## **Control and Authority in Organizations**

*James R. Barker*

*University of Waikato*

Although scholars take differing perspectives on the purposes and functions of control and authority, the definitions of these two terms are quite clear. In an organization, to “control” means to constrain work processes, human activity, and environmental events so that the organization creates value. That is, a refrigerator-manufacturing business must control work processes so that it can produce refrigerators that work correctly. The company must control human activity so that the production staff actually gets the refrigerators produced on time, and the company must control the flow of new technology from the environment so that it can incorporate new innovations into its production.

In an organization, “authority” refers to that which makes control legitimate. The individuals working for an organization must see the control methods as legitimate; that is, the organization must control human activity reasonably, appropriately, and lawfully. A subordinate should accept the orders of a supervisor as long as the orders are reasonable, appropriate, and lawful. If a subordinate refuses legitimate orders, the subordinate gets fired. If the supervisor gives illegitimate orders, the supervisor gets fired. Regardless of perspective, control and authority both become manifest through the communication practices in an organization. For instance, a boss gives orders directly to a subordinate; a human resources department writes down employee guidelines and regulations; a company vision statement unobtrusively guides worker decision-making.

### THE PROBLEM OF CONTROL

Most often we consider organizational control as something to be resisted. Freudian psychology teaches us that humans are naturally *autonomous beings* and that we resist whatever constrains our autonomy. Thus, we would naturally resist a boss telling us what to do or a receptionist forcing us to follow a rigid bureaucratic rule, even if our resistance is no more than a simple frown and feeling of dislike. Hence organizations face the difficult communicative task of getting all these “autonomous” individuals to constrain their behavior in such a way as to enable the organization to create value. An organization needs its workers to show up for work, preferably on time. It needs workers to get products “out the door” on schedule. It needs workers to follow safety regulations and refrain from discriminatory practices. Organizational control presents us with a paradox: we naturally resist constraints on our autonomy, but we must willingly constrain our autonomy for our organizations to create value.

Experience of this paradox marks our everyday life in an organization. We feel a desire to be autonomous, but at the same time we recognize the need to constrain our actions so that we can get productive organizational work done with our fellow humans. Commonly, we deal with this paradox by entering into something of a contractual agreement with the organization. For example, when an organization hires an individual (or an individual agrees to join an organization, such as agreeing to accept enrollment in a particular university), the two parties enter into an *exchange relationship*. The individual agrees to labor in some way for the organization (working, studying, or volunteering), while the organization agrees to provide some form of reward for the individual’s labor (salary, a degree at the end of a program of study, or a feeling of having contributed to the common good). As a part of this exchange relationship, the individual agrees (most often tacitly) to allow the organization to control his or her behavior in ways functional and appropriate for the organization, such as showing up for work on time, wearing a particular uniform, following the company’s customer service rules, supervising subordinates in appropriate ways, and so forth. The organization now has the legitimacy to exercise that authority to control the individual’s behavior (in reasonable, appropriate, and lawful ways). The practice of control, as seen in this exchange relationship, is an inherently communicative process.

This exchange relationship of control, as with any communication process, is fraught with difficulties. If a firm fails to control the organization’s work effectively, then the organization itself will fail. Bosses can bully and intimidate subordinates. We may need to

work overtime to meet a deadline and miss a family activity. Yet, we still join organizations, we still subject ourselves to the control of the organization. We need what our organizations give us, so we willingly (in most cases) submit and let our autonomy be constrained.

Therein lies what scholars call “the problem of control”: how does an organization gain and maintain the uncoerced obedience of its members? The word “uncoerced” is important here because we assume that humans willingly (more or less) join organizations, as depicted in the exchange relationship described above. Thus, we willingly allow the organization to control our behavior rather than having the organization coerce us into compliance, such as in a prison. In an organization, we assume that we have a choice in terms of control.

The problem of control has vexed organizational scholars for many years. Most notable among these scholars was the famed German sociologist Max Weber (e.g., Weber 1958; 1962; 1978), who wrote in the early 1900s and gave us far-reaching fundamental concepts and frameworks for analyzing organizational control and authority. So powerful was Weber’s work that his thinking has significantly shaped how we understand the practice of organizational control. The different elements of control and authority described in the remainder of this section all either extend directly from his work or have been shaped by scholars influenced by his ideas.

### **TYPOLOGIES OF CONTROL AND AUTHORITY**

Control becomes manifest in organizations as a communicative system; that is, the patterns of discourse and activity that legitimately constrain work in directions functional for the organization. Scholars have identified four main systems of control with the first three found in the work of Edwards (1979). *Simple control* refers to the direct and personal type of control most often seen in a → supervisor–subordinate relationship. The supervisor simply communicates orders directly to the subordinate. *Technical control* refers to a structural system developed around organizational processes, such as how the speed of an assembly line controls the pace of worker activity. *Bureaucratic control* identifies the system of control that derives from organizational hierarchy and rules, such as seen in an organizational chart or in employee regulations or contracts (→ Bureaucracy and Communication).

Tompkins and Cheney (1985) and Barker (1993) identified a fourth system of control, *concertive control*, a system that grows from modern day peer and team relationships at work. Concertive control extends from the peer pressures and expectations of peers as they are communicated to others. Control, when viewed across these four types, becomes more unobtrusive as we move from simple to technical to bureaucratic to peer. While we can readily experience the simple control of a boss or the need to maintain the pace of the assembly line, the rules of a bureaucracy or the expectations of a peer are much more subtle and difficult for us to experience as a form of control.

Our primary typology of authority comes directly from Weber’s work. Weber identified three types of authority, three foundations for legitimately controlling our behavior in organizations. In *charismatic authority*, legitimacy comes from the compelling personal power of an inspirational leader, such as a visionary company president. In *traditional authority*, legitimacy derives from the organization’s (or broader society’s) culture and traditions, as found in the tradition of a family business passing from one member to the next. In *bureaucratic authority*, legitimacy resides in the hierarchical structure and rational rule system of the bureaucracy.

While Weber's typology is valuable, control scholars find more utility in understanding the locus of authority in a control system, as in understanding where the source of authoritative legitimacy resides in a communicative control system (Barker 1999). For example, in simple control, the locus of authority resides in the power of the immediate supervisor. In technical control, authority extends from the power of the technology or work processes. In bureaucratic control, authority resides in the power of the organization's hierarchy and practical rules. In concertive control, peer relationships and shared values form the source of legitimate authority.

### THREE PERSPECTIVES ON CONTROL

Control scholars generally take three perspectives on control. Scholars may take a *managerial perspective* and study how to make a control system more efficient and effective. These scholars focus on the outcomes of control and may study how to improve superior-subordinate communication or work processes so that an organization increases productivity. Other communication scholars may take a *critical perspective* and study the effects and consequences of our control practices on individual autonomy. These scholars focus on the outcomes of power and domination in control systems and may study issues such as workplace bullying, resistance to unfair practices, the negative effects of peer expectations (→ Organizational Communication: Critical Approaches).

Communication scholars also take a *discursive perspective* which is concerned with the effects and consequences of our control practices as systems of meaning creation (→ Organizational Discourse). These scholars have studied such theories as identification, which is concerned with how individuals come to create their identity around the espoused values of the organization, thus unobtrusively acting in ways functional for the organization (→ Organizational Identification). Discourse-focused scholars also develop systematic theories for understanding the role of control in meaning creation, as found in the theory of structuration (→ Structuration Theory).

### DIRECTION OF DISCURSIVE RESEARCH ON CONTROL

Communication scholars are increasingly taking a discursive approach and focusing on how we construct meaningful discourses of control and the need for nuanced and sophisticated understandings of how we make ethical decisions about the reasonableness, appropriateness, and legality of control and authority (Sewell & Barker 2006). Such a concern for ethics helps bring together the three perspectives on control and enhances our knowledge of legitimate authority and truly productive control practices (→ Organizational Ethics). Barker (2005) recently argued that we should engage control by studying the discursive levels at which we make ethical decisions about control: the levels of peer, hierarchical, and governance relationships.

As globalization increases, as we work together in more collaborative, cooperative, and connected relationships, our need for effective but nonoppressive methods of control will also increase (→ Globalization of Organizations). Humans and organizations will still enter into exchange relationships regarding control. Our practice of control and our exercise of authority will still be tenuous. The best direction for future research involves

making the morality of control more transparent and finding ways for us to choose control practices with which we are comfortable.

## **Convergence of Media Systems**

*Hans J. Kleinsteuber*

*University of Hamburg*

A system is an assemblage of individual elements that together constitute a whole, with each component interacting with the others and with the outer world (→ Cybernetics;

Systems Theory). Using this approach, a media system may be seen as consisting of different publishing entities, such as → news agencies, the press, or → television, which relate to each other. To give an example, agencies provide news for the different media, such as the press and electronic media, which compete and cross-promote at the same time. There are also links between the media system or its entities and the outer world of other systems, like politics (e.g., broadcasting legislation and regulation), economics (e.g., conglomerate companies or advertising), society (e.g., as readership or audience), or culture (e.g., popular culture and entertainment).

The most common *space for a media system* is the nation state, where the central markets and most of the companies are based. But the center of activities could also be a small place, such as a locality with its *mélange* of local media. Also, in an increasingly integrating world, media actors may be active in a number of different markets of different states. In some respect, one may even talk about Europe as an emergent media system, which may be compared to other large systems, such as that of the US.

A media system may also be shaped by different levels of *media activity*, like the combination of national program producers and local affiliations. This may be found in the television network system of the US or the federal system in Germany, where broadcasting responsibilities rest with individual federal states. Another way to group media activities is by language spaces, e.g., the large world of English-speaking countries dispersed around the globe, the Spanish-speaking region consisting of Spain and Latin America, the Chinese-speaking region with China, Taiwan, and Singapore, or smaller regions such as the German space in the center of Europe, which besides Germany includes Austria, parts of Switzerland, and other bordering countries.

### THE COMPARATIVE APPROACH

It seems a natural approach to compare media systems across borders. Comparison is a method for obtaining evidence of causal effects by searching for similar or different elements between two or more systems. The British philosopher John Stuart Mill talked of the combination of a “method of agreement” and “method of difference” (Mill 1843/1972, 648ff.), meaning that every substantial comparison has to look for common and different features at the same time. Blumler and colleagues combine several aspects and argue that work is comparative, “when the comparisons are made across two or more geographically or historically (spatially or temporally) defined systems, the phenomena of scholarly interest which are embedded in a set of interrelations that are relatively coherent, patterned, comprehensive, distinct, and bounded” (Blumler et al. 1992, 7).

The final step of a comparative analysis is the designing of theoretical statements, which are created by separating individual differences from the things that are common to all. Out of the latter one may distill statements about common features that constitute models or types. This is how theories of convergence and divergence have been developed. Their special feature is that they describe developments in the course of time; they focus on a paradigm shift. A theory of convergence argues that media systems are collectively moving in the direction of increasing homogeneity (→ Comparative Research).

### **Early Comparative Theories of the Press**

The comparative perspective reveals that media serve different functions, appear in different forms, and differ in many other ways. In 1956 Siebert and colleagues wrote an influential study on “four theories of the press,” looking at the relationship between press and society, based on the assumption that the media always take on the form and coloration of the structures within which they operate. The four theories are called “authoritarian,” “libertarian,” “social responsibility,” and “Soviet communism.”

