. In a form of argument that paralleled his approach to communication media, McLuhan claimed that the spread of the railroad (and later the airplane) fostered the development of “new kinds of cities and new kinds of work and leisure,” regardless of “whether the railway functioned in a tropical or a northern environment, and . . . quite independent of the freight or content of the railway medium” (1964/1994, 8).

Walter J. Ong, who both studied with McLuhan and influenced McLuhan's own work, was one of a number of other scholars who deepened the analysis of the shifts from orality to literacy and from literacy to what he called the “secondary orality” of electronic media. One of the major themes in Ong's multifaceted works from the 1950s to the 1990s is how shifts in modes of communication fostered changes in forms of human thought and consciousness. Recent decades have seen explosions in both new generations of electronic and digital media and in the number and types of medium theorists.

### **SUB-GENRES OF MEDIUM THEORY**

While medium theorists tend to share a common view of general communication history, they also divide into sub-genres of medium theory. Harold Innis, for example, presented a theory based on media “biases,” such as the tendency of a medium either to last a long time (“time biased” media such as stone hieroglyphics) or travel easily through space (“space biased” media such as papyrus). Marshall McLuhan's medium theory focused on media as extensions of the human senses, with differential effects on the human sensorium and the balance among the senses. Joshua Meyrowitz has developed a role-system medium theory based on how different media change the structure of social information systems, including “who knows what about whom” and “who knows what compared to whom,” thereby restructuring roles of group identity, socialization, and hierarchy. Ronald Deibert's “ecological holism” medium theory shifts the focus away from the “inherent effects” of each medium to the ways in which pre-existing social forces and trends are

either favored or not favored by the new communication environment. He analyzes the unintended consequences of technological change, when a “chance fitness” between medium and message brings ideas at the margins of society to the center.

### STRENGTHS AND LIMITS OF MEDIUM THEORY

By exploring the influence of modes of communication, medium theory provides insights into social and psychological processes that are invisible in traditional content-based approaches to media. In that sense, medium theory is similar to studies of industrialization, which suggest that the means of production are as important, or more important, to examine than an inventory of the products that are produced. Medium theory, like industrialization theory, looks at the structural changes in human relations, social identity, institutions, conceptions of labor, changes in rural and urban settings, and so forth.

Nevertheless, some critics dismiss all medium theory as a simplistic and mechanistic form of “technological determinism,” where autonomous technologies are viewed as reshaping people and societies in predetermined and monolithic ways. Yet, an accurate reading of most medium theory work reveals a much subtler argument: about *tendencies* rather than absolutist mechanisms, about interactions between media and society rather than media wholly shaping society. Most medium theory, rather than advocating a simple causal view, describes how the characteristics of a widely used medium foster, enable, and encourage certain communication patterns while discouraging others. Even Marshall McLuhan, whose provocative, aphoristic style has led him to be tagged more than other medium theorists as a media determinist, said, “There is absolutely no inevitability as long as there is a willingness to contemplate what is happening” (McLuhan & Fiore 1967, 25).

Medium theory has been criticized more legitimately for tending to start with an analysis of existing forms of media rather than delving into the socio-political and economic forces that lead to the development of some types of media rather than others. Television’s initial development as a unidirectional form of mass communication from the few to the many (rather than as an interactive community medium), for example, certainly favored the economic and political interests of corporate and state elites over those of the public at large. Yet, most medium theory gives insufficient attention to critical theory concerns about who has the most power over the dominant media in society and how that control limits and shapes the design and uses of media (→ Critical Theory). Medium theory also offers few insights into how to counter dominant cultural narratives that permeate most of the media in a society, including the highly selective “stories” that are told across media to shape public perceptions of “enemies” and war. In general, most medium theory does not challenge the political and economic status quo, including corporate ownership of mass media.

In looking at the ways in which media may shape societies, medium theory tends to give less attention to how significant variations among cultures (e.g., differing perceptions of time, space, and of human–human, human–nature, and human–technology relationships) may differentially shape the use of media in different societies. Ironically, while medium theorists examine media as types of “environments,” very few of them examine the ways in which “advances” in technology may lead to the depletion of natural resources and an

increase in toxic environmental waste. Similarly, most medium theorists do not examine how third-world countries and impoverished communities in western countries bear the brunt of the exploitation of resources and labor, disruption of sustainable economies and food supplies, and hazardous techno-waste. Nevertheless, medium theorists typically do a good job at analyzing the long-term unintended social consequences of media, including the ways in which technologies such as the Internet, mobile phones, camcorders, and so on have been embraced by third-world and other activists to protest and undermine the neo-liberal agendas that fostered the development of these technologies in the first place.

The current era of hypermediation has created a milieu of enhanced appreciation for medium theory. The growth of the world wide web, mobile telephony, WiFi, blogs, video surveillance technologies, virtual communities, radio frequency identification (RFID) tags, social networking web sites, and many other mediated environments has led to broader acceptance of the basic medium theory premise: that such media must be looked at as creating new social settings, settings whose influence cannot be reduced to the content of the messages transmitted through them.

# Meeting Technologies

*Craig R. Scott*

*Rutgers University*

In an effort to enhance the functioning of the much-maligned meeting, a variety of technological solutions have been introduced. These *meeting technologies* represent part of a rapidly growing industry focused on improving the millions of meetings held daily across the globe (→ Technology and Communication). Indeed, the increased use of collaborative teams (→ Group Communication), the growing number of virtual workers (→ Telework), the rising “costs” of travel, pushes toward globalization (→ Globalization of Organizations), and the declining expense associated with these technologies have all created an environment ripe for the use of meeting technologies in workplaces, educational settings, and other contexts.

Meeting technologies typically refer to end-user computer-based communication tools used by groups as they conduct, participate in, and coordinate meetings. Historically, they are used for more formal/planned, same-time meetings with participants either co-located or dispersed across multiple locations. Meeting technologies, in this sense, do not typically include non-computer-based tools (e.g., agendas, facilitation) that are sometimes referred to as technologies, nor do they apply well to more informal one-on-one interactions. Meeting technologies can be usefully grouped into three categories: electronic meeting/conferencing systems, meeting room technologies, and meeting management tools.

## **ELECTRONIC MEETING/CONFERENCING SYSTEMS**

The most recognizable category of meeting technologies is the various conferencing systems allowing people to connect and interact when not co-present. These include video, audio, and computer (or web) conferencing (Collins 2003). Most electronic meeting/conferencing systems require additional training and tools; as a result, these meetings are usually planned in advance, are relatively structured, and may demand the help of technical assistants. These meeting tools provide the opportunity for two-way exchange, though they can also be used for broadcast purposes.

*Video conference meetings* come in several forms: (1) dedicated rooms complete with cameras, monitors, speakers, microphones, and other equipment housed in a specific location, (2) mobile systems that typically include at least a camera and monitor on a cart, and (3) personal systems such as desktop video or video phones (though these often facilitate only point-to-point connections and are not as useful for meetings involving multiple participants). Although video conferencing has been plagued by slow industry growth, user discomfort, and technical challenges, it now appears ready to become a key collaboration tool (Ogden 2004).

*Audio conference meetings* are especially feasible for many given the ubiquity and mobility of phones, and these meetings also occur in several ways. Basic conferencing can use speakerphones between multiple people at each site and/or three-way conference features to connect one or more people at up to three locations. Operator-assisted

conferences can include a moderate number of participants, with each being contacted by the operator and then added to the conference. Another service provided by large companies and many conferencing providers is supply of a number and access code, which invited participants may call to join the meeting. Audio conferences may involve people at a variety of remote locations, but may also include some co-located individuals gathered around a speakerphone or a dedicated audio conferencing system (complete with multidirectional microphones, multiple speakers, and keypad interface).

A new player to the conferencing scene is *web conferencing*, the fastest growing of all conferencing technologies (Ogden 2004). Web conferencing tools are usually focused around a shared environment on a web browser, which may be used to show presentation slides, pictures, or other material. As a result, many web conference meetings involve people at their desktop or with their mobile laptop, though such sessions may also occur in a meeting room. Many web conferencing tools also allow for sharing of documents or collaborating in a shared space, which can facilitate interaction usually not possible in mediated meetings. The most interactive of web conferences may be supplemented with online chat, polling questions, and/or an audio link. Today's web conference tools in some ways represent the evolution of early computer conferencing systems that pre-date the world wide web.

In addition to these conferencing systems, *group decision support systems* (GDSSs; also known as group support systems [GSSs]) represent a special type of electronic meeting system that combines computer, communication, and decision-making technologies to support teams. Unlike conferencing tools, which link participants who usually are physically separated, GDSS participants are often co-located in a decision room; however, their interaction still takes place primarily online. This is done for two primary reasons (Scott 2003). First, having participants type their comments rather than speak allows for parallel input – providing approximately equal opportunity for participation and avoiding meeting problems associated with turn-taking and conversational domination. Second, the online nature of these systems allows for anonymous input, which may be useful when brainstorming, discussing controversial issues, and voting – especially when meeting participants are of different status and may be unable to speak openly otherwise.

## MEETING ROOM TECHNOLOGIES

Another set of meeting technologies are those designed to supplement the face-to-face interaction that occurs in more conventional meetings. Many of these technologies are focused on improving information presentation. Such technologies range from microphones and speakers that allow presenters to be heard, to projectors and document cameras, and even to presentation screens and plasma monitors that display images. Also available are smartboards, or interactive whiteboards that allow for the creation and capture of drawings and words. These are often mobile units that can be moved to various meeting rooms, though some dedicated meeting facilities may have built-in boards or entire walls with such capability. In addition to this hardware, presentation software has become commonplace in many business and educational environments.

Other technologies may be used by non-presenting meeting attendees. Participants may use various mobile devices (laptops, BlackBerries, etc.) to take notes, explore related information online, or exchange messages with others during meetings. Another type of

meeting technology one might find in large community forums or with large audiences are various keypad response systems. Such systems, which today are usually wireless radio frequency devices, allow participants to take part in polling questions or provide other feedback during meetings.

## MEETING MANAGEMENT TOOLS

A final set of less frequently mentioned *meeting tools* consists of those that assist with the coordination and management of meetings. In many workplaces, groupware features provide shared calendars that assist with scheduling and meeting reminders. Such programs may also facilitate email exchanges and online document sharing before, during, and after meetings. On a much larger scale are various meeting management tools used by large corporations and industry/trade associations to assist with site selection, online registration, attendee management, marketing, meeting emails, reports, customized websites, etc. (Chapman 2003).

## RESEARCH FINDINGS

With the exception of a substantial body of research on GDSSs, only limited research exists on the use of these technologies by actual task groups in their usual meeting environments (→ Bona Fide Groups). Reviews of conferencing/meeting technologies suggest several *general conclusions* about these tools (Scott 1999). First, technology-supported meeting participants generally outperform participants in face-to-face meetings – especially when using a GDSS, but not necessarily with audio/video conferencing. Second, technology-supported group meetings are generally more efficient than face-to-face group meetings – but, again, this is truer for GDSS users than for users of other technologies. Third, satisfaction with the meeting process is often less in the technology-supported groups when compared to face-to-face teams; however, this is somewhat less true for GDSS meetings, where findings are rather mixed. However, much of the existing research is limited because of differences between laboratory and field settings where the technology has been studied, and due to a general lack of research on actual web conferencing and video conferencing meetings.

Research on various meeting technologies has also been conducted in educational settings. A recent review of the immensely popular presentation software *PowerPoint* noted that even though such tools are preferred by students, they do not necessarily enhance learning (Levasseur & Sawyer 2006). Similar “no significant differences” have been found when comparing traditional classroom meetings with various forms of mediated learning. A meta-analysis revealed only the slightest of differences in performance when comparing the two environments, and the type of channel used did not account for those differences (Allen et al. 2004).

Research and practical use of meeting technologies has also suggested a number of *guidelines* for effective and appropriate use of such tools in workplace and educational environments. With conferencing tools, meeting organizers are generally advised to determine meeting length and agenda in advance (and stick to it), be mindful of time zones, inform participants of technological requirements, keep participant and technical

help numbers at hand, and look for ways to increase interactivity. Other meeting attendees are well advised to ensure they have the necessary technology in place in advance of the meeting, listen carefully during the meeting, and focus on the meeting itself (rather than multitasking during these mediated sessions). Video conference participants need to pay special attention to clothing and background visuals, and must become comfortable talking to the camera (as well as sometimes seeing themselves onscreen).

Audio conference participants should always announce who is “on speakerphone” and should generally mute phones when not speaking to minimize background noise. Because many GDSS meetings occur with participants co-located, guidelines here have tended to focus more on encouraging appropriate use of the tools (e.g., not trying to determine who made an anonymous comment) and facilitating an appropriate mix of offline and online conversation. In all cases, the meeting facilitator, technical staff, or meeting leader plays a vital role in encouraging appropriate use. In distance-learning environments using conferencing and other technologies for class meetings, providing opportunities for interactivity – between student and instructor, student and student, and students and other experts – is an important element to include. Finally, a number of guidelines have been advanced for the appropriate use of computer-generated slides in various contexts, with the general advice that too much information actually reduces effectiveness (Levasseur & Sawyer 2006).

A number of developments related to meeting technologies are already under way. Advances in mobile technologies making them more portable, powerful, and affordable are increasingly making it possible to have meetings anywhere (→ Mobility, Technology for). Convergence of technologies is increasingly allowing for meetings that readily combine audio, video, shared web-based interfaces, polling, and more. Increased use of the Internet and Internet 2 (→ Internet, Technology of) as the infrastructure for audio and video helps facilitate this convergence as well. Development of tele-immersive environments that present increasingly realistic and even holographic images of others also holds the potential to enhance meetings. Such advancements also hold potential for involving greater numbers of meeting participants, allowing for greater citizen participation in community forums and important political processes as well as in more traditional meeting contexts (→ Communication Technology and Democracy).

# Memory

*Ian Neath*

*Memorial University of Newfoundland*

When most people think of memory, they tend to think of a place in which information is put and stored until it is needed, much like a library. Unfortunately, this metaphor is quite misleading in that it implies a static, veridical process. Nothing really happens to library books while sitting on the shelf; they may grow musty, they might be misshelved, but once one has the book, the contents are identical to the last time the book was consulted. In contrast, human memory is a dynamic, fundamentally reconstructive set of processes that enable previously encoded information to affect current and future performance.

## CONSTRUCTION AND RECONSTRUCTION

Memory works like perceptual and other cognitive processes: people use whatever cues and information are available to achieve a sensible interpretation of the information processed (→ Information Processing). Consider the case of recalling what happened at the college football game last week. The first time a retrieval attempt is made, there are three sources of information: (1) from the event itself, (2) from similar events, and (3) from general knowledge of what happens at football games. All three sources of information are involved in the construction of a memory. The spectator might remember a specific play, which most likely comes from memory of the event itself. But if asked whether he remembers the coin toss that starts the game, he might mistakenly recall a coin toss from the previous week's game, or he might base his response on his general knowledge that a coin is tossed to determine which team goes on offense first. Note that the information from general knowledge or from a different event might be accurate, even though it has been retrieved from a different source (→ Memory, Message).

The second time a retrieval attempt is made, there is an additional source of information: memory of the previous recollection. Memory is said to be reconstructive in that each time a particular event is recalled, a new version is constructed based on the cues and information available at that particular time. The constructed version is then a potential source of information for subsequent recollections.

## Remembering Things that Did Not Happen

One consequence of the reconstructive nature of memory is that it is quite easy to create a situation in which people recall events that did not happen. Unfortunately, this has been given the name “false memory.” There are two problems with this term. First, it suggests a dichotomy between those memories that are true and those that are false. The problem is that because all memories are a combination of details recalled about the event and information from other sources, at least part of every memory is likely to be “false” because at least some details are not of the original event. Second, it suggests that the memory system stored false information. This obscures the important point that the memory system is not like a library; rather, memory is dynamic and continuously changing, as the examples below demonstrate.

There are now so many laboratory demonstrations (→ Experiment, Laboratory), that show that people are easily led to remember events that did not happen that it is beyond doubt that this also happens with great frequency in everyday life. For example, people see a list of items (“molehill,” “valley,” “summit,” “goat,” “ski,” “bike,” “peak,” and so on) that are all related to a critical word. When people try to recall such lists, they usually recall the word “mountain.” More important than the fact that they recalled a word that was not presented is the finding that they are convinced that this word was in fact on the list. The explanation is that all the words in the list are related to “mountain,” and presumably the person thinks of this word often during list presentation. At test, the person has the same sort of evidence that “mountain” was presented as any of the other words.

Memories can be created (or implanted) in everyday settings also. One common paradigm is to get family members to play a game of “remember when.” Here, an older sister, for example, might ask a younger brother whether he remembers getting lost at a mall when he was about 5 years old. At first, he says no for the reason that this never happened. About a week later, however, he will now have some “memories” of this event. This is known as an *attribution error*: the memory of being lost is attributed to a real event rather than to a discussion held with a sibling a week ago. Like the laboratory demonstrations, this memory has the same characteristics to the brother as genuine memories. Simply showing a photograph in which a person’s face has been digitally implanted (such as a photograph of the person taking a hot-air balloon ride) can lead the person to begin to recall aspects of the event.

## Eyewitness Memory

Because memory is so malleable, and because eyewitness memory can have such important consequences, there has been much research on how to assess whether a particular memory is accurate or inaccurate. The general conclusion is that in the absence of objective evidence, there is no aspect of a person’s recollection that predicts whether the memory is likely to be accurate or inaccurate. This conclusion comes from both laboratory studies and “real-world” studies. In particular, factors that have been shown to be unrelated to the accuracy of a memory include: the emotionality of an event; the duration of an event; the importance of the event to the person; the amount of detail also

recalled about the event; the speed at which the event is recalled; and the accuracy of other related memories. Because of this, many countries do not allow for criminal prosecution if the only evidence is from an eyewitness.

If an eyewitness to a car crash is asked how fast the cars were going when they “hit” each other, the eyewitness will report a much lower estimate than if asked how fast the cars were going when they “smashed into” each other. People act as if they are making an inference: for cars to “smash” into each other they must be going fast, therefore the estimate is higher. Answers to subsequent questions are also affected by these initial answers. When asked if there was broken glass, people who receive the “smashed” question are more likely to report there was broken glass than those who receive the “hit” question.

It is important to note that in laboratory studies, it is assumed that the witness is trying to be as honest as possible and is trying as hard as possible to recall details. In the legal system, this may not be a valid assumption, which makes interpretation even more difficult. It is also important to note that this does not mean that all eyewitnesses are recalling information inaccurately or even that memory of an event cannot be accurate. What it does mean is that there is no way to assess the accuracy of a particular memory: It could be very accurate, it could be very inaccurate, or it could be somewhere in between.

### **Hypnosis and Memory**

In studies of the effect of hypnosis on memory where there exists objective information that allows the researcher to assess the accuracy of recall, there is no evidence that hypnosis per se facilitates recall. On the contrary, people under hypnosis are easier to mislead than non-hypnotized people, and they have difficulty distinguishing between what happened under hypnosis and what happened when not hypnotized. Moreover, there is evidence that whereas hypnotized people are no more accurate than non-hypnotized people, they often express far greater confidence in their recollections.

Related to the finding that people have difficulty distinguishing between events that happened while hypnotized and those that happened when not hypnotized are compelling results from a slightly different paradigm. People are asked to perform a task or are asked to imagine performing the task; in another version, they are shown pictures of objects or asked to imagine a picture of the object. At test, they are asked to categorize the test items as either real (they performed the action or saw the picture), imagined (they imagined performing the action or imagined the picture), or new (the item was not part of the experiment). The judgment of real versus imagined is much more difficult than the judgment of whether the item is new or not. Items are more likely to be judged as “real” when they were imagined than the other way round.

### **THE ENCODING RETRIEVAL INTERACTION**

One of the primary determinants of recollection is the relation between the conditions at encoding (when the information was acquired) and the conditions at retrieval. If a person is happy when studying a particular set of information, more information will be recalled

if the person is happy at test than if unhappy. More information will also be recalled if a person is unhappy at both encoding and retrieval than if the emotional state differs. Similar results are found with environmental context and with pharmacological state. People taking scuba-diving lessons need to learn decompression tables that tell them how to ascend to avoid decompression sickness; they will do much better if they learn the information underwater, the same environment in which they will need to recall the information, than if they study only on land. In general, information acquired under a particular pharmacological state (e.g., alcohol intoxication) will also be better recalled under the same state than when sober.

The reason is that items and events are not processed in isolation but rather as part of ongoing mental processes. People who are happy (or underwater or intoxicated) will process words and events differently than if they are unhappy (or on land or sober). Thus, when trying to access information originally processed in a different state, people will generally be trying to process the information inappropriately.

There is a very important consequence of acknowledging that whether something will be remembered depends on the relation between the conditions at encoding and the conditions at test: one cannot make absolute statements about the mnemonic properties of an item, a process, or a cue. This means, for example, that one cannot say recognition is easier than recall, or pictures are easier to remember than words, or one particular cue is better than another kind of cue. It is always possible to change the retrieving conditions to render the absolute statement false.

## THEORETICAL ACCOUNTS OF MEMORY

There are two basic theoretical accounts of memory. One views memory as a set of different memory systems (the systems or structuralist account) whereas the other views it as a single system and emphasizes the role of processing (the processing or proceduralist perspective).

### The Multiple Systems View

Among proponents of the systems view, most hold that there are five different memory systems. *Working memory* (also known as short-term memory) is used for the temporary storage and manipulation of information. Long-term memory is made up of two systems, *episodic memory* (also called autobiographical memory) and *semantic memory* (also called generic memory and general knowledge). The difference between the two lies in whether the rememberer recollects just the fact itself or whether there is also awareness of the context in which the information was learned. For example, most people know that Paris is the capital of France, but they have no memory of when they learned this. In contrast, imagine that you are just told that the capital of Samoa is Apia. In addition to knowing the fact itself, you have information about when you learned it (you read it in the *International Encyclopedia of Communication*, you were sitting in a library, and so on). In short, you can place yourself back at the learning situation. Episodic memory is sometimes described as having the property of mental time travel: you can project yourself backward into particular episodes. Thus, there is no difference in the type of information stored in

the episodic and semantic systems; the sole difference is whether the information is accompanied by awareness of the learning episode.

The last two memory systems differ from the preceding three in that they are not part of the declarative group of memory systems. A rule of thumb is that if one can say that one *knows that* something (e.g., one knows that  $2 + 2$  is 4, one knows that the capital of Assyria was Nineveh), it is in a declarative memory system. If, on the other hand, one *knows how* to do something, then it is in a procedural memory system. A mother may know how to ride a bicycle, but this information cannot be usefully communicated to her son. She can say, “Balance, peddle, and steer,” but he will most likely fall off. The two nondeclarative memory systems are *procedural memory* and the *perceptual representation system*. Both of these are sometimes referred to as *implicit memory*.

Implicit memory is the term used to refer to situations in which memory is affected by prior events but the rememberer has no awareness of this influence. People with anterograde amnesia, who have difficulty remembering new information, often demonstrate unimpaired implicit memory. For example, such people might not remember the name of their physician even though the same physician has treated them for months. However, they can acquire and use information implicitly. The Tower of Hanoi (also called the Tower of London and the Tower of Babylon) problem has three pegs and a number of different-sized disks that must be moved from the first peg to the last peg. A larger disk cannot be put on a smaller disk, and only one disk can be moved at a time. People with anterograde amnesia demonstrate that they can learn this task: each time, it takes them fewer trials to succeed. However, they often claim to have never performed the task before and to not know the rules.

Episodic memory requires conscious awareness of the original learning episode. Semantic memory requires awareness of the information, but not of the original learning episode. Nondeclarative memory requires no awareness of the information at all.

### **The Processing View**

According to the systems view, the mnemonic properties of an item depend on the memory system in which it resides. According to the processing view, the mnemonic properties of an item depend on the relation between the conditions at encoding and the conditions at test. According to the former view, one cannot make generalizations about memory as a whole because each memory system operates according to different rules. According to the latter, there are important principles of memory that apply to all memory regardless of the type of information, the type of processing, the hypothetical system supporting the memory, or the time scale.

The *difference between the two approaches* can be readily appreciated from Table 1, which characterizes short-term memory (STM; also known as working memory) and long-term memory (LTM; also known as episodic memory). When an item is in STM, it will be stored using an acoustic code (how it sounds), the capacity will be limited to seven plus or minus two items, and the items will decay within about 20 seconds. In contrast, when an item is in LTM, it will be stored using a semantic code (what it means), the capacity will be (almost) unlimited, and the item may never be forgotten.

**Table 1** Short-term and long-term memory characteristics

System	STM	LTM
Format	Acoustic	Semantic
Duration	20 s	Indefinite (?)
Capacity	7 ± 2	Infinite (?)

A proponent of the processing view would agree with almost everything in the table, with one exception: what does the top row in the table add to our understanding? In other words, we could delete the top row and still have a complete and accurate description of memory. When words are processed on the basis of how they sound, there will be a very small capacity and the information will not be available for long. When words are processed on the basis of what they mean, however, there will be an enormous capacity, and the information will be available for a long time.

### TRANSFER-APPROPRIATE PROCESSING

The leading processing account is known as transfer-appropriate processing and it states that memory will be best when the processing done at encoding is appropriate for the processing required at test. Consider two types of tests commonly used in academic settings: multiple choice and short answer. Each requires a different kind of processing at test. In multiple choice tests, students are given all of the key terms, and the task is to be able to generate definitions of those terms and concepts. Thus, studying for a multiple choice test should include practicing generating definitions of key terms and concepts. Reading and re-reading notes is *not* a good study technique, as this is not appropriate for the kind of processing required at test. For a short answer test, students are more likely to need to be able to generate not only information about key concepts and terms, but also those terms and concepts themselves. Therefore, studying for this kind of test should also include practice generating the key ideas.

### Mnemonics

Transfer-appropriate processing naturally lends itself to helping people improve memory. Keep in mind that the goal is to anticipate the kind of processing that will be required at test, and then organize studying around it. For example, how can memory for people's names be improved? At test, the only constant is typically the person's face. Therefore, the face should be used as the retrieval cue, and studying should be built around that. Second, information can be recalled only if it is encoded. Get into the habit of repeating the person's name as soon as the introduction is made. Third, form a link between the cue (i.e., the face) and the name. Fourth, use the person's name a couple more times before moving on to the next person.

## **Memory, Message**

*Michael A. Shapiro*

*Cornell University*

Memory is critical to communication (→ Memory). The near-instantaneous understanding of a familiar word in a conversation, recognizing an advertising image, mentally disagreeing with a politician's speech, feeling sympathy for a → soap opera character, understanding why today's events in an ongoing news story are important, and countless other responses to communication are all connected in some way with what we have stored in our nervous system. In many ways our personhood and our interactions with the world are defined by the memories we store and use.

### **THE FUNCTION OF MEMORY**

Three decades ago investigators focused on message and viewer characteristics that influenced message recall. Communication scholars now understand this focus does not

capture the complex interactions between messages and memory. Messages are not just stored. When we process messages, their nature can influence how we process them. But what we already have in memory influences how and what we process. For example, highly arousing messages (→ Excitation and Arousal) are processed differently than messages that are not arousing, and how arousing a message seems depends on what is already stored in memory. Retrieving a memory is not just a matter of pulling something out of a mental file. Judgment is important in memory.

Much of what we remember is a *reconstruction* based on inferences about what usually happens. This works well much of the time, adding to the efficiency of memory, but it also means we sometimes remember things more the way we expect them to be than the way they really were. Memories also vary in strength. Sometimes we are willing to believe we remember a weak memory. Other times, when the consequences of a mistake are greater, we may hesitate to act on a stronger memory. You might be willing to guess at a waiter's name in a restaurant, but you may not want to guess at your employer's spouse's name.

Also, different measures of memory reveal different things about memory. Early studies of memory for television focused on recall. That is, offering few cues, investigators asked people what they remembered about a message. Recall is difficult and only measures some aspects of memory. Today, in addition to recall, researchers use measures that can separate judgment from memory strength (signal detection), measures that detect traces of memory we are not aware of (implicit measures), and measures of how quickly and efficiently we can retrieve a memory (latency measures). Thus, scholars now look at memory as a complex interaction among the nature of the message, our perceptions, conscious and unconscious mental processes, and what we already know.

The memory phenomena associated with communication are almost unlimited. A few are discussed below. One way to look at this is by examining what it is about communication that influences what gets stored, and how what is stored influences what we get out of communication.

## MEMORY FOR NEWS

Memory for news was one of the earliest concerns of modern communication scholars. While early studies looked at relatively crude differences such as whether print was better remembered than television, contemporary scholars know that a variety of structural and audience characteristics influence memory for news. Keep in mind that there are many things that can be remembered from the news, including visual information and text.

In general people better remember stories that are perceived as negative, relevant, and vivid, contain contextual information, are of human interest, and are about personalities. Considerable research indicates that for both print and → television news, congruence and redundancy between visuals and verbal elements help memory (→ News). Stories that are heavily covered are also better remembered. Audience members who are better educated and more informed remember more. Memory may actually increase over time if people continue to think about a news story. The current trend is to see these structural and audience characteristics in light of how the information is processed (→ News Processing and Retention).

## STRUCTURE, PACING, RECALL, AND RECOGNITION

Psychologists have known for many years that at any given moment (a moment in this case is usually between about two-tenths of a second and about a second) people can process only a limited amount of information (→ Information Processing). This is known as *limited capacity* (→ Limited Capacity Model). Such processes happen too fast for conscious control; they happen automatically. According to Lang's limited capacity model (Lang 2000) there are *three stages to memory*, depending on how much mental effort a person reflexively exerts and how much limited mental capacity is available. First, material passes through a short-term store. It is then encoded and, finally, stored. Typically, encoding is assessed using recognition memory measures (such as true/false or multiple choice) and storage is measured using recall measures (such as cued recall). One interesting phenomenon is that getting viewers to work harder at first improves their memory performance, but if they have to work too hard memory performance gets worse. If we choose to watch television, for example, both the nature and the pace of the message are out of the viewer's control.

The limited capacity model says that while viewing television we must process both the structure and meaning of the message. As a result, several interesting things happen related to memory. Many things in a message can cause a viewer to automatically allocate more processing capacity to a message. Such message features include novel or unexpected information, new information unrelated to the old information, and arousing content, as well as other features. These features initially cause the viewer to mentally work harder and remember more. However, at some point the capacity needed is greater than the capacity available for processing. Tradeoffs occur. Since storing material takes more mental effort than encoding the material, storage tends to suffer first. If the demands are great enough, encoding may also diminish.

## IMPLICIT MEMORY

Recognition and recall tests of memory ask explicitly if the viewer was aware something was seen or heard. Exposure to information can also influence performance on a variety of tasks that do not refer to the information to be remembered. This apparent memory without awareness has been called implicit memory. Implicit memory is measured using tasks such as word completion or indicating a preference. In some cases there is evidence of implicit memory, but not of explicit memory. For example, brands that were central to the plot of a television show were best remembered using explicit recall and recognition measures (→ Branding). Brands that were not central to the plot were less likely to be explicitly remembered, but were more likely to be selected when given a choice of brands (→ Advertising Effectiveness). Similar results were found after children were exposed to messages containing soft drink brands. The children became more likely to select a particular brand after seeing it in a film (Auty & Lewis 2004).

## RETRIEVING MEMORIES

Even under the best conditions, what is retrieved from memory is a complex interaction between the actual memory traces and our judgments and expectations. Memories are

not just available or not available. Often we are uncertain about whether we remember something (e.g., did you remember to lock your house this morning?). Our judgments about memory seem to depend not just on the strength of the memory but also on our judgments and motivations. If you live in a high-crime neighborhood you may want to be more certain you remembered to lock your house than if you live in a low-crime neighborhood.

One advantage of recognition measures of memory is that they can be used to mathematically separate the signal-strength aspect of memory from the judgment aspect, using signal detection theory. From correct recognition of true items (hits) and mistaken recognition of false items (false alarms), one can calculate a measure of the strength of the memory (sensitivity) and a measure of judgment about the memory (criterion bias). In some cases what appears to be poor memory may simply represent a more conservative judgment about memory. For example, Shapiro and Fox (2002) found that while it appears that typical information in a story is remembered better over time, that is a consequence of people using a much more conservative criterion judgment for atypical information.

Memory sensitivity for *atypical information* is actually better than for typical information over time. Signal detection has also been used to show that redundant visuals in television news result in better information discrimination than dissonant visuals, even though that difference doesn't appear in more conventional recognition memory tests. Also, it has long been known that retrieved memories are shaped by our expectations, and that our recalled memories are a combination of actual memory traces and inferential processes about what we would expect to be in that memory trace. Schemas are mental structures that reflect a person's knowledge and expectations of the world. Memory retrieval is often contaminated by what we expect to happen.

### CONTEXT EFFECTS, AROUSAL, AND ACCESSIBILITY

Along with memories of events, we store the *context of those events*. That context can be used as a memory retrieval cue and to characterize the memory. The source of a memory appears to be stored with memories of media events (Mares 1996; Shapiro 1991). How well people remember where an event memory came from can influence how those memories are used in making judgments based on those event memories.

Memory, both recognition and recall, appears to be much better for *arousing messages* than for less arousing messages. Several studies indicate that this may be one explanation for why negative messages are often more memorable: negative messages are usually more arousing. However, arousing messages also increase the allocation of processing resources to those messages. In some cases, the combination of arousal and other message features that increase allocation of processing resources (such as a large number of scene changes) can overload limited capacity and reduce memory for the message (→ Emotional Arousal Theory).

How easily a memory comes to mind (→ Attitude Accessibility) can influence a variety of decision processes. For example, when a public service announcement about HIV made it seem easier to retrieve memories of ways in which HIV is transmitted, participants' perceptions of their own risk increased. That effect disappears, however, if recovering such a memory is made to seem more difficult (Raghubir & Menon 1998). One can also

measure how quickly a memory comes to mind. Samu and colleagues (1999) timed how quickly people associated a product category and a particular brand to test competing advertising strategies.

*Future studies* are likely to focus less on memory as an outcome of a message and more on the interaction between memory and other mental processes. New methods of measuring memory and complex learning network models of memory are likely to increasingly influence studies in communication.

# Memory, Person

*Heather M. Claypool*

*University of Miami*

*Jamie DeCoster*

*University of Alabama*

Researchers who study person memory examine how perceivers store and recall information about a social target in order to understand how that information is structured in the perceiver's mind ( $\rightarrow$  Memory). Understanding the structure and organization of social information is important because it influences the way we perceive and process subsequently encountered targets, making it a crucial part of person perception ( $\rightarrow$  Media and Perceptions of Reality; Information Processing).

The study of person memory assumes that we have *concepts* stored in memory. A concept (sometimes called a  $\rightarrow$  schema) is a mental representation of a category, where a category is defined as a group of items perceived to fit together (Kunda 1999). Concepts contain the set of features thought to define a category, as well as specific examples of category members. We have concepts for all sorts of objects, including types of people. An "athlete" concept, for example, might contain the notion that athletes have excellent physical skill and a competitive nature, as well as specific examples of athletes like Michael Jordan, Babe Ruth, etc.

The usefulness of concepts is twofold. First, a concept helps us identify new stimuli. When we see a furry, meowing animal, we can identify it as a cat, even if it is a cat we have not seen previously. Second, having applied the concept to the object, we can infer its characteristics to guide how we should interact with the object. Once an animal is identified as a cat, we may infer that it is friendly, is soft, and can be petted, even if we have not directly observed that it has these features. Notice that one can only make these inferences to the extent that the concept contains information about its attributes, and that those attributes are linked together in some fashion. The person-perception process relies on the concepts that are brought to mind when one encounters a person. If features of an interaction partner trigger the concept "university professor," we may form quite a different impression than if the features trigger the concept "plumber." This is because these different concepts will likely contain different attributes that inform the impression we create.

## THE STRUCTURE OF CONCEPTS IN MEMORY

Two broad classes of models have been developed to describe how social memories are organized: associative networks and connectionist networks.

*Associative networks* suggest that each concept in memory is represented by a node, and that nodes that are conceptually related have links between them. Whenever a concept is directly perceived, the corresponding node receives a certain amount of "activation." When the activation in a node reaches a threshold, that concept becomes part of consciousness. In addition, activation spreads from the perceived concept to any other concepts to which it is linked. If enough activation passes through the links, concepts that are not

present in the environment may become part of consciousness. Even if the activation is not enough to bring a linked concept to consciousness, the incoming activation brings the linked node closer to its threshold, making it more likely that the concept will enter consciousness in the near future.

*Connectionist networks* represent one of the newest ways of thinking about person memory. These networks are composed of nodes and links, just like associative networks, but represent information in a different way. Connectionist networks do not associate particular concepts with particular nodes. Instead, a concept is portrayed by a pattern of activation over the entire set of nodes. This type of pattern is known as a “distributed representation.” This is similar to the way that an image of an actor is portrayed by different levels of electricity in the pixels on a TV set. There is no “Clint Eastwood” pixel stored anywhere in your television. Instead, we recognize that Clint is on our screen by the particular pattern displayed across all the pixels.

One important advantage of distributed representations is that they use the same nodes to represent all possible concepts, so the model never has to build new nodes when it encounters novel objects. As in associative networks, memories in connectionist networks are represented by the links between the nodes. Most connectionist models incorporate rules for adjusting the links after presenting a concept to make the network more likely to instantiate that concept again in the future. This allows the model to recreate the full representation of a concept even when it later encounters a stimulus that generates a partial pattern across the nodes.

## **INFERRING CONCEPT STRUCTURE FROM MEMORY MEASURES**

Although a single, definitive cognitive architecture of social information has not been identified, researchers have used a variety of measures to uncover what bits of knowledge are related in memory and the strengths of those relations. Below are examples of different types of memory measures and how they illuminate the structure of person memory (→ Research Methods).

### **Free Recall and Clustering**

In a free-recall measure, participants are presented with information and later asked to write down or recite as much as they can remember. In a seminal work, Hastie and Kumar (1979) used *free recall* to examine the organization of individual behaviors in memory. They created a personal expectancy by presenting participants with a list of traits that described an individual (e.g., “intelligent”). Participants then were presented with behaviors supposedly performed by that same person. Some behaviors were consistent with the expectation (i.e., were intelligent actions), some were inconsistent, and some were unrelated. Later, participants recalled the behaviors. The proportion of behaviors recalled was greatest for the inconsistent behaviors, followed by consistent and unrelated behaviors.

Based on these and related findings, Srull and Wyer (1989) developed an *elaborate model* to explain how such social knowledge is organized in memory. This model suggests that when participants have a pre-existing trait expectation about an individual, perceivers will form an “evaluation-based” representation of the person, wherein the

social target is represented by a person node that is linked to separate nodes for each behavior the target performed (Srull & Wyer 1989, 64). Links from the person node to the consistent behaviors should be stronger than links to the unrelated and inconsistent behaviors, making them easy to recall. This occurs because perceivers think about the consistent behaviors in relation to the person node to further solidify the original expectancy. However, links will also form between behavior nodes as behaviors are thought about in relation to one another. This will happen most frequently for the inconsistent behaviors, as the perceiver tries to reconcile their incongruence with expected behaviors. Therefore, the inconsistent behaviors will have more linkages emanating from them, improving their memorableness. These mechanisms allow the model to explain why both consistent and inconsistent behaviors should be better recalled than expectation-irrelevant behaviors, and why inconsistent behaviors will sometimes have a recall advantage over consistent ones (→ Consistency Theories; Cognitive Dissonance Theory).

Researchers have also investigated the *sequence* in which information is retrieved. Hamilton et al. (1980) presented participants with a list of behaviors. Those who read with an intent to form an impression showed more “clustering” in their recall than did those instructed to memorize the behaviors. That is, they showed a greater tendency to recall behaviors that shared the same trait implication at roughly the same time. To explain this finding, Srull and Wyer (1989) suggest that when initially forming an impression, participants encode behaviors in terms of what traits they exemplify. Doing so results in the formation of “trait–behavior clusters,” with a node representing the trait, linked to separate nodes representing each of the associated behaviors (Srull & Wyer 1989, 66).

### Implicit Measures

Free recall tells us a great deal about the structure of social information, but relies on participants’ ability to consciously recollect past experience (e.g., that a person performed an intelligent behavior). However, past experiences may foster connections in memory between social constructs and attributes, even when the perceiver lacks the ability to recall those experiences and is unaware of those connections. Free-recall measures are often not sensitive enough to detect these types of “memories.” Fortunately, so-called “implicit measures” can. Below are examples of implicit measures and how they have influenced thoughts about person memory.

Many implicit measures are used to understand what attributes or evaluations are associated with social groups. As one example, Fazio et al. (1995) exposed participants to photographs of black and white faces on a computer screen. Immediately afterward, an adjective appeared and respondents categorized it as positive or negative. Participants’ *response times* for these decisions were analyzed. Compared to baseline response times to the words when presented without the photos, white respondents made decisions faster when positive adjectives followed white faces and when negative adjectives followed black faces. Black participants showed the opposite pattern. These findings suggest a linkage in memory between one’s own group and positive evaluations.

Similarly, the *implicit association test* (Greenwald et al. 1998) has been used to explore unconscious associations with social groups. In this task, participants use a single pair of keys to make distinctions between two types of stimulus. As an example, when using

this procedure to examine implicit associations with blacks and whites, the first type of stimulus would be black and white names, whereas the second type would be positive and negative words. In one block, respondents press one key if they see either a black name or a negative word, and press a different key if they see either a white name or a positive word. In a separate block, these key mappings are reversed. White participants typically respond faster to the block pairing white names with positive evaluations than to the block pairing black names with positive evaluations, suggesting an association in memory between negative evaluations and black names.

## IMPLICATIONS OF CONCEPT ACTIVATION FOR IMPRESSION FORMATION

Person-memory models imply that the perception of a stimulus is determined jointly by information available in the environment and information available in memory. The extent to which memories of past experiences influence the impression of a newly encountered person or situation depends on several factors.

One factor receiving much empirical attention is *accessibility*. To examine the effect of concept accessibility on impressions, researchers expose perceivers to a concept (typically a trait) in one context and then ask them to form and report an impression of a social target presented in an unrelated context. Exposure to the trait concept in the initial context is said to “prime” (or make more accessible) that construct (→ Priming Theory). Researchers consistently find that trait-priming influences impressions of social targets. For example, Bargh and Pietromonaco (1982) showed that participants subliminally primed with the trait “hostility” judged the ambiguous actions of another as more hostile than did those not primed.

# Memory and Rhetoric

Stephen Howard Browne

Pennsylvania State University

For several decades now the role of public memory in shaping the present has occupied the attention of scholars across the humanities. From Holocaust studies to architecture, literature and → visual culture, colonialism, and queer theory, students of the subject are seeking to explain how and to what ends we avail ourselves of the past. Among the most recent and instructive contributions to this enterprise are those issuing from the study of rhetoric, which attends in particular to the discursive and strategic dimensions of public memory (→ Rhetorical Studies).

Historians of the art will note that the relationship between rhetoric and → memory is scarcely novel; indeed, it may be traced to antiquity, when early theorists counted memory as one of the five canons of rhetoric (the others being invention, arrangement, style, and delivery). It may be seen as closely related to Aristotle's system of topical recall, for example, and Cicero held it to be crucial in the education of the orator (→ Rhetoric, Greek; Rhetoric, Roman). Significant modifications of this relationship in the present age, however, warrant a new set of considerations (→ Rhetorics: New Rhetorics). The following offers a brief definition of the subject and three suggestions for framing it as a rhetorical phenomenon.

*Public memory* may be defined as a cultural process in which a shared sense of the past is created from the symbolic resources of human community (→ Symbolism). This understanding is provisional and shaped by the vested interests and aspirations of its members. From a rhetorical perspective, such a view presupposes that public memory is never neutral, natural, or without consequence. It is rather constructed, both a process and product of human ambition (→ Constructivism). Because we can only know the past as it is symbolically mediated, any given representation of it must be partial; and because memory is the form of knowledge through which we access the past, it too is necessarily selective and purposive. Public memory, therefore, may be taken as intrinsically rhetorical.

As a symbolic construction, public memory embeds itself in culturally available forms of mediation, or texts (→ Text and Intertextuality). These texts may range from monuments to orations, rituals of remembrance, photographs, quilts, tattoos, music, and so on. But whatever the various modes of expression through which memory speaks itself, they collectively serve to align the present to the past and the past to the present. And because public memory is created through such symbolic resources, any given message it is designed to communicate remains open to interpretation, debate, and revision, evidence for which may be found in the interminable contests over Holocaust revisionism, history textbooks, and public monuments.

As situated in *contexts of power and politics*, public memory raises serious questions as to its authority, ownership, and influence (→ Power and Discourse). Who or what is invested with the power to determine a given version of the past? To what political ends does a particular memorial practice operate? What are the differences between official and vernacular forms of public memory? Such questions lead invariably to contests over sanctioned memorial practices and those that seek to challenge them. Any comprehensive

understanding of public memory thus requires a principle of counter-memory, or those practices that aim to disrupt or extend in ways unintended by the powerful. Examples of such counter-memorial practices include African-American “5th of July” celebrations, Gay Pride parades, and European counter-monument movements.

As a form of production, public memory entails a *key paradox*. Stated axiomatically, this paradox holds that every act of remembering is also an act of forgetting. That is to say, the construction of one memory may well displace, elide, or otherwise erase a competing sense of the past. Here indeed is the political rationale for much memory work: to install and sanction a version of history thought to be advantageous to a given interest. The emergence of the “lost cause” tradition in the post-bellum south, for example, is thought by many historians to have obfuscated the legacy of slavery and the ends for which the Civil War was undertaken.

For the ancients, memory was taken to be a technology of recollection (Yates 1999). That function still exists, of course, but the terms in which we now understand memory have expanded greatly. To understand public memory from a rhetorical perspective in our time is to grasp it as symbolically constructed, as situated within contexts of power and politics, and as inherently related to the process of forgetting.

## **Mentoring**

*Timothy G. Plax*

*California State University, Long Beach*

Defined as a communication process involving a seasoned professional who counsels, guides, and tutors a protégé (Waldeck et al. 1997), mentoring within the instructional context refers to a teacher–student relationship. In this context, mentoring consists of a

communication relationship between teachers and students, where the teacher provides academic, career, and social support to the student. Mentoring often extends beyond academic advising, fulfilling important personal and professional functions for the student. Mentoring provides students with invaluable information on university policies and politics, explicit and implicit rules and regulations, and other faculty in their program of study. In short, effective mentoring relationships promote personal growth as well as a professional development for protégés.

Central to the mentored relationship is the personal connection between the teacher and the student. The mentor usually has much to offer the more inexperienced protégé. Having achieved professional success, the mentor provides the protégé with both covert and overt practices to assist him or her in becoming successful (Kalbfleish 2002).

Research on mentoring relationships has identified a range of mentoring functions or mentoring roles. An overview of the literature points to two major functions: career and psychosocial (Clawson 1980). Career functions are more task-oriented and focus on ways the student might advance professionally. Psychosocial functions are more person-centered and focus on enhancing students' personal growth and sense of identity. Together, both functions assist students in their abilities to adapt to the challenges of their personal and professional lives.

The benefits of mentoring within the academy are numerous (Kogler-Hill et al. 1989). Important to student retention, academic progress, and graduation is student face time with faculty (Ewell 2005). Initiating and sustaining relationships between faculty and students increases the opportunities for face time and subsequent counseling. Mentored students most likely have more face time with faculty. As a result, they are more likely to stay in school and graduate. Mentored protégés tend to secure better jobs, achieve higher incomes (Whitely et al. 1992), gain in self-confidence, empowerment, and self-worth, become more skilled, and are exposed to greater professional networks.

Mentored students typically characterize their relationships with their mentors as "extremely pleasurable, meaningful and productive" (Waldeck et al. 1997, 105). They further perceive their personal relationships with their mentors as "very close, warm, relaxed, and friendly" (1997, 105). In fact, Waldeck et al. found that for graduate student mentoring, the psychosocial function predominates over the career function. Students who developed social, personal ties with their professors also reported their work relationship to be more satisfying.

The effectiveness of the mentor-protégé relationship resides primarily within the communication skills of the participants (Kalbfleisch & Davies 1993; Waldeck et al. 1997). Individuals high in communication competence and self-esteem are more likely or more willing to engage in mentoring relationships (Kalbfleisch & Davies 1993; → Student Communication Competence). Correspondingly, these same individuals experience greater levels of satisfaction with the mentored relationship. Conversely, those individuals who may need mentoring the most are less likely to seek mentoring experiences. Waldeck et al. (1997) report, e.g., that students representing minority groups in the United States (e.g., African-Americans, Latinos, Asian-Americans) are noticeably underrepresented in mentored relationships. Moreover, student attempts to initiate mentoring relationships are perceived to be especially difficult. Graduate students, e.g., indicate that their initiating

attempts are relatively ineffective, often requiring additional communication strategies and attempts before securing a mentor.

In response to these research findings, more formalized mentoring programs are needed. Faculty could be assigned protégés, reducing the need for either mentor or protégé initiation attempts. Without formal mentoring programs, faculty need to proactively recruit protégés who require academic or social guidance. Whereas much of the mentoring that occurs focuses on the task or career function, students need support and guidance about their personal and social requirements. Face time with students is perhaps the most important mentoring tool that instructors can provide. Interacting with students beyond the classroom opens opportunities for student discussions about those issues that most concern them. Kram (1988) makes similar recommendations in her guides for action for promoting mentoring relationships in organizations.

# Mergers

Duncan H. Brown

Ohio University

In the late 1970s and early 1980s two books were published that tracked the growing concentration of ownership in the media industries (→ Concentration in Media Systems). The first, published in 1979 by Benjamin M. Compaine, was titled *Who owns the media?* The first edition of Benjamin H. Bagdikian's book *The media monopoly* was published in 1983. Over the following years subsequent editions of these books continued to show how mergers between media corporations were creating a situation where a smaller and smaller number of media corporations controlled an increasing proportion of the media products audiences consumed. At the beginning of the new millennium, both series of books found it necessary to issue heavily revised editions to take account of the growing speed of change in the media industries (Compaine & Gomery 2000; Bagdikian 2004; → Media Conglomerates; Media Corporations, Forms of; Media Economics).

There are many reasons why media corporations have sought to grow in size through mergers and acquisitions. *Technological convergence*, particularly as a result of a shift toward digital technologies, has led some media industries to compete in ways that were impossible before. For example, → cable television companies now want to provide their subscribers with telephone service and high-speed → Internet access through their digital networks. Similarly, telephone companies now look to various broadband services as a way of expanding the services they provide their customers. Merging with a company already active in the new media sector you want to enter is often an attractive strategy (→ Digitization and Media Convergence).

But it would be wrong to suggest that it is only technological change that has intensified the urge to merge. A *search for synergy* and economies of scale has also been an important catalyst. Synergy is the ability of one part of a media corporation to promote the products of another. For a time during the 1980s and early 1990s, synergy became the "holy grail" of corporate strategies. Industry executives stared enviously at the ability of → Disney's television properties to promote the activities of its theme parks, while the theme parks could introduce new generations of children to characters from Disney's growing archive of animated movies (Wasko 2001).

There was also a belief that, by growing ever larger, media corporations could enjoy economies of scale that would *increase their profitability*. This was intensified by the fact that in many media industries, the initial costs of production are very high while the costs of creating copies and distributing them are comparatively low (→ Cost and Revenue Structures in the Media).

It should also be noted that the *growing globalization* of media industries convinced many governments that they needed to allow their media corporations to merge in order for them to become big enough to compete on a global, or at least regional, scale (→ Globalization of the Media). Thus, in the United States regulations stopping a corporation operating in one industry sector, such as local telephone service, from operating in another sector, such as cable television, were progressively weakened or

eliminated. And the portion of an industry sector that a single corporation could control was increased, relying mostly on antitrust laws, rather than sector-specific regulations, to protect the public from anti-competitive behavior (→ Antitrust Regulation). All of these governmental actions contributed to the momentum for mergers in the media industries.

Not everyone was convinced that these media mergers benefited anyone other than the individual media corporations. Against the tide of neo-liberal thinking, which argued that media industries should be treated just like any other industry, a growing undercurrent noted that, unlike many other manufactured goods, media products contribute to the collective culture and our understanding of the world around us and our place in it. Therefore, while a media merger might not create a situation where the merged corporation could use its new market power to fix prices, and thus attract the attention of antitrust authorities, there might still be a concern that the diversity of viewpoints and voices would be diminished (→ Plurality). Additionally, the merged media corporation might now feel unwilling to report critically on the activities of its new corporate parent.

But these concerns were countered by other observers. They noted several ways in which the creation of increasingly large media corporations could be beneficial. For example, if a community's newspaper was owned by a large corporation headquartered in some distant city, it might be less open to pressures from local elites to cover the news in ways that served the interests of those elites rather than most members of the community. Similarly, on a global scale, a transnational media conglomerate might be more willing than an organization based in that country to challenge restrictions placed on its operations by a government trying to restrict the flow of information to maintain its power.

## Message Design Logics

Melanie Morgan

Purdue University

The major premise of message design logics is that individuals have different ways of reasoning (“design logics”) about communication. These individual differences affect how messages are structured to achieve goals (→ Message Production; Goals, Cognitive Aspects of; Goals, Social Aspects of). As such, message design logic provides a “rational goal analysis” of a speaker’s understanding of means–end relations in communication, which results in a range of variations evidenced in messages across a spectrum of complex situations (O’Keefe 1988). Typically, rational goal analyses, such as Brown and Levinson’s (1978) work on politeness or O’Keefe and Shepherd’s (1987) work on arguments, see message variation in terms of “strategies.” The theory of message design logic extends rational goal analyses by arguing that strategy choice in the pursuit of goals can reflect underlying differences in fundamental premises individuals hold about communication (→ Interpersonal Communication).

O’Keefe (1988) argues that there are at least three different design logics that can explain message variation. These design logics, in order of functional and developmental sophistication, are labeled expressive, conventional, and rhetorical. An *expressive design logic* is the simplest logic and reflects the premise that language is primarily a vehicle for expressing thoughts and feelings. Expressive communicators generate messages that are often blunt and more or less straightforward articulations of their current mental state. They speak very literally and interpret incoming messages by the same logic. Because communication is presumed to be the vehicle for thought, messages generated by this logic often contain irrelevant or pragmatically useless content, unnecessary redundancies, and stylistically inappropriate forms of expression. The expressive communicator, therefore, is guided by an internal mandate to “say what you think.”

In contrast, a *conventional design logic* sees communication as a “game played cooperatively, according to social conventions and procedures” (O’Keefe 1990, 91). In other words, messages are seen as actions in the service of achieving goals in acceptable ways as defined by the situation in which they occur and according to common social norms and rules for behaving in that situation.

Finally, a *rhetorical design logic*, the most sophisticated, involves a conception of communication that goes well beyond viewing messages as expressions of thought or rule-governed responses to social situations. Rather, it views communication as the creation of social selves and situations. Social situations are not predefined entities to

which one responds. They are, instead, entities that are defined through messages that articulate a view of what could be. Messages are structured by rhetorical design logics in ways that can facilitate defining situations to be consistent with desired goals.

Not all communicative situations permit discernible manifestation of these logics. However, they do become evident in complex communication environments where multiple goals are relevant and, often, at odds. Message design logic has also been associated with other individual differences and message effects. For instance, individuals with more sophisticated design logics are more cognitively complex (O’Keefe 1988). Also, messages produced by more sophisticated logics are considered more effective and the message producers are perceived as more socially attractive than those with less sophisticated design logics (Lambert & Gillespie 1994; O’Keefe & McCornack 1987; → Interpersonal Communication Competence and Social Skills).

The theory of message design logic provides an alternative perspective on message variation that extends traditional notions of message production as “strategy selection.” It provides a framework for linking messages to the goals they seek to achieve, and it provides a methodology for identifying the operative design logic that is at work within a message producer and accounts for the structure and effectiveness of those messages.

# Message Discrimination

Peter V. Miller

Northwestern University

Message discrimination is a self-report measure of media exposure (→ Audience Research; Exposure to Communication Content; Information Processing; Cognition). In survey interviews, respondents are asked to recall → information about a particular topic that they have encountered in various media in the recent past. For example, respondents might be asked, “What have you seen or heard on television about family planning in the last month?” Open questions like this are repeated for other media (e.g., → newspapers, → radio, → magazines, → books). Responses are recorded verbatim and coded into “messages.” The message discrimination measure is the sum of messages reported by a respondent for the topic of interest across all of the media.

The term was coined by Peter Clarke and F. Gerald Kline (1974) in an article introducing the measure and its use in research on → media effects. The approach appears to have been presaged in the work of Edelstein (1974). His comparative research in the United States and Yugoslavia involved asking respondents (→ Interview; Survey) to nominate important problems confronting their local area and the world. Respondents were then queried about the sources of information on these problems (media), what solutions had been proposed, and what actors were involved in addressing the problems. Message discrimination features this “respondent-centered and open-ended” approach, as Clarke and Kline termed it. Clarke was a colleague of Edelstein at the University of Washington prior to joining Kline on the faculty at the University of Michigan in the early 1970s. Clarke and Kline (1974) illustrated the message discrimination measurement approach with a small study that employed Edelstein’s “problem – solution” questioning design. In subsequent research, the recall of information about solutions to a respondent-nominated problem was replaced by recall of information about a topic supplied by investigators.

## MOTIVES FOR USING MESSAGE DISCRIMINATION MEASURES

The rationale offered by Clarke and Kline for the use of open recall of information as a measure of media exposure rests on two claims. First, they asserted that frequently used measures of media exposure, which focus on reported time expenditure or frequency of contact with a medium, are too crude to capture what might be called “meaningful” exposure to the channel. At most, such measures denote the *potential* for exposure to particular content. Because they are so gross, the standard “exposure” measures are unlikely to show much predictive power when used as independent variables in media effects research. Clarke and Kline argued that media effects had been generally underestimated in the literature because “time spent” or “frequency of use” measures were so commonly employed as predictors (→ Exposure to Television; Exposure to Print Media; Exposure to News).

The second rationale for the message discrimination measure was normative. Clarke and Kline struck a decidedly egalitarian note when they declared that previous media research had relied too much on “researcher” definitions of media exposure and outcomes.

They contended that the extensiveness of respondents' cognitions should define exposure and that respondents' reported "information-holding" should replace elite "textbook knowledge" as the likely outcome of exposure. Thus, message discrimination may be seen as part of a more general reaction in mass communication scholarship in the early 1970s against the "limited media effects" viewpoint that had dominated in the previous two decades (see Klapper 1960; → Communication and Media Studies, History since 1968; Media Effects, History of). In sum, the contention was that genuine media effects had been overlooked in research to date because the independent and dependent variables had been erroneously defined.

### APPLICATIONS IN EMPIRICAL RESEARCH

An example supporting the latter argument may be seen in Clarke and Fredin (1978). This study involved analysis of data from the 1974 National Election Study post-election interviews (→ Election Surveys). The hypothesis examined was that message discrimination about the campaign and about respondent-nominated problems facing the country would better predict "information-holding" (in this case, the number of reasons offered for supporting or opposing senatorial candidates) than would estimated frequency of television news viewing or number of daily newspapers read. Message discrimination measures for television and newspapers did predict the number of reasons offered by respondents better than did the number of newspapers read or the frequency of television news viewing, controlling for education and political interest. A finding for which the authors had no ready explanation was the fact that the number of messages discriminated from television was a *negative* predictor of information-holding. But the principle that exposure measured through message discrimination should predict knowledge better than exposure measures based on frequency of use was buttressed.

Two field experiments (→ Experiment, Field) prominently featured message discrimination in their assessments of media use. The first study, conducted in Flint, Michigan, and Toledo, Ohio, focused on adolescent learning (→ Educational Communication) about such topics as family planning and drug abuse. The second experiment was conducted in several Minnesota cities and concerned heart disease prevention. Example publications from these studies are Kline et al. (1974) and Jacobs et al. (1986). There is some irony in the observation that the "respondent-centered" message discrimination measure received its major application in the evaluation of "researcher-driven" information campaigns (→ Health Campaigns, Communication in).

Finnegan et al. (1989) examine aspects of the measurement technique in detail. The authors note that there was considerable operational variability in the approach across studies. While some investigations focused the message discrimination sequence with respondent-nominated issues, the field experiments queried respondents about topics of mass media campaigns (e.g., family planning, heart disease). Kline et al. (1974) asked respondents what they had seen, heard, or read about the topic of interest, repeating the question for each of several media. Jacobs et al. (1986) asked a more general question: "What specifically have you read, seen or heard about heart attack and stroke during the past few months from any of these sources?" (Respondents were handed a card listing various media.) The reference period for recall also varied across studies, with some

delimiting a particular time frame (“the past two weeks” or “past month”), while others asked about more vague periods of time (“past few months” or “lately”). Thus, while the several studies that have employed message discrimination shared the free recall approach – allowing respondents to report on media exposure “in their own words” – there is a case to be made that message discrimination is not one measurement technique, but several.

### **LACK OF ADOPTION OF MESSAGE DISCRIMINATION MEASURES IN RESEARCH**

As Finnegan et al. (1989) note, the message discrimination approach has not supplanted the time-based or frequency-of-use media exposure measures in reaction to which Clarke and Kline offered their alternative. Apart from research in which they, their colleagues, and their students were involved in the 1970s and 1980s, message discrimination has not played a role in the literature. This situation obtains despite the undeniable weaknesses of the standard exposure measures and some empirical support for the proposition that message discrimination better predicts information gain. It is worth speculating on why this is the case.

One reason may be ambiguity in the measurement of the concept. Message discrimination is supposed to measure media exposure, but it does so by asking respondents to recall information that they have received via the media. This means that exposure is confounded with information gain, which is usually treated as a dependent variable in media effects research (→ Measurement Theory). The confounding is intentional – Clarke and Kline argue that exposure is topic-specific and that it has not occurred without evidence that the putative audience member has “discriminated some symbols” relevant to the topic (→ Symbolism). But how are these “symbols” to be distinguished from knowledge about the topic that is the *outcome* of exposure? Clarke and Kline assert that message discrimination is distinct from “information-holding,” the dependent variable in their model of media effects. As Salmon (1986) observed, however, both message discrimination and information-holding rely on long-term recall of information. There is nothing in the measurement procedure as applied to date to ensure that message discrimination picks up information that is antecedent to knowledge, or even to ensure that the “symbols” recorded are actually the result of contact with media. Unlike Southwell et al. (2002), who assessed exposure to a health information campaign through *recognition* of campaign messages, researchers who have employed message discrimination have not verified that *recalled* messages originated in the media. While in some instantiations of the message discrimination technique, respondents have been asked to recall information that they encountered in different media – as noted above – the “messages” reported were not checked against a compendium of media content so as to validate the reports.

Another, maybe more powerful reason for the lack of widespread adoption of the message discrimination measure is that it is more laborious and expensive to execute than the time-allocation or frequency-of-use measures. Like any open questioning approach, message discrimination involves questioning, probing, and careful recording of responses. Interviewers must be extensively trained and the interviews they conduct will take longer than ones that rely on closed questions. Interviewer variance is apt to be

greater for this sort of measure than for closed question approaches. Once obtained, the responses must be unitized (“messages” must be identified) and placed in categories by coders (→ Coding). Inter-coder → reliability is an additional concern. The message discrimination approach can be burdensome to respondents too, despite the claim that it allows them to “speak in their own words.” Responding to open questions often requires more difficult comprehension, retrieval of relevant information, organization of thoughts and articulation than is involved in responding to closed questions. Greater familiarity and ease of use probably gave an advantage to the traditional media exposure questions that Clarke and Kline sought to replace with message discrimination.

Advances in survey technology and computational → linguistics could make application of message discrimination measurement more tractable for media effects researchers. Computer-assisted interviewing, voice recognition, and automated content analysis software (→ Content Analysis, Quantitative) could reduce the burden and expense of collecting and summarizing reports of information gleaned from media sources. Validation of these reports and clear differentiation of them from outcome measures of media effects is required for the message discrimination approach to achieve more widespread adoption.

# Message Editing

Janet R. Meyer

Kent State University

Message editing is the process whereby speakers review and sometimes revise a message plan prior to speaking. At lower levels of linguistic output, a not-yet-spoken clause might be checked for consistency with phonemic, syntactic, and/or lexical rules. At more abstract planning levels, the acceptability of a message plan could be assessed by comparing it against a set of editing criteria, and/or by anticipating outcomes of the message (→ Goals, Social Aspects of; Message Production).

In order to investigate message editing at the phonemic and lexical levels, Motley and his colleagues conducted a series of experiments using laboratory-induced speech errors (Motley et al. 1983; → Experiment, Laboratory). In studies designed to elicit spoonerisms, for example, participants read aloud target word pairs, such as *shoe store*. When a target pair was preceded by a word pair containing a reversal of the initial phonemes in the target pair (*stoop short*), participants often produced a spoonerized version of the target pair (*stew shore*) (Motley 1985). Spoonerized versions more often contained lexically legitimate words than lexically anomalous words (“lexical bias effect”). To explain these findings, as well as other contextual influences on lexical selection, Motley et al. (1983) proposed a *model of pre-articulatory editing*. The model holds that the everyday production of error-free speech relies on an editor that reviews message plans for linguistic legitimacy prior to output. If the editor detects a linguistically anomalous construction, the plan may be vetoed or repaired.

In the mid-1980s, the notion that speech efficiency is due to pre-articulatory editing began to give way to the view that lower-level planning “decisions,” such as lexical selection, are often determined by the activation levels of nodes in an associative network. In a review of evidence from naturally occurring and laboratory-induced speech errors, Motley (1985) notes that speech errors at phonemic, lexical, and syntactical levels can result from highly activated competing output plans (→ Speech Communication, History of). He concludes that initial lexical selection depends on the activation levels of nodes in a spreading activation lexicon. As nodes do not exist for lexically anomalous items, the system is biased toward the production of speech errors containing lexically legitimate items (also see Dell 1986).

The editing of message plans at abstract, tactical levels of representation has been the focus of a program of research on *cognitive editing* conducted by Hample and Dallinger (→ Information Processing). In a typical study, participants read messages (arguments) that might be used to seek compliance in a hypothetical situation and indicate whether each message is acceptable. They also indicate reasons for finding messages unacceptable. The reasons (editing criteria) have been assessed using open-ended questions, checklists, and rating scales. Hample and Dallinger have found that the editing criteria fall into seven general classes. An argument might be rejected because it *would not work* (effectiveness criterion); is *too negative* (principled objection criterion); could *harm the speaker’s image*, *harm the target*, or *harm the relationship* (person-centered criteria); is *false*, or is *irrelevant*

(discourse competence issues; Hample 2005). Most of the editing criteria have also emerged in think-aloud protocols.

Cognitive editing research indicates that the frequency of use of editing standards depends upon both the individual and the situation. For example, use of the effectiveness, harm-to-other, and principled objection criteria, as well as the number of messages endorsed, are influenced by gender, verbal aggressiveness, and interpersonal orientation (Hample & Dallinger 1987). A secondary analysis of data from nine earlier studies showed that situational features, such as target dominance, relational consequences, and resistance, influence the use of editing standards and the likelihood of endorsing messages (Hample & Dallinger 2002). In requests following a rebuff, editing standards appear to change, such that aggressive messages are viewed as more acceptable. A comprehensive discussion of cognitive editing research and its relation to cognitive theory and other lines of inquiry is provided by Hample (2005).

A third approach to the study of message editing has explored factors that influence whether speakers become aware, prior to speaking, that a message would have an *unwanted outcome*. A cognitive model developed to account for such processes is described by Meyer (1997). The model holds that linguistic actions in message plans can become matched to the action components of implicit action-consequence rules. Once such a rule is activated, activation spreading from the action component makes the consequences of the action more accessible. Accessible consequences can activate beliefs about the relevance of the message to the speaker's goals. Such knowledge is initially activated preconsciously. The likelihood of becoming consciously aware of the knowledge is thought to increase with its level of activation and available processing capacity. The model predicts a positive relationship between the situation-specific importance of a secondary goal and the likelihood of realizing that a not-yet-spoken message would conflict with the same goal. Meyer (2005) found partial support for this relationship.

## Message Effects, Structure of

Kim Witte

Michigan State University

Message effects fall into at least three categories: behavioral (actions caused by a message), cognitive (thoughts caused by a message), and emotional (feelings caused by a message). By message, we mean any kind of symbol perceived by an individual to have some sort of meaning, be it through the printed, spoken, or felt word via intrapersonal, interpersonal, mass media, or other means. A message can affect behavioral, cognitive, or emotional outcomes separately or simultaneously. The large body of research on fear appeals, for example, shows that a message produces thoughts about a threat, feelings of emotional arousal, and behavioral actions (Witte & Allen 2000).

A message contains (1) content, (2) stylistic, and (3) extra-message features. The content of a message refers to the words and/or symbols used in the message. For example, message content can focus on anecdotal versus statistical evidence, or loss versus gain frames (→ Framing Effects; Instrumental Actualization). Often, the content of message research focuses on latent constructs, such as susceptibility, severity, response efficacy, self-efficacy, barriers, norms, social capital, and so forth. Latent constructs cannot be directly measured and thus must be clearly defined and operationalized before being used in a message (→ Content Analysis, Qualitative; Content Analysis, Quantitative).

*Stylistic features* of a message refer to the elements *within* a message that can be manipulated to determine the strength of its words or symbols (→ Style and Rhetoric). Stylistic features include such variables as language intensity, vividness, personalization, color, size of font, volume, etc.

*Extra-message features* have the capacity to influence outcomes but are outside the actual content or symbols used in the message. That is, those things that can be separated from the message content itself and can include features about the source of the message (credibility, dynamism), construction of a message (one versus two-sidedness, primacy/recentness effects, order of constructs in a message), medium of message, message repetitions, and length/duration of a message (→ Credibility Effects; Credibility of Content).

Typically, if people are motivated and able to process a message, they process the content features of a message thoughtfully and in depth (i.e., systematic or central processing). Extra-message and stylistic features act as cues about how to respond to a message (i.e., heuristic or peripheral processing; → Elaboration Likelihood Model). For example, if an important person gives a message (high source credibility), this is a cue that what she or he says is true and to be trusted. Petty et al. (1981) found that when people were

motivated to process a message (a high-consequence condition), strong arguments produced more attitude change than weak arguments, and source expertise had no effect on attitudes. In contrast, when people were not motivated to process a message (a low-consequence condition), the opposite occurred – source expertise (a cue) produced attitude change while the quality of the arguments (strong or weak) had no influence on attitudes.

In message effects research, typically message content or extra-message features are manipulated to assess effects on behaviors, → cognitions, or → emotions, and the stylistic features are used to strengthen or weaken the manipulations. It is fairly clear how to manipulate extra-message features (e.g., one versus three repetitions), but researchers need to clearly define and operationalize the content of message constructs (e.g., susceptibility or self-efficacy) in order to represent them as strong or weak in a message (→ Operationalization). Further, to prevent confusion, one must make sure that messages have similar styles, content/constructs, and extra-message features before manipulating key variables of interest.

Content, stylistic, and extra-message features all were addressed in a multimedia gun safety program in Michigan. The content of the message focused on the → *extended parallel process model's* (EPPM's) latent variables of susceptibility, severity, response efficacy, and self-efficacy. Stylistic variables such as vividness and personalization were focused on in the susceptibility and severity messages in order to increase the strength of these messages. For example, Michigan residents who had personally experienced traumatic gun accidents showed their serious injuries. Extra-message features also were addressed by presenting the threat message first, followed by the efficacy message (order effects), as well as offering multiple repetitions of the message by highly credible sources. The campaign successfully influenced behaviors, attitudes, and intentions toward using trigger locks to prevent gun accidents and won multiple awards (Roberto et al. 2000).

## Message Production

Dale Hample

University of Maryland

The object of research on message production is to answer the question, “Why do people say what they do?” The academic sources on this topic come from across the academy, notably → cognitive science, discourse studies (→ Discourse Analysis), and artificial intelligence, and from several specializations in communication, especially → persuasion, → interpersonal communication, and argumentation (→ Cognition; Compliance Gaining). Unconnected research was done by many investigators for decades, but the project solidified with the publication of Greene’s (1997b) *Message production*. From that point on, message production became an explicit topic for research and graduate seminars.

This work is now mainly done in the discipline of communication, which was originally framed by the classical tradition of rhetoric (→ Rhetorical Studies). The first canon of rhetoric is invention, which refers to the generation of content for a speech. Message production research is mainly relevant to this canon, although it makes little use of the ancient doctrines of *topoi* (the “places” from which orators can draw material) or *stases* (the logically required “resting places” of a controversy). For the most part, message production work is only beginning to address the remaining canons of rhetoric. Organization (the second canon) has received no attention at all, style (the third canon) is just starting to be a focus of research, and delivery (the fifth canon) has been treated to a small degree by nonverbal scholars. Memory (the fourth canon) is the chief exception because it is a continuing theoretical basis for message production theory (→ Memory).

### THE GOALS-PLANS-ACTION (GPA) MODEL OF MESSAGE PRODUCTION

The goals-plans-action model, first articulated for the message production community by Dillard, is straightforward at its kernel. The idea is that, upon encountering a situation that calls for communication, people spontaneously form communication goals, which stimulate message plans, and the message (or action) involves acting out the final plan. The most basic hypothesis, robustly supported, is that the message will be in service of the goals, and this relationship is mediated by the plan. As the research has grown more sophisticated, however, so has the GPA model.

## Situation

In the original formulation, the GPA model's initial processual focus was on goals. These were understood to have been activated by a match between a subjective situation and the person's cognitive stores. Little effort was made to theorize situations, although some work was done to identify dimensions of persuasive situations. Experimenters supplied respondents with an instruction (e.g., "you need to persuade a friend to give you a ride"), and simply assumed that the respondents understood the situation in the same way as the experimenter (→ Experiment, Laboratory; Experimental Design).

A notable advance was Dillard and Solomon's (2000) *conceptualization of situations as "social densities."* Just as the universe is mainly vacuum interrupted by densities of gravity and mass, so our social world contains recognizable clumps of social significance. An exploratory space vessel might aim at a particular mass, and similarly, people orient to repetitive kinds of interaction. These social densities are stored in long-term memory as nodes, which may well be labeled with a particular name (e.g., persuade, acquaint, etc.). Dillard and Solomon continue to formulate these social densities in terms of their goal structures.

Some other points of view appear in the literature. Hample (2005) suggests these omissions: obstacles, barriers, climates, and perception of both self and other. He believes that messages will be produced in respect to these situational elements, as well as to goals. O'Keefe (1988) objects to viewing goals only as subjective. Her idea is that situations have objective constraints, regardless of whether they are subjectively noticed. Persuasion, for instance, is inherently threatening to the face of the target, and a persuader who is oblivious to this will be punished, perhaps with ineffectiveness or disdain. And other scholars notice that not all communication-relevant situations actually generate messages (Berger 2004; Dillard 2004; Hample 2005).

## Goals

Message production is said to be under personal control, and therefore responsive to subjective goals. Dillard's initial formulation of the GPA specified that two sorts of goals would be activated. The first is what he calls the *primary goal*, which frames the situation, or defines it as a particular type (e.g., as influencing, comforting, joking, etc.). *Secondary goals* modify that frame, bringing to bear various other motivational issues, such as anxiety, protection of personal resources, and, most importantly, politeness. The secondary goals may be so immediately important that they overwhelm the primary goal (e.g., a person worried about giving offense might actually decline to try to persuade), but the situation remains subjectively defined by the primary goal (e.g., influence). No typological theory of specific goals is in wide use, although several have been suggested. Influence is the primary goal most often studied, because communication research on message production is a direct outgrowth of work on compliance seeking (Wilson 2002). The most common set of secondary goals concerns politeness (→ Politeness Theory).

Several investigators have explored the consequences of having multiple goals. Greene and his associates have shown in several studies (e.g., Lindsey et al. 1995) that people are

less articulate and more hesitant when producing messages that respond to two goals, as compared to single goal instructions. In Greene's work, the second goal is in some way inconsistent with the first (e.g., to give unwelcome information while ensuring that the other person is not offended). Samp and Solomon (2005) assess goal complexity (the number of activated goals) and goal strain (whether both pro-social and antisocial goals are activated). They find that both complexity and strain increase the number of clauses in messages. Thus, multiplicity of goals increases cognitive load, resulting in both immediate nonfluency and more eventual effort.

### Plans

A plan is a projected sequence of actions that is intended to achieve a goal. Messages are held to emerge from plans, which may be conscious but are much more likely to consist of unconscious assemblies and intentions (e.g., Greene & Graves in press). Berger (1997) is the leading scholar on this topic.

The plan is the point in the message production process at which content comes into play. For a message, many of the plan steps consist of things one will (or may) say. These items are understood to pre-exist in one's cognitive stores, and constitute a repertoire of possible messages or message elements. They might be understood as personal topoi, that is, places or resources. A plan, perhaps conceptualized as a memory organization packet (Kellermann 1991), assembles repertorial elements into sequences prior to utterance. Berger explains that one may have a simple sequence in mind, but may also have imagined a more complicated pattern that might even have various branch points at which choices must be made. Complicated situations may well require highly textured plans, but Berger has shown that complex plans reduce the fluidity of message production (→ Speech Fluency and Speech Errors). He has also demonstrated that a given plan exists simultaneously at several hierarchically organized levels of abstraction, ranging from general intention down to the physical requirements of pronunciation and performance.

Berger is aware that plans change during the course of invention and interaction. The planning stage is therefore also the site of → *message editing* (Hampe 2005). Berger shows that the least effortful available changes are those first attempted. Meyer (1997) says that cognitive stores contain two key kinds of associations: those between the situation and the message, and those between messages and their outcomes. The situation–message association system generates an initial draft of a message. Once a potential message is assembled and activated, it may in turn stimulate notice of various likely consequences (e.g., cursing causes social disapproval). These consequences reflect the presence of secondary goals, particularly politeness issues. Should the consequences have sufficient activation levels, they may stimulate message revision or abandonment. Rehearsing a message plan improves the fluidity and quality of the resulting message.

### Messages

Most message production research to date has a limited theoretical domain, mainly going either from one element of the GPA model to the next, or from one early component directly to the message. The main findings, which are robust, are that situationally

activated goals predict messages' apparent objectives, and that plan content predicts message content. These results are rather general, however.

Some more specific work has generated useful, if partial, descriptions of messages. Scholars have explored the fluidity of message production, focusing on onset latencies, pauses, and semantic variety. They relate these matters mainly to plan or goal complexity, respectively. Either sort of complexity increases cognitive load, interfering with ease of expression. Samp and Solomon's (2005) research program explores message embellishment, length, and focus (e.g., on self or other), linking these outcomes to goal strain and goal complexity. Both strain and complexity lead to longer and more elaborate messages. The *obstacle hypothesis* (Francik & Clark 1985) connects message content and phrasing all the way back to situation, so that requests acknowledge the situational feature most likely to impede a favorable reply (e.g., "If you're not too busy, could you find me a map?"). Repertoire features (e.g., degree of attention to face or argumentative issues) reappear as the parallel message features across topics. Not one of these research projects, however, spans every key component of the GPA model, and collectively their message characterizations are somewhat unconnected.

### INDIVIDUAL DIFFERENCES

The message production project is essentially a cognitive one, developing theories that are intended to apply with equal force to any competent person with an ordinary cognitive system. Distinguishing among people on the grounds of personality or cognitive differences has not been a central priority. People are certainly understood to have different goals in similar situations, for instance, but the theoretical impulse has been to say that whatever the goal is, it will be subjected to essentially the same cognitive dynamics as any other goal, by any other person. Nonetheless, some work has used individual difference measures as ways of understanding which goals, which plans, which revisions, and which messages will appear.