The last of these has obviously disappeared, nearly totally. Authoritarian reflects the longstanding (mostly European) tradition of control over the media by repressive regimes. Libertarian stands for free enterprise and freedom from government interference, and social responsibility for a government that not merely allows freedom, but actively promotes it (Siebert et al. 1956). This approach represented an American perspective on the postwar world and reflected the polarization during the age of the Cold War, and has often been criticized for this. It devised a world shaped by divergence, as such reflecting facts and visions of the time the theory was developed.

### **Comparative Analysis and the Theory of Convergence**

Hallin and Mancini (2004), in their study on comparing media systems, start from the argument of the “four theories” and attempt to update it, mainly by looking at capitalist countries on both sides of the Atlantic. They find *three models*: a “liberal” model (the UK, Ireland, the USA), with relative dominance of market mechanisms and commercial media; a “democratic corporatist” model (northern continental Europe, including Germany), with a historical coexistence tied to social and political groups and a relatively active but legally limited role of the state; and the “polarized pluralist” model (Mediterranean countries of southern Europe), with integration of the media into party politics, a weaker position of commercial media, and a strong role of the state. So far they emphasize the differences between the three models, but see many common aspects inside each group.

But this is mainly a description of the present situation, which does not include developments on a longer time scale. Hallin and Mancini also look at long-term changes and see as a consequence of ongoing commercialization an overall process of homogenization. They argue that considerable convergence has taken place, primarily in the direction of the “liberal” model. They assume that this process will continue into the future, but also see limits, such as the tendency in society toward differentiation and individualization. The Internet, with its interactive qualities, is the obvious medium that supports this process. In general, the thesis of convergence is well argued and describes an important trend in international media. But it is only based on analysis of the western part of the world, and it refers primarily to the interrelationship between the media and politics (→ Party–Press Parallelism; Political Journalists).

### **ASPECTS OF COMPARATIVE ANALYSIS OF MEDIA SYSTEMS**

Denis McQuail develops a scheme based on four models in his normative media theory. A “liberal-pluralist” or “market” model starts from the original “free press” (libertarian)

model of Siebert et al. A “social responsibility” or “public interest” model includes the right to freedom of publication but is accompanied by a positive notion of freedom, including social purposes for the media. The “professional” model emphasizes the journalistic profession as the guardianship of standards for the quality media. Finally, the “alternative media” model includes a range of non-mainstream media with purposely different aims and origins (McQuail 2005, 185ff.). It allows for the definition of different types that show an emphasis on the “free” model (prototype: USA) or the “public interest” motive (prototype: the UK with the BBC). The professional as well as the alternative type may additionally be found in both. Important for this approach is that it looks for features inside each media system, emphasizes convergence of different normative principles, and asks that all models should be combined to secure diversity.

Another approach was adopted by Wolfgang Hoffmann-Riem (1996), who compared six countries concerning their system of licensing and regulation of electronic media. After searching for common features, he identified two groups of countries, one with a long tradition of a privately owned sector (US, Canada, Australia), where a “market” model was established, financed from the revenues of free enterprise, in particular advertisement or viewers’ subscriptions, which differs clearly from the second group, with a strong public-service tradition (the UK, Germany, France), where a “trustee” model evolved; here broadcasting is legally organized in trusteeship for the whole of society. Even though the past was shaped by a difference between the two models, he also recognizes a converging future, following a trend from “the trustee to the market model” (Hoffmann-Riem 1996, 340). He therefore supports the convergence thesis of Hallin and Mancini, even though his focus is quite different, as it is mainly based on legal analysis.

Most of these approaches lack a global focus, as they place western systems at the center of analysis and do not recognize the fact that models that first evolved in a transatlantic environment have spread around the world. In consequence, one could group world systems according to their attitude toward the public-service traditions (besides Europe, British Commonwealth countries including Canada and Australia, also Japan) as opposed to regions with an unrestricted commercial dominance (USA, later Latin America, parts of Asia). In other regions (like the Arab world, the states of the former Soviet Union, China) the controlling state is still the leading force. Taking this distinction, one may arrive at another framework in which control over broadcast media may be separated into “public,” “commercial,” and “state.” Also, combinations of these are possible, as in the case of Latin America, where state-controlled broadcasters are financed via commercial spots and not by a general fee. The convergence argument of Hallin and Mancini may also apply to these findings, as public service is endangered in many states and commercial homogenization is the leading tendency, especially if one includes the ongoing digitization of media.

## FURTHER ASPECTS OF CONVERGENCE

Yet another comparative approach would take the *size of countries* – based on territory, population, and market forces – into account. Obviously, nations of a continental size (the USA, Russia, China) enjoy much more autonomy in terms of media actors, content, and policy than small and vulnerable states (Austria, Scandinavia). The small states react by emphasizing a variety of active media policy measures to protect their identity.

Therefore, in small states public broadcasters tend to be stronger and receive more public funding than in larger states. An interesting example in this respect is Canada – a country of huge size but with a small population compared to the US – which invests heavily in supporting “Canadian content” in broadcasting and films. Based on this distinction, one may argue that convergence takes place more inside the cluster of large or small states, where the large ones tend to be global players, whereas the small ones stress the autonomy of their own media resources.

Convergence could also be interpreted as a policy goal that should be attained in the course of time. The European Union has practiced an active media policy since the 1980s, and its central goal is to create a common audiovisual space. The main instrument for this is the 1989 Directive “Europe without Frontiers,” which attempts to support pan-European media actors, as they are best prepared – in the eyes of the European Commission – to reach this goal. In this case, one could talk about convergence as an explicit policy goal that combines with elements of commercialization and self-regulation – as seen in the present media policy of the European Union. (McQuail & Siune 1998; → European Union: Communication Law.)

Designing general frameworks of the media that consist of different models always creates the problem of a limited perspective. Obviously, the less-developed world is often not represented in these models. A dichotomy like the theory of a “digital divide” shows a different world. In this perspective there is a deep gap between rich and poor countries concerning access to the Internet and other forms of new media as a distinguishing characteristic. The end result of this view is a world dominated by increasing divergence that might only in the long run converge, when the new technologies are universally available.

# Conversation Analysis

Wayne A. Beach

San Diego State University

Conversation Analysis (CA) is a primary mode of inquiry for understanding how people talk with one another in everyday casual encounters, as well as in more specialized institutional settings involving bureaucratic representatives (e.g., medical, legal, educational, corporate, government). Research materials are naturally occurring audio and video recordings, and carefully produced transcriptions, of a broad range of interactions comprising the social worlds of diverse speakers, relationships, activities, and events. Examples are: telephone conversations and face-to-face interactions among family members, friends, acquaintances, and service providers such as telephone emergency hotlines; interactions among young children, parents, and daycare providers; patient–provider interactions (→ Doctor–Patient Talk); news and broadcast interviews (→ Broadcast Talk). Giving priority to recordings and transcriptions is based on the recognition that detailed features and contingencies of interactional events cannot be intuited, nor adequately reconstructed, through field notes, interviews, or other forms of self-reported information. Interactions that are “naturally occurring” are those that would take place whether or not a recording device were present, and are not significantly influenced by researchers prompting the origination, content, or length of the social occasion.

## BASIC PRINCIPLES

Speakers order their lives by collaboratively producing distinct courses of unfolding action. Discovering how these actions are sequentially organized is fundamental for explaining communication in everyday life. Through CA, priority is given to: (1) identifying how speakers utilize specific vocal and visible practices to manage the moment-by-moment design of turns-at-talk, and (2) the sequential and spatial environments within which actions routinely occur. Although CA has historically given primary attention to the ongoing orderliness of talk within single cases and collections of social interaction (e.g., see Atkinson & Heritage 1984; Sacks 1992), the embodied organization of gesture, gaze, and body orientation are basic and enduring concerns (e.g., see Goodwin 1981; Heath 1986; Beach 2007b).

Central to CA are ongoing, informal, yet systematic procedures for conducting what is commonly referred to as *data sessions*. Colleagues gather to repeatedly hear and view recordings, closely examine transcribed excerpts, and provide increasingly refined observations about practices comprising the organization of specific moments and interactions being examined. A defining feature of CA is the descriptive rigor and explanatory force brought to recordings and transcriptions, a proof-by-exemplar methodology of analytic induction: social problems are not brought to the data, but emerge from grounded and systematic inspections of moments not prematurely dismissed as lacking order or relevance. Observations about the ordering of interaction must be anchored *within the recorded and transcribed interactional data*, specifically, how speakers make available to one another their emergent understandings of local (i.e., “Why that now?”) interactional circumstances.

What speakers display and demonstrate in real time, in the first instance by and for them, become resources for analysts to warrant claims, progressively advance evidence about the organization of social interaction, and seek to establish consensus about the most compelling depictions of interactional conduct.

The analytic procedures of CA stand in marked contrast to attempts to understand communication by speculating about speakers' mental states, or background knowledge, which do not somehow get invoked during interaction. So too are analysts' imagined, hypothetical, and anecdotal possibilities minimized in favor of focusing on what is actually occurring between speakers. Attention is not drawn to individuals' interpretive or perceptual experiences, but to the turn-by-turn and embodied coordination of local actions within an *architecture of intersubjectivity* – an organization in which “a context of publicly displayed and continuously up-dated intersubjective understandings is systematically sustained” (Heritage 1984, 259).

Through systematic data sessions, and subsequent publications, empirical attention has been given to a wide variety of social activities. The *analytic dimensions of CA investigations* are broad and vibrant, revealing the organization of frequently recognized, yet taken-for-granted, features of language and action: recognition during telephone openings, repairing understandings, the systematics of turn-taking and overlapped speech, agreeing and disagreeing, acknowledging and closing turns-in-progress, establishing and withdrawing gaze, initiating and closing topics, questioning and answering (→ Questions and Questioning), referencing persons, the social construction of self, accounting, accusing, announcing, apologizing, blaming, complaining, complimenting, gossiping, offering, pursuing noticeably absent responses, requesting, storytelling, teasing, exhibiting and claiming entitlement to knowledge, grammar and syntax in interaction, dealing with embarrassment, laughing when displaying resistance to troubles, discussing uncertain and delicate futures, delivering and receiving good and bad news.

Across these diverse social activities, the empirical findings of CA reveal how ordinary speakers, in both casual and institutional interactions, routinely address and resolve emerging problems. For example, speakers manage the *allocation of turn-taking* by precisely coordinating the inception and completion of turns, minimizing overlapped speaking, and enforcing efforts to speak out of turn and/or interruptively. When monitoring the course and progression of another's speaking, recipients rely on acknowledgment tokens (e.g., *mm*, *mm hm*, *uh huh*, and *yeah*) to display attentiveness and facilitate others' extended talking (e.g., during stories). But words such as *yeah*, *okay*, or *all right* can also be recruited to close down prior speakers' talk and thereby secure speakership. Similarly, the word *oh* is utilized across a range of social actions, including displays of a “change of state” in knowledge, as well as treating prior questions as sufficiently problematic to avoid talk raised by another's query. What may appear to be small, insignificant, and otherwise benign features of everyday conversation are, in practice, employed as key resources by speakers to manage critically important activities such as speaker selection, topic organization, and reluctance (or willingness) to talk about particular issues.

Central to these social actions are ways speakers work together to negotiate and achieve *shared understandings*. One primary mode of CA research is to investigate how speakers work to repair their own talk (e.g., when a wrong word is employed), and/or exhibit an inability to understand another's talk (e.g., *What?*). Mechanisms comprising these sequential

environments have been identified, including how it is possible that “breakdowns” and “misunderstandings” are created and resolved, and how those who initiate repair about another’s talk are made out to be responsible for the trouble. Related studies of “troubles” have also revealed that while speakers may state they are “pretty good” or “fine,” such utterances may give rise to more elaborated talk about troubles they are experiencing – talk in which troubles-tellers display their resistance and ability to manage the troubles, just as recipients may (or may not) make available their receptivity to hearing and responding to another’s dilemma.

### HISTORICAL SKETCH

From the late 1970s, the empirical rigor and theoretical implications arising from CA have provided a viable alternative for communication scholars researching → *language and social interaction* (LSI). Although CA was emerging in sociology in the mid- to late 1960s, and strongly influenced by work in ethnomethodology (Heritage 1984), it was nearly a decade later when interdisciplinary relationships began to be cultivated. The work of CA, and its importance for communication research, was initially recognized with the reading of early publications such as Emanuel Schegloff’s (1968) paper on “telephone openings” (→ Telephone Talk), and the later (now classic) article on turn-taking published in the journal *Language* by Sacks, Schegloff, and Jefferson (1974). When contacted and visited in the Department of Sociology at UCLA, both Schegloff and his visiting colleague, Gail Jefferson, also generously provided “blue ink” mimeos of Harvey Sacks’ lecture notes – a bedrock for CA investigations. These notes were transcribed by Gail Jefferson, following Sacks’ untimely death in a car accident in 1976, and eventually published as an indispensable two-volume set (Sacks 1992). Emanuel Schegloff’s introduction provides a useful lens for appreciating Sacks’ contributions in historical and scholarly context.

As these mimeos, related earlier publications, and unpublished papers were read and disseminated among interested communication scholars, who otherwise had limited access to CA work, the integration of CA into the communication discipline became gradual yet progressive. Since the late 1970s, CA has been a primary focus of 11 special journal issues (and sections) involving communication researchers. The 1987 advent of the journal *Research on Language and Social Interaction* also provided a needed forum for LSI research, facilitating ongoing collaborations within and across traditional disciplinary boundaries.

Significant relationships between CA and alternative methodologies have been addressed (e.g., between ethnography and CA, and contrasting orientations to “context”). A variety of related and critical issues have also been examined (e.g., news interviews, conversational poetics, morality, verbal/non-verbal relationships, lay diagnosis, and turn construction).

Throughout these key developments, unequivocally the most important activities for a growing CA community in communication centered on the collegial discipline of *data sessions*: most gatherings included informal but rigorous analyses of recorded and transcribed data. The *doing* of CA occurred, first and foremost, when working directly with others analyzing interactional data. While data sessions were ordinarily conducted at separate universities, during conferences these sessions occurred more privately, among small groups in hotel rooms. But as interest grew and brainstorming increased, data

sessions became community-based, open events occurring (more or less “officially”) pre-conference and during programmed panel slots. Initiated during Western States Communication Association (WSCA) meetings, these sessions carried over into the National Communication Association (NCA) annual conferences: participants worked together with seasoned analysts to refine analytic skills and discuss the potential of CA for pursuing diverse and rich investigations into fundamental communication activities. These open data sessions continue and, especially at NCA and WSCA, related CA paper and panel presentations are now normalized conference events. It is particularly notable that NCA is internationally recognized as hosting one of the most prominent annual gatherings of CA researchers representing diverse disciplines and countries. This success is due, in large part, to growing openness and receptivity for CA as an innovative and substantive approach to how messages and social relationships might be examined.

### SITUATING CONTEXT-IN-INTERACTION

Fundamental to CA’s position on social order is the recognition that speakers construct, place, and participate within sequences of adjacently paired (i.e., contiguous) actions that are not random but highly organized. Each utterance and action occurs within structurally defined places, exhibiting what speakers treat as meaningful for unfolding interaction. In systematic ways, speakers work together to manage emerging interactions by constructing local contexts of meaningful, communicative actions. A speaker’s current turn-at-talk projects the conditional relevance of not just any, but a range of appropriate next responses. Next speakers design their responses by displaying understandings of what the prior speaker made available and relevant. Just as utterances cannot be understood when stripped from carefully designed sequential environments, for CA *context* is best understood as achieved through interaction – constantly renewing and shaping social actions – rather than external to or otherwise removed from communication (i.e., as located in roles, social settings, or institutions). Through close analysis of single cases and constant comparisons across collections of phenomena, it has become evident that numerous practices employed by speakers to organize specific moments of interaction (i.e., local and context-sensitive actions) also occur – in systematic and thus generalizable ways across speakers, topics, activities, and cultures (i.e., context-free and universal patterns of communication).

Locating context in speakers’ responses to immediately prior talk, and action, gives priority to capturing how speakers organize interaction. Alternative and more general descriptions of social settings cannot lay bare the details of how speakers collaborate to shape communication contexts (e.g., see Duranti & Goodwin 1992). In the last two decades, for example, turn-organized notions of context provided an empirically grounded alternative to creating and utilizing various “coding schemes” to capture message content and subtle features of relationships (e.g., control, dominance, and submission). With CA as a resource, it was recognized that many schemes utilized categories neither grounded in nor sensitive to interactional conduct. Coders’ decision rules were also ambiguous in that they were not focused on describing how current speakers project, and next speakers are responsive to, prior turns and actions. Even though arguments could be advanced that coders agreed on 80 percent or more of decisions made, such consensus did not translate into an ability to capture how speakers organized sequences of interaction.

Similarly, contextual approaches advanced by CA revealed the tendency to underspecify “speech act” functions of utterances (e.g., compliments, offers, requests), especially when the detailed and sequential environments in which such actions occurred were not fully articulated.

### MICRO/MACRO DISTINCTIONS AND RELATIONSHIPS

The social sciences in general, and communication scholarship in particular, have demonstrated considerable interest in what are often described as *macro* categories for explaining social order (e.g., power, status, race, ethnicity, gender, and culture). For CA, it is inherently problematic to claim that the existence of social order is the natural consequence of these (and related) attributes – overly general qualities that are too easily invoked, yet difficult to anchor within participants’ orientations to practical circumstances of choice and action. It is not sufficient, for example, to offer the following kinds of assertions: men dominate when conversing with women; persons with differing racial, ethnic, and cultural backgrounds are communicatively dissimilar; or judges, doctors, and politicians are obviously more powerful than those with whom they interact. In each instance, such declarations do not evidence how participants in interaction exhibit and achieve such actions – dominance, lack of similarity, being powerful – in specific and observable ways during the routine course of daily interactions. Since it is through the fine-grained organization of actual communicative events that “macro” concepts are accomplished, it remains for analysts to provide empirically grounded, compelling evidence that speakers are engaged in activities amounting to whatever power, gender, culture, and the like might be conceived to be.

Distinctions between “micro” and “macro,” so frequently debated in classes and at scientific gatherings, are unnecessary for CA: roles, categories of societal membership, and institutions (i.e., “macro”) get simultaneously and interactionally constructed (i.e., “micro”) as speakers enact and embody their orientations moment by moment. Such actions are neither small nor insignificant, but may well be taken for granted when attempting to describe “larger” societal structures.

### ACCESSING CA AND FUTURE DIRECTIONS FOR RESEARCH

Examples of recent CA investigations by communication scholars include work focusing on interactional activities such as laughter (Glenn 2003), narratives (Mandelbaum 2003), test results during medical consultations (Pomerantz & Rintel 2004), apologies (Robinson 2004), asserting speakers’ rights (Stivers 2005), and how family members talk through cancer on the telephone (Beach 2007a). Ongoing research involves an increasing convergence of studies on conversational and institutional interactions (e.g., patient–provider encounters), more frequent applications for external funding to support research efforts, and continued discussion of how empirical findings resulting from CA might be employed to refine communication skills across various relationships, settings, and institutions. These collective efforts seek understandings of the amazingly sophisticated and finely ordered nature of social interaction, extend fertile collaborations across disciplinary boundaries, and work toward developing grounded, universal, and relevant theories of social order. A seemingly

endless array of primal features comprising everyday communication awaits discovery, and CA is uniquely positioned to continue analyses of unexamined interactional involvements.

## Co-Orientation Model of Public Relations

*Dejan Verčič*

*University of Ljubljana*

Public relations (PR) is a strategic management function responsible for cultivation of good relations between an organization and its strategic constituencies (stakeholders and publics; → Stakeholder Theory; Grunig 2006). The ultimate goal of → public relations is social harmony. The co-orientation model of public relations assumes that organizations prefer harmony to conflict and that they can use communication for that purpose (→ Organization–Public Relationships; Consensus-Oriented Public Relations).

### ORIGINS

The co-orientation model of PR originates in psychological balance theory, which is a motivational theory of attitude change (→ Consistency Theories). Heider (1946) proposed the consistency motive that helps people toward psychological balance. Links between people, and an object or idea can be favorable or unfavorable, and people rationalize and adjust their attitudes and/or behaviors to achieve internal balance. Two friends should both like or dislike a third person; if not, each of them suffers a psychological imbalance that can be overcome by one of them changing their attitude toward the third person. If that change of attitude does not occur, friendship suffers and a psychological balance can be restored by breaking the friendship. Now they still do not value the third person in a similar manner, but they do not like each other anyway, so this is no longer problematic.

Newcomb (1953; 1956) developed the balance model by introducing the idea that people use communication as a tool to resolve an imbalance: our friends who like each other should be able to communicate their differences in perception of the third person and in that process of communication find a compromise or perhaps one of them changes their opinion. This is a symmetry theory where communication leads to more interpersonal similarity: if the two friends like each other, they will try to be similar and they will use communication to resolve disagreements.

Co-orientation entered PR via the interpersonal model developed by McLeod and → Chaffee (1973), which provided the terminology now used to describe the co-orientation model and its variables in PR. This model was adapted for PR by Broom (1977) and Grunig & Hunt (1984) to elicit key ideas on how organizations and constituencies relate to each other (→ Social Perception).

## CONCEPTUALIZATION

“Intraorganizational congruency” describes how close the views of an organization are with the views of its constituency. “Intraconstituency congruency” describes how close the views of a constituency are with views of an organization. Broom & Dozier (1990) described both congruencies as “perceived agreement” – or “disagreement,” arguing that this was crucial in determining how an organization deals with its strategic constituency and how a constituency deals with its focal organization. “Organization-constituency agreement” reveals the extent to which an organization and its constituency share similar evaluations of something of mutual interest, and “organization-constituency understanding” tells the extent to which an organization and its constituency similarly define something of mutual interest. “Agreement” describes instances of a situation being perceived as positive or negative, and more or less important, and how an organization and its constituency agree on a particular issue. “Understanding” is about the descriptive details of a situation – how much an organization and its constituency see the same elements defining the situation. “Organization-constituency accuracy” highlights the extent to which an organization’s view of a constituency’s actual view is correct, and “constituency-organization accuracy” tells us the other way around. Following Chaffee & McLeod (1970), Broom (2005) sees effective PR as two-way communication producing high accuracy.