When people react to a situation, they act and think in response to the *subjective situation*, not the objective one. Wilson (2002) shows that people exposed to what was apparently the same situation form different interaction goals, and that this difference is traceable to their interpersonal differentiation levels (→ Constructivism). The usual theory of situation-to-goal process says that goals will be activated according to how well they fit situational features, how strongly associated the goal and situational features are, and how recently the goal has been activated. Several researchers have explored how stable individual differences affect these matters, especially fit and strength.

*Personality traits* are understood as indicating what interaction goals are chronically accessible (i.e., strong). Introverted people will commonly activate avoidance goals, and other-oriented people will readily form relational and identity goals. Meyer (2005), for instance, shows that people high in verbal aggressiveness are less likely to reject potentially offensive messages, because relational goals are not chronically accessible to such people. Berger (1997) reports that high self-monitors produce more complex plans, because they are more oriented to their interactional partners. Research connects message behavior to argumentativeness and verbal aggressiveness (Rancer & Avtgis 2006). Other trait measures have been associated with editorial behavior,

predicting whether people will edit their messages at all, and if so, on what grounds (Hample 2005).

Individual differences other than personality traits have also been investigated. Interpersonal construct differentiation is a key variable. Other non-trait measures that have garnered some attention by message production researchers include cognitive speed and capacity, age, creativity, and academic ability. Several research programs have determined what beliefs or naïve theories people have about communication, and have shown that those belief sets predict various features of message production.

### **DYADIC INTERACTION**

The bulk of message production work has studied solitary communicators, who generate either a written message or an oral monologue. The lack of attention to dyadic or group interaction has been criticized by Waldron (1997), and his objections remain forceful.

Applying the theory and results bearing on a solitary communicator to individuals engaged in interaction may not be simple (Greene & Graves in press). Conversation has its own structure, to which people almost inevitably respond (→ Conversation Analysis). So a question creates an answer slot, a challenge calls out a defensive reply or a concession, and so forth. One's plans must be adaptable in the instant, because every action by the interlocutor alters the situation, and so may stimulate new goal configurations or plans. The finding that the power of individual difference variables evaporates once an interaction is under way is not uncommon. Once engaged in conversation, people's messages appear to respond mainly to what the other person says and does, rather than to private, pre-existing goals and plans. A few studies do show that people persist when the other person is uncooperative, forming more aggressive goals, and revising their plans in predictable ways. However, joint development of communicative action is not yet a substantial research topic, and neither is adaptation to topic changes. A fruitful approach to these difficulties may be that of Bruce and Newman (1978).

### **PROSPECTS FOR MESSAGE PRODUCTION RESEARCH**

This entry has featured the GPA model, which summarizes (or at least is compatible with) nearly all the current research. Several other theories either do not connect with the GPA very well, or go into remarkable detail about matters that are not otherwise prominent in the GPA. These include the local management of meaning theory (O'Keefe & Lambert 1995), action assembly theory (Greene 1997a), and O'Keefe's (1988) message design logic theory (→ Action Assembly Theory; Message Design Logics). This entry also omits mention of biological work on message production because such work is only beginning (→ Communiobiology). The prominence of the GPA has perhaps unfairly limited scholarly attention to these interesting approaches. Many scholars and teachers also integrate material from lines of research that are not explicitly about message production, for instance work on social support or self-disclosure. This sort of research is very helpful in moving message production work beyond its roots in persuasion.

In the last decade, message production has become an important topic among communication scholars. How people generate their utterances and writings is obviously

a fundamental matter, and it should not have been neglected for as long as it was. Potentially, the communication discipline could well be reorganized into three main divisions: message production, messages, and message reception. Academic tradition and inertia will probably prevent this, but the fact that it is sensible should immediately display the importance of this topic.

## Meta-Analysis

*Timothy R. Levine*

*Michigan State University*

*Craig R. Hullett*

*University of Arizona*

Meta-analysis is a set of methods and statistical analyses for summarizing the findings of an existing empirical literature. As the name implies, it is a study of studies. It provides a way to do a quantitative literature review that involves cumulating effects across studies (→ Quantitative Methodology). The purpose of a meta-analysis is to ascertain if the findings from a collection of studies investigating some specific issue lead to some consistent result and, if so, to estimate the magnitude of that finding. If not, it serves to reconcile findings that appear to offer mixed support for a hypothesis. Meta-analysis is also useful in identifying the reasons why findings are inconsistent from study to study (→ Generalizability) and to identify theoretically important moderators. Meta-analysis will likely play an increasingly important role in making sense out of social science research.

### THE USES OF META-ANALYSIS

The value of meta-analysis is particularly apparent when contrasted with the typical narrative review of sustained research on a topic. Due to the nature of social scientific research, the results of different studies investigating the same question will inevitably vary from study to study. Some of this variability is attributable to sampling error. That is, because studies seldom, if ever, include the entire population, estimates drawn from samples will likely depart from population values by some amount, with greater departures possible with smaller samples. Results can also vary across studies because of methodological artifacts (→ Validity). For example, differences in measurement and design validity, induction strength, and measurement → reliability affect results. Finally, results can vary from study to study for substantive reasons. That is, for theoretically meaningful

reasons, a finding might be stronger in some populations or contexts than in others. Thus, individual and contextual differences can produce differences in results because no two studies are done with exactly the same sample participants, in the same location and context, at the same time, etc. Put differently, known or unknown moderators can exist and cause variation in results from study to study. Because of variability attributable to sampling error, methodological artifacts, and unidentified moderators, it can be difficult to make sense of the findings in a literature through a narrative review. Most often, the collection of existing studies on a communication topic provides a collection of mixed results that makes a coherent account of the findings difficult. So, the existing research investigating some topic often contains studies that appear to lead to contradictory conclusions.

The picture is further clouded by the reliance on null hypothesis significance testing ( $\rightarrow$  Hypothesis). Analyses show that typical effect sizes are meager in many social science literatures (Richard et al. 2003) and that the statistical power to detect typical effects is low (Cohen 1962). Because of sub-optimal statistical power, true population effects may not always be detected. Given the variance in sample sizes used from study to study, even when consistent effects are observed across a set of studies, some studies would achieve significant results while others would yield nonsignificant findings simply due to the sensitivity of the dichotomous decision rule (significant vs. nonsignificant) to sample size. This makes literatures with consistent results appear inconsistent, and creates the false impression of mixed support. In practice, however, findings actually do vary because of sampling error, methodological artifacts, and substantive moderators, and this variability is further complicated by sub-optimal statistical power. This makes doing head counts of significant and nonsignificant results in the literature a problematic way of assessing the consistency of support a hypothesis has received across studies (Meehl 1978).

Meta-analysis provides a way to overcome a number of these problems. Because results are cumulated across studies, low statistical power is less of an issue. Meta-analysis focuses attention on effect sizes, and relies less on significance testing. The degree to which sampling error explains study-to-study variability is estimated, and corrections for many methodological artifacts are possible. Substantive moderators can also be tentatively identified.

## **PRACTICE OF META-ANALYSIS**

### **Procedure**

So, how is a meta-analysis done? Meta-analysis involves several steps. First, the relevant and usable studies investigating a topic are collected. Then, the findings of each study need to be converted to some common metric so that the results can be cumulated. Relevant study features are also coded. Next, an average effect across studies is calculated, and study-to-study variability is examined. Analyses are also done to see if and how coded study features affect results.

The first step is to gather relevant and usable existing studies, which serve as the data for the meta-analysis. Authors of meta-analyses typically will develop criteria for study inclusion. It is important that all the studies included test the same issue or hypothesis. It

does not make sense to average across apples and oranges, so to speak. This does not necessarily mean, however, that all studies must have used the same experimental inductions or measures. So long as there is consistency at the conceptual level, operational differences need not be considered cause for exclusion. Operational differences can be coded to determine later if those differences caused heterogeneity of study results (→ Coding). Studies must also report sufficient information so that an effect size can be calculated. Once the criteria for inclusion are determined, a search method is specified. Typical searches will include those studies already known to the authors, the use of relevant search engines and databases, and examination of reference pages of found studies. The goal is to collect all existing research meeting the inclusion criteria.

Once previous studies have been collected and determined to meet the inclusion criteria, the findings from each study need to be converted to a common metric, usually some unit of “effect size.” The most common metrics used in meta-analysis are  $d$  and  $r$ , where  $d$  is the standardized mean difference, and  $r$  is the correlation coefficient (→ Correlation Analysis). So, for each test of a hypothesis in the literature, an effect size (i.e.,  $d$  or  $r$ ) is obtained. If the previous studies report effect sizes, this is straightforward. But, unfortunately, many studies do not do so. Fortunately, however, a variety of conversion formulas exist (Rosenthal 1991; Rosenthal et al. 2000; Levine & Hullett 2002; Hullett & Levine 2003). For example, if either sufficient descriptive statistics (e.g., means, standard deviations, and cell sizes; → Statistics, Descriptive) or significance tests with degrees of freedom are reported, effect sizes can often be calculated. The effect sizes collected can be corrected for various methodological artifacts, such as measurement error, restriction in range, artificial dichotomization of continuous measures, and deviations from perfect construct validity (Hunter & Schmidt 1990). It should be noted, though, that some scholars argue against those corrections (Rosenthal 1991).

Once a set of effects has been collected reflecting the findings in the literature, the findings are cumulated and tested for homogeneity of effects. Findings are cumulated simply by averaging, although the average is usually weighted by study sample. This produces an across-study average effect, and this average effect can be considered an estimation of the population effect. The across-study average can be tested to see if it is likely different than zero, using confidence intervals calculated around the average. Because across-study average effects are based on much larger and more diverse samples than any one study, they provide a better and more stable picture of the findings than is obtained from individual studies.

In addition to examining the across-study average effect, meta-analysis considers the dispersion of effects; that is, how much the studies vary from one another. Given how much findings vary from study to study and the sample sizes of those studies, the extent to which the different findings might be attributable to sampling error is estimated. If the dispersion of effects is found to be similar to what would be predicted by sampling error alone, this means that all the findings from all the studies appear to be drawn from the same population, and the set of studies is considered homogeneous. When the results are homogeneous, then the average study effect can be meaningfully interpreted as summarizing the findings of the existing research. Heterogeneous findings mean that the results vary substantially more from study to study than can be attributed to sampling error alone. Heterogeneity can be caused by methodological artifacts in some studies but

not others that differentially impact results, theoretically important moderators, outliers, reporting errors, and/or the inclusion of some studies that are not assessing the same issue as other studies. The homogeneity/heterogeneity of effects is often tested with chi-square or Q statistics. If heterogeneity is found, the meta-analyst will attempt to resolve it with a moderator search.

### **Search for Moderators**

When studies are collected, they may be coded for study features. For example, some studies might use students while others might use working adults; some might use self-report measures while others might use open-ended coding. Any identifiable subject, context, or method feature could be coded. Although these features can be coded using a continuous metric (e.g., year of publication), one frequently sees moderators assessed categorically. In the latter case, analyses of the effects of moderators are accomplished simply by sorting effects into groups depending on some coded study feature, then calculating average study effects separately for each feature. If the feature makes a difference, then the average effect size will be different under one condition than under another. This is partial evidence of a moderator. The other key indicator of a useful moderator is that the average variance of the effects within each sub-group is substantially less than the variance of all the effect sizes when treated as a whole. Given these two conditions, the sub-groups are tested again for homogeneity. Ideally, all heterogeneity can be resolved by finding the cause of study-to-study variance, meaning that no further moderators are operating. Once a moderator has been identified with meta-analysis, it is good practice to design an experiment to test the moderator with original research.

### **Challenges**

A number of challenges face meta-analysis. One major challenge is that the results of meta-analysis are no better than the quality of the studies used. For example, if some common bias was evident in all studies of a given topic, then that bias would be reflected in the meta-analysis results and it would be undetectable. A second challenge is a publication bias favoring supportive (often, statistically significant) results. If supportive studies are published and nonsignificant findings are not, then the results of meta-analyses will show an upward bias. A third problem arises from having only small numbers of studies within a research domain. Just as any single study derives more credibility from having larger samples, meta-analyses provide more meaningful results when they incorporate larger numbers of studies representing larger numbers of participants. A meta-analysis of, say, five or six studies each with only 100 participants probably cannot be considered as providing a definitive statement about the nature of effects in a population. Finally, there is the question of what do to with heterogeneous effects. If heterogeneity cannot be resolved with moderator analysis, then it is questionable if average results can be meaningfully interpreted.

## **Meta-Discourse**

*Robert T. Craig*

*University of Colorado at Boulder*

Meta-discourse is talk about talk. The common term → *discourse* refers to the pragmatic use of language (including nonverbal signs such as → paralinguistic and → gestures in discourse) in extended texts or episodes of communication. *Meta*-discourse refers to the pragmatic use of language to comment reflexively on discourse itself. The prefix “meta” (from a Greek word meaning with, across, or after) here denotes a shift to a higher-order frame of reference. Meta-discourse shifts the focus of attention from ongoing communication, putting some stretch of discourse in a context or frame designed to influence the meaning and practical conduct of communication.

The frame shift performed by meta-discourse is most often local and momentary, as when a speaker uses the word “*first*” to frame an immediate following point as the first in a series of points, or says “*I understand completely*” to mark another’s statement as understood and accepted. Extended episodes of meta-talk also occur, for example, when a couple sits down to talk over a problem in how they have been talking with each other. Discourse about discourse-in-general is also meta-discourse. People trading stories about poorly run business meetings or writing newspaper columns about rules of etiquette for the use of mobile phones in public are engaged in meta-discourse with a relatively broad scope. So are scholars writing academic books and articles about media, discourse, and communication. All of these forms of meta-discourse participate in the ubiquitous social processes through which norms and meanings for communication are continually

negotiated (Craig 1999, 2005). With a growing cultural emphasis on the importance of communication in modern societies, explicit talk about talk seems to have become increasingly prevalent. A “communication culture” has evolved that “generates large quantities of meta-discourse” (Cameron 2000, viii).

Researchers have identified a wide array of linguistic devices used in meta-discourse. “Discourse markers” are used to indicate relations between segments of discourse (“*and*,” “*because*,” “*on the other hand*”), interpersonal relations (“*sorry*,” “*but*,” “*you know*,” “*as a friend*”), and cognitive attitudes toward what is being said (“*I mean*,” “*in a sense*,” “*certainly*”; → Discourse Markers). “Linguistic action verbs” are used to describe the social actions performed in discourse (“*she asked*,” “*don’t threaten me*”), and, in some cases, simultaneously to carry out those actions in “performative utterances” (“*I promise*,” “*I tell you*”). “Reported speech” (direct or indirect quotation) purports to represent for some present purpose something that was said previously (Lucy 1993, 18–21). “Indirect reported speech” highlights the effective content of what was said (“*Margaret told me that you would be late*”), whereas “direct reported speech” highlights the precise way in which something was said (“*Margaret told me [the following spoken in mock imitation of Margaret’s voice] ‘Of course, he will be late, as always!’*”).

Verschueren described these and many more linguistic devices as indicators of *meta-pragmatic awareness*. Insofar as all pragmatic language use involves making linguistic choices more or less consciously, “*all verbal communication is self-referential to a certain degree*” (1999, 187–188, italics in original). Reflexivity thus being a matter of degree, meta-discourse ranges along a continuum from the relatively blatant verbal framing moves just illustrated to relatively unconscious cues (such as a slightly noticeable word choice, vocal emphasis, or facial expression) in which meta-discourse may be hardly distinguishable from first-level discourse. Some of these subtle framing devices have been described as *contextualization cues* and it has been noted that they can be highly culture-specific (→ Interactional Sociolinguistics)

Although there are functional similarities in meta-discourse across languages (Verschueren 1989), meta-discourse also reflects communicative forms and *speech codes* specific to particular cultures (→ Ethnography of Communication; Speech Codes Theory). Speech codes comprise systems of concepts, beliefs, and rules of conduct pertaining to communicative practices, personhood, and social relationships. Cultural groups develop *meta-communicative vocabularies* (Philipsen 1992) that express their speech codes. Although a speech code may not be followed consistently in practice, the meta-communicative vocabulary is used rhetorically in meta-discourse to interpret, evaluate, or justify communicative acts. For example, the declaration that “we need to sit down and talk” about a problem may have a certain rhetorical power for the participants that depends on a specific meaning of “*sit down and talk*” in a cultural speech code.

Speech codes and meta-communicative vocabularies overlap with the more critically toned concept of *language ideologies*, “habitual ways of thinking and speaking about language and language use which are rarely challenged within a given community” (Verschueren 1999, 198; see also Jaworski et al. 2004). From this critical standpoint it becomes apparent that cultural speech codes incorporate historically contingent practices, beliefs, and standards of “correctness” that systematically favor more powerful segments of society over others, for example by stereotyping and devaluating the communication

of women, lower classes, and immigrant groups (→ Language Attitudes in Intergroup Contexts; Social Stereotyping and Communication).

Academic theory and research on communication, language, and media are forms of meta-discourse. Along with other forms of meta-discourse in mediated, public, and private interaction, academic meta-discourse participates actively in the social construction of communication practices (Craig 1999, 2005). Commonplace normative beliefs about communication – whether regarded as speech codes or language ideologies – provide much of the basis for academic theories (Taylor 1997). Critical scholarship is needed to illuminate, and thus open to contestation, the unreflective cultural assumptions and ideologies at work in all forms of meta-discourse, including academic forms. But communication theory also has a positive role to play as a source of carefully considered, alternative ways of talking about talk that can be useful for addressing practical communication problems.

## **Metaphor**

*Stuart Jay Kaplan*

*Lewis and Clark College*

Metaphor is widely regarded as a basic linguistic form in nearly all types of → discourse (→ Linguistics). In contrast to early thinking about metaphor, which emphasized its role

as a stylistic embellishment used for rhetorical effect, modern theories consider metaphor to be an essential feature of thinking itself. George Lakoff and Mark Johnson (1980) identified a variety of metaphor types that interconnect to structure how people conceptualize their experiences with their physical and social environments. This cognitive perspective on metaphor has stimulated scholarship on metaphor phenomena in a great many disciplines, including communication, organizational theory, political science, art, philosophy, computer science, and law. The role of metaphor in → persuasion is of particular interest to communication scholars. Research findings suggest, for example, that → advertising containing metaphors receives greater → attention from readers and evokes more positive affect toward the ad (McQuarrie & Mick 1999; → Advertising as Persuasion).

### FUNCTION OF METAPHORS

Metaphors present two ideas or terms in relationship to one another such that one is used to organize or conceptualize the other. For example, the statement “encyclopedias are gold mines” uses the idea of gold mines to clarify or modify the reader’s conception of encyclopedias. Various names have been given to the two terms that are combined in a metaphor. In the example just given, the subject of the metaphor, encyclopedias, is often called the topic or target. The idea that is used to transfer new → meaning to the topic (e.g., that encyclopedias store riches) may be called the vehicle or metaphor source.

For a metaphor to accomplish its work, there are two additional conditions that must be met. First, the *two terms must share some properties* and those common properties need to be at least minimally relevant to the claim made by the metaphor (i.e., A is B). Otherwise, the attempt at creating an analogy will seem implausible to the reader. Some metaphor theorists refer to the process of transferring the properties of the source to the target as one of “mapping” relevant aspects of the source onto the target (Lakoff & Johnson 1980). In this view of metaphor effects, the source transfers both some of its properties to the target and a structure for articulating the relationships among those properties. A somewhat different theoretical perspective is called “conceptual blending” (Turner & Fauconnier 1995). There, the metaphor is said to create a unique conceptual structure in which selected aspects of the source and target are combined.

The second essential condition for a metaphor to work is that the attempt to combine properties of the source and target must seem at least *mildly incongruous or initially nonsensical* to the reader or viewer. That is, the proposition that A is B cannot be literally true. An effective metaphor creates tension by intentionally violating norms of language use or the reader’s beliefs about the world (→ Rhetoric and Language). The interplay of simultaneous similarity and incongruity in an effective metaphor stimulates a problem-solving response in the reader or viewer and a higher degree of engagement in the process of decoding the meaning of a message. Greater engagement with the text is thought to facilitate the persuasion process.

### NONLINGUISTIC METAPHORS

The preponderance of metaphor research has been conducted with linguistic expressions. In recent years, however, researchers have turned their attention to nonlinguistic forms of

metaphor phenomena. Two primary emphases in the field of visual metaphor studies are metaphors in the visual arts and metaphors in advertising. Examples in the first category include studies of *metaphors in painting, sculpture, graphic design, architecture, and movies*. Trevor Whittock (1990) identified symbolic elements in popular films that created metaphoric effects through context, image distortion, or juxtaposition of one object with another (→ Film Theory). As an example of a visual metaphor created through context, Whittock cites the famous scene in Hitchcock's *Psycho* when the female lead takes a shower after a lengthy day of trying to flee the scene of the crime in which she had stolen a substantial amount of money. In the context of the emotions of guilt and remorse portrayed by the character prior to that scene, the shower becomes a visual metaphor for spiritual cleansing (→ Semiotics; Symbolism). In this example, the visual presentation of the metaphor adds little to what might have just as effectively been expressed through linguistic means. Other examples of metaphoric content in films are more distinctly *visual* in the way they achieve their effects (→ Visual Representation). Whittock describes a scene in *Dr Strangelove* in which a wide angle lens was used to distort the faces of a flight crew in such a way that the images of the men appear to merge with the shape of the military aircraft that they were commanding. In this visual metaphor, the airmen are made integral with the instrument of death that they operate.

Research by Kaplan indicates that visual metaphors are widely used in *product advertising*, appearing in one-third of ads for beverages, automobiles, and fashion products (1992, 2005). The visual presentation of metaphors varies from simply showing the source and topic side by side in the picture (e.g., in an ad for a car, the product is seen next to a fighter plane) to those in which the physical form of the topic is transformed such that certain features of the metaphor source become incorporated in the pictorial representation of the product. The first type is a visual version of "simile," while the second type is a visual metaphor of the form "A is B." Charles Forceville (1998) identified various formal features of metaphors in print advertising. Forceville's theory of visual metaphor in advertising distinguishes those cases in which only one of the two pictorial elements in a metaphor (either the topic or the source) is visually presented versus those in which both parts of the metaphor are depicted. When only one of the two parts of the metaphor is visually presented, the other metaphor term is supplied by text accompanying the ad or the reader's cultural knowledge. Forceville also describes visual "similes" and he differentiates these from metaphors by the degree of literalness in the comparison between the two elements (→ Visual Communication). Because visual similes are more literal, their effects presumably require less decoding effort on the part of the viewer.

*Architecture* is a type of visual text that combines elements of art and persuasion (→ Art as Communication). This dual function of architectural design was the focus of Kaplan's (2006) metaphor analysis of the effort to rebuild the World Trade Center site after the 2001 terrorist attacks. Visual metaphors were found to play a central role from initial planning efforts through the selection of architectural designs. Shortly after the attacks on the World Trade Center towers, extensive public hearings were held to solicit ideas for an apt architectural response to the tragedy. One image that emerged early in the process was the idea of memorializing the foundations of the absent twin towers. The visual metaphor of the buildings' "footprints" acquired rhetorical power for gaining

public acceptance of the master plan for the site and for a permanent memorial that integrates the footprints into its design (→ Rhetoric and Visuality).

### SOME CURRENT ISSUES

While there is general agreement on the similarities between linguistic and nonlinguistic metaphors, attention has also been paid to distinguishing characteristics between the two types. The *phenomenon of directionality* is one distinction that has been suggested. In common usage, linguistic metaphors are rarely reversible. That asymmetry is reflected in the use of terminology like “source” and “target,” and sentences containing metaphors are typically stated as “A is B.” However, metaphors in visual form may be more likely to be multidirectional. Hausman (1989) suggests that reversibility may be a common occurrence in painting and sculpture. But in the case of advertising, contextual cues generally leave little doubt as to the intended direction of a metaphoric combination because the advertiser’s goal is usually to invest the product (i.e., the metaphor target) with favorable properties borrowed from the metaphor source (→ Rhetoric, Nonverbal). Further research should be done on visual metaphors that occur in ambiguous contexts to determine how viewers determine which is the likely source and which is the target.

*Metaphor and irony* are generally thought of as similar in their construction and interpretation. Both metaphor and irony present an incongruous relationship between the two things being compared and invite the reader to discover similarities. However, for irony to be correctly interpreted, the reader must take the additional step of trying to guess if the speaker really meant the opposite of what appears to be the meaning of the statement. Thus, irony involves a second-order interpretive process in which the reader must assess the speaker’s intent. Colston and Gibbs (2002) found evidence for this second-order interpretive process in experiments in which readers took longer to process irony than metaphor. Little is known about *visual irony*. Are the cues for decoding irony in pictorial form different than is the case with linguistic irony (→ Code)? What are the contextual cues that seem to be useful? Again, advertising may be a good place to start research in this area. Advertisers sometimes introduce self-mockery in their presentations in order to deflect criticism of their industry or to appear more credible. Irony could also be used to discredit competing brands within a product category.

Most of the research on visual metaphor has involved static images, such as those found in a print advertisement. But the *movement of pictorial elements* in a visual frame could have independent metaphoric effects (→ Cinema). Another important area for future research is visual metaphors in multimedia presentations, including those where some degree of interactivity is possible. What happens, for example, when the viewer has a measure of control over the timing and order of a visual presentation? Similar questions arise regarding visual metaphors that might be created through linking in web-based media (→ Digital Imagery).

# **Metonymy**

*Linus Abraham*

*African University College of Communication*

On an evening newscast a news story about the US president includes a file photo of the White House in the frame over the news anchor's left shoulder. The picture of the White House is meant to cue the audience to the fact that the story is about matters associated with the president's office. The White House, a prop associated with the president, is used to signify the complex institution of the presidency. This mode of signification, in which a part or single characteristic of something is used to signify a more complex entity, or greater whole, is referred to as metonymy.

Metonyms are one of the many ways in which → signs work at the second order of signification, that is, when the denotative sign, the sign at the first order of signification, is interpreted in relationship to the particular cultural contexts and experiences of the user. Metonyms work by activating in the mind of the reader or viewer a chain of stereotypical associations that he or she has acquired through socialization (→ Information Processing: Stereotypes; Scripts). So when we use the expression “the *crown* has decided to sell of some of its lands,” the audience comes to understand the *crown* as a reference to the monarchy. We use a part of something to signify the imagined whole.

We can better understand how metonyms operate by distinguishing them from the common use of another trope, → *metaphor*. Much of our communication is made through analogies. When signifying meaning through metaphors, we create analogies – transposing the attributes of one object to describe a different and separate object. So when we describe a person’s insatiable sexual appetite by saying “he is an animal,” we transfer the sexual wildness of an animal to represent the man’s sexual behavior. While metaphors create their meaning by transposing attributes from different and unassociated spheres of reference, metonyms work on the same plane of reality, by associating objects that have a proximate or physical relationship. Metaphors cause us to understand one thing in terms of something different; metonyms cause us to refer to one thing (A) by using something (a) that is physically part of A or part of the world of A.

Metaphors and metonymy are different kinds of processes. Metaphor is principally a way of conceiving of one thing in terms of another, and its primary function is understanding. Metonymy, on the other hand, has primarily a referential function, that is, it allows us to use one entity to stand for another. But metonymy is not merely a referential device. It serves the function of providing understanding. (Lakoff and Johnson 1980, 36)

Drawing analogies through metaphors may be a common and useful way to create meaning in daily language, but metonyms may have an even more essential role in creating meaning because, as Fiske notes, “representation of reality inevitably involves metonymy: we choose a part of the ‘reality’ to stand for the whole” (1990, 95; → Visual Representation; Film Theory). In taking a photograph, editing a news story, or constructing a narrative film, we select pieces of a continuous reality (candid or staged) and elliptically join them together in an ordered, condensed, and oftentimes dramatized form to represent that “reality” (→ News Story; Narrative News Story). Thus, virtually all representations of reality are metonymic. When we tell stories, we do not relay all the details of the events in the story. We facilitate efficient storytelling by selecting only portions of the event narrative to convey the larger story (→ Storytelling and Narration; Rhetoric and Narrativity).

Invariably the metonymic selections we make in representation powerfully delimit and shape the way we come to understand the larger whole. In → news, metonymic selections frame important public issues for the audience (→ Framing of the News; Framing Effects). For example, images of “precision bombing” dominated television news representations of the first Gulf War. Metonymically, precision air-bombing became emblematic of the entire execution of the war. Its impact was to create for viewers an impression of a bloodless war, de-emphasizing collateral damage and human costs.

Metonymic images of precision bombing function as indexical signs, because of their existential relationship with the war itself. The photographic images trace actual reflections of light from the war captured on film, video, or charge-coupled devices (→ Video; Digital Imagery). In this way, metonymic representations exploit the “truth factor” associated with indices, and naturalize their meanings as truthful representation, even though we know the war as an event is much more complex than the narrow range of images we see (Griffin & Lee 1995). And metonymic representations function mythically, stimulating the viewer to construct a chain of associations related to the myth of modernization, technology, and progress. The images of precision bombing are seen as part of the world of progress through technological development, in which precision bombing reduces the human tragedy and collateral damage associated with even as tragic an event as warfare.

In → advertising and in → cartoons, metonyms are also used indexically, as a shorthand to activate mythical and stereotypical meanings socialized through acculturation (→ Acculturation Processes and Communication). For example, in a Boucheron perfume ad, an image of the perfume “Trouble” is juxtaposed with a bust-shot of a woman with a snake wrapped around her neck. Through socialization, we recognize the woman with the snake as an indexical sign that references the myth of temptation in the Garden of Eden. The image therefore metonymically associates seductive taboo with the perfume “Trouble.”

Similarly, editorial cartoons utilize a single frame to activate stereotypical associations in the viewers. Caricatured drawings of President Clinton with a long nose, during the Monica Lewinsky scandal, not only exaggerated a pronounced feature of his face to physically identify him, but indexically referred to the story of Pinocchio, identifying Clinton with Pinocchio as a liar (→ Caricature).

## **Mexico: Media System**

*Frank Priess*

*Konrad Adenauer Foundation*

Mexico gained its independence from Spain in 1810, and in 1822 it became a republic. Of the history prior to the 1910 revolution, the war between Mexico and the United States in the mid-nineteenth century needs to be mentioned, in which the former lost almost half of its territory – this became a permanent source of friction in the relations between the two countries. Nowadays Mexico is a federal republic with 31 states and a federal district constituted under specific provisions. It has a presidential system in which the

significance of the legislative branch is increasing. It has a population of 107 million people – to which around 20 million people living either legally or illegally in the United States should be added – with a per capita income of US\$6,230 per year, and almost 90 percent of Mexicans are Catholics. Nevertheless, the influence of evangelical groups is increasing. The presence of indigenous groups is another important factor. Mexico is the only Latin American member country of the OECD and it is shaping up as a booming developing nation. However, its development has always been hampered by overwhelming social and economic inequality.

During recent years, the Mexican media system has experienced significant modifications. These may be explained by the strong interdependence between the media and the country's democratization process. After almost 70 years of de facto hegemony by Partido Revolucionario Institucional (PRI), the election of Vicente Fox Quesada in 2000 meant that an opposition politician became head of state for the first time. This trend was confirmed in 2006. As a consequence, Mexico has a pluralistic media environment, particularly in its press. Within this scene, the audiovisual media system – primarily television – is shaped by oligopolistic structures.

### **LEGAL AND ECONOMIC CONDITIONS**

In Mexico, the rights of journalists and the media lack a modern context because their legal framework dates from 1917 (→ Journalism: Legal Situation; Media Policy). Also, many Articles are not enforced and this leads to arbitrariness. In 2003 a step forward was made by setting forward the *Ley de Transparencia* (Transparency Act) and the constitution of the Instituto Federal de Acceso a la Información (IFAI). The recent decriminalization of slander (→ Libel and Slander) constituted another improvement for the media. Nevertheless, users of the media lack rights such as that of rebuttal (→ Right of Correction; Right of Reply).

Notwithstanding, based on the number of journalists murdered, Mexico is one of the most dangerous countries for representatives of the press. It is necessary to highlight that the perpetrators and planners of crimes against the press are seldom searched for and prosecuted. According to the International Federation of Journalists (IFJ), 10 out of 150 media representatives subject to violence during 2006 were from Mexico. The state has been incapable of protecting and ensuring freedom for the media and their representatives (→ Violence against Journalists).

On the other hand, the economic conditions under which many journalists live lead to a decrease in the quality of their work. Many of them need to have several jobs at a time so that they can gain a decent way of life. This is why they are the privileged targets of corruption. The lack of job alternatives, particularly outside the capital, leads to risks for journalistic professionalism and independence.

### **PRINTED PRESS**

The social division that exists in the biggest Spanish-speaking country in the world has a strong influence on the media and on the benefits it confers to different parts of the population. Thus, printed media continue to be elitist and expensive. In some regions, the high percentage of illiteracy is also an exclusion criterion. According to available data,

the average Mexican reads half a book a year. The → book market has between half a million and seven million readers. The circulation of most of the 300 → *newspapers* is low, with the exception of a few tabloids (→ Tabloid Press), and they are concentrated within the biggest cities. In the capital there are 21 newspapers with very pluralist features.

Circulation numbers are still kept secret by the newspaper owners, and their economies do not reflect a need for autonomous control mechanisms. However, newspapers as influential as *Reforma* sell no more than 200,000 copies a day. Free newspapers are offered on street corners and on buses and the subway. Public opinion polls show that more than 40 percent of Mexicans never read a newspaper. Outside of the biggest cities, many of the printed media only survive by means of state → propaganda, which assures influence for both federal and state governments (→ Advertising). This “carrot and stick” situation also obstructs objective coverage (→ Objectivity in Reporting).

### BROADCASTING

Generally speaking, Mexico’s → television market is shared by the *Televisa* and *TV Azteca* networks. The former clearly gets the most significant benefits. *Televisa* owns the main cable TV supplier, *Cablevisión*. The Azcárraga family, linked to PRI for decades, holds the majority of shares in *Televisa*. *TV Azteca*, founded in the 1990s as a result of the privatization of two highly indebted channels, belongs to Ricardo Salinas Pliego. About 65 percent of concessions, along with 70 percent of commercial profits, fall on these two companies, which hold the majority of the 465 commercial television frequencies.

The remaining 257 additional suppliers are state-directed and provide educational and cultural content (→ Educational Media; Educational Media Content). Currently, a debate exists around the possibility of issuing licenses for the establishment of a third national broadcasting television network. This initiative has been strongly resisted by the “main actors,” who have used every resource available. At the federal level, only channels 11 and 22 enjoy national broadcasting, while inside the states the state-owned channels are opinion generators only because people lack alternatives (→ Communication Law and Policy: South America).

While this happens, *television* constitutes the main information and publicity medium on which much political-institutional and party propaganda are concentrated. During the 2006 presidential campaign, parties invested 82 percent of their extensive budgets in spots in *Televisa* and *TV Azteca*. Around 80 percent of Mexicans are reached daily by television programs, followed by 70 percent reached by → radio. The contents of television programming are mainly focused on entertainment, dominated by the popular → soap operas (telenovela), talk shows, and sports programs (→ Sports and the Media, History of; Sports as Popular Communication). News programs have a place of their own, but most of the time local and regional events of minor importance are overemphasized. Most of the content – 61 percent – is from Mexico, with 31 percent American, and between 2 and 5 percent Latin American and Japanese. Based on the research of José Carlos Lozano, from *Tecnológico de Monterrey*, Europe’s presence in the programming is only 0.4 percent. Rating is most important – and here public broadcasters are at a disadvantage.

In *radio*, there are 1,164 commercial channels, 306 of which are state-owned and have educational content. The latter are financed by the budget held by the Ministry of Public

Education or by universities. However, the number of channels cannot be compared with the variety of programs. Like television, commercial radio is dominated by certain networks, such as *Radiorama*, *ACIR*, *Grupo Radio Centro*, and *Cima Somer*, to which more than 100 stations belong. This is possible because there are no limits on the concentration of media ownership (→ Concentration in Media Systems; Ownership in the Media).

Just like in the rest of Latin America, the noncommercial sector of audiovisual media is both underdeveloped and underfinanced. This sector is made up of channels that, in one way or another, are under the direct influence of the state. This is why it is impossible to talk about open structures that guarantee freedom. These qualities do not apply to the NOTIMEX news agency either (→ News Agencies). What is more, public broadcasting depends on state subsidies for it cannot profit from advertising. Instituto Mexicano de la Radio, *Radio Educación*, and a broadcasting system for 13 million Mexicans with indigenous origins share radio stations – the latter broadcasts its programs in some of the 62 indigenous languages of Mexico (→ Public Service Broadcasting: Law and Policy).

An alternative medium of information is represented by what is referred to as “community radio,” the survival of which is made difficult due to legislative conditions (→ Community Media). These radio broadcasters lack state funding and do not have access to the commercial market. Such a situation has resulted in the illegal operation of many stations.

## PROBLEMS AND TRENDS

The current reform to the Ley Federal de Radio y Televisión (Radio and Television Act), which dates from 1960, was the result of intense debates within the Supreme Court of Justice, which reversed some of the Act’s establishments. In general terms, only Mexicans can be the owners of broadcasting concessions, with the exception of the churches and the political parties. Commercial suppliers get licenses and other suppliers get broadcasting permits. Those who supported the initial reform argued that the participation of Mexico in technological development depended on it. Most of this was related to *triple plays*, which is the interconnection of television with telephone and Internet services.

However, this modification and its almost unanimous and immediate approval in the electoral year of 2006 were referred to as the “Ley Televisa” (*Televisa Act*). The objections of experts, important civil organizations, and media associations and federations were completely ignored. The preference for commercial networks became clear when 20-year concessions (internationally uncommon) were granted to them. Also uncontrolled, nearly automatic extensions and access to new media services were granted. Even more, it is possible that the commercial networks benefited from their strong economic position, for new licenses were to be called for bid and then granted to the highest offer. These parliamentary actions demonstrated to Mexican society the power held today by the electronic media.

Complaints were expressed by 47 senators from the main political parties. After the Supreme Court declared in June 2007, surprisingly, that the Act was unconstitutional, the senators and the representatives had to retake and reconsider the issue. For the Justices of the Court, the radio spectrum is a “common good” that should be organized in accordance with the standards of plurality and freedom of expression and information. One of the central questions in the upcoming reforms will be how the autonomy of the Comisión Federal de Telecomunicaciones (COFETEL, the Federal Telecommunications Commission)

should be guaranteed, how their members are to be appointed, and how the legislative branch can ensure its right to participate. Currently, the Ministry of Telecommunications and Transportation is in charge of granting and managing the frequencies. The lack of transparency, the climate of favoritism, and the direct influence from the executive branch are among the most highly criticized aspects of the conservation of this process (→ Television Broadcasting, Regulation of).

## NEW MEDIA AND THE INTERNET

Mexican youth in particular began to use the → Internet as an alternative medium. Based on current figures, around 15 percent of Mexicans have access to the web. Social differences are also reflected here (→ Digital Divide). What is more, → cable television offers a pluralist – both the Congress and the Supreme Court have a channel of their own and international suppliers have a presence in several channels – but only a reduced number of Mexicans can afford them. Most of the population has to turn to the abovementioned channels and thus plurality is restricted.

# Microethnography

Curtis D. LeBaron

Brigham Young University

Microethnography, sometimes called video-based ethnography, addresses “big” social and organizational issues through careful analysis of “small” moments of human activity. Working at a particular site or institution, such as an archeological dig or an investment banking firm, researchers create video recordings of activities as they naturally occur, i.e., activities that would have happened whether or not a camera was present. These recordings are then analyzed repeatedly and rigorously, with attention to both the participants’ talk (who says what, when, and how) and their embodied behaviors (the relative location, movement, and orientation of people and things). Video analyses are combined with other kinds of information, such as ethnographic data gathered through observations and interviews, altogether providing a variety of macro- and micro-views of social activity.

Microethnographic research claims are grounded in the empirical details of actual behavior that are captured on video tape and made available to the scrutinizing audience. Researchers show how people interactively create and sustain the social and organizational realities that they inhabit. Although researchers may avoid explicit claims about the generalizability of site-specific findings, microethnographers assume that patterns and practices in one place will have relevance to other contexts.

## A HISTORICAL SKETCH OF MICROETHNOGRAPHY

Microethnographic research is a convergence of competencies from multiple disciplines, including anthropology, sociology, psychology, and communication. In 1942, anthropologists Gregory Bateson and Margaret Mead published a ground-breaking book, *Balinese character*, which included more than 700 photographs that were arranged to show recurring patterns of social life. Their account of Balinese culture was grounded in the visible details of everyday behavior: how people walked, attended to their surroundings, moved their hands when eating or dancing, and so forth. This photographic analysis was a precursor to work in the 1970s, when social scientists started to use video tape (a new technology) to capture human behavior in “the wild.” For example, scholars concerned about social inequality in public schools used video tape to examine “micro-behaviors” (talk and movement) as the building blocks of micro-cultures that developed within a particular classroom or school (e.g., Mehan 1979). The term *microethnography* was picked up as a label for this new approach to research.

From the field of sociology came the influence of → Erving Goffman, whose “micro-studies of the public order” focused on the social rather than the psychological, on the interaction rather than the individual. Goffman used fragments of human behavior from a variety of sources (e.g., excerpts from field notes, snippets from overheard conversation, lines from novels) to illustrate his theory about the fundamental order of social life. He was especially interested in ritualistic forms: the small verbal and nonverbal

behaviors that individuals use to show appropriate respect for one another during daily encounters.

The strongest influence on microethnographic research has been → conversation analysis, a research perspective developed by sociologist Harvey Sacks, in collaboration with Emanuel Schegloff and Gail Jefferson. As a challenge to the cultural determinism of Goffman's views, Sacks emphasized the *sequential emergence* of social life. He used audio recordings of real conversation to uncover the orderliness of everyday talk and to identify the micro-processes or "mechanisms" whereby social actions (e.g., greetings, assessments, questions/answers) are interactively accomplished. Sacks argued: "Whatever humans do . . . there is order at all points [and] a detailed study of small phenomena may give an enormous understanding of the way humans do things and the kinds of objects they use to construct and order their affairs" (Sacks 1984, 22–24). Conversation analysis has a kinship with → ethnomethodology, which is a revolutionary perspective promoted by sociologist Harold Garfinkel that regards social order as an ongoing product of people's sense-making practices and procedures.

Although microethnographic research regularly employs conversation analytic assumptions and procedures, the methods diverge in three important ways. First, conversation analysts typically create collections of some recurring phenomenon that they have found in a variety of contexts. For example, a study of assessments within conversation might include instances taken from telephone conversations, classroom discussions, medical consultations, and so forth. By contrast, microethnographies are typically case studies of a particular setting (e.g., a police department) or activity (e.g., a weekly board meeting). Second, rather than seeking to build generalized claims about what people do and how they do it, microethnography works to provide a rich description and a thorough account of scenes of social interaction. "How does a detective incrementally extract a confession from a suspect during a two-hour interrogation?" is the kind of question microethnography addresses. Third, conversation analysis has primarily focused on talk with less attention to visible interaction, including people's use of tools, artifacts, objects, architecture structures, and so forth. More often, microethnographic research has attended to the embodied features of human activity, including the subtle interrelationships between vocal and visible forms of interaction.

Microethnographic analyses of visible (nonverbal) behavior have been influenced by "context analysis," an approach pioneered by psychologist Albert Scheflen during the 1960s and 1970s. Scheflen carefully documented people's behaviors during therapy sessions, showing how their postural shifts marked phases of their meeting, and how their location and orientation in the room displayed interpersonal relationships. He also studied thousands of photographs of people within situations such as parties, hallway encounters, and office meetings. He explained the interactive affordances of different body parts and explicated social activities in terms of distance, orientation, and postures of the participants (→ Nonverbal Communication and Culture). Context analysis was further developed by Adam Kendon, who advanced a more interactionist and sequential approach. Context analysis is more reliable than the notion of "body language" that became popular during the 1960s and 1970s: rather than treating an isolated behavior (e.g., folded arms) as inherently meaningful (e.g., defensiveness), context analysis examines the social relativity and sequential unfolding of visible forms and interaction.

Microethnographic work is making a unique contribution to communication studies by addressing “big” social, organizational issues through careful analysis of “small” interactional moments. For example, Goodwin (1994) conducted a frame-by-frame analysis of the courtroom activity that led to the acquittal of the Los Angeles policemen who beat Rodney King. The study showed how defense attorneys organized the jury’s perception of the video-taped beating so that King, rather than the policemen, was seen as the aggressor. Similarly, LeBaron and Streeck (1997) used computers to analyze a covertly video-taped interrogation at a police station with a history of getting confessions from suspects later found to be innocent. Their study showed how interrogators constrained talk at the same time that their spatial maneuvers literally backed the suspect into a corner. Such attention to vocal and visible behavior, including people’s use of objects and artifacts, combined with concern for “big” social and organizational issues, resonates across sub-fields of communication.

### HOW TO CONDUCT MICROETHNOGRAPHIC RESEARCH

Although microethnography takes different forms, depending on the interests and practices of the researcher, it generally involves five steps.

(1) *Select a research site.* Selecting a site depends on the nature of the research project. Although an Internet chat room might be a legitimate place for research, sites are typically physical locations where people move and talk in ways that collectively constitute recognizable action. Traditionally, ethnographers have chosen sites without knowing what they will observe or discover. Basic communication research – that is, discovering and documenting features of the interaction order – could be conducted almost anywhere because patterns of interaction found in one place, such as a beauty salon, might also occur within a courtroom, a boardroom, and so forth. Increasingly, site selection is guided by a specific agenda or question that the researcher wants to pursue, such as, “How do surgeons at a teaching hospital work to save the life of a patient and at the same time instruct a junior apprentice?”

(2) *Collect data.* Participant observations, field notes, interviews, and field recordings (audio and video) are all considered premium data for microethnographic research. However, video has become the staple because it provides empirical grounding for interpretive claims, captures subtle details of interaction that analysts can review and others can verify, and helps researchers attend to both vocal and visible phenomena socially orchestrated. A variety of cinematic decisions influence the “quality” of video-taped data. Simply turning a camera “on” or “off” is an interpretive act – a decision about what is important or worth recording. The camera’s scope is often a dilemma: a wide-angle view that includes all participants will not include close-ups of facial expressions and other subtle behaviors; a close-up view of someone’s hands will exclude the eye gaze or facial orientations that direct the attention of others. Cameras necessarily embody a perspective. They must be placed and pointed, and analysis is always contingent upon the perspective a camera provides.

Thus, microethnography diverges from other research traditions: it does *not* rely on hypothetical data that depend on someone’s ability to imagine; on survey and self-report data that depend on a subject’s ability to remember; or on laboratory data in which the

subjects are removed from the people and things associated with their everyday lives (→ Research Methods).

(3) *Analyze video data.* By watching video-taped data carefully and repeatedly, analysts can identify patterns of interaction that provide empirical grounding for research claims. Occasionally, a video-taped moment “jumps out” as obviously noteworthy, but usually the significance of a moment emerges slowly as it is examined. Throughout this inductive process, an analyst’s eyes are unavoidably guided by research interests, as well as informed by existing literatures within the field of language and social interaction. Once a particular phenomenon is identified, induction may give way to abduction as the analyst looks for additional instances. Sometimes analysts work in groups (called “data sessions”), making rapid progress through synergistic observations and immediate evaluations of each other’s claims. In the end, research claims must agree with what can be seen and heard in the video-taped data.

(4) *Digitize and transcribe key moments of interaction.* When analysts become serious about examining a particular video-taped moment, they may use various computer software tools to transcribe the talk and study the frame-by-frame unfolding of visible behaviors. The computer offers different “views” of digital data: for example, the video can be slowed down or zoomed in, or different slices of behavior can be easily juxtaposed on the computer screen for comparison. New technology cannot replace the eyes and ears of a well-trained analyst, but it can support smart and rigorous research. Transcripts reduce interaction to a two-dimensional page to highlight (precisely) details of talk and nonverbal behavior. Transcription is a process of observing more exactly.

(5) *Describe and report research findings.* Microethnographic research is literally empirical. Analysts examine the visible and vocal behaviors that subjects make available to each other during their interaction, then make these data available to the reader. Research claims routinely appear on the same printed page as transcripts (featuring vocal behavior) and corresponding video frames (showing visible behavior). Recently, microethnographic reports have been published with a computer disk or Internet address that gives readers access to the raw video data (e.g., Jones & LeBaron 2002). Video-based claims are supplemented by ethnographic insights and evidence from participant observations, field notes, interviews, and so forth. Admittedly, these methods are fundamentally interpretive: social scientists are unavoidably symbol-using and meaning-making beings. However, video-based research is more rigorously empirical than traditional ethnography, as claims are grounded in the raw data that readers can see and scrutinize.

## Migrant Community Media

*Karim Karim*

*Carleton University*

The term migrant community media, also known as ethnic or diasporic media, refers to the print, broadcast, and Internet-based operations of ethnic minorities. They have emerged in recent decades as a significant category of global media (→ Globalization Theories). Previously, such media operated by minority groups in various countries were treated as being of minor academic interest. For a long time, migrant community media were usually underfunded and marginal to the mediascapes of most countries. However, ethnic media operated by community groups have increasingly become channels for transnational media flows (→ International Communication). Their relative prominence has come about due to a combination of factors, including the growing wealth of minority communities, the rising acknowledgment of ethnic media among host societies, and the increasing technological possibilities for “narrowcasting.”

Migrant community media are no longer confined within borders of nations but have transnational → audiences. The dispersed nature of diasporic settlements within countries and across continents has spurred them to adopt cutting-edge media technologies in order to develop links among themselves. Live or same-day programming is available from the homeland for its diasporas living around the world. Migrants who previously lived in the same neighborhood are also able to reassemble in cyberspace. But whereas the new technologies are becoming prevalent around the planet, diasporic individuals living in developing countries have less access to them than their fellows in the west. The growing corporatization of what were previously community-run ethnic media is also increasingly leading to the commercialization of diasporic media content (→ Community Media). Nevertheless, diasporic media do provide an alternative to the longstanding western dominance of international media flows (→ Cultural Imperialism Theories; Cultural

Products as Tradable Services; Free Flow of Information; New World Information and Communication Order [NWICO]).

## TYPES OF MEDIA FOR MIGRANT COMMUNITIES

The mass media, which usually look to serve the largest demographic groups, tend to exclude the cultural expressions of the smaller ones. This is often the reason why migrant groups establish distinct media organs to serve their members. These ethnic media are viewed as serving two primary purposes – they contribute to cultural maintenance and ethnic cohesion, and they help members of minorities integrate into the larger society (Riggins 1992; Husband 1994; Browne 2005).

*Newspapers* are the most common form of migrant media. There are hundreds of ethnic → newspapers in countries around the world. They usually tend to be in the language of the group that produces and consumes them, but some are also published in the language of the country of settlement. There are large variations in the form, quality, and frequency among ethnic newspapers. Some are well-staffed, established dailies that compete with mainstream papers; these print media usually have full-scale production facilities and strong → advertising revenues. Others may be very small outfits run by enthusiastic individuals out of their homes – such ventures tend to have fairly irregular production cycles and do not have a long life. They appear and disappear quickly, only to be replaced by other similarly short-lived publications.

The usually tight regulation of *broadcasting* by governments has historically made it more difficult for migrant groups to disseminate → radio and → television programming (→ Radio Broadcasting, Regulation of; Television Broadcasting, Regulation of). When ethnic broadcasters manage to obtain small time slots on the schedules of existing stations, they are often at the most inconvenient times for their potential audiences. “Vernacular services” of government broadcasters in Africa have allowed for some inclusion of migrant programming (→ Africa: Media Systems). In the UK, Channel 4’s public service remit includes the dissemination of programming which appeals to a culturally diverse society (→ United Kingdom: Media System). In Canada and the USA, community and campus stations have historically proved to be more accommodating, but ethnic minorities are also making inroads into commercial broadcasting (→ Canada: Media System; United States of America: Media System). Certain governments have taken strong initiatives to ensure the presence of the cultures of minorities on the airwaves. The Canadian Radio-television and Telecommunications Commission has been steered toward facilitating the development of radio and television programming for minority communities. It has developed an ethnic broadcasting policy, which specifies the conditions under which the dissemination of ethnic and multilingual programming can be carried out (→ Communication Law and Policy: North America). In Australia, radio, television, and Internet content is distributed by the publicly owned Special Broadcasting Services in some 70 languages (→ Australia: Media System). The largest Spanish-language US television network has hundreds of affiliates and is available to the vast majority of Hispanic households in the United States (→ NAFTA and International Communication). In a time of fragmenting audiences, niche marketers in an increasing number of countries look upon advertising on minority-ethnic electronic media as a way to reach growing minority populations.

Dávila (2001) has conducted a critical examination of these developments for the US Latino population.

## **THE OPPORTUNITIES OF NEW TECHNOLOGY**

The relatively small and widely scattered nature of migrant communities has encouraged diasporic media to seek out the most efficient and cost-effective means of communication. Technologies that allow for narrowcasting to target specific audiences rather than those that provide the means for mass communications have generally been favored. Minority-ethnic media have frequently been at the leading edge of technology adoption due to the particular challenges they face in reaching their audiences.

### **Satellites**

Digital broadcasting satellites are providing remarkable opportunities for diasporic communities (→ Satellite Communication, Global). Ethnic broadcasters, previously having limited access to space on the electromagnetic spectrum in northern countries, are finding much greater options opening up for them through digital broadcasting satellites. For example, France's main broadcast authority, the Conseil Supérieur de l'Audiovisuel, was actively encouraged by a center-right government to exclude Arabic stations from licensed cable networks in the 1990s (→ France: Media System). The response of a significant number of Maghrebi immigrant families was to subscribe to digital broadcasting satellite services, which provided them programming from North African countries from across the Mediterranean Sea (Hargreaves & Mahdjoub 1997).

Diasporic programming using this technology has grown exponentially in the past decade, well ahead of many mainstream broadcasters. Even as mainstream networks in Europe were making plans to introduce digital broadcasting, the Arab-owned and operated Orbit TV in Rome had begun by 1994 to provide extensive programming via digital broadcasting satellites to Arab communities in Europe and the Middle East. Med TV, a Kurdish satellite television station, is a case of a diaspora within and without the divided homeland attempting to sustain itself and to counter violent suppression with the use of communications technology (Hassanpour 2003; → Kurdish International Broadcasting). In examples of "reverse flow" of programming to home countries, Univisión and Telemundo, the two largest Spanish-language networks in the US, have been more successful than mainstream US media in exporting programming to Central and South America. Strong Indian diasporic subscriber bases exist for competing channels carrying material from → "Bollywood." Cable and satellite television services in northern countries have realized the viability of ethnic channels and are making them an integral part of their offerings (→ Cable Television; Satellite Television).

### **Internet and Online Media**

*Internet*-based media, which are able to support ongoing communication in the widely separated transnational groups, seem especially suited to the needs of diasporic communities (→ Internet). In contrast to broadcasting's highly regulated, linear, and capital-intensive

characteristics, the decentralized, interactive, relatively inexpensive, and easy to operate online networks prove attractive to migrant communities. In addition to extensively using online media like email, usenet, listserv, and the world wide web, diasporic groups are also publishing content in offline digital media such as CD-ROMs. The contents of diasporic electronic communications largely consist of cultural, heritage, genealogical, religious, and institutional information. Recent migrants separated from family and friends are placing notices on newsgroups giving particulars of individuals with whom they want to re-establish contact or to search for marriage partners. A number of web sites have established global directories of community members that include categorization under alumni of colleges, professionals, and businesses. The medical necessity to find human marrow donors from one's own ethnic group for the treatment of more than 60 blood-related diseases has extended these searches into cyberspace.

In facilitating global accessibility to Asian, Latin American, and African views of the world, community online networks provide a small but important counterweight to the enormous production and export capacities of the cultural industries of developed countries. This becomes a way to mitigate the effects of cultural imperialism and to foster worldwide cultural diversity. A primary motivation for migrant communities to go online seems to be survival in the face of the overwhelming output of the dominant culture and the limitations of immigrants' access to the cultural industries in their countries of settlement. Isolated members of diasporas who are using online media can participate to some extent in cultural production rather than merely consume media content. Information about reunions, festivals, and worldwide locations of community institutions facilitate the physical gathering of diasporic individuals. Current events and new publications of materials relating to the transnational group are regularly discussed in online news groups. Diasporas are increasingly turning to blogs (web logs) to engage in discussion with each other on contemporary political and cultural issues. Social networking sites such as MySpace and Facebook are also providing for diasporic community members to interact with each other.

The global dispersion from the home country over a period of several generations is seemingly reversed by bringing together disparate members of the ethnic group to interact in an electronic chatroom. For example, Sindhis, a South Asian ethnic group whose members were dispersed by the partition of colonial India and by migration patterns outside the subcontinent, and white settlers who remained in Zimbabwe after independence and those who emigrated, have sought to recreate their community electronically. A website operated from Germany provided extensive hypertext links to Iranian universities, research organizations, information resources, cultural industries, literature, art collections, media, sports groups, businesses, political and religious organizations, government agencies, discussion groups, and individuals, located inside and outside Iran. Cooperative arrangements between students and professionals of recent Chinese origins working in high technology sectors in Canada, the United States, and the United Kingdom have led to the emergence of online magazines that express their particular concerns. These new arrivals feel that their information needs are not met by the content of the thriving print and broadcast Chinese ethnic media, which is produced largely by older groups of immigrants from China. The restrictions of national borders therefore appear to be partially overcome in this alternative form of globalization.

A number of diasporic websites are designed to correct what are considered misperceptions by outsiders and to mobilize external political support. Several groups also use online media to challenge hate propaganda and to carry out polemics against other websites. Some anti-government organizations have taken even more strong action with the use of electronic technology. One Tamil group electronically disabled the websites of several Sri Lankan embassies that it viewed as disseminating propaganda. The speed of simultaneous, worldwide demonstrations in March 1999 by Kurdish protestors, who reacted immediately to the capture of a guerrilla leader by Turkish forces, was enabled through the Internet links maintained by that global community.

However, the ability of global communities to maintain and extend effective electronic links began to be affected by the controls that governments started to exert ever more intrusively over online networks, especially post-9/11 (→ Internet Law and Regulation). Additionally, as national borders came to be sealed more tightly in order to prevent terrorism and to allay political hostility to undocumented migration, transnational communication became increasingly difficult for migrants.

The extensive presence of the communications conglomerates that were increasingly buying up diasporic print and broadcast media, and the growing commercialization of online media were also having an effect on the kinds of material they carried (→ Commercialization: Impact on Media Content; Commercialization of the Media; Media Conglomerates). Whereas the improvements in infrastructure and software may have benefited transnational groups, commercial priorities risked overwhelming community considerations in the organization of communication networks and in the production and distribution of content. Participation by members of global diasporas in communication networks is far from equal. Migrant communities living in wealthier parts of the world have considerably more access to media technologies than their counterparts in developing countries.

Nevertheless, it is clear that diasporic connections have become integral to the networks of transnational communication. Even as diasporic media are piggybacking on the communications infrastructures established and maintained by states and corporations, they are also engaging in the further development of the means of global communications.

## Migration and Immigration

Sandra J. Ball-Rokeach

University of Southern California

With immigration and its attendant population diversity on the rise all around the world, how do we understand why people migrate, what they do when they arrive at their destinations, and what happens to the places they left? While immigration and migration are potentially rich sites of communication inquiry, communication theory and research is not well represented in the immigration studies literature.

There are excellent reviews of the wide scope of immigration literature (Foner et al. 2000; Joppke & Morawska 2003; Waldinger 2001). Our present aim is to focus upon two important *areas of overlap between immigration and communication research*: (1) models of cultural adaptation, namely the rejection of the 1940s static linear model of assimilation in favor of dynamic models of adaptation (→ Acculturation Processes and Communication), and (2) the negotiation of identity in places with relatively easy contact with the home country via new communication technologies and/or relatively inexpensive travel. Immigration scholars of the 1960s and 1970s shifted from the assumption of powerful structural constraints to assimilate (à la powerful media) to the idea that people could simply and with abundant agency transplant the home culture to the host country context. From the 1980s forward, we see more refined models of adaptation that privilege neither the host nor the home culture, but the dynamic and multidimensional process by which immigrants located in macro-structural contexts – but also in meso-level contexts of media, family, and social networks – negotiate their identities (Alba & Nee 2003; Morawska 2003).

Variations in preferred level of analysis are readily apparent in immigration studies. For example, a major debate centers on the issue of what we should call the *immigrant identity negotiation process*. Some ethnographers who study the daily practices of new immigrant groups characterize their identity negotiations as instances of “transnationalism”; that is, the bridging or linking of two societies (Levitt 2001; → Ethnography of Communication).

Others take exception to the term transnationalism, citing the absence of any implication of state-to-state relations (macro) and the presence of “highly particularistic attachments” to “here” and “there” (micro) that might be better characterized as “bi-localism” (Waldinger & Fitzgerald 2004).

The unanswered question is whether the immigrants of today will behave like the immigrants of yesterday. Will they construct a hybrid identity that is neither their “home” nor the “host” identity, but a dynamic product of the two? Is there any general pattern or do different groups living in different spaces (e.g., a global city or a suburban enclave) negotiate identity differently? Or will some, due to race, education, or other characteristics, be afforded upward mobility opportunities and, thus, appear to assimilate, and others be locked into the lower and underclass, and thus appear to resist assimilation (Morawska 2003)?

Communication processes and practices are the milieu through which identity negotiations, individual and collective, occur (→ Collective Memory and the Media). The consumption and production of what used to be called immigrant media (Park 1922), but are today more commonly called minority, ethnic, or geo-ethnic media (Kim et al. 2006), are central to processes of identity negotiation (→ Ethnic Media and their Influence; Ethnicity and Exposure to Communication; Migrant Community Media). The shift in terminology from immigrant to ethnic media is telling – *immigrant* suggesting that the problematic is assimilation, while *minority* or *ethnic* refers to group identity and boundaries that seemingly proliferate in a globalizing world where movements of peoples over space is one of the hallmarks. Immigrant social networks are constructed and maintained through interpersonal communication in kin and household networks and hometown associations, through ethnic media that afford a shared negotiation of home/host gaze, and through new communication technologies.

Communication research programs that seem particularly well positioned to contribute to immigration studies include the growing body of *social and personal networks research* (e.g., Monge & Contractor 2003), which affords a multilevel framework for tracking the communicative actions of immigrants and their consequences (→ Communication Networks). Consequences would include migration decision-making, identity construction, and the effects of continued communication between networks back home and in the new place (→ International Communication). For communication researchers to become more involved in immigration studies, they should broaden their focus (typically upon mainstream traditional media or Internet- and computer-based media) to include the world of ethnic media of traditional and new media forms. The multilevel and ecological communication infrastructure perspective (Kim & Ball-Rokeach 2006) reflects such broadening, and affords a grounded methodology for observing the everyday practices of adaptation among new immigrants and between new and old immigrants, a central feature of the globalization of everyday life.

## Mindlessness and Automaticity

Kathy Kellermann

ComCon Kathy Kellermann Communication Consulting

Robert M. McCann

University of Southern California

Mindlessness is the automatic (nonconscious) management of behavior. Mindless behavior is studied under many varied and related names: mindlessness, → automaticity, tacit knowledge, implicit learning, implicit cognition, nonconscious processing and, as one recent popular book puts it, “blink” (Langer 1978; Lewicki 1986; Reber 1993; Bargh & Ferguson 2000; Gladwell 2005; Litman & Reber 2005). Langer introduced mindlessness into social psychology nearly three decades ago (Langer 1978). As editor of *Communication Monographs*, Judee Burgoon devoted a five-article “Chautauqua” to the concept in 1992 (see, e.g., Kellermann 1992).

### MINDLESS AND TACITLY LEARNED BEHAVIOR

*Mindless behavior* is automated because it is familiar and overlearned; the behavior no longer needs conscious monitoring. Kellermann (1992) argued that communication is

inherently strategic and mostly automatic due to familiar and overlearned → schemas and → scripts guiding → message production and comprehension. Such overlearned and mindless behavior can be beneficial or hurtful. For example, intimate partners may fall into mindless, habitual patterns of disagreement or withdrawal in which they fail to consider even the simplest alternative pathways toward resolving their interpersonal issues. These partners also might develop a morning greeting ritual that starts each day on a positive note (→ Marital Communication). Increasing mindfulness is studied as an antidote to communication problems arising from mindless behavior (Burgoon et al. 2000).

Unlike mindless behavior, which requires prior conscious monitoring, *tacitly learned behavior* is acquired without ever being consciously mediated. Such automatic behavior is acquired implicitly and used unconsciously (Lewicki 1986; Reber 1993). Natural language, interpersonal perceptions, and nonverbal behaviors are believed to be mostly acquired and used implicitly (→ Nonverbal Communication and Culture; Rhetoric, Nonverbal). Many aspects of complex language structures are unconscious and best learned implicitly rather than explicitly. The human ability to produce previously unheard-of lexical patterns such as sentences, or a child's quick mastery and use of untaught or unlearned grammatical rules (without even the adult being able to explain these rules), are illustrations of tacit learning in human communication (see, for review, Lewicki 1986; Kellermann 1992; Reber 1993; → Linguistics; Language Acquisition in Childhood).

### RELEVANCE OF AUTOMATICITY FOR SOCIAL BEHAVIORS

Mindless and tacit links exist between → *social perceptions* and *social behaviors*. A definitive connection exists between → stereotype activation and subsequent behavior in accordance with the content of that stereotype (e.g., McCann et al. 2005). For example, Bargh and associates (1996) explored the hypothesis that “what you perceive is how you behave,” by using priming mechanisms (elderly stereotypes such as wrinkle, sentimental, Florida) to activate single and multiple trait perceptions in elderly test subjects. Participants primed with the elderly-related material walked more slowly down the hallway after leaving the experiment, thus activating the stereotype by unconsciously thinking about it. Initial automatic evaluations of an individual, which could be based on age, gender, or even choice in hairstyle or clothing, can have far-reaching implications for future interactions with that individual due to a positive or negative evaluation of their behavior (Hill et al. 1990; Ferguson & Bargh 2004). Studies have extended work on nonconscious activation to cultural ideologies, power differentials, and corruption.

*Situations* alone can even be enough to automatically activate group norms and subsequent group evaluations (including ingroup biases) and behaviors. Decades of → media effects studies explore how viewing a film with violence or aggression can automatically activate tendencies to behave in the same manner as represented on the screen, and automated nonverbal and verbal mimicry have been tied to outcomes as diverse as persuasibility, conflict resolution, and group harmony.

### CONSEQUENCES FOR COMMUNICATION RESEARCH

Considerations of mindlessness, tacitness, and automaticity can profoundly affect the way communication scholars approach areas of inquiry. Numerous interpersonal theories

invoke various types of automatic mechanisms. Action assembly theory maintains that lower-level actions are automatically assembled, allowing a role for mindful behavior at higher levels (Greene 1997; → Action Assembly Theory). Research on memory organization packets (MOPs) argues that conversations between strangers are mostly mindless, while remaining flexible and adaptable (Kellermann 1995). Berger's planning research places a fundamental role on the internal workings of individuals' cognitive systems during social interaction (Berger 1997). Some persuasion theories assume automaticity (e.g., conditioning theories), some assume mindfulness (e.g., cognitive dissonance), and some allow for both (e.g., → Elaboration Likelihood Model).

Assumptions about tacit and/or mindful processing affect what phenomena are studied and the perspective taken on what is studied. For example, conscious efforts to try to interfere with implicit processes for the acquisition of linguistic rules have been found to decrease, rather than increase, the quantity of what is learned (Reber 1993). The implications of this finding are not only that complex structures such as languages are best learned implicitly rather than explicitly, but also that conscious regulation of the resultant highly regulated linguistic behavior is difficult. Implicitly learned linguistic rules unconsciously prime particular linguistic behaviors.

In recent years, some researchers have shifted focus from mindlessness to mindfulness, outlining health, business, education, and communication improvements due to mindful behavior (Burgoon et al. 2000; Langer & Moldoveanu 2000). By contrast, Gladwell (2005) argues for the power of thinking without thinking in everything from social perception to policing, discussing problems of mindful interference in automatic processes. Automatic behavior can be powerful or problematic, and present-day researchers are teasing out the conditions driving each.

## Minority Journalism

*Rebecca Ann Lind*

*University of Illinois at Chicago*

In a social context, scholars conceptualize minority groups on the basis of social status. Whether from a domestic or an international perspective, minority status is not predicated on numerical representation within a culture; it has to do with social or cultural difference, based on language, religion, or other cultural practices (→ Ethnic Journalism). When language differences exist, the dominant social group considers the news reports minority groups themselves produce as “foreign-language journalism.” Most scholars discount biological theories of race, which attempt to mark minority groups on the basis of physical characteristics, but some attempt to differentiate between racial or ethnic minorities. Even so, the key relationship between the minority group and the dominant social group is that the former is subordinate to the latter. As a result, members of minority groups frequently do not enjoy the same access to education, economic or political power, or other cultural capital as do members of the dominant social group (→ Access to the Media; News Ideologies).

The scholarly research literature on the history of minority journalism reveals an especially rich history in the United States, where nearly all nationalities and language groups have supported their own press (Wittke 1957). Minority journalism, especially when written in a culture’s native tongue, fulfills a vital function for its → audiences. At a minimum, the foreign-language press provides news of the homeland and its relationship with the host country. Such media can also keep the language alive, preserve cultural ties with the homeland, bring immigrants together in their new land, and socialize newcomers to

the cultural and other traditions of their host countries (→ Advocacy Journalism). The concept of minority journalism seems specific to the United States. Other countries tend to subsume the idea into ethnic, partisan, or political categories of journalism.

The characteristics of minority media include not only a desire to educate and improve the lives of their audiences but also an overtly activist mission (→ Activist Media). Racial and ethnic minority media often strive to protect the group's civil rights as well as to monitor the economic, cultural, social, political, religious, and economic development of the community (→ Civil Rights Movement and the Media).

The first foreign-language newspaper in the United States was published even before the Declaration of Independence was signed (→ Journalism, History of). The first of many successful German-language newspapers, *Philadelphia Zeitung*, appeared on May 6, 1732. In 1789, the US French-language press was born (with the *Courrier de Boston*). By the mid- to late 1800s, minority media had mushroomed: newspapers appeared in Norwegian, Chinese, Czech, Ukrainian, Polish, Italian, Yiddish, Hebrew, and many other languages. The period of rapid growth included Spanish-language newspapers. The first two such publications, *El Misisipi* (1808) and *El Mensajero Luisianés* (1809), served the New Orleans Spanish-speaking community.

Most historians consider the *Cherokee Phoenix* the first Native American newspaper. Published by the Cherokee Nation, this bilingual newspaper appeared on February 21, 1828 (→ Bi- and Multilingualism). African-Americans owned and operated *Freedom's Journal*, which appeared a year earlier, on March 16, 1827, when editors Samuel Eli Cornish and John Brown Russwurm launched the US black press (→ Black Feminist Media Studies).

When the new media of *radio and television* came onto the scene, activist functions and aspirations frequently carried over. Initially, minority broadcasts aired through what were called *time-brokering* arrangements (→ Broadcast Journalism). Less powerful radio stations often divided their day into discrete segments, which they sold to members of ethnic or racial minority groups to use as they saw fit. Time-brokering yielded a kaleidoscope of programming in Polish, Lithuanian, Greek, Spanish, Italian, and other languages. Many communities were served, but not at any given moment.

The first full-time Spanish-language radio station in the United States (KWKW, Los Angeles) took to the air in 1942. The first radio station fully committed to serving the African-American audience was WDIA, launched on October 25, 1948, in Detroit. Its white owners were desperate, not altruistic. When other formats had failed, the owners put the station on the market. One last-ditch experiment with what they called *Negro programming* ultimately launched a legend. WDIA became a powerhouse, and though it served the black community, it remained under white ownership. Though less of a powerhouse, WERD (Atlanta, Georgia) was the first black-owned US radio station. It wasn't until 1977 that the first Native-American-owned commercial radio station (KMDX, serving Parker, Arizona) launched.

Many societies have created a social structure that marks minority groups by their language, religion, or other traditions. Continued research into the historical use of the mass media by minority groups, across many societies and from a domestic and international perspective, can help reveal the social relationships between the minority and dominant social groups. Such research should examine whether the journalistic

output of minority groups using new communications technologies continues to reflect the activist goals and mission observed in the earliest minority journalism.

## **Mobility, Technology for**

*Rich Ling*

*Telenor R&D*

Within a decade of its commercialization, mobile communication is now often used more than landline telephony. In the early 1990s, only the privileged few used mobile communication, but by the mid-2000s, approximately one-third of the world's population had a mobile telephone. This period of seemingly effortless adoption has been accompanied by changes in our sense of safety and security, the way we coordinate everyday life, the way teenagers experience their coming of age, and the way we use and experience the

public sphere. The use of voice communication and the growth of texting have revised the way we think about interpersonal communication.

## **TECHNICAL HISTORY**

Mobile, radio-based communication, including what is known as mobile telephony, has its origin in the work of Marconi and radio telegraphy. The ability to modulate voice signals allowed for the development of services such as police radio, which first appeared in the 1920s in Detroit. This use of radio to “dispatch” various services expanded to include police and fire departments, taxis, and even rural veterinary services.

Radio-based communication in the switched telephony era had to wait until after World War II. Some of the first experiments with radio-based telephony – the so-called wireless local loop – were carried out in the eastern Colorado town of Cheyenne Wells in the United States. Local farmers, living as far as 30 kilometers outside town, were tied into the traditional telephony system via a radio link to their homes. The calls were manually routed via an operator in town, but the essentials were there, i.e., a radio link that was “switched” into the traditional telephone system. At this time, the so-called radio cell was many kilometers in diameter.

The next advance was the development of cellular technology whereby a conversation was “handed” from one relatively small radio cell to another; hence the name cellular telephony. The ability to support this type of routing of signals led to the current form of mobile communication. The first true cellular telephone system that used multiple radio cells and a handoff was the Amtrak Metroliner between New York and Philadelphia in 1969. Miniaturization of handsets and the digitalization of communication resulted in today’s mobile telephony systems.

The future development of mobile communication is likely to see movement away from circuit-switched to packet-switched communication. Traditional telephony (both landline and mobile) relies on a specific circuit that is established for the duration of the conversation. With the development of the Internet, a different approach is used. Instead of monopolizing a fixed circuit, the conversation is broken into smaller packets that are routed through the communication network and reassembled at the end address. This is the essence of VoIP (Voice over Internet Protocol) communication, and it has the advantage of making more efficient use of radio spectrum bandwidth.

## **SOCIAL CONSEQUENCES OF MOBILE COMMUNICATION**

Several consequences of mobile communication are discussed in the literature, including its role with respect to safety and security, the micro-coordination of everyday life, teenager emancipation, its disturbance of the public sphere, the growth of texting, and mobile communication in the developing countries.

### **Safety and Security**

Many people adopt mobile communication to enhance their personal safety or their sense of security. The mobile telephone gives people the chance to call for assistance when they

find themselves in difficult settings. A crisis need not be major or life-threatening. A crisis may simply be that a car breaks down or that someone is marooned with no possibility of finding a taxi, or becomes lost, or forgets a PIN code to a bank card, or – in the case of parents – a concern for the well-being of children. A mobile phone may also simply be a latent type of insurance should a problem arise, as in the case of people with chronic medical conditions. Mobile communication allows contact with others when there is a need for assistance or information.

While mobile communication provides security and safety, it can also be used in ways that threaten public safety. The mobile telephone has been used to organize criminal activities and by terrorists and insurgents to manage their affairs. On a mundane level, the use of the mobile telephone while driving has been shown to be dangerous. Thus, while mobile communication helps to avoid crises of various types, there are other aspects of its use that have negative consequences.

### **Micro-Coordination**

Perhaps the most profound impact of mobile communication is the ability to call individuals regardless of where they are. Rather than having to call specific geographic locations on the chance that an individual is there, an individual can be called, no matter his or her location. This allows for fleeting and subtle forms of coordination. In the case of landline telephony, there is no guarantee that the caller will reach an intended interlocutor. Agreements regarding meetings or the execution of errands are agreed upon and are relatively inviolable. Should something come up that makes a commitment difficult to keep, there are few means of rearranging encounters. Mobile communication changes this in that there is less need to make specific agreements, which instead can be made in an ad hoc way. If there is a traffic jam that causes a delay, we simply call ahead and let others know the situation.

It is sometimes asked whether this flexibility comes at the expense of treating such agreements responsibly. There is a difference between a firm attitude toward commitments and toward punctuality and loose understandings that are firmed up as a situation coalesces. A variety of power issues, courtesies, and potentially awkward situations may arise. Regardless of how these work themselves out, the ability to contact individuals and the resulting changes in the way we organize and coordinate everyday life are the most profound changes introduced by mobile communication.

### **Teen Emancipation**

One of the unexpected social consequences of inexpensive mobile communication has been its impact on the teenager emancipation process. During the emancipation process, teens move from being securely within the sphere of the family to being, in many ways, independent of their parents. In this process, the peer group serves as a sort of midwife, and the role of the mobile phone is important in this process. The ability to contact peers via a communication channel that the teen himself or herself controls allows for immediacy in interactions. This immediacy helps to integrate the peer group and it contributes to the emancipation process.

There is also a fashion dimension. The ownership and use of a particular type of mobile telephone have become a fashion statement. As with other artifacts (shoes, baseball caps, purses, the cut of clothes, etc.), the model and style of the mobile telephone tell the observer something about the user's taste and style. The establishment of a personal style, one that also resonates with that of the peer group, is part of the emancipation process. Given that mobile communication provides for inter-peer communication and is an expression of style, it is not surprising that teens have established themselves as the quintessential mobile communicators (→ Youth Culture).

### **Disturbance of the Public Sphere**

Telephone calls are being made and received in places that, only a short time ago, were not sites for this type of interaction, and this is a change in a social norm. It has given rise to new rules of social interaction and new ideas as to where and when it is appropriate to use the telephone. There is even a new urban legend that plays on public unease about the public use of mobile telephones. Examples of this include the inappropriate use of a mobile phone at a gas station causing a fire, or a case where a diner at a restaurant becomes so enraged by a fellow diner's use of the mobile telephone that he or she grabs it and throws it on the floor. In each case, the use of mobile communication results in a spectacle.

The growth of texting has reduced the disruptions created by mobile communication to some degree. We can silently send and receive messages without causing offense to others in the social setting. In addition, users may be becoming more adroit at managing their calls and those in the immediate area are learning to "turn a deaf ear" to the use of mobile communication in public places.

### **Texting**

Mobile communication has occasioned the growth of texting. The popularity of this feature cannot be overstated. Many hundreds of millions of text messages are sent every day. They include the exchange of information, coordination requests, endearments and other pleasantries, and a wide variety of other content. Their popularity also has encouraged the emergence of a variety of new linguistic forms. It is likely that the technology for sending and receiving text messages will change, but mobile, text-based messaging has found a niche in society, making this one of the great contributions of mobile communication (→ Text and Intertextuality).