By putting accuracy of perceptions into the focus of the co-orientation model, the model loses its meliorist theoretical assumptions (from the balance and symmetry theory). Foci of the model instead become descriptions of agreement between an organization and its constituencies. We can now answer questions such as: how does an organization view something of common interest with a strategic constituency? How does that constituency perceive that area of common interest? How does the organization perceive the constituency’s views? And how does the constituency perceive the organization’s views? By answering these questions and by replacing the term “agreement” with Scheff’s (1967) term “consensus,” we get four possibilities: (1) *consensus*: an organization and its strategic constituency have similar evaluations and definitions of a situation; (2) *dissensus*: an organization and its strategic constituency do not agree either on an evaluation or on definitions of a situation, or both; (3) *false consensus*: one or both sides perceives a higher level of consensus than there is; and (4) *false conflict*: an organization or its constituency perceives a higher level of disagreement than there is.

This type of questioning is known in PR practice as a “gap analysis,” a method where practitioners audit organizations and selected constituencies and describe their perceptions as being more or less distant. Where discrepancies are the greatest, intervention is proposed and communication is used to increase accuracy of perceptions, albeit well short of helping to produce a balanced relationship.

## APPLICATION

Co-orientation in PR exists when an organization and its strategic constituency are simultaneously oriented to one another and to something of mutual interest. Based on its original assumptions, the co-orientation model enables organizations to adjust their goals in response to the expectations of their strategic constituencies and vice versa. In

that way, the co-orientation model serves as a tool for PR strategy development. The notion of balance focuses attention on the core idea of co-orientation: internal balance in both an organization and its strategic constituencies. This is possible only through continuous research and open, two-way and symmetrical communication between the dominant groups in organizations and the dominant groups in strategic constituencies.

Accuracy of perceptions is too narrow a goal for such a process, and the ideal of harmony should return to the core of this endeavor. When an organization and its strategic constituencies really value their mutual relations, they are interested in maintaining their mutual favorability. What original balance theory tells us is that accuracy may only produce cognitively correct relations, but it is highly questionable if they can be emotionally sustainable. By limiting the objective of a PR gap analysis to accuracy, internal tensions in organizations and their strategic constituencies may be stored (or even created), with a good chance of eruption in the future.

The co-orientation model has been recently used in PR not only for studying perceptions between organizations and their constituencies, but also for developing PR ethics (Pearson 1989), analyzing consultants (Johnson 1989), nation-building (Taylor & Kent 2006), and international relations (Verčič et al. 2006).

## Copyright

*Matt Jackson*

*Pennsylvania State University*

Copyright is the branch of law that provides property rights in expression, and it is the primary legal regime for the cultural and information industries, including print publishing, music, film, television, radio, theater, computer software, photography, and fine art. Copyright only protects expression, not the ideas being expressed. Ideas are the thoughts inside our heads and expression is the way we communicate those thoughts to others (→ Freedom of Communication). A book may include many facts and ideas. The author then uses specific expression, including words or pictures, to communicate those facts and ideas. A second author (or artist or musician) can use any of the facts or ideas contained in the book but would need permission to copy the first author's expression.

Only original expression can be protected by copyright. Under international treaties, copyright protection begins the moment the expression is fixed (stored) in a tangible medium, which might include words on paper, paint on canvas, music on tape, or digital bits stored in a computer file. The copyright owner is granted control over the reproduction, distribution, public performance, public communication, and public display of the work as well as control over any derivative works that are based on the copyrighted expression. Derivative works include translations and adaptations, such as when a written story is made into a film (→ Intellectual Property Law).

### ORIGINS AND JUSTIFICATIONS FOR COPYRIGHT

Though copyright is entrenched in modern legal systems, it is a law of recent origin. For most of human history, anyone could copy someone else's expression without asking for permission. When the printing press was introduced to western Europe in the fifteenth century, many cities granted special "printing privileges" to encourage the development of this new technology (→ Printing, History of). Printers were granted exclusive rights to print certain books in a given territory. This encouraged printers to invest in developing their fonts and presses, and it also gave the authorities leverage in enforcing censorship against heretical and seditious books (→ Censorship, History of). By the eighteenth century, many printers wielded monopoly power. In 1710, England passed the first copyright

statute to break the printers' monopoly. For the first time, rights were specifically granted to the author rather than the printer. As more nations passed their own copyright laws, two rationales emerged to shape those laws: economic incentives and moral rights.

The *economic rationale* for copyright law is based on two related concepts, → “public goods,” and “economies of scale.” A public good is an economic term referring to situations where a resource can be consumed without depleting the resource and it is difficult to exclude individuals who don't pay for the use. For example, an unlimited number of individuals can sing or listen to a song without “using it up.” Moreover, it is very difficult to exclude non-payers from listening to the song. Few investors would be willing to invest in a product where there is no mechanism for recouping the investment and where it is easy for consumers to use the product or service without paying. Copyright law creates a legal right to exclude nonpayers in hopes of encouraging investment in the production of new expression.

Economies of scale create a similar problem. As communication technology has advanced, the cost to reproduce and distribute expression has declined dramatically. Yet the cost to create the expression in the first place can still be quite high. For example, some movies cost more than US\$200 million to create, but a DVD copy of the movie can be made for less than US\$1. Without copyright protection, a competitor could purchase a DVD and then make and sell copies far more cheaply than the producer who had to spend US\$200 million to make the original film (→ Media Economics).

The economic purpose of copyright is to give the creator an incentive to invest time and money in producing the expression. Copyright creates a market for content and is the legal foundation of modern mass media including the film, music, television, book publishing, computer software, and video game industries. Ultimately, society benefits because more works are produced. However, economists acknowledge that there is a tradeoff in that while more works are created, those works are also more expensive than they would be without copyright, which limits society's access. In recent years, alternatives to the market-based copyright system have been introduced. Open source software is written by individuals contributing to a project without claiming copyright (→ Open Source). Nonprofit organizations like *Creative Commons* have established copyright licenses and websites to encourage creators to share their expression with very few restrictions, creating a regime for individuals to share their content freely.

In addition to the economic rationale for copyright, many nations' laws are influenced by the *concept of moral rights*. From this perspective, the author's expression is an extension of her personality and therefore personal to her. Moreover, the author invests time and labor in creating the expression. Many argue that the author therefore has a natural right to control how her expression is used. So while the economic rationale for copyright is based on a public policy objective of encouraging creation for the benefit of society, the moral rationale is based on the author's private right to control her expression (→ Ethics of Media Content).

Moral rights include the right of paternity (attribution) and integrity (the right to prevent mutilation or distortion of the work that would harm the author's reputation). Moral rights are incorporated into the Berne Convention for the Protection of Literary and Artistic Works but nations can use other “equivalent” rights to comply with the moral rights provisions. For example, the United States does not include moral rights in its copyright statute (except for works of fine art).

## INTERNATIONAL COPYRIGHT TREATIES

Each nation has its own copyright law which is enforced within its borders. Most nations are signatories to one or more international treaties that set out minimum standards of copyright protection for domestic and foreign works. The most important of these treaties is the *Berne Convention*, first established in 1886 and amended six times since then. Before the Berne Convention, most nations did not grant copyright protection to foreign works or foreign authors unless agreed to by a bilateral treaty.

The Berne Convention is founded on three fundamental principles. First is the principle of national treatment: foreign works should be granted the same protection as domestic works. Second, there should be no formal requirements before obtaining protection; that is, the work should be protected from the moment it is created. Third, an eligible work should be protected even if it is not protected in its country of origin. As an indication of the increasing importance of copyrighted works in international trade, the number of countries that belong to Berne Convention has grown from 58 in 1970 to 162 in 2006.

In addition to the Berne Convention, the other major copyright treaties include the *Agreement on Trade-Related Aspects of Intellectual Property Rights* (TRIPS Agreement) and the World Intellectual Property Organization's (WIPO) *Copyright Treaty and Performances and Phonograms Treaty*. The TRIPS Agreement was negotiated along with the establishment of the World Trade Organization (WTO). Under TRIPS, all WTO member states must adhere to the three basic principles of the Berne Convention even if they are not members of that convention. TRIPS was also significant for adopting WTO enforcement measures which are seen as having much more force than the enforcement measures included in the Berne Convention. The two WIPO copyright treaties were created in 1996 in response to the proliferation of digital communication technologies.

## COPYRIGHT, FREE SPEECH, AND NEW TECHNOLOGIES

Copyright gives the creator the ability to control how her expression is used and can reduce the public's access to information and limit free speech. The primary safeguard against the restrictive nature of copyright is the idea/expression dichotomy. Copyright only protects expression – everyone is free to use the ideas, facts, and discoveries that are being expressed. However, many commentators argue there are situations where copying someone's expression serves important free speech interests. Quotes are often useful as evidence, such as quoting sources in a newspaper article or research paper. There may also be times when the expression is so intertwined with the idea being expressed that it cannot be separated. For example, photographs often capture the essence of an idea in a way words cannot match, such as pictures from wars or natural disasters. Most nations include myriad exceptions and limitations to the copyright owner's control over her expression. The United States has one of the broadest exceptions, known as "fair use," which allows limited copying for the purpose of news reporting, research, comment and criticism, and other uses.

Copyright law has changed dramatically as *new technologies* are invented to create, store, and distribute copyrighted expression (→ Information and Communication Technology, Development of). Expression contained in a digital file can be copied endlessly and

effortlessly, increasing the disparity between the cost to create content and the cost to copy and distribute that content. This extreme form of economies of scale makes it even more difficult for the creator to recoup her costs without some form of legal protection. The proliferation of consumer recording equipment makes it almost impossible for the copyright owner to prevent infringing copies from being made. The Internet makes this problem even greater. Once a copy is made available online, millions of users can copy the content and distribute it globally. One example of this phenomenon was the proliferation of peer-to-peer (P2P) software between 1999 and 2005. *Napster* became synonymous with illegal file sharing and billions of infringing copies of MP3 music files have been made and distributed using P2P software (→ P2P Networking).

To reduce the economic losses associated with piracy, the content industries have lobbied for stricter domestic and international laws that increase the penalties for infringement. Moreover, copyright owners have begun to use technological protection measures (TPMs) to prevent users from copying and distributing content without authorization. TPMs are controversial because they prohibit all copying even though most copyright statutes allow some copying in certain circumstances. In addition, TPMs may continue to prohibit access or copying even after the copyright has expired and the expression has fallen into the public domain. The WIPO treaties mandate that each member country pass legal protection for TPMs to prevent users from circumventing the protection measures. The increasing use of TPMs to control access to content has reawakened concerns about the tension between copyright and free speech. But copyright owners argue that without TPMs it will become more and more difficult to enforce their rights. How TPMs are implemented and regulated is one of the most contentious issues facing regulators (→ Internet Law and Regulation).

New technologies such as satellite broadcasting (→ Satellite Television) and the → Internet also have led to more content crossing national borders. This has increased the trend toward harmonization of domestic laws. Copyright owners fear that if copying is legal in one jurisdiction, users all over the world will be able to access that content via the Internet. Some commentators argue that each nation should be free to forge its own copyright law in response to its own domestic information policy objectives. Developing nations in particular often argue that they need increased access to content to stimulate their own domestic economies. It is clear that this conflict over harmonization, like the tension over technological protection measures, will increase for the foreseeable future.

## Copy Test and Starch Test

*Rüdiger Schulz*

*Allensbach Institute*

The term “copy test” refers to a group of different test methods designed to measure the usage of adverts or editorials in the print media. During the course of an interview, readers who state that they have read the test issue of a → magazine or → newspaper are shown an original copy of the issue in question. The interviewer then goes through this copy with the respondent page by page, asking questions about all, or certain, selected adverts or editorials to establish whether each one was “read in full,” “only glanced at” or “paid no attention at all” (→ Readership Research; Test Theory).

Although such tests are conducted as close to the actual reading event as can be arranged, normally within a time span of just one or two days, it is still impossible to completely avoid memory distortions. Tests that employ technical equipment, for example eye cameras, to monitor respondents' field of vision while reading have shown that readers forget about some of the pieces that they in fact read (“underclaiming”). Other pieces are cited by readers even though they actually had no eye contact with them (“overclaiming”). In this respect, copy test findings often reflect respondents' interests and habits. For example, readers who usually always read the lead article but are not sure in the case of the test article, are likely to say that they read it even though they cannot clearly remember actually having read that particular one. Although copy tests use a clear investigative approach and solid memory aids, giving the outward impression that findings must correct, it is evident that there are still limits on the → validity of the information they can provide.

One of the most commonly used copy tests is the so-called *Starch Test*, which was developed by American media researcher Daniel Starch in 1931 and is still in use in

America and around the world today as a standardized procedure for investigating ad noting and advertising effects. In line with copy tests in general, the Starch Test is a recognition test based on the ability of readers to remember advertisements presented to them in their original context in actual issues of publications (newspapers, magazines). Respondents who identify themselves as readers of a particular magazine or newspaper are posed the following three questions to establish the Starch categories:

- 1 *Noted score*: Question: “Have you seen or read any part of this item?” (percentage share of readers who noted this advertisement).
- 2 *Associated score*: Question: “Have you seen or read sufficient of this advertisement to know what it was advertising?” (percentage share of readers who say that they have noted this ad (ad noters) and are able to recall the product advertised, the advertiser, or the brand).
- 3 *Read most score*: Question: “Have you read more than half of the words, or less than half of the words?” (percentage share of readers who say they have read at least half). In addition, it is possible to expand on these three standard measures by ascertaining two further parameters:
- 4 *Involvement score*: Question: “How involved do you feel with the ad?” (responses “involved” or “very involved” contribute to the score).
- 5 *Persuasion score*: Question: “How likely are you to try the brand?” (responses “likely” and “very likely” contribute to the score).

Responses are accepted on face value without any form of verification. Doubts thus exist as to whether all readers are equally able to provide sufficiently reliable responses considering the substantial demands the test places on their memories (→ Reliability). During the course of a typical advertising campaign, an ad is often run either in one advertising medium consecutively or in several different media simultaneously (e.g., several different magazines), meaning that it is often not possible for respondents to recall with certainty whether they saw the advert in question in the test issue or actually in an earlier issue or in a different advertising medium altogether (multiple exposure, overlap). For this reason, the Starch Test has its limitations when it comes to drawing conclusions about the performance of one particular advertising medium (→ Advertising Effectiveness, Measurement of).

In contrast, the Starch Test can clearly say a great deal about the quality of an advertisement itself. For example, investigations by Wells came to the conclusion that a Starch “noted score” in fact measures “whether, in the consumer’s judgment, the ad is worth at least a passing glance” (Wells 1964) and, according to Krugman (1985), what the Starch scores primarily convey is an advertisement’s “attention-getting quality.” Despite Starch scores being widely used by advertisers, for example also to optimize advertisement copy and form, there remains skepticism concerning the meaning of Starch data. Based on the findings of their own validity tests, Zinkhan and Gelb (1986) come to the conclusion that “however justified the qualms are about Starch scores as valid recognition measures, they are not useless numbers. They may only point out “ads the respondents believe they would have noticed”; but even if so, they predict, at least modestly, responses in which advertisers have a far greater stake.

## **Corporate Communication**

*Joep P. Cornelissen*

*University of Leeds*

Perhaps the best way to define corporate communication is to look at the way in which the function developed in companies. Until the 1980s, professionals responsible for communication within their organizations had used the term → “public relations” to describe communication with stakeholders (a term still used in academic circles across the world). This public relations (PR) function, which was tactical in most companies, largely consisted of communication to the press. When other stakeholders, internal and external to the company, started to demand more information from the company, communication professionals within organizations subsequently started to look at communication as being more than just PR. The roots of the new corporate communication function started to take hold. This new function came to incorporate a whole range of specialized disciplines including → corporate design (→ Design), corporate → advertising, employee or internal communication, issues and crisis management (→ Issue Management; Crisis Communication), → media relations, investor relations, change communication, and → public affairs. An important characteristic of the new function was that it consolidated a range of communication disciplines and expertise into a single corporate communication or corporate affairs department. This department has a single mandate that is focused on the organization as a whole and on the important task of how an organization is presented to all its key stakeholders, both internal and external (→ Stakeholder Theory).

This broad focus is also reflected in the word “corporate” in corporate communication. The word of course refers to the business setting in which corporate communication became established as a separate function (alongside other functions such as human

resources and finance). There is also an important second sense with which the word is being used. “Corporate” originally stems from the Latin expressions for “body” (*corpus*) and for “forming into a body” (*corporare*), which emphasizes a unified way of looking at internal and external communication disciplines. That is, instead of looking at specialized disciplines or stakeholder groups separately, the corporate communication function starts from the perspective of the “bodily” organization as a whole when communicating to all internal and external stakeholders (Christensen et al. 2008).

Within corporate communication, a stakeholder is defined as any group or individual who can affect or is affected by the achievement of the organization’s purpose and objectives (Freeman 1984). In this broad definition, a stakeholder can be anyone who (1) has direct or indirect ownership of an organization (e.g., owners or important creditors), (2) has an economic bond as a worker or consumer in relation to the organization (e.g., employees and customers), or (3) has a legitimate moral interest in its operations (e.g., the local community in which an organization is located). Van Riel (1995) has argued that organizations communicate and interact with a whole range of stakeholders beyond publics (e.g., activist groups) who actively mobilize themselves against an organization on the basis of an issue of concern to them (→ Organization–Public Relationships).

Edward Freeman, one of the intellectual leaders of stakeholder theory, suggested back in 1984 that “the stakeholder approach requires a redefinition of the public relations function which builds on the communications skills of PR professionals, yet is responsive to the real business environment of today” (1984, 219). He argued that “in the current business environment the concepts and tools that have evolved for PR managers to use are increasingly ineffective” (1984, 220) by which he meant that traditional concepts and tools such as press releases, annual reports, and corporate publications would not be sufficient to manage the organization’s relationships with key stakeholders. Freeman also felt that the term “public relations” is associated with “spin doctoring” and “window dressing” (→ Spin and Double-Speak; Spin Doctor). Instead, he argued for a new concept that would embody a more managerial understanding of communication; one that would help communication professionals manage the organization’s communication with stakeholders (→ Communication Management).

## DEFINITION

The definition of corporate communication and the conceptual terrain that it covers has evolved as a result of its incorporation into management degrees at business schools. Whereas communication courses had traditionally been part of undergraduate and postgraduate degrees in schools of communication and journalism (→ Communication as a Field and Discipline), the business equivalent of the subject was refashioned in terms of management theory and education. This development echoed the sentiments expressed above about the need for a redefinition of communication as a management function. Argenti (1996, 74), one of the first professors in corporate communication at a US business school, puts it this way:

business schools are the most appropriate home for the discipline, because like other functional areas within the corporation (such as marketing, finance, production, and human

resource management), corporate communication exists as a real and important part of most organizations. As such, it should rightfully be housed in that branch of the academy that deals with business administration or graduate schools of business.

Shelby (1993, 255) defined corporate communication as “an umbrella for a variety of communication forms and formats” that “includes public relations (speech writing, press/community relations), public affairs (including lobbying activities), and employee, customer, and stockholder communication.” All of these forms of communication in Shelby’s view share a focus on communicating about the organization to “collectivities [i.e. stakeholders] that exist inside and outside organizations” (1993, 255). Van Riel (1995) added to Shelby’s early definition the idea that all these forms of communication need to be actively managed and coordinated to present a consistent image of the organization to all stakeholders. He defined corporate communication as “an instrument of management by means of which all consciously used forms of internal and external communication are harmonized as effectively and efficiently as possible,” with the overall objective of creating “a favorable basis for relationships with groups upon which the company is dependent” (1995, 26).

The original definitions by Shelby and Van Riel characterize corporate communication as a management function within organizations that involves communication professionals engaging in different forms of communication (e.g., public affairs, media relations) with internal and external stakeholders. In line with these early definitions, Van Riel (1997) stressed the importance of “orchestration” of all forms of communication. “Orchestration” refers to the coordination or integration of all forms of communication so that its contents convey the same corporate image or “corporate identity” of the organization and leave a consistent impression or “reputation” with stakeholders (→ Corporate and Organizational Identity; Organizational Image; Corporate Reputation; Image). Much theory-building and research has since focused on these concepts of “corporate identity” and “corporate reputation” and has argued that an organization conveys an image not only through forms of communication, but also through its products and services, the quality of its management, the behavior of its employees, its financial performance, and the economic and material support that it provides to different stakeholder groups. This has led some to define corporate communication in very broad terms as “everything a company says, makes, or does,” which emphasizes the fact that not only forms of communication “communicate”, that is, leave an impression with stakeholders, but also behaviors of managers and employees (Cornelissen & Harris 2001).

## **THEORETICAL CONCEPTS**

To describe the scope, processes, and objectives of corporate communication, researchers have developed a number of concepts. These concepts reflect developments in professional practice and draw upon ideas from management theory and education (Argenti 1996; Van Riel 1997).

The original set of concepts that were introduced to describe the field of corporate communication involved corporate identity, corporate image, and corporate reputation. The concept of corporate identity grew out of a preoccupation in the design and

communication communities with the ways in which organizations present themselves to external audiences; for example, in their visual images as well as through more elaborate forms of corporate advertising and communication. Initially, the term was restricted to logos and other elements of visual design, but it gradually came to encompass communication and all forms of outward-facing behavior in the marketplace (e.g., Birkigt & Stadler 1986). Larçon and Reitter (1979) added a further dimension to the concept of corporate identity when they argued that it not only involves the visible outward presentation of a company, but also the set of intrinsic characteristics or traits that bestow the company with its specificity, stability, and coherence. In their view, a corporate identity is not merely a projected image in the form of visual design and communication, but is fundamentally concerned with “what the organisation is” – the core of the organization as it is laid down in its strategies and culture. The notion of corporate identity traits resembles the conceptualization of organizational identity as involving identity anchors that are central (inimitable organizational traits), distinctive (differentiated from other organizations), and enduring (stable over time). These traits specify the general meaning of a corporate entity that resides in the values, beliefs, roles, and behaviour of its members as well as in the shared symbols and other artifacts that they create, in particular, through conscious acts of corporate → branding (Hatch & Schultz 2001). Accordingly, empirical research on corporate identity has explored links between a corporate identity, as the projected image of the organization, and both its underlying organizational identity or culture (e.g., Ravasi & Schultz 2006) and its received image or reputation in the eyes of stakeholders such as employees, customers, and consumers (e.g., Simoes et al. 2005).