## **MOBILE COMMUNICATION IN THE DEVELOPING WORLD**

Mobile communication has grown surprisingly quickly in many areas of the developing world. In the mid-1990s the International Telecommunication Union statistics indicated that about half the world's population had never used a telephone. The introduction of mobile communication has helped to address this problem. A mobile communication system is often easier to install and maintain than a landline system. There is no need for an extensive network of telephone lines to originate or terminate calls. In addition,

batteries and solar recharge equipment can be used where other sources of electrical power are unreliable or absent. While it can still be expensive to purchase a mobile telephone, mobile communication is increasingly seen as a way to ensure access to communication networks. In many developing countries there are now more mobile subscribers than landline telephone customers.

In addition to access, mobile communication supports new forms of entrepreneurship. As with its use in the industrialized countries, the ability to be available to customers regardless of location, the ability to gather information on market prices, and the ability to arrange financial transactions mean that mobile communication is a useful tool that supports entrepreneurial activity in developing countries (→ Development Communication).

# Modality and Multimodality

Klaus Bruhn Jensen

University of Copenhagen

The modalities of communication – speech, song, writing, images, etc. – constitute general registers of human expression and experience. As such, they lend themselves to different forms of technological mediation, both individually and in combination as multimodal communication.

The various modalities are at once biologically conditioned and culturally shaped. On the one hand, the human senses enable people to identify particular *affordances* (Gibson 1979) or possibilities for action in their environment. On the other hand, representations of this environment are realized in culturally conventional forms, in embodied as well as technologically mediated communication. Such representations, further, come to constitute affordances in their own right. Research on, for example, computer-mediated communication has examined media as cultural artifacts with specific affordances for social interaction (Norman 1990). Hutchby (2001) identified distinctive affordances of interaction that takes place either face-to-face, via telephone, or in online chat. In a perspective of media and communication theory, the modalities can be considered potentials of the human senses for meaningful discourse in and about the natural and cultural environment – potentials that are extended through information and communication technologies.

While everyday language, like Aristotle, distinguishes five main senses – sight, hearing, smell, taste, and touch – communication research has focused special attention on aspects of sight and hearing in social interaction, even while recognizing, for example, the role of touch in interpersonal communication and experiments integrating smell into cinema (“odorama”). A key issue is how to *typologize modalities* in relation to sight and hearing: how many modalities are there? With reference to face-to-face interaction, Stivers and Sidnell (2005) employed a main distinction between a vocal–aural and a visuospatial modality, sub-dividing the latter into gesture, gaze, and body posture (→ Gaze in Interaction; Gestures and Kinesics) and the former into lexico-syntactic, vocal, and prosodic channels, because each of these could be said to make a difference in the process and outcome of communication. From a perspective of technologically mediated communication, Kress and Van Leeuwen rather suggested that language as such is a modality or mode, “because it can be realised either as speech or as writing,” adding that writing is itself a semiotic mode that can be realized as “engraving in stone [or] print on glossy paper” (Kress & Van Leeuwen 2001, 6).

In a *historical perspective*, modalities can be understood as an intermediate category between the material vehicles of communication – human bodies and information technologies – and its discursive vehicles – texts or messages (→ Media; Text and Intertextuality). Technologies – from writing to the Internet – have separated and recombined modalities in specific ways. As brought home by → McLuhan (1964), the material and modal forms of messages affect their interpreted contents (→ Medium Theory). In an oral culture, face-to-face communication is, by definition, multimodal, involving several

sensory registers at once. Writing and print focus the vision of the individual reader into a communicative gaze on texts, although reading aloud and subvocal reading persist. Radio reproduces a different, secondary orality (Ong 1982), and simultaneously integrates multiple modalities of language, music, and soundscapes. Cinema and television, in public and private contexts of reception, recreate a rich experience of natural and social settings, and of other humans, in sound as well as vision. Digital media, such as online virtual worlds, arguably, take multimodal communication to the next degree, simulating features of face-to-face interaction.

While it may, thus, be argued that communication history has witnessed a trajectory from multimodal, via tendentially monomodal, and back toward multimodal media, the configuration of modalities in any given period has been complex, both within the available technological media – for instance, illustrated books and magazines – and in the multistep flows involving such media and face-to-face communication (Katz & Lazarsfeld 1955). All along, language has been a master modality of sorts, providing both a model for other communications and the means by which all other modalities could be redescribed and explained (→ Linguistics). As noted by Émile Benveniste (1969/1985, 236), “the signs of society can be interpreted integrally by those of language, but the reverse is not so.” Also in this regard, language can be considered a key component of individual psychological development (→ Language Acquisition in Childhood) as well as of self-reflective cultures.

The concept of modalities remains relatively undeveloped in media and communication research. The coming of more explicitly and emphatically multimodal digital media technologies may be an opportune moment to reconsider the definition and operationalization of modality, also in historical studies of analog media. A renewed round of sound media studies has raised questions, for instance, of whether music and speech should be considered media, or modalities that are realized in different media (Cook 1998; Jensen 2006). In retrospect, “new” multimodal media can throw light on “old” media, their aspects and degrees of mono- and multimodality (→ Digital Media, History of).

## Models of Communication

*Denis McQuail*

*University of Amsterdam*

A model is a simplified description in graphic form of some aspect of reality. A model of communication seeks to show the main elements of any structure or process of human social action and the relations between these elements, plus any flow or exchange that takes place. The main benefits are to organize disparate elements and observations and to give a simplified picture of the underlying dynamics. The purpose of such models is thus primarily *heuristic* – an aid to the description and explanation of communication. To a lesser extent, they can help in predicting the outcomes of certain communication processes and situations by drawing attention to factors to take into account and forces at work. In this way, they are useful as a source of hypotheses, a guide to research, and a format for ordering the results of research.

To exemplify, the concentration of research effort in the early decades on the unintended effects of mass media violence and aggression led to a model (Comstock et al. 1978) that organizes the result of many findings. The form of the model is that of a typical sequence, beginning with “exposure” to some mass media representation of violence, with varying degrees of arousal and a probability of imitation of the violence depicted depending on the degree of perceived realism, the perception of consequences of imitation, and the opportunity to carry out imitation.

The term “model” can be used in other senses. For instance, *statistical* models are developed from empirical research to provide a precise account of the strength and direction of co-variance or causality (→ Statistics, Descriptive; Statistics, Explanatory). A model can also be developed as an *ideal type* to represent a certain concept, accentuating key or typical features. Similarly, it can help in creating typologies of sub-concepts, derived from certain fundamental dimensions. Models do seem to play a more central part in communication than in other social sciences as well as humanities. In humanistic traditions, the influence of Roman Jakobson’s (1960) model, deriving from linguistics and poetics, and re-emphasizing the role of a symbolic *code* over and above the channel or contact, is comparable to that of Shannon and Weaver (1949) in social-scientific traditions (→ Media). One possible explanation is that time, space (distance), and direction are key variables in many communication processes, and all three lend themselves to graphic representation especially in combination.

## EARLY MODELS

The beginnings of communication as a separate branch of study or discipline date from the early 1950s, mainly in the United States or under its influence. This phase was marked by a search for a unifying concept of communication (→ Communication: Definitions and Concepts). Although no agreed definition could be found, it resulted in the formulation of a simple graphic representation of communication as a process linking a sender and a receiver by a channel carrying messages from one to the other. Shannon and Weaver (1949) are usually credited with this invention, inspired by and intended for wireless or telephone transmission, but providing an embryonic model that could be applied to a wide range of situations, ranging from interpersonal conversation to mass communication on a national and even international scale. Their “mathematical” model was meant for calculating capacity and efficiency of communication (→ Information).

In this version, communication is represented as a linear, one-way process, concentrating on what is physically observable or measurable. In fact, this bias suited practitioners of mass communication research at the time, since they focused primarily on the *effects* (intended or not) of messages from the mass media, which were typically considered as strong, direct, and one-directional (→ Media Effects, History of).

The initial tendency of communication researchers was to elaborate this basic model to make it more appropriate to a fuller notion of human communication, especially by way of the mass media as characterized by center–periphery transmission, multiple channels, standardized content, and very large audiences. Wilbur Schramm (1954; → Schramm, Wilbur) drew on the work of Charles Osgood to redraw a basic model of communication as a circular process of exchange of messages, requiring a process of *interpretation* (encoding and decoding) at each stage, with a potential interchangeability of sender and receiver roles.

Probably the first elaborated “general” model of communication was that proposed by → George Gerbner (1956). This included a number of new elements, especially the process of perception of some event that precedes the formulation of a message, and also a recognition of the fact that messages are formulated in varied forms and by varied symbolic means (linguistic, aural, visual, etc.; → Modality and Multimodality). The process of reception was represented in the model as a repetition of the initial act of perception (the message being now the “event” perceived). This model was intended to apply not only to human but also to “machine” communication.

In the early phases of developing a viable model of communication, there were a number of innovatory ideas that have had a later application. For instance, F. E. X. Dance (1967) argued for a *helical model* to reflect the fact that communication is an essentially dynamic and exponential process that changes participants, as well as contexts and the future probabilities of communication, as a result of its own operation.

Another fundamental principle that has entered into later theory is that of *balance*, based on the observation that communicative exchanges are governed by the relationships of like or dislike between participants and by the attitudes of like and dislike toward objects of communication. Newcomb (1953) was the first to formulate these ideas into a simple model, known as the ABX model, with A and B being two persons and X an object of attention. According to this theory, flows of information (amount and content)

**Figure 1** Westley and MacLean's (1957) conceptual model for mass communication research, in which a channel role, C, is introduced between sender A and receiver B

will be governed by a “strain to symmetry” with reference to X. Discrepancies or differences will stimulate communication in order to reduce mental discomfort, a notion related to Festinger's (1957) theory of *cognitive dissonance*. In relation to mass communication, the main adaptation of the idea of balance can be found in Westley and MacLean's (1957) “conceptual model for communication research.” This displays the mass media as playing a mediating role between potential communicators and potential receivers, their activity being governed by the need to balance the motives and interests of senders with those of receivers. In this model (Fig. 1), we observe important *feedback* loops from audiences to original sources as well as to the mass media. For their part, the mass media have to orient themselves to sources, the audience, as well as to the environment in which they operate and the objects of media attention in that environment. Like some early models, this represents the mass media as essentially neutral and without purpose of their own.

### SPECIALIZED MODELS

As the field of communication diversified, there was a move away from general models and toward models applicable in particular sub-fields of research or theory. An early example was the modeling of influence in persuasive campaign situations, as in elections or advertising. The idea advanced by Katz and → Lazarsfeld (1955), on the basis of research into voting and consumer behavior, that influence does not typically flow directly by way of the mass media but indirectly by way of personal contacts, was very readily captured by a *two-step flow* model of communication (→ Two-Step Flow of Communication), in which the intermediaries were identified as *opinion leaders* or *gatekeepers*.

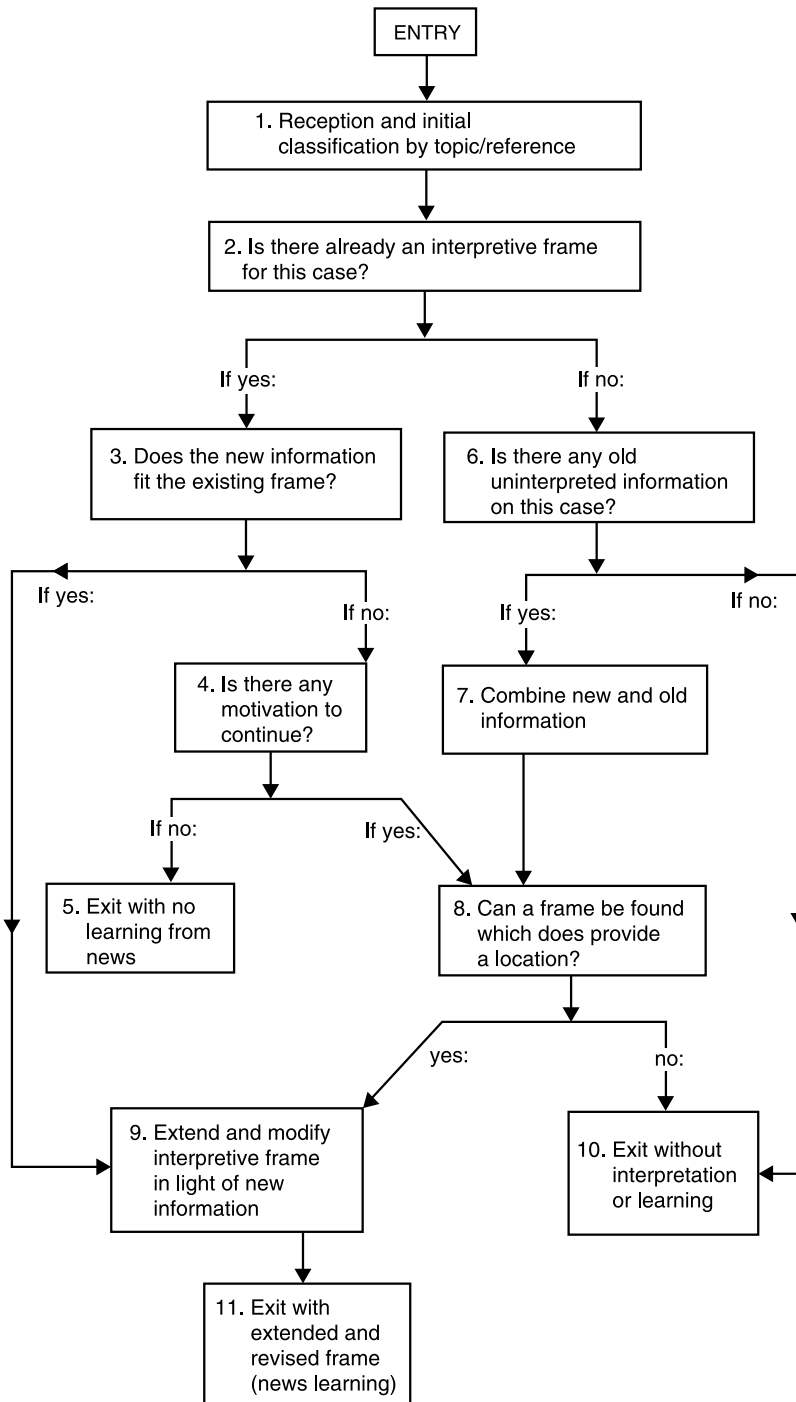

More elaborate models were developed to deal with the larger issue of the relations between types of society and types of media system. An early example is the *dependency* model proposed originally by Ball-Rokeach and DeFleur (1976), positing a relation between the degree of stability of a social system, the capacity and type of its information system (especially mass media), and the degree of dependence of the mass audience on the information system (→ Dependency Theories).

The concept of *diffusion* – the spreading of knowledge, awareness, or behavior within a population – is another key aspect of communication processes that has lent itself to modeling (→ Diffusion of Information and Innovation; Rogers, Everett). Research and theory led to a model for diffusion of innovations in developing countries that took account of a number of variables beyond those of sender, message, and recipient. Rogers and Shoemaker (1973) sketched a basic general model of four stages of successful diffusion (from knowledge to persuasion to decision to confirmation), influenced at various stages by a set of key variables, including characteristics of the target group, characteristics of the (local) social system (including the location of opinion leaders), and perceived characteristics of the innovation in question. The model, however, was still one of linear or even top-down influence. Subsequently, Rogers abandoned this approach in favor of a “convergence” model in which successful communication would have to involve a mutual co-orientation and mutual understanding (Rogers 1976).

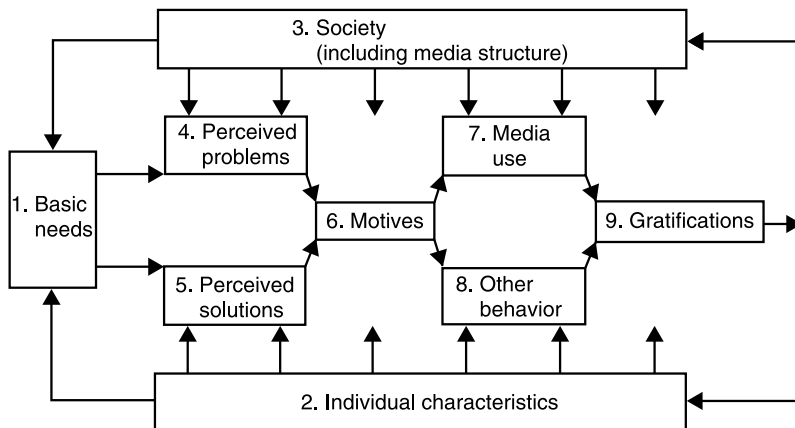

Also, the spreading of news from media to people and from person to person has been fruitfully modeled. Large differences in rates of diffusion of knowledge have been found according to differences between people, countries, and categories of events. A key point of variation is the relative extent to which news is diffused by word of mouth rather than only by mass media. The *J-curve of diffusion* expresses a finding arrived at by Greenberg (1964) regarding the 1963 Kennedy assassination and later exemplified in the diffusion of news of the 9/11 attacks in the US: the higher the proportion aware of an event, the higher the proportion who learned it from a non-media source.

Diffusion aside, both news production and reception have been modeled. Regarding production, the scheme of Ericson et al. (1987) displayed a complex sequence of activities, beginning with ideas for stories and input from sources and ending with a news page or news bulletin (→ News Routines; News Sources). Most models adopt a “transmission” approach, similar in kind to Comstock’s model of media effects, seeking to account for the potential success or failure of news learning as if the news were purposeful instruction. The alternative of looking at news through the eyes of the audience member requires a different kind of model. Graber’s (1984) model, based on constructivist “schema theory” (Fig. 2; → Constructivism; Schemas; Schemas and Media Effects), suggests that news learning proceeds by way of frames of interpretation in people’s heads.

Latterly, research has paid more attention to the receiver than to the sender in assessing or planning for “successful” communication. A popular model, proposed by Petty and Cacioppo (1986), envisages the processing of information by two broadly different “routes,” one a “central” route that pays attention to the logic of argument and facts as presented, another a “peripheral” route, in which there is no close attention and outcomes are determined more by associations, images, and incidental learning. The choice of routes is made by the receiver, although the would-be communicator may usefully choose which to expect and exploit (→ Persuasion).

**Figure 2** Schema-theory news-processing model  
 Source: Adapted from Graber (1984)

**Figure 3** Paradigm for uses and gratifications research  
 Source: Rosengren (1974)

The topic of audience selection and attention has also lent itself to models that either express propositions of explanatory theory or help to make sense of audience research data. The theory of audience → *uses and gratifications* rests primarily on the view that audience choice of media content is active, purposeful, and subjectively rational, and that media use is structured according to various perceived needs and gratifications sought, deriving from the social background of the individual, modified according to a number of individual differences. Media use is only one of the means available for achieving the goals sought. A general model of media use along these lines (Rosengren 1974) is given in Figure 3.

### POTENTIALS AND PROBLEMS OF MODELS

It is clear from the examples that models have various purposes, and can suit alternative theoretical perspectives. Even so, they seem most suited to representing planned communication efforts, where there is some underlying logic and sequence, with discernible criteria of success or failure. This implies the *transmission* view of communication (Carey 1975), much criticized for its narrowness and simplicity, which is not remedied by inserting some feedback loop. Carey's *ritual* view of communication offered an alternative in which the core meaning of communication is not purposeful action, but sharing, celebrating, and maintaining identities, beliefs, and relations through many forms of cultural expression. By its very essence, this open-ended, constructivist, and interpretive approach defies the efforts of the model-builder – it also reminds the field of the boundaries to the sensible deployment of its dominant models, including the tendency toward linear, causal, and mechanistic conceptions of communication.

There are few areas of communication research that have not produced at least one theory or concept that can be described in terms of a model (McQuail & Windahl 1993), including some of the most current approaches, such as gatekeeping, agenda setting, and news “framing” (→ Agenda-Setting Effects; Framing Effects), as well as entire areas such as international communication. It is likely that fundamental changes in public and

private communication stemming from technological convergence and the rise of the Internet will stimulate yet more models (→ Technology and Communication). Already Bordewijk and Van Kaam's (1986) model of information traffic has led to an important typology of modes of communication. This differentiates four communicative relations: allocation (mass communication), consultation (of a database), conversation (exchange), and registration (at a central node). The increasing importance attached to the idea of a *network society* is favorable to the use of models of communication (→ Network Analysis).

## Modernity

Joseph Straubhaar

University of Texas at Austin

Since the 1990s, academic debates have revived modernity as a key concept. Tomlinson (1991) argued that much of what was labeled “cultural imperialism” (→ Cultural Imperialism Theories) was in fact a broader spread of a globalized pattern of modernity. This discourse argued, in particular, that beneath much of what was seen as Americanization or westernization lay a more general, deeper globalization of capitalism, “the broader discourse of cultural imperialism as *the spread of the culture of modernity itself*” (Tomlinson 1991, 89–90, original italics; → Americanization of the Media; Globalization Theories).

A related question is whether modernity is a singular tendency or one with many possible versions and outcomes. A number of aspects of globalization tend to standardize certain kinds of economic modernity, such as financial institutions, trade rules and regimes, and commercial media models (→ Media Economics). However, Tomlinson (1999) also argued later that a “decentering of capitalism from the west” was taking place. A number of writers, e.g., Iwabuchi (2002), argued for distinct Asian or Japanese versions of both capitalism and media/cultural modernity. China has also steadily emerged as a major site and alternative form of capitalist production in the current neo-liberal system (Harvey 2005), with many features of current global capitalist modernity, but with a distinctly different emphasis. The fact that China has refused western prescriptions for the sort of democracy that is supposed to accompany modern capitalist development presents a long list of contradictions to traditional notions of modernity.

One problem with this new modernity-focused analysis in globalization, which relies on a rather *systemic notion of modernity* as the key concept, is losing sight of real issues of differential power between different parts of the world in economics, in politics, and in cultural industries such as television. Some forms of cultural production, e.g., commercial → television genres such as → soap opera, could be analyzed either as forms of capitalist production or as manifestations of modern approaches to media. The two angles offer somewhat different insights. Both imply limits placed on – and resources available to – cultural producers (television networks) and cultural consumers (television audiences; → Audience; Audience Commodity). One virtue of cultural imperialism is that it reminds academics to consider that different actors within the world system have different resources and levels of power.

One problem with classic, neo-Marxist approaches, in contrast, is that they tend to reduce too many things to *linear conceptions of political economic power* (→ Political Economy of the Media). For some authors, e.g., Schiller (1969) and Herman & McChesney (1997), the power of ownership is paramount, but as the Chinese government's limits on Murdoch's attempts to enter China's television market shows, simply owning a → media conglomerate, even one as apparently powerful as Star TV, is no guarantee of obtaining access to a nation's audience. In fact, this example shows that while China may be pursuing its own version of modernity, using television as a tool, it is seemingly trying to avoid as far as possible dependency on outside actors like Murdoch.

# **Modernization**

*Silvio Waisbord*

*Academy for Educational Development*

As in other social sciences, modernization was the dominant paradigm in communication studies that sought to understand and define the role of communication in development in the late 1950s and 1960s. Modernization was originally proposed as synonymous with development. Development was understood as a transition toward a social order that mirrored the politics and economy of the west, namely, liberal democracy and capitalist and industrialized economies. Modernization's time of intellectual and policy ascendancy was the postwar years during the period of decolonization. Western scholars and powerful policymakers viewed modernization as an unavoidable and desirable transition for non-western societies (→ Communication as a Field and Discipline; Communication and Media Studies, History to 1968; Development Communication).

As a theory, modernization offered both an explanation and a prediction for social change. As a process, modernization was used to describe the experience that so-called

“developing” countries had to undergo in order to achieve the levels of economic and political development found in the west.

### **COMMUNICATION AS MODERNIZATION, MODERNIZATION AS DEVELOPMENT**

One of modernization’s central ideas was that culture should be considered the independent variable that accounts for specific outcomes (e.g., political, economic, social). Drawing from classic sociological theories, namely Max Weber’s and Emile Durkheim’s views on culture (→ Culture: Definitions and Concepts) and social change, modernization posited the existence of a necessary fit between culture and a specific economic and political order. Culture had the capacity to switch developmental tracks. Cultural change was proposed as a precondition for political and economic change. The low rate of agricultural output, the high rate of fertility and mortality, or the low rates of literacy found in underdeveloped countries resulted from the persistence of traditional values and attitudes. Modernization theory concluded that values such as individualism, rationalism, and secularism had been intrinsic to the consolidation of modern capitalism in the west (→ Modernity). Because it held up the western experience of development as the model on which non-western countries could break away from poverty and tyranny, it suggested that the rise of “modern” societies in “developing” countries had to follow the same path (→ Planned Social Change through Communication; Secular Social Change).

If culture was viewed as the obstacle in the way of modernization, then, instilling “modern” values was crucial for change. Modernization’s call for cultural change as the necessary harbinger of social change was embedded in functionalism, then dominant in the social sciences (→ Functional Analysis). From this perspective, communication was assigned a crucial role in spearheading cultural changes through the dissemination of “modern” information, values, and innovations through “modern” communication technologies (→ Communication Technology and Development; Technology and Communication).

As theorized by → Daniel Lerner (1958) and → Wilbur Schramm (1964) in their seminal works, communication basically referred to the transmission of → information. Among other factors (e.g., urbanization, increased literacy), exposure to mass media was seen as the catalyst of modern attitudes. From this perspective, development communication as a field of practice in support of international aid programs was assigned the role of introducing media technologies to promote modernization, and the widespread adoption of mass media such as → newspapers, → radio, → cinemas, and → television (→ Radio for Development; Television for Development).

Modernization largely reduced communication to the mass media. Such reductionism was based on the premise that large-scale media were central agents for the diffusion of modern culture. Also, the media indicated the degree of modernization of any given society. The numbers of television and radio sets and the level of newspaper consumption were taken as proxy of levels of development (Lerner 1958, Inkeles & Smith 1974). Researchers found that where people were more exposed to modern media, they were more likely to hold favorable attitudes toward modernization and development.

Everett Rogers's study on the "diffusion of innovations" became one of the most influential representatives of modernization thinking (→ Diffusion of Information and Innovation; Rogers, Everett). Rogers's intention was to understand the adoption of new, modern behaviors. The premise was that innovations diffuse through five stages: awareness, knowledge and interest, decision, trial, and adoption/rejection. Populations were divided into different groups according to their propensity to incorporate innovations and their timing in actually adopting them. Rogers proposed that early adopters act as models to emulate and generate a climate of acceptance and an appetite for change, and that those who are slow to adopt are laggards. This latter category was assumed to describe the vast majority of the population in the third world.

For Rogers, the culture of the peasantry offered important psychological constraints on the incorporation of innovations, and consequently on development. His view on development reflected the transmission bias also found in Lerner and Schramm. According to Rogers, development communication entailed the transfer of information from a source to a receiver with the intent to change behavior. The goal was to change knowledge and attitude in order to modify behaviors. Diverging from the media-centrism and "magic bullet" theory of effects that underpinned earlier analyses (→ Media Effects, History of), Rogers and subsequent "diffusion" studies concluded that the media had a great importance in increasing awareness, but that → interpersonal communication and personal sources were crucial in making decisions to adopt innovations (Rogers 1983).

### Critics and Legacies

In the mid-1970s, main representatives of modernization theories considered it necessary to review basic premises. In a widely quoted article, Rogers (1976) admitted "the passing of the dominant paradigm." Schramm and Rogers recognized that early views had individualistic and psychological biases. It was necessary to be sensitive to the specific socio-cultural environment in which communication took place, an issue that had been neglected in early analyses. To a large extent, these revisions resulted from the realization that the "trickle-down" model that was originally championed was limited.

Critics charged modernization on various fronts. One of the most powerful critiques called attention to its profound misunderstanding of communication. Modernization sidestepped a long tradition that understood communication as a process of community-building. Communication cannot be reduced to a diffusionist, media-centered process. Communication is not about the use of modern technologies to disseminate ideas and values; instead, it fundamentally entails different forms and spaces where people meet to discuss common concerns. More importantly, such a misconception of communication was problematic on conceptual and political grounds. It had ideological implications that conveniently fit prevailing conceptions of development as a top-down, exogenous process. Challenging its analytical premises was not just an academic exercise, but a way to question the kind of development politics that modernization justified.

In response to these criticisms, Rogers (1976) suggested that communication should not focus on → persuasion (the transmission of information between individuals and groups). Instead, he proposed that communication had to be understood as a process by

which participants create and share information with one another in order to reach a mutual understanding.

Modernization theory presented other problems in understanding the role of communication in development. The theory's focus on individual changes downplayed the influence of structural dynamics at both national and global levels that affect development. As long as communication is seen as a matter of changing individual attitudes under the assumption that they will translate into positive and wider social processes, political and economic forces are ignored. In reaction to modernization's culturalist bias, a substantial literature has argued that "underdevelopment" is not a matter of countries having the "wrong" cultural equipment to achieve better health and literacy, or higher agricultural productivity. As *dependentistas* and Marxists put it, historical global economic and political linkages explain "underdevelopment." Consequently, answers to redress problems cannot be limited to spreading the "right" cultural values. Instead, what is necessary is to analyze the complex dynamics (e.g., trade, political relations, domestic politics) that are responsible for poverty and marginalization in the south.

This premise informed studies that criticized modernization theorists for approaching the mass media without considering their relation to economic and political dynamics. For so-called "media dependency" positions (→ Dependency Theories), the media are not a set of technologies that function independently, nor do they necessarily contribute to development. Rather, they are political and economic institutions whose functioning is linked to the dynamics that perpetuate underdevelopment (→ Political Economy of the Media).

Another shortcoming of modernization theory was its patronizing, ethnocentric tone. Modernization's prescriptions were based on the deep conviction that only western ideas could spearhead global development. Modernization posited development as the irreversible process of progressive westernization of the world that would absorb, if not eliminate, indigenous cultures. While critics lamented that process of cultural change on the grounds that it represented the imposition of western values, modernization celebrated it. The latter viewed traditional cultures as nothing but obstacles in the way of modernity, and dismissed local knowledge as a likely casualty in the unstoppable march of western progress.

Several questions have been raised about these ideas. First, experience shows that traditional cultures are resilient. Cultural change is certainly possible, but it is not a necessary process. The modernization juggernaut that, according to its crusaders and critics, would change cultures forever has had dissimilar impacts around the globe. Thus, the question becomes, under what conditions might cultural change occur?

Second, cultural change does not follow a pre-determined, direct path according to western models and experiences. Rather, it is unpredictable, elusive, and full of contradictions.

Third, there has been a slow yet growing realization that solutions to development challenges are ultimately based on local knowledge and capacity. Modernization's disparaging views (and, at times, outright forgetfulness) of indigenous knowledge revealed its underlying universalistic premises. Championing western solutions to a myriad of development challenges is problematic for two reasons: it is ethically deplorable, for it assumes the inherent superiority of western-based forms of knowledge; and it is analytically misguided, for it ignores multiple ways of knowing, engaging, and addressing social problems.

Along this line of argument, one should also point out that modernization was largely inattentive to racial and gender issues. While offering an explanation for how social change was possible among non-European populations, modernization deracialized both knowledge and action. Also, while modernization implicitly discussed how the lives of third world women could change (e.g., in matters of education and health), gender remained conspicuously absent from the theory (→ Development, Gender, and Communication). Modernization failed to address the power dynamics underlying class, gender, race, and ethnic relations that largely account for unequal access to social services and persistent levels of poverty.

Although its intellectual and policy heyday may be past, key modernization concepts are still present in contemporary thinking and practice in development communication. Current policies and studies that uncritically embrace the latest information technologies follow in the footsteps of modernization's brand of optimistic techno-futurism. Technologies have proven to be useful to facilitate different types of communication if they are properly integrated into social and political processes that drive change. However, they are not cure-all solutions to deep-seated problems of power and exclusion.

Shades of modernization's culturalism are also visible in studies and development interventions that aim to modify cultural norms to promote social change. Just to give some examples: programs that aim to prevent early marriage among young girls, eliminate female genital cutting, increase female education, or change gender relations around sexuality confront the challenge of radically transforming cultural norms. Certainly, such interventions are informed by a myriad of theoretical and ideological frameworks. However, they share with modernization the belief that cultural changes (e.g., changing expectations about the proper roles of women) are crucial for effective social changes.

It is worth noting that programs that aim to catalyze cultural changes are less likely to be imbued with deterministic and media-centric views as found in modernization. In fact, it has been recognized in the literature that such changes are difficult. They require a combination of communication processes. Neither the purposeful diffusion of "modern" ideas nor the demonstration effects that result from exposure to alternative norms (e.g., through the media) inevitably lead to cultural and social changes.

That modernization has significantly less influence in contemporary development communication is not only a reflection of its overall falling fortunes in the social sciences. It is also the result of the fact that some of its key arguments fit today's sensitivity in the field of communication uneasily. Modernization's unbounded optimism about cultural change, its uncritical view of media technologies, and its confidence about the inevitability of social change seem incompatible with prevalent views in development communication. Current studies and programmatic evaluations advocate the integration of various forms of interpersonal and mediated communication, offer a moderate realism about the contributions of communication to social change, and are skeptical, if not critical, about prescribing other people's experiences to improve the lives of marginalized populations in the global south.

## **Mood Management**

*Silvia Knobloch-Westerwick*

*Ohio State University*

The term “mood management” stands for a theory that aims to predict people’s choices from media messages. The audience is confronted with an enormous diversity of media channels and messages, thus selectivity in media use is inevitable. Hence, a classic key question in communication research is what drives the choices made by media users.

Mood-management theory (Zillmann 1988) has been proposed by Zillmann and Bryant and was initially called the theory of affect-dependent stimulus arrangement (Zillmann & Bryant 1985). The core suggestion is that media users’ moods have a strong influence on media content choices because the individual aims to manage or, more specifically, optimize his or her feeling state. This motivation then drives what media content is selected, as different messages produce different effects on mood. This

proposed pattern pertains to all media channels and genre types such as → news, music, movies, and online content (→ Internet) – even a → documentary film can be employed to enhance mood as the current “frame of mind.”

### THREE DIMENSIONS

Mood-management processes involve three dimensions on which the individual’s feeling state can be described and that are also linked to mood-enhancing media choices (Zillmann 2000, 104): “the indicated hedonistic objective is best served by selective exposure to material that (a) is excitationally opposite to prevailing states associated with noxiously experienced hypo- or hyperarousal, (b) has positive hedonic value above that of prevailing states, and (c) in hedonically negative states, has little or no semantic affinity with the prevailing states” (→ Selective Exposure).

The first dimension relates to regulation of stress and boredom. Media messages are excellent means of lowering *arousal*. For instance, most people will find watching a peaceful wildlife documentary relaxing. On the other hand, many types of media content are designed to heighten arousal; for example, fast-paced rock music typically has this effect and might even be chosen for a workout for that reason. Hence, depending on current arousal level and the personal appraisal thereof, media users select relaxing or exciting content. When stressed from work, choosing an innocuous comedy might help to unwind, a movie type that could be considered lame under other circumstances of mood. In contrast, after a boring uneventful day, many will turn to a suspenseful thriller for some excitation (→ Emotional Arousal Theory; Excitation and Arousal).

The second dimension of *mood valence* looks at whether the media user is in a positive or negative mood. Negative feeling states call for improvement through selective media use, for example by watching a movie with a “guaranteed” happy ending. When in positive moods, media users will try to maintain that state by choosing content that does not disrupt it and reinforces it instead. However, concerns have been raised (e.g., Knobloch-Westerwick 2006; also Zillmann 2000) because the theory seems incommensurate with any selective exposure to decidedly sad content, e.g., tragedies like the movie *Titanic* or Holocaust documentaries.

Finally, pertaining to the *semantic affinity* dimension, when in a negative feeling state, the individual will avoid all media portrayals that remind him or her of the source of the ongoing distress. For example, a student who has just failed badly at an exam (and cares about it) should avoid watching a campus comedy, according to mood-management theory. Even though the general tone of such a movie would be uplifting, under circumstances of stress caused by campus-related events, that association would ruin the amusement and thus not serve mood optimization.

### MEDIA FEATURES RELEVANT FOR MAKING CHOICES

Mood-management theory outlines the characteristics of media messages that are relevant for choices. The *excitatory potential* of a message relates to its capacity to either increase or decrease arousal levels. For example, fast-paced music typically has a high excitatory potential, whereas slow-paced music is usually low on that dimension.

The *absorption potential* may have some overlap with the first aspect, yet does not fully converge with it. For example, a newscast with many display elements in the style of *CNN Headlines* (→ CNN) is more absorbing than a more traditional newscast with just a news anchor and very few additional elements. The former type may be preferable for enhancing a negative mood, simply by distraction.

Furthermore, very much related to the aspects of media users' moods, the *hedonic valence* of media content will obviously affect whether it will be selected or avoided, depending on prevailing feeling state. The hedonic valence characteristic can be easily explained with some news stories – large-scale disasters such as the tsunami catastrophe in 2005 will be unanimously considered bad news and depressing, whereas reports about a newly found cure for a frequent and deadly disease are good news to most of us and might brighten our day.

Lastly, the *semantic affinity* is an aspect of the message that is very much related to the individual's perspective and assessment of his or her situation. When the current mood is positive, semantic affinity might actually be welcome. For instance, a teenager who is happily enamored might especially prefer watching a movie about a happy romance. In contrast, a teenager in unrequited love will avoid this movie type as rubbing salt into open wounds, and instead might actually go for an action thriller without any connections to the cause of personal misery.

Although mood-management theory is applicable to choices of any media content type, it has gained the most prominence in the context of entertainment exposure. In fact, it can be seen as the overarching theory for the entertainment context (Knobloch-Westerwick 2006) that can explain why we turn to a great variety of different entertainment media, designed to play on our → emotions, and furthermore offers specific predictions about actual choices.

## SELECTED RESEARCH FINDINGS

In the following, some selected research findings from the mood-management framework are presented. In a classic study, Bryant and Zillmann (1984) induced different levels of stress in their participants by having them perform tedious mechanical tasks or challenging test assignments under time pressure. Then, in a purportedly unrelated situation, participants were free to 'surf' some television channels on which pre-categorized programs, being either high or low in their excitatory potential, were shown. The TV set provided was set up to record the choices unobtrusively. The selective exposure patterns clearly differed according to induced stress level. The stressed participants spent more time on soothing programs, whereas the bored individuals allotted more time to the exciting programs.

Meadowcroft and Zillmann (1987) examined whether the menstrual cycle influenced women's reported preferences for TV genres. In a survey, female college students indicated their intention to watch various TV programs, presented in a list, on the same evening. At the end of the questionnaire, they were asked to report information regarding their menstrual cycle. Premenstrual and menstrual women showed higher interest in comedy than other females in the midst of their cycle. The authors concluded that women aim to overcome noxious mood states, resulting from hormonal phases, by watching comedy. Helregel and Weaver (1989) presented parallel results for mood states during pregnancy.

Anderson et al. (1996) examined questions that go beyond the original mood-management claims but are very much in line with the overall perspective. These researchers conducted a field experiment in which participants reported stressful events and also recorded their television consumption. This field dataset revealed that stress resulted in longer TV consumption. Stressed participants furthermore spent more time on TV entertainment, such as comedy, while neglecting news and documentaries under such circumstances. Apparently, entertainment programs hold more promise to counteract such negatively experienced arousal levels. Men and women differed in their choices when under stress – stressed women watched more game shows and variety programs, while stressed men preferred action programs.

Knobloch and Zillmann (2002) used yet another research design by conducting a computer-based experiment. The first part consisted of an ostensible test with bogus feedback and actually served as an induction of moods of difference valence. In the second part, respondents were asked to select from current pop songs available on the computer while exposure was recorded by software. As expected, participants who had received the pre-assigned negative test feedback spent more time with joyful, energetic music than participants who had received more positive feedback and who were thus in better moods. These more positive moods obviously made efforts to enhance the feeling state through consumption of joyful music less relevant.

### **POTENTIALS AND LIMITS OF THE APPROACH**

This review shows that the overall notions of mood-management theory have been supported by a variety of research designs. Additional studies have examined selective exposure to news and world wide web content. More recently, the mood-adjustment approach, an extension of the theory, has been proposed by Knobloch-Westerwick (Knobloch 2003; Knobloch-Westerwick & Alter 2006).

This perspective suggests that we do not always aim to optimize our mood but sometimes try to instigate a mood that we consider appropriate or desirable in a given or anticipated situation. For example, when preparing for a sports competition, an athlete might not listen to a song that would distract him or her from the upcoming stressful situation, although not thinking about the competition would probably be more enjoyable. Instead music that actually helps to focus on the event might be preferred in the interest of better performance. Such exposure patterns are also likely to change across time, as the anticipated event approaches. Indeed, in an empirical investigation, music exposure across time of those participants who anticipated a tedious task after a music-listening period differed significantly from listening choices of those who anticipated a joyful game (Knobloch 2003). Apparently, the anticipation of different upcoming situations instigated different efforts at adjusting one's mood to them.

Overall, mood-management theory is a key perspective in → media effects and selective exposure research. Empirical evidence for it has accumulated over the years. Some criticism has emerged because of difficulties in explaining selective exposure to upsetting content such as tragedy or horror. Furthermore, in its beautiful parsimony, mood-management theory does not offer straightforward explanations for the commonly found gender differences in media choices (→ Women's Media Genres) and in studies investigating the theory (Knobloch-Westerwick 2007).

## **Morality and Taste in Media Content**

*Theodore L. Glasser*

*Stanford University*

Tensions and contradictions abound in claims about media content and its relationship to popular taste and public morality. Media, especially mainstream media, reinforce prevailing norms of taste and morality by catering to them, but they also legitimize new and different standards of good and bad by circulating provocative and unorthodox material. Media coverage of scandals focuses on what is self-evidently or demonstrably wrong and thus conserves the status quo, except when the scandal involves the media themselves, in which case the theme of the coverage can conveniently shift from what is

right to do, properly the domain of ethics, to the right to do it, properly the domain of law (→ Scandalization in the News). In many parts of the world, particularly at times when audiences condemn what they crave, the producers of media content struggle to navigate a course between serving the public interest, typically a high-minded standard crafted by media practitioners or promulgated by the state, and serving the public's interest, a baser standard established by market forces (→ Media Production and Content).

One of the classic accounts of the effects of media content on taste and morality comes from an essay, first published in 1948, by two Columbia University sociologists, → Paul Lazarsfeld and Robert Merton. "Mass communication, popular taste, and organized social action" set an agenda for decades of research by articulating, mostly in response to concerns about the "ubiquity and potential power of mass media" (Lazarsfeld & Merton 1948/2004, 230), three broadly distinguishable "*social functions*" of the media, two of which bear directly on questions of morality and taste (→ Functional Analysis). The "status conferral" function of mass media refers to the "enhanced status that accrues to those who merely receive attention in the media" (Lazarsfeld & Merton 1948/2004, 233). An explicit judgment in favor of someone or something – an editorial → endorsement, for example – counts as status conferral, but media also confer status "on public issues, persons, organizations and social movements" (Lazarsfeld & Merton 1948/2004, 233) regardless or in the absence of any judgment about them, which amounts to a process that can be fairly described as a "charismatic transfer of positive social value" (Simonson & Weimann 2003, 28).

The "enforcement of social norms" refers to the power of media to "reaffirm social norms by exposing deviations from these norms to public view" (Lazarsfeld & Merton 1948/2004, 235), a process that functions to close the gap between "private attitudes" and "public morality." Media enforce social norms, then, not simply by informing the public about breaches of morality, for often the public is keenly aware of these violations; rather, media bring *publicity* to these violations, which invites the public to confront their private tolerance of what they know to be wrong. "Publicity," Lazarsfeld and Merton explain, "exerts pressure for a single rather than a dual morality by preventing continued evasion of the issue. It calls forth public reaffirmation and (however sporadic) application of the social norm" (Lazarsfeld & Merton 1948/2004, 234; → Public; Public Opinion; Public Sphere).

Decades ago, Lazarsfeld and Merton worried that the "certified knowledge" about these social roles and their effects on society was "impressively slight" (Lazarsfeld & Merton 1948/2004, 231), but a considerable body of research now documents, clarifies and refines the basic proposition that, as Roger Silverstone (2007, 7) put it, media, new and old alike, "are an increasingly significant site for the construction of a moral order." Media aid in the construction of a moral order as they confer status on some groups and not others, a vitally important issue in multicultural societies where minority groups struggle for visibility and political parity. While media enforce social norms as they expose violations of them (Gans 1979), media also interrogate these norms by deciding which to ignore and which to accentuate, which in part accounts for – to take but one prominent example – a shift in the American press "toward a more rigorous standard of personal conduct among politicians" (Bird 1997, 118).

Still, the *role and responsibility of media* in the crafting of a moral order remains a difficult and unpleasant topic for many media practitioners, especially journalists, who cling to a view of themselves as “professional communicators,” whose sense of independence and autonomy turns them into adversaries of accountability. To even raise a question about the content of expression threatens their freedom of expression (→ Accountability of the Media; Accountability of the News; Journalists’ Role Perception). Remarkably, but not surprisingly, when in 2005 the *Economist* ran a cover story on the controversy surrounding a Danish newspaper’s decision to publish several cartoons depicting the prophet Muhammad, which prompted massive and at times deadly protests throughout the Middle East and elsewhere, the editors downplayed questions of morality and taste and instead framed the issue as “the battle for free speech.”

## **Muckraking**

*Anthony R. Fellow*

*California State University, Fullerton*

US President Theodore Roosevelt in 1906 admonished writers who exposed the wrongdoings by business, industry, and government. Borrowing a phrase from John Bunyon’s *Pilgrim’s Progress*, he called them “muckrakers,” who only rake the muck of life and never see the stars. Irish dramatist George Bernard Shaw later put another spin on the

term, making it synonymous with → investigative reporting, saying journalists see the stars and want to cleanse the muck so others can see as well (→ Journalism, History of).

Associated with American journalism, muckraking flourished during the Progressive Era, roughly 1902 to 1912. At the time, nine-tenths of US wealth was owned by one-tenth of the population, some of whom became known as “robber barons,” with controlling interests in railroads, steel, banking and finance, and meat-packing. They were also able to gain control of some state legislators, who succeeded in erecting high protective tariff walls. Freed from foreign competition, American manufacturers could make large profits and force higher prices on the consumer. They also benefited from immigration policies providing cheap labor. Unskilled western Europeans, some of whom faced poverty, lack of education, and political persecution, became workers in the US manufacturing mills. Immigrants filled the great manufacturing cities; families crowded into cellars or tenements without windows, light, or ventilation. Drunkenness, vice, and crime flourished, leading to a *new power-structure America* (Cook 1972): the political machine with an all-powerful boss. New York boss William Marcy Tweed, for example, set an unsurpassed record for public thievery. Politics became increasingly depraved.

The muckraking writers *focused on three issues*: corruption in government, irresponsible trusts, and exploitation of women and children. These “reformer-reporters” included professionals and amateurs, stylists and tyros, who shared concern for the physical and moral well-being of a nation dominated by laissez-faire thinking, dedicated to the status quo, and paying homage to the dollar as a symbol of success. They felt urgency to alert fellow citizens to what went wrong and the need to put things right (→ Scandalization in the News). Reporter-reformers were unique because, for the first time, a group of writers and a concentration of → magazines hammered away at the ills of American society. No comparable, relentless drive for exposure has emerged in US periodical literature before or since. Muckrakers exposed crooked politicians; criminal police; child labor exploitation in mills, mines, and factories; malefactions by capitalists; food adulteration; fraudulent patent claims; interstate prostitution; and unscrupulous businesses.

Thirty years later, muckrakers had more reach through national magazines and daily newspapers. Unlike earlier writers of exposure, Progressive-Era muckrakers reached broad → circulations and had large research resources (Hofstadter 1955). The *great muckrakers* included Ida Tarbell, whose 17-part series on the Standard Oil Company resulted in the breaking up of the oil giant (Tarbell 1904); Lincoln Steffens, whose investigations saw corrupt politicians removed from office in several cities (Steffens 1904); David Graham Phillips, whose *The treason of the Senate* brought about a constitutional amendment giving voters the direct election of US senators (Phillips 1964); and Upton Sinclair, whose *The jungle*, about horrible conditions in meatpacking, ushered in Congressional passage of the Meat Inspection Act, protecting the public from poisoned meat (Sinclair 1906).

Many factors contributed to the *decline of muckraking*. Some, particularly Phillips, went too far, and readers tired of confronting the ills of society. Since then, US literature of exposure has faced vast public apathy and an unwillingness to think about the unpleasant, especially anything attacking establishment values (→ Advocacy Journalism). Few want to interfere with the pursuit of money or pleasure. Newspapers as bearers of bad news (→ Negativity) face attack, and, ironically, magazine and book writers who substitute facts for fiction have more credibility.

During World War I, Americans turned their attention from national to international issues. Meanwhile, President Woodrow Wilson worked to resolve the problems the reformer-reporters exposed. US newspapers considered themselves in a better position in Washington once the new president came out in favor of pitiless publicity for public business. He backed this conviction by instituting the first formal, regular White House → press conferences (→ Objectivity in Reporting).

However, muckrakers retreated in the face of counterattacks from business, organized through → advertising and → public relations. Ad revenue became too important for magazines to continue their activism (→ Advertising, Economics of). *Everybody's* magazine, for example, when running a series on the beef trust, lost seven ad pages for ham, preserved meats, soap, patent cleaners, fertilizers, and a railroad (Fellow 2005).

Muckraking did not die out entirely but spread internationally in other forms (→ Sensationalism). *Washington Post* investigations helped topple US President Richard Nixon (→ Watergate Scandal) and put other corrupt political and business practices under scrutiny. More recent English and Italian investigations decried the antics of their prime ministers. However, no literature exists from other parts of the world on the muckraking movement itself, which was an American phenomenon.

# Multitasking

*Cees Koolstra*

*Free University Amsterdam*

Multitasking may be defined as the performance of two or more → information-processing activities simultaneously. The term originated in computer science as a description of a central processor performing two or more tasks at the same time. In the context of communication and media studies, multitasking is the term used for the situation in which an individual is using a → medium while doing one or more other information-processing tasks at the same time. If multitasking pertains to using two or more media simultaneously, for example the combination of watching → television and reading the → newspaper, one can speak of “media multitasking” (e.g., Foehr 2006) or simultaneous use of (multiple) media.

## ASSUMPTIONS AND EXPLANATIONS

Although most people are used to doing more than one thing at a time, the term “multitasking” generally applies only to combinations of information-processing activities, with the (unspoken) assumptions that (1) combining non-information-processing tasks, such as smoking a cigarette while washing the dishes, is easy, whereas (2) combining information-processing tasks, such as doing homework while watching TV, is more difficult, and information might get lost.

The second assumption is based on the “limited capacity” information-processing model (e.g., Basil 1994; Kahneman 1973; Lang 2000; → Limited Capacity Model). This model holds that people are continuously busy with selecting and processing (i.e., encoding, storing, and retrieving) information and that the ability to process information is limited. Information might get lost because a person chooses to allocate too few resources to a task, or because a task requires more resources than the person has available. In multitasking, the tasks compete for limited information-processing resources, which might result in an overload of information (→ Information Overload) exceeding the processing capacity, so that only part of the information can be processed and the rest of the information is lost.

Limited-capacity theorists hold two alternative views to explain capacity overload when people are multitasking (Bourke et al. 1996). One view is that there is a general processing capacity that can be exceeded: information processing might suffer when two or more tasks require more capacity than is available in our general resources. Another view is that resources work more specifically. Overload might occur when two tasks compete for the same specific information-processing resource and the capacity of the specific resource is exceeded, a phenomenon called “structural interference” (Bourke et al. 1996). According to this view, tasks might interfere with each other even if the total processing capacity is not exceeded. Structural interference may arise, for example, when reading is combined with watching a talk show, because both activities require the processing of linguistic information.

A supplementary explanation as to why multitasking might lead to loss of information is that some messages elicit “*orienting responses*” (Lang 2000). Orienting responses involve automatic allocation of resources to a medium as a reaction to novel or interesting stimuli such as sound effects, visual complexity, movements, cuts, and zooms presented in a television program (Lang 2000). If a medium elicits orienting responses, most or all of the processing resources are allocated to the newly presented stimulus, with the result that fewer or no resources are left to process the former (non-eliciting) information-processing task(s).

A distinction should be made between *primary and secondary information-processing tasks*. An example is when a person is reading a newspaper (primary task) while using the → radio as a background medium (secondary task). Another example is a student doing homework while having the TV on in the background. The idea is that people choose to focus most of their attention on the primary task and little attention on the secondary task. During multitasking, primary tasks may become secondary and secondary tasks may become primary when the originally secondary task asks for more attention. An example is when a person (almost) stops reading the newspaper because most of their attention is focused on an interesting song on the radio.

## EMPIRICAL STUDIES

There are two types of studies on multitasking. One type of study pertains to the question of whether multitasking is done frequently, whereas the other type focuses on possible problems in information processing during multitasking. A recent study among American 8–18 year olds (Foehr 2006) shows that for young people multitasking is very common. This conclusion is based on two types of data: → survey data collected among a representative US sample ( $N = 2,032$ ) and diary data collected among a sub-group of the sample ( $N = 685$ ). When asked how often additional media were used when using each of four media (print, TV, music, and computer), a majority of the adolescents (53 percent or more) reported media multitasking “most of the time” or “some of the time.” Depending on the type of media, only 12–19 percent said they “never” engaged in media multitasking. The diary data, in which time spent with multiple media use was measured regardless of primary or secondary use, showed that for 17 percent of the time, television viewing was combined with another medium. Much higher percentages were found for media combinations while using email (83 percent), visiting websites (74 percent), instant messaging (74 percent), playing computer games (67 percent), and doing homework on the computer (60 percent).

Additional data that did make a *distinction between primary and secondary media use* showed that television (to which young people still devote the biggest amount of time) is the least likely and computer the most likely primary medium to be shared with other media. For example, of the total time devoted to computer use as a primary activity, 27 percent was spent doing secondary tasks on the same computer (i.e., computer-based multitasking), 13 percent on listening to music, 8 percent on reading, and 7 percent on doing homework (not on the computer). There is some evidence that media multitasking among young people is increasingly popular: whereas in 1999 children aged 8–18 spent 16 percent of their media time on multiple media use, in 2004 the percentage had risen to 26 percent (Roberts et al. 2005). Adults are also engaged in media multitasking: one study estimated

that almost 24 percent of adults' media time is spent with more than one medium (Papper et al. 2004).

Until now, although there was earlier psychological research on distraction effects of background noise or speech (e.g., Broadbent 1979; Salamé & Baddeley 1989), few media studies focused on possible *distraction effects when multitasking*. A series of studies conducted by Armstrong and colleagues indicated that background television might cause performance decrements in reading comprehension and spatial problem-solving (Armstrong & Greenberg 1990), and that deleterious effects on reading arise during the encoding process (Armstrong & Chung 2000). A series of experiments conducted by Pool and colleagues showed that the content of the media background is influential, with radio music and → music video clips (such as shown on MTV) not leading to decreases in homework performance (Pool et al. 2000, 2003a), but background TV soaps causing a decreased performance on difficult tasks and extension of the time needed to complete the tasks (Pool et al. 2003b).

### OPEN QUESTIONS

Many questions about multitasking are still unanswered. Does multitasking really involve doing more than one task simultaneously or does it involve switching between tasks? Observational data indicate that when concurrent tasks ask for much attention, people switch between tasks (e.g., Pool et al. 2003b; Schmitt et al. 2003), although some monitoring attention may be focused on the secondary task while doing the primary task.

To what degree does experimental research on media effects overestimate effects now that we know that in daily life people are frequently multitasking? What are the effects of media multitasking? As compared with media behavior 50 years ago, nowadays the explosion of new forms of communication seems to have reshaped our media behavior, with many more media concurrently competing for our attention.

## Museum

*Catherine Waite Phelan*

*Hamilton College*

The visitor to a museum engages in a dialogue, enters a political space, or constructs a visual legacy, all of which signify membership in a larger community that links past, present, and future. Membership in such a community is made possible through communication. Whether one views the museum as an exchange of information or as the construction of a shared identity, communication serves as the starting point. The museum offers a public space, distinct from the mundane activities of everyday life, designed to communicate a sense of time and place distinctly different from workplace and home (→ Public Sphere).

One can think about the museum in terms of specific tasks: for example, the role of the guide, curator, designer, fundraiser, or conservator. One can also consider the specific tasks of communication: for example, to display objects within a space, to explain the significance of the display, or to educate the viewer about the historical implications of the display.

Yet communication includes more than merely making the right choices for the layout of a display or the design of a brochure to illustrate that display. Just as a museum is much more than a collection of objects, communication is more than a collection of skills. In this context, communication as a field of study offers a theoretical perspective for understanding why the design and construction of some environments lend themselves to engagement while those of other environments do not.

Understanding the complex ways in which the structure of the museum depends on communication can reveal the *essential features of the museum*. The concept of museum and the concept of communication stand as reciprocal terms (→ Communication: Definitions and Concepts). The museum deals with the cultural transmission of information, typically through the conservation and presentation of objects. The study of communication is also concerned with the ritual transmission of cultural information (Carey 1992). For example, the museum curator may be interested in the study of indigenous tools. In like manner, the communication scholar may be interested in the ways in which the rituals of communication construct cultural identity. These are related activities; understanding how the tools of an earlier era identified the workman with a guild suggests that artifacts symbolically structure both past and present relationships (→ Culture: Definitions and Concepts).

Prior to the earliest museums, there were private collections of art and artifacts that served to display the wealth and prestige of kings and aristocrats. The *first public museums* opened in Europe during the Age of Enlightenment. As the concept of public museum took hold, the private collections were slowly replaced by art-historical arrangements. The concept of the museum encouraged a new way of thinking about art as a necessary component of every society, rather than as a luxury for a privileged few (Duncan 1995).

Today the museum offers not only new ways of thinking about art, but also new paradigms to encourage innovation, interdisciplinary teaching, and learning (e.g., the Frances Young Tang Teaching Museum, Skidmore College). Displays, exhibits, presentations, and lectures enlarge our understanding of education and provide opportunities to develop robust educational models. As museums have moved from modern to postmodern configurations, the opportunity for engagement has expanded to include virtual tours, hypothetical constructions such as the experience of the coal mine (Museum of Science and Industry, Chicago) or the internal plumbing of the human anatomy (Franklin Institute, Philadelphia).

Collections of valuable artifacts can *teach the viewing public* about the significance of everything from rare butterflies (American Museum of Natural History, New York) to the Japanese tea ceremony (Asian Art Museum of San Francisco). This requires that the curator carefully consider not only the conservation of such objects, but how best to display and represent the essential qualities of those artifacts. The space is constructed for a particular effect, thoughtfully arranged to engage the eye, heart, and mind of the visitor. The museum can serve as a training ground for the communication scholar who is interested in → *visual culture* (→ Visual Communication). Though the experience of the museum may be described as sometimes auditory or kinesthetic, it is often primarily a visual experience. At the center of the museum experience resides a profound riddle that has long fascinated communication scholars: how is the image different from the word? One's experience of the museum embodies crucial questions relevant to the study of communication. How does the grammar of the text capture and yet fail to capture the visual display? How does the visual display move different viewers to a verbal understanding of their cultural history?

Consider the exhibit of the Book of Kells (Trinity College, Dublin, Ireland). This rare manuscript required a display under dim lights and glass, making it very difficult to examine the detailed design of script and decorative elements. Trinity College wisely provided

a second room with large copies of the text plus translations, displayed with full lighting. The juxtaposition of the two rooms, one with large prints and the other with the cherished manuscript under dim lighting, provided a delightful contrast that engaged the viewer.

Whether large or small, urban or rural, the museum *preserves shared memories* through the critical use of artifacts and displays. The varied spaces of museums often create an educational experience, sometimes offer exploratory play, and inevitably provide a sense of social engagement. Despite the diverse types of museums and variations in mission, all museums share common elements, which can best be illustrated through the study of communication.

## **Music Industry**

*C. Michael Elavsky*

*Pennsylvania State University*

The music industry is a term most commonly deployed in reference to the activities of the four largest transnational record corporations – often designated as the “majors” or the “big four,” namely SonyBMG, EMI (Electric and Music Industries), the Warner Music Group (WMG), and the Universal Music Group (UMG) – which collectively account for approximately 75 percent of all legal commercial music sales globally (→ Bertelsmann Corporation; Sony Corporation; Time Warner Inc.). All of these corporations are umbrella organizations linking smaller music labels, subsidiaries, and supplementary organizations together through complex corporate ties to larger transnational → media conglomerates (→ Global Media, History of; Globalization of the Media). Emerging from a long series of mergers occurring over the past century, these music corporations wield significant influence over the contemporary global music market.

Consequently, many scholars point to the ways these corporations “control” global music production, sustaining their position through the technological, political, and economic power they bring to bear on the ways music operates transnationally as culture

and commodity. Other scholars, however, suggest that the complexities behind this term are not properly engaged within such arguments. Still others critically point to the ways in which the term *music industry* has come to stand in for all global music practices, ignoring the significant ways music is produced, consumed, and circulated beyond the immediate logics and power of the big four. While debates on specific aspects of the power, identity, and future of these entities continue, their impact on the historical growth and development of music as a global commodity is not in question.

## HISTORY OF THE MUSIC INDUSTRY

The term “music industry” initially referred to activities surrounding sheet music publishing and its ancillary industries (theaters, music education institutes, publishing houses, etc.), responding to a growing general interest in music in European societies in the sixteenth century. The economic relationships surrounding music became further enhanced with the advent of music → copyright protection, which additionally regulated and stimulated music market commerce. By the end of the nineteenth century, the use of music had morphed from being primarily a secular pursuit of the wealthy or local communal activity to being structured through a range of commodities (e.g., sheet music, concerts, instruments, etc.) commonly bought, engaged, and enjoyed through market practices. Through the increasing intersection of these disparate markets and technological developments, the “recording industry” came into being.

Music recordings were initially but one of many kinds of recorded performances utilized to sell gramophone machines, the initial objective of the nascent “*gramophone industry*.” However, the transnational sales success of Enrico Caruso’s recordings in particular steered this industry to focus on music as its primary venture with these machines. Caruso’s success demonstrated that recorded music sales could transcend local markets and served to establish global production strategies as the industry norm early on. Anglo-American music products were positioned for success through these strategies due to the ways in which western colonialism established and directed global flows of culture and communication. Some local music cultures were simultaneously developed as a means to nurture gramophone sales in regional markets, while others were ignored for cultural or economic reasons (e.g., Sub-Saharan Africa), allowing them to subsequently develop alternative dynamics to their music cultures.

## EMERGENCE OF DOMINATING COMPANIES

Several companies – the Gramophone Co. (UK), Deutsche Grammophon (Germany), and Pathé Frères (France) in Europe, and the Victor Talking Machine Co., Edison, and Columbia (CBS) in the USA – quickly emerged to dominate the developing global music market, for several reasons. First, the increasing consumer pool and demand that materialized in industrialized countries (where all were headquartered) meant *greater profits* for these companies (as opposed to those in developing markets), and in turn, greater assets and a stronger potential for broader investment globally.

Second, these companies intentionally developed *extensive global* → *distribution* channels and networks for their products, understanding quickly that rapid delivery of

products to meet/create demand in more markets was the key to building their operations. Third, by producing *complete systems of recording technology* (recording equipment to records), these companies controlled access to most of the scarce and expensive music pressing facilities and recording technology of the time. Fourth, these companies possessed and fostered *active research and development divisions*, which kept them at the cutting edge of technological innovation and market developments (→ Marketing). Finally, the undeveloped retail sector for records and gramophones placed *constraints on market competition*, further strengthening the dominant position of these companies, while demand for records was skyrocketing.

Consequently, the emerging global music market quickly became an *oligopoly* by the time of World War I. Local record production remained vibrant, however. Small market activities were often regulated through the regional factories, network subsidiaries, and licensee agencies the dominant companies had established in these outlying areas. Consequently, global music production was structurally “filtered” by these companies, a position only strengthened by the transnational extension of patent and copyright law through international treaties and agreements regarding the circulation of cultural products.

However, despite largely controlling the emergent infrastructure surrounding global music commerce, these companies’ attempts to dictate or predict the sale of records were consistently thwarted by *local cultural proclivities*. A series of market fluctuations occurred in the 1920s and 1930s, initiating several mergers and moves toward consolidation in the industry. The global shift in interest toward American culture, coupled with developments in media and technology (radio, jukeboxes, the 33 and 45 rpm, etc.) and the USA’s increasing presence and power in global affairs after World War II served to stabilize the global music market oligopoly once again.

By the 1950s, the six biggest companies – now RCA-Victor, Columbia, Decca, Capital, MGM, and Mercury – accounted for 50 percent of global sales. By 1960, four companies (RCA-Victor and CBS in America; Decca and EMI in Europe) dominated the global market, expanding their influence by extending their distribution and financial networks and consolidating their power by forming music corporations. Growth and integration continued in the global music market as trade barriers were relaxed, standards of living increased in developing nations, and music technology and products spread farther and faster than ever before.

The majors facilitated and kept a careful watch on global trends, as their advantages in capital, distribution, production capabilities, and market influence positioned them more effectively to exploit product potential across a wider spectrum of interest and markets. As such, by the mid-1960s, the majors had commonly become characterized as bloated impersonal corporations interested only in producing superstars, blockbuster albums, and profits, despite releasing and promoting a wide array of records, artists, and musical genres.

## GLOBAL EXPANSION

The 1970s brought new investment in the music industry from larger entertainment media entities, which viewed the industry’s profits as a means to bolster their corporate bottom lines. Polygram and Warner joined EMI, RCA, and CBS to become “the big five.”

Industry growth into the 1980s was fueled by the eventual co-optation and incorporation of *disparate sub-cultural genres* (disco, punk, new wave, reggae, ska), the development of communication technologies and networks (the Sony Walkman, MTV, the compact disc), and the integration of international markets and disparate voices (“world music”). All of these extended the commercial logics related to music ever deeper into the global realm. The emergence of internationally oriented perspectives – stimulated by the extended reach of communication technologies and the ways in which transnational corporations began to conceptualize “global” culture, markets, and strategies – served to intensify the means with which, and the scale on which, the majors approached their business.

The *concept of the global music superstar* was redefined after the success of Michael Jackson’s *Thriller*. The subsequent transnational success of other stars (Madonna, Prince, Bruce Springsteen, etc.) coupled with the increasing awareness of music’s profits in international markets only solidified emerging conceptions and ideas regarding global music trends and the “logic” of marketing English-speaking global superstars transnationally. The enormous profits generated in the 1980s reinforced the power and priorities of these companies.

The switch to *digital technologies* as the industry standard generated another series of mergers and acquisitions, with several foreign companies entering the arena in search of further integration and synergy (→ Digital Media, History of). At the close of the 1980s, six integrated music firms – Warner, EMI, Polygram, MCA, Sony, and BMG – controlled 66 percent of the global music industry. The dawn of the 1990s brought developments in media synergies, cross-media marketing strategies, and initiatives to further exploit music profitability in many new markets (e.g., China, the former Soviet bloc; → Cross-Media Production). Sales soared and optimism abounded, with the industry recording an all-time high profit of \$40 billion in 1995. The euphoria, however, was short lived.

## THE INDUSTRY IN CRISIS

By 1998, it became clear that the industry dynamics were changing. Sales began to stagnate, music piracy increased, and Polygram divested its music divisions, leaving Universal, EMI, BMG, Sony, and Warner as the big five in 2000. Digital formats and technological innovations allowed for the confluence of organized hard piracy networks, CD-R technology, the Internet, and peer-to-peer file sharing to present a dramatic, extensive, and sustained threat to the majors.

The big five’s hold over global distribution – its primary source for profits – was substantially undermined despite the Trade-Related Aspects of Intellectual Property Rights (TRIPS) agreement (1994), the US Digital Millennium Copyright Act (1998) (utilized to enforce global rights management policies at the state level), and a proliferation of lawsuits against file-sharing companies, individual users, and → Internet servers (→ Internet Law and Regulation). Judicial progress was most often offset by the arrival of new and more advanced file-sharing technologies and networks, and efforts to develop digital rights management (DRM) software and legitimate online distribution or subscription networks often caused more difficulties than solutions, disrupting integrated marketing capabilities and angering customers and industry professionals alike (→ P2P Networking).

In 2004, the latest successful merger out of several ongoing attempts between the majors produced *SonyBMG*, rearranging the field into the big four. Despite downsizing,

restructuring their organizations, and reconfiguring their business models, the majors' situation remained dire: 2006 marked the industry's sixth consecutive year of losses. In light of virtually unabated music piracy and file sharing, the imminent demise of the CD and most specialized retail music stores, and shifts in practices and capabilities related to music production, consumption, and distribution (e.g., Pro Tools software, the rise of the iPod and the single format preference, ring tones, MySpace.com, YouTube), the majors were forced to aggressively pursue alternative income streams (e.g., commercial and television song placement) as a means to offset their losses.

### EXPECTATIONS FOR THE FUTURE

It remained to be seen how the big four would adapt to the new media landscape. Although the majors retained for the time being a dominant position with regard to global retail market share and their ability to impact developments related to global music culture and commodities in general, scholars have begun to reconsider the complexities related to their contemporary situation and how the global dynamics regarding music are being reconfigured. For some, this means reconceptualizing the big four: exploring the complexity of these organizations' networks, procedures, and strategies on multiple levels, so as to ascertain a more intricate understanding of how they actually "dominate" global music production, and also how the current global "crisis" for these corporations is related to the nexus of cultural identity, globalization processes, and neo-liberal policies and practices. These studies equally address how (on multiple levels) ideas of structure, culture, determination, agency, music, identity, geopolitics, and corporate power are conceptualized and enacted.

Others have begun to focus on how music is produced, used, and circulated transnationally within and beyond the reach and logics of the big four, suggesting that conceptions of the global music industry need to be broadened. Still others are considering how alternative spaces, innovative technologies, new "products," and emerging policies are redefining the commercial use and value of music. As these research trajectories suggest, much work remains to be done with regard to understanding the emerging dynamics surrounding music as both symbolic culture and transnational commodity in relation to how the music industry – as a cultural industry – is globally organized.

## Music Videos

*Will Straw*

*McGill University*

“Music video” commonly designates a short audiovisual text in which a recorded song is accompanied by moving images. The term “music video” refers, as well, to the broader phenomenon of video clips and the television programs or networks that show them (→ Television Networks). Research on music video has typically used the video clip as an example with which to investigate larger issues concerning the status of image and music within media forms of the late twentieth and early twenty-first centuries. It should be noted that large numbers of so-called music videos are, in fact, shot on film rather than tape-based or digital video (→ Digital Imagery).

The *first wave of scholarship* on music video followed shortly behind the introduction in 1981 of MTV (Music Television), a cable-based specialty television network operating in the United States (→ Cable Television). In the 1970s, short films had been produced by the → music industries to promote artists and recordings, through playback in record stores and on television programs typically shown late at night (e.g., Wagman 2001). The launch of MTV was inspired by the availability of such films, and by the enormous growth in specialty television services over the previous decade. MTV’s birth and subsequent rapid rise to popularity came in a decade marked by the growth of → cultural studies and theories of postmodernity within Anglo-American media scholarship (→ Postmodernism and Communication). Music video quickly became a popular focus of such scholarship, in a wave of writings published in the late 1980s. Chang (1986) and Kaplan (1987) were among the first scholars to use music video as a privileged example in broader diagnoses of the state of contemporary media. It was common, in this first wave of writing, to see

the video clip as evidence of a new, image-saturated culture of celebrity (→ Celebrity Culture), or as exemplifying the fleeting, fragmentary assemblages of sound and image seen to characterize media under the conditions of postmodernity.

These claims receded in the 1990s, as more focused studies of the phenomenon were published (e.g., Goodwin 1992), and as the reach and popularity of music video programming on television changed. By the end of the 1990s, music video networks were available throughout most of Europe, Asia, Australasia, and the Americas, reaching national and transnational communities through satellite or cable distribution systems (→ Satellite Television). During this same period, the novelty and appeal of programs based on the unbroken flow of video clips declined. Many music video networks (such as MTV) moved to develop new programming forms (such as reality shows) to hold on to their youthful → audiences. Video clips themselves were now more easily available on the → Internet (on sites devoted to individual performers or upload-based sites such as YouTube) and in DVD packages sold at retail. By the early 2000s, the music video clip had become both a ubiquitous tool for the promotion of music and a familiar cultural form that seemed to inspire little controversy or high-level academic theorizing.

Academic treatments of music video have pursued a variety of issues since the 1990s. Historical studies have sought to locate music video within a longer history of interaction between popular music and the film or television industries. Ongoing work has focused on experiments in combining music and moving images that extend back to the early days of → cinema and challenge well-entrenched beliefs about the “coming of sound” to cinema. The musical shorts produced by Pathé and Warner Brothers in the first half of the twentieth century are now seen as precursors of music video, as are the Soundies (musical shorts) and Scopitone visual jukeboxes of later decades (Herzog 2004). Since the 1980s, the increased use of songs within the soundtracks of motion picture and video games is viewed as having reduced the specificity of music videos, which are now seen along a continuum of cultural forms combining image and music.

Feminist media scholars have devoted considerable attention to music videos, addressing the ways in which their visuality foregrounds the *role of gendered and racialized bodies* within popular music (e.g., Railton & Watson 2005; → Stereotyping and the Media). Ethnographic research on the making of music videos has described a complex production process marked by ongoing tensions between the personal visions of directors, the promotional imperatives of record companies, and the desire of musicians for creative autonomy (Vernallis 2004; → Ethnography of Communication).

Since the early 2000s, a body of scholarship on music video has examined its role within *cultural diaspora*, such as those of Vietnamese immigrants to Australia or transnational communities of South Asian background. Music videos are increasingly seen as elements within complex assemblages of image and sound that circulate the world and are recombined within a variety of diasporic media, from satellite television networks through DVDs and Internet video clip sites, such as YouTube. For many scholars of the area, music videos function within cultural diaspora as part of their “interocularity” – matrices of images that sustain identities and identifications across several media.

## NAFTA and International Communication

*José-Carlos Lozano*

*Instituto Tecnológico de Estudios Superiores de Monterrey*

Media flows between countries have always been controversial. Fears of cultural consequences if imbalances occur and concerns about the symbolic value of cultural and media products have historically been at the heart of academic and political debates as well as public policies from governments (→ New World Information and Communication Order [NWICO]; UNESCO). These dimensions of culture and media have generated great numbers of exceptions and qualifications in regional free trade agreements.

This was precisely the case when Canada, Mexico, and the United States signed a trilateral trade agreement that came into effect on January 1, 1994. The North American Free Trade Agreement (NAFTA) had as *main goals*: (1) to facilitate the cross-border movement of goods and services among the three territories; (2) to promote conditions of fair competition in the free trade area; (3) to increase substantially investment opportunities in the territories of the parties; and (4) to provide adequate and effective protection and enforcement of intellectual property rights in each party's territory. Lack of consensus with respect to cultural industries among the three countries left these, by and large, out of NAFTA, although the implicit approach has been to treat media and cultural products like any other commodity (→ Cultural Products as Tradable Services; Culture Industries).

*Canada*, historically overwhelmed by US imports due in part to the lack of cultural discount (particularly in Anglo-Canada) and the economies of scale of the American market, included an exemption for its cultural industries "to prevent the cultural standardization of content and the complete foreign control of distribution" (McAnany & Wilkinson 1996, 65). The United States, advocating the view that cultural industries produce commercial goods no different to any other, reluctantly agreed to the clause, but added a "notwithstanding" one that allowed it to take countermeasures of equivalent commercial effect if Canada were to introduce a cultural measure that would be inconsistent with the provisions of NAFTA. This clause has had the effect of dissuading Canada from resorting to legislative or regulatory measures that are inconsistent with NAFTA, prompting it to, in the case of the film sector, abandon any intervention concerning film distribution and, in the case of the magazine sector, agree to a settlement with the United States.

In contrast to Canada, *Mexico* decided not to ask for a cultural exemption clause. The dominance of local content in the broadcasting sector, due to the existence of large

conglomerates like Televisa and TV Azteca, and the cultural discount of most US cultural products due to linguistic, historical, and cultural factors, inclined Mexico not to seek an exemption clause (→ Mexico: Media System; Media Conglomerates). In addition, Spanish-language audiences in the United States were very attractive to Mexican media industries, and the government was interested in avoiding barriers to that important market, not only for commercial reasons, but also for the political objective of preserving cultural and linguistic ties with the large number of Mexicans living and working in the United States.

After the NAFTA pact, *media flows* grew steadily between Canada and the United States and between Mexico and the United States, but not between Canada and Mexico. The growth seems to be explained mainly by factors unrelated to the provisions of the Agreement. In Mexico, the United States dominated the distribution and exhibition of films in theaters, with around 90 percent of the screening time (in the first years of NAFTA, Mexico decreased the quota of Mexican films' screening time from 50 to 10 percent). In the first 10 years of NAFTA, the production of films in the country decreased from around 100 to fewer than 10 per year (Ugalde 2004). Also, most paid television channels came from the United States, dominating the supply of contents available for viewers. However, local contents accounted for more than 60 percent of global and prime-time schedules of over-the-air television (still dominant in Mexico, since only 20 percent of the population had access to pay-TV) and got much higher ratings than US imports.

In Anglophone Canada, audiences tended to prefer imported television contents over local contents by a factor of two to one (Statistics Canada 2007), though in Quebec local Francophone TV drama was popular (→ Canada: Media System; Francophonie). Despite Vancouver's position as the second largest film and television production center in North America after Los Angeles (→ Hollywood), the situation of the Canadian film industry closely resembled the Mexican case. US companies controlled 83 percent of the share of theatrical exhibition revenues and 48 percent of home video distribution revenues (Leong et al. 1996). In the federal capital Ottawa, around 90 percent of total exhibition time was devoted to US or US co-produced movies (Martínez 2007), while Anglo-Canadian films accounted for less than 1 percent of Canada's box office (Seguin 2007). In the United States, by contrast, foreign imports were almost nonexistent, both on television and in theaters. For instance, out of total screenings in commercial movie theaters in the federal capital Washington, DC, foreign films accounted for a meager 10 percent, of which 30 percent originated in Canada and none in Mexico (Martínez 2007).

With NAFTA, Canada, the United States, and Mexico formed the world's largest free trade area. This economic integration, plus technological developments and the globalization of culture, has influenced the structures, flow, contents, and processes of consumption of the mass media. But what García Canclini (1996, 146) argued three months after NAFTA became law continued to hold: the changes in culture and media are "part of a longer process of the national and international reconstitution of cultural markets . . . in relation to the new requirements of production and international commerce." Focusing exclusively on creating a free trade zone and not on cultural integration measures, as in the European Union, where regional bodies or cooperation projects were created to stimulate the audiovisual industries, NAFTA ended up legitimizing the treatment of culture as a simple commercial product, ignoring its socio-

cultural, ideological, and symbolic implications (→ European Union: Communication Law; Free Flow of Information).

## **Narrative News Story**

*John Nerone*

*University of Illinois at Urbana-Champaign*

The term “narrative news story” refers most broadly to any sort of nonfiction storytelling, but more specifically to a → news story that begins with an anecdote rather than a summary lead and then is organized in temporal sequence rather than either by inverted pyramid style or analytically (→ News). Narrative news has a long and varied history, an interesting connection with literary history, a vibrant present, and a hopeful future (→ New Journalism).

Many of the earlier formats of news were narrative in form (→ Newspaper, Antecedents of). Ballads and newsbooks dwelled on spectacular events – shipwrecks, murders, executions – and told their stories from beginning to end. One common form of narrative, especially for crime, was first person, as in the standard “gallows speech.” This form was common enough to work as a template for fictional narratives, the most famous being Daniel Defoe’s *Moll Flanders*.