In relation to these links, researchers emphasize that it is strategically important for organizations to achieve “alignment” or “transparency” (e.g., Fombrun & Rindova 2000; Hatch & Schultz 2001). According to Fombrun and Rindova (2000, 94), transparency is “a state in which the internal identity of the firm reflects positively the expectations of key stakeholders and the beliefs of these stakeholders about the firm reflect accurately the internally held identity.” Along these lines, researchers stress the particular importance of consonance between (1) the organizational culture as articulated by senior managers and as experienced by employees, (2) corporate identity (i.e., the image projected by the organization), (3) corporate image (i.e., the immediate impression of an organization in relation to a specific message or image), and (4) corporate reputation (i.e., an individual’s collective representation of past images of an organization, induced through either communication or past experiences). Importantly too, where these elements are nonaligned (so that, for example, the rhetoric of corporate identity does not match the experienced reality), a range of sub-optimal outcomes are anticipated, including employee disengagement, customer dissatisfaction, and general organizational atrophy (e.g., Hatch & Schultz 2001).

Organizations can achieve such alignment, it is argued, through consciously coordinating (“integrating”) the timing and content of messages that are communicated to stakeholders. Back in 1994, Robert Heath formulated this challenge as follows:

Some companies and other organizations are well known for their ability to conduct a truly integrated communication campaign designed to get the message across even though it is tailored to various stakeholders. Not only is the matter one of providing a coherent and

consistent message that fosters an understanding of the company as its management and employees want it to be understood, but it also means that key audiences are addressed in terms of the stake each of them holds with regard to the organization. (1994, 55)

Such integration is also seen as important when one considers the multiple stakeholder roles that any one individual may have, and the potential pitfalls that may occur when conflicting messages are sent out. The concept of “integration” has been described in terms of (1) consistency in messages that are produced and communicated to stakeholders, and (2) organizational coordination between communication professionals. Consistency in messages (i.e., similarity in content, tone, and visual design) is facilitated through guidelines on design and communication, including a specification of the central corporate identity or corporate brand values of the organization and of the general corporate story that the organization wants to tell (e.g., Fombrun & Van Riel 2004). Organizational coordination between communication professionals is facilitated through mechanisms such as teamworking, job rotation, corporate brand committees, networking events, and a dedicated intranet. These allow communication professionals from different disciplines (e.g., public affairs, marketing communication, media relations, internal communication) and from across the organization to interact and to align their work (e.g., Cornelissen 2008).

## EMPIRICAL RESEARCH

Researchers have applied a variety of methods and empirical indicators to measure the concepts of corporate identity, corporate image, and reputation. Most research has used → survey methods to establish stakeholders’ perceptions and evaluations of organizations (e.g., Fombrun & Van Riel 2004) alongside in-depth → case studies of an organization’s culture and identity (e.g., Ravasi & Schultz 2006). Such case studies are often based on a variety of data sources including → interviews, (participative) → observation, and analyses of company documents (→ Document Analysis) and communication campaigns.

Fombrun and Van Riel (2004) have carried out comparative analyses of corporate reputations of the most visible organizations across the world. Based upon stakeholder evaluations of the strongest corporate reputation within their country, they inferred that organizations with the strongest reputations are on average characterized by high levels of *visibility* (the degree to which corporate themes are visible in all internal and external communication), *distinctiveness* (the degree to which the corporate identity or positioning of the organization is distinctive), *authenticity* (the degree to which an organization communicates values that are embedded in its culture), *transparency* (the degree to which an organization is open and transparent about its behavior), and *consistency* (the degree to which organizations communicate consistent messages in all internal and external communication channels) in corporate communication. This broad picture of linkages between corporate communication, corporate identity, and corporate reputation has been further refined in recent empirical research. Recent research has established that organizations in specific industry sectors may become more similar in the kinds of corporate identity that they project (e.g., Deephouse & Carter 2005; Lamertz et al. 2005) and that such convergence may be more or less appreciated by stakeholders dependent upon their expectations regarding appropriate corporate behavior in a particular industry

(Brammer & Pavelin 2006). Deephouse and Carter (2005) have demonstrated that isomorphism (i.e., the similarity of an organization to others in its industry) improves the degree to which an organization is deemed legitimate (socially acceptable) by stakeholders, presumably because organizations converge on images and behaviors that are expected of them by stakeholders. They also found that organizations with stronger corporate reputations were able to deviate from such mimetic behaviors and improve their status without losing their legitimacy. Lamertz et al. (2005) similarly identified social pressures at the level of an entire organizational field, which stimulated organizations in the Canadian beer-brewing industry to construct similar images (corporate identities) of themselves to meet stakeholder expectations. At the same time they found that alongside such similar images, organizations also claimed distinctive attributes as part of their corporate identity.

The development of corporate communication as a separate function within organizations and its grounding in management theory has led to research being rather disconnected from the PR and mass communication literatures. Recent years, however, have seen the emergence of new lines of research that bridge the two domains. For example, the research by Carroll and Deephouse on the role of the media in the formation of stakeholders' views on the reputation of organizations integrates management theory (i.e., the resource-based view of organizations) with mass communication theory (i.e., agenda-setting theory; e.g., Deephouse 2000; Carroll 2004; → Agenda-Setting Effects; Public Relations: Media Influence). Similarly, Cornelissen (2008) has connected management literature on → sense-making, professional identity, and career transitions with existing ideas from PR on “technician” and “manager” roles of communication professionals (→ Public Relations Roles; Professionalization of Public Relations).

## Corporate Design

*Birgit H. Jevnaker*

*Norwegian School of Management*

Corporate design is an umbrella term for all of a company's design-oriented approaches to creating and projecting products/services, messages, brands, and other business or cultural propositions to external or internal audiences. Corporate design points to a potentially value creating, integrating business function. It deals with many design matters, embracing much more than the company logo (→ Corporate Communication).

It may encompass work spanning everything from company letterheads to orchestrations of the company's core offerings, identities, and → brands, transactional and presentational places, and communicative messages (Olins 1989). Corporate design thus includes functional, use-oriented, and symbolic concerns related also to system architectures, production platforms, buildings, interiors, websites, and other business interaction spaces, which

typically need to be thought about in systematic ways. Corporate design can become a nexus for design/business-inspired creative action that may reinvent, help organize, and express future offerings or otherwise serve a customer's experience. In advanced or large corporations, it may include managing a mixture of digital, artistic, technical, and visual-expressive means, which often calls for specialist resources and partner relationships.

### SENSITIZING CONCEPTS

In doing its multilevel activities, corporate design is concerned with the conception and expression of a *gestaltung* that can help create, synthesize, and communicate whatever the business enterprise offers – currently or as an opportunity. Also, exemplary corporate design leaders and allied designer consultants have taken an interest in cultivating the company's heritage while engaging in renewal and innovating (e.g., Peter Behrens at AEG, and Knut Yran, Robert Blaich, and Stefano Marzano at Philips; Sparke 1986; Marzano 2005).

Although corporate design often taps some personalized, blurred mixtures of cross-disciplinary backgrounds, it is fruitful to know about the rich variety of design specialties. Expertise involves a multifaceted designerly knowing. One traditional way of *categorizing design* is by discipline. Multiple design disciplines exist, such as graphic design, fashion design, product design, transportation design, textiles design, furniture design, interior architecture, information design, design engineering, etc. New, composite specialist fields have emerged, e.g., industrial design and interaction design, while application domains for these specialists have become more focused; e.g., sports design, retail design, web design, maritime design, and medical design. Thus, corporate design functions may find it rewarding to connect to specialists and form multidisciplinary teams to leverage concept development and design innovation efforts. Hybrid business-related areas are also attended to, such as strategic design, design management, service design, and even experience design. Although traditional boundaries seem to break down, hundreds of sub-fields and angles are identified from a broad point of view on design.

Not surprisingly, it is not so clear how to distinguish the particular design-intensive innovation efforts or actions by relatively young disciplines, like industrial design and interaction design, that are clearly interdisciplinary (covering more than one area of study) or even transdisciplinary, i.e., moving in areas across and beyond established disciplines.

When corporate design departments organize user-centered research or wish to initiate new online or offline conversations, both scanning widely and further exploration with frequent design reviews and quality-oriented screening can be of interest. In doing a range of temporal projects, corporate design managers often strive to become focused, rewarding, and meaningful for others, and realize new designs within tight schedules. Working in between divisional managers and not yet fully recognized concerns is an ongoing challenge (Blaich & Blaich 1993; Marzano 2005). Corporate design typically deals with a variety of solutions as well as with ill-defined or awkward problems in the social realm (Krippendorff 2006, 27), which cannot be optimized in simple ways but must be engaged with by participating stakeholders.

These diverse viewpoints make corporate design work complex. Learning from the market needs to be understood beyond traditional marketing practices, and includes

tapping into latent problems or overlooked desires (→ Integrated Marketing Communications; Marketing; Marketing: Communication Tools). Another design tool is through the “gift of iteration” (Shaughnessy 2005, 144). *Iteration* involves exploiting the feedback loops from critical scanning, using, or testing of new designs. Relationship perspectives together with the multi-skilled interactive design views may help understand the intricacies of setting up and facilitating plug-in, screening, and editing of digital conversations, which unfold in social media on the → Internet with increasing speed of interaction, though the few seem to entice the many in this beta land. The challenge for corporate design work is not merely to signify the corporate offerings but to help bring together new interactions affecting users’ experiences in more genuine ways.

The term *design* has many meanings; no agreement exists as to what design covers. Both designers and managers may find it difficult to move beyond jargon or the everyday language of likes and dislikes. This is related to how design involves a multiplicity of aspects and also talks to our feelings, e.g., the “emotional design” of a car. Being both a verb and a noun (Rand 1993), design refers to *processes* and *outcomes*, encompassing technicalities of what is “below the line” or invisible for the consumer (Dormer 1990, 15), as well as symbolic meanings depending on the situation or context to be read fruitfully.

It is fascinating but complex to create something distinct and original, and complex to make what seems “brilliantly simple” in retrospect. A sensitizing concept is *multimodality* – combining different methods of communication – because multiple media are often explored by corporate design to invoke the customers’ experiences.

## WHERE TO DRAW THE LINES

Although corporate design can be described in a number of relevant ways, managers may still perceive only a fraction of it (e.g., color choice). Three points can be made. These are related to (1) corporate design’s organizing potentiality to take advantage of the cross-over nature of both design and business enterprise, (2) the enabling of design-inspired arenas fostering new connections, projections, and conversations, and (3) the expressive creation of something to flock around or enjoy, something both tangible and intangible.

First, corporate design works in *cross-organizational areas*, and may include products, services, corporate websites, and → e-commerce. In most organizations, the multimodal areas tend not to exist as neatly organized domains. Rather, they have to be enacted and mobilized so as to become relevant and interesting for business unit leaders and project groups (Blaich & Blaich 1993).

Second, corporate design engages not only with a branch of organization areas but with and beyond their respective close *networking areas* (e.g., suppliers to production, dealers to marketing and sales). A wider scanning and connecting is related to how experienced designers and other specialists working for corporate design can bring in entirely new perspectives, ideas, and technologies from other industries or life-spheres (Kelley 2001) and from sustaining their own experimental work, which can become strategic.

Third, corporate design may work toward a *distinct expression and sense-making of the business* as well as broader human enterprise. Creative endeavors can lead to extraordinary performances or an aesthetic “schwung.”

## LAGGING OR LEADING DESIGN

Although sparsely researched, reflective practitioners, scholars, and other observers have provided insight into the uneven development of good design and abilities to manage design in business organizations (e.g., Lorenz 1990; Gorb 1990). If well done, corporate design work may lead to increasing returns. Design work can also have external effects – positive or negative “externalities” – for other design teams. Creative design teams may reconfigure quickly to take advantage of new opportunities or otherwise leapfrogging. Corporate design work may seek to protect accumulated values and build on previous steps taken, but traditional ways of corporate design regulation may become reduced in a connectionist society. Employees tend to work in shifting, temporal projects and engage in their own power points and other media. Design management research suggests that design decisions are often made by others than profession-based designers. “Silent design” denotes design-related work by managers or corporate staff, often not thinking of it as design (Dumas 1993).

Whether properly managed or not, corporate design tends to shift over time, space, and situation. What are the most important issues of corporate design depends on the actual business or mission (Olins 1989), as well as the emergent engagements.

## COLLABORATION IN DESIGN

Corporate design work can be decentralized, outsourced, or run by mixed approaches, but it can also be neglected as a corporate function (Sparke 1986; Blaich & Blaich 1993). Even in companies that primarily use in-house resources, a new trend of external design-oriented cooperation has been registered, e.g., in Japanese corporations (Masuda 1996). Insights into companies’ design collaborations have helped to recognize how corporate design can become expanded through advanced prototyping, new user research, cultural trend work, co-created collections, or other collaborative approaches (Marzano 2005). Research suggests that particular designer/business collaborations may enable the creation and strategizing of current or future products and services, especially if retained as “design alliances” over some time, yet the personalized relations may also remain somewhat fragile (Bruce & Jevnaker 1998).

Design consultants working with managers of other companies appear to connect and mediate in ways that may provide new insight into the focus on more complex co-creative relationships between business and users. Working with particular talents and multi-disciplinary teams, and accumulating deeper experiences by collaborating intensely in the short term as well as over time, may lead to increasing economic returns (cf. learning from past failures, virtuous circles of good design work, and cumulative reputation effects). Whereas working with new specialists may lead to fresh thinking and “seen design” or differentiated approaches, it can also lead to bypassing of internal competencies and disruptive efforts (Dumas 1993). The processes and outcomes of design-oriented collaboration thus seem to differ significantly (Jevnaker & Bruce 1999). Also, a design team designing recurrently for and with a business enterprise with shifting customers in several regions needs to think in different ways from an architect who may design something for one customer in one place.

## **Corporate and Organizational Identity**

*Lars Thøger Christensen*

*University of Southern Denmark*

Identity is one of the most prominent issues of contemporary organizations. Like individuals, organizations increasingly talk about “having” identities, seeking identities, expressing identities, and even changing identities. And the emphasis on identity is not idle talk. Having become an arena of managerial attention and concern, identity-related activities consume a growing amount of organizational resources and involve a wide variety of disciplines and practices across the organizational spectrum.

In spite of this development, the question of what identity means in the context of an organization is far from settled. It is commonplace to think of corporate or organizational

identity as an answer to the question: who are we as an organization? Yet, this question immediately raises additional questions: who poses and answers this question? What purposes does the answer serve? Does an organization only have one identity? And (how) do organizational identities change over time? These questions and a number of conceptual issues occupy a remarkable place in the literature and indicate that corporate or organizational identity has become a highly contested terrain (→ Organizational Communication; Corporate Communication).

### **CONCEPTUAL ISSUES**

Our everyday language is often equivocal when we talk about identity. On the one hand, we use the notion of identity to describe the special or unique features that characterize a social entity and set it apart from its surroundings. In this sense, we think of identity as something solid, reliable, and continuous, in other words, something deeply rooted in the “personality” of the social entity. On the other hand, we frequently talk about shaping and changing identities, leaving the impression that identity is an ongoing project that can and should be planned, manufactured, and communicated into existence.

This equivocality is reflected in the managerial literature where descriptions of organizational identity as essence and continuity coexist with discussions of identity as projects of communication. With their now classical definition of organizational identity as the “central, distinct, and enduring dimensions of an organization,” management scholars Stuart Albert and David Whetten represent the former perspective. More specifically, Albert and Whetten refer to organizational identity as the inviolable core of an organization that shapes its choices and defines its integrity (Whetten 2006). By contrast, management scholars Blake Ashforth and Fred Mael regard organizational identity as more fluid and malleable. In line with the work of philosopher Friedrich Nietzsche, who conceived of identities as ongoing stories, Ashforth and Mael define organizational identity as “unfolding and stylized narratives about the ‘soul’ or essence of the organization” (Ashforth & Mael 1996, 21). From this perspective, organizations enact their identities through the stories they, directly or indirectly, tell about themselves, their past, their ambitions, and their perceptions of the environment.

In the hope of circumscribing conceptual confusion, some writings try to establish a clear distinction between “corporate identity” and “organizational identity,” reducing the former to the sum of symbols that organizations seek to manipulate in order to shape their identity (e.g., logos, uniforms, → design, → advertisements, stories, etc.), and reserving the latter for the “deeper” layers of identity, that is, the organization’s “intrinsic” traits or characteristics. From a communication perspective, however, such a definitional solution is problematic for several reasons. First, because it implies a clear division line between the world of communication and the world of reality “behind,” excluding the possibility that corporate symbols and messages are significant forces in the transformation of organizational identities. Second, because it suggests that some observers have a privileged access to a deeper layer of identity – a layer untouched by corporate communications and other symbolic representations. When, for example, a scholar or a consultant of organizational identity points out that some corporate symbols (logos, architecture, advertisements, etc.) do not match the true character of an organization,

they claim to have access to a world behind those symbols, a world behind appearances or beyond representations. From a semiotic perspective, Christensen and Askegaard (2001) point out that our access to organizations is always mediated by representations, some of which are more carefully designed and managed than others. Following this line of thought we can define corporate or organizational identity as *the way an organization is commonly represented*.

Because different audiences refer to different representations (products, logos, stories, behaviors, reputations, etc.) when they describe an organization, it is evident that the identity of an organization is not a given feature, but a reference point or a theme that we activate whenever we try to express what we believe an organization “is.” Obviously, some versions of this theme are more powerful than others – at least in the short run – backed up, for example, by corporate advertising campaigns or managerial decisions. Still, such official readings of organizational identity are frequently challenged by alternative interpretations provided, for example, by inquisitive journalists (→ Investigative Reporting) or critical interest groups who claim that their description of the organization is more true or realistic than the official version.

Such conceptual complexity characterizes also the related notion of *corporate or organizational* → *image* (→ Organizational Image; Corporate Reputation). While some writings seek to reserve “identity” for the sender side and “image” for the receiver side of the communication process, the picture becomes fuzzier when we acknowledge, along with social psychologists, that identities are shaped through the perceptions of significant others. In an often-cited study of the Port Authority of New York and New Jersey, management scholars Jane Dutton and Janet Dukerich (1991) illustrated how the issue of identity is entwined with the ways organizations define, diagnose, and respond to problems in their surroundings. In their study of the organization’s reaction to homelessness in the 1980s, Dutton and Dukerich found that the organization’s self-perception at the time was affected by how organizational members thought outsiders viewed their organization. Corporate images and reputations, in other words, play significant roles when organizations develop and articulate their identities, just as their identities unavoidably influence the images they discover in their surroundings (e.g., Cheney 1992; → Social Identity Theory).

## THE SOCIAL-HISTORICAL CONTEXT

The explicit preoccupation with identity, which we find intensified in contemporary western societies, is historically speaking a fairly recent phenomenon. In tribal or so-called “traditional” societies, identity is not an issue that is constantly discussed, enacted, and negotiated. As social theorists have pointed out, a person’s identity was given by the local community based on, for example, the lineage and the status of their family, the authority of the sovereign and the church, and other social institutions. Identity, in other words, was relatively fixed, ascribed by traditions and practices beyond the influence of the individual person.

In modern society, by contrast, identity is an ongoing issue, pursued and contested at many different levels. The rise of modernity implied a questioning of traditional practices and authorities that gradually eroded the institutions through which people previously

had defined their roles and positions in society. Without stable markers of orientation, the modern individual is constantly in search of answers to the question of who they are and who they want to be. While modern institutions like the nation-state, democracy, economics, rationality, and bureaucracy provide some points of guidance, the question of identity is an ongoing concern for the individual. This is especially the case in today's late-modern or postmodern society, where these institutions are frequently challenged.

Increasingly, individuals define and shape their *identities through practices of consumption*. Their choices of clothing, electronics, food, health-care, music, housing, etc. have become important dimensions of their extended selves. With their provision of products, messages and stories, organizations (workplaces, sports clubs, interest groups, etc.) play an important role in this project of identity. In fact, the organization may be one of the most important sources of identity for the modern individual. Accordingly, the pressure on organizations to stand out and supply its members, customers, and other stakeholders with clear signs of community and belongingness is more pronounced today than ever before.

This, however, is a precarious role. At the same time as contemporary organizations find their boundaries blurred by globalization (→ Globalization Theories), mergers, new information technologies (→ Information and Communication Technology, Development of), inquisitive stakeholders, and new types of organizational arrangements, they are expected to articulate clearly and unambiguously who they are and how they define their role in society. Simultaneously, organizations face the challenge of being heard in a communication environment saturated with corporate messages crying for attention and interest. Yet, since the communication "explosion" has only intensified their urge to stand out in this environment, identity management has become an organizational imperative in almost all sectors of society (Cheney & Christensen 2001a).

## MANAGING IDENTITIES

The management of corporate or organizational identity is defined especially by the fields of design management, marketing, and public relations, although insight from human resources management and corporate culture plays a role too (e.g., Cheney & Christensen 2001b). The objective of these disciplines is to manage → *corporate design* (logos, uniforms, architecture, etc.) *corporate communications* (commercials, manuals, publications, etc.) and *corporate behavior* (corporate values, norms, attitudes, customer contacts, etc.) in order for the organization to build a single, unified, and consistent identity.

The notion of *integrated (marketing) communications* refers to the ambition of aligning everything the organization says and does (its symbols, messages, procedures, and behaviors) so as to help the organization communicate with clarity, consistency, and continuity across different media and different audiences. Without such consistency, it is argued, contemporary organizations will have difficulty in sustaining visible, credible, and legitimate identities in a world of growing complexity. The integrative efforts are often centered on the identity of a strong → brand, for example Levi's, McDonald's, or Coca-Cola. In recent years, the notion of "corporate branding," defined as the systematic effort to develop and present the organization as one unified brand, has gained momentum as a response to the notion that consumers increasingly "buy" the organization behind its products (Balmer & Greyser 2003; → Communication Management).