Newspapers also featured items in narrative style. Early newspaper content tended to be composed by printers and other non-writers (→ Printer-Editors); stories appeared in vernacular form. Reports often included the provenance of the information – “The ship xxx, captain yyy, arrived Wednesday, carrying a letter from a gentleman in Warsaw, which states that . . .” (→ Journalism, History of; Newspaper, History of).

Though common sense to early modern readers, this form, which takes so long to get to the point, became cumbersome by the mid-nineteenth century. Three developments encouraged a less intuitive style: pictures, popular journalism, and bureaucratic efficiency, which in turn promoted the *inverted pyramid style*.

Pictorial journalism (→ Illustrated Newspapers) developed quickly in the middle of the century in the various western countries. Using engravings, usually woodcuts, rather than photographs, these news pictures compressed time and freely combined elements to allow for narrative effects and a pointed representation of character. Only at the beginning of the twentieth century did narrative illustration yield to → photojournalism, a less lucid form of picturing that provides traces of a story rather than a full account.

At the same time, *mass circulation newspapers* appeared – in the 1830s in the US, and in following decades in other western countries where taxation and censorship (→ Censorship, History of) retarded their appearance. These papers featured more routinized forms of earlier narrative content, especially crime news – the police court reports of the *New York Sun*, for instance. War correspondence – the Crimean War for British papers, the Civil War for US – and a second wave of “penny papers” in the last quarter of the century intensified the development of narrative style by coupling it with the persona of the reporter (→ Penny Press).

This “*story model*” of journalism competed with an “information model” that came to rely on the inverted pyramid style (→ Objectivity in Reporting). Although it became common only in the 1890s, examples of the inverted pyramid style appeared earlier in newspapers in items like the Civil War dispatches of war secretary Edwin Stanton. Designed for efficiency, it became the preferred style of bureaucrats first and then reporters, as they became subject first to the rigors of the newsroom and then to the teachable styles of the new university-level journalism courses and schools (→ Professionalization of Journalism). The inverted pyramid style never fully conquered journalism, though. It was resisted by a verbose tradition of reporting, by the cross-fertilization of journalism with literature seen in the careers of storytellers like Charles Dickens and Mark Twain, and by magazine journalism (→ Magazine, History of), especially as practiced by the great muckrakers, like Lincoln Steffens and Ida Tarbell, who focused on telling compelling stories and often inserted their own pursuit of the truth into the story (→ Muckraking). The narrative news story survived in the twentieth century, though it was eclipsed by long-form expert journalism, which became the new gold standard in the high modern period. Narrative inspired innovations in the theory and practice of

journalism, including emerging styles of broadcast journalism, especially live journalism, long-form documentary, and the literary work of the so-called “new journalists.”

Narrative currently is experiencing a *revival in print media*. As newspapers recede further from mass circulation and breaking news, they have developed a new openness to narrative and literary styles. Harvard’s Nieman Center has hosted annual conferences on narrative news since 2001, and among other US newspapers the *Virginian-Pilot* has a narrative news team. The revival of narrative follows a generation of theoretical analysis of how narratives are constituted across a range of literary genres. Although scholars of journalism are occasionally attentive to this literature, the impulse toward storytelling in the working press comes from more pragmatic sources – the desire to captivate readers foremost among them. But the construction of a storyline out of reporting raises inevitable questions about accuracy and detachment and invites the perception of a blurring of the line between fact and fiction. The enduring fascination with narrative classics like Joseph Mitchell’s *Joe Gould’s Secret* and Truman Capote’s *In Cold Blood* underscores the liminal status of the form.

As a result, the narrative form remains on the margins of hard news reporting, deployed more for color or human interest than for public affairs reporting, which still prefers the more apparently neutral inverted pyramid style, with its obvious capacity for balancing sourced opinions and quotations.

## **Navigation**

*Werner Wirth*

*University of Zurich*

The concept of navigation refers to the interpretation of user actions in hypermedia as a movement through virtual space. Navigation can thus be seen as → selective exposure to

hypermedia on a micro-level. Hypermedia commonly includes graphics and fragments of audio, video, and plain text (nodes), which are all knotted via hyperlinks. Navigation research is dedicated to the study of personal, situational, and media influences on how users move through hypermedia, select links, search for → information, and learn from hypertext contents (→ Learning and Communication).

The *standard situation while navigating* in hypermedia can be characterized as follows: information about the destination of a link is mostly marginal, while structure is decentralized. Moreover, the paths of decision are rather long. At each step, there are a large number of available alternatives. All of these produce low transparency and high uncertainty. On the other hand, users can determine the way information will be processed and the speed at which it will do so, which leads to high situational control. Additionally, it does not require much effort to revise a wrong decision; users only need to click on the “back” button. Therefore, navigation can be described as a low-cost situation (time, money, physical effort). Finally, without the active selection between given alternatives (hyperlinks), the reception process will not proceed. Therefore, navigating hypermedia is associated with high selection pressure (contrary to other forms of media, such as television; → Exposure to Television).

The majority of recent research is *based on information-processing theories* (mental and situational models and a → limited capacity model). Some researchers deploy more specific approaches, like psychological decision theory, problem-solving theory, or text → comprehension models. Typical research questions deal with typologizing search strategies and selection behavior, task differences, the effects of the structure of hypermedia on learning and understanding, individual differences (→ Individual Differences and Information Processing), and problems of disorientation and cognitive overhead. Methodologically, one can roughly distinguish between the two types of studies. On the one hand, there are non-reactive web server log studies with large data samples but little insight into the mental states of users. On the other hand, there are experimental or quasi-experimental studies (→ Experimental Design) with smaller data samples but extensive information on user strategies, → emotions, motivations (→ Intrinsic and Extrinsic Motivation and Volition), and → cognitions. The latter studies use quantitative or qualitative questionnaires (→ Qualitative Methodology; Quantitative Methodology), observational and think-aloud methods (→ Observation), and, sometimes, → physiological measurements. Several researchers try to combine both types of study.

There are several attempts to *systemize search strategies and selection behaviors*. By emphasizing the differences between single actions or action sequences, formal patterns, such as paths, rings, loops, spikes, and hubs-and-spokes, can be found rather frequently. For example, stressing the structure of a (well-advised) information-seeking process, Marchionini (1995) describes eight stages: (1) recognizing and (2) defining the problem; (3) choosing a search system; (4) formulating a query; (5) executing a search; (6) examining the results; (7) extracting information; and (8) reflecting on the results.

It is expedient to distinguish between *different search tasks* (Chen & Rada 1996). “Closed tasks” are information retrievals where a single type of information can be found (e.g., name, year, or date). “Open tasks” are retrievals where an undefined amount of information about an issue or a problem can be found and cognitively integrated (e.g.,

information about a country or historic event). Finally, scan browsing or “serendipitous browsing” is a more explorative navigation with no or weakly defined goal-orientation that enables the user to discover new and surprising information. Results suggest that closed, as opposed to open, tasks are conducted faster and more efficiently. However, it seems that at times types of tasks and task complexity are confounded.

Additionally, navigation depends on the *structure of hypermedia*, or how the information (e.g., the web pages) is linked. There are linear and hierarchical network structures, as well as several hybrid forms. Hierarchical structures provide some advantages regarding clarity and orientation. However, they hamper explorative and associative browsing and make serendipity effects less probable.

Studies focusing on *individual differences* in navigation behavior deal with the effects of involvement, motivation, age, gender (→ Gender and Discourse), domain expertise, Internet (or search engine) expertise, and cognitive styles (Chen & Rada 1996) on navigation behavior. For example, experts in domain knowledge possess more comprehensive and better-structured mental representations of the concepts in the domain. Structures set by novices are less organized and more chaotic. Foremost, novices tend to achieve an overview using breadth-first strategies, while experts are able to locate detailed information by navigating through specific content links (depth-first strategy). In contrast, the differences between more or less experienced Internet users (→ Exposure to the Internet) are of little consequence for information seeking or learning success, but Internet experience interacts with domain expertise. On the one hand, missing domain knowledge can hardly be compensated for; on the other hand, double experts (domain and Internet experts) are apparently most successful in searching and learning information on hypermedia (Hoelscher 2002).

Empirical studies identify *problems* of interaction with hypermedia, particularly disorientation and cognitive overhead. Both contradict assumptions that a structural isomorphism between the structures of hypermedia (nodes and links) and the structure of human memory as an associative network postulates advantages for information processing and learning in a hypermedia environment. *Disorientation* (often referred to as being “lost in hyperspace”) emerges as a result of navigation behavior in complex hypermedia environments. Usually novices report more disorientation than experts.

*Cognitive overhead* describes the idea that under the assumption of limited cognitive capacity, users spend cognitive effort navigating instead of comprehending tasks in order to orient themselves (Zumbach 2006). Both problems seem to be more severe for users with low prior domain knowledge and those navigating less structured environments. Disorientation may be reduced, especially for novices, by appropriately using tools like advisements, advance organizers, human support, graphical overviews, and structural cues (Chen et al. 2006). Alternatively, providing learners with adequate content structures will also lessen disorientation.

## **Negative Campaigning**

*Frank Brettschneider*

*University of Hohenheim*

Negative campaigning is a widespread technique, using the method of comparison and attack. It does not focus on one's own strengths, but rather on the alleged weaknesses of one's political opponent. The attacks can be directed at the platform of the political opponent or at his or her personality. Whenever the attacks aim at personal integrity, address aspects of someone's private life, and "go below the belt," it is also called "playing dirty" or "mudslinging."

Negative campaigning is a common practice in US election campaigns (→ Election Campaign Communication). It is most frequently applied in close races: the tighter the contest, the meaner the campaign (Ansolabehere & Iyengar 1995). But in other western democracies the tactic has been used as well (Kaid & Holtz-Bacha 1995). Negative campaigning is generally more accepted in countries with a competitive culture and less so in countries with a consensus-based political culture.

Negative campaigning rests on the conclusion that voters perceive negative messages less selectively than positive messages (→ Media Effects; Political Persuasion). It is therefore easier to demobilize the supporters of one's political opponent with the help of

negative messages than to convince them of one's own merits through positive messages. Negative messages are more likely to be perceived and remembered than positive messages (→ Memory; Memory, Message; Selective Perception and Selective Retention).

Campaign managers choose the type of messages they intend to send according to an analysis of strengths and weaknesses of their own candidate and their opponent (→ Political Marketing). When candidates' own positions on a variety of issues are largely in sync with the majority of public opinion, putting them on the road of victory, they will mainly run their campaign on positive messages about themselves. They will avoid negative campaigning, since attacks on their opponents would only create publicity for them. Candidates are more likely to resort to negative campaigning when they are relatively unknown, trailing behind in the polls, or their platform positions are contested (→ Election Polls and Forecasts; Election Surveys). It allows them to increase their profile, divert attention from unfavorable issues, and try to put their political opponents under pressure (→ Candidate Image). More often than not, challengers employ negative campaigning against incumbents. Candidates also use it when they have much less access to campaigning resources than their opponents, trying to reach the mass media's attention with the help of negative campaigning (→ Negativity).

For attacks on the political opponent, the method of choice is → television ads (→ Political Advertising). The ads blame the rival for being dishonest, untrustworthy, inexperienced, or lacking in leadership qualities. In the case of incumbents, campaigners often use political or personal records as "proof" for such accusations. Negative campaigning is a tightrope walk. On the one hand, the tactic creates public attention; on the other hand, the attacks can turn into a boomerang. Such a backlash is likely whenever the candidate's personality is under assault. In order to reduce this risk, the candidates do not execute the attacks themselves. Instead, they leave this job to seemingly independent or third-party groups that are in fact close to them. Campaign professionals also try to leak information to the media that discredits the political opponent, without revealing the source of that information.

Negative campaigning corresponds to the attention logic of the mass media (→ Attention; Media Logic). It focuses on conflict and argument, on candidates' personal characteristics, and it provides a competition story (→ Conflict as Media Content; Horse Race Coverage; Personalization of Campaigning). All of this relates to journalists' news selection criteria, especially to negativism (→ News; News Factors; News Values). The fight itself often becomes the story (Ansolabehere & Iyengar 1995).

Negative campaigning and the journalistic coverage of the attacks have led to fierce criticism. According to critics, the mudslinging sheds a bad light on politicians and the political system as a whole. Negative campaigning and its enhancement through media coverage may lead to voter alienation and → political cynicism. According to some studies, negative campaigning manages to mobilize the loyal supporters of a party, but it keeps the undecided from voting (Ansolabehere et al. 1994). But these results are contested (Lau et al. 1999; Kaid 2004). Other studies show that negative campaigning has the potential of increasing interest in a campaign. Fierce fighting between political opponents is a signal to the voters that the stakes at the elections are high. According to the proponents of negative campaigning, it can put important topics onto the political agenda (→ Agenda Building), thereby offering some orientation to the voters through

direct comparison. “If negative commercials persuade voters that the choice between the candidates is an important one, then they are likely to increase rather than decrease turnout” (Wattenberg & Brians 1999, 896).

Yet the accusation that journalists acquiesced to being used, thereby contributing to increasing political cynicism, has led to some rethinking (→ Journalism: Normative Theories; Journalists’ Role Perception). So-called ad watches have become relatively common in recent US campaigns. In them, journalists critically scrutinize and analyze the messages transmitted by the TV ads. But this practice has been criticized, too: taking up and repeating the negative ads over and over again only reinforce their messages, critics say. Thus the negative TV ad rather than its analysis gets planted in the recipients’ conscience.

## **Negativity**

*Jan Kleinnijenhuis*

*Free University Amsterdam*

Negativity is the tendency of humans to pay → *selective attention* to events and behaviors that could have a negative impact on themselves or their group. Selective attention to negative events by primary observers, such as journalists, may result in overly negative reports to those who were not witnesses, which may result in anger or fear (→ Fear Induction through Media Content).

Whether events, people, behaviors, or gestures – abstractly called objects – are negative or positive is easily judged by humans, as is apparent from our ability to rate almost every object on scales with a positive pole (e.g., good, beautiful, trustworthy) and a negative counter-pole (e.g., evil, ugly, untrustworthy). The semantic differential → scale is based on this ability. Experimental research shows that humans are able to build positive and negative impressions within milliseconds, for example about whom should be distrusted or trusted (Todorov et al. 2005). This suggests already that first and casual observations are important, but when someone or something could become dangerous, impressions may be updated continuously, with great weight being placed on the most recent observations. Thus, in addition to continuous “online” monitoring, a *primacy effect* and a *recency effect* are observed (→ Availability, Cognitive). The underlying rating scales (e.g., good vs. bad, beautiful vs. ugly, strong vs. weak) are deeply rooted in the vocabulary of every human language, as is evident from thesauri with synonyms and antonyms, such as *Roget's thesaurus* for English.

The tendency to pay selective attention to negative events, as well as the tendency to report selectively about them, probably arose from the need of *Homo sapiens* to use the human language as a warning system when predators or competing tribes entered the scene. One of the foremost important human reactions to societal danger is alerting others by shouting rather indiscriminately, which may produce a mobilization effect and may additionally frighten predators. Crying out negative emotions is also a good means when the aim is to drum up companions who could possibly help to overcome a danger for oneself, as when a baby cries loudly. “Negative news” – in its varieties of shouting and crying – strengthens the tendency to pay selective attention to negative events. Men appear to be more hardwired for selective attention to negative news than women (Grabe & Kamhawi 2006). Negative news may foster mobilization in the case of a societal danger and the impulse to come to someone's aid in the case of individual neediness. Differential effects of societal and personal dangers have been demonstrated experimentally (Shah et al. 2004). It should be noted that other species have developed quite different reactions to danger. An ostrich will stay where it is, only hiding its long neck. A hare will jump away, zigzagging in all directions. A sheep will run toward the flock, which will prompt the complete flock to start running in one direction.

## NEGATIVITY IN VARIOUS DOMAINS OF COMMUNICATION

Negativity poses a variety of different challenges for each of the major fields of communication: for interpersonal communication and media entertainment, for organizational communication and public relations, but especially for mass communication.

### Interpersonal Communication

In → interpersonal communication and in media entertainment (e.g., the enjoyment of books, movies, stage plays, and games), negative or positive first impressions of characters are often counterbalanced by later impressions (→ Enjoyment/Entertainment Seeking). Tension may result when both negative and positive observations are available “top of mind,” and thus when → *cognitive dissonance* is apparent, e.g., when only a Samaritan is

willing to help a Jew, or when only a small David dare challenge Goliath, or when a character is beautiful but evil, or trustworthy but ugly (→ Consistency Theories). Since deeper thoughts and additional observations are required to solve the inconsistency, inconsistency gives rise to *increased attention* for its sequel. In media entertainment the combination of negativity with tension is therefore a well-known device for raising viewing figures, circulation, and sales. While watching television, the tension raised by a particular program diminishes the likelihood of viewers zapping to another channel.

Research on the effects of negativity in media entertainment has concentrated on the impact on aggression of violence on television and in video games. Meta-analysis of research results indicates a moderate relationship indeed (Bushman & Anderson 2001).

### **Organizational Communication**

In → organizational communication negativity in the workplace (→ Dissent in Organizations) is counterbalanced by → communication management, or corporate communication (a term more often used in business administration). Negativity in organizations may originate outside or inside the organization. Negative external circumstances such as falling profits or innovations by competitors do not necessarily lower morale when communication management succeeds. Internal circumstances resulting in negativity are less easy to tackle. A negative mood throughout an organization may arise from a variety of internal issues, such as boredom at work, a lack of career prospects, organizational injustice, incompatible personalities, imprecise or impossible tasks, inconsistent performance criteria, poor leadership, or conflicting sub-cultures. Communication audits, analysis of internal → communication networks, and analysis of leadership communication (→ Business Discourse) may help to achieve a precise diagnosis of the origins of negativity and dissatisfaction.

### **Mass Communication**

In *mass communication*, negativity is prevalent at every layer of the communication process (→ Media Production and Content). For journalists, negativity of events is one of the guiding principles of news selection (→ News Factors; News Values). The negativity bias in the news is quadrupled by news consumers, who usually pay selective attention to dramatic, negative news reports. Since many journalists' powerful sources, such as ministries, political parties, politicians, companies, and CEOs, are generally not dependent on the ratings of news consumers, but on their rankings (e.g., which investments are least risky, which product is least expensive, which presidential candidate is least incompetent), they may adapt to the media logic that negativity increases newsworthiness with newsworthy negative attacks on their competitors (Kepplinger 2000).

## **NEGATIVITY IN THE PRODUCTION OF MEDIA CONTENT**

The negativity bias in the news entails that, for example, the news will not report upon every fire, but will focus on fires that cause a lot of damage. The negativity bias becomes less transparent, however, when additional criteria for newsworthiness play a role also, as

was spelled out in a seminal article by Galtung and Ruge (1965). Geographical proximity, and the involvement of powerful actors, for example, render events newsworthy also, which means that heavily negative events abroad must compete for attention with negative domestic events. Heavy negativity abroad – for example, famine or tribal wars in third-world countries – will not become newsworthy unless its profile is raised by media events created by powerful domestic actors. The selective indignation about domestic negativity combined with the relative indifference about negativity abroad easily contributes to negative → stereotypes about outsiders.

The possibilities and the readiness for disclosing and disseminating negative news depend on social and political structures. Authoritarian regimes will typically censor negative news about domestic events, while encouraging negative news stories about foreign enemies. In democratic nations the negativity of the news depends on → journalists' role perceptions. As early as the nineteenth century, Alexis de Tocqueville suggested in *De la démocratie en Amérique* that newspapers may shift from a partisan style of news reporting, with positive news about a preferred party, to a more detached, sensational style in order to attract more readers. Especially during recent decades, a shift toward a more negative, interpretive style of news reporting has been observed in many democracies, including the United States (Patterson 1993). When the media became the foremost important battlefield for politicians and businesspeople to compete for voters or consumers, the arrogance of journalists toward them increased. Newspaper journalists and television talk show hosts alike have arrogated the right to introduce and to interpret extensively the games that politicians and businesspeople play, to the detriment of news attention for issue news about policy aims and policy results or about business plans and products.

Negativity has also become one of the research topics in the study of the new media. Interactive media such as emails, Internet discussion forums, and blogs provide an opportunity to express one's thoughts and to reveal one's emotions. One of the consistent findings in computer-mediated communication is that the web enhances the disclosure of personal feelings. Flaming, defined as an uninhibited expression of hostility, such as swearing, name-calling, ridiculing, and hurling insults toward another person, is a common practice (Kayany 1998).

### EFFECTS OF NEGATIVITY

Research results are inconclusive when it comes to the question of whether fear or anger is the primary reaction to negativity. Negative news, e.g., news about the 9/11 terrorist attacks in the US, has the effect of making one's mortality salient, which may result in a sudden fear of death. Protecting oneself by rallying behind the flag after dramatic negative events such as 9/11 is explained in *terror management theory* as an attempt to suppress the fear of death (→ Mediated Terrorism). Other studies indicate, however, that especially fearful citizens will be critical of aggressive counterattacks, which suggests that anger rather than fear is a motive to support indiscriminate aggression in one's own group.

Much research has been done to establish whether negative, conflict-oriented news raises feelings of apathy and → political cynicism among the public in the long run (Cappella & Jamieson 1997). The empirical evidence is mixed. On the one hand, negative news may indeed decrease trust in particular companies or parties, although this effect

may not become apparent immediately (Kleinnijenhuis et al. 2006). Patterson found that negative impressions of presidential candidates increased step by step with the increase in negative coverage (Patterson 1993). On the other hand, many studies indicate that exposure to the news, negative or otherwise, has a mobilizing effect on political participation (Norris 2003).

## **Negotiation and Bargaining**

*Michael E. Roloff*

*Northwestern University*

“Negotiation” is derived from a Latin term that means “to conduct business,” and a great deal of research is focused on economic transactions such as sales and collective bargaining.

Over time, the use of negotiation has expanded to other contexts such as marriage (→ Marital Communication; Marital Typologies) and hostage negotiations (Rogan et al. 1997), and in addition to its traditional role as a tool for creating exchange agreements (→ Social Exchange), it is now recognized to be an important component of conflict management (→ Conflict Resolution). Because of its widespread use, negotiation research is conducted throughout the social sciences including anthropology, communication, economics, management, political science, psychology, and sociology.

## THEORETICAL CONCEPTS

Negotiation is a process by which at least two parties interact in an attempt to reach an agreement. Negotiators are acting in “good faith” as long as they are honestly trying to reach an accord. Negotiation is *goal driven* (→ Goals, Cognitive Aspects of; Goals, Social Aspects of). At a minimum, successful negotiation occurs when the parties agree to the terms of a contract or informal understanding, and negotiators often have an agreement bias in which they are willing to accept inferior terms just to avoid a deadlock. However, negotiation objectives extend beyond simply reaching agreement. Frequently, negotiation goals are focused on gaining resources and reflect the specific amount that negotiators wish to obtain as well as the least they are willing to take rather than reaching no agreement. These tangible goals often reflect underlying interests such as the desire to enhance one’s well-being, establish a particular type of relationship, or control the negotiation process and values (Lax & Sebenius 1986).

During negotiation, individuals *focus on issues* (Putnam & Holmer 1992). Price is often a critical issue in buyer–seller transactions just as wages, benefits, and productivity are often key issues in collective bargaining. The positions that negotiators express reflect the manner in which they frame the issue. Frames constitute their understanding of issues and can be cognitive biases (Thompson et al. 2004). These include the “fixed pie bias,” which reflects the tendency of negotiators to assume they want the same things, to overlook issues about which they agree, and to focus primarily on disagreement. Gain frames are focused on the benefits of a proposed agreement and may cause a premature commitment, whereas loss frames arise from perceived costs and prompt negotiators to prematurely reject agreements in the hope that better ones will come along.

Negotiation involves a complex *set of communication processes*. During negotiation, individuals bargain by exchanging offers and counteroffers. Arguments are made in support of positions (→ Argumentative Discourse). Information is exchanged about priorities and goals (→ Questions and Questioning). Negotiators try to establish a certain type of relationship through their communication (Donohue & Ramesh 1992). Finally, coercion is used as a measure of last resort (→ Power, Dominance, and Social Interaction). These processes often reflect distributive and integrative strategies. Distributive strategies are attempts by negotiators to gain the best deal by demanding outcomes of greater value. These strategies can involve making an extreme opening offer, making few and small concessions, attacking each other’s positions while defending their own, disclosing supportive information while withholding damaging data, acting as though hostile or indifferent to each other, and making a take-it-or-leave-it offer. Distributive strategies can be successful, but when reciprocated, they often lead to deadlock. Integrative strategies

focus on integrating the needs of all parties by creating solutions that are valuable to all sides. These strategies could involve offering concessions on low-priority issues in exchange for concessions on higher-priority ones, disclosing information about interests and priorities, focusing on the benefits and workability of proposals, expressing mutual concern, and developing alternatives to reaching an agreement. Integrative strategies allow both parties to meet their needs.

Negotiation processes may *change over time* (Weingart & Olkeans 2004). Goals and strategies are not fixed and individuals often adjust and adapt them as negotiation unfolds. Negotiators may find their original goals are unrealistic or their initial strategies are ineffective. In addition, some negotiators may find it useful to start negotiations by strongly justifying their position and demanding outcomes of great value. By doing so, they communicate strength and may cause their counterpart to take them seriously. To avoid a deadlock, they then shift to an integrative approach and try to create a solution that benefits both. Alternatively, negotiators may shift their orientation throughout a negotiation depending on factors such as resistance.

Negotiations are influenced by the *context* in which they occur. Negotiating on the behalf of others can make negotiators more distributive and require them to negotiate simultaneously with the opposition and their own constituency. Time pressure limits the ability of negotiators to consider alternatives, and instead, they may rely heavily on distributive strategies.

## MEASURES AND FINDINGS

Researchers have developed schemes for coding the content of negotiations. These have been used to study the strategies that are used during the negotiation, and some have examined both the strategies that are used and the responses to them (Weingart & Olkeans 2004).

Most researchers are interested in *integrative agreements*, which afford high joint benefits and are often creative. The integrativeness of an agreement is often evaluated relative to other possible agreements that could have been reached. Hence, the most integrative agreement is the one that affords both parties the highest benefits. Compromises such as “split the difference” are moderately integrative since both parties give up something. Integrativeness is lowest when both parties do poorly, such as when they reach deadlock or one party wins while the other loses.

Alternatively, some researchers have focused on the type of integrative agreement. Costcutting agreements are those that allow another negotiator to save face, sometimes by providing a symbolic concession. Logrolling agreements occur when all parties receive what they want on high-priority issues but make significant concessions on those of low priority. Bridging agreements involve the creation of novel solutions that frequently result from approaching the problem in a counterintuitive fashion. Nonspecific compensation occurs when negotiators provide each other with resources that are not specifically part of a contract. Contingent agreements reduce risk by specifying future conditions that must be met before resources are exchanged, or the reopening of negotiations at a future time so as to modify the agreement.

The dual concern model has guided a great deal of integrative negotiation research (Pruitt & Rubin 1986). To discover integrative agreements, individuals must be willing to exert considerable energy during negotiation so as to discover each other's needs and to

formulate creative agreements that are mutually beneficial. To do so, they must be rigidly committed to achieving their goals while flexible as to the means of doing so. Hence, integrative bargainers resist giving up their objectives but are willing to consider alternative ways of meeting them that will also serve the needs of their counterpart (De Dreu et al. 2000). This dual concern facilitates reaching integrative agreements by prompting negotiators to ask questions, share information about priorities, logroll, discuss the merits and problems associated with proposals, and build rapport. Individuals with a dual concern avoid blaming one another and making threats.

### FUTURE DIRECTIONS

Negotiation is a tool for exerting influence, and individuals want to become effective negotiators. Researchers are therefore beginning to investigate the critical cognitive and behavioral skills required to be a *successful negotiator* (Roloff et al. 2003). Beyond cataloguing skills, researchers are investigating how best to train individuals to be more skillful, including the use of case studies and other training methods.

Because of the pervasiveness of electronic media, researchers are also exploring *mediated negotiation* (→ E-Commerce; Mediated Social Interaction; Personal Communication by CMC). This includes the degree to which face-to-face negotiations differ from those occurring through email and other electronic media (McGinn & Croson 2004).

With increasing globalization, negotiation researchers are becoming interested in *inter-cultural negotiations*, and especially those involving business transactions (→ Globalization of Organizations). This research focuses on cultural norms for negotiation as well as identifying cultural differences in the manner in which negotiators frame negotiations and the strategies they use (Brett 2001; → Intercultural and Intergroup Communication; Intercultural Conflict Styles and Facework). Perhaps the most important focus for future research arises from the need to understand how negotiation can be used to *resolve intractable disputes*. Individuals, groups, and nations often have difficulty resolving their disagreements, and these can escalate into prolonged aggressive encounters. Researchers are beginning to turn their attention to such disputes with an eye to identifying how they might be made ripe for a negotiated settlement (Putnam & Wondolleck 2003). This means expanding the focus of negotiation to include third-party interventions such as mediation, facilitation, and arbitration.

## Netherlands: Media System

*Jo Bardoel*

*University of Amsterdam and Radboud University Nijmegen*

Despite its open borders and its central location between big European countries, the Netherlands (with a population of 16.3 million) has its own tradition with respect to both press and broadcasting, a tradition that is closely related to the country’s overall socio-political structure during most of the twentieth century. In the early years of the twenty-first century we notice, however, that this “Dutch model” is eroding rapidly and beginning to follow a more “European” or even “global” media model, in which concentration (→ Concentration in Media Systems) and internationalization have become paramount.

In terms of Hallin and Mancini’s typology (2004), the Dutch media model fits into the “democratic corporatist” category, relying heavily on the role of organized social groups in society, as against a more individualistic concept of representation in the “liberal” model and considerable levels of politicization, state intervention, and clientelism in the “polarized pluralist” model (→ Public Broadcasting Systems).

## PRESS

The Dutch press has a strong tradition of private enterprise, and the basic model of Dutch press policies is, as elsewhere in the western world, one of freedom from state intervention (→ Freedom of the Press, Concept of). The Dutch press tradition goes back to the seventeenth century, when the relatively tolerant and prosperous Dutch republic served as a safe haven for → newspapers that could not be published in other, more absolutist countries (e.g., *Gazette de Leyde*, 1677–1811; → Newspaper, History of). At the end of the nineteenth century the abolition of the “newspaper stamp” (1869), the introduction of the rotation press (→ Printing, History of), and the rapid rise of literacy finally created favorable conditions for the modern mass press. Next to the traditional liberal-bourgeois papers, calling themselves “neutral,” so-called “tendency papers” arose, representing the “pillarized” (denominationally segregated) Protestant, Catholic, and socialist emancipation movements. In the 1960s we notice a major trend toward concentration, triggered by rapidly decreasing revenues as a result of the introduction of broadcasting → advertising and of the erosion of the old socio-political pattern (“depillarization”). In the period between 1970 and 2004 the number of autonomous newspaper publishers was further reduced from 35 to 9, and the number of editorial independent titles from 54 to 31 (Bakker & Scholten 2005, 18). The market share of the four largest newspaper publishing houses rose from 54 percent in 1974 to 95 percent in 2000. In most regions and cities the pluralism of several “pillarized” newspapers has been so reduced that they are “one-paper cities.”

This process of press concentration has raised serious concern, both in the media sector and in society at large, as to its potential negative impact on press freedom and pluralism. The most important instrument for support for newspapers in difficulties is the *Bedrijfsfonds voor de Pers* (Netherlands Press Fund), founded in 1974. It supports newspapers on the condition that the loan is temporary and that the profitability of the newspaper will eventually be restored. Another important instrument of press policy is restrictive rules on press mergers. After a fierce political debate, a gentlemen’s agreement was made in 1993 – following earlier suggestions by the government and the Press Fund – to forbid mergers that would lead to any publishing house having a market share of over 33.3 percent, and to monitor market shares between 20 and 33.3 percent (→ Antitrust Regulation). Only five years later a new, general competition law replaced this internal code and installed a new supervising body, the *Nederlandse Mededingingsautoriteit* (NMa, Netherlands Competition Authority). But in practice, the limitation of the market share seems to have worked well; after the most recent takeovers each of the three major publishing houses has a market share of close to but not more than 33 percent (→ Markets of the Media; Consolidation of Media Markets).

All national newspapers are now in the hands of one or two more or less specialized newspaper holdings (four out of five national newspapers are owned by PCM, and one is owned by *Telegraaf*), and the regional newspaper market is to a large extent in the hands of just one company (*Wegener*). All these three companies happen to have an overall market share of about 30 percent, the politically acceptable maximum. The total → circulation of paid-for newspaper copies is stagnating recently and penetration is decreasing, especially among young households. On the other hand the new, free-tabloids

*Metro* (Swedish based) and *Sp!ts* (owned by Telegraaf) have proven to be a big success, especially among young people.

## RADIO AND TELEVISION

Broadcasting in the Netherlands started as early as 1919. The Dutch public broadcasting system is unique in the sense that broadcasting as a public service is in the hands not of private corporations or national organizations, but of associations of viewers and listeners. In the second half of the nineteenth century, Roman Catholics and Calvinist Protestants, and later also socialists, opposed the hegemony of the Liberal-Conservative establishment of the time. Their efforts to achieve emancipation for their followers led to the creation of “pillars”: parallel, closed compartments in society for each belief or ideology, which applied their own way of thinking and living to all areas of life, and created a socio-cultural “pillarization” ranging from their own political parties and trade unions to schools, hospitals, and leisure associations (Bardoel 2007). When → radio started up in the 1920s, NCRV (Protestant), KRO (Roman Catholic), VARA (socialist), VPRO (liberal Protestant), and AVRO (neutral) were established, broadcasting over two radio stations, Hilversum 1 and Hilversum 2. Advertising was not allowed, and until World War II there was no license fee; the organization’s members paid for radio broadcasts.

The introduction of → television in 1951 was left to the radio broadcasting organizations. The first television channel, Nederland 1, was soon followed by a second, Nederland 2, in 1964. After numerous attempts to introduce commercial television (→ Commercialization of the Media) by legal and illegal initiatives and even the fall of a government in 1965 on this issue, a political compromise was laid down in the first *Broadcasting Act* (1967). First, commercial television had proven to be a bridge too far, but instead commercial block advertising between programs was introduced. Second, next to the traditional pillarized broadcasting, new organizations that could prove they represented a social stream in society and had substantial membership were allowed to enter (and leave) the system. Airtime on television and radio was allocated on a proportional basis, corresponding to the number of members of each association. The first new entrant, TROS in 1966, was the successor of the pirate station TV North Sea, previously operating from an offshore oil platform. Later an orthodox Protestant broadcasting association (Evangelical Broadcasting Association [EO], 1970), intended as a counterweight to growing secularization, and a popular but illegal pop station also operating from the North Sea (Veronica, 1975) joined the system. The third component of the compromise implied the strengthening of the cooperation in Hilversum through the foundation of NOS (Netherlands Broadcasting Corporation). NOS began to broadcast a “joint program” (news, sports, events, etc.), to pool studios and other technical facilities, and also to become the coordinating body for policy matters and international issues.

The 1980s also witnessed ruptures in the system, this time caused by external challenges. A cable penetration of over 90 per cent opened up new opportunities for commercial interests to undermine the public hegemony (→ Cable Television). During the 1980s, national initiatives to introduce commercial broadcasting in the Netherlands, by publishing houses such as VNU and Elsevier as well as independent producers, were denied access to the market by the omnipresent Christian Democratic Party. Ten years

later, in 1989, an attempt by Luxembourg-based RTL was successful thanks to the liberalizing nature of the European “Television without Frontiers” directive (1989; → European Union: Communication Law). The newly adopted *Media Act* of 1988, which attempted to modernize the broadcasting system but left the public monopoly intact, had to be almost immediately overhauled directly after its publication. On October 2, 1989, RTL-Veronique, soon to be called RTL 4, began broadcasting via satellite-to-cable. Within a year it had become the market leader in the Netherlands. The market share of the three public television channels fell from 85 per cent in 1989 to 50 per cent in 1994. RTL 4’s success acted as a catalyst for the large number of private television channels that emerged in the 1990s, the first of which was RTL’s second channel, RTL 5, in 1993. Another international player, SBS, also entered the market in 1995 with the launch of SBS 6, and in 1999 a second SBS channel was launched, Net 5. The market for independent production companies also emerged rapidly. One of these was Joop van den Ende’s company, which brought together program formats, stars, and production potential under one roof. After a merger with the equally successful John de Mol in 1994, Endemol Entertainment was created and became the largest independent producer in the Netherlands, and a major global player with a catalog of highly successful formats including *Big Brother* (→ Media Conglomerates).

At present three large parties dominate the television market (Bardoel & Van Reenen 2004; Commissariaat voor de Media 2005). The public broadcasting system, HMG, and SBS have three nationwide channels each. Commercial television in the Netherlands is owned by foreign companies that enjoy minimum program obligations, other than the provisions of the “Television without Frontiers” directive. There is a total of 19 national channels, 10 of which are generalist and mainly operated by the three large groups; the other 9 are thematic channels operated by other commercial broadcasters. In 2005 John de Mol, one of the founders and by this time former owners of the Endemol production company, launched a new channel, Talpa (later renamed “Tien” or “Ten”), which has a market share of about 5 percent.

## NEW MEDIA AND THE INTERNET

The Netherlands is a very densely cabled country; 95 percent of homes with TV are connected to cable, and 5 percent have satellite dishes (→ Satellite Television). As a result of the liberalization policy of the 1990s, most local public cable nets were sold to specialized private cable companies. At present the three major operators, UPC, Essent, and Casema, cable 86 percent of homes with TV. In 2003 Casema was sold to Anglo-American investors, which leaves only Essent still in Dutch hands. To counter the distribution market dominance of the cable operators, the government wants to stimulate competition from other infrastructures like satellite and digital terrestrial TV. The DTT operation Digitenne started in April 2003, but audience interest was modest.

Pay-TV has been offered since 1984 in the form of subscription television, but after 20 years the present provider, Canal Plus, was still not profitable. In 2000 its digital package (→ Television Technology) started, with a roster of European channels, thematic channels, the public and private Dutch stations, and a classic movie channel. The number of subscribers to the digital services is slowly growing.

According to the latest figures about 65 percent of the Dutch have access to the world wide web, and about 75 percent have access to a PC. Internet usage in the Netherlands is among the highest in Europe, in third position out of the 15 European countries covered (→ Internet). Time budget research shows that PC and Internet usage is at the expense of both listening (radio, records, etc.) and reading (→ Book; Magazine) and not so much at the expense of watching TV. Only among the young (12–19 years) is watching television considerably reduced.

For public broadcaster NOS, the Internet and thematic channels – 17 by now – are the spearheads of its new media policy. Therefore, the Association of Netherlands Newspaper Publishers (NDP) and the commercial broadcasters have put in a complaint with the European Commission about the “excessive support” the Dutch government gives the Internet activities of public broadcasters, whereby press organizations are forced to reduce their own Internet activities. Commercial television channels have shown less interest in developing full-blown Internet strategies, but they have been keen to add phone calls, SMS messaging, and games to television programs, which sometimes bring in more profit than the original program itself. The first and most famous example of such a multimedia production is *Big Brother*, first aired in the Netherlands by Endemol.

# Network Analysis

*Thorsten Quandt*

*Ludwig Maximilian University of Munich*

The term “network” denotes a central concept in the social sciences. The underlying idea of a structure that consists of elements (sometimes also called points, nodes, or vertices) and their relations (called lines, edges, arcs, or connections) has been used to illustrate and explain such diverse things as human action, information exchange in communication processes, peer groups, social formations, organizational coordination, markets and even whole societies, to name but a few of the application contexts. In many of these cases, the term “network” is used in a purely metaphorical sense, which remotely refers to a web-like phenomenon. However, it can also stand for a clearly defined analytical concept, which can be described on the basis of a formal mathematical language. By applying mathematical network logics to the analysis of social phenomena, researchers gain insight into their structures, i.e., the arrangement of the constituent elements and their connections. Furthermore, social phenomena can be compared on the basis of their (structural) network properties when using a standardized mathematical description language and uniform measurements.

## ROOTS AND DEVELOPMENT OF THE NETWORK IDEA

As with many approaches in social sciences, there is not just one historical source of network analysis. Some of the mathematical and logical foundations were laid in the eighteenth century with so-called graph theory. As early as 1737, Leonhard Euler introduced some basic ideas in a mathematical proof, including the concept of the “graph” – a figure consisting of points and lines, whose structural properties can be transformed into mathematical formulas. Since then, these fundamental assumptions have been further developed, resulting in a unique mathematical and logical perspective, offering descriptions and explanations of complex phenomena, in both the natural and the social sciences.

The more specific roots of network analysis in social analysis are diverse, to say the least, and various opinions on the lineage of network analysis exist. In social anthropology and social psychology, network approaches have been discussed by several schools of thought, starting in the first half of the twentieth century. To the public, probably one of the best-known psychological approaches in this field is Jacob Moreno’s sociometry, with origins in the 1930s. Moreno introduced the sociogram, a way of visually depicting the structure of social groups in the form of points (the persons) and directed lines (the social relationships). There were also other psychologists at that time, like Kurt Lewin and Fritz Heider, who were working on the interrelations of social structures and the behavior of individuals or groups (→ Group Communication; Group Communication and Social Influence).

In contrast to psychologists, who mostly focused on smaller groups of people, social anthropologists were interested in the structure of larger social entities. Alfred Reginald Radcliffe-Brown in the 1930s was one of the first actually to use the term “network” – still

in a metaphorical way – to describe social structures (→ Social Networks). In the following decades, Radcliffe-Brown's basic network approach was developed both in the US by scholars like Lloyd Warner, Elton Mayo, and George C. Homans, and in the UK by John A. Barnes, J. Clyde Mitchell, and others. Barnes's studies on kinship and community structures in the 1950s, in particular, can be seen as an important step in expanding the approach toward a modern network analysis, since he understood networks as a structural and logical concept rather than a metaphor. In some later works of his Manchester colleague Mitchell, the social scientific tradition finally met the mathematical approach again: Mitchell applied and developed ideas of graph theory in his sociological studies. In the years since then, network analysis has embraced mathematical models, for example in Harrison C. White's works on block modeling in the 1970s; recently, the rapid development of computer technology has offered further possibilities, especially in the analysis of large networks.

In communication studies, network analysis still plays a minor role, especially when compared to the number of studies based on traditional data analysis. For example, Schenk has analyzed the importance of interpersonal networks for opinion building and the relationship of social networks and mass media, starting in the 1980s (→ Communication Networks; Media Content and Social Networks). However, it was not until lately that the network idea became more popular in communication studies – a development maybe somewhat related to the growing importance of computer networks in the discussion of media and communication processes.

### **NETWORK DEFINITION AND CONCEPTS OF ANALYSIS**

As described above, the term “network” has a clearly defined meaning in social network analysis:

- A network is a specific structure, consisting of a number of points and their connecting lines.
- In most cases, the points refer to individuals, sometimes also groups or companies, and the lines depict their relations (based on the analysis of friendship or hate, power and influence, economic partnerships, to name but a few of the relationships that have been used in network analysis). That said, social network analysis is not necessarily restricted to actor or group networks – the researcher is certainly free in the choice of elements, and some have already proven that network analysis can be applied to other types of networks as well (like action networks, which focus on human action instead of the relations between human beings or social entities).
- The network structure can be described using formal mathematical language and depicted using network graphs (Figure 1).

Certainly, networks can be further qualified beyond this very rough outline. For example, one can differentiate between a directed and an undirected network. While the latter just focuses on the existence of relations, thus depicting them in the network graph via lines, the directed version includes information on the direction of relations, for example if point A influences point B (usually depicted with an arrow instead of a simple line).

**Figure 1** A network graph and its corresponding adjacency matrix

Relations and influences cannot only be identified by the connections of the elements and the direction of these lines, though – they can also be described by their intensity. If information about the relation’s intensity is included in the network graph (for example, by adding a number indicating the strength of a line), one speaks of valued graphs, in contrast to binary graphs, which only hold information about whether a line exists or not. Last but not least, there are not only networks that combine elements of one type. Sometimes, researchers are interested in the links between different elements (for example, individuals and certain events). The resulting “mixed” networks, which combine two distinct groups of elements, are called “bipartite.”

In many publications, network researchers use depictions of networks in the forms of graphs. This information can also be contained in data matrices equivalent to the graphs. For data (re)organization and analysis, these matrices are much more important than the actual graphics, which are limited by the possibilities of two-dimensional visualization. In contrast to standard statistical datasets, network matrices contain information on the relations of elements, rather than various variable values in columns and cases in rows (or vice versa). The most important type of organizing relational data is the so-called adjacency matrix (see Fig. 1). Here, all points of the network are organized in both rows and columns. In the individual cells, one can find a number that represents the relation between the row and column elements, which can be binary (existing/not existing) or valued. Another type of matrix is the affiliation matrix, which shows the relations between elements of different types (like actors and events, as described above).

On the basis of data matrices, the researcher can calculate various indices focusing on specific network properties. There are mathematical descriptions for the characteristics of individual elements, network structures, and the attributes of a whole network. Using these, the researcher can answer questions like: How important or central is an element in the network? Are there areas of high density in a network, hinting at strongly connected social groups? How big, dense, and centralized is a given network in comparison to another network? While the mathematical analysis of network data offers interesting solutions, there are still some areas in network analysis that need to be developed further. For example, there are no common measures for dynamic networks – most network analysts merely focus on static networks, which are very often just snapshots of a social situation. While there are solutions (for example, measures of network stability), they are

not widely accepted so far. So network analysis is still seeing many changes and innovation, unlike other, more conventional, approaches to social reality.

### **APPLICATIONS OF NETWORK ANALYSIS IN COMMUNICATION STUDIES**

While network analysis has been successfully applied in the larger field of social sciences, there have not yet been many reports in communication studies that use this approach, at least when compared with other methods of analysis. As described above, there has been some empirical work on interpersonal networks. These researchers chose to follow the classic approach of network analysis, which defines humans as elements of the networks and focuses on the relations of these actors. In a similar vein, there are also several studies on the structure of media markets that apply a network logic, in this case with the basic elements of corporate actors (media companies) (→ Markets of the Media; Media Economics). When going below the level of individual actors or groups as elements, one could use the network logic as well, for example when trying to find relations between human actions or communicative acts. However, the approach is not restricted to groups, individuals, or their actions; it can also be useful whenever there is relational data, as described above. For example, textual information could be analyzed in this way as well, looking for links between information elements. It will be interesting to see how network analysis develops in the future, both in theory and in empirical practice.

# Network Organizations through Communication Technology

Lee Sproull

New York University

Caryn A. Conley

New York University

Network forms of organizations are characterized by reciprocal, lateral communication ties. They are often contrasted with hierarchies, which are vertically organized, and markets, which exhibit an atomistic structure of buyers and sellers. Powell (1990) and Nohria (1992) provide classic statements of the comparisons. Networked organizations are often viewed as more flexible and “intelligent” than hierarchies and markets. From the 1990s to the present, computer-mediated communication technology has been increasingly employed to extend the scale and scope of networked organizations in order to “connect multiple organizations and people into new entities that can create products or services” (Contractor et al. 2006, 682).

*Key attributes* of computer-mediated communication technology for networked organizations are that they: (1) reduce physical, organizational, and social constraints on communication, and (2) create a digital record of communication for processing and preservation. Widespread use of these technologies increases reciprocal, lateral communication within organizations and between an organization and its external constituents – customers, suppliers, and partners. Both internally and externally, networked organizations are characterized by the increasing use of distributed work processes and knowledge-sharing processes (→ Communication Networks; Technology and Communication).

Internally, employees who are separated by geographic or functional distance can use communication technology to contribute to common goals and projects. In distributed or virtual work teams, employees use communication and project management software to coordinate their work on a common project. *Distributed work teams* can bring employee expertise to bear on a project independent of the employee’s geographic location. When employees are located across the globe, distributed work teams can make progress 24 hours a day, 7 days a week. As employees on one continent are finishing their work day, they electronically hand off their work to team mates on another continent who are beginning their work day.

Effective deployment of virtual work teams requires careful attention to their *social psychology and group dynamics*. Many laboratory and field studies have demonstrated that people who work together electronically have a relatively difficult time developing common ground and interpersonal trust (Kraut et al. 2002). Misunderstandings and coordination difficulties can compromise work quality and delay work completion. Nevertheless, as organizations increasingly deploy employees across the globe, distributed work teams allow them to flexibly deploy their workers across geographic and functional boundaries.

Networked organizations make use of *knowledge management systems*, which are information technology systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application (Alavi &

Leidner 2001). Three *common applications* include capturing and sharing best practices, creating corporate knowledge directories, and creating knowledge networks. Capturing and sharing best practices encourages knowledge transfer and reuse among organization members, while corporate knowledge directories help map the expertise of employees. Knowledge networks provide opportunities for relevant employees or organizational units to interact and transfer knowledge electronically. In all cases, employees can contribute to and access these applications independent of their geographic or functional location, thereby diffusing knowledge broadly across internal organizational boundaries.

Two pragmatic *challenges* for internal knowledge management systems are inducing contributions from employees and ensuring the quality of these contributions. Contributions to knowledge management systems are often represented as a public goods problem, in which everyone benefits from other people's contributions, but the incentives to contribute one's own knowledge are weak (e.g., Thorn & Connolly 1987). In practice, employees contribute to these systems out of feelings of loyalty to the organization, altruism, or generalized reciprocity more than because of expectations of private gain. Mechanisms for quality control typically rely upon visibility of contributions, which are subject to informal peer review.

Networked organizations increasingly use *communication technology* to reach beyond the formal corporate boundary. Whereas a focal organization has always had supply-chain relationships with vendors and suppliers, current communication technologies enable one organization to virtually embed its processes (for delivering and billing goods, for example) within another organization's processes (for sales or manufacturing and inventory management, for example). For example, proprietary electronic data interchange (EDI) technology allowed more efficient supply-chain management relationships, but was very expensive and available only to select organizations and industries that could afford the technology. The increasing ubiquity of the → Internet now allows many more organizations to participate in supply-chain networks. Interorganizational supply-chain networks support just-in-time manufacturing and lean inventory sales from the focal organization's perspective. These networks also deliver benefits to suppliers and vendors by providing real-time information on customer requirements. General benefits to all organizations include increased bandwidth of communication across organizational boundaries and decreased response time in information exchange.

*Increased networked communication* can change the relationship between an organization and its customers. Some organizations use the Internet to actively involve customers in product design. Communication technology enables customers to share their innovations with other customers through discussion groups, as well as with manufacturers. "Lead users" have always been a source of product innovation, but with increasing connections among organizations and their customers, the scale and scope of customer contribution to the product design process can increase (von Hippel 2005). Other organizations use the Internet to involve non-employees in customer support. Particularly within the computing industry, technical support activities are increasingly accomplished through voluntary technical support groups on the Internet. Whereas some organizations may assign employees to monitor electronic communication for quality control, many organizations rely upon the norm of voluntary peer review to sustain quality.

The most ambitious forms of networked organizations are those that use communication technology to link multiple formal organizations in the collaborative *design and production of complex products* (→ Interorganizational Communication). The Boeing 777, the most technologically advanced commercial aircraft of its time, was produced by a consortium of more than six independent organizations working on three continents, which relied extensively upon communication technology to perform their work. Digital records of the work process – from design specifications to engineering analyses to contracts – were produced, distributed, and accessed via communication technologies. The resulting networked collaboration was so successful that the collaborators transitioned from digital representations directly to an airworthy prototype without building any of the heretofore-required costly, full-scale mockups (Committee on Advanced Engineering Environments 1999).

## **Neutrality**

*Heikki Heikkilä*

*University of Tampere*

Neutrality is a concept deployed for safeguarding one's position in the complex and sometimes hazardous world. Since the fourteenth century, the word neutrality has

predominantly denoted *nonalignment* in the realms of politics, diplomacy, and war, in which no firm ground for neutrality can be assured. Thus, neutrality as nonalignment is dependent on the political judgment of others: whether they acknowledge one's neutrality to be sincere or expedient to *their* interests. The history of politics shows that in some cases the neutral political status was accepted (for instance, Switzerland since the Congress of Vienna in 1815) and in others it was not (Laos during the Vietnam war).

Another understanding of neutrality is derived from natural sciences. Here, neutrality is anchored in the facts of nature, which are independent of the individual investigating them. Thus, in natural sciences neutrality can be warranted, insofar as one sticks to the methodological rules set by science and does not allow any value-laden interests to interfere with one's relationship with the object. Neutrality *as allegiance* to the set of rules, too, can be charged methodologically and/or politically. It is particularly vulnerable to questions about the ethics of supposedly neutral actions. Currently, the neutrality of natural sciences is a hotly debated issue in connection with biotechnology.

In communications, neutrality is rarely connected to fiction, but it is treated as more or less indispensable to fact-based news. For news(papers) the concept was first introduced by the commercialization of the press, which took different forms at different times in different parts of the world (→ Commercialization of the Media). The most widely documented case is the emergence of the → penny press in the US from the 1830s (Schudson 1978; Altschull 1984; Barnhurst & Nerone 2001; → Journalism, History of). Neutrality as nonalignment was aspired to by publishers, who sought to reach larger audiences and greater advertisement revenues by conveying information, not opinion. Gradually, this distinction enabled the emergence of "professional communicators," who began to understand themselves as brokers in symbols, and in this role the messages they produced had no necessary relation to their own thoughts and perceptions (Carey 1969, 27–28). Consistent with the frailty of neutrality, the nonalignment of news and journalists had to be acknowledged by "the modernizing societies," and this was not a straightforward process.

A natural scientific version of neutrality was introduced to → journalism by the acceptance of positivistic epistemology and photographic realism in the late nineteenth century. This resulted in the development of *objectivity* as professional doctrine (→ News Ideologies; Objectivity in Reporting). It presumed "a world prior to all imposed values and rendered the periodic construction of accurate and universally recognizable copies of events as the newspaper's fundamental business" (Schiller 1981, 87). This naïve empiricism was soon to be superseded by the emergence of the public relations industry, which asserted that absolute neutrality was unattainable. Facts were there to be manipulated: the only issues were who did the manipulating and to what ends (McNair 1994, 27).

In a more modest understanding of objectivity, it was admitted that news and truth are not the same thing, and must be clearly distinguished (Lippmann 1922/1963, 226) (→ Lippmann, Walter). In this framework, neutrality and words with parallel meanings – "unbiased," "nonpartisan," and "disinterested" – did not refer to epistemology, but to a style of journalistic expression in which the journalist distances himself or herself from a subject, and leaves the resolution of the disagreement to the parties whose voices figure in the story. In the sociology of news, neutral styles of journalism became known as strategic rituals, which were said to aim at enhancing the credibility of news, diminishing allegations of bias and avoiding dangers of libel suits (Tuchman 1978, 83).

This perspective marked a strong critique towards news journalism and its insistence on neutrality. In Europe, this criticism was to a great extent organized around critical cultural studies, which argued that neutrality is an effective tool in sustaining dominant ideologies and the status quo in society. In the same vein, the neutrality of news has been questioned by gender studies and multiculturalism (→ Feminist and Gender Studies). Their general argument is that allegedly neutral practices of news more or less systematically regard the male or the cultural majority as the standard and the female or minorities as deviants from it. These lines of argument aim at (re-)politicizing the neutrality of news. It is claimed that the legitimacy of neutrality of news should be submitted to open scrutiny by the social institutions and groups that are talked about in the news.

The mounting criticism notwithstanding, neutrality still enjoys a special status in the news. Journalists regard neutrality as indispensable to their task of truthful and fair reporting, and some researchers contend that neutrality in the news is an important element for the common language that makes collective life possible (Adam & Clark 2006, 155). One should still note that the interconnection of neutrality and news holds appropriate to one particular news genre: hard news. Outside this genre the neutrality of news is less of an issue.

## **New Journalism**

*John J. Pauly*

*Marquette University*

The term “new journalism” commonly refers to a style of literary reportage created in the 1960s by predominantly young American nonfiction writers such as Tom Wolfe, Norman

Mailer, Gay Talese, Joan Didion, Hunter Thompson, George Plimpton, Truman Capote, and Michael Herr. Commentators have periodically declared other moments in the history of journalism as new. Most famously, the term was used in 1880s Britain to describe the popular newspapers of George Newness and W. T. Stead, then later applied in the 1890s to the mass circulation dailies being published by Alfred Harmsworth in Britain and by Joseph Pulitzer and William Randolph Hearst in the United States (→ New Journalism, Nineteenth-Century). More recently, one commentator (Boynton 2005) has referred to writers such as Susan Orlean and Ted Conover as members of a generation of “new new journalists” influenced by the literary experiments of the 1960s (→ Journalism, History of).

In its time, the new journalism of the 1960s proved contentious, especially among journalists, because it seemed to call into question the profession’s most cherished values. Critics condemned the extravagant language of Wolfe because it brought reporters into the limelight, focusing readers’ attention on their literary performance rather than on the events being covered. Critics similarly objected to the personalism of writers like Mailer and Thompson – their habit of implicating themselves in the events being chronicled – because it undermined the profession’s claim to objectivity and impartiality (→ Objectivity in Reporting). Others worried about what they considered the carelessness of the new journalists’ research methods, especially their seeming habit of *blurring the boundary between fact and fiction* in works such as Wolfe’s satire of the “tiny mummies” who wrote for the *New Yorker*, Capote’s “nonfiction novel” *In cold blood*, and Herr’s use of composite characters in his Vietnam reports (→ Accuracy). Still others argued that the much-vaunted literary devices of the new journalism – scene-by-scene construction, attention to symbolic detail, experimentation with point of view – were nothing new. They argued that earlier writers such as Stephen Crane, George Orwell, Lillian Ross, John Hersey, Joseph Mitchell, and A. J. Liebling had used all those techniques (→ Literary Journalism).

And yet, journalists around the world have subsequently emulated the research methods and literary strategies employed by the new journalism. The work of Talese and Wolfe established the value of in-depth, immersive reporting (→ Interpretive Journalism). The *storytelling techniques* thought avant-garde in the 1960s have become a mainstay of the newspaper feature story, Sunday supplement article, and magazines (→ Narrative News Story). Although new journalists’ willingness to consider humans’ accounts of reality as tentative, provisional, and contingent once vexed professional journalists who hoped to discover a more stable truth in the flux of experience (→ Construction of Reality through the News), the new journalists’ acceptance of ambiguity has resonated with many writers in other countries. Latin American writers who work within fabulist traditions of literature have acknowledged the new journalists as philosophical *compadres*, and eastern European writers such as Ryszard Kapuściński have found the blurring of fact and fiction a plain description of the experience of living under communist rule.

In retrospect, the new journalism looks like one more sign of the social and economic changes transforming the journalism profession (→ Professionalization of Journalism). By the mid-1960s, disillusion with the American daily newspaper ran deep and wide. Many journalists found it personally difficult to find a neutral position from which to report contentious social issues such as the Vietnam War, civil rights, and the counterculture. As

the increasing prosperity and education of the reading public made readers more critical and discriminating, newspaper editors found themselves assailed from all sides by accusations of bias.

Magazine journalism faced its own challenges (→ Magazine). The decline of once-popular publications such as *Collier's*, *Life*, *Look*, and *Saturday Evening Post* encouraged a search for edgy new voices to help magazines recover their cultural standing and financial health. Magazines such as *Esquire* used the new journalism as a marketing strategy to attract the hip, up-scale readers whom advertisers coveted. The freedom granted writers by editors such as *Esquire's* Clay Felker and Harold Hayes made that magazine a showcase for top talent, which in turn helped those writers win lucrative book contracts that freed them from the intellectual and literary constraints of daily journalism. Capote's bestselling 1965 book *In cold blood* taught journalists this single lesson: that one might make an independent and lucrative career writing book-length journalism.

The term "new journalism" thus marks a turning point in the history of journalism: an influential moment of self-criticism and an acknowledgement of the cultural contradictions of objective news. What the new journalism bequeathed was not only a different way of telling stories, but also a commercially compelling strategy for making a living as a journalist in a rapidly changing media market.

# New Journalism, Nineteenth-Century

Mark Hampton

Lingnan University

“The New Journalism,” a phrase made famous by cultural critic Matthew Arnold in 1887, refers to a wide range of changes in British → newspaper and → magazine content and format, aimed at making print culture more accessible to working class and female readers. The controversial changes, some influenced by American practice, included formatting innovations, such as headlines, and new types of content, such as interviews, human interest stories, celebrity features, and a shifting emphasis from opinion to → news, facilitated by the emergence of Reuters and other → news agencies. Lengthier columns were replaced by paragraphs, often derisively called “snippets,” and the tone grew more personal. To its detractors (such as Arnold), the New Journalism entailed a challenge to the mid-nineteenth-century daily newspaper’s authority and political seriousness. To its defenders, including such innovating editors and proprietors as T. P. O’Connor, George Newnes, and Alfred Harmsworth (subsequently Lord Northcliffe), the New Journalism represented an awareness that life was broader than parliamentary politics and the belief that press content should reflect readers’ actual tastes rather than an elite’s conception of readers’ needs (→ Exposure to Communication Content; News Audience).

Although the mid-nineteenth-century daily morning newspaper had certainly been based on commercial motivations, many observers in the 1880s and afterwards perceived a decided heightening of commercialization. To be sure, the expansion of readership following the repeal of paper, → advertising, and newspaper taxes between 1853 and 1861, and significant innovations in print technology, changed the economics of publishing and paved the way for newspaper chains to begin emerging in the 1870s, a trend that expanded even further in the twentieth century (→ Information and Communication Technology, Development of; Media Economics; Printing, History of).

The resulting economies of scale allowed a dramatic expansion of circulation, while the growth of advertising revenues ultimately allowed newspapers to lower their sale price below the cost of production; the *Daily Telegraph* had emerged as a penny daily in 1855, but the *Daily Mail* in 1896 pioneered the half-penny daily paper. By this point, selling newspaper copies to readers was no longer the most important financial transaction; rather, newspaper companies were selling circulation to advertisers. Whereas in 1856 *Reynolds News* and *Lloyds Weekly* had both become the first (weekly) papers to reach sales of 100,000, the *Star* reached 200,000 in the 1880s, and by 1900 the *Daily Mail* reached nearly a million. To the horror of many champions of the mid-century “educational” daily press, a venerated cultural icon had been turned into a mere commodity, an impression only magnified by a trend toward using contests and giveaways to attract purchasers (not necessarily readers). This type of practice reached a peak in the “circulation wars” of the 1930s. Champions of the sober educational press worried not only about the impact on readers of the popular press, but also about the danger that even such elite papers as *The Times* and the *Manchester Guardian* would be influenced by the New Journalism.

While many critics lamented the commercialization of the press, and many defenders scorned the idea that newspapers should be viewed differently from any other product for sale, the New Journalism also had champions who insisted that the press's transformation had truly *democratic consequences*. Not only did such defenders doubt that very many people had actually read, say, the lengthy verbatim parliamentary reports in *The Times* and other mid-century elite papers, but they also argued that high circulations gave newspaper editors a daily democratic legitimacy that Parliament could not match. For W. T. Stead, editor of the *Pall Mall Gazette*, a London evening paper, a daily paper could publicize wrongs that needed addressing, acting as a people's tribune and forcing Parliament's hand. Putting these views into practice, his 1885 campaign to raise the age of sexual consent did not offer reasoned legal opinions, but instead featured sensationalistic and melodramatic tales of aristocratic rakes ruining innocent and helpless young women and forcing them into a "white slave" trade, as well as a "stunt" that landed him in prison: the purchasing of a virgin in order to demonstrate how easily it could be done. For the controversial Stead, this (successful) crusade showed that campaigning journalism could blur the line between politics and entertainment, giving the New Journalism just as serious a purpose as its mid-century predecessors. On the other hand, it would be hard to find any political significance in Lord Northcliffe's 1920 campaign to create a *Daily Mail* hat (→ Political Media Content, Quality Criteria in).

The early scholarly response, including that of R. A. Scott-James (1913), R. C. K. Ensor (1992, 1st pub. 1936), and Alan J. Lee (1976), tended to reaffirm the Arnoldian view of a fairly rapid introduction of largely frivolous new qualities. More recently, Jean Chalaby (1998) has argued that the 1855 repeal of the Newspaper Stamp Tax marked the decisive break between a press oriented toward political "publicity" and a new commercial product deserving of the name "journalism." On balance, though, the past generation of scholars has demonstrated considerable continuity between the New Journalism and its predecessors, as well as challenging the distinctions between popular and elite forms in the late nineteenth century. For example, Raymond Williams (1961) and Joel Wiener (1988) have shown that many of the qualities offensive to the New Journalism's critics were borrowings from the working-class Sunday press of the mid-century, while Kate Jackson (2001) and Michelle Tusan (2005), among others, have shown that methods of the New Journalism could be employed in the service of the education and advocacy more commonly associated with mid-nineteenth-century daily newspapers. This scholarship shows that the undeniable transformations in format, style, and content that characterized the New Journalism should be seen as gradual changes, dating perhaps from the 1840s through the 1930s, rather than sudden products of the 1880s. For contemporary critics and defenders, though, the New Journalism was above all a concept through which to debate the merits of an emerging mass democracy.

## **New World Information and Communication Order (NWICO)**

*Claudia Padovani*

*University of Padua*

The New World Information and Communication Order (NWICO) is the result of a political proposal concerning media and communication issues emerging from international debates in the late 1970s. The term originated in discussions within the Non-Aligned Movement (NAM), following the proposal for a “new international economic order,” and became the expression of the aspirations of many countries in the global south to democratize the international communication system and rebalance information flows worldwide. UNESCO played a major role in fostering the debate until the early 1980s, especially through the work of an independent commission chaired by Irish diplomat Sean MacBride (→ UNESCO). The commission’s report, *Many voices, one world* (MacBride Commission 2004), outlined the main international problems in communication and summarized NWICO’s basic philosophical thrust. It was adopted at the twenty-first general conference of UNESCO in Belgrade (1980) and still remains a milestone in the history of global debates around communication issues.

### **THE CONTEXT**

In order to fully appreciate the relevance and implications of the NWICO debates it is important to stress the political climate of the time. Confrontations between the Soviet

and western blocs were paralleled by the growing importance of north–south confrontations: a large number of former colonies had gained political independence over the 1950s and 1960s and corresponding political weight in international institutions such as the United Nations. These states formed the NAM (initiated in Bandung, Indonesia, in 1955) and began to question the constraints of the Cold War climate on their development perspectives. Between the market-oriented western model and the state-centered communist paradigm, they attempted to develop a “third way,” by criticizing the international economic system as well as structural imbalances in flows of information and culture.

Information and communication issues were not new to international debates (Carlsson 2003; Raboy 2004; Vincent 2005); yet the changes in power relations in the 1970s due to the global south’s new strategic relevance (following the 1973 and 1979 oil crises and the position of the Organization of Petroleum Exporting Countries [OPEC]), allowed for a strong coalition of social forces contesting imbalances in information flows between global north and south. Access to communication technologies in development processes and the need to protect cultural diversity became defined as crucial for genuine autonomy on the international scene. Starting from the Tunis Non-Aligned Symposium on Information (March 1976), a series of regional meetings was held between 1976 and 1979 in which the need for a “new international (later, world) order on information and communication” was developed (→ International Communication).

Notwithstanding evident differences among NAM members, the NWICO platform allowed for a unified front, but the whole discourse became hostage to the Cold War climate; western states, especially the United States, saw in NWICO a potential threat to their cultural industries’ global opportunities, and an attack on the doctrine of the → *free flow of information*, their basic normative reference. On the other side, the USSR took advantage of the situation to promote state control over information flows and reduce the capacity of communication satellites to interfere with Soviet-bloc media control.

## KEY ISSUES

Several problematic trends were addressed in those debates: from imbalances in information flows, summarized in the *one-way-flow formula* (indicating the univocal direction of news and cultural flows from the north to the south), to the threats to cultural identities in the global south; and from the monopolistic positions of trans-national communication corporations to the inequitable distribution of communication resources (such as satellite orbital spaces). Communication systems were accused of serving the industrialized countries’ interests instead of helping developing countries, whose national communication infrastructures were poorly developed.

The content of the debates has been effectively summarized in a “4 Ds” *formula* (Nordenstreng 1984). There was a request to *democratize* the international information and communication system, overcoming univocal flows and promoting the right of peoples to acquire a comprehensive picture of the world while participating in the international exchange of information. There was a request to *decolonize* the system, reducing dependency on northern countries by fostering self-determination and local cultural identities. There was a need to *demonopolize* the system, reducing the influence exercised

by transnational corporations so that every state could develop their own independent information systems. There was finally a transverse challenge, that of *development*, to be faced through the creation of national communication policies, information infrastructures, national and regional information agencies, and journalism training institutions (→ Development Communication).

These general themes were articulated in terms of different types of information and all kinds of media. They also emerged as constitutive components of a new overarching principle: a → *right to communicate* conceived as a new social right, more extensive than the right to information (D'Arcy 1969).

### UNESCO AND THE MACBRIDE COMMISSION

Being responsible for “assuring everyone . . . the free exchange of ideas and knowledge” and for facilitating “the free circulation of ideas by means of words and images” (UNESCO Constitution, preamble and art. 1), UNESCO was entitled to deal with communication and information matters as a specialized UN agency, and to operate within its different roles – development assistance, fact finding, and norm-setting – to bring third world countries’ perspectives into the broader international arena. It did so through its general conferences from the early 1970s, when the focus of debates shifted from freedom of information and development assistance in communication technology to new perspectives that challenged prevailing principles (Carlsson 2003).

In 1976, during the nineteenth general conference in Nairobi, a “*Mass Media Declaration*” was drafted, and the director-general, Mathar M’Bow, opened the session by calling attention to the global nature of communication and the efforts made by third world countries toward regional cooperation in communication and information. Western states and media, however, saw the declaration as an attempt to limit the free flow principle. The whole NWICO discourse was conceived as inspired by the USSR in order to foster its own agenda internationally. There was great tension during the conference. No declaration came out of that conference, but an International Programme for Development in Communication (IPDC) was initiated, reflecting a technical-assistance approach to the problems under discussion. Nevertheless, an *International Commission for the Study of Communication Problems* was set up with the mandate to “analyse communication problems . . . within the perspective of the establishment of a new international economic order and of the measures to be taken to foster the institution of a new world information order” (UNESCO work plan 1977–1978).

Chaired by Sean MacBride and composed of 17 scholars, media professionals, and policy-makers from different regional and cultural contexts (seven from NAM countries), the commission was to study contemporary communication problems, and identify possible solutions according to the specific needs of developing countries. It organized several seminars, addressing a variety of communication processes as central to human societies, not just developing ones. It also engaged experts to produce specialized reports on specific issues (over a hundred works), all of which would analyze current trends while identifying constitutive elements of a new information order.

Attempts were made to define NWICO as “an international exchange of information in which states, which develop their cultural systems in an autonomous way and with

complete sovereign control of resources, fully and effectively participate as independent members of the international community” (Hamelink 1979). The commission produced a final report, *Many voices, one world* (2004), where data and analysis were accompanied by 82 concluding recommendations arranged in thematic chapters. Throughout the text a comprehensive vision of communication prevailed, linking media institutions, organizations, and audiences with a strong development perspective that resonated with the NAM proposal. The report can be considered as the highest point in the NWICO debate; it created awareness, consolidated existing knowledge, and influenced the academic field of international communication.

The report was presented at the twenty-first UNESCO general conference in Belgrade (1980) and adopted with a unanimous vote for Resolution 4/19, paragraph 14 of which set out the NWICO essentials: the elimination of information imbalances and of the negative effects of media concentration (→ Concentration in Media Systems); the removal of obstacles to a free and better-balanced dissemination of information and ideas; the → plurality of channels of information; and the need for developing countries to improve their equipment, personnel, and infrastructures, with the support of developed countries (→ Communication Technology and Development). The right of all peoples to their cultural identity was emphasized, as was the right to participate in communication and international exchange of information on the basis of equality, justice, and mutual benefit.

## **FOLLOW-UPS AND RECENT DEVELOPMENTS**

Following the Belgrade conference, controversies on NWICO continued, led by western agencies at a big 1981 conference in Talloire, France, promoted by the US World Press Freedom Committee. Meanwhile, with the election of President Reagan, the shift to unilateralism, and his administration’s strong pro-market push, the NWICO discourse began to fade from view. The MacBride recommendations did not influence UNESCO’s 1984–1989 plan, and the US mentioned the organization’s implication in NWICO as one of the reasons for its withdrawal in 1984 (soon followed by the United Kingdom and Singapore). This led to a severe restriction of the organization’s budget and to a depoliticization of communication-related issues. The focus remained on practical and technical development assistance, as promoted by the IPDC, but funding remained a major problem.

NWICO debates underlined the centrality of information and communication developments to societal transformation as the twenty-first century approached. Yet the global shift toward a purely market logic, the interplay between eastern and western superpowers, the lack of political will to address unequal information structures concretely, and the incapacity to engage a wider public in discussions, did not allow this global debate to live up to the many expectations it had raised. By the end of the 1980s NWICO had been left to scholars and communication specialists and to some civil society organizations (Traber & Nordenstreng 1992).

Yet international communication issues have again been discussed in world fora fostered by the UN-promoted World Summit on the Information Society (WSIS, Geneva 2003 and Tunis 2005). Nonetheless a major historical silence was evident: no mention was

made of previous international efforts (from the MacBride report to the 1985 Maitland report on telecommunication policies and development priorities, promoted by the International Telecommunication Union). According to some observers (Padovani & Nordenstreng 2005) this lack of historical depth in facing contemporary global communication challenges reflects a problematic tendency to understand them as complete novelties, thereby fostering superficial policy approaches. Much was learned through the NWICO experience that is of great relevance to contemporary world communication realities.

## News

Hillel Nossek

*College of Management, Academic Studies*

News is a genre of mass media content resulting from journalists' information gathering and editors' decisions and following professional practices and norms (→ Ethics in Journalism; News Routines; Standards of News). News is the product of teamwork in media outlets. According to functional-structural social theory, news content is information that seeks to meet social needs by observing the natural and human universe in order to help people survive in their physical and social world (→ Functional Analysis). News is the product of mass media, which began with the printing press and later developed into → radio, → television, and the → Internet (→ Media History; Newspaper; Newspaper, History of). The main critical question regarding news is whether there is a consensus on how news is defined and who creates and controls news production and news content. Is it the media proprietors, the government, interested sources, political and/or economic social and cultural elites, the hegemonic majority, public relations agencies, spokespersons of the business community, advertisers, journalists/editors, or the → audience and the → public (→ Advertising; News Sources; Ownership in the Media; Public Relations)?

Some *theories and critics* credit the end product of news to one or more of the related actors in defining, producing, and disseminating mass media news. Other theories are concerned with the organizational and social environment, and the constraints of news production. Some address media and communication technologies or news sources (→ Technology and Communication). Some scholars believe in the good intentions of the actors and explain imperfect or unprofessional outcomes by revealing the constraints of news production, while others attribute imperfections to ill-meaning actors who deliberately bias news to suit their goals, with news the product of conspiracy and manipulation based on ideology or other political, economic, and social interests (→ Bias in the News). The five main components of the system of news production and dissemination are: (1) journalists and news editors (producers and decision-makers); (2) media organizations (the organizational, professional, and social framework); (3) the social systems in which journalists and media organizations operate (the political/economic/idiosyncratic and universal culture/legal systems); (4) the news product; and (5) the news audience/consumers.

## VIEWS ON THE NEWS

News can be examined from four main *viewpoints by the participants* in news consumption and production concerning these major components. First, the audience-needs perspective relates to ideas on the meaning of news and its production, and normative expectations of what news should be and how it should meet the public's needs (not as consumers or advertisers). Second, the journalists-as-professionals perspective involves insights, perceptions, and opinions on the professional process and finished product. Third, the intellectual perspective concerns the opinions and criticism of news by intellectuals in and outside academia. Intellectuals provide the normative definitions of what news should contain and how it can respond to important social needs. It focuses on the "watchdog" role of the media in a democracy and the special role of the news in providing public information and criticism of the government and its organs. And, fourth, the academic-theoretical and research perspective examines the conceptual constituents of news and explains news and its social implications. Research aims to corroborate or refute the intuitive insights of the other three perspectives.

*News theories* stem from sociology, psychology, and social psychology. They examine newsroom decision-making, professional socialization, and news creation and production (→ Journalism Education; News Production and Technology). Some research uses participatory → observation, quantitative and qualitative → surveys of journalists and editors, and product content analysis (→ Content Analysis, Qualitative; Content Analysis, Quantitative). Other studies perform sociological surveys to map journalists' social and educational characteristics and professional training and attitudes, in an effort to understand professional decisions (Weaver 1998). Other studies survey the psychological needs of journalists, and conclude that journalists' decisions reflect a desire for social validation of perceptions of reality and reinforcement of stereotypical beliefs. The journalist's reference group is mostly other journalists and the media (→ Journalism: Group Dynamics). Contrary to the popular myth, they tend to prefer publishing predictable items and news published by others (Donsbach 2004). Zelizer (1993) sees journalists as a community of commentators and a source of reinforcement of decisions and interpretations of reality.

## WHAT MAKES NEWS?

The first academic research to pose the question "what is news?" was as early as 1920. In his pioneering work, → Walter Lippmann (1922) sought to see news as something that could be described as a "natural phenomenon." Lippmann believed that news had certain characteristics that made it news and as such different from other phenomenon. He saw journalists as scientists, working with a mental guide (like a plant guide), applied to observations of physical and social reality helping assess what is and is not news. This requires certain steps that resemble the steps scientists or judges take to evaluate facts and determine the truth (→ Truth and Media Content). A related approach is to assign qualifications criteria to phenomenon, which decide what makes events "news." Events can thus be defined as "news" based on inherent factors: → news factors and their → news values. Following the seminal study by Galtung and Ruge (1965) to determine the structure of foreign news coverage and the role of → news agencies in the process, studies continued

to map the factors that define events as news in general and foreign news in particular. Harcup and O'Neill (2001) contributed an accurate map to this discussion of the news factors that influence coverage selection. The ten factors they identified include a fresh presentation of some of the twelve factors suggested by Galtung and Ruge (e.g., → negativity, celebrity, audience relevance, and follow-up). Shoemaker and Cohen (2006) took this approach a step further by seeking common cross-cultural factors helping to predict the end product of news. They identified two primary criteria that classify events as newsworthy: deviance (often negative) of the event from the norm, and social significance.

## NEWS AS A PRODUCT

Contrasted with the “natural” approach to news, other approaches conceive of news as a product of actions by interested parties, ranging from journalists’ independent and regular sources through sources with vested interests that leak scandals (Molotch & Lester 1974; → Scandalization in the News), to public relations agents who actually “create events.” Today, professionals who create and exaggerate events for commercial and political clients are called → spin doctors (→ Spin and Double-Speak). Boorstin (1964) described spin as pseudo-events, and argued that they already constitute the lion’s share of the news (→ Media Events and Pseudo-Events).

Research has investigated the media outlet, the journalist’s work and workplace, and the journalists’ and editors’ roles as “gatekeepers” of news selection and producers of the media’s view of social reality (→ Gatekeeping). News selection occurs on several levels and journalists have professional guidelines and standards that mediate their subjectivity. They function within media organizations, each with its own priorities, in a matrix of other organizations. Media organizations also function in the wider social sphere of “the social institution of communication,” with its reciprocal relations and influence by other social institutions (the “social system”): the political, economic, and cultural institutions or fields. Shoemaker and Reese (1996) proposed a hierarchy of influences model, ranging from individual media workers to larger societal forces affecting the news message (Reese 2001; → Media Production and Content).

## MAIN THEORETICAL APPROACHES TO THE STUDY OF NEWS

The theoretical approaches to news vary widely. The *normative professional-functional approach* focuses on news production, and argues that although journalists and editors follow professional norms, the economic, political, and cultural environment for news distorts the end product. Constraints on editors and journalists, not conspiracies or manipulation, account for any news bias. A general *political-economic approach* argues that news is used by capital and government to maximize business and political interests (→ Political Economy of the Media).

More *critical approaches*, including Marxist and neo-Marxist, regard news as a capitalist tool for preserving the social and economic status quo, and ask the question of whether the news helps explain and clarify events in the real world or mystifies and obscures them (→ Critical Theory). The Glasgow University Media Group analyzed news on strikes, the Falklands, and nuclear defense, as well as other political and work relations issues

(Glasgow University Media Group 1985; → Labor in the Media), while others researched the news coverage of the new left movements in the US (Gitlin 1980; → Social Movements and Communication). Among the way news helps governments to survive, in this view, is to provide alarming news, destabilizing the public's sense of personal safety – and for journalists to survive, they must, in this view, adapt to the system's demands (Herman & Chomsky 1988).

A *cultural approach* recognizes the many different ways news can be presented, even within capitalist organizations and nation-states (→ Cultural Studies). The media, for example, treat events differently, depending on whether a conflict is internal (concerning the media's nation-state) or external (not concerning the media's nation-state; Cohen et al. 1990; Nossek 2004; → Conflict as Media Content).

According to some schools, the audience is a passive consumer, manipulated by media owners, and offered increasingly → soft news stories or → infotainment. However, recent approaches (see, for example, Wall 2005) recognize that audiences are increasingly active in producing news via the Internet, photos, video footage, mobile phones, etc., and might change the definition of news as a product of media outlets and journalistic professional norms and news work.

### **NEWS AS PROFESSIONAL AND CULTURAL NARRATIVES**

There are two basic forms of narrating news: the chronicle and the story. Chronicle serves an informational function, presenting details of an occurrence in a direct fashion, providing a basic record of society's goings-on. Story, on the other hand, involves more of an entertainment function that couches information as something akin to the folklorist's work (Bird & Dardenne 1988; Nossek & Berkowitz 2006). Story is most like the cultural narrative, blending past cultural meanings with present events (→ Narrative News Story).

News as a professional narrative involves two important factors: journalistic practices and cultural background. First, professional journalism has a professional ideology of objectivity, with norms and procedures to eliminate subjective bias – supposedly presenting only the facts (Schudson 2001; → Objectivity in Reporting). Ironically, these norms produce a consistently stylized form of news. Journalists learn to polarize issues and define their parameters as they gather information from “expert” sources – sources with allegedly factual rather than self-interested information (Shoemaker & Reese 1996). Studies of → journalists' role perceptions show a close but distinct relationship between their professional and domestic-cultural attitudes (Weaver 1998). Journalists use news frames to create instant meaning for the data they collect, which they organize into stories comprehensible to their audiences (Entman 1991; → Framing of the News). The second factor in professional narrative is cultural context. As part of their cultural role as storytellers, journalists “manufacture” news by tapping into cultural narratives. Journalists are both part of their culture and its storytellers. They construct narratives based on conventions that resonate culturally with them personally and their audiences.

Cultural narratives are also referred to as “myths,” enduring yet dynamic conceptions of society, its social institutions, and values (Lule 2001; → News Myths). They are stories with identifiable narrative structures (Roeh 1989). They resonate culturally because they suggest meaning to the present in terms of the past in a way that will have impact on the

future (Nossek & Berkowitz 2006). Myths are marked by definable narratives, which are familiar, acceptable, and reassuring to their host culture and can also be interpreted as ideological forms – cultural symbols evoking taken-for-granted interpretations about what a society has been and should be.

### **ALTERNATIVE FORMS OF NEWS**

Although much of news originates from within large media organizations, alternative forms are widely available. The underlying premise of “alternative news” is that media ownership, with its bias toward capital and government, is an impassible barrier to news of public importance (→ Alternative Journalism). Editors and journalists cannot operate independently according to their professional norms and ethics. Therefore, the only way to produce and distribute adequate news is by alternative routes: through media that is not subject to ownership, capital, or government interests and/or control, where journalists do not owe their livelihood to these groups or consider them part of the establishment. Also called community, development, civic, and peace news, the idea is that it is possible to change the quality of news by curtailing the role of the “gatekeepers” or by re-educating journalists and editors to seek alternative criteria for identifying and publishing “good,” “constructive,” or “positive” news (→ Community Media; Development Journalism; Peace Journalism). The main question in regard to these activist approaches to the news is the extent to which this kind of journalism and news production is possible as a permanent and visible product.

The growing phenomenon of open news publication is a transparent, interactive process of creating, producing, and reading news (Platon & Deuze 2003). Journalists and audiences work together creating, editing, and distributing news, with no commitment to a single truth or to following up items, yet coexisting with professional journalists as the formal gatekeepers of conventional news organizations (→ Access to the Media; Citizen Journalism; Citizens’ Media; Public Access Television). Interestingly, research shows that despite the promise of openness and freedom, “open” sites are still censored and each organization has a way of dealing with articles considered problematic (Platon & Deuze 2003).

### **MEDIA GLOBALIZATION AND THE DEFINITION OF FOREIGN NEWS**

Following changes in the world communication map and the advent of new media technologies, especially the advent of global news channels, it has been necessary to reassess foreign news flow. Thus, for example, the focus in foreign news on issues perceived as “bad news” is most marked in the west’s coverage of the third world. Regarding foreign news flow, a study from the late 1970s initiated by UNESCO stressed two important findings. First, it found that most foreign news coverage was political, economic, and security related (“hard” news; it also established that most actors in foreign news items were political figures). Second, it identified a “continent-based orientation.” The study also exposed a consistent imbalance in international coverage, with the United States and western Europe as the main producers of news, developing countries appearing mainly in the context of tension and crisis, and vast geographical regions receiving no coverage at all (Sreberny & Stevenson 1999).

A follow-up study of some 40 countries was conducted over a two-week period in September 1995. This → International Association for Media and Communication Research (IAMCR) sponsored study investigated whether changes since the 1970s had affected foreign news flow. The comparison showed similar localization trends despite the persistent increase in global information sources. Although news organizations use new technologies to communicate information, they still tackle foreign news from a local angle. This indicates an inherent bias in foreign news reporting resulting from the local “lenses” that news editor “gatekeepers” use (Nossek et al. 2007).

### CURRENT RESEARCH AND PROSPECTS

Current research asks whether new types of events (e.g., new kinds of political violence, especially atomic, biological, and chemical warfare, terrorist attacks, and the enormous number of casualties in dramatic attacks such as those of 9/11), new media technologies, economic globalization, media outlets, and audiences will change the traditional definitions of news (see, for example, Katz 1992, on the CNN effect on the news coverage of the Gulf War of 1991).

Potentially, new communication technologies allow journalists a more meaningful role not only in shaping the news agenda, but in influencing the orientation of news stories. Another question is whether news will cease to be a product of professionals and media outlets and become an interactive process produced by audiences with no editors or censors, but with no control or accountability for its evidential truths, as is the case of blogs and → bloggers on the Internet, writing their personal stories and observations as news (Singer 2003; → Accountability of the News).

## News Agencies

*Chris Paterson*

*University of Leeds*

News agencies are transnational media organizations that write and distribute stories and their components, such as images and interviews, to the news media (→ News). Audiences see their words and images upon almost every exposure to news, without usually knowing it. The original news agencies formed between 1835 and 1850 to fill the growing newspaper industry demand for stories. They later distributed photographs and eventually merged with newsreel companies or their successors, coming to dominate the distribution of television news images as well (→ News Agencies, History of).

### RESEARCH QUESTIONS ON NEWS AGENCIES

The *practices* news agencies follow to create the international affairs journalism that the public are exposed to every day is an underresearched area of journalism studies and international communication, perhaps because two research traditions failed to intersect. The sociological tradition began in the 1970s with ethnographic research projects in newsrooms (Tuchman 1978; Gans 1979) but declined without extending to news agencies. Also in the 1970s, scholars of international communication subjected previously little-known news agencies to scrutiny as potential agents of cultural imperialism and neo-colonialism (→ Cultural Imperialism Theories). Their role as the dominant sources of news from developing countries highlighted imbalances in the flow of news and the power of these institutions to shape perceptions of other cultures (especially those least able to mold their own images) (→ New World Information and Communication Order [NWICO]). But then interest in news agencies also declined, and the two research traditions have rarely combined, leaving little understanding of production within these influential institutions.

News agencies exist around the world at the national and local levels, some publicly funded, some commercial, but in the production and distribution of global *wholesale news* (Boyd-Barrett 1980), only two companies dominate: UK-based Reuters and US-based Associated Press (AP). Many factors led to the emergence of a duopoly in international news provision. Agence France-Presse (AFP) competes in some spheres, but its presence online and on television is small. The formerly powerful American agency

United Press International once spurred greater investment in international reporting from the AP (Boyd-Barrett 2000), but after numerous ownership changes and its eventual takeover by the Unification Church, now has little influence or credibility among journalists. AP and Reuters dominate global news distribution in text (newspaper and websites), in still pictures, and in video; they are the only multimedia, fully international news services providing original reporting on events worldwide.

Critics often accuse news agencies of producing a bland product, devoid of color and enterprise reporting, and dependent on official definitions of news. But in the realms they know well, such as conflict zones and developing regions, the agencies frequently break stories that other media miss. Even so, research has demonstrated a constrained, homogeneous content dictated by the ideology, structure, and culture of these organizations (Wallis & Baran 1990; Hjarvard 1995; Cohen et al. 1996; Paterson 1998).

### NEWS AGENCY PRODUCTION

Recent large-scale research on news agencies is rare. Two major studies published in the 1980s did not include extensive research on the production process (Boyd-Barrett 1980; Fenby 1986). A later study of global news wholesalers was mostly interview based (Johnston 1995). The most recent published scholarship examines television agencies (Paterson 1998), focusing on video news production but not on the processing of photos or, more crucially, text. The remaining literature includes master's dissertations, brief insider accounts of agency work, and some features in other media. For example, two disenchanted Reuters journalists wrote about the financial woes of the company (Mooney & Simpson 2003), but revealed little about the news production process. The existing observations and anecdotal evidence, along with earlier research, allow some generalizations about agency news production (→ News Production and Technology).

News agencies claim to follow the interests of the news media they serve, but they frequently lead that interest, or set the news agenda, by providing the first coverage of breaking stories. A story the agencies deem unworthy is unlikely to gain global exposure through other means. The agencies have separate *divisions* for text, photography, and video, which occasionally coordinate their work but more often act autonomously to distribute their product quickly. Whether the ability to deliver these previously distinct media forms in a unified digital transmission from anywhere in the world will challenge that autonomy remains to be seen. Speed drives everything in news agencies, and observation of rival agencies (and major broadcasters like the BBC and CNN) is the key determinant of what is fast enough. To their credit, agencies continue to maintain standards of accuracy that some media outlets have sacrificed.

Each major news agency maintains about 200 *bureaus around the world*. Although many of these are little more than a one-person operation, the largest employ hundreds of journalists. The role of the bureau is to send information and images as quickly as possible to a central processing and distribution point, generally the London, New York, or Paris newsroom, and follow up soon after with further details and interviews.

The *central newsrooms* will assist in that process or commission other coverage, as long as the bureaus deliver some information and images rapidly to get something out to clients in (literally, at times) seconds. Bureaus and the central newsrooms also monitor

other media for information and story ideas, and take coverage requests from client media. As with newspapers, writers work quickly to craft stories with basic, verifiable information, and then send it on to an editor for review. That editor will then put it out to clients. The difference with video is that editors must select and edit the images coming in and then send them, with a list of shots and the accompanying textual information, to clients by satellite.

In a 2006 two-part series for the Poynter Institute, a trade organization based in Florida, media business analyst Rick Edmonds writes that practices are evolving to replace what AP staff call “the fire hose”: the massive, continuous stream of content pumped to clients in the mode of the old clattering wire service teleprinter once present in every newsroom worldwide (Edmonds 2006a, b). Television journalists call the overload of news agency images “video wallpaper.” Agencies have always trusted clients to select and sort the news themselves, as in the classic research by White (1950). Now an agency can use new technologies to deliver to specific clients the specific content they want, and can devote more resources to specialized topics than to the old bread-and-butter of political news and international conflict.

News agency workers commonly speak of *moving* the images (whether still or video) to their clients, a term that trades on the myth of objectivity (→ Objectivity in Reporting). It enables agency workers to imagine themselves as simple conduits for information and pictures, rather than determinants of *the news* (a more onerous responsibility). But in the classic response, even choosing where to put the camera is making a subjective choice. The term obscures the process of story choosing and framing, deciding news-gathering approaches, selecting and editing images, determining what information does and does not accompany images, and choosing which client sees which image.

In the television divisions of agencies, bureau chiefs (who often are also producers or videographers) strive to obtain television pictures of interest to their editors in London (or in regional hubs like Hong Kong) by whatever means possible. When the ideal – having a staff photographer at the scene – is impossible, the bureau chiefs or London editors try to obtain pictures through other means, including bidding for images from anyone who might have them. Such decisions have a secondary or incidental effect, because expensive footage purchased today may require the bureau to drop some costly coverage from the agenda tomorrow.

The headquarters of television agencies typically divide labor between *intake* and *output*; the former is focused on bringing in information and images via satellite links, the latter with figuring out how and where to disseminate it. An Editor of the Day oversees the development of story coverage and resource deployment around the world and determines minute-to-minute priorities (while seeking also to control costs). A Managing Editor, sometimes in cooperation with senior executives, determines the agency’s focus on larger stories (a process media scholars might call *framing*) and decides on the most sensitive issues, such as how to deploy the staff in dangerous areas.

Morning and afternoon editorial meetings ensure that everyone is working toward common goals and knows what coverage needs are coming up. A similar process unfolds through the day in the photo and text divisions of each company, although these may have offices in other parts of the world. In the 1990s, Reuters held a weekly meeting between senior television and text journalists to plan and coordinate future coverage.

Most *news* is really *olds* – that is, expected and planned for, especially internationally (Galtung & Ruge 1970). Key to news agency coverage, to a greater extent than for other media, is *future* or *forward* planning. The manager assigns several journalists to this task, assembling complex diaries of anticipated events and briefing editorial meetings about them. On lesser stories, how sure the journalists are about a story's prospects can make the difference in whether an event reaches the newsrooms of the world or not. Planning is especially crucial at news agencies because other media use the planning diaries that agencies circulate to decide on their own world and national coverage.

The importance of planning at news agencies highlights the considerable power that agency coverage budgets have over what does and does not become the news of the world. It also highlights the probably dominant role of *pseudo-events* (Curran & Seaton 1997): the scheduled, staged media events of key actors seeking to be the dominant voice on some issue of international importance.

### CONSTRAINTS ON PRODUCTION

The production processes of news agencies permit them to be efficient news factories, but also perpetuate many general problems scholars have identified with the standard western model of journalism (→ Bias in the News; News Factors). For instance, to meet the expectations of their clients, agencies typically seek out news elites for interviews and so legitimate the status quo and further exclude alternative perspectives in international affairs (Galtung & Ruge 1970; Golding & Elliott 1979).

Management and news processing structures in news agencies, at least in television divisions, seem designed not to insulate a journalist's decisions from commercial considerations but to insure that these prevail (Gitlin 1980; Paterson 1998). In television news agencies, the main concerns were the preferences and cultural biases of the wealthiest news agency clients and, to a lesser extent, the European public broadcasters with whom they collaborate in the Eurovision News Exchange (Cohen et al. 1996). The power of the Exchange is fading, and agencies now provide video straight to consumers online, in competition with their traditional television network clients.

News agencies are unique entities because a fairly homogeneous core cadre of news workers commissions, processes, and edits – that is, has control over – an enormous flow of words and images from around the world. Each news agency promotes its internationalism and lack of allegiance to any single cause or nation, but patterns of prioritizing particular nations, news actors, and values are clear (Schiff 1996). News agency workers do tend to be exceptionally knowledgeable and cosmopolitan, as well as culturally and linguistically adept. Their isolation from commercial pressure is generally more genuine than is typical of commercial newspapers and broadcasters.

Reuters and the AP are equally ubiquitous in cyberspace, but they have pursued different online strategies. Reuters moved away from the distribution pattern of its roots, while the AP has remained mostly tied to the subscription model it has relied on for 150 years. Consistent with its origins, the AP provides links to its content only through the websites of member newspapers, as a means of protecting the print media that own it. Reuters still depends on subscriptions in its agreements with media organizations that receive video, audio, and text feeds, but it has also gone into competition with its

subscribers, becoming an online news service marketing directly to the consumer and supplying its branded stories through news websites.

In 2006, Reuters announced a partnership with Yahoo! to bring in photographs from the general public and circulate newsworthy ones internationally. The announcement seems a striking contradiction to Reuters' long-held line that its essential value lies in the professional creation of the news product, but it may represent one more necessary adaptation to a changed media world. And, as Edmonds describes, agencies increasingly call on journalists to produce a multimedia product, just as other kinds of newsrooms do (Edmonds 2006a, b).

In 2004 Reuters announced that it would shift some news production for its business services to India. It argued that writing about the press releases of small US companies could be accomplished more cheaply there than in the UK or US, but also promised no job losses as a result. It is reasonable to expect news agencies to continue to shift more mundane aspects of news production to low-wage countries, further decentralizing production, without decentralizing command and control.

A crucial aspect of news agency production is safety. News coverage for some of the most common agency stories, those of international conflict, is becoming so risky that new and probably less effective news-gathering strategies must be developed. In Sierra Leone in 2000, guerrilla fighters killed two of the leading news agency journalists in an ambush, one from Reuters, the other from AP. Some leading *hotspots* are proving that in war, no journalist is safe and no side in the conflict can be counted upon for protection. The efforts at censorship, the direct violence, and the imprisonments have imposed an especially high price on news agency journalists.

The Palestinian government, for example, confiscated video tape of a cheering Palestinian crowd, shot by an AP television news photographer on September 11, 2001, and deleted portions of the tape, presumably to stop the international exposure of images that could fuel a backlash against Palestinians after the attacks in the US. For its part, the US military is known to have killed four Reuters journalists in Iraq (Paterson 2005). US forces have held news agency workers for long periods without charge, and Reuters alleged in 2004 that some were tortured. The US government has labeled each case justifiable or accidental, but the calls for independent investigation continue. Journalists are under threat in many parts of the world, but in Iraq the toll for news agencies has been unusual. Being a news agency photographer in proximity to military activity in Iraq is clearly a risky endeavor.

In other ways, governments show a growing sophistication in their understanding of global news distribution. The government of Saddam Hussein in Iraq, shortly before it fell, banned CNN from Baghdad and permitted Reuters to remain only on condition of refusing to feed images to a most valued client, CNN. Reuters agreed, in deference to the remaining clients around the world. Agency journalists admit privately that the threat of manipulation or outright bans prevent them from engaging in the investigative or highly critical journalism about host governments that other media might attempt.

News agencies create much of the public image of the world. It is nearly impossible to consult a national or international story online or in a newspaper without reading the words of AP, Reuters, or AFP, and one is unlikely to watch television for long without seeing images from these agencies (although rarely identified as such). After 150 years of news agencies shaping the public image of the world, scholars still know little about how

and why they cover what they do, report as they do, and disseminate their journalism as they do. The processes of convergence and the demands of the new media environment are changing news production processes and expanding the influence of news agencies while further limiting public understanding of these institutions (→ Digitization and Media Convergence).

# News Agencies, History of

*Oliver Boyd-Barrett*

*Bowling Green State University*

News agencies are among the oldest electronic media, having survived as a genus at least since 1835, the year that the French agency Havas was established. Havas was the first of the world's agencies to engage in significant international activity. It was followed by Associated Press (AP) in the USA in 1846, Wolff in Germany in 1849, Tuwora in Austria in 1850, and Reuters in the UK in 1851. Very soon there was a national news agency in almost every European country. Outside Europe the pace of development was slower, but no less comprehensive. Generalist and specialist news agencies operating at international/global, regional, national, and sub-national levels have constituted a networked system of news gathering and news distribution for well over one hundred years (→ News Agencies; International News Reporting).

## TYPES OF AGENCIES

Rantanen and Boyd-Barrett (2004) identified at least *four major phases in the development* of the major news agencies: (1) global domination of international news flow by a European-based formal news cartel dominated by Reuters (UK), Havas (France), and Wolff (Germany), 1870–1917; (2) dissolution of the cartel, 1918–1934, and the rise of the US agencies AP and United Press International (UPI); (3) market domination by the “Big Four” (AP, Agence France-Presse [AFP], Reuters, and UPI) in the 1980s–1990s, and (4) dissolution of the “Big Four” domination from the 1980s onwards. In the latest phase, AP and Reuters continue to dominate among the older generation of “wholesale” news agencies. UPI is no longer a major global player. Reuters, transformed by 1980 into a primarily financial news agency serving financial and business markets, has been significantly challenged by US financial news agency Bloomberg. Additionally, there has emerged a new generation of news media, primarily audiovisual, claiming global market reach.

Throughout this period there were always strong *national news agencies* engaged in significant international news gathering and distribution, although not on the same scale as the majors, nor, in some cases (e.g., TASS in the Soviet period), operating on a commercial basis. Their number in recent decades has included China's Xinhua, Germany's Deutsche Presse Agentur (DPA), Japan's Kyodo, Russia's TASS, and Spain's EFE. From time to time throughout the history of the global news system, there have emerged regional agencies, sometimes in the form of consortia of national news agencies, such as the Pan-African News Agency (PANA) providing news of Africa for Africa and the world since 1979, or involving entirely new formations, such as Inter Press Service (IPS), which started as a cooperative of journalists focusing primarily on news of and for developing countries. Some strong national or regional agencies have claimed to provide news services that are *alternative* or even oppositional to the news services of the major (western and big power-based) agencies. The scope for alternative news services has magnified with the development of the Internet.

News agencies such as AP and Reuters were classically defined as “*wholesale*” media, gathering news for the purpose of distributing it to other – “*retail*” – media, mainly newspapers and broadcasters, which packaged news agency news for their own distinctive readers and audiences. Until recently, news agencies did not have direct access to individual news consumers; their services were *mediated*, subject to the selection and rewriting practices of their media subscribers, which repackaged agency news for local audiences.

In addition to their traditional “wholesale” role, news agencies have become increasingly important as “retail” sources of information not only for media, but also for *individual consumers* who access news agency services through the Internet and may pay nothing for the privilege. Though they may go direct to news agency sites, Internet consumers more typically access news agency stories through secondary, or “retail,” agents consisting of general-interest portals (e.g., Yahoo!), corporate websites, and the websites of newspaper and television stations.

Some media that were once “retail,” servicing discrete geographical markets, have launched themselves as distributors of news services across major regions of the world or around the entire globe. The best-known examples of this phenomenon included BBC World (headquarters in London, UK), and → CNN (headquarters in Atlanta, US) in the 1990s (→ BBC World Service); Al Jazeera (headquarters in Qatar) joined their ranks a decade later, and others will follow (→ Arab Satellite TV News). Distribution of these global or regional broadcast services is typically mediated through satellite and cable operators, which package them along with other channels for the benefit of individual consumers in local markets. In this sense, therefore, global broadcasters have become “wholesale” news providers. Additionally, their services frequently become sources of footage and information for local media, sometimes on a paying basis, another sense in which they have become “wholesale” providers. Many Internet news providers have also emerged, of which some, but by no means all, are online editions of established “old” print and broadcast media, their services of value to both individual news consumers and other news producers. Internet sources have sometimes become sources of news for “old” print and broadcast media.

With the weakening of semantic boundaries, the term “news agency” has become more diffuse, sometimes used as indistinguishable from “news media” in general.

### GLOBAL NEWS AGENCIES

The number of traditional agencies that can be described as “global” has diminished: at one time, some scholars spoke of the “Big Four,” meaning AFP, AP, Reuters, and UPI (Boyd-Barrett 1980). These were headquartered in London, Paris, and New York. To their number could be added the Soviet-era TASS, headquartered in Moscow. By the mid-1990s it was clear that there were only two powerful agencies, Reuters and AP, headquartered in London and New York, respectively, of which one, AP, was operating on the basis of a “not-for-profit” model that constricted its business strategies. These two were followed by a third, the French AFP, while both TASS and UPI had significantly reduced the scale of their operations. In the field of news agency television news, there were only two significant contenders by 1998, Reuters Television News and Associated Press Television News (APTN), the latter being the result of a merger between AP’s APTV and Disney’s WTN, both headquartered in London.

News agency identity, therefore, has a variety of geographical markers. Most celebrated of the genre are the major global news agencies, including AFP, AP, and Reuters. These built their reputations by means of print-based news services delivered to press and broadcasting clients, later expanding their operations to include photo, audio, moving image, and Internet services. While these large agencies do operate globally, gathering news independently from most countries of the world, and selling it to clients in most countries of the world, each of them also has a long-established national identity (though Reuters rather less than the other two), and two of the “Big Three” have a strong European identity. Once a private limited liability company owned by the national and provincial daily newspaper press of the UK and Ireland, Reuters is today a commercial company quoted on the London stock exchange. Over 80 percent of Reuters’ revenue is denominated in non-sterling currencies. Europe is the principal source of its revenues, but all major global markets are important. Reuters’ major competitors in the financial news markets include Bloomberg LP and Dow Jones, both of which also combine financial with general news. AP is a not-for-profit cooperative news agency owned by most of the daily newspapers of the US (and extending associate membership to broadcasting and overseas clients). AFP is a public entity constituted according to French law, with headquarters in Paris and controlled by a governing council on which is represented the French newspaper press, the agency’s journalists, and its major state clients. State clients, including both government agencies and government-owned or government-controlled media, still accounted for approximately half of the agency’s revenue in 2005, while the remainder derived from private media and other clients. The world of television news agencies (providing “wholesale” footage to “retail” media) has shrunk to two major players, Reuters Television News and APTV (which absorbed what had been the third largest player, WTN, in 1998). The cooperative Eurovision News Exchange is another significant source, but one that also purchases footage from the other agencies.

The global news agencies represent the archetype of “syndication,” and in this way they raise questions about whether the apparent diversity of “retail” media is much less than it seems if those same diverse media are in fact drawing from the same sources of supply. The argument applies not only to the *number* of supply sources but also to how far these can claim to be meaningfully representative of all the major divisions of interest among peoples around the world. Similar concerns extend to content. The so-called “international” news agencies – AFP, AP, and Reuters – reflect the usual “western” news values (e.g., priority to elite nations, elite sources, recent events, negativity), values which today probably influence the news selection practices of most mainstream media in most parts of the world (Galtung & Ruge 1965). They are primarily in business to provide news of major “national” stories of economic, political, and military affairs, and sport – the stories thought most likely to interest international audiences – as well as news of international relations and conflict. They have been critiqued for focusing on *events* more than *processes*.

### **NATIONAL NEWS AGENCIES**

The global news agencies are sometimes regarded as the most significant players of a global news system made up of global, national, and city news media. Global news

agencies monitor local media; they often develop stories that have first been identified in local media, and they customize local news for distribution to and consumption in global markets. Their local clients include national news agencies, with which they often maintain close ties. National news agencies are popular: most nation-states have them, and new nation-states are generally quick to establish them. They may be seen as component parts of the iconography of nationhood (Boyd-Barrett 2000). National news agencies are sometimes the largest domestic news-gathering organizations, connecting central and peripheral media in a network with the national agency at its center, collecting news from the different provinces, and compiling a service of national and regional news for national dissemination. Some national agencies were originally established directly by or with the aid of the global agencies, and many were junior partners in a global network of news exchange in which the global agencies were dominant.

The global agencies typically supply their international news services to national agencies. Directly, or indirectly through national agencies, national media take international news from the global agencies (which are often the sole first-hand news sources for such news), and their news priorities are influenced by the global agencies. Local media usually have access to other sources of international news, including the international press and broadcasters (much of them North American and European, including publications such as *Time*, *Newsweek*, the *Asian Wall Street Journal*, and the *International Herald Tribune*, or broadcasters such as the BBC or CNNI). These international “retail” media are not necessarily first-hand sources, since their international coverage will have been influenced by, and to a varying extent drawn from, the global news agencies, even while they are also adding valuable and sometimes more in-depth coverage of leading news events and issues.

Many national news agencies demonstrate some features of “cooperative” structure, inasmuch as they depend on the cooperation of different and possibly competing media that share a common interest in securing a cheap and reliable source of news, or, sometimes, on the cooperation of private media, public media, and state agencies. Cooperative agencies often experience tensions that result from multiple conflicts, including the interests of their owners in saving money as against the interests of their managers in improving/conserving service. National news agencies that have or have had strong ties to their respective national governments, among them the agencies of central and eastern Europe, face a somewhat different range of problems. Just as dependence on government for subsidy or for custom is itself a problem for agencies that are dependent on such funding, equally so, and for different reasons, are reductions in government subsidy or custom, a worldwide trend in the wake of processes of deregulation and political transition. Globalization, deregulation, privatization, and commercialization are all processes that have changed the nature of the relationship between state, agency, and media clients, in particular driving news agencies to provide for more fragmented broadcast, satellite, cable, and Internet news markets, more concentrated print media markets, and overall more “infotainment-ization” of news.

## **News Audience**

*Marcus Maurer*

*Johannes Gutenberg University of Mainz*

The news audience is the sub-group of the general media → audience that is exposed to → newspapers, news magazines, → television news, → radio news, or online news (→ Internet News). Analyses of news audiences usually deal with their size and their structure. This can be done on the micro-level (audiences of particular newspapers, news broadcasts, etc.) or on the macro-level (audiences of news in general). On the micro-level, looking at the distribution of particular newspapers or the ratings of particular news broadcasts is especially important for commercial reasons. Just as in the case of any other magazine or television program, potential advertisers like to know where to place their ads in order to attract their intended audience (→ Audience Research). On the macro-level, dealing with news audiences in general is especially important for democratic reasons. Because in democracies citizens are expected to keep informed about political life, it is important to know whether they really do so and which kinds of media they use for that purpose. In this case, for example, the size and structure of news audiences in different parts of the world or trends in news consumption can be analyzed.

Although there are several academic studies on news audiences, data on the micro-level typically comes from commercial organizations like Nielsen Media Research (→ Nielsen Ratings). The most extensive data on the macro-level comes from surveys, more or less regularly carried out by governmental and nongovernmental organizations like the Pew Research Center for the People and the Press in the USA, or Eurobarometer in Europe. During the 1990s, organizations collecting these kinds of data have also been established in Latin America (Latinobarometro), Eastern Asia (Asia Barometer), and some parts of Africa (Afrobarometer).

In 2006 about 80 percent of US Americans aged 18 or older were exposed to any kind of → news on an average weekday. Conversely, a significant number of Americans (about 20 percent) were not exposed to news at all. This percentage is somewhat lower in most European countries (about 10 percent) but significantly higher in most countries in Latin America and Africa. Comparing the primary source of news in 34 countries, Plasser & Plasser (2002) found that in almost all countries under examination most people's primary news source is television, followed by newspaper. This holds true for North and Latin America, Europe, Australia, and East Asia but not for Africa. The primary source of news for most people in Africa is radio. Looking at trends in the size of news audiences, it is obvious that especially in the USA news consumption is in decline. While in 1994 72 percent of US Americans watched television news on an average weekday, in 2006 only 57 percent did so. The number of people reading newspapers and listening to radio news is shrinking to about the same extent. On the other hand, due to technical developments more and more Americans use the Internet as a source of news. About the same trends are visible in many other western democracies, although in most of them the decline is not that sharp. In contrast, due to technical progress in Latin America, Asia, and Africa news audiences – especially the number of people watching television news – are increasing further.

Analyses of the structure of news audiences usually focus on recipients' characteristics, like age, gender, education, income, and political interest (→ Media Use by Social Variable). When comparing the characteristics of those who are exposed to news with the characteristics of those who are not, several constant patterns occur in most countries worldwide. First, older people are clearly more exposed to news than younger people (→ Media Use across the Life-Span). This holds especially true for reading newspapers but is also the case when watching television news is concerned. In contrast, just like the average online user the average online news consumer is rather young (→ Internet Use across the Life-Span). Second, men are somewhat more exposed to news than women. This holds especially true for reading newspapers, listening to radio news, and consuming online news. In contrast, there are almost no differences between men and women when television news consumption is concerned. Third, better-educated people are clearly more exposed to news than more poorly educated people. This is most obvious in respect to online news consumption but holds true for every kind of news media except television news. About the same results have been found for income and for socio-economic status, which is a combination of both variables. Fourth, those who are interested in politics are clearly more exposed to news than those who are not interested in politics. This, again, holds especially true for reading newspapers and news magazines, and consuming online news. While the connection between political interest and news consumption is quite strong,

the direction of causality is unclear. In most studies, a reciprocal causality is assumed: political interest leads to news consumption and vice versa.

Although some general patterns have been found, the field of news audience research is still in motion. More and more people will have access to more and more media. Three questions especially will have to be answered by future research. The first is whether the decline in news consumption in western democracies can be stopped. The second is whether the increase in media supply in Latin America, Asia, and Africa will also lead to a further increase in the size of news audiences. The third is whether the increase in media supply also improves recipients' abilities to engage in elaborative news processing (→ Information Processing; News Processing and Retention).

## **News Corporation**

*Mara Einstein*

*New York University*

News Corporation (or “News Corp”) is an international media company with annual revenues of more than \$28 billion, making it the third largest entertainment and → media conglomerate behind → Time Warner Inc. and → Disney (Hoover’s Company Records 2007). The company produces and distributes filmed entertainment for the theatrical (→ Cinema) and → television markets as well as being a leader in direct broadcast satellite (DBS) distribution (→ Satellite Television). News Corp is a major competitor in the print category with holdings in → magazines, → newspapers, and → books. While it is an international company, more than 50 percent of revenues were generated in the United States and Canada (→ United States of America: Media System; Canada: Media System). The Murdoch family owned 30 percent of News Corp as of 2007.

While News Corp began as an Australian company in the late 1970s, it became an American company, having been incorporated in the United States in 2004. The company’s chairman, Rupert Murdoch, was famous for producing racy newspaper headlines and titillating photographs of women to sell newspapers around the world. He

brought that successful marketing strategy with him as he acquired an increasing number of media properties within the United States. In the satellite television business, as well, Murdoch transferred international successes – BSkyB in the United Kingdom (→ United Kingdom: Media System) and STAR in Asia – to the US market, acquiring 39 percent of DirecTV in 2003.

Mr Murdoch was famous for shaking up the industries in which News Corp competed. In 1986, Murdoch launched Fox Broadcasting – the first new broadcast network in almost 40 years. Eight years later, the Fox Broadcast Company forced the realignment of the American television landscape when the company acquired New World Communications, a television station group made up of major network affiliates (→ Television Networks). New World affiliates became Fox-owned and -operated stations, forcing the Big Three (the television networks ABC, CBS, and NBC) to find comparable stations in major markets throughout the United States. Simultaneously, Fox purchased the rights to air National Football League games – a bold move by a start-up network and one that led to significant growth for the fledgling network. Murdoch also shook up the 24-hour news business (→ Newscast, 24-Hour) in 1996 with the ultra-conservative Fox Newschannel, demonstrating that viewers would watch a channel with a definitive point of view. A major strategic misstep, however, was the purchase of *TV Guide* magazine. The combination of a recession and high interest rates led to decreased sales, and Murdoch was forced to sell most of his US magazine holdings in 1991.

As of 2007, News Corp had eight divisions, including filmed entertainment, television, cable, DBS, magazines and inserts, newspapers, books, and other assets, which included sports, outdoor, and → Internet properties.

Filmed entertainment included both motion picture and television production and was the largest division, representing 25 percent of the organization's revenues annually. Twentieth Century Fox produced three of the top five bestselling pictures of all time – *Titanic*, *Star Wars*, and *Star Wars Episode I: The Phantom Menace*. Other hits included *X-Men*, the animated feature *Ice Age: The Meltdown*, and *Walk the Line*. This division was also one of the major suppliers of programming for prime-time broadcast television as well as syndicated product. Notable shows include *24*, *Bernie Mac*, and *King of the Hill*, as well as syndicated fare such as *Divorce Court* and *Judge Alex*.

Fox Broadcasting was made up of its on-air networks – Fox Broadcasting and My Network – as well as its station group. Fox was the largest US television station group, with 35 stations reaching 38 percent of the country (Albiniak & Downey 2007). Fox held duopolies – markets where they own more than one station – in nine markets, including New York, Los Angeles, and Chicago. The Fox Network grew to be a major broadcaster by using a strategy of cutting-edge programming. The network appealed to a younger target audience (18–34) than the traditional networks of ABC, CBS, and NBC, which served adults (18–49). My Network TV was created in 2006 after CBS surprised the television industry by announcing the → merger of Warner Brothers and United Paramount Network (UPN) into the *CW Television Network*, a joint venture of CBS and Warner Brothers Entertainment. Fox had been a major owner of UPN affiliates because of its 2001 purchase of Chris Craft, a company that had founded UPN with Paramount. Rather than change these affiliates back into independent stations, Fox developed a new network, MyNetworkTV, so named to be synergistic with MySpace.com, another News Corp

property. This network presented 12 hours of programming per week, which consisted mostly of prime-time *telenovelas*, a popular international → soap opera format.

Like its broadcast division, *Fox Cable* was known for edgy programming (→ Cable Television). Fox Newschannel, the home of Bill O'Reilly and *Hannity & Colmes*, was until recently the highest-rated news channel (→ Television News) on cable, using the marketing line "Fair and balanced," a claim perceived by some as perfectly accurate, and others as perfectly absurd. FX, the organization's entertainment outlet, was home to highly acclaimed programs such as *The Shield*, *Rescue Me*, and *Nip/Tuck*, which pushed the envelope in terms of sexual and violent content. In addition, the company had a movie network, Fox Movie Channel, as well as numerous sports networks including Fox Sports Net, Fox Soccer Channel, and Fox College Sports. Fox Family, a children-oriented network, was sold to Disney in 2001 for close to \$5.3 billion, and became ABC Family. News Corp also planned to launch a business news channel in late 2007 (Angwin 2007).

*DirecTV* is News Corp's direct satellite television service, as of 2007 a duopoly in the United States. DirecTV leads DISH, a division of EchoStar, with 13.5 million subscribers to DISH's 10.5 million. To be competitive with cable systems that offered bundled services of television, cable modem, and phone service, News Corp created alliances with regional phone companies, such as Verizon and BellSouth, to provide comparable services to customers. In 2006, however, the company decided to exit the DBS category. DirecTV went to Liberty Media in exchange for Liberty's 20 percent voting shares in News Corp. This deal solidified Murdoch's control over News Corp while extricating the company from a slow-growth business.

News Corp also had *magazine, newspaper, and book properties*. While magazines had been a large segment of the company's business, by 2007 most of its holdings in this area were newspaper inserts, including SmartSource® coupons. Its newspapers were primarily in Australia and Britain, with just one newspaper – the *New York Post* – in the United States. HarperCollins and Zondervan, a Christian book publisher, made up the book division.

News Corp's other assets were a smattering of media properties, but most important was Fox Interactive Media. Twentieth Century Fox began selling downloadable movies through this division as well as through AOL. The most significant holding in this division was MySpace.com, an online networking site. There are also a number of online sports outlets including FoxSports.com, whatifsports, and Scout.com, a sports site with an emphasis on recruiting. In September 2005, News Corp also purchased IGN Entertainment, a community-based site for digital media, primarily video games. While News Corp stayed away from the dot-com space during the run-up of the early 2000s, through these recent acquisitions they made a significant commitment to increasing their online presence.

## **News Cycles**

*Kathryn Jenson White*

*University of Oklahoma*

A news cycle is a round of coverage once measured in the number of hours between each issue of a newspaper (→ News Production and Technology). The term originated in the United States, and the *Oxford English Dictionary* dates the earliest use to a 1922 *Los Angeles Times* article. Major metropolitan newspapers back then published multiple editions daily, but smaller local and most international newspapers followed a cycle of 24 hours, publishing at about the same time daily, either morning or evening (News; Newspaper). The Associated Press (AP) sent stories to its member organizations designated AM or PM, indicating whether the member belonged in, and could publish the content in, a morning or afternoon slot. AP sent corrections and updates over cable (first the wire, then computer) as news broke (→ News Agencies). Broadcast news initially scheduled programs in daily time slots, although stations did interrupt regular programming for breaking news (→ Television News; Radio News).

The transition to shorter cycles emerged slowly. With the introduction of *The Today Show* on the US ABC network in 1952, the broadcast news cycle added a morning to its existing afternoon arc (→ Newscast; Radio Networks; Television Networks). The 24-hour news channel → CNN launched in 1980 (→ Newscast, 24-Hour), and in the UK Sky News followed in 1989. Al Jazeera (→ Arab Satellite TV News) began broadcasting on its pan-Arab network in 1996, and the → BBC's News 24 channel began in 1997. Responding to the way news outlets were delivering information, the AP in 2000 replaced AM and PM designations with BC, signifying *both cycles*, which some considered continuous.

The phrase “24-hour news cycle” emerged in the 1980s to express the idea that satellite transmissions (and, later, Internet postings) produce a nonstop flow of news updating events internationally (→ Satellite Television; Online Journalism). Journalism practitioners and scholars have expressed concerns about a negative impact on news, because the rush to publish limits how much sourcing, fact checking, and editing news producers can do and allows rumor and speculation to disseminate (e.g., Merritt 2006; → Accuracy). Faster news cycles may not lead to better-informed citizens.

The global, *continuous, or rolling news cycle* has redefined – although not done away with – the traditional daily round of print or broadcast journalists (→ News Routines).

They update the website throughout the day (→ Internet News), while still reporting and writing within the daily production framework (→ Convergence of Media Systems; Cross-Media Production; Digitization and Media Convergence). In March 2007, the UK *Guardian* became a web-first newspaper, publishing “Principles of 24/7 Working” ([www.cyberjournalist.net](http://www.cyberjournalist.net)) to address the challenges journalists face when reporting news instantly.

Some researchers suggest that increasing how fast the media push a story to audiences decreases how much context journalists can provide (Kansas & Gitlin 1999; → Media Production and Content). Others say faster news cycles have replaced the competition for scoops (winning the race to publish news first) with a competition for immediacy (→ News Values). Immediacy favors spectatorship over investigation and creates the *feeling* of discovery while doing little to enhance understanding (Lewis et al. 2005). The websites of major newspapers may be doing more to exploit immediacy than depth in their reporting. Researchers conclude that constant, live coverage encourages questionable strategies to compensate for a lack of new facts to report (→ Quality of the News). They point to a strategic use of silence, not just the absence of talk or sound but a metaphorical silence that covers up the lack of new (by incessantly repeating old) information. The live broadcast shifts news from reporting to keeping in touch with the audience, a more interpersonal function (Jaworski et al. 2005).

The nonstop cycle may degrade news in other ways (→ Standards of News). “*Breaking news*,” the very kind that ongoing cycles would seem best suited to serve, may devolve into firsts only because no other channel finds the stories worth reporting. The content of broadcast news becomes more focused on trends and lifestyles, because scheduled newscasts are less current than the stations’ own websites or the cable channels (Montopoli 2005).

The research literature explores news cycles in Europe and North America but rarely in other parts of the world. The so-called *CNN effect* suggests that global 24-hour media have an impact on political and military behaviors in other countries. Despite the lack of strong empirical evidence, the effect continues to be a topic of interest (Hess 2002; Livingston 1997).

Although news may always be on the air or online, the constant flow is not necessarily proof of a continuous cycle. The repetition of most news outlets turns the news cycle, in some ways, into the news *recycle*. Google News on one day offered access to about 14,000 stories from its front page, but these recounted the same two dozen news events (Project for Excellence in Journalism 2006). On cable, just half the stories in a 12-hour span were new, suggesting that the notion of an all-day, all-week news cycle is an exaggeration. That said, news organizations face relentless time pressures in the speed required to produce news and in the stretches of time and space online requiring filling (García Avilés et al. 2004).

## News as Discourse

Christiane Eilders

University of Augsburg

“News as discourse” marks a theoretical framework for the analysis of news. News is considered as a complex communicative event – as discourse – including the social context of news reports (→ Discourse; Political Discourse). Rather than exclusively focusing on text properties such as the thematic structure of news reports, the actors, and the opinions addressed in the reports, the framework directs attention to the participants, the production, and the reception processes, as well as to the possible effects. “News as discourse” starts from the assumption that texts are a “result of social and professional routines of journalists in institutional settings, on the one hand, and an important condition for the effective cognitive processing of news texts by both journalists and readers, on the other hand” (van Dijk 1985, 70). Investigating text and context, the approach aims to assess the systematic relationship between the two.

The theoretical framework of news as discourse differs from more traditional approaches to news analysis by its holistic perspective. It integrates findings from linguistics, cognitive and social psychology, speech communication, micro-sociology, and ethnography. The methodological basis of the framework is referred to as → discourse analysis. It mainly draws on linguistic and → information processing approaches in order

to reconstruct the meaning that is established in the news (→ Discourse, Cognitive Approaches to; News Processing and Retention). It is complemented by a special emphasis on social and cultural differences between groups and individuals that characterizes the concept of social cognition. This concept bridges the gap between psychological and more sociological approaches since it sees journalists or audience members not as unique individuals but as social actors and group members (van Dijk 1988a, 20).

The discussion of the power structure in news discourse adds a critical dimension to the approach. Journalists are considered part of a dominant cultural elite who often contribute to the expression and legitimation of the national and international power structures. The approach examines how the press reproduces this power (→ Power and Discourse).

News as discourse also implies a critical attitude toward quantitative content analysis. It employs a more qualitative content analysis and tries to reconstruct the underlying meaning and the effects of the news (→ Content Analysis, Qualitative). Since this approach is limited to small amounts of data, however, it often draws upon additional, more traditional, methods of analysis when emphasizing general structures like the imbalance of the international news flow (→ International News Reporting).

The approach was developed by Teun van Dijk, a linguist by education, who was heavily engaged in the investigation of the organization of news text and the related processing strategies. In cooperation with Walter Kintsch, he developed the concept of mental models as a conceptually driven strategy for discourse comprehension (van Dijk & Kintsch 1983; → Discourse Comprehension). The respective ideas were also incorporated in his investigation of the structures of international news discourse (van Dijk 1988a,b). In dealing with international news discourse, however, van Dijk adopted a broader perspective by taking the social and cultural context of news into account.

By integrating textual properties and contextual conditions, the framework shows considerable similarity with → cultural studies approaches. The same applies to the clear preference for a predominantly qualitative methodology. Yet the framework is strongly rooted in cognitive psychology and linguistics, and frequently employs quantitative content analysis, if appropriate. The critical perspective to news as expression and legitimation of the existing power structures also relates to cultural studies, in particular to the French and British Marxian analysis (van Dijk 1985, 72). The conceptualization of news as narrative is another research area closely related to the framework of news as discourse (→ Narrative News Story). These approaches not only relate formal news structures and typical topics to traditional story patterns, but they also emphasize the functional character of those narrations for the development of societal self-conception (Fiske & Hartley 1985; Fiske 1987).

The thematic framework can be applied to a variety of topics in news discourse. It addresses turn-taking or strategic moves in interviews or talk shows, the structures and textual functions of headlines or leads of news reports in the press, and the style, ordering, and thematic organization of media stories, as well as the subtle meaning constructed in the discourse and the functions of this discourse in society. The most prominent application is the analysis of news on the assassination of Gemayel of Lebanon in 1982, a study conducted for UNESCO (van Dijk 1988a, b). It included a more general

analysis of possible differences in international news coverage among 15 first-world and 15 third-world papers, as well as a number of smaller studies of marginalized groups in national news reporting. Results show that the theoretical framework serves as a useful tool to relate contextual properties of news such as social, economic, and institutional conditions of news production to various structural properties of news reports.

## **News Factors**

*Hans Mathias Kepplinger*

*Johannes Gutenberg University of Mainz*

The term “news factors” denotes characteristics of news stories about events and topics that contribute to making them newsworthy (→ News; News Values). Other than events (e.g., the attacks on the US of September 11, 2001) and topics (terrorism), news factors like “damage” are scientific constructs, which can be related to all kinds of events or topics. News factors are regarded as – among other things – causes which make news stories newsworthy: the more news factors a news story carries, the more newsworthy is it. For example, a news story about a well-known actor killed in a car accident (two news factors: “prominent person” and “damage”) is more newsworthy than a news story about an unknown person killed (one news factor: “damage”). Besides the number of news factors, their intensity has an influence on the newsworthiness of news stories. A news story on three people killed is more newsworthy than a news story on one person killed.

### **HISTORY OF THE CONCEPT**

The concept was first used in the seventeenth century by the German author Stieler (1969), who particularly elaborated on the importance and proximity of events and on

the relevance of damage (war) and deviation (crime; → Negativity). After Lippmann (1961) had published his reflections on the newsworthiness of events, Merz (1925) presented the first quantitative analysis of news factors in the press (→ Lippmann, Walter). A decade later, the term “news factor” was familiar in the US and catalogs of news factors had become a standard element of textbooks for journalism students (Warren 1959). They had become aids for the training of students and the processing of news in the news media (→ Journalism Education). From there, the term spread into public discourse about the production of news, offering a plausible and socially desirable explanation for a complex phenomenon (→ News Ideologies; News Routines).

In the mid-1960s, Östgaard (1965), and Galtung and Ruge (1965) presented catalogs of news factors that were not only inspired by previous contributions, but were also parts of elaborated theories of newsworthiness. According to Östgaard, one set of news factors is “foreign to the news process” (influences of news sources, publishers, etc.) and another set is “inherent in the news process” (simplification, identification, sensationalism, etc.). Later, only the second set was regarded as news factors; the first was dealt with in different contexts. According to Galtung and Ruge, culture-free news factors, such as unexpectedness, and culture-bound news factors, such as reference to elite people, can be distinguished; that is, not all news factors are of the same relevance in different cultures. These news factors have different news values. Östgaard describes a “news barrier,” and Galtung and Ruge a “threshold,” which has to be surmounted before an event gets a chance to become a news story, and before a news story has any chance of being published. A similar assumption can be found in theories of media effects (→ Linear and Nonlinear Models of Causal Analysis).

Until the mid-1970s, many authors used the terms “news factors” and “news values” synonymously. Schulz (1976) explicitly distinguished news factors from news values as indicated by the placement and space or time devoted to a news story. In addition, he developed Likert-type → scales, which indicate the intensity of news factors, for example the degree of damage. According to Schulz, the news value assigned to a → news story is a function of its “news value index.” The latter is defined as the sum of news factors weighted with their intensity. A similar concept was presented by Shoemaker and Cohen (2006), who proposed a second-order factor called “complexity,” which indicates the number of deviant and/or socially significant dimensions in news items.

## CATALOGS OF NEWS FACTORS AND THEIR USE IN RESEARCH

Whereas most authors derived their catalogs of news factors more or less explicitly from psychological theories, Shoemaker (1996) presented a partly new catalog derived from theories of biological and cultural evolution. In addition to known news factors, it includes three types of deviance (statistical, normative, and social change). Catalogs of up to 22 news factors have been developed. They can either be exactly measured (geographical proximity), or fairly well identified by multiple indicators (cultural proximity, reach/relevance, continuity), or approximately estimated (success, failure, controversy/conflict, unexpectedness) (Staab 1990; Eilders 2006). In the course of time, all extrinsic news factors – that is, news factors “foreign to the news process” – have been excluded from the catalogs, leaving only intrinsic factors. An example is the history of the news factor

“consonance.” It was introduced by Galtung and Ruge (1965) with two sub-categories – consonant to expectations (neutral) and consonant to ideals or wishes (normative). It was excluded by Schulz (1976) for methodological reasons: both sub-categories cannot be reliably coded using quantitative content analysis. This methodologically reasonable decision, which was accepted by other researchers, had significant theoretical consequences: it totally excluded a potential influence of the individual perspectives of journalists on the selection of news and thus reduced it to a technical process guided by professional norms (→ Professionalization of Journalism).

Some news factors have repeatedly been shown to correlate significantly with the place, space, or time devoted to news stories: relevance/reach, damage/controversy/aggression/conflict, elite person/prominence, continuity, proximity, elite-nation, and complexity, as defined by Shoemaker and Cohen. Some news factors have repeatedly been shown to correlate with the selection of news by the audience: relevance/reach, conflict/controversy, elite person/prominence, continuity, and unexpectedness (Eilders 2006). Most authors regard significant correlations between the number and/or the intensity of news factors and the presentation of news in the mass media as evidence for a causal relation between both variables. For three reasons, this is questionable. First, most studies present no clear evidence that the journalists processing the news attribute the same news values to news factors as social scientists do. They support their assumptions with plausible arguments, but do not present empirical evidence for them. Second, most studies present no clear evidence that news items selected for publication display more news factors than those that are disregarded. Third, as far as the news coverage at different points in time or in different countries has been analyzed, in nearly all studies a possible influence of occurrences in reality is neglected (→ Extra-Media Data). This is in line with neither → journalists’ role perceptions, nor recipients’ expectations.

## News Ideologies

Mark Deuze

*Indiana University and Leiden University*

“Ideology” has two related definitions: a set of shared ideas that order group life, and the ways that such a set of ideas reinforces existing power relations (Barnhurst 2005). Following the first definition, an *occupational ideology* refers to a system of beliefs characteristic of a particular group of workers, including but not limited to their processes of producing meanings and ideas within the group (→ Journalism: Normative Theories). In news, a diversity of approaches across cultures has produced distinct journalisms in different locales, as for example documented in more than twenty countries all over the world (Weaver 1998). Regardless of cultural specificities, the existence of an increasingly isomorphic news ideology has consistently been documented in international journalism studies (Westerstahl & Johansson 1986). Research thus suggests that news workers around the world have in common an occupational ideology consisting of a generally shared system of ideal-typical values (Deuze 2005).

In the course of the twentieth century, the professionalization of news media work consolidated thinking among journalists in different countries. Journalism scholars see professionalization as a distinctly ideological process (→ Professionalization of Journalism). The emerging ideology continuously refined a consensus about who was a *real* journalist (→ Journalists’ Role Perception) and what (parts of) news media at any time qualify as examples of *real* journalism. Through such definitional debates, and through the processes of legitimizing or excluding particular participants in these discussions, journalists establish (largely informal) barriers of entry to the profession (→ Journalists: Professional Associations).

In electoral democracies, journalists speak of similar values in the context of their daily work, but they apply these values differently. *Objectivity* for American journalists may, for example, primarily mean doing their work without interference from marketers, whereas in China journalists actively use market-driven values to wrestle some editorial control away from the political stamp of the ruling party (Pan 2000; → Objectivity in Reporting). Because journalists in all media types, genres (Van Zoonen 1998), and formats share similar values, it is possible to speak of a dominant occupational ideology of news. Most news workers base their professional perceptions and praxis on that ideology (→ Journalism: Group Dynamics), but interpret or apply it differently across media (Shoemaker & Reese 1996).

Reporters and editors use news ideology as a *strategic ritual* to position themselves in the profession and in relation to media critics and the audience (Tuchman 1971). They use ideology as an instrument to naturalize the structures of news organizations or media industries (Soloski 1990). When faced with criticism, journalists apply ideological values to police themselves or to legitimate their recurring selections and descriptions of events and views (Golding & Elliott 1979).

Five *ideal-typical values* give legitimacy and credibility to what journalists do (→ Journalists, Credibility of): public service, objectivity, autonomy, immediacy, and ethics. Journalists provide a public service as watchdogs or newshounds, active collectors and disseminators of information. They strive to be impartial, neutral, objective, fair, and (thus) credible (→ Balance; Neutrality). They must be autonomous, free, and independent to do their work effectively. They have a sense of immediacy, actuality, and speed inherent in the concept of news (→ Standards of News). And they have a sense of ethics, validity, and legitimacy (→ Ethics in Journalism).

In its second definition, ideology is a process of constructing → meanings in the *service of power*. News ideology is a global factor influencing journalistic decision-making, and scholars analyze how symbolic content in the news media connects with larger social interests. One way journalists exercise power is by defining what “real” journalism is, a process enacted, for example, through mainstream debates about journalistic quality (→ Quality of the News). By legitimating self-appointed arbiters of professional debates and by excluding sources, stakeholders, and audiences from positions of power, news ideologies also serve to advance the status and internal coherence of an occupation.

Journalists generally do not see inconsistencies or contradictions as they integrate these ideal-typical values into debates about the character of the news. News executives and journalists regularly revisit issues of commercialization, bureaucratization, new technology, audience declines, and ownership concentration (→ Commercialization of the Media; Concentration in Media Systems). In all these debates, they deploy ideological values to maintain control on internal operations and to keep outside forces at bay.

Through news ideology, journalism continuously reinvents itself. Changes in society and fast-paced developments in technology, as well as the ongoing convergence of companies, genres, and media in the field, translate into anxiety about the state of the profession. Journalists, along with scholars and educators, inevitably explore news ideology whenever they ask themselves: what is journalism?

## News Magazine, History of

Byron Scott

University of Missouri-Columbia

The concept of → news as a component of a → magazine's editorial content is as old as the medium (→ Magazine, History of). The *Gentleman's Magazine* is regarded by magazine historian Frank Luther Mott (1938) and others as the first to use the word as part of a periodical's title; it was begun in 1731 by a London printer, Edward Cave, and contained tidbits of doings in the royal court and around the town. But the idea of devoting an entire magazine to in-depth articles and interpretive features on recent events worldwide is far more modern. To remain topical, news magazines had to be weekly or at least fortnightly. Their introduction had to await an array of historical developments, including an efficient postal service, faster printing presses, and general literacy. This article deals only with the genre in print and not the labeling of television or radio shows as “newsmagazines” (→ Television).

Depending on definition, the first news magazine (or “newsmagazine,” as a single word, in much contemporary writing) was either British or American. Earlier periodicals of other sorts were almost certainly a continental innovation, such as Johann Rist's *Edifying Monthly* (Hamburg, 1667) or Denys de Salls's *Journal des scavans* (later *savants*; Paris, 1665), but these concentrated more on fashion, theology, and philosophy, confining recent events to digests of the news or satirical comments. News was thought to be too unsophisticated for most writers, as well as their audiences, particularly women.

### EUROPEAN ORIGINS

Originally an Arabic word meaning a “storehouse for valuables,” magazines have always distinguished themselves by their ability to get the news and context needed to particular groups of readers. Business and trade, mixed with politics, were an early driving force for

periodicals in general. Those people concerned with these topics, and educated enough to read and appreciate such news, became the core → audience. In England, from its beginnings in September 1843, *The Economist* has concentrated on these subjects, only recently mixing in science and technology, personalities, and aspects of popular culture. Arguably it is the oldest continuously published news weekly. Even in the modern, multimedia era, *The Economist* occasionally refers to itself as a “newspaper,” but there is no doubt that in its glossy appearance and content, as well as in the minds of its more than a million transatlantic readers, it is a magazine, whether encountered in print or online.

The founding editor, James Wilson, came from a family of Scottish Quakers and was self-educated. Ironically, he failed in international investment, losing most of his fortune in the indigo trade during the 1837 depression, but recovered nicely to start both a bank and the magazine while also becoming a successful politician. Wilson was a Liberal member of the House of Commons and a member of several British governments. From the outset, his magazine took strong positions on most issues, opposing, among other things, the secret ballot and a privileged position for the Church of England.

The modern *Economist* continues to be known for its unequivocal stances, which have caused it to be banned in China, Zimbabwe, and elsewhere, as well as for its precise writing, laced with dry wit. Its international studies and analyses are widely quoted and well respected for their in-depth, independent research; and today are often published separately in books and online. Articles rarely identify authors, unless the writer is not on the staff. There is no masthead and, by tradition, not even the editor is listed. John Micklethwait, who previously edited the US edition, became editor-in-chief in 2006. Past *Economist* editors have included the constitutional scholar Walter Bagehot (1861–1877), after whom the weekly UK column is named. The philosopher Herbert Spencer worked as a sub-editor under the founding editor, Wilson.

While the current politics of the magazine are unstated, it favors globalization and is generally favorable to the Anglo American alliance (→ Globalization of the Media). Its criticisms are handed out to both sides of both US and UK politics, and its editorial independence is part of *The Economist's* tradition. It is one of the few European-published magazines, other than specialized journals such as the *Lancet*, to make a success in the United States. Feisty independence is thought to enhance its credibility (→ Credibility of Content). For example, the editor can only be removed with the permission of an independent board of trustees, not the publisher or stakeholders.

Generally, news magazines worldwide carry a strong social or political philosophy. International success depends on demographic factors, such as widespread diasporas, but also on quality reporting and writing (→ Quality of the News). In this category come such well-regarded weeklies as Germany's *Der Spiegel*, started in 1947, France's *L'Express* (1953), and *Le Nouvel Observateur* (1964). England's popular *The Week* (1933), begun as a frankly Marxist periodical, has not been continuously published. Its current life, much more apolitical and popular, began in 1995; it also publishes a North American edition. Other news periodicals throughout the world, influential within regions or nations, include Brazil's *Veja* (founded 1968), censored and repeatedly closed by a military regime in the early 1970s, Mexico's *Proceso* (1976), founded by left-wing journalists and invariably critical of government, and *New African* (1966), published in London but popular at African kiosks for its aggressively post-colonial, anti-imperialist approach to world events.

### UNITED STATES BEGINNINGS

Journalism scholars (Mott 1938; Scott & Sieber 1992; Kitch 2005) have made the argument that the modern newsmagazine is an American invention. Their rationale centers on the departmentalized editorial formulae, publishing profits, and continuing multi-million circulations of three periodicals aimed at a heterogeneous audience: *Time*, *Newsweek*, and *U.S. News and World Report*.

In terms of publishing success and international prominence there has been nothing to surpass the publication founded in March 1923 by two young Yale University graduates, Henry Robinson Luce and Briton Hadden. With a circulation exceeding four million, *Time* is the largest-circulation newsmagazine in the world. It is also the flagship of one of the three largest media companies in the world, Time-Warner Communications.

In their prospectus for *Time* Magazine, Luce and Hadden (who died in 1929) caught the flavor of their product well. "People in America are, for the most part, poorly informed . . . To say with the facile cynic that it is the fault of the people themselves is to beg the question. People are uninformed because no publication has adapted itself to the time which busy men are able to spend on simply keeping informed." Both the writing of the magazine's articles ("Time-speak" as it is sometimes called) and the positions it took were heavily those of Luce for more than three decades. The son of Christian missionaries to China, Luce lobbied the US government to recognize Chiang Kai-shek's Taiwanese government. A frequent guest at the White House, he advised Republican President Dwight D. Eisenhower on Asian affairs, United Nations policy stances, and anti-Communism. *Time* readers were never in doubt about where its publisher stood, even though his byline never appeared. In point of fact, the magazine did not carry bylines until the 1990s.

*Time*'s distinctive, red-bordered cover was soon joined on newsstands by a number of rivals. Two continue in a triumvirate that has remained among the top 20 circulated US magazines for generations. *U.S. News and World Report* began in 1933 as *U.S. News*, which merged with *World Report* in 1948. Founded by David Lawrence, a Washington, DC, "insider," it is now owned by Mortimer Zuckerman, owner of the tabloid *New York Daily News*. *Newsweek*, established in 1933 by Thomas J. C. Martyn with a hyphenated logotype (*News-Week*), appeared in New York City in the same year. Each carries more advertising and has more readers, in the United States and worldwide, than any of its rivals in other nations. Their circulations have remained relatively stable since a brief circulation war ended in 1990: *Time* at the top with just over four million readers, *Newsweek* next with over three million and *U.S. News* (it downplays the title tail) at about two million.

The circulation détente persists because each takes a different approach to the news and draws a somewhat different reader to its pages. *Newsweek*, purchased in 1961 by Katherine Graham and her *Washington Post* company, displayed in the late twentieth century a more liberal approach than Luce's product. In addition to Democrats, it attracted somewhat younger, upwardly mobile readers. In contrast, *U.S. News* discovered its most comfortable audience "inside the Beltway" with government insiders and bureaucrats, and in school libraries, where students pored over its extensive tables and charts for their own reports. This distinction has begun to fade.

News periodicals have been less studied by scholars than newspapers or broadcast media. Many studies use content analysis to determine how news magazines reflect or promote social issues, from women's rights to free trade, anti-smoking to computer games. The covers of *Newsweek* and *Time*, particularly the latter's "man of the year" (now "person of the year"), have been a particular point of focus. Perhaps the most-cited work is that of the Columbia University media sociologist, Herbert J. Gans. His 1979 study, *Deciding what's news: A study of CBS evening news, NBC nightly news, Newsweek, and Time* (2005), placed news weeklies firmly in a hierarchy of influential opinion-making and of setting the agenda for public issues among elites in particular. Gans blamed these influential news media for underreporting and even ignoring some segments of society through their "unwritten rules." On the twenty-fifth anniversary of his classic work, he insisted this was still the case. But much else has changed.

### TWENTY-FIRST CENTURY CHANGES AND CHALLENGES

While retaining their print editions, modern newsmagazines are turning to the online world and to other products (→ Online Media). This is particularly true in the United States, where general-circulation magazines are yielding to specialized periodicals. *U.S. News* has become known for its special reports on various institutions, particularly its annual ranking of American colleges and universities, first compiled in 1983 and now an object of annual attention, controversy, and institutional envy. *Time* and *Newsweek* both have international editions, whose major articles and advertisers, as well as their commentaries, are often stridently different from what domestic readers encounter. All three magazines also offer a variety of regional and demographic "split runs" that carry specialized ads and sometimes editorial matter to various parts of the United States, to students, to physicians and lawyers, and to those in the highest socio-economic groups. All of this is in an effort to compete with specialized purveyors of news, from sports to business, delivered in print and online.

First *Newsweek* and then *Time* broke tradition in the last two decades by carrying bylined articles. Now, not only columns, but all articles except the briefest items, carry the names of journalists who, the editors believe, will attract a following of readers. In common with most other magazines, the US rivals have undergone multiple redesigns, primarily aimed at attracting the attention of a younger, TV-oriented generation. In January 2007 *Time* announced that, after more than 50 years, it was changing its publication day to Friday in order, as managing editor Richard Stengel explained, to "set the news agenda, not just mirror it." Media observers believed the purpose was equally to attract the leisurely weekend reader, and not those Luce and Hadden envisioned as needing the news during their working week. Media usage studies reflect that for immediate news needs, broadcasting and the Internet are now favored by audiences. In his same editorial, Stengel directed readers to *Time.com*, calling the interactive website and the print magazine "complementary halves of the TIME brand."

In the first decade of the twenty-first century, in common with daily newspapers in the United States, newsmagazines laid off hundreds of staff members. They also closed overseas bureaus and fired international correspondents worldwide. Alarmed commentators worried that this signaled a narrowing, even trivialization, of news magazine reportage,

or even the impending death of a publishing genre. Evidence from other nations suggests otherwise. As they emerge and stabilize, the economies of individual nations appear to include an expressed need for the kind of in-depth reports carried in newsmagazines (although sometimes the travails of emergence get in the way). Examples include Brazil's *Veja*, mentioned above, which despite a decade of military censorship now boasts a weekly circulation of more than a million; and *New African*, which is distributed and read throughout the continent.

The most frequently consulted online directory of news-oriented periodicals, [www.world-newspapers.com](http://www.world-newspapers.com), indicates that the family of newsmagazines, particularly those linked with politics, continues to grow. The trend appears to be strongly toward those that have a global or at least a multi-national perspective, and that have both print and online products. The method for encountering the "storehouse for valuables" has not changed the essential role of the newsmagazine.

## **News Myths**

*Jack Lule*

*Lehigh University*

Myth is a concept used to explore the storytelling practices of journalists. From this perspective, myth is not a false belief or an untrue story, nor is it contrasted with reality. Myth is a story that a society produces by drawing on archetypal figures and forms to express prevailing beliefs, ideals, and values. Journalists appear to apply these fundamental forms and narratives as they compose their stories (→ Narrative News Story; News Story; Attitudes, Values, and Beliefs, Media Effects on).

By extension, myth is also useful for examining the social role of the news media (→ Popular Culture and the News Media). Because myth is an essential aspect of social life, the news media fulfill the roles and functions that myth-making institutions fulfilled in ancient societies. Journalists, like ancient storytellers, offer accounts of the origins of things. They tell stories that instruct and inform. They present portrayals of heroes and villains. They warn of disaster and disease. They offer dramas of order and disorder, of justice affirmed and justice denied. In doing so, the research suggests, journalists' stories fulfill the social role of myths (→ Journalists' Role Perception).

Study of news as myth has a rich tradition. Scholars of American studies in the mid-twentieth century, such as Henry Nash Smith and R. W. B. Lewis, made connections among myth and modern cultural forms (→ Popular Mythology). Writers such as Mircea Eliade, in *Myths, dreams and mysteries* (1960) and other works, extended such inquiries by linking myth to modern mass media narratives, including news. The French philosopher and writer → Roland Barthes explored the ideological implications of news as myth in *Mythologies* (1957), arguing that news, as myth, is political speech that attempts to make a particular ideology seem beyond question.

Based in part on these early, disparate works, researchers have adapted myth to study the role of journalists in society. For analytical purposes, the research might fall into two distinct but overlapping traditions. One emphasizes *social and cultural links between news and myth*. American → cultural studies have produced notable analyses of the capacity of news as myth to express culture. For example, James Carey (1975) understood the news story as a dramatic presentation of a shared reality. Reading a newspaper, in his evocative metaphor, is less like sending or gaining information and more like attending a mass, a setting where one learns nothing new but witnesses a particular view of the world portrayed and confirmed. The works of journalists are symbolic narratives that represent cultural values and beliefs one may affirm or contest. Researchers have used Carey's work to study the mythological role of journalism (Lule 2001).

A second tradition of research on news and myth, following Barthes, emphasizes *political and ideological dimensions of journalists' stories*. These scholars argue that news, like myth, has a primary function to create, shape, and sustain an ideological order. News and myth are inherently social and political narratives that support the status quo and maintain social order. Much of this work has come out of the British cultural studies tradition. Stuart Hall (1982), for example, found that news, like myth, draws from the prevailing codes of a culture, so that writers unknowingly maintain the dominant ideology. Just as the tellers of a myth may be unaware of the basic elements they use to generate their particular version, Hall says, so journalists may be unaware of the frameworks and ideological inventories that shape their stories.

Studies of news and myth continue in these research veins. Scholars have found, in particular, that the news reporting of terrorism is fertile ground for exploring news and myth (→ Mediated Terrorism). Overall, however, the research has remained isolated in pockets of cultural studies, American studies, political science, and sociology. Myth is understood in many different ways and the research has not yet produced an organizing framework to encompass these varied approaches (Coman 2005). Yet study of news as myth offers rich opportunities and can situate journalists in the long line of storytellers and scribes that have always informed human societies.

## **News Processing across the Life-Span**

*Barrie Gunter*

*University of Leicester*

The → news is like lifeblood to democratic societies. The information provided daily through the major mass media → television, → radio, → newspapers, and increasingly the → Internet – keeps citizens up to date with the latest political, economic, and social developments, world events, natural and man-made disasters, lives of famous public figures, scientific breakthroughs, and sports and weather. It serves to keep electorates apprised of the performance of their elected political representatives, helps people to cope with bad news, and also provides a sense of continuity in an increasingly varied media landscape and a sense of security even during times of extreme adversity (→ Journalism: Normative Theories).

### **FUNCTIONS OF THE NEWS**

The news media bring governments and politicians to account, expose scandals and antisocial behavior, and remind citizens of their own responsibilities within democratic societies (→ Investigative Reporting; Objectivity in Reporting). In non-democratic and developing regions of the world, the news media are used to maintain social order, but may also lead the people to question the actions and motives of their leaders

(→ Development Journalism). Where citizens display a lack of engagement in democratic processes, however, as evidenced for example by falling turn-outs in major political elections, attention often turns to the role and performance of the new media. On such occasions, questions may be raised about the failure of news media to capture the interest and attention of news consumers and to provide them with the types of information and a style of delivery that are palatable (Hargreaves & Thomas 2002).

In particular, questions are raised about whether the news media provide the news that the people want. Such questions, however, have been asked over many years. One observation – fueled by empirical evidence – is that news appetites vary across media consumers. The extent to which media audiences, as citizens or consumers, process news often displays a developmental pattern linked to age and experience. What adds to the complexity of news impact, though, is that while the appetite for news evolves with age, greater maturity eventually brings psychological deterioration, which results in reduced news-processing capacity (→ Developmental Communication). News is appreciated and consumed more by older members of the audience than by younger ones. At the same time, the ability to effectively process complex new information in single packages declines with age (see Gunter 1987).

An examination of news processing across the life-span can be articulated in terms of patterns of news consumption; relationships between news exposure and news and political awareness; and ability to recall information from specific news packages.

## NEWS CONSUMPTION ACROSS THE LIFE-SPAN

The main sources of news have consistently been identified as television, followed by newspapers, then radio (Towler 2003). Since 2000, the Internet has emerged as a key news source that rivals other news media in the extent to which it is endorsed (→ Internet News; Digital Media, History of). Such macro-level findings disguise variations in news consumption that occur with age. Children, teenagers, and young adults exhibit less interest in mainstream news provision than do middle-aged and older adults. For children, mainstream news on television and in newspapers tends to be articulated in a style that holds little appeal. Attempts to produce news broadcasts targeted at the younger audience, though, such as *Newsround* (produced by the BBC in the UK), have met with some success in both attracting young news audiences and creating an appetite for news with this age group.

What has also emerged is that young media consumers in the twenty-first century turn to newer information sources such as the Internet for their news. Evidence that audiences switched from major news media such as television over the final years of the twentieth century indicated that those aged 25 to 44 turned away more than did older adult news consumers, and more than did those aged 16 to 24 (Hargreaves & Thomas 2002). By way of compensation, though, younger news consumers outstrip older consumers in their use of the Internet and of interpersonal communications networks to find out about news. (→ News Audience; Exposure to Communication Content)

In general, therefore, it is an oversimplification of the research evidence to conclude that young people lack interest in the news and that news appetites only really emerge in later life. Young people do possess interest in the news but their consumption is driven by

the way in which the news is presented. The convenience of news sources in terms of when and where they are available holds paramount importance for the young consumer, who does not wish to be constrained by the fixed news formats and times of availability associated with traditional “old” news platforms such as mainstream television and newspapers.

### **NEWS AWARENESS**

The news media potentially bring a wealth of information into people’s homes. To what extent awareness of the issues and events that the media report upon is enhanced through news exposure is a debatable question. In the case of young media consumers, knowledge of recent news and of political affairs in general has consistently emerged as poorer than that found among older adults (→ Political Knowledge). While the news tends not to be named among children’s favorite content, they do begin to tune into news increasingly as they pass through their adolescent years. (Chaffee et al. 1973).

Even before they reach their teens, young people may display some elementary likes and dislikes in relation to prominent political figures, though it is not always clear whether these opinions have been rationalized or are simply imitated from influential adult role models in their immediate environment. It has long been known that the more children report consumption of televised news and newspapers, the greater their civic awareness (Conway et al. 1975; → Citizen Journalism).

Pre-teenage children who acknowledged an interest in the news, who watched it on television, and who discussed news with their friends tend to exhibit greater knowledge of current news issues and have a greater political awareness. Further, research that has tracked such links over time has indicated that news exposure tends to lead to political knowledge growth (Atkin & Gantz 1978). Children were found to pay attention to news about local conflicts in Northern Ireland. Greater reported exposure to news about such events was linked to greater awareness of them (Cairns 1984).

### **RECALL OF NEWS PACKAGES**

Another way in which news processing can be assessed is to investigate more directly how much information people remember from specific news packages. In this context, a news “package” could be a news broadcast or a printed news story. Researchers have used survey interviews and interventionist experiments (→ Experimental Design) to explore this type of news impact (→ News Processing and Retention).

Comparisons of news recall via different media among children, teenagers, and young adults have produced conflicting findings. Many early studies consistently reported that print presentations yielded better content recall scores than audiovisual or audio-only presentations (e.g., DeFleur et al. 1992). Later research found, in contrast, that television-style presentations could yield better news recall among children than printed versions of the same content, especially if the narrative in the televised versions occurred alongside supportive pictures (Gunter et al. 2000; Walma van der Molen & van der Voort 1997). The essential feature was that the pictures should contain the same basic propositional meaning as the text.

Research with American children aged 8 to 13 years found that their learning from a television news story presented to them in the classroom improved with age and was also associated with how much they enjoyed the item (Drew & Reeves 1980). A follow-up study found that 10–16-year-olds recalled news stories better if they were presented with film footage rather than simply with “talking head” formats (Drew & Reese 1984). Television news programs, such as *Channel One* in the USA, made especially for young people have been found to enhance their political knowledge (Brand & Greenberg 1992). Across the age-span, advancing years can eventually bring a decline in memory capacity that undermines news consumers’ ability to process complex news packages, especially if they have poor verbal abilities (Dixon et al. 1984).

With emerging new technology platforms that have opened up a wider array of new news sources and an increased diversity of news presentation styles, there is a need to discover more about the news processing demands of different news media. The growth in news sources and the greater convenience in terms of news availability of new news sources may be regarded as positive developments by those who believe it is important to find new ways of engaging the public interest in news. For older news consumers, however, some new formats may prove to present significant barriers to effective news processing.

## News Processing and Retention

*Vincent Price*

*University of Pennsylvania*

*Lauren Feldman*

*University of Pennsylvania*

Of the numerous functions the news media perform in contemporary society, perhaps none is so basic as their role in distributing information. In many democratic theories, broad and equitable distribution of timely → news is viewed as necessary for sound → public opinion and popular decision-making (→ Political Discourse). Students of journalism, mass communication, and politics have consequently invested considerable effort in studying the ways people process news stories and how much information – and what types of information – they retain as a result.

While democratic concerns animate much of the research in the area, however, its significance extends well beyond this particular normative framework. Because news processing and retention are centrally implicated in mass learning and → persuasion, they are critical in any social system, no matter the governing ideology of the state. Learning from the media is often conceptualized as an essential first step in many models of media effects.

### RESEARCH APPROACHES

#### Methods

In seeking to understand the ways people learn from the news, most studies adopt an information-processing perspective (→ Information Processing). By the “processing” of news, researchers generally refer to an interrelated series of cognitive and behavioral phenomena, including exposure to news stories, paying attention, encoding information, comprehending and interpreting its → meaning, rehearsing or elaborating content, and storing some information relevant to the stories in memory (→ Cognition; Exposure to News). By “retention,” researchers refer to the ability of audience members to keep stored

memories of the news over time, and to retrieve that information when necessary (→ Attending to the Mass Media; Comprehension; Memory, Message).

Studies of news processing and retention have employed a variety of methods, mainly relying upon either general population → surveys or laboratory experiments (→ Research Methods; Experiment, Laboratory). The former allow researchers to estimate basic relationships between self-reported news exposure, audience characteristics, and knowledge of the news (→ Political Knowledge), and to make generalizations about patterns in news retention among heterogeneous mass audiences. When coupled with assessments of news coverage (e.g., through content analysis), survey data also allow comparative assessments of learning about different types of stories. However, surveys are of limited value in examining cognitive processes. For examining the way people interpret and process news, then, researchers typically turn to experimental methods involving manipulation of exposure to stories that can be systematically varied along dimensions of theoretical interest, such as narrative structure, print, audio or visual characteristics, pacing, message complexity, and the like (→ Experimental Design). Laboratory studies also permit examination of message processing, sometimes employing physiological as well as self-report measures, and memory for particular story elements.