In the effort to streamline all symbols, messages, and behaviors, the communicative roles of organizational members attract growing managerial attention. While organizations have been significant sources of individual identity throughout modernity, identification has today become a far more explicit managerial strategy. Organizational identification refers to situations where people define themselves in terms of an organization, including its products, its missions, its slogans, and its values. When organizational members identify with their workplace, they internalize its customary ways of doing things and eventually develop a feeling of oneness with the organization. In the hope of stimulating such behaviors and feelings, contemporary organizations launch a wealth of employee programs designed to manage the hopes, fears, and aspirations of their members. Such attempts to foster, regulate and control processes of loyalty and commitment, however, are frequently challenged by employees who fail to see, or reject the notion, that the identity defined by management is inclusive enough to embrace the differences among organizational members (Alvesson & Willmott 2002). Such resistance calls attention to the problems of managing multiple selves under the umbrella of a single, unified organizational identity.

In a world where many corporate and organizational identities call for attention, there is a real danger that such constructions are ignored, disapproved of, or resisted. Under such circumstances, organizational projects of identity may have a tendency to develop a world of their own, where corporate symbols and messages become autonomized signifiers without reference to anything else but themselves. Although identity is fundamentally social, inasmuch as it rests on its reflection and accreditation in its surroundings, we see today a tendency for corporate or organizational identity projects to become rather self-centered undertakings that reduce the ability of organizations to see and respond openly to their surroundings (Christensen & Cheney 2000).

## Corporate Reputation

*Craig E. Carroll*

*University of North Carolina at Chapel Hill*

Corporate (or organizational) reputation refers to what is generally said about an organization. Corporate reputation is different than organizational identity by its focus on what other people say about the organization, rather than what the organization itself or its members say. Corporate reputation is distinguished from → organizational image in the sense that it is generally more durable and substance-based rather than fleeting and impression-based. Generally, there is some story, an activity, or a topic associated with the firm, which is, in effect, regarded as remarkable.

Corporate reputation gains credence because it is believed to be something that is widely held; that is, it is a form of → public opinion. Having a reputation, without specifics to its contents, has social value for an organization. Reputations can be for various things or of being or doing something. There are different kinds of reputations, and more than one reputation can exist. Reputations may exist within networks or be geographically distributed across unrelated groups. A reputation does not necessarily correspond to the truth. Instead, general sufficiency is found in that it is supposed to be true. Once organizational reputation moves from being a general public opinion to being accepted as a social fact, additional information-seeking behavior about the organization's nature, or whether to even become involved with the organization, is reduced (→ Organizational Communication).

Public interest in corporate reputation began in 1983 when *Fortune Magazine* first published its rankings of the “Most Admired Corporations.” The edition was so popular that the magazine turned it into an annual survey. Since then, many other magazines in the US have published their own reputation rankings, including *Wall Street Journal*, the *Financial Times*, and *Business Week*. Reputation rankings have become popular worldwide. Similar reputation assessments are made and published by NGOs, social monitoring organizations, and other third parties issuing their own assessments of reputation. Besides the promotion and proliferation of reputation studies through the news media, reputation affords an opportunity for advocacy groups to exert pressure on companies.

There are three general *components of corporate reputation*: name recognition, sentiment, and attributes and associations. Before a firm can be said to have a reputation, people must be familiar with the company's name. This raises the question of whether all firms even have or desire a reputation. Some firms do not; rather, they prefer to be anonymous and under the radar. This allows firms to stay out of the public's eye. Other firms, typically business-to-consumer (B2C) firms, are well known for being well known. The second component is sentiment or emotional appeal. This is largely the degree of favor that the firm has, whether positive, negative, neutral, or mixed. Then finally, firms usually have a reputation for something, but not always. The most common attributes in corporate reputation research are executive leadership, workplace culture, and environmental and social responsibility (→ Leadership in Organizations; Organizational Culture; Organizational Ethics). Attributes that are receiving increasing attention are innovation, litigation, legislation, corporate governance, and ethics. An emerging area of scholarship concerns associations (distinct from issues or attributes). Firms may develop reputations by being linked to larger social or public issues, their involvement with other organizations (in the same industry or not), and their affiliation with individuals of particular repute (such as their CEO), or other firms in the same market or industry. For example, firms that operate in larger markets or industries are more likely to gain recognition faster because there are other players in the same field.

A central question in corporate reputation scholarship is whether it can be managed or whether one should try. Certainly, a focus should be placed on improving the character and nature of the organization, rather than on the reputation. Yet, the general view is that it is easier to adjust the organization's symbolic environment than it is to adjust its behavior. The *can-reputation-be-managed question* is often tied to where the focus should be placed. In theory, the debate is framed in terms of reputation vs organization–public relationships; in practice, advertising vs public relations.

In theories of corporate reputation management, Carroll (2006) noted there have been two general views. One camp, at the University of Maryland, suggests that organization–public relationships leads to corporate reputation, and that firms should be concerned with managing their relationships rather than their reputation. This view focuses primarily on existing stakeholder relationships and how they contribute to reputation, but it does not consider whether or how reputations may affect the quality of the relationship. The other major camp, at the University of Texas, suggests that corporate reputation leads to relationships. That is, individuals who are largely unfamiliar with the organization may base their decision on whether to become associated with the firm based on the firm's reputation. The two camps are not incompatible, but simply reflect a difference in starting points, particularly whether concern is with existing stakeholder relationships, or with the potential for relationships with new or unidentified stakeholders. Both camps agree that the focus should be on reputation-cultivation, rather than on reputation management.

*In practice*, the answer to the management question has largely come through where the focus should be placed – on advertising or public relations. The answer has been mixed. Firms with favorable reputations benefit more from public relations because there is an upper limit to the payoff achieved through → advertising, at which point any more money spent is simply wasted. On the other hand, research has found that firms with poor reputations are better off postponing news releases until there is a considerable change, which is achieved through advertising, including advocacy and issue ads.

The proliferation of corporate reputation research indicates that corporate reputation can be *measured*. The earliest academic study on corporate reputation was Charles Fombrun and Mark Shanley's (1990) study of *Fortune Magazine's* Most Admired Corporations. They used the original survey data, though stripped of information from the respondents. Since this study, most reputation studies using secondary data have had to rely on the top-level published rankings available through the news media. Still others have conducted primary research using personal interviews, media content analysis, survey questionnaires, case studies, Q methodology, scorecards, experiments, and focus groups (→ Case Studies; Content Analysis, Quantitative; Experimental Design; Interview, Standardized). An under-explored methodology waiting to be examined is the quasi-judicial case study method.

Valuation remains a priority across disciplines involved in corporate reputation scholarship, but still remains as an unexplored topic in communication research.

# **Corporate Social Responsibility**

*Jennifer L. Bartlett*

*Queensland University of Technology*

The concept of corporate social responsibility (CSR) comprises stakeholder expectations of the social, ethical, legal, and economic impacts of an organization. These expectations and the perceptions stakeholders have of an organization's corporate social responsibility are central outcomes of business planning, management and operations, → marketing, → advertising, → corporate communication, and → public relations. Organizations seek to be perceived to be meeting their obligations to society, thereby gaining and maintaining a license to operate. Legitimacy is a major driver of corporate social responsibility (Sethi

1979). Increasing their attractiveness to potential and existing employees, investors and investment fund managers, and consumers is another motivation for organizations to adopt CSR principles. As such, CSR forms a central charter for public relations in communicating and creating mutual understanding, managing potential conflicts, and to achieving organizational legitimacy (→ Corporate Reputation; Organizational Image).

CSR is studied from communication, management, legal, ethical, and political perspectives. These various strands of research focus on the ethical and moral rationales for organizations, the institutional pressures from legal, economic, and political imperatives, and the management of perceptions about the alignment of organizational practice with social expectation.

CSR has been described as encompassing “the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point of time” (Carroll 1979, 500). The rationale for corporate social responsibility to society has shifted from the purely economic toward a broader conceptualization of the role of the stakeholder (→ Stakeholder Theory). Whereas the classical notion of an organization’s social responsibilities centered on short-term profit making (Friedman 1970), the emergent alternative view focuses on an organization’s reciprocal relationship with a range of stakeholders in society (Freeman 1984). Hence Sethi’s suggestion (1979, 66) that corporate behavior should be congruent with the prevailing norms in society. Whetten et al. bring the stakeholder into sharp focus in their view of CSR as “societal expectations of corporate behavior: a behavior that is alleged by a stakeholder to be expected by society or morally required and is therefore justifiably demanded of business” (2002, 374).

*Stakeholder theories* suggest that there is a wide range of groups in the social environment that an organization can affect through the secondary impacts of its activity and that these groups have legitimate claims on the organization due to concepts in agency and property theories. For example, a combination of economic, ethical, and legal rationales underpins the CSR slogan of “doing well by doing good.” It is also accepted that the idea of CSR involves “actions that appear to further some social good, beyond the interests of the firm and that which is required by law” (McWilliams & Siegel 2001, 117).

The *nature of social responsibility* has also evolved. Early conceptions involved notions of business ethics and business philanthropy. Sponsorship and cause-related marketing are often included as examples of socially responsible practice, while at the same time providing a type of commercial advantage to the organization. Social responsibility is now likely to be couched in terms of business sustainability and corporate citizenship. The sustainability case is linked to social, environmental, as well as economic implications of organizational decisions and their longer-term implications for organizational success.

*Corporate social reporting* provides a core channel for organizations to communicate with stakeholders about their social responsibility activities. It also seeks to measure and assess an organization’s responsibility. The term “triple bottom-line reporting” refers to the economic, social, and environmental dimensions of organizational activity. A fourth dimension, governance, is sometimes added. These four distinct types of CSR practices can be described in the following taxonomy of CSR practices (see Table 1).

Reporting on social and environmental impacts is voluntary in most countries but some, such as France, have made it mandatory. However, many large organizations produce externally audited social impact reports as a competitive strategy within their

Table 1 Taxonomy of CSR practices

Taxonomy of CSR practices	Examples of CSR practices
Philanthropy	Donations Foundations
Commercial advantage	Sponsorship Cause-related marketing
Business legitimacy or sustainability	Employee programs Community engagement and development Political positioning ISO standards
Performance	Triple bottom-line reporting Reputation measurement Internal audit Social audit

industry, or to build their legitimacy (as is the case for tobacco companies). Critics question whether issuing a report equates with real commitment to social responsibility and sustainability principles, or whether they are simply “spin” (→ Spin Doctor). Proponents, on the other hand, claim the focus is on balancing the needs of all stakeholders with the organization’s profit motives. There is no universally accepted standard or definition of what CSR entails, or of its evaluation methodology, or reporting standard. However, the global reporting initiative (GRI) and the associated AA1000 standard are emerging as the internationally accepted standard for reporting on organizational activity.

# Correlation Analysis

*René Weber*

*University of California, Santa Barbara*

A correlation analysis is a statistical procedure that evaluates the association between two sets of variables. The association between variables can be linear or nonlinear (→ Linear and Nonlinear Models of Causal Analysis). In communication research, however, correlation analyses are mostly used to evaluate linear relationships. Sets of variables may include one or many variables. Associations between two variables (two sets of one variable) can be analyzed with a *bivariate correlation analysis*. Associations between one (dependent) variable and a set of two or more (independent) variables can be studied using *multiple correlation (regression) analysis* (→ Regression Analysis; Discriminant