### Conceptual and Measurement Issues

Sound measurement of exposure and retention is central to the study of learning from the news. Surveys depend on self reports and thus face a variety of significant measurement challenges, which are especially pronounced with respect to assessing news exposure. Use of many mass media, particularly television (→ Television News), may be a low-salience affair and thus difficult for people to estimate and report. The exposure experience may also vary considerably across different media – newspapers, television, radio, or the Internet – rendering comparisons across outlets problematic. For example, relying on simple self-reports of exposure frequency, such as hours per day or days per week spent using various media, may underestimate the learning benefits of television news relative to newspaper reading, since the latter typically demands higher levels of attention. Taking into account both self-reported exposure and attention paid to news may thus produce “fairer” comparisons and appears to explain more variance in news knowledge (Chaffee & Schleuder 1986). Refinements in standard questions about news media exposure and attention have aided survey researchers considerably, although most acknowledge that surveys are limited by necessity to rather gross and indirect measures of news media use. One of the principal values of experimental methods, despite the potential loss of sample generalizability, is the reliable manipulation of exposure to particular news stories and some degree of control over the attention paid to those stories.

When researchers turn to measuring news *retention*, several options are available in either survey or experimental contexts. “Recognition” measures expose people to parts of a news story, for example a visual frame from a broadcast news item, asking for a report of whether they remember having seen it. “Free recall” measures simply ask for open-ended reports of information that was contained in a story, while “cued recall” offers some content-related stimuli to assist in information retrieval from memory.

Other measures aim to assess *comprehension* of a message by asking not for retrieval of discrete memories, but instead about the gist or meaning of a story. Because the interview or questionnaire is generally a verbal exchange, measures are most often aimed at retrieval of verbal information, though recognition measures incorporate visual memories as well. The particular manner in which knowledge is assessed is of critical importance when drawing inferences about learning from the news. In experimental studies, for instance, television news exposure produces different effects on free recall, cued recall, and recognition outcomes. Verbal knowledge tests may privilege certain groups, for example those who are better educated. Conventional approaches to measuring public affairs knowledge may also fail to reflect outcomes of online processing of news, whereby information processing results in updating evaluations and opinions, after which the information itself is discarded (Graber 2001).

## EMPIRICAL FINDINGS

Research indicates, as one would expect, that the amount of coverage given to a particular story in the news predicts the rate at which audience members are able to recognize and recall the story (Gunter 1987). However, the impact of news coverage varies considerably across different types of media outlets, across various kinds of news, and among different audience members. Price and Czilli (1996) found, for example, that domestic news is better remembered than foreign news among US audiences, and that stories involving identifiable persons (such as celebrities) are better remembered than other stories, particularly for those who are low in prior knowledge of public affairs. In general, studies have focused on *four main sets of factors* that influence news processing and retention: audience characteristics, differences among various news media; specific message features, and characteristics of news stories.

### Audience Characteristics

A number of studies have examined characteristics of audience members that facilitate or impede learning and retention of news (→ Audience Research). Among the strongest facilitators is *pre-existing knowledge* of general public affairs, which has been shown to be a consistent predictor of awareness and recall of specific news stories, indeed often a stronger predictor than news media exposure (Price & Zaller 1993). In some cases, survey researchers have failed to find any news media effects on learning after prior political knowledge and other variables are controlled. Knowledgeable people tend to be more engaged and attentive news consumers than their peers, and also have more developed → schemas for processing information contained in the news. There is some evidence that general knowledge may interact with the nature of news stories in predicting recall as well. Less knowledgeable members of the audience appear to be more strongly affected than their more knowledgeable peers by stories receiving large amounts of coverage, personality-based stories, and stories that have a domestic rather than international focus.

Learning from the news is associated with *motivated and active processing* of media content. Research in the → “uses and gratifications” tradition finds that people who use the news for surveillance or informational purposes have higher levels of political

knowledge and news recall than do those who report mainly entertainment-related or boredom-reduction uses of the news media. Surveillance appears to affect knowledge through increased attention to and elaboration of news content (Eveland 2001). However, motivated media use, while it facilitates learning, is not a necessary condition: There is also evidence for incidental learning from the news.

Because surveillance motivations and pre-existing knowledge tend to be higher among people of higher socio-economic status, “*knowledge gaps*” in the population are common. The knowledge-gap hypothesis, proposed in 1970 by Tichenor and colleagues, submits that when new information enters a social system, those who are advantaged by socio-economic status take up that information at a faster rate than those of lower status, widening gaps in knowledge (→ Knowledge Gap Effects). Measured relationships between media use and knowledge are consequently stronger for people with more education, and the knowledge gap appears most pronounced for stories disseminated through print media and the Internet. Knowledge gap effects, though common, may be diminished when those of lower socio-economic status are interested and motivated to follow the news (Kwak 1999) or when information is distributed primarily through more accessible channels such as television news.

### Differences among Media

A number of studies have compared *newspapers and television* as sources of public affairs knowledge. A sizable body of survey research, mostly conducted during political campaigns (→ Election Campaign Communication), indicates that newspaper reading is the superior predictor, with television news exposure appearing to have little predictive value (e.g., Robinson & Levy 1986). There are, however, some exceptions to this pattern. In particular, it appears that television news – aside from local news, which typically does not seem to contribute much to knowledge – performs on a par with newspapers when attention to news is considered along with exposure. Differences in the effect of newspaper and TV exposure are sometimes less evident in experimental research, but a series of experiments by Furnham and Gunter (e.g., 1989) find better recall following exposure to print than audiovisual channels.

With the growth of the → *Internet*, researchers have undertaken comparisons of learning from conventional print newspapers and online news (→ Internet News). The research is somewhat equivocal, but several experimental studies suggest that news recognition and recall are higher for print than for online news (Tewksbury & Althaus 2000), and survey research suggests only a minor role for Internet news use in political learning.

Beyond the mass media, *interpersonal channels* of information dissemination have also been examined. Discussing the news appears to improve learning outcomes, with surveys finding that self-reported frequency of conversation predicts knowledge about as well as or better than reported news media exposure. Studies of the interactive effects of media use and discussion have produced mixed effects, with some suggesting interpersonal discussion might weaken the effects of media use on knowledge, and others finding that frequent discussion enhances learning from news media (Scheufele 2002; → Two-Step Flow of Communication; Interpersonal Communication).

### Message Features

A number of studies of television news have demonstrated that *complex production formats* and complicated narratives may interfere with learning. These generally find that fast production pacing decreases recognition and recall, relative to slow or medium pacing, and that using a variety of audio and visual elements decreases story recall (e.g., Lang et al. 2003). Tabloid-style production features increase arousal and attention but do not necessarily improve levels of recognition or recall. Slower pacing, simple language, concrete imagery, matched audio and video, recapping strategies, and presenting stories in chronological order all tend to increase the accuracy of recall. Recent studies of Internet news also indicate that complex formats may produce confusion and interfere with learning. Interactive website features that permit nonlinear navigation across news stories, for instance, can increase confusion and result in reduced acquisition of factual knowledge.

The *interplay of audio and visual elements* of news stories has received significant research attention (→ Television News, Visual Components of). Findings suggest that the audio track typically dominates audience's understanding of audiovisual presentations and that redundancy of the audio and visual elements enhances learning (→ Dual Coding Theory). When stories are non-redundant, viewers attend to the video at the expense of the audio and comprehension suffers (Drew & Grimes 1987). There is mixed evidence regarding the relative advantage of talking-head formats and filmic or pictorial formats. Pictures can impair learning recall of concurrently spoken information, but enhance recall of information presented in talking-head lead-ins that preceded the pictures. Film has been found to enhance recall compared to a talking-head format; however, a varied presentation combining a talking head and film is better than a uniform presentation of either type (Brosius 1991).

### Story Characteristics

Often message features are dictated by the nature of new stories themselves. Some stories, for example those related to violence or disaster, naturally produce arousing and emotionally evocative material. Such materials influence viewers' processing of information, though not always in consistent ways. *Violent news* appears to increase recall relative to nonviolent news, although this may depend in part upon the viewer's gender (→ Violence as Media Content). While arousing content increases viewers' attention, it has mixed effects on recognition and recall. Some studies find that arousing television messages increase cued recall but decrease recognition (→ Excitation and Arousal); others find that arousing content increases recognition and free recall of news stories, but decreases cued recall (Grabe et al. 2003). Although visual materials in general may improve overall recall of story content, *emotionally evocative visual imagery* may lead to recall errors, likely because they narrow and focus viewers' attention (→ Emotion). Compelling negative imagery has also been found to reduce memory for the information that precedes it in a news story and to decrease long-term recall. The *type* of emotion induced by a visual image may also affect memory for news. Stories containing emotional images inducing an approach reaction, like anger, seem to be better remembered than those with emotional images evoking an avoidance reaction, like disgust (Newhagen 1998).

Story content may *interact* with formal message features in influencing processing and retention. When stories are focused on personalities, for example, more complex and extensive reports including redundant information appear to increase recognition, while event-centered news seems to be best conveyed using simple formats. When television stories are not particularly arousing, recognition and recall increase with faster production pacing, typical of tabloid-style production; when stories *are* arousing, on the other hand, faster pacing reduces both recognition and recall (Lang et al. 2003). The way in which news is framed, for example around human-interest elements, or conflict, or game or strategy aspects in the case of election news, also has consequences for audience processing and recall (→ Framing of the News). Cognitive responses generated in response to a news story tend to mirror the frame used in organizing that story, and there is some evidence that human-interest frames or strategic-campaign frames may result in lowered rates of recall relative to other types of news frames (e.g., Valkenburg et al. 1999).

The emergence of so-called → “*soft news*” outlets for candidate communication during the 1992 US presidential campaign – including late-night comedy, talk shows, and music television – attracted the attention of empirical researchers (→ Infotainment). Little evidence was found, however, to suggest that these alternative news sources produced much learning, either in the 1992 election or in the 1996 presidential elections. More recently, Baum (2003) found that soft news exposure predicted knowledge of information that was a primary focus of soft news coverage, although Prior (2003) found that a preference for infotainment did not predict knowledge measures, even when the latter reflected issues typically covered on such programs.

## News Production and Technology

*Siegfried Weischenberg*

*University of Hamburg*

*Clemens Matuschek*

*University of Hamburg*

The term “news production and technology” describes the process and the tools that are necessary for formatting and disseminating journalistic content to an audience. Communication always needs a medium – be it air, paper, or electricity – to travel from

producer to recipient, and the advance of technology has had a deep impact on forms of communication. Any kind of communication that goes beyond direct, local, interpersonal oral or visual interaction depends on a means of technology as a medium. The development of modern mass media, allowing journalists to reach dispersed, large audiences, is interrelated with technological innovations such as the invention of printing and electricity (→ Media History). Thus, production of media content is largely dependent on and shaped by technology, which in itself can be seen as a *necessary condition* for journalism as a profession and its economic as well as social and political relevance (→ Communication Technology and Democracy).

## HISTORY

The invention of movable type for book printing around 1450 by Johannes Gutenberg (1394?–1468) is usually seen as the advent of the age of modern mass communication – despite the fact that block printing and movable type had been used in Korea and China hundreds of years earlier (→ Printing, History of). However, Gutenberg’s invention laid the basis for the mass (re-)production of media content. The “Gutenberg Revolution” – an expression coined by media historians such as → Marshall McLuhan (1962) – marked the beginning of a new age. Besides flyers and pamphlets, the first periodical newspapers were established in Strasbourg and Augsburg at the beginning of the seventeenth century (→ Newspaper, History of). Printing was taken to the level of industrialization when Koenig developed a steam-powered high-speed cylinder printing press. The *London Times* was the first newspaper to be printed on it in 1814. Innovations in the field of printing, such as the rotary printing press (1863) and the Linotype typesetting machine (1886), allowed for even faster production – essential for up-to-date news media. More advanced layout became possible through the embedding of pictures and color. The introduction of personal computers in the 1970s caused yet another revolution. Today, digital newsrooms use desktop publishing (DTP) and computer-to-plate (CTP) technology, which has increased speed and quality dramatically and rendered many job profiles – such as typesetter – obsolete.

The invention of the electrical telegraph in the first half of the nineteenth century and the telephone in the second half paved the way for the rise of wire services and → news agencies (→ Telegraph, History of). Today, the global news flow has shifted from telegraphy to emails and the Internet.

Wireless transmission of signals became possible by the modulation of electromagnetic waves (→ Radio Technology). Guglielmo Marconi (1874–1937) is often referred to as the “father of radio” (Kleinstauber 2005), but many other scientists, such as Braun, Popov, and Tesla, contributed to the new monodirectional medium. From about 1920, private households were able to receive newly founded private and public radio stations, which broadcast not only news but also music.

It was only a relatively small step from radio broadcasting to television. Karl Ferdinand Braun (1850–1918) had built the first cathode ray tube as early as 1897, but the rise of television did not set in until after the end of World War II. Terrestrial television only allowed for a limited number of channels and was broadcast in black and white until the introduction of color TV in the 1950s and 1960s (→ Television Technology). Other

developments were stereo sound and videotext. In the 1980s, cable and satellite TV evolved. The transmission of signals via coaxial cable or the direct connection to a geostationary satellite dramatically increased the broadcasting volume and thus enabled the rise of private commercial channels.

Both radio and television broadcasting have long been taking place in analog mode. However, broadcasting has successively switched to digital since the 1980s for quality and capacity reasons – several digital signals can be transmitted on the frequency needed for a single analog one (→ Digital Media, History of). Today, all types of media are produced digitally, i.e., computer based. Content can easily be interchanged. Thus, the term “Age of Digitization” not only refers to the binary codes that computers are based on, but also to the convergence of media. The best examples are online media, which include aspects of all three previous types of media.

Online media represent the fourth and most recent category of media. Its infrastructure – the Internet – evolved from the ARPANET, a network of connected computers at research institutes and universities created by the US Department of Defense in 1969. Today, the network spans the whole world and consists of academic, business, domestic, and government networks, which themselves connect many single computers, which “communicate” through the standard Internet protocol (IP; → Internet, Technology of). The Internet provides hardware and space for the content of the world wide web – be it text documents, images, or multimedia – including the “classical” three media forms. With the evolution of the Internet, email has become one of the central channels of worldwide communication and fuels globalization. The end of the 1990s saw a process of Internet hype, which eventually led to the so-called dot-com bubble. Nevertheless, the availability of broadband connections (as opposed to slow dial-up modems) has led to yet another stage, known as “web 2.0,” in the twenty-first century.

## **RESEARCH AND THEORY**

Mass media and communication scientists have underestimated the relevance of research on media technology for decades. Especially in Europe, this field was left to the natural sciences while the social sciences focused on other factors as variables defining media content: political systems, economy, culture, etc. This perspective, known as the indeterministic view, models technology as a neutral element. The opposing deterministic view accepts technology as a decisive factor determining the shape of media content and thus the content itself. This view was supported by Canadian scholar Marshall McLuhan, who coined the expression “the medium is the message” (McLuhan 1967). Some communication scientists have tried to classify media technologies by the relation of senders and recipients, and thus describe their evolution stepwise from one-to-one communication (oral or written) to one-to-many (through printing or broadcasting) to many-to-many (the interactive world wide web) (Neverla 2005).

## **CURRENT AND FUTURE MEDIA PRODUCTION**

History shows that whenever new technologies become available, they are immediately implemented in the media production and dissemination process. In return, the

availability of new technologies spawns new genres and forms of media. For example, the development of photography and the possibility of including photos in the printing of newspapers allowed for the rise of yellow press or tabloid media (→ Tabloid Press; Yellow Journalism).

The production processes of today's media are defined by the technology they use. The use of computers in particular has led to a digital revolution, which has proved to be as relevant as the first printing of books. In the modern newsroom, a journalist controls everything – the electronic gathering of information (e.g., through an online news ticker), the text processing software, the layout, and the printing. In fact, a single computer can serve as an entire newsroom. Satellite modems allow foreign correspondents to produce and broadcast with almost no time delay from the most remote spots of the globe. Obviously, today's journalists need to know not only how to research and write stories, but also how to handle their electronic equipment.

In → television, the age of digitization brought a huge increase in the number of channels. This affects media economy as well as journalists' work: there is a huge difference between producing a full program as opposed to a niche channel, and pay TV is a relatively new economic model. Content production is affected on yet another level: modern digital cameras and camcorders are much easier to handle than their bulky predecessors and allow for a more "natural" feeling in TV content. The direct electronic transmission of the material allows broadcasting practically without time delay, both on air or online. Through digital editing, content can even be altered or generated from scratch. While this may serve a good purpose, e.g., for explaining complicated matters in animations or infographics, it creates ethical issues, which journalists and audiences have to be aware of – manipulation has always existed, but it has never been so easy.

There is no doubt that the world wide web has changed not only the media, but the world. Its success has been dependent on several technological factors. Even electronically stored content takes up space – server capacities have to be provided. This goes along with a certain connection speed, the software to run the network, technical resources in the hand of the recipient, and the knowledge to handle them. The fascination of the Internet stems from its decentralized network structure, its global reach, and its ability to adopt any known form of communication, from oral interaction (voice over IP) to content providing to text messaging to genuine news media in text, sound, and (moving) pictures. This integrative aspect leads to a convergence of formerly independent media types (→ Digitization and Media Convergence). Today's journalists have to be capable of cross-media content management and promotion – a factor that alters classical job models. Apart from the combination of media, the web offers new possibilities such as interactivity. Since technological barriers for access to the Internet have become relatively low (cheap equipment, usability of software, fast bandwidths, internet cafés), user-generated content plays an increasingly important role. The idea of citizen journalism had been made popular in the late 1980s and early 1990s, but its potential became clear when phenomena such as blogging (web-logging) emerged. This is even more important as the web not only spans the globe but is also accessible through wireless devices such as PDAs, mobile phones, and notebooks. Defining professional journalism becomes increasingly difficult. For example, online journalism calls for a certain organization of content through hyperlinks but at the same time easily links into non-journalistic spheres such as

advertising. Whether the “classical” media will eventually merge into one online medium – as debated at the beginning of the twenty-first century – will depend on the technology to come.

## **News Routines**

*Wilson Lowrey*

*University of Alabama*

News routines are repeated practices and forms that make it easier for journalists to accomplish tasks in an uncertain world while working within production constraints. The routines journalists employ serve functional ends for journalists, news organizations, and audiences. Routines also result in dysfunction.

All work relies on routines, but tasks become more routine in organizations that produce on a mass scale, that face little environmental uncertainty, and that do not seek innovation. Journalists face uncertainty, but predictable mass production is more important

than innovation for news organizations. To manage work and insure a flow of incoming information, news organizations have adopted factory-like practices and processes (Berkowitz 1997; → Organizational Communication).

*News routines emerged* where the organization and the social environment intersect, say journalism historians. The development of western democratic market societies and the rationalization of economic life in the 1800s led to the pursuit of wide audiences, increased scale of production, and larger news organizations (Schudson 2003). As staffs increased, management attempted to control production bureaucratically. Rules and new technologies facilitated control, as did professional routines such as balancing sources and writing in a neutral style, which serve organizational purposes (Berkowitz 1997). Rivalry with other occupations also prompted routinization. To differentiate itself from public relations, journalism embraced detached neutrality as a professional value, encouraging mechanized, impersonal processes (Schudson 2003; → Journalism, History of).

Routines persist because they are familiar and deeply naturalized. Change is difficult and risks undermining professional legitimacy, as publics and other institutions identify with, and even depend on, journalism's routine practices (Ryfe 2006).

Scholars depict these macro-social influences on journalism organizations as hierarchical models. Although the levels differ, all the models propose that influence grows from the individual communicator through the organizational and environmental (community, government) to the social and cultural (e.g., Shoemaker & Reese 1996). Higher levels constrain decision-making at lower levels and encourage routines. For example, using official sources reflects an organizational need for easily available information, but also reflects the power officials have to shape the community agenda.

Different routines across press systems exemplify the social-cultural level. The highly differentiated, mechanized structure of large British and US news organizations constrains individual journalists more than do German news organizations of similar size, which have more-redundant roles and less-formal processes (Esser 1998). Russian journalists differ by routinely including analysis in news stories, likely a consequence of their historical association with elite intelligentsia (Wu et al. 1996; → Journalists' Role Perception).

Other news routines are more consistent across cultures. One way journalists deal with the clash of organizational constraints and macro-social uncertainty is through *typification*. Because they cannot control the stream of real-world events, they reconstitute it (→ Phenomenology). They typify news into discrete categories such as hard vs. soft and spot vs. developing, thus gaining greater predictability of production. Typification eases work processes but may blind journalists and audiences to rival interpretations of issues (Tuchman 1978).

The routines of *objectivity* and *news beats* also cross cultures (Hafez 2002). Objectivity routines require balanced sources, personal detachment, factual reporting, and authoritative sources. These practices help news organizations gain wide audiences and avoid criticism, but may lead journalists to ignore non-official voices (→ Objectivity in Reporting; Balance; Bias in the News). Coverage routines establish *news beats* around officials with reliable supplies of information, decreasing uncertainty but letting officials shape the media agenda (Tuchman 1978; → News Sources).

Routines exist in *news production* as well. Journalists write hard news in inverted pyramid style, leading with content they think readers will find compelling (→ News; News Story; News Production and Technology), and page designers regularly anchor layouts with dominant photos (→ Newspaper, Visual Design of). Both routines reveal a marketing orientation, itself a consequence of higher-order economic factors.

Scholars find that routines aid journalists and news organizations in practical ways. Routines protect journalists by allowing individuals to assign the consequences of routinized decisions to a system. Shared conventions and routines also help journalists establish agreed-upon criteria for evaluating professional status (→ Professionalization of Journalism). Routinization aids managers in hiring. More widely accepted routines make the work of assessing job candidates easier, although perhaps leading to homogeneous candidate pools. Agreed-upon conventions, such as making the inside page less consequential than front-page stories, help journalists perform despite uncertainty about audience preferences. Conventions also ease audiences' interpretations of news but may delimit their understanding (Altheide & Snow 1979; → Media Logic; News Audience).

However, routines that free journalists from investing in repetitive tasks can also stifle their creative expression (Ettema & Whitney, 1982; → News Workers). If practices become too routine and easy for others, journalists' jurisdictional authority over news work may erode. Thus journalists tend to portray their work as highly uncertain, subject to the whims of the "world out there."

# News Sources

Lawrence Soley

Marquette University

Sources are the individuals that reporters interview to obtain information. It is on this information that news stories are based. Because no standard definition exists for what constitutes a source, documents such as accident reports, corporate press releases, and even other news media reports sometimes serve as sources, providing information that becomes part of, or the basis of, news stories (→ News).

Sources also originate news. They call reporters, send press releases, or provide documents in an attempt to disseminate their views through the mass media. By originating news stories and providing viewpoints to reporters, sources have a major influence on the framing of news stories (Sigal 1973; → Framing of the News).

## TYPES OF SOURCES

Studies have examined the types of sources used by reporters in countries such as New Zealand, Hong Kong, the United States, Great Britain, and Denmark, and the results show similar sourcing patterns in most cases. Individuals interviewed and identified in stories are called *on-the-record* sources. Reporters are expected to quote and identify these sources accurately. Reporters have been dismissed for falsifying sources' identities and quotations (Quill 2004).

Different types of news stories use different sources. With breaking news, which concerns unplanned events, reporters locate individuals who were involved in, or who observed, the event. The term *breaking news* originated in television and refers to *breaking into* other programs to report on an important, unfolding event. In breaking news about accidents, crimes, and disasters, sources may include victims, police, relatives, or bystanders, who give the reporter their understanding of the event. The use of multiple sources gives news stories a multidimensionality they would lack if they relied on a single source. Reporters can also turn to so-called *expert sources*, who provide insights not available on the scene (Albaek et al. 2003; Soley 1992). For example, in the case of natural disasters following a hurricane, reporters interview meteorologists, oceanographers, or other scientists who can explain the causes. Typically, breaking news stories use a wider variety of sources than do routine, beat news stories.

For *beat news*, reporters cover a particular topic, government branch, or industry they consider newsworthy (→ News Factors; News Values). Typical beats include city government, the legislature, political campaigns, and education. As beat reporters cover the issues, they develop and maintain relationships with sources of information, who usually have an appointment in a government agency, a trade association, a political campaign, or a public relations department of a corporation. These individuals are referred to as *routine sources*. A reporter depends on regular interaction with these sources, who in turn rely on the reporter to disseminate their views. The two have a reciprocal relationship that meets the needs of both (→ News Routines).

In the United States, for instance, routine sources are not typical of the general population, tending to come from businesses, the professions, and government. For example, studies

of routine sources quoted in news stories show that over half are government officials, and the next largest group is made up of spokespersons for businesses and industries (Berkowitz & Beach 1993; Brown et al. 1987; Comrie 1999). These sources tend to be higher-status white males with more influence than the average citizen, which is why news tends to reflect the viewpoints of those in power. Entrenched, powerful institutions are the focus of news stories, and reporters predominantly draw on sources from these institutions. Studies of news sources show that women, minorities, labor union representatives, and other less powerful groups are underrepresented compared to their numbers in the population (Freedman & Fico 2005; Manning 2001; Whitney et al. 1989).

Another reason why news sources in the United States tend to be white, male, higher-status, and more influential than the general population is that reporters tend to locate and interview sources who are like themselves. As sociologist Herbert Gans observed, journalists “find it easier to make contact with sources similar to them in class position, as well as race, age, and other characteristics” (1979, 125). This contention is born out by research showing, for example, that women reporters are more likely to use women as sources than are male journalists (Zeldes & Fico 2005).

Studies of reporters show that they are also college graduates, and as the prestige of the medium for which they work increases, so does the prestige of the college from which they took their degree. In the United States, Washington reporters, who represent many of the most prestigious national media, are predominantly men from the northeast who attended highly selective universities such as Columbia, which explains why their sources have similar characteristics. European journalists are demographically similar to US journalists, being male, white, and well educated (Manning 2001).

### IDENTIFICATION OF SOURCES

Journalists usually identify most sources by name and official position in news stories, but not always, particularly in Washington, DC, where officials prefer to speak with anonymity. When anonymous, the sources cannot be held responsible for their statements. Reporters may describe such anonymous sources in news stories as a “high-ranking official” or a “senior official.”

Many news media have *policies on using anonymous sources*. The Associated Press (AP) wire service “Statement of news values and principles” advocates using anonymous sources only when (1) the information provided by the source is fact rather than an opinion, (2) the information would not be available otherwise, and (3) the source is reliable and has direct access to the information. Even under these conditions, reporters “must get approval from their news managers before sending the story to the desk.”

These principles developed in the United States because presidential administrations anonymously provided reporters with information that later turned out to be false. This happened so much during the Nixon years that *Washington Post* editor Ben Bradlee temporarily banned reporters from using unnamed sources in their stories (Bagdikian 2005).

However, non-US media and journalism associations (→ Journalists: Professional Associations) have similar policies. The Finnish Union of Journalists’ “Guidelines for good journalistic practices” (2007) states that the “identity of a person providing confidential

information cannot be disclosed without permission,” but also warns that sources “must be treated critically,” particularly in controversial matters: “the information source might have personal interests or the intention to cause damage.”

### RULES FOR CONFIDENTIALITY

Anonymous sources provide reporters with information in several ways, including “off the record” and “on background,” although there is no accepted definition of these terms. In response, some news organizations have developed their own definitions, which they expect their reporters to use. According to the AP (2007), “off the record” means that the information “cannot be used for publication.” For *U.S. News & World Report* reporter Edward Pound, “off the record” means that he “can’t use it unless I can get it elsewhere” (Shepard 1994, 23). AP journalists can publish *background* information along with a description of the source’s position, but without the direct identity of the source. They can also publish *deep background* information, but without identifying the source in any way. Those providing deep background are sometimes called *confidential sources*.

Despite differing definitions, anonymous sources are generally unavoidable, but must be used cautiously, because the information they provide would simply not be available if they had to identify themselves. One reason for caution is that they cannot be held publicly accountable for what they say. The confidentiality agreement between the reporter and source can also interfere with the reporters’ responsibility to the public to provide as much information as possible. US courts, however, using *Branzburg v. Hayes* (408 U.S. 665, 1972) as precedent, can order reporters to break their confidentiality agreements (→ Source Protection).

In the early 2000s US courts displaced a lenient interpretation of *Branzburg*, asserting that they can now require journalists to divulge information about sources. In contrast to those of the United States, courts of other countries, including Australia and Great Britain, have concluded that the confidentiality of news sources is necessary to protect the public right of access to information about government.

### CONTROVERSIES ABOUT NEWS SOURCES

Several other controversies surround news sources, including reporters’ use of supposedly *expert sources*, who are not themselves participants in news events. The reporters interview these sources to gather either background information or predictions about the outcome of still-unfolding events. Research suggests that expert analysts, whom reporters refer to with such titles as Political Scientist, Scholar, or Economist, influence public opinion because journalists present them as well-informed, detached observers rather than as biased participants (Elliott & Sothirajah 1993; Page et al. 1987).

Although presented as unbiased experts, many such analysts are neither experts nor unbiased. Among many examples, one frequently quoted US expert, described as “the coauthor and editor of twelve books on government,” had actually coauthored only one book (Cooper & Soley 1990, 24).

Like Washington reporters, expert sources tend to be elites or have appointments at so-called *think tanks*. Think tanks are institutions whose primary purpose is to influence

public policy and public opinion. The London-based Royal Institute for International Affairs (now called Chatham House), the Tel Aviv-based Jaffee Center for Strategic Studies, and the Cairo-based Al-Ahram Center for Political and Strategic Studies house experts that reporters interview for stories in those countries.

Most think tanks have ideological orientations, but the news consumer usually remains unaware of their ideologies. For example, analysts from the Center for Strategic and International Studies think tank in Washington, DC, appeared frequently in interviews about the 1990s Gulf War (Kurtz 1991). The news reports, however, failed to reveal the conservative bent of the think tank and its sources of funding, which included the Pentagon and other government agencies, along with corporations holding large military contracts.

A related controversy surrounds the *revolving door* between sources and the news media, where the news media later hire influential sources to work as journalists. The practice raises the question whether partisan spokespersons can shed their party politics and become non-partisan journalists. In the United States, television hosts and reporters for ABC News and NBC News worked, and served as spokespersons, for government leaders (including US presidents and the partisan leadership of Congress) before being hired to work as journalists.

## News Story

*Siegfried Weischenberg*

*University of Hamburg*

*Thomas Birkner*

*University of Hamburg*

A *news story* is the standard format that journalists employ for producing the texts they publish in the media. In contrast to feature narratives or subjective reviews and editorials, the news story aims to give a direct, succinct, and fact-based account (→ Objectivity in Reporting), but instead the news story does political work and gives orientation in a complex world (Schudson 1982). This difference causes problems not only for storytellers but also for news researchers.

The news story is an invention that responded to commercial necessities. When news wire services emerged around the middle of the nineteenth century, they needed to sell the same stories to newspapers with competing party alignments (→ News Agencies). Neutral and brief factual stories were less likely to offend partisan sensibilities. The first news stories of this sort probably appeared from the New York Associated Press, forerunner of the Associated Press (AP), which served both Republican- and Democrat-leaning newspapers.

Since then news agencies such as Reuters and Agence France-Presse have influenced practices for news story writing (→ Standards of News). Many newspapers or agencies have their own stylebooks that guide the practice of news writing, including the best-known *AP Stylebook* (updated annually by the AP).

### ELEMENTS OF PRACTICE

Journalists consider themselves *news people*. Interviewing, note taking, and research are daily duties, whether they work in a television newsroom full time or for a small local newspaper freelance. Among the accidents, games, press conferences, scandals, and other incoming occurrences, they decide which are worth telling in a news story (Molotch & Lester 1974). From an idealistic point of view, journalism practice involves what reporters

and editors call “checking a story out” with a “nose for news.” They also come up with their own story ideas and initiate investigations (→ Investigative Reporting).

From their notebook, they try to tell an interesting story. The usual task is to produce a short, informative report, which itself limits the range of storytelling elements possible. Journalists have developed routines for checking and quoting sources and composing what editors consider a good news story (Mencher 1983).

One standard for the story is to begin with a summary *lead* sentence. Here the technical means of distribution may have constricted the roots of news story practice. Newspaper editors had always clipped stories from other sources to republish, but telegraphy formalized the sharing of news (Barnhurst & Nerone 2002). In the lore of journalism, putting the summary first was a safeguard in case the telegraph lines did not function correctly. The lead might have resulted from such organizational imperatives, but not all media scholars accept the popular explanation (Pöttker 2005).

Another standard is to choose the most important facts of a story. Other information then follows in descending order. Journalists display their analytical competence by answering the five Ws (and one H): *Who* did *What*, *Where*, *When*, and *Why* (and *How*)? The standard of presenting facts in priority order produces a form called the *inverted pyramid*. Journalism handbooks say the form allows editors to shorten stories quickly by cutting from the end of a text, following another organizational imperative to fit copy into limited space.

When producing a story, journalists keep in mind several reference groups, including editors, co-workers, outside sources, colleagues at other media, politicians, interest groups, friends, family members, and a generalized audience (Darnton 1975).

Journalists also adjust the news story to fit the intended medium. Different narrative structures and forms have emerged in print, broadcast, and interactive media. Journalists consider radio, for example, a fleeting medium consumed as a background, and so they write in short sentences and accept some repetition, especially for names and numbers. For newspapers, in contrast, journalists may write in a more elaborate style, but they tolerate less redundancy because they know the reader (unlike a radio listener) can consult the text a second time. Newspaper journalists write to accommodate pictures and graphics, and television journalists also integrate moving pictures with audio. Studies reveal a gap between pictures and text on television (Griffin 1992), with video images reverting to symbolic pictures such as politicians shaking hands.

Internet journalists work in a *multimedia* setting, which can combine elements of all previous media on the computer screen. Hypertext allows individual users to follow links to find background or related information online. The inverted pyramid model makes less sense in the online story, but research has not yet documented the impact of the Internet on the form and practice of the news story (Weischenberg 2001).

Specific topics of journalism emphasize different aspects of the news story. Sports journalists working live on TV or radio, for instance, narrate the play-by-play or chronicle of an event, but those reporting for print media tend to write a *next-day* story, with more explanation. Arts topics call for formats that integrate subjective judgments into otherwise fact-based reports about performances or events.

Writing the news story thus involves creating a text genre that follows standards (objectivity, summary leads, inverted pyramid, and the like), attends to different constituencies, and adapts to the medium and the topic at hand. Journalists consider the

resulting stories neutral and professional. News agencies see these qualities as desirable for attracting and retaining customers, especially small-town newspapers. The resulting journalism aims to focus mainly on information rather than interpretation.

## RESEARCH THEORY AND METHOD

The news story is one of the main objects of journalism and communication study. News stories are central to how news workers interact (→ Journalism: Group Dynamics), how the gatekeeper works (→ Gatekeeping), and how newsrooms function (→ News Routines), among other aspects of journalism practice. News stories are the product of news selection decisions (→ News Factors) and manifest news judgments (→ News Values). Most journalists do not reflect on these factors or values, but instead follow the routines that have become habit through the process of professional socialization.

A key issue for producing news stories is truth. Press freedom protects the media from direct influence of the state over the news they can offer the public (→ Freedom of the Press, Concept of). Walter Lippmann's book *Public opinion* (1991) made it clear that news and truth are not the same (→ Lippmann, Walter). The media present only those occurrences chosen according to established criteria, and how journalists reformat and present them depends on work routines. In the process, media workers construct realities, and their work matters to the degree that it influences public perceptions (→ Constructivism).

Because of that influence, journalists bear a responsibility toward society. The objectivity norm of professional journalism is an ideal to encourage journalists to minimize the gap between news and truth (Schudson 2001). They achieve a symbolic objectivity by following such routines as using neutral expressions, presenting opposing positions and actors, and making quotations from others distinct from their own voice or prose. These markers of objectivity lend authority to their output (Zelizer 1990).

A central element of journalism ethics is to draw a clear distinction between fact and fiction. A journalist writing a news story above all does not invent facts. A further, formal separation divides fact from opinion. Officially, opinion appears on pages and in locations designated for such expressions. The forms for presenting news stories thus reinforce the emphasis on information in the standard news story.

Since its emergence in the early twentieth century, critics have objected to *information journalism* as shallow, lacking in context, and omitting background information. In the US, a key moment of such criticism occurred during the McCarthy era of the 1950s, when journalists issued news stories that reported the statements of a powerful US congressman and the actions of the House Un-American Activities Committee he chaired, without expressing judgments against the resulting tyranny.

In reaction to such failures of the standard news story, US journalists have increasingly infused news stories with analysis and interpretation, and the resulting form has grown consistently longer (Barnhurst & Mutz 1997). During the last quarter of the twentieth century, cultural critics also engaged in a sustained critique of objectivity, and journalists began to abandon the term in favor of the phrase *fairness and balance*.

Another influence on the production of news stories is the rise of public relations (PR), which emerged along with twentieth-century mass media as corporations tried to influence public perceptions (→ Media Relations; Public Relations: Media Influence).

Journalists have little time to do thorough reporting, a limitation that PR practitioners use as an opening to provide information prepackaged to imitate the standard patterns of the news story. Although both spheres are interdependent, the balance between journalism and PR is constantly shifting. Journalists generally consider the influence of PR a growing, serious threat to their own independence and standing, which depend on audiences believing their news stories cover any corporation without favor.

Other commercial trends in the media have also influenced news story writing (→ Commercialization: Impact on Media Content; Commercialization of the Media). The founding and growth of private commercial TV stations in Europe threw into sharp relief a hybrid form of news, which combines information and entertainment and bridges the divide between serious and light media fare (→ Infotainment). Examples of new, mixed news stories combine public affairs reporting with other practices, such as public service or advocacy (→ Advocacy Journalism; Public Journalism). Hybrid news stories shift the practice of journalism toward production of so-called “news you can use.”

The news story today has to fulfill two functions at once: to maintain its close connection to reality and to appeal to the media recipient as an entertaining genre. Journalists call these the *hard* and *soft* news functions of stories, which may be fundamentally at odds. Not all occurrences can be entertaining, and so a core of hard stories remains for news storytellers to tell.

## News Values

*Hans Mathias Kepplinger*

*Johannes Gutenberg University of Mainz*

The composition of news in the mass media is shaped by a broad variety of causes – by the number and type of topical events, by the type of the media and the interests of their audiences, by professional routines and individual preferences of journalists, and by technical constraints and economic conditions (Shoemaker & Reese 1996; → Media Production and Content). Among these causes are the news values of → news factors. They are the basis of the theory of news values. This theory explains the selection of news for publication, and the prominence of news stories in newspapers and news programs, by professional criteria of news factors in news stories (aspects of events) and the news values of the news factors (selection criteria). In the theory of news values, non-professional influences like individual preferences of journalists, political leaning of news organizations, and pressures from their owners, advertisers, or other social forces are neglected. Therefore, it deals only with a small part of the whole process of newsmaking. The term “news factors” denotes characteristics of news reports, with respect to the events covered. The term “news values” denotes the relative impact of news factors on the processing of news stories by journalists. The term “newsworthiness” denotes the chances of news stories getting published and the prominence of their presentation.

### APPROACHES TO NEWS VALUES AND NEWSWORTHINESS

The term “news value” was introduced by → Walter Lippmann in 1922 (1961) to explain the newsworthiness of events. The theory of news values was developed by Östgaard (1965) and Galtung and Ruge (1965). Major theoretical and methodological contributions were made by Rosengren (1970, 1977), Schulz (1976), Staab (1990), and Shoemaker

(1996). The range of news value theory has been extended by Donsbach (1991) and Eilders (1997) to explain also the selection of news by newspaper readers, and by Eilders and Wirth (1999) to examine the retention of news. Kepplinger has proposed and tested a two-component theory (Kepplinger & Ehlig 2006). Based on it, the newsworthiness of news stories can be calculated, and the predictions compared with empirical findings. Different authors have based their theory of news values on partly different assumptions. Some authors (such as Östgaard, Galtung & Ruge, and Schulz) derive their theories from assumptions about the complexity of reality and the necessity of gaining attention for parts of it. Shoemaker's theory is derived from biological and cultural conditions for the survival of societies, while Rosengren's theory is derived from – among other reasons – the economic relevance of the source of information on foreign countries to its receivers. Most authors do not explain the selection of news by (among other reasons) the reality covered (e.g., Östgaard, Galtung & Ruge, Schulz, Shoemaker, Eilders); some insist that sufficient explanations require some information about reality (e.g., Rosengren and Staab) (→ Extra-Media Data). While most authors neglect the question of whether the mass media present an adequate (“objective”) picture of reality, Galtung and Ruge explicitly want to explain the (according to the authors) biased coverage of western media about developing countries (→ Bias in the News; Objectivity in Reporting). Some authors especially deal with foreign news (e.g., Östgaard, Galtung & Ruge, and Rosengren); others include foreign and domestic news (e.g., Schulz, Staab, Donsbach, Shoemaker, and Eilders).

The publications of Galtung and Ruge, Rosengren, and Schulz initiated an intensive discussion about the theoretical and methodological role of real-world indicators, in which two related questions were mixed: “How can we explain the selection and presentation of news?” and “Do the mass media present an objective picture of reality?” In this discourse, two meanings of the term “objectivity” have been used – objectivity in the epistemological sense of knowledge without preconditions, and objectivity in the methodological sense of reliability of information. The discourse is closely related to the impact of media coverage on the perception of reality and related behavior (→ Media Effects; Reality and Media Reality).

## **TWO-COMPONENT THEORY OF NEWS SELECTION**

All nonrandom decisions to select objects are based upon at least two conditions: characteristics of objects to be selected and selection criteria (two-component theory). If decision-makers do not employ any selection criteria or if there are no characteristics that distinguish the objects selected, only random selection is possible. Some news factors might be more relevant for some media outlets than for others. For example, the news factors “physical damage” and “prominence” may have higher news values for tabloids than for quality papers. For quality papers, the news factors “relevance” and “status” may have higher news values than for tabloids (→ Quality Press; Tabloid Press). Therefore, the same news factor can have different news values for journalists working for different media outlets. News factors given in a news story can be identified by experts or by quantitative content analysis, and this has often been done by numerous researchers (→ Content Analysis, Quantitative). News values of news factors – that is, the relative influence of a news factor on the newsworthiness for certain media outlets – could be

identified in representative surveys of news people responsible for decision-making in newsrooms, but this has never been done. News values of news factors have been identified in an experiment with journalism students, however (Kepplinger & Ehmig 2006).

### **MEASURING THE INFLUENCE OF NEWS FACTORS ON THE NEWSWORTHINESS OF NEWS**

To test the influence of news factors on the newsworthiness of news, five research designs have been applied. First, content analyses of media output were conducted (Galtung & Ruge 1965; Schulz 1976; Staab 1990; Shoemaker & Cohen 2006). Significant correlations between the prominence of news (space, time, and placement) and either single news factors in the articles or complex indices representing them are interpreted as evidence for the influence of news factors on news decisions. In this case, it cannot be excluded that news stories not published have more news factors than news stories published. It is also possible, for unknown reasons, that long articles necessarily include more news factors. Therefore, the number of news factors might not be a cause but a consequence of the long articles. In addition, some news factors in a news story might be the consequence of enhancing a news story to improve its newsworthiness.

Second, comparisons of real-world indicators with news about indicated events were undertaken. Using this design, one can control the influence of real-world factors on correlations between the prominence of news and news factors. For example, a high proportion of news about politics in developing countries dealing with top leaders might not indicate a strong influence of the news factor “elite people,” but reflect a typical pattern of policy-making in these countries. Therefore, Rosengren (1970, 1977) has proposed the use of extra-media data, specified the conditions which these data must fulfill, and applied his approach to empirical research. Intra- and extra-media data are especially useful when the stability or change of news values over a longer period of time is to be researched (Best 2000). But because of the lack of sufficient data, they can be applied only to some topics.

Third, with experimental studies and surveys, tests are done with news stories in which news factors are systematically varied (→ Experiment, Laboratory). Subjects rank the news stories according to their newsworthiness. The relevance of individual news factors in comparison to combinations of news factors can be calculated (Buckalew 1969/1970). Results allow a valid test of the news value theory. Because of the small number of subjects and the artificial nature of the news stories tested, the results of these studies cannot be generalized.

Fourth, input–output studies were conducted. Based on the input available in newsrooms, the comparison of news factors in news discarded from the pool with those accepted for inclusion in the news coverage indicates the relevance of news factors for decisions made (Buckalew 1969/1970; Kolmer 2000). The design offers valid tests of the news value theory, but does not allow precise identification of the relative impact of single news factors, because the type and combination of news factors cannot be manipulated.

Fifth, predicted and measured newsworthiness were compared. Using regression analysis, the newsworthiness of news stories can be predicted on the basis of information

on news factors included in news stories and the news values of news factors measured in advance. Predicted newsworthiness of news reports as indicated by their prominence (length, placement) can be compared with their empirically measured newsworthiness (Kepplinger & Ehmig 2006). The design has similar advantages and disadvantages to the one mentioned above.

## RESEARCH ISSUES

After several decades of research in news value theory, several basic questions are still open. First, do news factors have different news values for different types of media outlets, for example street sold papers and national quality papers; commercial TV stations and public broadcast stations, etc.? This can be answered by determining correlations between news factors and prominence of news calculated for different types of media. Because of the limited evidence of this design, a definite answer cannot be given.

Second, do news factors have different news values in different countries or – as Galtung and Ruge (1965) have speculated – in different cultures? There are hints on similarities as well as on differences (Shoemaker & Cohen 2006), but for the reasons mentioned above there is no clear evidence.

Third, are news values of news factors constant or do they change in the course of time? Quantitative studies in the news coverage over several decades (Westerstahl & Johansson 1994) and several centuries (Wilke 1984) indicate that the relevance of at least some news factors has changed. For example, in foreign news of the Swedish press from 1912 to 1972, in some periods the news factor “negativism” explains more than twice as much variance as in others (→ Negativity). In addition, news on spectacular events increases the news value of news factors (→ Crisis Communication; Disasters and Communication). Therefore, after so-called “key events,” similar but relatively unimportant events become very newsworthy (Kepplinger & Habermeier 1995).

Fourth, are news values of news factors independent of the available input of news stories? So far, news factors have been counted and their intensity added, assuming that the news values of news factors do not depend on the competition between news stories. This assumption most likely does not hold. Instead, there is strong evidence from experimental studies that the news value of a news factor given in a news report decreases if the same news factor is given in a competing news story with higher intensity (e.g., more victims in an accident). To put it differently: the news values of news factors (and the newsworthiness of news reports) depend on the competition between the available inputs.

Fifth, are news values of news factors independent of the events or topics covered? Most authors who apply content analysis to research the relevance of news factors code the topics or the type of events covered (accidents, crime, unemployment etc.), rather than just the news factors of news stories. But when the relevance of news factors is analyzed, the topics of the news are rarely controlled. Nevertheless, there is clear experimental evidence of correlations between the news values of some news factors and some types of events. For example, in news reports on train accidents, the news factor “damage” has a high news value, even if only little damage has been reported (Kepplinger & Ehmig 2006).

Sixth, can news values of news factors always be regarded as causes of the newsworthiness of news reports? Nearly all authors apply causal theory to the interpretation of correlations between news factors and newsworthiness. As Staab (1990) has demonstrated, this interpretation is questionable, because newsmakers might intentionally add news factors to their news stories to make them more newsworthy. For example, when they cover an accident they might mention an uninvolved, distant, but prominent relative of a victim. In this case, the news factor “prominence” would not be a cause of the newsworthiness of the news report but a means to make the story newsworthy. To put it differently, the news factor would be a functional prerequisite of the report’s newsworthiness and we would have to add to the causal a functional theory (→ Functional Analysis). If this is true, a paradox exists: the use of news factors as means by journalists requires a functional explanation. But their attempts to increase the newsworthiness by the inclusion of additional news factors is only successful when the causal theory is correct; that is, when the included news factor actually has the impact on newsworthiness which it is supposed to have.

Seventh, what is the relationship between the events covered, news stories about events, and news factors included in these news stories? Here, several important questions come into play: How do mere occurrences become events and how does an event become a news story (Fishman 1980)? Which parts of occurrences belong to an event? Does a statement by a top official (news factor “elite people”) belong to an air crash or are these two events? What influence does the definition of an event have on the inclusion or exclusion of news factors? Obviously, the inclusion of the statement (news factor “elite person”), that is, a broad definition of the event “air crash,” increases the number of news factors and thus the newsworthiness of the news report. If this is correct, the news factor “elite person” is not an independent but an intervening variable (Staab 1990). From this, one can conclude that news value theory only provides a comprehensive explanation of the selection and presentation of news if information on reality is covered or the activities in the newsroom are taken into consideration. Therefore, it is not an alternative but a supplement to other theories of news selection.

## News Workers

*James S. Ettema*

*Northwestern University*

News workers are those engaged in the production of the written, visual, or audio texts designated as news and information appearing in print media and on broadcast and cable television, radio, and the Internet. These workers assign, report, research, write, and edit reports as well as produce and assemble visual images and the graphic forms for news and information. News workers also include senior editors, news directors, and others who manage these functions (→ News; News Routines; News Story).

As an occupational category, news work does not usually include those engaged in any manufacturing, distribution, or advertising functions (such as press operators, broadcast engineers, or sales representatives). Although larger than that of journalist, the category includes only a small fraction of the workforce in communication industries (→ News Production and Technology). The *United States*, for example, had about 1.5 million workers in those industries (including telephony) at the turn of the twenty-first century. By one estimate, however, fewer than 120,000 were full-time editorial workers in mainstream media, about 50 percent in daily newspapers and somewhat less than 20 percent in television news. In *China*, by contrast, full-time editorial workers numbered about 87,000, distributed across the media in similar percentages. By comparison, approximately 30,000 people are so employed in *Germany* and 15,000 in the United Kingdom (Weaver 1998). Clearly news workers have a social and political importance disproportionate to their small numbers relative to the whole workforce.

The tasks of news workers as well as the differentiation of news work from other communication-related occupations, like most work since the beginning of the Industrial Revolution in the late eighteenth century, reflects an evolving *division of labor* (Hardt & Brennan 1995). The occupation of printer evolved into that of newspaper editor-publisher, with the tasks of information gathering folded into the day's work (→ Journalism, History of). With expanding commerce, increasing literacy, and developing print technology in the nineteenth century, these tasks divided as newspapers grew in size and circulation (→ Information and Communication Technology, Development of). To meet the growing need for capital, publishers became financiers while editors became managers of content production. With the arrival of the telephone and the typewriter, the production of news stories separated, at least for a time, into reporting, i.e., gathering information, and rewriting that information into story form. Through the twentieth century, reporting became more specialized as the *beat system* emerged to engage a more complex social and political order. In broadcasting, editors evolved into news directors and reporters into producers and correspondents. But with the emergence of independent journalism on the Internet, these functions sometimes merged once again (→ Journalists' Role Perception).

As in other occupations, the differentiation of news work accompanied an increased *routinization of its tasks*. For journalists whose job is to quickly generate news of broad public interest, these routines are more intellectual than mechanical. The summary lead (or lede) emerged late in the nineteenth century along with the emphasis on the 5Ws formula – the most basic elements of contemporary news stories: who, what, when, where, and why (or how) – as essential features of news. In the early twentieth century, these practices along with others, such as reporting alternative positions on controversial issues and citing official sources (→ News Sources), converged into the now globally ascendant and much criticized conventions of journalistic objectivity (→ Objectivity in Reporting). While granting news workers some autonomy to deal with situations that deviate from the completely routine, news organizations retain substantial control of these workers through the inculcation of occupational norms that promote efficient news production. Journalists claim professional status based on routine capabilities (→ Professionalization of Journalism), including accuracy, meeting deadlines, presentation style, and shared news values, noted an observer of journalism in the United Kingdom (Elliot 1977).

These competencies serve organizational purposes as well, and so professional status is as valued by executives as by workers. A study of television newsrooms, for example, found news workers consumed with a competitive ethos in which *not getting beaten* by the competition is the basic measure of performance. This ethos gives news workers a standard of accomplishment, but also serves organizational interests in competing for ratings (Ehrlich 1995).

The features of professions (such as law or medicine) attributable to journalism – command of specialized knowledge, commitment to performance standards, and the like – are also organizational strategies for accomplishing the work at hand (→ Organizational Communication). This understanding renders suspect any claims for news work as one of the professions. Under these circumstances, unionization of news workers has a long history and is now common around the world (→ Labor Unions in the Media). This is not to say, however, that news workers are indifferent to the call of public service, but their conception of it varies around the world. Surveys indicate, for example, that large majorities of journalists in the United Kingdom (88 percent) and United States (67 percent) rate investigating the claims of government (→ Investigative Reporting) as important to their mission (Weaver 1998). Journalists in China, although spared that question, did report that explaining government regulations and party policies was important.

Such differences in news workers' conceptions of their socio-political role do not map neatly onto cultural or political differences, however. American journalists did not rate their role as adversary to business nearly as highly as did their British counterparts (14 versus 45 percent), who in turn rated it less highly than did Brazilian journalists (53 percent). The most common element in the self-conceptions of news workers around the globe is simply the importance of getting timely information to the public. Even after two centuries of constant social, technological, and organizational change, timeliness remains the core definition of news work (→ News Values).

# Newscast

Andrew Hoskins

University of Warwick

The newscast has anchored broadcast media schedules since their invention and has delivered mundane and momentous news and information daily from near and far, entwining itself with society, culture, and the politics of the day. Synonymous with the great conflicts and crises of mediated history – particularly US-centered history – the televisual nightly newscast has embedded itself into the narrative of nations (and even, at times, their conscience), connecting an apparently simultaneous, unified, and collective audience (→ Television: Social History).

## CHANGING SIGNIFICANCE OF THE NEWSCAST

For instance, the long US military involvement in Vietnam became known as “the living-room war” because this was where the consciousness of the nation was deemed to reside. Partly, it was the arbiters of late twentieth-century mediated events, and notably network television’s heyday – the news anchors – that provided daily continuity, ritual, and reassurance to millions of viewers across the States, helping to contain and negotiate a way forward through even the most catastrophic and anxiety-provoking news. The nightly news format, its success and potential power, epitomized in the Oscar-laden 1976 movie *Network*, became a global format, mimicked in countries around the world.

However, the mid-1990s appeared to mark a shift and a *decline of the television evening newscast* as a national investment of discrete viewing time in a shared space and time – that of the living-room. The centrality of the newscast and its pivot – the news anchor (→ Celebrity Journalists) – has appeared to be under threat in relation to massively increased competition and transformations in the very architecture of news gathering and dissemination. For instance, the rapid departure of the leading presenters of the period, with, e.g., the retirement of NBC’s Tom Brokaw in 2004 and CBS’s Dan Rather in 2005, and the death of ABC’s Peter Jennings in 2005, appeared to mark a *shift to a new news order*. What then are the newscast’s prospects in the apparently fragmenting news cultures of the twenty-first century?

Wholesale deregulation, the technological transformations of the digital era (→ Digital Media, History of), and the subsequent mass proliferation of news providers and news channels (→ Newscast, 24-Hour) have transformed the news landscape into a patchwork of interconnected, mobile, and colliding discourses. The constancy and ubiquity of television and online news in particular has led to some commentators characterizing its presence as “ambient.” For instance, television screens (and audiences) are sometimes concentrated but sometimes scattered throughout private and public spaces, including in airport lounges, bars, and railway stations (McCarthy 2001), not to mention reception areas of company buildings, waiting rooms, and a whole variety of transport: planes, coaches, taxis, etc. Hargreaves and Thomas (2002, 44) define “ambient news” as “like the air we breathe, taken for granted rather than struggled for.” More usefully, Cottle (2006, 51) situates news in his

mapping of a complex “new media ecology” of “public sphere(s) and public screens.” Similarly, audiences for news and other programming have become increasingly “diffused” (Abercrombie and Longhurst 1998) as they both consume and apparently constitute the new → media ecology through the “red button,” → citizen journalism, and Web 2.0.

### PECULIARITIES OF THE NEWSCAST

However, despite the heralding of the portability and availability of the tools of news production and the apparent blurring of the distinction between producer and consumer, mainstream national news media and public service television channels in the UK remain the primary source of news for the majority (Gillespie et al. 2007). Furthermore, the evening newscast (especially in the US and UK) still exerts significant presence in the mainstream television schedules, and contributes the reassuring familiarity of a constant view of catastrophic and disturbing events. One can go further and state that the globalization of news formats has tended to assert a dominant and recognizable frame through which the world is routinely represented to us on television.

For some, this is significantly a matter of *presentational style*, or what Caldwell (1995) identifies as television’s self-aware display of exhibitionism, part of its “televisuality.” For instance, on-screen brevity and movement have become the predominant framing devices as television news has become a concatenation of the tabloid front page headline and byline, and a busy computer desktop.

Despite the emergence of televisuality as a defining feature of the newscast at the turn of the century, the significance of → broadcast talk in our more intensely visual news culture should not be underestimated. For instance, a key dynamic in the construction of news is found in its “*rhetorical structure*,” notably, “a patterned way in which language comes to be used; once used, referred to; and when referred to, remembered and drawn upon as part of what ‘everyone knows’” (Schudson 1990, 118). It is unsurprising then that studies of media discourses have made claims as to the discourses’ “circulation” or to their being a “circuit” (Miller et al. 1997), their self-referentiality or “metacommunication” (Esser et al. 2001), and their heavy reliance upon repetition and archival use (→ Discourse Analysis; Collective Memory and the Media).

Among this fluidity and connectivity, the separation of texts from audiences in the study of the media is widely recognized as highly problematic (→ Audience Research), as Allan (2004), for instance, recognizes in his rejection of the model of a “media/society dichotomy.” Instead, television discourse is partly contingent on the context of its production, which may also exist simultaneously with the context of its broadcast. The temporal and spatial context and content of talk, i.e., its “embeddedness,” are more than ever defining characteristics of mediated discourse in the new media ecology.

### RESEARCH DIRECTIONS

So the transformations in the media and news landscapes require transformations in the theoretical and empirical approaches. Unfortunately, in the same way that the nightly newscast is associated with a *mythical living-room era* of collective reception and its

“effects,” television news is associated with a golden age of content analysis. In the UK, for example, some of the pioneering content analysis was undertaken by the Glasgow University Media Group in the 1970s, notably investigating evidence of the ideological bias of broadcasters in covering industrial and economic affairs, as published in the group’s acclaimed *Bad news* (1976). Of course the Glasgow University Media Unit, as it is today, has moved on, and their latest work examines TV news and public understanding of the Israeli–Palestinian conflict.

However, the principle upon which a great deal of content analysis (→ Content Analysis, Qualitative) over the years has been based is that of an ideal “systematic” analysis, notably applied to a comprehensive and somehow exclusive corpus of news programs or data. With only three UK television channels in the UK in the mid-1970s, one can see the relative appeal and validity of this task at that time. However, there is a long tail to this legacy that appears surprisingly in vogue in US communication studies, for example. Indeed, conventional content analysis approaches tend to focus upon what words or images are present in media and how these cluster together, and then to attempt to produce “systematic” analyses and comparisons, and to make inferences from this positive data. Instead, the claims generated by such systematic analyses appear increasingly out of touch with the new media ecology characterized by mediated conditions of connectivity, saturation, and immediacy (Hoskins & O’Loughlin 2007, forthcoming).

Some commentators go further in defining the temporal, spatial, and discursive relations of news with its environment. Cottle (2006), in relation to conflict, for instance, claims that news is “mediatized,” with the media constitutive of events so that the events cannot be considered to exist without their media dimension. And Hoskins and O’Loughlin (2007), drawing upon Goffman (1972), argue that ontologically speaking there is an *interaction order* composed both of what appears in news media and of what happens beyond the media text – “out there” in the world. What happens on-screen is inseparable from off-screen events, but more and more it is the case that off-screen events become inseparable from media representations of those events.

At the same time, there is an increasingly *interdisciplinary body of work* that takes media discourse (broadcast talk, image, sound) as central in developing a critical understanding of the construction of news, the shaping of its agendas, and its local, national, and global influences. These developments have been driven by (socio)linguistics (e.g., Fairclough 1995; Clayman and Heritage 2002), ethnomethodology (e.g., Jalbert 1999), and the significant growth in media and cultural studies and in the academic study of journalism (e.g., Zelizer 2004; Allan 2005). It is clear that the study of the newscast and emerging news cultures requires a collaborative and multidisciplinary approach to begin to become adequate to the dynamics of our new media ecology. One such innovation is the integrated multidisciplinary media analysis (IMMA) approach, which I have hinted at here and which is outlined in Gillespie et al. (2007).

## **Newscast, 24-Hour**

*Andrew Hoskins*

*University of Warwick*

The rise of 24-hour news programming, associated with the shift from the electronic news gathering (ENG) of the 1970s to the satellite news gathering (SNG) of the 1980s, marks a shift in the temporal and spatial connectivity of the globe. The continuousness and sheer expanse of 24/7 news has driven an appetite for immediacy, proximity, and

simultaneity, so that today these are the dominant modes of television news programs, defining how the world is represented to millions and shaping news agendas and allegedly the events being represented (→ Television News).

The so-called “CNN effect” or “phenomenon” is the idea that television news shapes the behavior of influential, sometimes disparate, and especially political actors in events that are being covered as they happen “live” in “real time” (→ CNN). This term is synonymous with CNN’s name-making coverage of the 1991 Gulf War. With the war in the living room, the accountability of politicians, diplomats, military strategists, and journalists was subjected to the unblinking eye of the television camera, as the relentless if simulated intimacy and urgency of the coverage created the first significant global TV audience. For all its vacuous images, this was a new kind of present history and it was an emotionally involving experience. The war had a continuous presence in everyday lives – an experience usually localized to actual conflict areas became a global phenomenon (→ War Correspondents).

Today, the 1991 Gulf War seems barely remarkable in the context of the inexorable rise of the so-called “media event,” to the extent that it has become almost a standard frame of the conflicts and catastrophes that appear to have dominated the opening of the twenty-first century on television. In less connected and less frenetic times, the media event stood out as marking a momentous and sometimes catastrophic occurrence, so that the routine schedules of television channels would be interrupted to signify “news” worthy of intensive, extensive, and continuous attention. Media events are the ultimate live frame, for they are based on a particular (mostly televisual) discourse that at one level at least reflexively situates the medium and its participants in the production of an unfolding event. The term is often related to the work of Dayan and Katz (1992), who identify *three sub-divisions of media events*, namely, “contests,” “conquests,” and “coronations.” Their focus is on the narrative of the “festive viewing” of television and the celebratory and ceremonial unifying of audiences on such occasions (→ Media Events and Pseudo-Events).

Since the publication of Dyan and Katz’s influential work, however, the media event has become devalued in two key ways. First, 24-hour-news networks are part of a hypermedia environment that tracks events continuously; there is no “time out.” The very term “rolling news” is something of a paradox, not only because of the segmented and repetitive nature of “rolling” news, but also because of the presumption of there being sufficient “news” to fill such an expanse of time. Second, television news coverage has become permeated by a series of stories connected through a discourse around terrorism and the so-called “war on terror.” Twenty-four-hour networks may on the one hand bring an apparently more attuned connection with local and global events, but on the other they bring a pervasive sense of insecurity and even fear.

The 24-hour newscast phenomenon acquired new global spaces through the advances of Rupert Murdoch’s → News Corporation into Asia with his takeover of STAR (Satellite Television for the Asian Region) in the mid-1990s (→ Satellite Television). Elsewhere, the perceived international influence of the Qatar-based Al Jazeera’s coverage of 9/11 and the war on terror (e.g., its broadcast of audio and video messages from Al-Qaeda leaders, picked up by western channels) provoked the establishment of other pan-Arab satellite channels. For instance, it was no coincidence that the news channel Al Arabia was

launched in March 2003 at the beginning of the Iraq war. Furthermore, the launch of the English-language Al Jazeera International in 2007 demonstrates a demand for ever-greater connectivity from broadcasters attempting to shape global news agendas (→ Arab Satellite TV News).

However, a deep or enduring impact of the satiation of global television news remains to be seen. From a viewer perspective, at least, what matters is not so much whether one spends the day at home with the → BBC's *News 24* or CNN as background noise, but that cumulatively, the “network news society” delivers a persistent and highly unsettling contiguity with conflict and catastrophe. Yet this very routinization of representation is also said to have a paradoxical effect in numbing responses. For instance, the media event of the 2003 Iraq war soon converted into habitual coverage of the inconclusiveness of its aftermath (more reminiscent of the coverage of the period of the Vietnam War).

The built-in obsolescence of all television news always ultimately extinguishes the intensity of the media event, and reduces it to a serial narrative of the everyday and the familiar, as with its recapitulative exhausting of the events of 9/11. So 24-hour television “modulates” between chasing immediacy, instantaneity, and novelty as primary news values, and the reduction of events into familiar, manageable, and “safe” narratives, through its compulsion to repeat and its reliance on its ever-accumulating archive (Hoskins & O'Loughlin 2007). Twenty-four-hour TV, then, is a significant node of the global connectedness of late modern society that both amplifies and assuages the experience of events continuously represented as “news.”

## **Newspaper**

*Salma I. Ghanem*

*University of Texas-Pan American*

Known as the chroniclers of daily life, newspapers assemble large amounts of information in the form of words, pictures, and graphics printed on lightweight, inexpensive paper stock for the purpose of informing and entertaining the public. Newspapers are portable, inexpensive, and printed either daily or weekly in tabloid or broadsheet format. Estimates

indicate that there are approximately 60,000 newspapers in the world and about one in eight are dailies. The daily operation of a newspaper varies with the size of the paper, but most papers consist of five departments: advertising, editorial, production, circulation, and business. Newspaper revenue comes from sales and advertising. According to the *International Journal of Newspaper Technology* (Chisholm 2004), over 80 percent of revenue in the United States comes from advertising, while in the United Kingdom the figure is over 60 percent, and in Germany over 55 percent (→ Advertising; Cost and Revenue Structures in the Media). Because revenue is linked to circulation, the commercial potential of newspapers is constrained by the size and economic prosperity of their markets. Newspapers account for the biggest segments of the publishing world, with 40 percent of the industry's revenue.

## HISTORY AND CONTENT

Newspapers have existed in one form or another since 100 BCE, and their content is linked to their historical development. Newspapers became more complex over time. The Roman government issued the *Acta Diurna* around 59 BCE to inform the populace of state affairs. By the late fifteenth century, newsheets were being circulated in German cities. In 1556 the Venetian government published *Notizie scritte*, for which readers had to pay a fee. Modern newspapers appeared in the first half of the seventeenth century, with *Relation* in Germany in 1605, *Nieuwe Tijdingen* in Belgium in 1616, *Gazette* in France in 1631, and the *London Gazette* founded in 1665 in England. The first Japanese daily newspaper, *Yokohama Mainichi Shimbun*, started in 1870. In colonial America, early newspapers consisted of local gossip interspersed with economic and political information copied from newspapers in London.

After the conflict with England in 1765, newspapers became mouthpieces of political parties and factions. With the creation of the United States, partisan newspapers were founded (→ Partisan Press). In the 1820s, the → penny press was developed and newspapers included less partisan news, more local news, and more advertising. Newspapers in the United States today have become more informational as a result of the penny press. European newspapers still tend to be more partisan than their American counterparts (→ Party–Press Parallelism). Because of competition among newspapers, the idea of the “latest” news developed, along with simpler language and more illustrations, to attract readers. The competition between Joseph Pulitzer and William Randolph Hearst at the beginning of the twentieth century resulted in the rise of sensational news and non-news items such as comics (→ Newspaper, History of).

*Technological innovations* in the mid-1800s also affected the content of the newspaper (→ Technology and Communication). Telegraph transmissions of news stories led to the development of the inverted pyramid style of writing, which includes the most important information in the first one or two paragraphs (→ News; Telegraph, History of; Telegraphic News). In the event of a telegraphic transmission interruption, the most important information would have gotten through. The wire services allowed newspapers to share expenses and provide more breadth in coverage. Additional technological innovations in the early twentieth century led to the inclusion of photographs and visual elements in the newspaper (→ News Agencies, History of).

The *political climate* influenced the content of some papers. *Iskra*, published by Lenin in 1900, provided a venue for revolutionary propaganda, and in 1925, *Thanh Nien* introduced Marxism to Vietnam. The Progressive era in the early twentieth century also had a significant impact on American journalism that led to objective journalism (→ Objectivity in Reporting). In addition, newspapers focused on the reporting of facts and providing both sides of an issue, with opinions relegated to the editorial pages. The Kennedy era, the Vietnam War, the 1960s, and the → Watergate scandal were associated with the adversarial role of the newspaper. The focus on conflict has become the staple of front pages of national and metropolitan dailies.

Because of television, newspapers lost their role as a primary source of news and thus the amount of hard news was reduced and more soft or feature-type news was printed (→ Soft News). The development of other new media has also had a strong impact on the readership of newspapers and on news-gathering techniques. The loss of readership to other media has led some newspapers to explore a different news paradigm. In the mid-1990s, a group of newspapers in North Carolina started actively engaging the community in reporting civic issues via polls and focus groups. This movement, known as civic journalism, is an attempt, according to Baran (1999), to strengthen the identity of the newspaper as an indispensable local medium and thereby attract readers (→ Public Journalism). The loss of readership and the resulting economic pressures have also led to a reduction of the number of newspapers and the growth of chain ownership (→ Concentration in Media Systems). In the United States, four out of every five newspapers are owned by chains. Because of the Internet, computer-based reporting is replacing traditional in-person reporting and library archive research. In addition, most newspapers now have an online presence (→ Exposure to Print Media). Despite the growth of online newspapers, the World Association of Newspapers (2007) estimates that one billion people in the world read a daily newspaper.

## RESEARCH ON NEWSPAPERS

Hallin and Giles (2005) provide broad theoretical *categories of media systems*, dividing the western world into the liberal model, the polarized pluralist model, and the democratic corporatist model. The United States tends to follow the liberal model, in which state intervention is limited and where the profession of journalism centers on the objectivity norm. In this model, newspapers tend to be politically neutral. The Mediterranean countries of Europe follow the polarized pluralist model, in which newspapers are not market-driven but are an intellectual vehicle for elite discussion. In this model, political parallelism is high and the state plays more of an interventionist role. The democratic corporatist model combines features of the first two and is seen more in northern Europe (→ Political Journalists).

Newspapers were one of the first subjects of mass media research and continue to provide fertile ground to be mined by researchers. Academic research on newspapers varies according to the interest and approach of the scholars involved. The important role of newspapers in society in the areas of public affairs and politics has been examined on the local, national, and international levels. Some researchers approach the study of

newspapers from a sociological perspective, such as Tuchman in *Making news: A study in the construction of reality* (1978) and Shoemaker and Reese in *Mediating the message: Theories of influences on mass media content* (1991). These scholars focused on the interplay among the external and internal factors influencing the content delivered by newspapers. These factors include the socialization of the journalist, the organization of the newsroom, external influence from politicians and → public relations professionals, and the ideology of the cultural environment (→ Journalists' Role Perception). Similarly, but focusing more narrowly, some researchers have examined the influence of newsroom diversity on content production (→ Media Production and Content). Researchers have also examined legal and ethical issues pertaining to newspapers, such as access to government records, lawsuits, defamation, and freedom of the press.

The representation of news issues and the coverage of certain groups are also a popular research area. Relying predominantly on textual and content analysis, researchers have examined how events are portrayed in the newspapers and have compared coverage among different newspapers. Comparative studies of newspaper coverage range from examining what issues are covered and how issues are covered in privately and publicly owned newspapers, in dailies and weeklies, and around the world. Representation of certain groups is also examined in an abundance of studies examining the portrayal of women and racial and ethnic minorities, with most studies indicating that minorities are underrepresented and negatively represented (→ Media and Perceptions of Reality; Reality and Media Reality).

Newspapers have also been a staple of → media effects research. In the 1940s, researchers focused on newspaper readership and its effects on political attitudes and political participation. Traditional agenda-setting research focused on the salience of issues in newspapers and their impact on public salience (→ Agenda-Setting Effects). Uses-and-gratifications research originated with the examination of newspapers, focusing on their surveillance, correlation, and escapist functions (→ Uses and Gratifications).

Applied researchers focus on readership studies and circulation research to help management determine content. These studies include reader profiles, analysis of who reads what topics, and the motives and rewards for reading a newspaper. Another management tool is typographical research, which focuses on news design elements such as headlines, white space, type, and their effect on readability and legibility. In addition, management is constantly exploring new delivery methods, specifically electronic ones (→ Applied Communication Research).

## **Newspaper, Antecedents of**

*Joad Raymond*

*University of East Anglia*

The first newspapers appeared in western Europe in the seventeenth century, in forms that laid the basis for, and anticipated the form and content of, the contemporary newspaper (→ Newspaper, History of). While they developed out of sixteenth-century print and manuscript news media, their advent constituted an early modern media revolution that was central to state formation, reading, and politics in this period. The quantity of news provision increased, resulting in a qualitative transformation, and news media became embedded in politics and culture (Zaret 2000; → News; Political News).

Newspapers can be defined by six specific characteristics: (1) publication, i.e., commercial availability to a public, (2) regular periodicity, (3) serial publication, (4) continuity in title and physical format, (5) topicality of content, and (6) heterogeneity of content (→ Newspaper). While the *Acta Diurna* of ancient Rome, and the newsletters that circulated in Europe from the mid-fifteenth century onwards, are clearly antecedents of the newspaper, they do not sufficiently meet these criteria. Elements of all six can be found in several kinds of news media in the sixteenth century, but these characteristics are first united in the seventeenth century across most of western Europe. The newspaper, as understood here, did not appear outside Europe prior to 1700, though other countries have older news media.

### PREDECESSORS IN SCRIPT AND PRINT

The history of newspapers demands some account of forms of news communication prior to 1600. The first newspapers developed out of the *printed pamphlet*. Since the Reformation, the printing press had increasingly been used for → propaganda purposes by governments and for commercial purposes by printers and publishers (→ Printing, History of; Printer-Editors). These stationers developed and exploited the public interest in topical events – wars, sensations, disasters, crimes, and punishments – by producing short, printed pamphlets in the vernacular. Printed pamphlets were occasional, but created the business practices, distribution networks, literary forms, and the market that would later be exploited more systematically and regularly by the first newspapers (Raymond 2003).

Newspapers also have their origin in *manuscript culture*. Manuscript newsletters satisfied interest in remote events, in wars but also rumor and gossip, among Europe's elite. From the sixteenth century, professional suppliers of manuscript news appeared. The Fugger family, for example, the proprietors of a financial house in Augsburg, supplied Europe's merchants with political and financial news in a series of newsletters from 1568 (Von Klarwill 1924). Venetian scribes produced *avisi* or *gazette*, containing regular updates of local and international news, from the 1530s onwards. These contained digests of other letters, indicating date and place of origin as a heading to the report: the same format that the earliest printed newspapers would follow. University students offered a more personalized news service in England later in the century. Paolo Sarpi gathered news within Venice by ear, and from correspondents across Europe, and supplied it in regular manuscript newsletters supplemented with shrewd political analysis through the 1610s, long before that city had printed news (De Vivo 2006). These were commercially published (publication applies to commercial manuscripts as well as printed items) and distributed at regular intervals, and, while their purpose was to supply privileged information, access to them was limited by cost. Manuscript news, unlike printed news, was not ordinarily subject to censorship or pre-publication licensing, though senders and recipients risked their correspondence being intercepted, read, and pursued with legal actions such as libel (Love 1993).

### THE EMERGENCE OF THE NEWSPAPER FORM

Printed news periodicals appeared in the late sixteenth century. *Mercurius Gallobelgicus*, a semi-annual volume mainly concerned with military conflict, was published in Cologne

and then Frankfurt between 1594 and 1635. Serial and consecutively numbered news pamphlets appear in London in 1592, containing news of the French wars of religion; these were followed in the 1620s by *corantos*, near-periodical, numbered pamphlets of foreign news, printed first in Amsterdam and then in London; and in 1641 the first English weekly newspaper, fitting all six criteria, appeared. A weekly newspaper (*Relation*) appeared at Strasbourg (then part of the German Reich) in 1605; another at Antwerp in the same year. An official French news periodical, *Le Mercure Français*, was founded in 1613; a more heterogeneous periodical, *Nouvelles Ordinaires*, appeared in 1631; the same year, political division and a propaganda war resulted in the *Gazette*, sponsored by Cardinal Richelieu, which was for many years France's dominant news publication. Similar developments took place in Basel from 1610, Frankfurt and Vienna by 1615, Hamburg and Berlin shortly afterwards, Amsterdam in 1618, and Sweden from 1645. The *Gaceta de Madrid* appeared in 1661, initially annually, becoming weekly in 1667. A daily publication appeared in Leipzig in 1650. The first newspaper in Russia appeared in 1703. An attempt was made to found a newspaper in Britain's American colonies in 1690, but Boston's *Publick Occurrences* was suppressed after a single issue; the *Boston News-Letter* was established with greater longevity in 1704 (Dahl 1952; Solomon 1972; Chartier 1982; Clark 1994; Raymond 1996; Raymond 2003, 106–108).

The pattern, in most countries, is to move from occasional publication, through serial publication, to periodical publication, followed by an expansion of contents, an increase in frequency, and subsequently by regional differentiation within the country. The conventions and contents of manuscript newsletters and occasional pamphlets are appropriated and adapted, resulting in rapid *formal experimentation*. The publishers (or financiers) of newspapers would employ an editor to digest news from various sources, often soldiers and postmasters; soon editors would take a more active role, exploring new styles for presenting the news, including editorials. Publishers targeted specialized markets, including groups defined by political opinion, profession, or interests. Advertisements were soon introduced, and publications thereby included the three elements of content that would be seen as defining the form: news, → editorial, → advertising. Also to be found are: accounts of sport, word games, public notices, reviews of books, cultural affairs, inserts on recent history, and introductions to political theory. Medical and science journals borrowed the medium of the newspaper for other purposes in the later seventeenth and eighteenth centuries.

### **NATIONS, WAR, AND TRADE**

News follows war and trade. This is partly because of public interest in these matters, but also because news concerning war and trade insists on regular updates. Much of the rapid spread of newspapers in Europe took place during the thirty years' war (1618–1648). Moreover, governments were not reluctant to let their subjects or citizens read news of overseas wars (see → censorship, below; → Conflict as Media Content). The economic and transport infrastructure that was essential both to the supply of news to editors, and to the movement of printed newspapers to their readers, depended on postal networks and trade routes. The history of newspapers in the seventeenth century could be written as a series of annotations on a map of these networks, stretching from Antwerp to Brussels and the Habsburg Netherlands, to Augsburg, Cologne, Frankfurt, Hamburg, and Leipzig,

to London, to Venice and thence throughout Italy, Seville, and throughout Scandinavia, thence to Edinburgh (Arblaster 2006). These points were connected by roads that saw communications and trade, and news and newspapers, spread along these major routes.

*Trade* provided an impetus for news distribution: merchants needed to know where military or political conflict might support or undermine their business, and information about goods and prices elsewhere formed a modest element of early newspapers (it was more plentiful in bespoke manuscript news). Yet trade networks were exploited in ways that were entirely indifferent to these financial interests: they provided an infrastructure that facilitated the gathering and commercial supply of all kinds of news.

There is, then, a series of paradoxes at the heart of newspaper culture. Newspapers exploit existing technologies and infrastructures, but frequently in ways that go against the perceived nature of those technologies and infrastructures. Newspapers are national phenomena – hence the nationalism of much newspaper historiography that seeks to assert the priority of one country or another in establishing the newspaper – yet they supply international news, cut across national boundaries, and enhance a sense of local and international as well as national communities (→ International News Reporting).

### CENSORSHIP AND “PROPAGANDA”

Most early newspapers shied away from news of the country in which they were published. This was because news, especially political news, was regarded as privileged information and was governed by norms of secrecy. In many states, to publish news was to risk imprisonment, and this fact alone operated as a significant impediment to the development of indigenous, regular, periodical news out of an existing market for occasional and imported news (→ Violence against Journalists). News was available to a political elite, and fears were commonly expressed that popular access to news would produce political instability. News was seen to belong to the secrets of state that preserved majesty and authority. Moreover, it was said, if the general populace – shopkeepers, tradesmen, apprentices, agricultural workers – was to spend time reading newspapers and discussing news they would devote less time to their proper professions, and trade would begin to decline. These fears or commonplaces were iterated and reiterated as soon as print became a relatively cheap commodity, and long after the newspaper was an established fact of social and political life.

The consequence was a series of *obstacles to the distribution of news*, in the form of pre-publication licensing and post-publication censorship, particularly focusing on printed news. These obstacles ranged from norms and conventions, through parliamentary legislation to royal proclamation; some form of restriction was in place across most of the world. Where news was published, it was frequently limited to foreign news (though it needs to be remembered that there was real interest in foreign news, in part because of the interest in trade, war, and religion). Surreptitious publication and surreptitious importation of books could circumvent these restrictions, which meant that news distribution occasionally developed as a strategy used by political oppositions.

Some states, France pre-eminent among them, pioneered the use of the *newspaper as an official medium*, communicating authorized views. Such activity promoted a government's point of view – though government bodies were frequently not unified during this period

– and created an official market that could drive out the surreptitious market in news. To speak of “propaganda” during the early modern period is an anachronism: the word was specifically associated with the *Sacra Congregatio de Propaganda Fide* and did not arrive at something like its modern meaning until the early nineteenth century. Early modern apologists for the state would have used a different and less value-laden group of words to describe their activities. In France, Théophraste Renaudot was hired by Richelieu to edit the *Gazette*, restricting rumor and promoting an interpretation of the news that served Richelieu’s purpose. Though Renaudot’s view of his purpose may have been quite idealistic, there is no doubt that his office was an instrument of the government (Solomon 1972). In England, both Charles I and the Long Parliament established weekly newspapers during the Civil War to boost the morale of their armies, to depreciate that of their opponents, and to curry support for their cause (Raymond 1996). After the Civil War, Charles II employed a licenser to the press who tracked down illicit publications, sought to silence dissent, and enjoyed a monopoly of news while editing the official newspaper. Promotion of one’s own view, combined with the suppression of the views of others, was established as the most effective means of governing opinion.

To conclude, the earliest newspapers should not be viewed solely from the perspective of their antecedence to the contemporary, or defined by the characteristics of the modern press. This Whiggish and frequently patriotic approach characterized newspaper historiography from its origins in the later eighteenth century until recently, and it impeded appreciation of the historical and cultural complexity of early newspapers. The media revolution that gripped seventeenth-century Europe produced a dynamic culture of news publication, consumption, and analysis.

## Newspaper, History of

*Martin Conboy*

*University of Sheffield*

Historians tend to agree that the *Acta Diurna* in ancient Rome, a daily gazette of official news, was one of the most important precursors of the → newspaper as a public disseminator of topical information in the western world. (Newspapers, in their modern sense, would not emerge in countries such as China, Japan, and Korea until centuries later, but forerunners such as newsheets – containing official edicts and decrees – had limited circulation). Handwritten copies publicized news from police courts, accidents, deaths, the reporting of municipal councils, courts of law, and even the Senate. These reports were posted outside a variety of public buildings for the perusal of interested citizens. It would be over a thousand years, however, before technology, politics, and education would allow the regular commercial distribution of printed news in the form that we recognize today as the newspaper.

The introduction of printing to Europe around 1440 did not immediately prompt the development of anything resembling a modern newspaper (→ Newspaper, Antecedents of; Printing, History of). Economic and political conditions meant that newspapers took a longer period to make the most of this technology. The *Gazetta* of Venice was arguably the first newsheet of modern times, providing the merchant and political classes of Venice with eagerly awaited → news of the perceived threat from the Turkish empire. They were handwritten from 1536, but from about 1570 they were making the best use of available printing techniques. To a large extent, the newspaper as we know it became shaped by events and conditions in northwestern Europe from the seventeenth century and North America from the eighteenth century. It is on these areas that this brief account will concentrate.

### EARLY PERIODICAL PUBLICATIONS

Periodical newsbooks and newsheets began to spread across the cities of Europe from the early seventeenth century. The *Relation*, published by Johann Carolus in the then German city of Strasbourg from 1605 onwards, is generally regarded as the first regular newspaper in print. The first newspapers in other countries, depending on the definitional criteria

used, emerged shortly thereafter: France (1631), Italy (1643), Sweden (1645), Spain (1641), Poland (1661), and Russia (1703). In the nonwestern world, newspapers began to replace earlier types of bulletins in the nineteenth century, such as in Mexico (1805), Brazil (1808), India (1819), Japan (1870), China (1874), and Egypt (1867).

Relatively liberal political conditions made newspaper production a viable activity in England from 1621, with the publication of the first *coranto* translated into English. The first dated and sequential newsbooks began to be published in England the following year. They required a certain sort of writing that was to distinguish newsbooks from other literary forms (→ Literary Journalism), one which was centered on the transitory and the contemporary, and foregrounded the political and the → public like no other. The first publication to be able to break the taboo on reporting the proceedings of Parliament was the *Heads of Severall Proceedings in this Present Parliament* from November 22 to 29, 1641, written by Samuel Pecke. The years of the English Civil War were the laboratory for many of the permutations of early journalism (→ Journalism, History of). They saw the birth of many modern techniques of modern political journalism, for instance: the planted item, the inadequately denied → rumor, and the inside story (Frank 1961, 54). From 1643, the *Mercuries* introduced satirical writing and scurrilous innuendo about public figures and overt political → propaganda, in the first regular attempts to create a public forum through a consistently partisan idiom in print. The period also witnessed the first experiments with → advertising in periodical publications. It would not be long before the interdependence of advertising and news became a characteristic combination of newspaper journalism with all the benefits and compromises this brings.

### THE FORMATION OF A PUBLIC SPHERE

By the Restoration of 1660 in England, there was a return to a situation of central and licensed control over newspaper journalism. The term “newspaper” is first used around 1670 with reference to a specific form of print culture beginning to take on its identifiable characteristics. The *Licensing Act* lapsed in 1695, not because the ruling political classes felt secure about unrestricted printing, but because it could no longer be administered efficiently. From this point we see the emergence of newspapers as central to what → Habermas (1989) has called a → “public sphere.” Habermas sees this public sphere as an arena in which a compromise between the competing interests of the bourgeoisie and the aristocracy was negotiated to the benefit of the bourgeoisie, making use of its critical judgment. The first daily newspaper, the *Daily Courant*, was published from 1702. Barbers’ shops, taverns, and especially coffee shops all formed part of a spreading national network of outlets for newspapers and other periodicals where people gathered informally to read, exchange opinion, or catch up on the latest rumor or gossip (→ Coffee Houses as Public Sphere).

Similar developments enabled the newspaper to become established within political constraints through much of western Europe. In 1777 the *Journal de Paris* became France’s first daily newspaper. In the German-speaking territories, the *Intelligenzblatt* was from the early eighteenth century a regular supplier of a wide range of commercial information, together with news about trials and deaths. Political content was usually confined to officially sanctioned newspapers edited and published by governments.

In *colonial America*, Boston was the birthplace of newspaper production with Benjamin Harris's *Publik Occurrences* of 1690, John Campbell's *Boston News-Letter* of 1704, and the *New England Courant* of John and Benjamin Franklin of 1721. After 1769, Isaac Doolittle printing machines enabled speedier and more voluminous production, and this technology enabled the country to become united in its aspirations for independence from Britain. The freedom of the American press from colonial control became one of the founding principles of the republican cause (→ Freedom of the Press, Concept of). The newspapers of Isaiah Thomas and Samuel Adams's *Boston Gazette and Country Journal* provided journalism to stoke the revolutionary fires in the 1770s, and the interest in home news during these years occluded all else.

Newspapers played a central role too in the *French revolution* of 1789. Many of the leading figures were journalists or pamphleteers including Brissot, Marat, and Robespierre, and they produced newspapers such as *L'Ami du Peuple*, calling upon the absolute freedom of the press to represent the wishes of the people.

By the end of the century, three daily London-based newspapers had begun to draw together the strands of the extended experiment in newspaper journalism into a successful format. The *Morning Chronicle* edited by James Perry, the *Morning Post* edited by Daniel Stuart, and *The Times* were all combining credibility, probity, and financial success, and the first two were demonstrating the benefits of control of the whole newspaper by one manager, although this function was not described as "editor" before 1802. From this point, the financial success of newspapers was to be exploited by owners and editors to emphasize their editorial independence from government (→ Ownership in the Media). The rise of the leading article was a device that allowed this claim to be demonstrated on a daily basis on the important issues of the day, and increasingly newspapers sought out the best writers to articulate distinctive political and economic arguments for their readership.

## THE DEFEAT OF A RADICAL PRESS IN ENGLAND

As one set of developments was moving newspapers toward commercial respectability and political independence, a long suppressed radical impulse gained renewed momentum at the start of the nineteenth century in England (→ Radical Media). Under the impact of social and intellectual developments abroad in the shape of the American and the French revolutions, and at home in the wake of the unemployment and radical social upheavals of the early Industrial Revolution, readerships were being increasingly politicized along class lines. Newspapers began to address their readers in one of two ways: as a market for economic purposes or as a social class for political purposes.

Government fears of the impact of revolutionary ideas led them to raise the stamp duty twice between 1789 and 1797, but this merely encouraged the radicals to publish illegally and, in doing so, raise their oppositional credibility with their readers. The first phase between 1815 and 1819 included the writings of Cobbett, Carlile, Wade, and Wooler. This journalism, in the form of a weekly polemic, provided an organic link to the readerships it was targeting, the working classes.

The second phase of radicalism in the 1830s accompanied the push toward parliamentary reform, but expressed a strand of radical thinking that went beyond a mere shift in suffrage. Hetherington and O'Brien, for instance, ran unstamped newspapers to push for

political representation from the perspective of a specifically socialist critique of property, but the reduction of stamp duty from 1836 meant that the radical press was drowned in a torrent of cheap publications aimed at the working classes as a market.

## NEWSPAPERS AND MARKETS

By the early nineteenth century the aspirations for press freedom of the great revolutionary movements of the late eighteenth century had been moderated. It was to be in the commercialization of newspaper production that their editorial independence would come (→ Commercialization of the Media). This was linked to increased efficiency and speed in both production and distribution as new printing techniques and transport, both driven by steam, moved newspapers into the industrial age.

In the US, Benjamin H. Day produced the first successful *penny newspaper*, the *New York Sun*, from 1833. It was the first to target the ordinary people of the growing metropolis of New York in a language they could identify as their own (→ Penny Press). The success of the newspaper was also dependent on its sale on a daily basis on the streets, breaking with the tradition of more respectable papers for advance subscription and delivery (→ Quality Press). Gordon Bennett followed this successful pioneer in 1835 with his *New York Herald*, which perfected a popular blend of sport, crime, business, general news, and an increasing use of interviews with personalities in the news.

The removal of taxes and duties on newspapers between 1836 and 1855 in England shifted the onus of control definitively from political to commercial interests. The newspapers that emerged were commercially and politically incorporated and acted as a conciliatory, consensual channel between politicians, commercial interests, and the press rather than as an inflammatory intervention on behalf of a radicalized people in pursuit of rights and progress. Dropping taxation had made investment more attractive and paved the way for more competition between politically stable newspapers in the hands of so-called respectable men of property.

In newspaper form, the first entrant into this new order was the *Daily Telegraph* in 1855. This was a paper that at a penny was intended to introduce a different clientele to the daily newspaper. It brought together elements of the human interest of American popular journalism, public campaigning around issues of concern to its readership, and celebrity interviews. On the other hand, the continuing dominance of *The Times* in the elite market was based on its ability to enhance its political and editorial independence by investment in the latest technologies and maintenance of hugely profitable circulation and advertising.

In the US, the private transmission of news via telegraph assumed considerable importance during the Civil War (1861–1865; → Telegraph, History of). This had an impact on journalism in the systematization of its language and the development of the inverted triangle of the news story. The telegraph, in combination with the advanced system of shorthand introduced in 1840 by Pitman, meant that there was more of a verifiable base to much reporting of news, and therefore more scope to develop angles conforming to the particular identity of the individual paper. This was followed by further developments in printing and telegraphy into the 1870s including web rotary presses, the private wires, and the telephone. The new communication technologies allowed increasingly for information to be double-checked, which is considered by many to be

one of the defining features of modern journalism. The increased quantity and reliability of news, combined with the increase in advertising from the 1880s, meant that newspapers began to be able to concentrate on how the paper was put together rather than simply filling the space. Under the influence of more interventionist editors, newspapers developed identifiable house styles. Newspapers had always been a commodity, but they were rapidly becoming a more streamlined and capitalized commodity.

Improvements in print quality and better incorporation of visual material, including advertisements, forced newspapers to look increasingly to their visual aspect as consumers of journalism became more attuned to a wider range of aesthetic considerations in the layout and illustration of their papers (→ Newspaper, Visual Design of).

Pulitzer launched his New York *World* in 1883 and developed an invigorated version of popular journalism that was to be as influential in the US as it was in the rest of the world (→ New Journalism, Nineteenth-Century). It combined lively, topical writing, interviews with the celebrities of the day (→ Celebrity Culture), campaigns, and even stunts to attract publicity to the newspaper and an astute courting of the reader through its language and worldview.

Hearst, with his New York *Journal* from 1895, provided the competition that was to drive American newspapers more in the direction of → sensationalism and scandal (→ Scandalization in the News). He did much to refine the template for successful popular newspapers. The drive for readers led to the labeling of such newspapers as → “yellow journalism.” Both these newspapers were drawn into ever more populist appeals to an increasingly chauvinistic mood in the country during the Spanish–American war of 1896–1898, demonstrating the potential for newspapers to become agents of unbridled jingoism.

With the expansion of advertising, popular magazines in England tested markets for journalism lower down the social and financial scale and soon began mapping products onto that market (→ Magazine, History of). The first to try was George Newnes’s *Tit-Bits*, which was the herald of the new penny weeklies of the 1880s. Whatever their stylistic innovations, the penny weeklies’ most significant contribution was their enormous financial success, which enabled Harmsworth and Pearson in particular to found the two most influential newspapers of the early twentieth century, the *Daily Mail* (1896) and the *Daily Express* (1900). They built on the well-established tradition of an intimate form of address with their readers, a popular feature of both radical pamphlets, women’s magazines, and Sunday newspapers.

### THE LONG POPULAR CENTURY

Harmsworth’s reworking of the popular newspaper as primarily a vehicle to attract readers and advertisers had a lasting effect on the shape and content of journalism across the twentieth century, forcing other proprietors to adapt the content of their newspapers to match or improve upon the pattern he had set.

The *Daily Express* was launched to rival the *Daily Mail* and to exploit the new market for popular daily journalism that Harmsworth had opened. It innovated itself with news on the first page from 1901. These newspapers relied upon more editorial intervention to make copy fit the format and style of the paper. The role of the subeditor was pivotal in the creation of this new discourse, in fitting the copy into a format that allowed a newspaper

to be read on the move and tailoring it to fit the space available within the pictorial and advertising space. The “story” becomes the basic molecular element of journalistic reality and the distinctions of categories of news into “hard” and → “soft news” become institutionalized (→ News Routines).

### THE INTENSIFICATION OF PRESS COMPETITION

By the twentieth century, newspapers had become identifiably big business. The leading proprietors presided over a period that continued the trends toward concentration, competition, and entertainment in print media. This competition led among other things to a concentration of the market and a narrowing of political range (→ Concentration in Media Systems). Sensationalism, special offers, campaigns, layout, and aspects of writing style of the 1930s all became defining features of the popular newspapers of the age.

The relaunched *Daily Mirror*, from 1934 under the editorial direction of Bartholomew, triggered the tabloid revolution with its signature heavy black boldface for headlines, pin-ups, youthful style, simplified language, and prominent use of pictures to reach a new readership. It redrew the map of the popular newspaper by integrating all the visual appeal of popular culture and consumerism for the first time. After the war, the *Daily Mirror* soon began to climb to a pinnacle of influence in popular journalism, ousting the *Daily Express* with a populist, proletarian, and youthful appeal encapsulated in the slogan that ran from May 11, 1945: “Forward with the People.”

### TABLOIDIZATION

The most sustained and widespread set of debates around contemporary journalism emanates from the tabloid newspaper (→ Tabloid Press). “Tabloidization” may refer to: (1) an increase in news about celebrities, entertainment, lifestyle features, and personal issues, (2) an increase in sensationalism, the use of pictures, and sloganized headlines, (3) a decrease in international news and public affairs news including politics, (4) a reduction in the length of stories, and (5) a convergence with the agendas of popular and in particular television culture.

Elite newspapers have also been enmeshed in the clustering of trends characterized as tabloidization. The late twentieth century has seen a further narrowing of ownership and the incorporation of newspapers into more broadly defined → media conglomerates that have eroded the boundaries between journalism and media entertainment (→ *Infotainment*). In order to survive the intensification of competition, elite newspapers have become heavier and have more lifestyle and consumer coverage. They have increased the numbers of specialist supplements and size and quantity of high-profile advertisements. Most significant is the almost universal shift to a tabloid format. In the expanding tide of newsprint, the elite press’s relative coverage of foreign news has decreased (→ International News Reporting), yet they are providing a very different service from that of their predecessors in that, freed from the necessity to be first with breaking news, they can concentrate much more on opinion, commentary, and selective in-depth reporting.

Global trends such as online journalism and the rise of *freesheets* and blogs (→ Blogger) mean that the format and content as well as the social use of newspapers is

in the process of intense renegotiation, but it seems certain that some form of newspaper will survive: one which successfully incorporates these developments as part of a more diverse media package. Rupert Murdoch is the best example of a contemporary media mogul who is confidently positioning his newspaper empire in a convergent media environment. Newspapers are now at the hub of an increasingly hybrid operation that makes the whole newspaper package more akin to an extended magazine with specializations ranged around the core of a more general news function (→ Digitization and Media Convergence; News Corporation). Elite newspapers, in particular, at the start of the twenty-first century give a glimpse of a radically altered, more open-ended journalism under the influence of the → Internet, with its archival potential and more direct reader intervention via emails and blogs.

## **Newspaper Journalism**

*Donald Matheson*

*University of Canterbury*

The newspaper is the oldest and arguably the most important of all media for journalism. More journalists work in newspapers than in any other media. Moreover, dominant ideas of news – as a factual, independent account of the day's principal events, set out in an

ordered way for a geographically defined audience – emerged historically along with the business of the → newspaper (→ Newspaper, History of). Newspapers thus provide much of the form or architecture through which journalists and their audiences recognize news (Barnhurst & Nerone 2001), such as the division of journalism into the categories → *news*, *features*, and *sports*, as well as journalistic ideals, including independence from power and speaking to and for a public. Changes in newspaper journalism are therefore the focus of particular scholarly concern, and some commentators suggest that recent changes signal the end of journalism (Hardt 1998).

In countries shaped by liberalism, the ownership of newspapers tends to be in private hands, and journalism experiences the characteristic tension between a dependence upon the marketplace and a jealously guarded freedom from political control which allows newspapers to claim status as the defenders of the public interest (→ Commercialization: Impact on Media Content; Journalism: Normative Theories; Political Economy of the Media). Critics argue that the balance tipped in the 1990s toward a dumbed-down, market-driven journalism, leading local and regional newspapers in particular to employ fewer journalists and to place emphasis on sensation and lifestyle at the expense of serious political news (Franklin & Murphy 1998; → Local News; Tabloidization). Scholars have documented a greater reliance on the *information subsidy* of public relations and a blurring of the line between advertising and reporting in many western countries.

Wider cultural trends are also likely responsible for changes in some newspaper → news values. With the rise of → identity politics, particularly the women's liberation movement, distinctions between public affairs and private lives have become less tenable, and newspaper journalism has responded by replacing so-called women's pages with large features and lifestyle sections and by moving features to the front of the paper. Historical studies further caution against making too much of declines in specific qualities of newspaper journalism. The ethical standards of the tabloids, for example, have risen and fallen many times (Engel 1996; → Tabloid Press).

The *traditions* of watchdog journalism, specialist correspondents, and in-depth investigations remain powerful influences on journalists' idea of the newspaper (→ Investigative Reporting; Journalists' Role Perception). Cultural studies of journalism point to the importance of the myths that journalists construct (see Zelizer 2004 for a review), such as exaggerating the role of the *Washington Post* in the resignation of US president Richard Nixon (Schudson 1995; → Watergate Scandal) or celebrating heroes as seen in responses to the murder of Anna Politkovskaya, of *Novaya Gazeta* (see [www.annapolitkovskaya.com](http://www.annapolitkovskaya.com)). The culture of independent, morally serious, and analytical reporting has found fresh impetus as first television and later the Internet weakened the newspaper monopoly on daily news, impelling newspapers to shift toward interpretation (Barnhurst & Mutz 1997), such as the *Independent* in the UK or the weekly *Die Zeit* in Germany, which devote whole pages to in-depth treatment of a single issue (→ Interpretive Journalism; Quality Press). Few newspapers can sustain a business producing such journalism, despite its high value to journalists. Some scholars characterize western newspaper journalism today as polarized between a mass of clerks retyping press releases and a few critical journalists who set news agendas (Bromley 1997).

Questions about what the *changes in newspaper journalism* mean have grown more complicated as recent scholarship has re-emphasized models not reducible to the liberal

one that informs the dumbing-down debate. The variety of models includes the distinctive newspaper traditions of many countries, such as the Italian tradition of politically affiliated newspapers (Hallin & Mancini 2004; → Italy: Media System), the complex democratic politics of popular newspapers (Conboy 2002; → Populism and Responsiveness), and the alternative press as an agent of political change (Downing 2001; → Alternative Journalism). Liberal models have also come under question from within, partly in response to a weakening of public trust in the authority of newspaper journalism. In the US, these concerns crystallized around the movement for public or civic journalism (→ Public Journalism), but dissatisfaction exists in many countries over such matters as journalists' claims to objectivity and their positioning of readers as spectators rather than as participants.

The case for studying newspaper journalism separately from the rest of the media is steadily weakening as news businesses and technologies converge (→ Digitization and Media Convergence). Converged *digital newsrooms*, with journalists producing news for multiple platforms, are emerging particularly in the US. Journalists rarely celebrate newsroom efficiencies, but the evidence of the impact on news quality is conflicting. Some analysts note that digitization has increased editorial control and facilitated more in-depth reporting (Avilés & León 2002). Journalists' relationships with the news public have changed across all media with the rise of the Internet, increasing the public demand for instant news and for greater participation in newsmaking (→ Citizen Journalism).

# Newspaper, Visual Design of

*Robert L. Craig*

*University of St. Thomas*

*Elio Leturia*

*Columbia College Chicago*

Newspaper design refers to the process of planning, selecting, organizing and arranging the → typography, photographs, illustrations, and graphics of → newspapers (→ Photography; Infographics). It also refers to the *look* or *style* of a newspaper (→ Design; Graphic Design). Newspaper design is highly conventional, so historians have noted visual features that comprise different stylistic periods. These styles are closely related to how publishers, editors, and journalists define the role of journalism in society (Barnhurst & Nerone 2001; → Journalism, History of; Journalists' Role Perception). Changing technology also profoundly influences newspaper design.

Visual newspaper design as a specialized profession within newspaper publishing is a recent occurrence. Before the 1960s, the organization of printed elements depended on journalistic custom and editors' and typesetters' daily production considerations (→ News Factors; News Routines; News Values).

## HISTORY OF PRINT AND NEWSPAPER DESIGN

The newspaper in the sense that we know it today – as a regularly occurring publication for the gathering and dissemination of news and opinions concerning current events – first made its appearance in Venice in 1536 (→ Newspaper, Antecedents of; Newspaper, History of). By the end of the seventeenth century in England, newspapers had become essential reading for citizens participating in government by public opinion in the new democracy taking shape there.

The conventions of book design developed in the sixteenth century (→ Book), and early newspapers followed them into the nineteenth century. They were visually dominated by text type, which was meant to be read like a book, from top left to bottom right. Initial letters (drop caps) or text-sized headlines often started the page or signaled a new story. The newspaper title, now called a *nameplate* or *flag*, was set in larger type, centered at the top of the page like a book title, establishing the practice of designing flags to carry a publication's identity. Following eighteenth-century calligraphic trends, some newspapers designed more decorative flags.

Nineteenth-century industrialization saw the rapid rise of a literate middle class and the development of mass consumption. With the press's role in politics now secure and business's need for advertising space expanding exponentially, the number and size of newspapers exploded (→ Political Communication; Advertising). New technologies supported this growth. Machine papermaking allowed editors to increase the size and number of pages in newspapers. Power-driven rotary presses and machine-set typography replaced vastly slower hand-production methods. These advances created space for experimentation in content and design, ever-larger staffs, and competition for readers (→ Information and Communication Technology, Development of). Publishers divided their staff into three parts – editorial, advertising, and print production. Although complementary, each became a separate sphere that worked independently. Advertising began to drive design innovation. Early nineteenth-century ads had looked like editorial copy, set in the same type and to the same measure as editorial copy. But by mid-century, businesses sought visual advantage in their *ads*. Department stores and manufacturers began advertising heavily, employing more space, larger, decorative type, and illustrations. Ads became increasingly sophisticated as artists and advertising agencies were engaged (→ Advertisement, Visual Characteristics of). The editorial side had no choice but to adopt larger, more varied headlines. This established a visual syntax that made page position and scale communicate the relative importance of stories (→ Visual Communication). Larger headlines allowed readers to scan pages and locate stories of interest.

*Illustration and photography* had a profound impact on newspaper design. Starting in the 1820s, illustrated news magazines (→ News Magazine, History of), such as the *London Illustrated News*, Germany's *Illustrierte Zeitung*, and America's *Harper's Weekly* and *Frank Leslie's Illustrated News*, assigned illustrators to cover stories, draw portraits, and capture important events, such as coronations, funerals, and wars (→ Illustrated Newspapers). With artistic license, illustrators even sketched and interpreted events they had not witnessed. Illustrations were reproduced in newspapers as woodcuts and wood and zinc engravings (→ Prints; Printing, History of).

The invention of photography in 1834 created even more pressure to illustrate the news, and photographers were sent to cover it (→ Photojournalism). But due to printing limitations, photographs had to be reproduced as woodcut copies. In 1880 Stephen Horgan produced the first practical half-tone line screen for the *New York Daily Graphic*, which enabled photographs to be printed directly. Magazines initially pressed the quality limits of photographic technologies, but they were followed by large, city newspapers with the resources to experiment. In the twentieth century, the popularity of photo-magazines like *Life* led newspapers to develop their own Sunday rotogravure magazine supplements (→ Picture Magazines).

By the end of the nineteenth century, all the features of modern newspaper design – display type, photography, illustration, and graphics – were in place. In the hands of respectable editors, they provided readers with different kinds of information. But these tools could also attract readers by sensationalizing the news with giant, emotional headlines and attention-getting, if often misleading, images (→ Yellow Journalism). Even good newspapers fell victim to the temptation of large circulation. In 1898, most of the American press printed accusations that a Spanish mine had blown up the US battleship *Maine* in Havana harbor, killing 266 Americans. The resulting public outcry led to the

Spanish–American war and the US invasion of Cuba. Although these claims were never substantiated, newspapers manufactured graphics to explain exactly how the mine had sunk the ship. In the twentieth century, professional codes of ethics evolved that restricted editors’ use of misleading photos and layouts, although sensationalist tabloids that attract readers through newsstand sales continue such practices today (→ Standards of News; Ethics in Journalism; Historic Key Events and the Media).

Early twentieth-century newspaper designs were cluttered. They utilized rules between columns, above and below headlines, and after stories. As late as the 1950s more than a dozen stories might appear on the front page (Barnhurst & Nerone 2001). In production, advertisers first staked their claim on space, then section editors dummied or mocked-up the remaining “news hole.” The production side set the hot metal type and locked it into the press, often changing editors’ layouts to meet deadlines and fill space (→ News Production and Technology).

### PROFESSIONALIZATION OF NEWSPAPER DESIGN IN THE TWENTIETH CENTURY

The professionalization of journalism in the latter half of the twentieth century produced more thoughtful design (→ Professionalization of Journalism). Studies of the ease of identifying letter-forms (*legibility*) and understanding words (*readability*) contributed to a more functional approach (Zachrisson 1965). Editors began to make typographical decisions based on observing how readers scan pages and process reading material. Social changes, such as the increasing pace of life and the availability of alternative media, influenced newspaper readership. Edmund C. Arnold (1981) and Mario Garcia (1981) were among the first to argue that designers must address young readers and semi-illiterate adults who were turning from newspapers to → television news (→ Newscast). Of chief concern were the lost advertising dollars chasing them. With the invention of → cable television and the → Internet, their insights became more profound (→ Newscast, 24-Hour; Internet News).

Functionalist ideas about design began to emerge in the 1960s as hot metal type gave way to *photocomposition* and letter-press gave way to *offset lithography*. Photocomposition used paper type and half-tones that could be cut and pasted together in any configuration, and made it easy to change the size of type and pictures quickly. New technology also altered production. In hot metal printing, typesetters and page makeup artists were closely aligned with the press operators. With photocomposition, responsibility for design shifted more onto the editorial and advertising staffs. Printers simply created and printed the offset plates, effectively removing them from the design process.

*Grid sheets* for pasting-up paper type and photos replaced rigid columns of type. Every newspaper created its own grid with standard columns and gutters. Grids served more as guides than a straightjacket, providing a standard horizontal and vertical template necessary to lay out large newspapers on a daily basis. A key question for visual designers became how to violate the grids creatively, while still adhering to their overall parameters.

Modular design simplified newspaper layout by packaging headlines, stories, photos, and graphics into rectangles and squares. With fewer modules per page, readers were meant to be attracted by a cleaner, less daunting look. The more staid look of modular

design was enhanced by the reintroduction of color, which had died out during the Great Depression. Color added a powerful form of emphasis and was easy to print with offset.

With the advent of electronic publishing and *computer layout programs* like Quark XPress and PageMaker, more backroom jobs were eliminated in favor of *editorial designers* or *visual journalists* who resided in the newsroom (→ News Workers). As a result, by the 1990s design had become central to the planning and news-gathering processes rather than an afterthought. Editors, writers, and photographers were asked to “think visually” and to imagine new possibilities for creating photographic and graphic information. Designers helped them conceive, plan, and develop *story packages* that are central to today’s newspaper marketing strategy (→ Media Marketing). Photojournalists provide a caption explaining what and who appear in the image, an early step in framing the preferred meaning (→ Framing of the News; Framing Effects). But newspaper designers crop, scale, and adjust light and color balances in Photoshop (→ Digital Imagery). Other digital manipulations transform photos into photo-illustrations, and designers must indicate such alterations in print.

Maps were the world’s earliest news graphics. Other graphics include diagrams that explain how a system works, *tables* that array data and lists, and *graphs* (Tufte 1990). Designers believe *infographics* facilitate readers’ comprehension by presenting numerical information, processes, and procedures more succinctly and clearly than text (Harrower 2002). Today, drawings and photo-illustrations are mostly used to visualize what cannot be photographed live: courtroom proceedings; fashion or product designs; personal memories and accounts; impressions, sensations, feelings, and other intangibles. Feature sections such as lifestyle, travel, health, and food use the most illustrations, following a longstanding pattern of innovation in newspaper design (Barnhurst 1994). Editorial or opinion content provided an early and continual location for political → cartoons, appearing as line drawings, the same way → comics do (→ Caricature).

Stylistically, photo treatments have changed with the times, first appearing in black and white, then in color. Posed portraits gave way to candid images before designers entered the newsroom, and today designers use photographs from sources outside the newspaper. Citizens’ ability to take and send mobile phone photos electronically has added a new dimension to photojournalism (→ Citizen Journalism).

Due to media convergence, newspaper design is evolving rapidly (→ Digitization and Media Convergence). Major newspapers have designed web pages to make their content available online. Their sites often contain more information – through sidebars, links to other sites, slide shows, and even video – than the newspaper itself. It remains to be seen whether such innovative design and packaging strategies can significantly slow or reverse the loss of newspaper readership. Some believe the emphasis on newspaper design has been a misdirected, futile attempt to save paper media, and that the future of news is electronic.

## **Newsreel**

*Luke McKernan*

*British Universities Film and Video Council*

A newsreel was a single film reel of topical → news items, shown in cinemas across the world for much of the twentieth century. The term “newsreel” is too often loosely applied to mean any kind of cinema film depicting a news story, so that the topical films of the 1890s made by the Lumière brothers are sometimes misleadingly called newsreels (→ Cinema; Cinematography, History of). But the newsreel was a specific form that arose with the habit of regular cinema-going in the late 1900s, when a short reel of news stories came to be accepted as a suitable component of the emerging mixed cinema program.

Newsreels were thereafter issued once or twice a week, to match the changes in cinema programs. The first newsreel proper was *Pathé Fait-Divers*, subsequently *Pathé Journal*, first issued in France in 1908, although there were examples of regular programming of news film by some cinemas that preceded it. The form soon spread worldwide, encouraged by the spread of the French multinationals Pathé and Gaumont. The first newsreel in Britain was *Pathé's Animated Gazette*, in 1910; the first in America was *Pathé's Weekly*, in 1911. The newsreel achieved prominence during World War I, when its acceptance by

audiences led the American, British, and French governments to create their own → propaganda newsreel (as America did with *Official War Review* and France with *Annales de la Guerre*) or co-opt an existing reel (as the British did with *Topical Budget*; → War Propaganda). But it was in the 1920s that the newsreel rose to new heights of popularity and influence; by now it was a feature of most cinema programs, and benefited both from the general rise in cinema-going and from the giddy round of sport, celebrity, achievement, and disaster that characterized the decade.

Newsreels until 1929 were silent. Such commentary as they provided was in the form of titles preceding and then intercut into the action. The *appearance of sound newsreels* coincided with increased dominance by the major → Hollywood studios. Fox Movietone, Paramount, and Universal began to be the names most familiar to newsreel viewers across the world, as local versions were issued in various countries. A newsreel was a difficult financial proposition for an independent, given the small part of the cinema program that they occupied (10 minutes or so), while they became a convenient part of the programming package that a major producer might offer, as well as being a branding tool.

World War II brought further prominence to the newsreels. There was no government takeover in Britain, as had been the case in the previous war, but there were specialist reels directed toward workers and the armed services. In America the five main newsreels (Fox Movietone, MGM, Paramount, Universal, and Warner-Pathé) continued to operate independently throughout the war, while each also contributed to a government reel, *United Newsreel* (1942–1945), designed for overseas exhibition. In Germany, all of the newsreel production was subsumed under a single service, *Deutsche Wochenschau* (1940–1945; → Propaganda in World War II). In the years immediately following the war, an Anglo-American re-education newsreel, *Welt in Film* (1945–1952), was exhibited throughout Germany. The war gave the newsreels a new importance, and in many ways represented the peak of the medium. But it also sowed the seeds of the medium's decline, as audiences were exposed to issues and territories that widened their sense of what the news could be. In peacetime the newsreels, trapped in rigid formulae, would struggle to regain that same degree of audience respect.

Television spelled the *end of the newsreels*. The audience was moving away from the cinemas and into the living-room, and television news was simply quicker with the news. Early → television news services, such as the → BBC's *Television Newsreel* (1948–1954), followed the newsreel style, and often employed former newsreel staff, but evolution to daily news broadcasts and a presenter-led format made the bi-weekly newsreels seem old-fashioned in both presentation and news values. The newsreel had always favored the noncontentious, news as part of a cinema program whose prime purpose was to entertain. If the common perception of the newsreel as being fixated on trivia, sensation, and ceremony (“a series of catastrophes ended by a fashion show,” in Oscar Levant's cruel summing up) is oversimplified, it was nevertheless a medium whose time had gone. Gradually the newsreels passed away, the last newsreel in America, *Universal News*, closing in 1967, the last in Britain, *British Movietone News*, closing in 1979. Some anomalies remained (the Belgian *Belgavox* continued, with government support, into the 1990s), but essentially the newsreel ceased to be a vital medium by the end of the 1950s.

The newsreel was a powerful means of communication, whose historical significance has been sorely neglected. Newsreels were seen by hundreds of millions across the globe

for several decades. Through this particular medium the public was exposed to the issues and personalities of the time, and introduced progressively to news matters beyond the confines of particular countries. It was also a communicative medium in the way its homely style and populist agenda suited the mass cinema audience. Newsreels, at their height, were produced with a sound understanding of what their audience was looking for.

This considerable power was, however, colored by a pusillanimous attitude that was eventually rejected by audiences who, postwar, expected more from a visual news service and found this in the newsreels' logical successor, television news. But if the newsreels were a subservient medium, strongly criticized for their cautious approach and support of the political status quo, they were nevertheless immensely influential. Very much a twentieth-century medium, newsreels played a major part in conferring visibility on things, in making the visually emphatic newsworthy (→ Visual Communication; Visual Culture). If we judge things by appearances, by what our screens show us, and how people of influence comport themselves on those screens, then the newsreels were a medium of real historical importance, not least because their images of the twentieth century now lie in footage libraries and will continue to color our view of the past for as long as we still believe what we see on our screens.

## **Nielsen Ratings**

*James G. Webster*

*Northwestern University*

Nielsen is a name synonymous with television audience measurement throughout much of the world. Today, it is associated with a family of services that provide estimates of the size and composition of media audiences, loosely referred to as Nielsen ratings. Those numbers are essential to the operation of commercial media, since they constitute a currency used to sell audiences to advertisers.

Advertiser support of American *radio broadcasting* began in the 1920s. However, for radio to compete with print for advertising revenues, the industry needed to quantify its audience. By the early 1930s, telephone surveys were used to produce what came to be called radio “ratings” (→ Rating Methods). Technically, a rating is the percentage of the total possible audience tuned to a particular station or program, but the term is often used to label all estimates of audience size and composition. In the late 1930s, a market researcher named Arthur C. Nielsen (1897–1980) developed a meter, called an “audimeter,” which could keep a running record of the wavelength to which a radio receiver was tuned. In 1942, Nielsen launched a “Radio Index,” which estimated American radio network audiences using audimeters placed in a sample of 800 homes (→ Exposure to Radio). In 1950, Nielsen adapted the constantly evolving audimeter to the business of measuring *television audiences* (Beville 1988). By the end of the twentieth century, the A. C. Nielsen Company had emerged as the sole supplier of television audience ratings in the United States, and the term “Nielsen’s” became a kind of shorthand for TV ratings used by media executives and the general public alike (→ Exposure to Television).

The company originally founded by A. C. Nielsen Sr. has since been sold and reorganized a number of times. But the Nielsen brand and core businesses remain. Nielsen companies and/or their partners now provide audience measurement services in the United States and dozens of countries in Asia, Europe, Africa, and Latin America. Indeed, as advertising-supported media proliferate around the world, so too does the need to measure audiences.

In the United States, Nielsen Media Research provides a variety of audience estimates. The principal television measurement services are the *Nielsen Television Index (NTI)*, which uses a panel of roughly 10,000 households equipped with → people-meters to estimate television network audiences, and the Nielsen Station Index (NSI), which uses a combination of meters and diaries to estimate TV station audiences in 210 local market areas in the United States. In recent years, Nielsen has expanded its measurement operations to include video games, cinema, outdoor advertising, product placement, and, through its subsidiary Nielsen//NetRatings, various Internet-related user behaviors. The company has also announced an “anytime anywhere media measurement” initiative to track all manner of video consumption regardless of the technology involved (e.g., digital video recorder, portable, and web-based distribution).

As the most visible form of audience measurement, Nielsen ratings play a critical role in the operation of commercial electronic media. In the US alone, tens of billions of dollars in advertising are spent in accordance with Nielsen audience estimates. Television programs are either canceled or renewed largely on the basis of their ratings performance – as are the contracts of media executives. As the quasi-official scorekeeper for television, Nielsen even draws the ire of politicians and cultural critics with some regularity. Though the methods Nielsen uses to produce ratings will change along with the media environment, the Nielsen name and core businesses are likely to remain a fixture of the media industries for a long time to come.

## **Noelle-Neumann, Elisabeth**

*Michael Meyen*

*Ludwig Maximilian University of Munich*

Elisabeth Noelle-Neumann stands for a paradigm shift in the field of media effects research. In 1972 she presented her → spiral of silence theory in Tokyo in a lecture entitled “Return to the concept of powerful mass media.” This paper can be seen as a break with the “minimal effects” hypothesis (→ Media Effects). Noelle-Neumann argued that research confined itself to short-term media influences, that it used poor measures, and failed to see crucial factors such as the consonance of the media, their cumulative effects, and their influence on the climate of opinion (→ Media Effects Duration). She argued that these effects could only be measured by using a combination of media content analyses and representative public opinion polls – preferably by conducting several waves of → surveys. Above all in the USA, her spiral of silence theory gave rise to a great number of empirical investigations that made Noelle-Neumann one of the best-known figures in communication research worldwide.

Elisabeth Noelle-Neumann (b. 1916) studied *Zeitungswissenschaft* (newspaper science), history, philosophy, and American studies in Berlin. In 1937/8 she received a scholarship at the University of Missouri School of Journalism. In 1940 she obtained her doctorate in Berlin with a dissertation on public opinion research in the USA, Emil Dovifat being her doctoral supervisor. She then worked as a journalist until the end of the Third Reich. For this she has come under repeated attack (Simpson 1996; Kepplinger 1997). In 1947, Noelle-Neumann founded the *Institut für Demoskopie Allensbach*, where she paved the way for opinion research in Germany. She regarded her institute as a bridge between commercial and academic research. Thanks to the innumerable method experiments that she dedicated above all to questionnaire design (→ Interview, Standardized), to the set-up of rating → scales, and to sampling methods (→ Sampling, Random; Sampling, Nonrandom), Allensbach indeed gained an exceptional position among survey research firms. Her textbook on the methods of opinion research (Noelle-Neumann 1963) has been translated into several languages (→ Research Methods).

In addition to developing methodology, Noelle-Neumann helped Allensbach to acquire a strong profile as an advisor for political parties (election research), as well as in the fields of market research (media analyses) and social research. Among other things her institute assisted in election campaigns for the German chancellors Adenauer and Kohl (both from the Christian Democratic Party). As far as her sympathy for this political party is concerned, Noelle-Neumann neither kept it secret, nor concealed her conviction that academics should intervene in public → discourse. In Germany more than anywhere else, this commitment earned her criticism implying that she was producing results that were politically useful (→ Communication Research and Politics). Studies on press concentration (→ Concentration in Media Systems; Germany: Media System), on press editorial department structures, and on the media's influence on voters' behavior (→ Political Communication) came under particular attack.

In 1964 Noelle-Neumann was offered the newly created chair of *Publizistik* (public communication) at the *University of Mainz*. Trying there to win support for the use of empirical research methods (especially in the case of representative surveys, experiments, and quantitative content analysis), she became the most important driving force for a shift in the German-speaking scientific community toward an empirical social scientific approach (→ Communication as an Academic Field: Western Europe). To her, the way things had developed in the USA was declaredly the model for imitation.

Cooperation between the Institut für Publizistik in Mainz and the Institut für Demoskopie Allensbach made it possible for Noelle-Neumann to encourage or herself carry out pioneering studies in several areas of research. In addition to media effects research and election research, special attention has to be drawn in this context to international comparative research on → journalism (→ Journalists' Role Perception), to vocational field research (self-understanding and the social condition of journalists, relations between editorial staff and media owners), and to happiness research (*Glücksforschung*). Furthermore, in developing the personality strength scale Noelle-Neumann made a major contribution to opinion leadership research (→ Opinion Leader). Composed of 10 items for self-description, this scale makes it possible to identify people with great charisma and assertiveness. Sociometric tests have shown that influentials hold central positions in networks and have a large circle of acquaintances, and that this enables them to overcome social communication barriers (Weimann 1991). Noelle-Neumann's scale is used in political research, marketing, media planning, and network research.

Under Noelle-Neumann's direction, the Mainz Institut für Publizistik became the discipline's leading institution of learning in Germany. The "Mainz School" has produced communication scientists of international renown such as Winfried Schulz, Hans Mathias Kepplinger, Jürgen Wilke, Wolfgang Donsbach, and Hans-Bernd Brosius. Establishing links between scientific findings and training issues (→ Journalism Education) is part of the Mainz Institute's tradition. So is its international orientation; in this context, particular emphasis must be put on Noelle-Neumann's cooperation with the National Opinion Research Center (NORC) in the USA, and especially with Norman Bradburn. Between 1978 and 1991 Noelle-Neumann spent six trimesters in Chicago as a visiting professor, teaching political science.

Noelle-Neumann's major contribution to the study of mass communication is her spiral of silence. That this theory follows the "powerful effects" principle is one of the

reasons why it has given rise to debate. Wherever powerful effects are supposed to exist, media criticism is not far away, and neither is the resistance of journalists. Despite the debates, it is beyond dispute that Noelle-Neumann brought to the discipline of communication one of the most important theoretical innovations of the second half of the twentieth century. The spiral of silence theory is a macro-theory that comes as a challenge to the social sciences. It has brought the notion of public opinion back into the center of scholarly debate.

## **Nollywood**

*Jonathan Haynes*

*Long Island University*

"Nollywood" – the Nigerian direct-to-video film industry – has become the third largest film industry in the world, producing a staggering 1,500 titles per year. It began during the Nigerian political, social, and economic crisis of the late 1980s and early 1990s, when the collapsing national currency made celluloid film production prohibitively expensive and when rampant crime made people hesitate to go out to cinemas at night. Widespread ownership of video cassette recorders, an infrastructure developed to sell pirated cassettes of foreign films, numerous personnel who had been working in film, television, or

theatre, and a huge potential market allowed the creation of a novel film industry based entirely on video (→ Video; Africa: Media Systems).

The pivotal figure in the creation of the Nigerian video film industry is Kenneth Nnebue, an Igbo dealer in electronic goods who in 1992 produced *Living in Bondage*, the first film in Igbo, followed by *Glamour Girls* in 1993, the first film in English. The industry is still dominated by Igbo businessmen, who often finance films as well as control their marketing and distribution. In some cases, marketers such as Nnebue and Ojiofor Ezeanyaeche have evolved into writing and directing roles, shaping the creative vision of films (→ Cinema).

The business model is to make films very cheaply and very quickly: the average budget is about \$20,000, and films are normally shot in a week or two and released a couple of weeks later. The Nigerian penchant for quick returns on investments informs this model, but it is also determined by the need to stay ahead of pirates, who copy any successful film. Profits leak away in other ways besides piracy. There is no mechanism for producers to receive revenues from the thousands of video rental shops. The lucrative foreign export market for Nigerian films is dominated by pirates, and → television stations that broadcast Nigerian films in Nigeria and elsewhere in Africa pay little or nothing to filmmakers (→ Globalization of the Media). All this, coupled with the glut of films in the market, makes heavy investment in a single film risky. Budgets over \$60,000 are rare. The result is visible deficiencies in everything from script development to rehearsals and lighting. Many films are now shot with good digital cameras, but sound recording is a particular problem due to lack of equipment and trained personnel (→ Film Production).

The term “Nollywood” is of recent coinage and is not universally accepted. It refers primarily to films made in English and therefore obscures the important Yoruba and Hausa branches of Nigerian video film production. Yoruba films stem from the Yoruba traveling → theatre tradition, which flourished for half a century on stage, on television, and on celluloid film. Deeply rooted in the Yoruba artistic and cultural heritage as well as responding to contemporary urban life, the Yoruba filmmakers are noted for their clannish social organization and their loyal ethnic audience. Hausa filmmaking is heavily influenced by → Bollywood rather than → Hollywood and responds to a very different moral, religious, and cultural climate. Kano State, the heart of the Hausa film industry, established its own → censorship board after it introduced Islamic Sharia law in 2000, enforcing a ban on any on-screen touching between the sexes.

Nollywood films, on the other hand, are notoriously freewheeling and sensationalistic. Melodrama pervades the acting, directing, and writing. Their convoluted plots normally sprawl across sequels. In keeping with African cultural values, family relationships tend to be the focus of attention, though there are also plenty of love stories and a gallery of heart-throb actors (Richard Mofe-Damijo, Genevieve Nnaji, Ramsey Noah, Omotola Jalade-Ekeinde). A star system is highly developed: the publicity posters and jackets of the films are invariably covered with the faces of actors who the producers hope will be familiar to the perhaps illiterate consumers (→ Stars). Actors like Pete Edochie and Zach Orji have appeared in literally hundreds of films. Directors like Chico Ejiro, Lancelot Oduwa Imasuen, and Andy Amenechi have shot well over a hundred films each.

Most films register the anxiety that besets contemporary Nigeria, where violence is endemic, corruption is pervasive, economic life is precarious, the social fabric is fraying, and spiritual warfare rages. The films are full of supernatural elements: witchcraft attacks

by family members, consultations with diviners about fertility problems, guardian spirits enforcing the traditional morality of communities, businessmen and politicians seeking wealth and power through human sacrifice, and Bible-wielding pastors combating the forces of darkness.

Because video technology is so cheap and easy to use (→ Technology and Communication), Nollywood has arisen as a grassroots phenomenon of petty producers and as an expression of urban popular culture (→ Popular Culture; Film as Popular Culture). In these respects, as in its spectacularly successful conquest of Nigeria's screens, it contrasts with African celluloid filmmaking, which has had minimal distribution in Africa and so has had to rely on external, mostly European funding and foreign festival, art-house, and school audiences.

Nollywood films have flooded the African continent. They are shown on television in Namibia and Congo, imitated in Ghana and Kenya, sold wherever there are Africans in Europe and North America, and can be bought or downloaded from the → Internet. Tunde Kelani, the most respected of Nollywood filmmakers, has shown *Thunderbolt*, *Saworoide*, and *Agogo Eewo* at many international film festivals. Nollywood has truly revolutionized the African media environment.

# **Nonparametric Analysis**

*René Weber*

*University of California, Santa Barbara*

A class of data analysis procedures for statistical hypothesis testing that, unlike parametric statistical analysis, makes no assumptions about the sampling distribution of a statistic

being evaluated ( $\rightarrow$  Sampling, Random), *nonparametric statistical analysis* is also called *distribution-free statistical analysis*. The two terms have a slightly different meaning but are frequently used interchangeably. While nonparametric statistical inference is not bound to a priori specified parameters of a statistical model, distribution-free statistical inference is not bound to an a priori specified sampling distribution of a statistic that serves as estimation for a parameter in a population.

### NONPARAMETRIC OR PARAMETRIC STATISTICAL ANALYSIS?

Two indications suggest preferring a nonparametric over a parametric statistical analysis: (1) measurement problems and (2) problems with the assumptions of a parametric statistical test.

*Measurement problems:* in a strict sense, the results of a parametric statistical analysis cannot be meaningfully interpreted if the data were measured on a measurement level other than an interval or ratio level ( $\rightarrow$  Measurement Theory). While most statisticians and researchers agree on the fact that ordinal data require a nonparametric approach, there is still disagreement over whether statistical tests for analyzing nominal data require a parametric or nonparametric statistical analysis. Given large samples, the common practice is to analyze nominal data in a parametric fashion by referring to a chi-square sampling distribution. However, operating with small samples requires analyzing nominal data with a nonparametric approach (see example below) since a specific sampling distribution with known parameters is missing. For the same reason, nonparametric statistical tests are commonly labeled as *statistical tests for the analysis of small samples*.

*Problems with the assumptions of a parametric statistical test:* parametric statistical tests are bound to mathematical-statistical assumptions such as homogeneous variances in populations or normally distributed variables. If the collected data suggest that mathematical-statistical assumptions are violated, the results of a parametric statistical analysis may be biased. Many parametric statistical analyses are either robust or conservative test procedures. This means that results are either unbiased or favor the null  $\rightarrow$  hypothesis in a statistical test decision even if assumptions are violated. Communication (empirical) researchers usually consider this a minor problem. However, conservative parametric test decisions typically are associated with a reduced power of the corresponding statistical test ( $\rightarrow$  Test Theory). In other words, it is more difficult to detect a statistically significant result with a parametric statistical test analysis if the mathematical-statistical assumptions are violated. It can be shown that under the condition of violated assumptions a nonparametric test analysis may result in an unbiased test decision with higher power than its parametric equivalent.

In summary, a nonparametric test analysis is recommended if data have been collected on an ordinal or nominal level, if sample sizes are small, and if there is evidence that mathematical-statistical assumptions of a parametric test analysis have been violated.

### A SELECTION OF NONPARAMETRIC STATISTICAL ANALYSES

Communication researchers can select among numerous nonparametric statistical procedures for analyzing data. Typically, a useful categorization of nonparametric procedures

refers to measurement level and the number of variables as categorization criteria. The following (limited) selection of nonparametric statistical analyses covers just a few of the most common nonparametric test procedures.

*Nominal data, one variable:* the *binomial test* analyzes the statistical significance of deviations from a theoretically expected distribution of dichotomous observations (such as the flip of a coin). The *multinomial test* generalizes the binomial test for observations with more than two categories.

*Nominal data, two variables:* the *Fisher-Yates test* (see example below), which is also called *Fisher's exact test*, examines the significance of an association between two variables with two categories each (which defines a  $2 \times 2$  contingency table). The two versions of the *Fisher-Freeman-Halton test* generalize the Fisher-Yates test concept for  $k \times 2$  (two variables,  $k$  categories of the one and 2 categories of the other variable) and  $k \times m$  (two variables,  $k$  categories of the one and  $m$  categories of the other variable) contingency tables.

*Ordinal data, one variable:* the *median test* and the *Mann-Whitney-Wilcoxon test* (also called *Wilcoxon rank-sum test*) analyze whether the difference in medians between two independent samples is statistically significant. The *Kruskal-Wallis test* can be applied for more than two independent samples (as in a one-way analysis of variance). Similar to a repeated measures analysis of variance, a *Friedman test* can be applied to analyze differences in dependent samples. Both the Kruskal-Wallis test and the Friedman test require a transformation of measurements into ranks. There are nonparametric statistical test analyses for more than one variable and more than two independent samples. These procedures, however, are rather complex and require a profound mathematical-statistical background to understand.

*Interval data:* unlike the aforementioned statistical tests, nonparametric statistical tests for interval data do not require a prior transformation of measurements into ranks, which usually results in a loss of information. These test procedures are indicated if the size of samples is small and, therefore, parametric analytical procedures are out of the question. The *Fisher-Pitman Randomization test*, for example, analyzes whether differences between two independent samples are statistically significant (or in other words, whether two samples originate from the same population). The *Fisher Randomization test* analyzes the same hypothesis for two dependent samples.

In addition to nonparametric procedures for testing differences in two or more samples, numerous nonparametric correlation coefficients for the analysis of associations between ordinal variables are available ( $\rightarrow$  Correlation Analysis). The most common nonparametric correlations are the *Spearman's Rank Correlation* ( $\rho$ ) and *Kendall's Rank Correlation* ( $\tau$ ) for ordinal data.

## EXAMPLE

The nonparametric Fisher-Yates test and the corresponding parametric chi-square test for  $2 \times 2$  contingency tables will be used as an illustration of the nonparametric test concept.

A media researcher is interested in analyzing whether men tend to prefer nonfiction TV programs, such as documentaries or news, and women tend to prefer fiction TV programs, such as movies. Hence, the specific (one-sided) research hypothesis ( $H_1$ ) under evaluation

is: “There is an association between gender and preference (in the population). The preference for TV programs is specific. Men prefer nonfiction TV programs while women favor fiction programs.” The null hypothesis ( $H_0$ ) is: “There is no such association in the specified direction; the variables gender and preference (fiction vs. nonfiction) are independent (in the population).” In mathematical terminology, the research hypothesis can be written as  $H_1: \pi(\text{men/nonfiction}) > \pi(\text{women/nonfiction})$ , and the null hypothesis as  $H_0: \pi(\text{men/nonfiction}) \leq \pi(\text{women/nonfiction})$ .

In a first study a sample size of just  $n = 15$  men and women could be realized. The data collection results in the following  $2 \times 2$  contingency table:

	Nonfiction	Fiction	Sum
Men	4(a)	1(b)	5
Women	3(c)	7(d)	10
Sum	7	8	15

The sample data seem to indicate an association in the right direction: men tend to favor nonfiction and women fiction TV programs. The question, however, is whether this association is statistically significant, i.e., is not a random result. As a significance level we choose  $\alpha = 0.05$ . Due to the small sample size the nonparametric Fisher-Yates test will be applied. For the first step, we will determine the random probability of the  $2 \times 2$  frequency distribution above. For this we use the hypergeometric probability function according to the following formula:

$$p = \frac{(a + b)! \cdot (c + d)! \cdot (a + c)! \cdot (b + d)!}{n! \cdot a! \cdot b! \cdot c! \cdot d!} = \frac{5! \cdot 10! \cdot 7! \cdot 8!}{15! \cdot 4! \cdot 1! \cdot 3! \cdot 7!} = 0.093$$

Given the observed marginal sums, the probability that the  $2 \times 2$  table above occurs at random is 0.093 or 9.3 percent. This, however, is just the probability of the observed frequency distribution. In a second step we need to determine how many *more extreme* frequency distributions (more extreme in the direction of  $H_1$ ) are possible given the observed data. For example, here is another  $2 \times 2$  frequency distribution in which we have moved one man from the fiction to the nonfiction category, and one woman from nonfiction to fiction. The marginal sums remain unchanged:

	Nonfiction	Fiction	Sum
Men	5(a)	0(b)	5
Women	2(c)	8(d)	10
Sum	7	8	15

Since one cell already has a frequency of 0, it is impossible to find another more extreme  $2 \times 2$  frequency distribution. The probability of this frequency distribution is:

$$p = \frac{5! \cdot 10! \cdot 7! \cdot 8!}{15! \cdot 5! \cdot 0! \cdot 2! \cdot 8!} = 0.007$$

Thus, the probability that the observed frequency distribution or more extreme frequency distributions occur at random (the null hypothesis) equals the sum of both probabilities:  $p = 0.093 + 0.007 = 0.1$ . The null hypothesis cannot be rejected since  $p > \alpha$ . Men do not prefer nonfiction over fiction TV programs compared with women – the association observed in the sample is not statistically significant.

In a second study, a larger sample of  $n = 40$  could be reached. After data collection the  $2 \times 2$  contingency table looks like the following:

	Nonfiction	Fiction	Sum
Men	5(a)	5(b)	10
Women	6(c)	24(d)	30
Sum	11	29	40

Assuming the variables are independent in the population and given the marginal frequency distribution, the expected cell frequencies can be calculated with the following formula:

$$e_{ij} = \frac{\text{row sum } i \cdot \text{column sum } j}{\text{total sum}}$$

According to this formula only one of the four cells has an expected frequency of less than 5 (cell a). This result suggests that one has a sufficiently large sample to assume a chi-square distributed sampling distribution of the chi-square test statistics, which is used to evaluate the association between gender and preference in the  $2 \times 2$  table above. Thus, one can use a parametric chi-square test for the analysis of this  $2 \times 2$  contingency table. The empirical chi-square value can be calculated by using the following formula:

$$\chi^2 = \frac{n \cdot (|a \cdot d - b \cdot c| - \cdot n/2)^2}{(a + b) \cdot (c + d) \cdot (a + c) \cdot (b + d)} = \frac{40 \cdot (|5 \cdot 24 - 5 \cdot 6| - \cdot 40/2)^2}{10 \cdot 30 \cdot 11 \cdot 29} = 2.05$$

Chi-square values of zero indicate no association between the variables in the sample. Negative chi-square values do not exist. The greater chi-square values are, the less plausible is the null hypothesis. A chi-square value in a  $2 \times 2$  contingency table has one degree of freedom ( $df = 1$ ), since only one of four cells can be freely modified given fixed marginal sums. Further, the formula provided for calculating an empirical chi-square value refers to a two-sided test (i.e., for testing unspecific hypotheses). To test a specific hypothesis by means of a one-sided chi-square test with one degree of freedom, one can use the relationship between a chi-square distributed and a normal distributed random variable, which is:

$$\chi_{(df=1)}^2 = z^2$$

Thus, this example would yield a standard normally distributed z-value of  $z = 1.43$ , which is the square root of 2.05. The corresponding probability for this and more extreme z-values is, according to the tabulated standard normal distribution,  $p = 0.076$ . Again,

since  $p > \alpha$  we cannot reject the null hypothesis. The parametric test, too, suggests that the observed association between gender and preference in a sample of 40 people is not statistically significant.

# **Nonverbal Communication and Culture**

*Han Z. Li*

*University of Northern British Columbia*

Humans communicate verbally through words and nonverbally via facial expressions and body movements. Nonverbal communication refers to any human behavior, other than words, that serves a communicative purpose (→ Interpersonal Communication). Such behavior can occur voluntarily or involuntarily, either simultaneously with words or alone. Nonverbal communicative behaviors that have been under intensive research include high–low context, silence, turn-taking, facial expressions of emotion, head nod, and gaze and mutual gaze.

Culture is defined as “the way of life of a people” (Hall 1959, 31), who often live in a well-defined geographic area, speak the same language, and use the same nonverbal codes, with a set of norms and values regulating their thoughts and behaviors (→ Intercultural Norms). The relationship between culture and communication, verbal or nonverbal, is a reciprocal one, as crystallized by Hall (1959, 169): “culture is communication” and “communication is culture.” People communicate according to the dictates of their culture, and, in turn, through communication, culture is manifested, specified, and developed.

## **RESEARCH BACKGROUND**

In the long journey of human evolutionary processes, cultural groups have formed distinctively different languages and nonverbal communication cues, which are understood

among themselves but can be enigmatic for outsiders. As nonverbal communication is often implicit, fleeting, and hidden, it creates a major difficulty for intercultural communication.

*Nonverbal cues serve several purposes* in interpersonal interactions. They can convey → attitudes (e.g., likes and dislikes), express → emotions (e.g., being pleased or displeased), provide information about personality (e.g., being outgoing or reserved), provide a context for exerting influence (e.g., using silence to show disagreement), and complement, repeat, contradict, or substitute verbal messages (e.g., using a smile instead of words to show happiness). For example, when nonverbal cues illustrate what is being said, they are called illustrators; when they regulate the flow of the conversation, they are termed regulators; when they have a direct verbal translation (e.g., “V” for victory), they are termed emblems.

The main conceptual framework under which nonverbal communication has been studied is *cultural relativism and universalism* (CRU). CRU categorizes nonverbal communicative behaviors according to their meaning and function. For example, the North American *okay* sign (the thumb and the index fingers form a circle, with the other three fingers in an upright position) means *money* in Japan, *zero* in France, *sex* in Mexico, and *homosexuality* in Ethiopia. The *thumbs-up* gesture also means *okay* in North America and Europe. But in China, it means *you are the best*. In Japan, it means *boyfriend*, and in Iran, it is an obscene gesture. In these instances, the meaning of the *okay* sign is compared cross-culturally. Conclusions are made in terms of whether the meaning of a certain nonverbal behavior is culture-specific or culture-universal. Under this scheme, cultures are not divided into clusters. Rather, each culture is taken as it is. In the following sections, representative literature on culture and nonverbal communication is reviewed.

### **HIGH-LOW CONTEXT COMMUNICATION, SILENCE, AND TURN-TAKING**

Hall (1976) distinguished two *communication styles*: high-context and low-context. With high-context communication, the verbal message is indirect and restricted, and the listener is expected to infer the full meaning or intention of the speaker by analyzing the words in the specific context (→ Language and Social Interaction). Low-context communication is characterized with direct and elaborated verbal messages, leaving little room for the audience to conjecture. Research indicates that low-context communication is the predominant communication style in North American and European cultures, whereas high-context communication is frequently used in Asian and African cultures (→ Intercultural and Intergroup Communication).

Although both the east and west employ *silence* as a communication strategy, it is viewed and used differently. For example, silence is viewed positively in Japan. Japanese of few words are trusted more than Japanese who speak a lot. A well-known Chinese proverb says that sometimes silence is more eloquent than words, and those who know when to be silent know how to communicate. In Korea, a candidate losing political debates may receive more votes because the less verbose candidate may be judged as a reticent man, capable of deep thought and practical approaches to his country's economy. Indigenous people of northern Canada and Alaska, including Athabaskans, Northern Tutchone, Carrier, and Cree, prefer silence to talk when social relations are uncertain. This communication tactic is known as “the rule of the bush which bore two reasons”: talking too much is disrespectful, especially with a stranger, and it is strategic to leave

enough time to think over how to express something that is very complex and connected to many other things. On the other hand, North Americans are uneasy with silence in conversations. To avoid awkwardness, they tend to fill it with words.

A related concept is *turn-taking*, which refers to who speaks, how often, and for how long. Euro-Canadians tend to take long, monologic turns, and take a high percentage of turns in topics that they initiate. Japanese, however, tend to take short turns, and distribute them evenly regardless of who has introduced the topic (→ Conversation Analysis; International Communication).

### EYE CONTACT DURING CONVERSATION

Past research indicates that eye contact serves an important communicative function, and that cultural upbringing dictates the way we gaze and mutually gaze (for a review, see Li 2004; → Eye Behavior; Gaze in Interaction; Visual Communication). Researchers found that among the Chinese, conversational partners do not usually look directly at each other's eyes. Black and white Americans differed in their listening behavior. During a conversation, whites gazed steadily at the speaker while blacks avoided looking into the eyes of the speaker. Comparing gaze behavior between native English speakers (Australians of British descent) and native Japanese speakers, researchers found that the Japanese participants gazed at their partners more frequently but for shorter durations than Australians. The Australians tended to look up at the end of utterances, yet no pattern of looking up was found among the Japanese participants. Japanese felt uneasy when being directly gazed upon. Researchers compared gaze behaviors of 22 pairs of Swedes and 22 English pairs during laboratory conversations. In both conditions there were 11 male/male and 11 female/female dyads. It was found that length of glances was higher for the Swedes than for the English. Frequency of glances was higher for the English than for the Swedes.

Li (2004) reported that in both *gaze and mutual gaze behaviors*, Chinese/Chinese interlocutors looked less frequently and for shorter durations than did Canadian/Canadian interlocutors, thus documenting an evident cultural difference. This finding has practical value in today's multicultural world. Suppose a Canadian professor finds her Chinese student not looking at her when he is spoken to. She may interpret the student as inattentive or disrespectful. Or imagine a Canadian businessman finding that his Chinese negotiator is not engaging in eye contact. He may infer that the Chinese person is insincere or uninterested. Similarly, a Canadian doctor finding that his Chinese immigrant patient looks away when spoken to may surmise that this individual is not telling him all of the symptoms. If intercultural interlocutors are aware of such findings – differences in eye contact behavior between Chinese and Canadians – they may be less likely to make erroneous judgments, which are the first step toward miscommunication. Li also found that when Chinese were paired with Canadians, they gazed slightly more frequently than when they were paired with fellow Chinese, while the Canadians maintained their frequent gaze pattern.

This finding provides obvious support for → communication accommodation theory (CAT). CAT states that interlocutors have a tendency to converge or diverge their linguistic codes either for power or desire for social approval (Gallois et al. 2005). In this

instance, the second-language speakers (the Chinese) had both linguistic and cultural disadvantages in comparison with their Canadian partners; the Chinese, therefore, converged to the more frequent gaze pattern of the Canadians. The Chinese may have converged their gaze pattern to that of their Canadian partners because they wanted to be agreeable. Immediately after the conversations, the Chinese and Canadians were asked about their experiences. Both parties said that they had experienced a pleasant interaction. In some cultures there seems to be a rule specifying that interlocutors should look at each other, while in other cultures the rules are not specific. This point is illustrated by an interesting anecdote (Li 2004, 6) concerning an encounter between a Chinese and two Americans: “On the second day of my arrival in the US, I went to see the Department Chairman accompanied by my American friend Judith. To show my respect for the Chairman, I sat straight, my hands on my knee. Most of the time I looked down; sometimes I looked at Judith, who was sitting on my right hand side. Then I heard Judith saying ‘Xiao Li, you are supposed to look at the speaker, not me.’ They both smiled, and I smiled too, but for a very different reason: I smiled to hide my awkwardness.”

Li (2004) goes on to explain that in Chinese culture, there are no clear rules regarding where one should look in a conversation, except for when one is speaking with a superior or a parent. In this case, one should look down to show respect. Looking into the eye of your mother while she is criticizing you would make her angry because that is tantamount to “talking back.” Looking down would be interpreted as being modest and accepting her criticism.

Researchers have also found that Asians, Indians, and Africans relate constant gaze with being superior, disrespectful, threatening, or insulting. Southern Europeans, Arabs, and Latin Americans, on the other hand, interpret lack of gaze as insincere, dishonest, or shy. Eye gaze of blacks is minimal when interacting with a superior, as a means of showing respect. Evidently, black children have learned to lower their eyes when an older person or a teacher is talking to them, or when they are being scolded. Among the Navaho Indians, direct gaze at one’s conversational partner is a taboo. Among the Wituto and Bororo Indians in South America, the speaker and listener both look at outside objects during a conversation. In Japan, people look at the neck level, not at the eye level. Intense gazing at the eye level during conversation may be interpreted as being disrespectful.

### **WHAT DOES A NOD REALLY MEAN?**

Greeks express *yes* with a nod as North Americans do, but they express *no* with head jerking back, eyes closing and eyebrows lifting for a while. The Bulgarian head movement for *no* consists of throwing the head back and then returning it to the upright position. When emphatically displayed, the return to the upright position can involve a slight bend of the head forward, thus appearing very much like the North American nod for *yes*. Cultural groups may share the use of nodding the head, especially while listening. However, the interpretation of a nod differs from culture to culture. The Japanese nod signifies continued attention while a North American nod signifies both continued attention and agreement. Without knowing this difference, North Americans can be very frustrated when, at the end of a long presentation, they find that their listener disagreed with them wholeheartedly in spite of constant nods.

Li (2006) found that when Chinese conversed with Anglo Canadians, the more back-channel responses (including head nods), the less information was correctly communicated between the speaker and the listener. On the other hand, when a Chinese talked with another Chinese or a Canadian with another Canadian, the more back-channel responses, the more information was correctly communicated. This finding showed that back-channel responses function differently in inter- and intracultural discourse. In the former, they impede information communication, while in the latter, they facilitate it. Li also found significant cultural differences in the frequency of back-channel responses. The Chinese/Chinese participants had the highest frequency, the Canadian/Canadian participants the lowest, and the intercultural participants (Chinese/Canadian) were in between. This pattern provides support for CAT in that a back-channel convergence occurred in the intercultural conditions.

### FACIAL EXPRESSIONS OF EMOTION

The earliest scientific study of *facial expressions of emotion* was published by Darwin (Ekman 1973). He postulated that emotions and their expressions were observed across cultural groups, as well as species. Therefore, they are innate and biological in nature. This theory was supported by later researchers, who identified six emotions across cultural groups: anger, fear, happiness, sadness, surprise, and disgust (Ekman 1973). Although humans are equally capable of the six emotions, whether, when, and how they display them are decided by their cultural upbringing. Ekman found that Japanese participants displayed the same negative facial expressions as American participants when watching a stress-inducing movie about sinus surgery. However, in the presence of an interviewer, the Japanese displayed fewer negative expressions than when they were alone. But the Americans were as expressive in the presence of the interviewer as when they were alone. It was concluded that culture is dictating certain rules about what feelings one should reveal to whom and under what circumstances. Matsumoto and Kupperbusch (2001) replicated Ekman's (1973) study and they found that Americans also masked their emotions in the presence of others, but to a lesser extent than the Japanese.

Ekman et al. (1987) asked participants from Estonian SSR, Germany, Greece, Hong Kong, Italy, Japan, Scotland, Sumatra, Turkey, and the United States to watch slides and judge six emotions and their intensity. They found that cross-cultural agreement was very high. However, cross-cultural agreement in judgment accuracy was lower for high-intensity emotions than for low-intensity emotions (Matsumoto et al. 2002). This finding has important implications for intercultural business and political communication, because in these situations, emotional intensity is usually high. Inaccuracy in judging each other's emotions can lead to misattribution, misunderstanding, and miscommunication, and the consequences can be severe.

Major findings on nonverbal communicative behaviors seem to illustrate a saying by Confucius: our common human nature brings us together whereas our different customs and habits set us apart. Because we are similar, we can communicate, to some extent, nonverbally even when we do not speak each other's languages. But our different cultural norms may erect barriers. For members of different cultural groups to communicate

effectively, it is *essential* that we learn each other's nonverbal ways of expression, especially rules concerning when and how to use which nonverbal signals.

## **Nonverbal Signals, Effects of**

*Gary Bente*

*University of Cologne*

*Nicole C. Krämer*

*University of Duisburg-Essen*

Human communication is a *multichannel reality* comprising verbal, paraverbal, and nonverbal signals. Although some authors subsume paraverbal aspects, like pitch, tone of voice, etc., under the heading of nonverbal behavior, it is most common to preserve the term “nonverbal” for those aspects of communicative behavior that are transmitted visually, such as gestures, body posture and movement (→ Gestures and Kinesics), facial displays (→ Facial Expressions), gaze (→ Gaze in Interaction), and interpersonal distance (→ Proxemics).

There is ample empirical evidence that the visual communication channel plays a prominent role, not only in face-to-face interactions but in mediated communication as well (Burgoon et al. 1989). Beyond so called discourse and dialog functions closely tied to speech production and conversation, such as illustrative gestures or turn-taking signals, nonverbal behavior constitutes the major basis for the perception of persons and the formation of social impressions (see Bente & Krämer in press). Based on nonverbal cues, humans are prone to make inferences about the emotional states, intentions, and even personality attributes of other people. Impressions on the basis of nonverbal behavior are formed within extremely short time periods, and even minimal variations in posture, movement, or facial expression can have a deep impact on the emotional attitudes of an observer.

Based on the observation that nonverbal cues, like all visually perceptible stimuli, possess an overwhelming suggestive force, Frey (1999) introduces the concept of *inferential communication*. Referring to Helmholtz's concept of *unconscious conclusions*, he highlights the fact that the inferences based on visual cues are not subject to conscious cognitive control but leave us defenseless, while affecting our judgments immediately and sustainably. With regard to the *neuro-biological bases of inferential communication*, recent neuro-imaging studies could identify specialized brain areas for the processing of visual communication cues, especially sensitive for human faces and gaze behavior. Further, the discovery of the so-called mirror-neurons enforced the assumption of a hardwired *empathy system*, which takes advantage of the fact that observed movement produces the same neural activation patterns as the production of this behavior.

The conclusion, however, that this neural reflection leads to a simulation of comparable emotional states (→ Emotion) in the observer is still a hypothesis. This hypothesis also draws upon another implicit assumption, namely that emotional states more or less involuntarily lead to specific expressive behaviors on the part of the sender that can then be informative for an observer (see Manstead et al. 1999 for a review). This position, however, has been challenged in recent years. Referring to empirical findings in evolutionary psychology, Fridlund (1991) argues that it is not functional to disclose emotions to an observer, and that it makes much more sense to assume that nonverbal cues are used independently from the affective state in a socially purposeful or manipulative way. Based on recent findings, Manstead et al. (1999) suggest that both emotional and social contexts can determine nonverbal behavior and that both views are thus not mutually exclusive.

## SIGNALS AND BEHAVIORAL QUALITIES

In an attempt to systematize nonverbal cues according to their communicative functions, Mehrabian (1972) identified three basic effect dimensions and associated signal categories: (1) the *evaluation dimension* (liking) is communicated by so-called *immediacy cues* such as smiling, forward lean, close proximity, and touch; (2) the *potency dimension* (power) is conveyed by *relaxation cues* such as asymmetry, side lean, relaxed hands, and backward lean, and moreover by staring, averted gaze, and expansive gestures; and (3) the *activity dimension* is associated with *activity cues* comprising vivid and extensive use of gestures, frequent facial displays, etc. A broad literature exists dealing with those functional

categories, the identification of particular cues or signals, and the proof of their distinct effects. In recent years, however, scholars discovered that dynamic characteristics or movement qualities, such as speed, acceleration, dimensional complexity, symmetry, etc., may have an even stronger impact on the observers' impressions than the so-called semantic aspects (Grammer et al. 1997; Krumhuber & Kappas 2005). These aspects exert a subliminal influence on the observer and thus are rarely identified as a cause of social judgments and interpersonal feelings. Against this background, Grammer et al. (1997) suggest a view of nonverbal communication that differs radically from traditional category-oriented "body language" approaches and that has been labeled the *analogous communication* perspective.

Experts of propaganda and political campaigns long since discovered the power of televised images and the crucial role of visual presence, physical appearance, and nonverbal behavior in influencing the attitudes of a mass audience, as in televised presidential campaigns. In fact, it has been shown that politicians' facial expressions (the presentation of happiness/reassurance, anger/threat or fear/evasion displays) are even more decisive for the perception of the actor than the observers' political partisanship or ideological beliefs (Sullivan 1996). Referring to the *facial feedback theory*, the socio-emotional effects of facial expressions have been interpreted in this context as *vicarious instigation* (Vaughan & Lanzetta 1980). This view holds that the observation of the actor's facial displays leads to the automatic mimicry of facial movements and subsequently – due to the interlinkage of facial muscles and brain regions associated with emotions – to the corresponding feelings in the observer. This affective resonance is assumed to be the basis of empathic reactions to the screen actors, which may also account for emotional involvement and identification processes in fictional offerings.

### **NONVERBAL BEHAVIOR IN TRADITIONAL MEDIA**

It is evident that the interpretation of mediated nonverbal behavior depends heavily on the context information presented. The Kulechov effect describes the fact that even neutral faces can lead to such different emotional attributions as terror, joy, or contentment when embedded into different stories (Pudowkin 1961). Moreover, the staging of nonverbal behavior implies numerous influences by the medium itself, including camera perspectives, production techniques, or journalists' decisions about the selection and placement of nonverbal material. As visual attention is a valid indicator of power and status in social groups, presence on-screen not only reflects the relative importance of the personalities presented, but can also subtly influence the audience's perception of leadership and dominance (Masters et al. 1991).

Physical distance is a highly influential nonverbal cue in interpersonal communication. It is also an intriguing example of how staging variables can simulate or substitute variations in nonverbal behavior. Meyrowitz (1979) coined the term "para-proxemics" to account for the fact that camera distance, judged by the relative size of an actor on the screen, is capable of triggering psychological mechanisms similar to the real distance to another person. A close-up could thus create intimacy but could also be threatening when penetrating virtual personal space abruptly, whereas a wide shot could create a psychological distance between the observer and the screen actor.

The camera perspective also determines the observer's field of view and thus directs the attention of the audience to particular nonverbal cues. For instance in close-ups the focus is on facial activity, which stimulates inferences about the emotions and intentions of the actor. On the other hand in half or wide shots the view is opened up to communicative gestures, interpersonal constellations, and information about context. It is likely that these perceptual constellations also influence the direction of the audience's *causal attributions*, so that the causes of observed behavior are located within either the actor or the particular situation.

With regard to angle of view, the results are equivocal. Kepplinger (1982), for example, found politicians presented on TV from a straight angle to be the most likeable, while deviations in either direction (up or down) led to less positive evaluations. Other studies (Kappas et al. 1994) show the low-angle shot to be preferred. Messaris (1997) states that low camera angles can make actors appear more powerful, provided that they are already recognized as high in status, as in the case of known political leaders. It has to be noted that the camera angle as a surrogate for the observer's perspective and gaze direction interacts with the gaze direction of the actor portrayed. Here, looking directly into the camera can reduce the impression of an actor's power. In line with results from gaze research, powerful people are expected to be looked at by inferiors rather than to look at observers themselves.

The subtle interplay between nonverbal behavior and presentation variables is also reflected in the concept of *parasocial interaction* (Horton & Wohl 1956; → Parasocial Interactions and Relationships). Although in mass communication large audiences are present, each member might still feel they are being addressed in relative privacy and thus get the illusion of a face-to-face encounter with the performer or persona. To achieve this, the persona attempts to duplicate the gestures, conversational style, and milieu of a small informal gathering, and turns on eye contact by facing the camera. This behavior is supported by formal presentation techniques. While the persona is facing the camera, zoom activity can enhance intimacy by making the persona appear actually to approach. Whether the emotional response of the viewer will be positive or negative depends on the communication behavior of the persona.

## NONVERBAL COMMUNICATION IN THE NEW MEDIA

So-called "cues-filtered-out theories" of computer mediated communication (CMC) consider the partial or complete lack of nonverbal signals as a deficit with particular socio-emotional consequences (→ Personal Communication by CMC). On one hand it is considered as detrimental, in the sense of resulting both in emotional impoverishment and in the facilitation of antisocial and deviant behaviors. On the other hand the lack of nonverbal signals, in particular the lack of status and dominance cues, is expected to foster a balance of power and influence, and to equalize participation and mutual attention in net-based communications (Kiesler et al. 1984). Both positions use face-to-face encounters as normative reference. In his "social information processing" (SIP) theory, Walther (1996) challenges the deficit conception of mediated communication and highlights the creative processes in the users. These processes might not only find substitutes for the nonverbal channels (e.g., by using so-called emoticons or avatars), but

also result in new forms of human interaction that are not possible in face-to-face meetings at all. It is still an open question, though, under what circumstances the inclusion of nonverbal channels in CMC (e.g., by video or avatar representations) will enhance the experience of *social presence* (Biocca et al. 2003) and lead to beneficial socio-emotional effects and better task performance (→ Presence). As in face-to-face interactions, the outcome will depend more on what the actors do than on which channels are available. This also holds for the implementation of so-called embodied conversational agents (ECAs) in → human–computer interaction (HCI). By decoding but also by showing expressive nonverbal behaviors, ECAs are expected to personalize the interactions between humans and electronic devices and to facilitate acceptance and intuitive usage (Cassell et al. 2000). As Blascovich (2002) states in his “threshold model of social influence,” the social influence of virtual interlocutors depends on at least two factors: the perceived agency (whether the behavior is directly or indirectly human in origin or is computer-generated) and the behavioral realism. With regard to the latter, it is assumed that verification of the entity being a social actor depends largely on the processing of subtle nonverbal cues and transient movement dynamics.

## North Africa: Media Systems

*Mohammed Ibahrine*

*Al Akhawayn University*

This entry focuses on the media systems in the Maghreb countries. The Maghreb (Algeria, Morocco, and Tunisia) as a political entity is characterized by authoritarian structures. The regimes are omnipresent in almost every aspect of daily life, including the media sector. The countries in question share strong similarities in terms of their early historical development, their French colonial past, the nature of their media systems, the journalism practiced, their media laws, and their common struggle to increase press freedom, access to information, and protection of journalists. Tunisia has the most authoritarian regime and thus the most restrictive media policies. Morocco is the most liberal of the countries and thus has the least restricted media. Algeria exists in the middle of the spectrum. In recent times, the media landscapes in the three North African countries have changed under the combined impact of the globalization process and information and communication technologies.

### ALGERIA

In Algeria there are about 40 daily → *newspapers* and → *magazines* in circulation. The daily newspaper with the widest circulation is *Al Khabar* (400,000). The circulation of

daily newspapers is about 3 million, which is 9 percent of the population. Since 1990, the Algerian press has been governed by the “Information Code.” Politics is viewed as combat rather than contest, and journalists are hampered by a lack of adequate training and by low pay; they are not financially self-sufficient. Journalism remains more of an intellectual passion than a real profession. Over the past decade, ongoing civil strife between the regime and Islamic extremists has made journalism one of the most dangerous professions; 58 commentators and editors were murdered between 1993 and 1996. Journalists in this North African country continue to suffer from legal and physical harassment.

In 1926, → *radio* broadcasting began in Algeria, but it was only after independence in 1962 that a wide range of radio content was developed and broadcast. The state-run Radio-Television Algerienne (RTA) consists of four national stations. In Algeria there are an estimated 244 radio receivers for every 1,000 inhabitants. Radio Algeria programming is available via the Internet. Radio remains under the control of the government, with coverage biased strongly in favor of state policies. While the 1998 amendments allow for the licensing of private stations, the regime continues to maintain its monopoly over radio broadcasting.

In Algerian Television, Enterprise Nationale de Television (ENTV) oversees the two state-run channels, *Canal Algérie*, broadcasting to Europe’s Algerian community, and *Al Thalitha TV*, broadcasting to Arab countries. *Berbère Television (BRTV)* is a Berber station that is broadcast from France to Algeria via satellite and targets the Berber communities. RTA broadcasts in Arabic, Berber, and French and operates an international service broadcasting in Arabic, English, French, and Spanish (→ International Radio). The 1990s witnessed an unexpected explosion of → satellite television; more than 60 percent of Algerian households have access to European channels through satellite dishes. Recent studies of television viewing habits in Algeria suggest that regime-run broadcasting is less popular, especially among the young, than satellite broadcasting, which is uncensored and often viewed as more credible. The 1998 amendment allows for private television broadcasting, but so far no licenses have been provided.

The Centre de Recherche sur l’Information Scientifique et Technique (CERIST), a state-owned research center, introduced the first access to the → *Internet* in Algeria in 1993. There were approximately 1,920,000 Internet users in Algeria in the beginning of 2007. In terms of Internet penetration, Algeria is lagging behind the other two North African countries in question. Several newspapers now operate online versions of their publications.

## MOROCCO

From independence in 1956, Morocco has had one of the most open *print media* environments of the Maghreb countries. There are 26 newspapers and 136 weeklies with a total circulation of 350,000 per day; less than 1 percent of the population reads a newspaper every day. Many Moroccan newspapers maintain websites. While Morocco does have an open and relatively free press, there are three no-go areas: Islam, the monarchy and the Sahara. Journalists who overstep the boundaries often face persecution, harassment, and in some cases have even suffered imprisonment (→ Violence against Journalists; Freedom of the Press, Concept of). Print media organizations continue to need a license to publish. However, → censorship has been softened in the country since 1997.

*Radio* began broadcasting in 1928. By 1962, the regime had reorganized the country's broadcasting structure and become the "*Idaa wa At-Talvaza Al-Mahgrebiya*" (Moroccan Radio and Television: MRT). There are an estimated 6.62 million radio receivers in the country. The four Arabic stations are the National Arabic Channel, Koran channel, Radio Tamazight and International radio channel. The National Channel, which has 24-hour broadcasting, features coverage of local news and events, call-in talk shows, drama, and educational and cultural programs. Radio programming is state-run and is broadcast live over the Internet. Moroccan audiences also have access to Tangier-based radio station *Medi 1*.

*Television* began in Morocco in 1952 as a private enterprise. In 1961, ownership of television broadcasting and content development was transferred to the regime. Until 2002 the regime had a monopoly on television broadcasting, except for *2M*, originally privately owned, but bought by the state. In 2002 the Broadcasting Supreme Authority (HACA), was created by royal decree to regulate the broadcasting system. Another development is the creation of the National Company of Radio and Television Broadcasting (SNRT), a convergence of the Moroccan broadcasting channel (RTM) and the Autonomous Service of Advertising (SAP). The Moroccan audiovisual system has witnessed five additional channels: (1) *Al Maghribia*, an international news channel for the Moroccan community abroad; (2) *TVM international*, a general entertainment channel for the Moroccan community abroad; (3) *Arabia or Tarbawiya*, Morocco's leading education and culture channel, aimed at a youth audience; (4) *TVM Layoune*, designed for the southern region; and (5) *Assadisa*, a religious channel. In 2006 the radio station *Medi 1* launched its own TV channel, *Medi Sat 1*. The most popular way to watch television in Morocco is through satellite TV. Moroccan audiences have access to international satellite televisions. There are an estimated 3.1 million television sets in Morocco. Moreover, 67 percent of households own a satellite dish. In 2007 SNRT started full-scale digitization of Moroccan TV. The digitization process covered 54 percent of the population and full coverage is expected by 2015.

The history of the *Internet* in Morocco dates back to the early 1990s. The first general users of the Internet in Morocco were scholars, businesspeople, and students in 1995. There are approximately 5 million Internet users in Morocco, 15 percent of the population, but 95 percent of the use is oriented to international websites. The Internet is an important part of youth subculture in Morocco. Many young people choose the 3,500 Internet cafes for social media use; *YouTube* is the most popular net-based activity among young people.

## TUNISIA

The history of the Tunisian press began in 1860 with the creation of the periodical *Al-Raid Al-Tunisi*. In the 1930s the nationalist press fought for the independence of Tunisia. During the reign of Habib Bourguiba (1956–1987), the Tunisian media functioned as a key instrument for the legitimization of the political hegemony of one party. In 1987 the Tunisian media sector witnessed a kind of political opening up that positively affected the media landscape. There are nine dailies and 15 weeklies, and the total circulation of newspapers in Tunisia is 250,000 copies a day. Approximately 3.7 percent of the population read newspapers every day. However, these publications rarely provide information that

diverges from the official line and have become an ardent propaganda instrument for the regime. Foreign publications are also subject to censorship, including the 70 accredited foreign correspondents.

*Radio* in Tunisia is an absolute monopoly and functions under direct supervision by the regime. The primary reason for continuing to keep broadcasting under state control is the expressed desire to preserve national unity and maintain centralization of the regime and administration. Today, the state-run Tunisian Radio and Television Establishment (ERTT) has several radio networks, including *Sfax*, *Gafsa*, *Tataouine*, and *Monastir*. Tunisian radio is a state business, subsidized by the regime and partially financed by advertising revenues. There are an estimated 1.9 million radio receivers in Tunisia, or 607 per 1,000 inhabitants. *Radio Mosaïque* FM, the first ever private radio station in Tunisia, started broadcasting on November 2003. Tunisian radio has also been available via the Internet since December 1996.

*Television* transmission in Tunisia began in 1966. As of 2007, there were three television stations. There are an estimated 1.9 million television receivers in Tunisia. ERTT operates two national television channels. Tunisian TV broadcasts news, sports, soap operas, religious and cultural programming, cartoons and children's programming, and films. Sixty-five percent of the television programming is produced in Tunisia. The remaining 35 percent comes mainly from the Arab world, Europe, and North America. Since 1994 there has been a special youth television channel, *TV 21*. In addition to state-run television, since 1988 many Tunisians have been able to receive satellite television, and thus can watch Arab satellite news, including the first opposition satellite channel, *Al Mustaqillah*, which was launched from London in January 1999. There are an estimated 500,000 satellite dishes. Since March 20, 1998, national television has been available online. A private satellite TV channel, *Hannibal TV*, started broadcasting in February 2005 as a response to the initiative by President Zine El-Abidine Ben Ali to open up and privatize audiovisual broadcasting.

In 1991 Tunisia became the first Arab and African country to introduce the *Internet*. Since then the country has continuously improved its infostructures as part of the promotion of the Tunisian economy both at home and abroad. It occupies a leading position among developing countries in terms of digitization, ranking highest in Africa and in the Arab world. It is ahead of several European countries, being placed thirty-fifth in the World Economic Forum's Networked Readiness Index (NRI) in 2006–7. Tunisia has the highest Internet penetration (953,000 households and businesses). The ability to access broadcast radio and television on the Internet reveals the sophistication of the regime's use of the Internet in Tunisia. However, in spite of wide Internet access, the Internet in Tunisia is still censored via a proxy server.

The North African countries have witnessed the emergence of a new media regime, characterized by greater diversification and multiplication of news sources and leading towards a richer and more pluralistic communication environment. However, the three countries are still classified as non-free countries according to the most recent Freedom House rankings.

# Objectivity in Reporting

*Robert A. Hackett*

*Simon Fraser University*

The concept of “objectivity” connotes a set of practices and ideas, such as a stance of → neutrality or → balance in relation to the people and events being reported. It is a central ethos in journalism, especially in the Anglo American liberal democracies (→ Ethics in Journalism). It is also acquiring global significance as journalists seek new roles and institutional supports within the “transition societies” of formerly communist and third world dictatorships. What objectivity means in practice, however, and whether it is a desirable and achievable goal for reporting in a democratic society are questions very much debated.

Objectivity sounds like a positive value, the pursuit of truth without fear or favor. Few reporters would want to be considered unobjective or too biased to produce the accurate, truthful accounts that citizens of democracies presumably need in order to make informed judgments about public affairs. But the matter is not so simple. Objectivity is not a single, fixed “thing.” One research team identified four possible meanings, each commanding some support among journalists in western liberal democracies: the negation of journalists’ subjectivity; the fair representation of each side in a controversy; balanced skepticism toward all sides in a dispute; and the provision of facts that can contextualize an issue (Donsbach & Klett 1993; → Journalists’ Role Perception).

Hackett and Zhao (1998) suggest that in contemporary North American journalism, objectivity constitutes a kind of multifaceted discursive “regime,” an interrelated complex of ideas and practices that provides a general model for conceiving, defining, arranging, and evaluating news texts, practices, and institutions. They identify five general levels or dimensions in this regime.

First, objectivity is a normative ideal, a set of valued goals that journalists should strive for. These can be divided into values concerning the capacity of journalism to impart information about the world (separation of fact from opinion, accuracy, completeness), and values concerning the stance that reporters should take toward the value-laden meanings of news: detachment, neutrality, impartiality and independence, avoiding partisanship, personal biases, ulterior motives, or outside interests (→ Bias in the News). Second, these values imply an epistemological stance, a set of assumptions about knowledge and reality, discussed below. Third, objectivity is embodied in a set of news-gathering and presentational practices, such as “documentary reporting practices” that

allow reporters to transmit only facts that they can observe or that “credible” sources have confirmed (Bennett 2005, 184; → News Sources), and the separation of “fact” from “opinion” in newspaper pages. Fourth, the regime of objectivity is embedded in an institutional framework, including media independence from the state, legal guarantees of free speech, the separation of editorial and marketing functions within news organizations, and the conduct of reporting by reporters with requisite skills and ethics. Finally, objectivity is an active ingredient in public → discourse. It provides the language for everyday assessments of journalistic performance, including synonyms (“fairness,” “balance”) and opposites (“bias,” “partisanship”).

### HISTORICIZING OBJECTIVITY

As an ideal, objectivity is neither universal nor timeless. It has emerged in specific historical, political, and cultural contexts, though there are debates over the causes of its emergence in American journalism. Geopolitically, proclaimed adherence to objectivity is more typical of journalism in the US, the UK, and Canada than in continental Europe, with its stronger tradition of partisanship in the press (→ Journalism, History of), or in theocratic or authoritarian regimes such as China, where journalism is mandated to serve the state and/or an official ideology. Even where it is most entrenched, the objectivity regime is more characteristic of some news media – the → “quality” press, → public service broadcasting, or news reports – than others, e.g., → tabloid press, entertainment-oriented television, opinion columns.

Historically, objectivity as a paradigm in Anglo American journalism displaced the partisan press during the nineteenth and early twentieth centuries. One interpretation sees its roots in the democratic, universalizing discourse of the nineteenth-century labor press (Schiller 1981). A more conventional view links objectivity’s origins to the emergence of technology – photography, the telegraph (→ Photojournalism; Telegraph, History of) – and associated organizational forms (news wire services, the “inverted pyramid” form of reporting) that appeared to capture reality. The emergence of advertising for mass markets contributed greatly to the decline of the → partisan press; nonpartisan “objective” journalism enabled newspapers to pursue the broadest possible readership, and thus advertising revenue.

Cultural currents also contributed. Faith in the scientific method contributed to a “reverence for facts” in the late nineteenth century (Stephens 1988, 253). But the carnage of World War I, the apparent impact of wartime propaganda and the new public relations industry, Freudian psychology, historically unprecedented totalitarian regimes in Europe, and the Great Depression all contributed by the 1930s to a culture’s loss of confidence in the reliability of facts, the rationality of citizens, and the viability of liberal-democratic capitalism (Hackett & Zhao 1998, 40). Objectivity in North American journalism became more narrowly and technically defined, as “a method designed for a world in which even facts could not be trusted,” (Schudson 1978, 122) rather than a universalizing discourse of truth in the public interest. Over the next few decades, the objectivity regime adapted and incorporated other related approaches, including interpretive reporting, adversary/critical journalism, enterprise reporting, and others (→ Precision Journalism; Interpretive

Journalism; Investigative Reporting). Approaches that more directly challenged the objectivity ethos have been contained or marginalized (→ Advocacy Journalism; Alternative Journalism; New Journalism; Underground Press).

## **EPISTEMOLOGICAL AND POLITICAL CRITIQUES**

Underlying various critiques and defenses of journalism objectivity are contending epistemologies – different models for understanding the relationship between reports and the reality they are intended to describe. Positivism, once a dominant position in western thought, was firmly based in the European Enlightenment’s confidence in scientific method, rationality, and progress. It asserts the possibility of accurate descriptions of the world-as-it-is, through the careful observation of events, perceivable through the senses. Positivism underlies the commonsense criticism of news that it should be objective and accurate, but often is not, due to various factors that introduce “bias” in reporting. Often, conservative critics cite the presumed “left-liberal” political views of journalists, an interpretation of news bias common in the US, but less so in other western liberal democracies; it is a view that has in turn been criticized for intellectual inconsistency and for its assumption that journalists rather than economic and political structures shape the news (McChesney 2004, ch. 3). A contrary view sees news as failing to obtain objectivity due to the “conservatizing” pressure of powerful elites, such as media owners, advertisers, governments, and/or official sources. The best known of these interpretations is Herman and Chomsky’s “propaganda model” (1988). This view has also been criticized, mainly on grounds that it is unduly reductionist: it regards news as the instrument of some elite, disregarding both the institutional autonomy of journalism and the full range of external influences (such as those identified in Shoemaker and Reese’s five-level model (1996) operating upon news.

If the above critiques rest upon the epistemological assumptions of positivism, a contrary epistemological position is evident in recent social theory, in trends that emphasize the importance of language or “discourse” in shaping human understanding of reality. “Conventionalism” holds that human perception of the world is always mediated by our mental categories and our procedures of knowledge production. In this view, news reporting is as much a construction of the social world as a reflection of it; objective journalism cannot live up to its ideal, because knowledge of the world independent of the standpoint of the observer is impossible (→ Construction of Reality through the News). Claims to achieving objectivity in the news, then, must be regarded as assertions of the power to define reality, rather than legitimate claims to have accurate knowledge of it. In the view of its critics, however, this epistemological position tends towards a self-contradictory relativism, which sees no independent way to assess the truth-value of competing news accounts or discourses. For some critics (e.g., Norris 1992), this position implicitly enjoins journalists to abandon any effort to distinguish between truth and propaganda.

A third epistemology, critical realism, avoids both positivism’s superficial faith in facts, and conventionalism’s dead-end relativism. Knowledge of the real is possible, it asserts, but only through engaging in the work of theorizing, and exploring the structures and

processes that underlie individual events. From this standpoint, news reporting may be criticized not because objectivity is impossible in principle, or because individual journalists or news reports have departed from the (otherwise desirable and achievable) standards of objectivity – but because the structures and procedures of actually existing journalism constitute a deficient *form* of objectivity. This standpoint offers some sophisticated critiques of the objectivity regime as generating, paradoxically, *ideological* accounts of the world, accounts that are partial and one-sided, or that reinforce existing relations of power. One line of critique suggests that objectivity serves to disguise the value assumptions and commitments that unavoidably influence the selection and presentation, the framing, of news reports. Reports may quote “both sides” in a controversy, thus appearing to be balanced and impartial – while at the same time confining the definition of what is at issue, and marginalizing other perspectives. Thus, US television reportage of the Iraq war policy often features Democratic and Republican party leaders criticizing each other, while leaving unexamined their shared assumption that what is at stake is how to achieve victory or reduce American casualties, rather than (for example) reducing Iraqi suffering or strengthening international law.

An even stronger critique asserts that the objectivity ethos directly contributes to the production of ideological news accounts, for example, by legitimizing media practices that undermine democratic public life, such as a stance of cynical negativism divorced from coherent analytical perspectives, and the framing of politics as a game of insiders motivated only by electoral success (→ Negativity). In this view, the partisan press historically characteristic of western Europe offers a more positive democratic alternative.

Interestingly, the epistemology of news objectivity has contradictory aspects. The aspect of accuracy entails a positivistic faith in “facts,” while the aspect of balance between contending viewpoints implies a concession to conventionalism.

## RECENT CHALLENGES AND CONTEXTS

Arguably, objectivity has remained a dominant norm in North American journalism during much of the past century because it has served a variety of functions and interests: amassing broad audiences, providing political legitimacy for the monopoly press, and helping to define and manage the symbiotic relationship between news media and politicians (Hallin 1989, 68–70). It also enhances journalists’ claim to professionalism, and constitutes a “strategic ritual” to protect them from such hazards as lawsuits and editors’ reprimands (Tuchman 1972; → Professionalization of Journalism).

Yet current developments in the political economy of news media are potentially undermining the objectivity regime. The Internet facilitates the diffusion of opinion and personal experience, blurs the distinction between producers and audiences, and bypasses journalists as professional gatekeepers (→ Citizen Journalism). The deregulation of broadcasting and the relative decline of public service broadcasting have intensified commercial pressures since the 1980s. Channel proliferation has fragmented audiences. More and more conventional media are owned by conglomerates seeking high and immediate profits. Consequences arguably include the erosion of the universalizing stance of objectivity and of public affairs information in the conventional news media, and,

conversely, the rise of opinionated pundits, politically partisan media (most dramatically Fox News), and infotainment.

Contrary to the objectivity norm, recent reform movements within journalism have called for the explicit pursuit of specified goals. In the US, civic journalism challenges reporters to abandon the stance of detachment in favor of reinvigorating public political life (→ Public Journalism). Internationally, and particularly in strife-torn countries such as Indonesia, the Philippines, and Rwanda, practitioners and educators critique conventional news reportage of conflicts as tantamount to “war journalism” that too often exacerbates violence (→ Peace Journalism). For Lynch and McGoldrick (2005), far from being neutral observers, journalists are caught in a “feedback loop” with political players; and the ethos of objectivity, with its emphasis on official sources, two-sided conflict, and events rather than processes, impedes a morally and professionally justifiable incentivization of peaceful outcomes. Critics, however, dismiss peace journalism as another form of advocacy, usurping what should be the role of public relations (Hanitzsch 2004).

In its Anglo American heartland, faith in objectivity in reporting may be eroding, but no single norm or regime has emerged to supplant it. Meanwhile, in many nonwestern “transition societies,” objectivity may be gaining a new lease of life under the impact of media globalization, and as an alternative to the state-oriented authoritarianism of the past.

# Objectivity in Science

James A. Anderson

University of Utah

Objectivity has been a criterion of both science and its practice throughout the modern era. Its principal meaning is that the effect of the individual scientist has been removed from the findings and what is left can be considered both non-ideological and agenda-free. The term is used as a global epistemological principle across all traditional science and as a specific property within tests and measurements.

## OBJECTIVITY AS AN EPISTEMOLOGICAL PRINCIPLE

As an epistemological principle, objectivity anchors one end of a continuum of claim that begins with the idiosyncratic. Idiosyncratic claim in its most extreme is claim that is true only in the presence of the individual making it. An example might be of a very persuasive speaker who under the force of rhetoric gathers followers at a rally. Once removed from the force of the moment, the truth of the matter disappears. Subjective claim is also located in the particular individual but the insight is exportable and moves from banal to resonant such as from a summer beach novel to an enduring work. Objective claim cannot originate in the individual but must originate in the inescapable properties of the object.

While approving of the principle, philosophers of science have wondered how it might come to be. For objective claim to be possible there has to be a direct and unbiased transmission of information from the object to the observer. For objective claim to be presented there has to be an unbiased method (symbolic form) for retransmitting the information to other observers. Most contemporary commentators reject the possibility of these two necessities, and, therefore, agree that objectivity at the individual level is either not attainable or not demonstrable.

Although the individual cannot be declared an unbiased observer, bias can be mitigated within a research community through a process of *intersubjective cross-examination* and critique that involves conventionalized protocols, independent replication, and critical review. The traditional view of the scientific method, for example, starts with the individual's freedom and duty to pose falsifiable hypotheses that are then tested empirically, and presented in sufficient detail to any interested person for scrutiny and replication. This process represents a commitment by the scientific community to achieve propositions of the highest quality. Conventions – agreed upon rules – govern everything in this process, including the propositional structure of a hypothesis, the conditions of *falsifiability*, the character of a fair test and its empirical evidence, and the manner of its publication, from the terms of its acceptance to its presentational style (→ Critical Rationalism). Compared to the physical sciences, replication and critical review in communication, as in many social sciences, are considerably less conventionalized. Authors are not obliged to make data and instruments available to others and routinely refuse requests. None of the mainline journals maintains a regular feature of published reviews. These may be perceived as threats to the objectivity of the discipline.

## OBJECTIVITY AND TRUTH

Objectivity does not guarantee the truth of the matter. A declaration of objectivity means that the intellectual community's standards of quality have been met. Those standards, however, may not be adequate: they may be founded on false premises; they may be applied in an inappropriate matter; the enforcement of conventions may be haphazard; their practical enactment may be compromised. These are all human practices subject to human error. There is, however, no simple statement about what this possibility of error means. For the strict realist, who holds to an addressable, objective world about which true and false statements can be made ( $\rightarrow$  Realism), the community can fall into error but it will not remain in error. It is self-correcting. Any single proposition may be wrong, but, on the whole, science works in progressive ways to a better approximation of that reality.

The social constructionist cannot be so sanguine. Most of the variants of social constructionism would consider both a material and ideational reality as the subject of inquiry in the social sciences ( $\rightarrow$  Constructivism). The components of the ideational reality as the product of social processes cannot be objective. They are culturally produced and exist in the time and place of their constituting cultural practice. Consequently for social constructionists, at least some elements of what is true come with an expiration date. Time erodes knowledge; science cannot be linearly progressive as what is justified as true becomes false.

Relativists and many postmodernists reject the first premise of realism – that there is an addressable, objective reality that provides a self-corrective to claim ( $\rightarrow$  Postmodernism and Communication). Knowledge and the declaration of the true are both social processes that are held in place through material practices and power relationships. The intersubjective critique is a high quality gloss for the rough and tumble politics of knowledge. The most that it will grant science is that it works, but its instrumentality is encased in political rather than veridical characteristics.

Practitioners of the *interpretive turn* that appeared throughout the social sciences in the early 1970s have a problematic relationship with objectivity and truth. Their epistemology is social constructionist, which leads them to reject notions of an independent reality that provides a corrective to erroneous claim. Further, the individual researcher is considered the instrument of analysis in a reprise of Max Weber's *verstehen* or special understanding that humans have for human life. For the more radical of interpretivists, the comparison is not between the objective and the subjective but between the resonant and the idiosyncratic.

Interpretivists, social constructionists, relativists, and postmodernists, arguably, all conflate the true with the good, which is to say that claims about what is true are advanced politically rather than on some intrinsic character. In doing so they close the gap that David Hume struck between what is or is not and what ought or ought not to be, for in arguing that something is so they are forced to argue that it ought to be believed to be so. This belief in something is constitutive in a socially constructed, ideational world, leading to material consequences based on that constitution. In this formulation, objectivity is a rhetorical property rather than an epistemological principle.

## **OBJECTIVITY IN MEASUREMENT AND TESTING**

An objective method of measurement is one in which any one observer following the rules of measurement will assign the same values/qualities to the observed object as any other observer following those same rules. The premise is that the properties of the object will interact in a consistent way with the rules of measurement to produce the reported values. These values are necessarily a function both of the object properties and the rules of measurement: any belief that it is possible for the object to report its properties to observers in the absence of a measurement protocol would require a brute sense empiricism – an epistemological position that has been universally rejected by commentators.

### **Protocol Interaction**

The notion that the rules of measurement participate in the values reported can lead to the erroneous claim that those values are contaminated by the protocol. But consider measuring a board using a metric scale (millimeters), an imperial scale (inches), and a story pole (a pencil line on a stick). All three measurement protocols can give the exact same answer to the question of whether the board is long enough, although each will report different values (→ Measurement Theory).

Further, there is some belief that the bias of a protocol can be contained by using multiple protocols. This practice is often called triangulation and is an extension of the multiple-observers convention in that it produces multiple observations by using different methods. What has not been conventionalized, however, is the resolution of the differences that typically appear among the protocols. Determining what will be held as true will always be contentious.

### **Objectivity and Validity**

Objective measurement does not guarantee valid measurement (→ Validity). Every measurement protocol is designed to return a value for every application. It is possible that the rules of measurement may auto-indicate a value in the absence of a property or even an object. Some commentators argue that attitude studies fall into this category. The rules may not interact with the properties of the object at all or in consistent ways.

It is also true that inference is a necessary part of any measurement, objective or not. Inference assigns meaningfulness to some measurement value. To say that 31 people checked the number 3 out of choices ranging from 1 to 5 has little value without the inference that the value of 3 represents a neutral attitude. If the source of the behavior is not an attitude but some other cognitive property, then the inference will be false. If the properties measured appear only in the presence of the rules of measurement, then the measurement will be true but the inference drawn from them will most likely be false.

In the end the validity of a measurement is always unknown. Consequently, a measurement (as well as a claim) can be objective and also false. In the absence of contrary evidence, however, we may act in some confidence that it is true. The irreducible

possibility of error in measurement and testing, however, requires a skeptical stance even when acting in confidence.

### UNDERSTANDING OBJECTIVITY IN COMMUNICATION

Traditional science houses few interpretivists, social constructionists, relativists, or postmodernists, but they are well represented in the communication field. The result is that objectivity is a contested term across the domain of the discipline but within given areas is either assumed or ignored.

There is one part of the debate as it is commonly framed that can be quickly set aside: there is nothing about objective measurement that requires numbers; the requirements for objectivity are rules governing multiple observers who consequently generate the same observations *given the same conditions*. Numbers are simply a convenience of analysis. There is, consequently, no necessary impediment to objectivity in qualitative or interpretive studies at the level of observation. Interpretivists can establish rules of observation, and communication research is seeing an increasing conventionalization of participant-observation fieldwork.

Multiple observers can work the same observational domain using the same rules. The results are expected to differ, however, because the communicative practices that are the objects of observation are held to be contingent to the time, place, enactors, and observers of their origin. It is expected that *conditions will not be the same* across those contingencies.

That difference may be paradigmatic and potentially incommensurate, but it has little to do with objectivity. It is the rules of observation and their systematic application that establish the objectivity of the observations. The differences across observations that are expected to appear, given the interpretive paradigm, may simply be the facts of the case. The result is that no one has a unique claim to objectivity and no one is released from specifying systematic and reproducible rules of observation, if they choose to declare themselves scientists.

# Observation

*Thorsten Quandt*

*Ludwig Maximilian University of Munich*

Observation is a very “natural” way of gathering data and information – probably everybody can identify situations where humans are scrutinizing their surroundings. Selltiz et al. note: “We are constantly observing – noticing what is going on around us . . . ; as long as we are awake, we are almost constantly engaged in observation. It is our basic method of getting information about the world around us” (Selltiz et al. 1967, 200). However, these everyday observations are not sufficient for social research, since their informational basis stems from unclear viewpoints, undocumented (re)constructions of the observer, and random events. So in order to become a scientific technique, an observation study has to follow some rules – most notably, it has to be systematic in both its planning and recording phases. This does not mean that it has to be standardized; however, even if an observation study collects information in an open way, it has to follow a clear research strategy.

In comparison to the other two central ways of data gathering in communication studies – content analysis and → interview – observation plays a smaller role in research nowadays (→ Content Analysis, Qualitative; Content Analysis, Quantitative). In many handbooks of communication studies, it is just noted as a means of getting some ideas “from the field” in order to develop items for survey studies or categories for content analysis – and sometimes it is missing altogether. This is not necessarily the case in neighboring disciplines, like sociology or psychology: here, observation studies play a central role in research. In sociology, field studies are a core instrument for getting access to social phenomena, and in psychology, observations play an important part in experimental study designs (→ Experiment, Laboratory; Experimental Design).

## **ROOTS AND DEVELOPMENT OF OBSERVATION AS A SCIENTIFIC METHOD**

While observation as a mode of perception is simply a part of human existence and therefore cannot be traced back to some historical roots, its scientific origins can be identified more clearly. Anthropologists of the nineteenth and early twentieth centuries were among the first who used observations systematically as a way of gathering information during their travels around the world, and their ethnographic studies of cultures foreign to them can be seen as one central developmental branch of sociological studies. Still, these observations were very open in their focus and methods, so the resulting travel reports were not scientific when judged by modern standards.

With the dramatic changes of societies during industrialization, sociologists started to study the life of the working class and new forms of existence in metropolitan areas in contrast to traditional rural life. While there were still many smaller, open studies among the observations applied in this context, some researchers followed a more coherent and methodologically strict perspective on social phenomena. One of the most prominent examples of this development is the so-called Chicago School, with sociologists like Nels

Anderson concentrating on urban life, using observation as a central tool for getting access to social realities.

However, observation studies of human behavior are not limited to anthropology and sociology, and accordingly, one will find some roots of the method in other fields as well, most notably in psychology. Behaviorists (e.g., B. F. Skinner and J. B. Watson) started to analyze animal (and later human) behavior in the first half of the twentieth century, using observations in controlled experimental settings. Later on, some spectacular psychological experiments like the Milgram study or the Stanford Prison experiment led to a certain image of psychological observation studies, which is still influential in popular beliefs of what psychology is about.

In media and communication studies, (field) observation studies were a central research tool right from the beginning of the discipline. Both the behavior of audience members in natural home environments and the work routines of journalists in newsrooms were the targets of many observation studies. As within sociology, the early studies did not stick to methodological standards and the documentation of the data gathering was often very weak. For example, Walter Gieber notes about the method of his early study of 16 telegraph editors: “Field visits to the newsrooms were in two waves to permit an extensive interview with the deskman and observation of the editing process” (1956, 424). Following the development in other social sciences, later studies became more rigorous in their study methodology. However, large-scale observation studies with standardized instruments are still rare in communication studies, at least when compared to the other types of data gathering.

Just lately, the influence of → cultural studies in communication and media studies has led to a growing number of observation studies, mostly based in the “qualitative” paradigm – so they favor open instruments and exploration studies, based on a few hand-selected cases (→ Qualitative Methodology). This has been criticized by some researchers as well, who regard these as being merely “chance observations,” so there is an ongoing debate on the status of the method in communication studies.

## **OBSERVATION CONCEPTS**

When mentioning the term “observation,” many researchers in communication studies think of their first steps when doing a study, just as Donohew and Palmgreen (2003, 119) describe it: “Most theory building begins with rather crude observations of events or other phenomena that seem to be related. At first, the scientist does not know exactly what to look for. Observation at this point tends to be rather unstructured and informal.” This type of information gathering could be identified as open, (probably) participant observation without a structured instrument. While this is a typical part of the research process, it is usually not mentioned as a special method. There are other variations of observations, however, that deserve this status.

When trying to differentiate between several types of observations, one can discern several dimensions for discriminating these types. Three dimensions are especially useful for such a differentiation, since other variations could be related to them:

- 1 level of standardization;
- 2 involvement of the observer;
- 3 visibility of the observer.

First, the level of standardization refers to the use of strict observation rules, which may be defined in code-books and formal observation guidelines, in contrast to open documentation or diary methods. Very often, researchers use a combination of both open and closed elements, in order to control the observation process while retaining the openness for surprises from the field.

Second, in many cases, access to the field is only possible if the observer becomes part of the observed reality: “The participant observer gathers data by participating in the daily life of the group or organization he studies” (Becker 1958, 652). So the observer is directly involved in the field – for example if he or she is working as a journalist when doing an observation study of newsroom selection processes.

Third, the involvement of the observer is often confused with the visibility of the observation process. However, active participation of an observer in the field does not necessarily mean that the observed persons are aware of being studied – for example, if the observer is working undercover. On the other hand, a completely passive observer can be very visible, for example sitting next to and observing somebody, thus being obtrusive and probably causing reactivity.

### **TYPICAL STEPS OF AN OBSERVATION STUDY**

No matter what type of observation study a researcher chooses as adequate for a given research interest, it will follow a few typical steps, which are somewhat different from those of interview studies or content analyses. Of course, observation studies start with a research interest or research questions, like other types of empirical research. One should extract and clarify the underlying dimensions of meaning and central concepts touched by these questions – even when doing a “qualitative” exploration study. The identification of dimensions in the research interest/questions is not only aimed at the (sometimes unknown) social phenomena, but also at one’s own perspective – thus, it is also necessary if the researcher does not know a lot about the field itself. Based on this first clarification, the researcher has to decide where, when, what, and whom he or she wants to observe – which means: identifying the research field (place, time, social context), subjects/objects (individuals, groups, inanimate objects), and cases (actions, events, time units). Usually, this leads to refined research questions, and, in some cases, also to a further clarification of research questions, up to testable hypotheses and variables in the case of highly standardized studies. Following this step, the researcher has to develop observation procedures, which include a research plan and observation tools, like code-books or diaries, and might involve the use of technical devices for recording aspects of the social phenomena under observation (microphones, digital audio recorders, cameras etc.).

When working with several observers, the researcher has to train them. Very often, this means a simulation of the observation situation or just an explanation of the code-book, since advance access to the field is not possible or is problematic. The same applies to pre-tests. Sometimes, one could choose to do the training and pre-tests in a “test” field similar to the actual observation field, with comparable observation objects/subjects. However, even with advance training, going into the field can be problematic, for example if an observer starts to openly observe an editor in a newsroom. Both the observer and the observed subject(s) have to become accustomed to the situation, so the field phase needs some kind of introductory phase as well. Material from these first observations should be

left out of the final data analysis and interpretation. In some cases, the data analysis and interpretation can also lead to further research questions – and to a second “loop” of the whole research process, including the development of refined research instruments and more field time.

### APPLICATIONS IN COMMUNICATION STUDIES

As described above, observations are frequently used as a first “explorative” access to social phenomena, for example if there is not sufficient in-depth knowledge to design “closed” items for questionnaires. The method can be applied in a much broader way. For example, it is often the method of choice when it comes to newsroom studies (→ Gatekeeping; Media Production and Content). Observations are also used to gain access to the everyday life of media audiences, especially if one is interested in habitualized use patterns that cannot be reflected upon by the audience members themselves (→ Audience Research; Nielsen Ratings). There are many reasons why subjects might not be able to verbalize certain aspects of their social reality, both in open interviews or closed surveys. They might not be aware of them, or they might not have the language capabilities to describe them (for example, children); here, observations are sometimes the only solution.

Observations of newsrooms and media audience members in everyday settings are usually direct observations by human observers. However, one should not forget other types of observation studies. There are also (sometimes automatic) observations with the help of technical equipment. These machine observations are used heavily in market research (TV quota measurement) and in experimental studies (→ Physiological Measurement). It has to be noted, though, that the analysis of automatically acquired behavior traces (for example, computer log files) and experimental studies are very different from the classic “role model” of field observations, and many researchers actually do not even think of these types of research as being observation studies.

## Observational Learning

*Albert Bandura*

*Stanford University*

Observational learning is concerned with the acquisition of attitudes, values, and styles of thinking and behaving through observation of the examples provided by others (→ Attitudes, Values, and Beliefs, Media Effects on). Psychological theories have traditionally emphasized learning from direct experience. Natural endowment provides humans with enabling biological systems but few inborn skills. These must be developed over long periods and altered to fit changing conditions over the life course. If knowledge and skills had to be shaped laboriously by trial-and-error experiences without the benefit of modeled guidance, human development would be greatly retarded, not to mention exceedingly tedious and hazardous.

Errors can produce costly or even fatal consequences. Moreover, the constraints of time, resources, and mobility impose severe limits on the situations and activities that can be directly explored for the acquisition of new knowledge and competencies. Fortunately, humans have evolved an advanced capacity for observational learning that enables them to expand their knowledge and competencies rapidly through the information conveyed by the rich variety of models. Social modeling shortcuts the learning process.

Observational learning is governed by *four sub-functions*. *Attentional processes* (→ Attention) determine what people selectively observe in the profusion of modeling influences and what information they extract from modeled events. A number of personal and social factors influence what people choose to explore and how they perceive what is modeled in the social and symbolic environment (→ Selective Attention; Selective Exposure; Selective Perception and Selective Retention).

People cannot be much influenced by observed events if they do not remember them. A second sub-function governing observational learning concerns cognitive *representational processes*. Retention (→ Memory) involves an active process of transforming information about modeled events into conceptions for generating new patterns of behavior. The third sub-function in observational learning involves the behavioral *production processes* by which symbolic conceptions are transformed into appropriate courses of action.

The fourth sub-function in observational learning concerns *motivational processes*. People do not perform everything they learn. Whether or not they put into practice what they have learned observationally is influenced by three major types of incentive motivators. These include the directly experienced costs and benefits of the modeled style

of behavior; the observed detriments and benefits experienced by others; and the positive and negative self-evaluative reactions to the conduct, rooted in personal standards (→ Bandura, Albert).

Observational learning is not simply mimicry of what one sees. The proven skills and established customs of a culture may be adopted in essentially the same form as they are modeled. However, in most activities skills must be improvised to suit different situations. Modeling influences convey rules of behavior. For example, individuals may see others confronting moral conflicts involving different matters but applying the same moral standard to them. In abstract observational learning, observers extract the rules and principles embodied in the specific judgments or actions exhibited by others. Once observers learn the underlying principles, they can use them to generate new instances of behavior that go beyond what they have seen or heard.

Social modeling not only promotes *higher-level learning*, but *creativity* as well. Modeling unconventional ways of thinking increases innovativeness in others. Creativity usually involves synthesizing existing knowledge into new ways of thinking and doing things. When exposed to diverse modeling influences, observers often adopt advantageous elements, improve upon them, synthesize them into new forms, and tailor them to their particular circumstances. Through these processes, selective modeling serves as the mother of innovation.

Social modeling for observational learning comes in a *variety of forms*. Some of the observational learning is based on the models in the environment one inhabits. In contemporary society, attitudes, values, and styles of thinking and behaving are adopted from the pervasive modeling in the symbolic environment of the mass media that occupy a major part of peoples' daily lives. In addition, verbal modeling often substitutes for or supplements behavioral modeling as a source of observational learning. By drawing on verbal descriptions of how to behave, people are aided in mastering social, occupational, and recreational skills and learn appropriate conduct for different situations. In symbolic modeling using inspirational exemplars, people learn values, lifestyles, and guides for daily living personalized in idealized figures in treatises and biographical writings about past visionaries and reformers.

As already noted, observational learning plays a key role in the acquisition of knowledge, cognitive skills, and new styles of behavior. Modeling influences also have strong motivational *effects* based on the outcomes that flow from the actions of others. Observed desired effects can create outcome expectancies that serve as positive incentives, whereas observed punishing effects can instill negative outcome expectancies that function as disincentives for similar behavior.

People are easily aroused by the emotional experiences of others (→ Excitation and Arousal; Emotion). Therefore, observers can acquire lasting attitudes, values, and emotional reactions toward persons, places, or things that have been associated with modeled emotional experiences. They learn to fear the things that frightened others, to dislike what repulsed them, and to like what gratified them. Fears and intractable phobias can be weakened or eliminated by modeling coping strategies for exercising control over the things that are feared.

During their daily lives, people have direct contact with only a small sector of the physical and social environment. They inhabit a limited locale, work in the same setting, travel the same routes, visit the same places, perform the same routines day in and day out, and interact with the same circle of friends and associates. Consequently, the public

consciousness and images of reality are greatly influenced by vicarious experiences – by what people see and hear (→ Media and Perceptions of Reality; Emotions, Media Effects on). Many of the shared views of occupational pursuits, ethnic groups, minorities, the elderly, social and gender roles, and other aspects of life are partly cultivated through symbolic modeling of → stereotypes (→ Mainstreaming).

Global broadcasts now show sociopolitical conflicts, the strategies and countermeasures used, and their effects, as they are happening. Televised modeling is becoming an especially influential vehicle for social and political change. The revolutionary advances in communication technologies (→ Technology and Communication) are conferring growing primacy on observational learning from the variety of models who populate the vast cyberspace.

## **Online Journalism**

*Jane B. Singer*

*University of Iowa and University of Central Lancashire*

Online journalism involves the delivery of news content through a networked, digital medium. The → Internet and world wide web are primary vehicles for online journalism, but other options include mobile phones, personal digital assistants, and other devices. The question of whether those not traditionally considered journalists can or do produce journalism is important but unresolved (→ Citizen Journalism).

### **DEVELOPMENT**

Online journalism dates to the development of prototypes in the late 1970s and early 1980s, a period when the Internet was a cumbersome, text-based system mostly for

scientists and researchers. Proprietary online services intended for general public use evolved separately and in tandem with a growing consumer market in personal computers. Early forms included teletext, which transmitted information through a portion of the television broadcast signal, and videotex, which sent information to an individual terminal via telephone lines (Sigel 1983).

Videotex services, many of them government-supported, attracted media participants throughout western Europe, notably in Britain, France, and Germany, as well as in Japan, Canada, Brazil, and Australia (Branscomb 1988). Early journalistic *information providers* for these online services included the BBC and *Financial Times* in Britain. In the United States, media companies that owned videotex ventures supplemented their own content with information from wire services, major newspapers, and other sources.

Online journalism gained traction once a structure for *hyperlinking* Internet documents developed in the late 1980s and a graphic interface allowed easy navigation around the rapidly growing network (→ Digital Media, History of). Its growth in the United States illustrates similar trends throughout the developed world: About 20 US newspapers offered some sort of online product at the start of 1994, mostly bulletin boards plus a handful of alliances with proprietary commercial services such as America Online. The first consumer web browser, Netscape Navigator, launched that year; by December, about 100 online newspaper services were either operating or in development, and the first online advertisement had appeared, on the *Wired* magazine site, hotwired.com. The number of US newspapers online climbed to several hundred by mid-1995.

Newer browsers and ongoing technological developments made it easier to use the Internet and the web (→ Exposure to the Internet). More users started getting news online, and the more they did so, the more media companies and marketers could reach them there. News media executives quickly realized that an exclusive arrangement with a closed, proprietary service was unnecessarily limiting: They could create and maintain their own websites and reach the expanding online market no matter which service provider users favored. By the mid-2000s, almost all news outlets in the developed world had an online presence.

## ECONOMIC CHALLENGES

After moving to the web in the 1990s, it took nearly a decade for most media organizations to turn a profit there. The two primary revenue sources for commercial media, subscriptions and advertising, did not transfer easily to the emerging medium. With millions of information sources available for free, users were reluctant to pay for content. And advertisers struggled to adapt their placement and pricing strategies to fit the online environment (→ Advertising).

At first, parent organizations subsidized online journalism sites. They saw them largely as vehicles for extending their brand name and geographic reach. Some major organizations employed dozens of journalists to maintain their websites, but most online staffs remained small. Content online originated in the parent outlet, which then repurposed it, commonly through an automated process, for digital delivery. A few editors typically worked in a separate location, handling whatever the parent outlet could not automate, such as adding links or rewriting headlines. Online content was otherwise identical to offline content.

By the mid-2000s, changes were apparent. In the US market, 95 percent of newspaper websites reported that they were profitable by 2005. Although most broadcast-affiliated sites remained in the red, revenue was rising. Enhanced placement, tracking, and targeting tools bolstered advertising, which generated most of the profit. Keyword search ads generated the greatest revenue, followed by display and classified advertising.

Major news media also succeeded, to varying degrees, in charging consumers for some content. For example, the *New York Times* offered paid access to archives, a Sunday preview feature, and selected columnists through the Times Select service. The *Wall Street Journal*, one of the only online journalism sites to charge for access from the start, in mid-2005 reported making more profit from its online news division than from its print counterpart.

Economic challenges remained. Print media sites competed for classified ads with sites such as monster.com, ebay.com, and craigslist.org. News aggregators such as Google News and Yahoo! News were popular and attracted commensurate numbers of advertisers. Local ad revenue that once went either to local media or to telephone directories now divided among more competitors; newspaper sites no longer received a majority of it.

Although its contribution to the bottom line increased through the mid-2000s, online news still accounted for a small fraction of revenue at most mainstream media outlets, and traditional sources of revenue were down. Even strong online growth seemed unlikely to make up for the losses buffeting parent companies. Whether they would invest in technology or in journalists was of particular concern because journalists provide the investigative power and creativity that companies require to move beyond headline services.

## DIGITAL JOURNALISTS

News outlets throughout the world now not only maintain websites but also are expanding use of newer digital formats, such as RSS (really simple syndication) feeds, reporter blogs (→ Blogger), and podcasts. The digital media environment has also become central to journalists' view of what they do (Teeling 2006).

Creating online journalism differs from traditional media production in at least three ways. Many of those producing online journalism also work for other, affiliated media. Growing amounts of what they produce does not translate across platforms. And much of the online content does not come from journalists at all.

A majority of the most widely used online news sites are affiliates of traditional media organizations, and the stories that journalists produce for print or television also typically are disseminated online. The process works in the opposite direction as well, particularly for breaking news: Stories reported first on the Internet subsequently appear in the traditional product.

However, journalists contributing material to the web handle increasingly diverse content. Newspaper sites, for example, offer audio, video, and other multimedia content. Many also provide user-generated material, from blog entries to audience members' texts and visuals. An *online newspaper* is no longer simply the newspaper online; it has evolved into something unique to the Internet.

For journalists, this shift has called for gathering information in multiple formats, such as audio clips along with written notes or video along with still images. Online staffers

create multimedia story components, and develop and oversee interactive elements. The result is a trend toward an integrated newsroom, where journalists produce content for several types of media (→ Cross-Media Production). Many organizations are desegregating the print and online newsrooms, creating a *platform agnostic environment* where journalists with good ideas for telling a story in a different medium can do more than suggest that someone else develop those ideas for online publication (Glaser 2005).

Such transitions are not necessarily smooth. Reports on *newsroom convergence* (→ Digitization and Media Convergence) have suggested problems related to everything from differences in newsroom cultures to a lack of training with new tools and techniques. Some journalists see the cross-platform trend enhancing professional goals for public service as well as personal goals for career advancement. Others disdain the emphasis on branding and promotion, dislike the demand for more content without more pay, and suspect organizational motives that may lead to staff reductions.

The growth of online information from outside any newsroom may exacerbate these misgivings. News aggregators generate a lot of traffic with little or no editorial input, relying instead on sophisticated technology to collect, organize, and present stories targeted at the individual user. Bloggers share the role that opinion columnists, news analysts, and television commentators once held. Social networking sites such as *myspace.com* and open-source publishing sites such as *ohmynews.com* or *YouTube.com* enable users to publish their own version of news (→ Open Source). Journalists at traditional news organizations debate whether or when none, some, or all of this output is *journalism*, but acknowledge the undeniable competition for user time and attention, as well as for advertising revenue.

## ROLES AND NORMS

Journalism has never been a perfect fit for the sociological construct of professionalism, which entails autonomy, prestige, and a particular set of criterion skills and normative values. Nonetheless, journalists generally consider themselves professionals in the important sense of their loyalty to the ideals of a profession and to a particular set of norms (→ Ethics in Journalism; Professionalization of Journalism; Journalists, Credibility of). They also share conceptions of broad professional roles, such as being a *watchdog* of the government and a *gatekeeper* of information (→ Journalists' Role Perception).

Online journalism most obviously challenges the role of determining which stories reach the public (→ Gatekeeping). There is simply no gate to keep when anyone can be a publisher, and the notion of guarding one becomes absurd (Williams & Delli Carpini 2000). The emerging forms of political and government communication, transmitted to and from the public, also are at least partially displacing journalists as information providers and interpreters (Tumber 2001).

The change may shift the conceptualization of such professional roles away from the practical realm and into the normative one (Singer 2006). Rather than keeping an item out of circulation, journalists may focus more on vetting items for veracity and illuminating the context. As other online information providers challenge their role, status, and autonomy in deciding what is news and what makes it so, journalists may find that their self-definitions revolve less around the job they do and increasingly around the standards they apply in doing it.

## **Online Media**

*Wolfgang Schweiger*

*Dresden University of Technology*

The term “online media” primarily refers to technical communication media where digital content is transmitted from any kind of server to distant receivers via the → Internet (TCP/IP [transmission control protocol/Internet protocol]) or other digital networks, e.g., mobile services, and presented on a computer or a comparable terminal device (notebook, PDA [personal digital assistant], or mobile phone). Not all kinds of digital media are online media: multimedia CDs, DVDs, DVD players, mp3 players, or media applications on standalone computers are referred to as “offline media,” as content is stored at the place where it is presented. In opposition to broadcasting media (→ Television; Radio), where analog or digital content is broadly transmitted (via terrestrial or satellite broadcasting or broadband cable; → Cable Television; Satellite Television) to all receptive devices, in online media a client computer requests specific content from a server that, in turn, directly – i.e., point-to-point – delivers the content. According to this technical

definition, online media facilitate a broad variety of different forms of computer-mediated communication (→ Internet, Technology of). They can be described along several dimensions dealing with (1) basic aspects of communication structure, (2) aspects of exposure and user interaction, and (3) theoretical and institutional aspects of mass media.

### **BASIC ASPECTS OF COMMUNICATION STRUCTURE**

The first dimension is the *direction of communication and number of communication partners*. Online communication can take place between single persons who are mutually exchanging messages (interpersonal or one-to-one communication, e.g., email, chat, or Internet telephony; → Electronic Mail); between several persons, often organized within issue-based groups, e.g., in MUDs (multi-user dungeons), discussion, or chat forums (group or many-to-many communication) where some members are actively participating while passive “lurkers” are only reading the others’ contributions; and between a sender and an arbitrary number of recipients (one-to-many, e.g., websites or weblogs). If each member of a society has at least the potential opportunity to be a recipient – i.e., a medium addresses the public and if the audience size exceeds a critical mass of recipients – one-to-many communication is called mass communication.

A second basic aspect is *synchronicity*. Here we have to distinguish between interpersonal and mass media. Some interpersonal media enable synchronous communication between communication partners, which means that each side instantaneously receives the other side’s messages and can, in turn, immediately react (e.g., chat, Internet telephony, video conferences). This permits a direct and truly interactive communication situation, requiring the simultaneous disposition and attention of both partners. Other interpersonal media offer asynchronous communication: the sender’s message is stored and can be received and answered whenever the recipient wants, e.g., email, voice mailbox (→ Interpersonal Communication). Referring to one-to-many or mass communication, there are also two basic variants of synchronicity. Asynchronous online media permit recipients to receive content whenever they wish. Most online news media offer an archive where old articles can be retrieved even years later. In contrast to print media, where content cannot be changed after publication as there are too many original copies, digital content can be updated, revised, or altered easily and at any time. This is the main reason why online publications can be problematic to cite, as a cited version can significantly differ from later versions. Synchronous online media are the equivalent of broadcasting by streaming video, music, or spoken word in real time. Different from “traditional” broadcasting, many synchronous online media additionally offer archived material for later, asynchronous use, e.g., as video on demand.

Third, online media can contain *different forms of digital content* ranging from text, photographs (→ Photography), drawings, sound clips, videos, and → animations (multi-media) to any imaginable information service or software application. Thus, online media can display all kinds of content from the traditional media, and the concept of hyperlinks allows interconnection of any form of content. This has major implications for the debate on technical media convergence and the replacement of traditional media by online media: theoretically, online media can substitute for any existing medium (→ Digitization and Media Convergence). If a so-called “multimediality” emerges incorporating all earlier media and offering additional services in the future, it will be digital and online. If

a multimediu, i.e., one device for all media content, user needs, and situations, ever exists it is unclear how long its diffusion within society will take. Most researchers, academic and commercial, forecast that although the Internet and mobile media will continue to gain audience share, the established media (television, radio, press) will not be replaced in the medium term (see, e.g., Lehman-Wilzig & Cohen-Avigdor 2004; Adoni & Nossek 2001).

## ASPECTS OF EXPOSURE AND USER INTERACTION

### Place of Use

Until around the year 2000, online media were almost exclusively used on computers situated in (home) offices and mainly used for informational purposes, so-called “laid forward media.” Computers are increasingly used as entertainment media, so-called “laid back media,” and have started to displace television and other entertainment media in living-rooms, children’s rooms, and bedrooms (e.g., Bakardjieva & Smith 2001; Berker et al. 2005).

Today, most online offerings can be used at any kind of media terminal as long as a sufficiently fast data connection is established and the terminal’s input and output facilities (display, loudspeaker, keypad) are adequate. This allows not only home use, but also the development of mobile media services for portable devices like notebooks, PDAs, mobile phones, game paddles, and digital music or video players. Broadband mobile media offering multimedia capabilities and location-based services (the “third generation of telecommunication,” UMTS [universal mobile telecommunications system]) are seen as the most promising media markets.

### Interactivity

There are two different concepts of interactive media (→ Interactivity, Concept of). In a sociological sense, interactive media allow individuals or groups of individuals to communicate with each other (computer-mediated interpersonal communication). Examples are online marketplaces like eBay, online communities where users can share personal photographs (e.g., Flickr), and videos (e.g., YouTube) or discuss specific issues. The other meaning refers to → human–computer interaction. Here, media content is stored on a server (the computer, usually a web server). The user can access the desired content by selecting one option (hyperlink) or an array of options (e.g., a restaurant database searchable by location, nationality of cuisine, price category) or by inserting text in a text field (e.g., → search engines or expert systems).

The more *options the medium provides* and the more easily users can control the content (range of options), the faster the medium reacts to users’ choices (speed), and the more flexibility users obtain to decide when to retrieve content (time flexibility), the more interactive a medium is. Highly interactive media can detect users’ needs and interests without user input or even awareness. Online media, for example, can track and save users’ visits and selected content and automatically present appropriate content at the next visit. Mobile media can identify a person’s location and deliver location-specific information (e.g., nearby restaurants or gas stations). Besides control, the number of senses a medium activates (visual, aural, tactile, olfactory, gustatory; “media richness” –

see Steuer 1992), the ease of control (usability), and the user's situational feeling of being personally, emotionally, and locally connected to the described content (established concepts are playfulness, connectedness, sense of place, presence, immersion) affect the degree of a medium's interactivity. According to this definition, online games are the most interactive online media (→ Computer Games and Reality Perception): In a conventional ego-shooter game, the player has a choice as to where to look, where to move, and what to say. The system instantly reacts to his or her actions, and for the player it feels like "being there" (see Kiouisis 2002; Lin 2003).

*Content modularization* is an indispensable prerequisite of human–computer interactivity. In the traditional media, specific media products (e.g., newspaper copies, magazines, TV or radio programs, movies) are produced and presented as one integral piece of content. In hypertext and interactive media, content is broken into singular modules that users can deliberately select or arrange by clicking on hyperlinks or applying other forms of control. Consequently, there is no fixed order of reception. The degree of modularization depends on two dimensions: the universality and the size of content modules. If modules are *universal*, they fit different contexts and can be understood even without context. Universal modules can be applied in any content configuration and can be easily distributed across different media channels (cross-media utilization).

If, for example, a one-hour TV news magazine consisting of several thoroughly composed films that are linked by a presenter is offered as a download on the web, the material has to be separated into self-contained films that users can arbitrarily watch and understand in any order and without the original linkages. The coherence of the initially integral content is, at least partially, lost. This example also illustrates the second dimension: while the initial TV news magazine is a consecutive content unit of one hour, the web version comprises several films of a much shorter duration, i.e., content modules are smaller in size. In many text-based news sites, module sizes are still similar to newspapers or printed magazines such that print and online articles are comparable in length.

There are also extremely modularized media offerings assembled from a huge number of micro-elements. An online restaurant guide is, for example, a database of thousands of cases, each one consisting of dozens of fields or attributes: name of the restaurant, phone number, email address, dishes and beverage prices, different quality ratings (atmosphere, service, taste, or tidiness), etc. Each bit of information is significant only in combination with other bits of content. Visitors, then, can search for information and view different configurations of restaurant lists and profiles. The same principle applies to online games. In an ego-shooter game, each motion sequence, weapon, enemy, monster, and landscape is based on a huge number of separate information bits that are combined according to the situation and the player's actions.

### **Personalization**

Unitized media content can be easily adapted to users' interests and wishes. Automated content configuration permits the permanent personalization of online media, i.e., the repeated provision of a package of content that is automatically selected and presented according to users' preferences. There are two basic variants of personalization. The user may

select his or her preferred topics, departments, genres, actors, and locations and is presented with the content in the future (“customization,” e.g., Daily Me). Personalization in a narrower sense means that the user is automatically presented with tailored content, i.e., without selecting it and sometimes without noticing the automatic adaptation. Mobile services, for example, automatically provide locally relevant information, such as the next restaurant, hotel, or gas station. Amazon is another example: customers are accurately profiled according to their past purchases and viewed products. In future visits, they are presented with new offers and other information fitting their personal profile. These and other profiling practices clearly affect the information privacy of customers or recipients and this is being debated critically in the scholarly literature (see articles in *New Media and Society*, 8(6)).

## THEORETICAL AND INSTITUTIONAL ASPECTS OF MASS MEDIA

### Meaning of Online Media

So far this discussion has referred to online media as “technical” media, like television sets, computers, mobile phones, broadband cable, or telephone lines. In communication studies, two other perspectives dominate.

First, there is the meaning of *institutional media*, including a complex and emerging configuration of companies or institutions offering media products, trying to reach defined communication goals, applying processes and rules of content production under public control and regulation, and producing media-specific types of content for audiences with specific needs, gratifications, and patterns of media exposure. According to this cultural meaning, we can distinguish different types of online media, e.g., news sites, television network sites, corporate or product sites, political campaign sites, thematic communities, or search engines (→ E-Democracy).

Another meaning refers to online media as concrete media offerings or products (e.g., cnn.com, msnbc.com, ft.com), which are produced by journalistically and/or economically oriented institutions, disseminated, and received with the help of a technical infrastructure and devices. Most online media providers strive to reach mass audiences with products in order to finance their costly production by advertising revenues (online media requiring a user fee are still restricted to premium content; → Media).

### The Internet as Mass Medium or Cross-Medium

In the early days of the Internet in the mid-nineties, scholars discussed whether the Internet is a mass medium or not. At that time, about 5–10 percent of the population in most western countries were online. The question arose whether the Internet could be seriously compared to the other mass media after having reached a “critical mass” of 10 percent of users (Morris & Ogan 1995). In this discussion, different meanings of media became blurred. The Internet as a technical medium was compared to television, radio, and the press as institutional media. Later, the potentially infinite number of visitors on any website provoked the question of whether the web per se is a mass medium or whether only those sites that are *actually* viewed by a large audience can be called a mass medium (see, e.g., Webster & Lin 2002). The question of what number of recipients is required to talk of a

mass audience is still unanswered, but there seems to be a consensus among scholars to exclude from mass media private sites that are viewed by only a small number of visitors.

In the traditional mass media, almost all → news and entertainment content (→ Entertainment Content and Reality Perception) is supplied by professional media companies, institutions, or networks. This also applies to most online news and entertainment media. The majority of today's successful online mass media were founded by already established media or publishing houses. Online start-ups or standalone online media are still rare, and there are several reasons for this. In the beginning of online media, established media brands were already known to the audience and had a good image concerning news and entertainment quality, and online users trusted the established brands in the online world. Established media houses also had the journalism infrastructure and know-how to produce content for new media. They were able to reuse existing media content in their online media and to produce or purchase content at a lower price (*cross-media utilization*). Finally, multimedia houses can offer different media products with complementary content and promote new content across media channels (*cross-media promotion*). They can, for example, produce a television show, deliver background information or additional videos on a corresponding website, and offer a sweepstake over a telephone line with a usage fee (Ha & Chan-Olmsted 2004).

### **Source of Content**

In the traditional mass media as well as in online mass media, news and entertainment content is selected, produced, and presented by professional journalists (→ Online Journalism; Journalism; Professionalization of Journalism). Today, many online news media additionally contain "user-generated content": more or less "average users" actively mount different kinds of personal content at a website. This content is, in turn, selected, revised, and assembled by professional site providers. Examples of user-generated content are discussion forums, weblogs (→ Blogger), user diaries, personal essays, sound files or films, reader ratings of articles, and opinion polls. Users' visits to web pages can be logged and transformed into presentable content (e.g., as "Today's top 10 most read articles"). These kinds of online content are produced in an alleged cooperation between professional content providers and active users, giving recipients the feeling of being fully respected as co-writers. However, the site provider has the power to modify or reject users' contributions with the aim of creating an attractive mass media product (see Schweiger & Quiring 2005). Other online media are completely user-generated and can be regarded as real communities insofar as users' contributions are not at all or only lightly controlled by professionals (e.g., Wikipedia, Flickr, YouTube).

The Internet and other digital networks are communication platforms for news and entertainment media for private individuals, but they are also a means for all social and economic actors to directly reach the public without the paid (advertising) or free (press relations) mediation of mass media (sometimes discussed as "bypassing journalism"). Most companies, associations, and other institutions in the industrialized world run corporate, product or institutional websites. The Internet is home to an infinite multitude of database applications and services: online games, information services like Yellow Pages, product comparison sites, navigation services, download sites, e-learning environments,

search engines, and sophisticated applications like Second Life. The question arises as to whether these are all online media or whether the concept needs to be bounded in some way. There is no simple answer to this question. There is such a variety of online media, services, and applications, and all imaginable combinations of them, that any rigid definition is bound to fail.

## **Online Relationships**

*Malcolm R. Parks*

*University of Washington*

Online relationships may form using real-time chats or email from associations originating in listservs, chatrooms, interactive games, social networking sites, and many

other social venues on the Internet. They may be limited to a single encounter or they may involve repeated interaction over time. They may be conducted exclusively online or involve additional media, including face-to-face contact.

### **EVOLVING THEORETIC APPROACHES TO ONLINE RELATIONSHIPS**

Early laboratory studies of computer-mediated communication and theories developed for other media raised doubts about the use of the Internet for interpersonal relationships (→ Mediated Social Interaction; Network Organizations through Communication Technology; Communication Networks). Computer-mediated channels lacked bandwidth and, because of the lack of nonverbal and social cues, were thought to be inadequate for interpersonal interaction. Theorists assumed that it would be difficult to express complex emotional messages in online settings without abundant nonverbal cues (→ Nonverbal Communication and Culture). Later researchers demonstrated that with sufficient time, text-based interactions could achieve the same level of content exchange as face-to-face interaction. Moreover, those with the online experience to take creative advantage of the expressive capacities of text-based media were more successful in forming and maintaining online relationships. The Internet also sometimes functioned in “hyperpersonal” fashion, allowing people to achieve higher levels of disclosure and intimacy than they would have been likely to achieve face to face. This effect was achieved by allowing senders to optimize their self-presentations, encouraging receivers to utilize idealized images of senders, making an advantage of asynchronous interaction, and generating positive feedback loops.

### **ONLINE, OFFLINE, AND MIXED MODE RELATIONSHIPS**

Online interaction and online relationships in particular were initially viewed as threats to offline relationships. Early studies involving inexperienced users indicated that people who spent more time on the Internet spent slightly less time with family members and with local social contacts and were somewhat more lonely and depressed. However, as users gained experience, they also gained confidence that in turn allowed them to take greater advantage of the Internet’s interpersonal capabilities (LaRose et al. 2001). In one particularly noteworthy study Kraut and colleagues (2002) reversed earlier findings on the same sample by showing that, as subjects became more experienced, they reported greater overall contact with family and friends as well as greater social support.

Negative effects on users’ offline social lives are more likely to occur among users who lack experience, are introverted or compulsive, are socially isolated, or whose social networks are generally not yet online. Studies in several countries now indicate the Internet typically encourages people to develop new, more diverse relationships while at the same time enhancing communication among those who already have well-established relationships with each other offline (e.g., Hlebec et al. 2006).

Consistent with the Internet’s larger social evolution, negative effects of online interaction were more common in the early stages of the Internet’s adoption when it was novel, was disconnected from users’ other activities, and attracted those who may have been less embedded in existing social structures. As the user population became more representative and users gained experience, the Internet was integrated into

users' lives and in most cases made a positive contribution to their ongoing social activities.

Although the term "online relationship" is usually reserved for relationships that begin online, distinctions between online and offline relationships are dissolving. Online relationships often migrate to other settings and relationships begun offline often entail periods of regular or even prolonged online contact (→ Long-Distance Relationships). These "mixed mode" relationships pose new challenges for existing theories of both relationship development and mediated interaction (Walther & Parks 2002). Online and offline interaction stimulate each other, promoting an overall increase in interaction between relational participants. People in mixed mode relationships also take advantage of channel differences in order to manage uncertainty and conflict. Individuals favor media with restricted cues over face-to-face interaction, e.g., when the topic is potentially threatening to their self-images.

The Internet is a rapidly evolving meta-medium in which new combinations of media elements appear almost daily. Email is currently the dominant social venue with 10 times more users than chats and 25 times more users than multiplayer online games (Quan-Haase & Wellman 2002). Social venues may be categorized according to their primary communicative function (e.g., social support, gaming), but users regularly complement or subvert the intended function with a wider range of social interaction. Social venues may also be categorized according to whether they are limited to text, allow synchronous interaction, or allow back-channel communication (e.g., private messages during interaction within a group). Although social venues support relational formation and maintenance, they are not all equally fertile. Venues that allow synchronous interaction with back-channels (e.g., chats, MUDs/MOOs [Multi-User Dungeons, Domains, or Dimensions/MUDs Object Oriented], some interactive games) have higher rates of relational formation than those that are limited to asynchronous exchanges with no back-channels or graphics (e.g., newsgroups, mailing lists).

## OPPORTUNITIES AND CHALLENGES OF ONLINE RELATIONSHIPS

Between 10 percent and 35 percent of Internet users have started a new relationship online. Over 80 percent use the Internet to augment contact with existing friends and family members. Online relationships can be described using the same concepts and measures as other interpersonal relationships, but they nonetheless create distinct social opportunities and raise distinct challenges (→ Relational Maintenance; Relationship Development).

### Opportunities

The Internet promotes the formation and maintenance of interpersonal relationships in several ways. The low effort required for email and instant messaging allow immediate, frequent, and easy interaction. Although the Internet lowers psychological and other transaction costs, it is not "frictionless." Time and energy are still expended and some costs are only delayed until such time as the participants in the online relationship wish to meet face to face or conduct a complex transaction. The Internet is also a powerful tool

for identifying and contacting those with common interests. It does so not only by transcending geographic barriers, but also by providing both powerful search tools and a myriad of interest-specific social venues.

Accordingly, most new social contacts on the Internet are with people who have similar interests. Carried to the extreme, the ability to select for common interests may result in the balkanization of social networks. Yet the same tools that help identify those with common interests can also be used to diversify one's social network. Moreover, similarity on one dimension does not imply similarity on others. Commonality thus opens avenues for diversity through discussion of differences in background and attitudes. Many interpersonal communication technologies allow relational participants to communicate asynchronously when differences in schedules and time zones limit opportunities for synchronous interaction. For those with Internet access, email has become the most frequent means of contacting friends and relatives who live more than 50 km away (Quan-Haase & Wellman 2002).

The Internet facilitates relationships by overcoming the limits of face-to-face interaction in offline settings. The relative advantages of online settings are illustrated in research on social support (Walther & Boyd 2002; → Social Support in Interpersonal Communication). Compared to face-to-face settings, online support venues may offer greater access to expertise, greater control over one's messages and self-presentation, and freedom from the confines of one's offline social network. Internet use has been associated with a larger overall social support network, particularly for those whose offline networks were limited (Hlebec et al. 2006).

### Challenges

One of the challenges facing online relationships is the *migration to face-to-face interaction*. Although 20–40 percent of online relationships migrate successfully, this transition often presents an insurmountable hurdle, particularly if the online acquaintance has been brief, if the participants did not first meet in conjunction with a shared interest, if there are barriers to getting together in person, and if participants have not already successfully managed conflict (Baker 2002).

*Deception* is always a possibility given the Internet's unparalleled freedom of self-presentation (→ Deceptive Message Production). It is most likely when online participants are less involved, do not anticipate meeting in person, and have no way to cross-check identity claims. When face-to-face interaction is desired, as in online dating, participants typically present idealized images of themselves in an effort to balance accuracy and desirability (Ellison et al. 2006; → Impression Management; Self-Presentation). Those who present themselves more honestly are more likely to develop successful online relationships.

Relative *anonymity* and lack of physical presence may breed other challenges, however, including unpredictable, disinhibited behavior. Although moderate disinhibition may encourage introverted users, settings in which people display extreme disinhibition make it difficult for users to engage in the sustained interaction needed for stable relationships.

Managing the *boundaries of online interactions* and relationships is also a major challenge. As network-enabled communication technologies become more ubiquitous, expectations regarding availability and access must be reworked. One point of tension is

the blurring of lines between work and home life. Another is the need to manage expectations about how quickly one will respond when others assume nearly continuous Internet connectivity. Finally, privacy concerns are inevitably raised as people provide increasing amounts of personal information and interaction in increasingly personal ways online. Individuals may not recognize the social boundaries or the lack of social boundaries in common online venues. Their privacy may be comprised, e.g., when they exchange personal information using work-related email or when they post information intended for intimates on sites that are publicly accessible and searchable.

## METHODOLOGICAL ISSUES AND FUTURE DIRECTIONS

Examining a wider range of relationships is necessary for a broad understanding of online relationships. Romantic relationships garner the greatest attention, while far more common relationships such as work relationships, friendships, and extended family relationships are understudied (→ Dating Relationships; Friendship and Peer Interaction). Cultural differences and similarities in the dynamics and appeal of online relationships are inadequately understood. Longitudinal work is needed to identify the trajectories of online relationships. Research examining specific communicative challenges such as impression and boundary management is still in its early stages. Because most online relationships involve or will involve multiple media, researchers can no longer productively isolate “online” relationships from relationships more generally. Researchers are just beginning to consider how people utilize multiple channels in strategic ways and how task performance might be enhanced by the staging of interaction across multiple channels. Going beyond global estimates of Internet use will be essential to understand the potentially different functions of the Internet’s many social venues, as will stronger multi-variate controls that help identify differences among sub-groups of users (Zhao 2006).

## Online Research

*Wolfgang Schweiger*

*Dresden University of Technology*

The term “online research” refers to two different concepts which are often confused: (1) applying online methods in social research, and (2) social research of online phenomena. The first part of the article sketches the most important empirical methods and their online version. The second part briefly illustrates how selected online phenomena or research questions can be methodically addressed.

### ONLINE METHODS IN SOCIAL RESEARCH

Many traditional methods in communication studies have been successfully transferred and adapted to the → Internet as a research tool (→ Interview; Interview, Qualitative; Interview, Standardized; Experiment, Field; Experiment, Laboratory; Observation). Only a few online methods are completely new developments (e.g., Internet data mining with robots or search engines).

#### Quantitative Surveys

The traditional methods of quantitative surveys are face-to-face interviews, (computer-assisted) telephone interviews, and self-administered questionnaires (paper and pencil), either disseminated via mail or administered in groups that are present (e.g., students on university courses). Online surveys apply self-administered questionnaires, which are usually presented as a series of web pages including questions, items, and answering

options. Three strategies are commonly used to establish contact between a questionnaire and potential participants: email invitations, hyperlinks on websites announcing a survey, and unexpected “pop-up” windows introducing a survey.

Web questionnaires have technical, socio-psychological, and economic advantages: all kinds of multimedia (photos, illustrations, animations, films, spoken word, music, etc.) can be displayed. Participants’ answers can be dynamically evaluated, commented, rejected, or corrected, which enhances data quality and reduces the need for manual data correction. The order of questions and items can be rotated, systematically or at random. Questions and answers can be filtered and modified in real time (for example, if a participant indicates that the “Tonight Show with Jay Leno” is his or her favorite television show, the program title can be directly inserted into the follow-up question: “what are your motives for watching the ‘Tonight Show with Jay Leno?’”). The interview situation is completely anonymous; thus, online surveys can deal with sensitive social or psychological issues (loneliness, exposure to pornography, drug abuse, etc.), where all traditional survey modes would imply grave effects of social desirability (→ Parasocial Interactions and Relationships; Pornography Use across the Life-Span). As no personal interviewers are involved, interviewer effects (sympathy/antipathy, accentuation or variation of questions and wording, etc.) can be ignored. The execution is almost free: online surveys can be run on a simple Internet server (with database server software), no interviewers are needed, no postal or telephone charges (as in postal surveys) have to be paid, and no manual data entry is needed. Consequently, the sample sizes of some online surveys can be gigantic (up to hundreds of thousands).

On the other hand, there are crucial disadvantages, many of them related to sampling procedure and sample quality. As there is still a significant number of people who are not online, online surveys cannot replace telephone or face-to-face interviews if a representative sample of a country’s population is aimed at. The total population of Internet users is unknown and there is no complete email directory. Hence, no valid random sampling technique is available, and no evaluation of a sample’s representativeness, as long as a survey aims at the whole population (→ Sampling, Random). If a restricted and known population is under analysis (e.g., visitors to a website, a company’s employees, students at a university), appropriate random sampling techniques permit representative samples (e.g., drawing email addresses from a list, presenting a pop-up questionnaire to every  $n$ th visitor to a web page). There is no safe method of barring individuals from completing an online questionnaire several times. This problem especially applies to polls yielding results of some public or personal relevance, where participants might try to achieve a higher weight for their personal opinion by repeatedly answering the questionnaire. As in most other surveys applying self-administered questionnaires, there is no control of the questionnaire completion situation in online surveys, i.e., participants can collaborate, look up an encyclopedia, or visit other websites during a test. As text reading on a computer screen is laborious, and Internet users are often impatient, online questionnaires should be comparatively short and easy to answer.

### **Qualitative Interviews and Focus-Group Discussions**

Qualitative personal or group interviews demand personal contact between interviewer and interviewee. Only in a face-to-face setting can a confident communication situation

be established, and paraverbal or nonverbal signals (e.g., emphasis, facial expressions, sweating) be properly registered. Nonetheless, high-quality audio and/or video conferencing techniques offering real-time and sensory-rich signals can be pragmatic and affordable tools for qualitative interviews. In in-depth interviews, collaborative software, which enables interviewer and interviewee to edit and comment texts, charts, or pictures together, may be a help. These and other tools may be applied in qualitative research if there are great geographical distances between interviewer and interviewee (e.g., in international studies) or if the interviewee prefers not being in personal contact.

### **Online Experiments**
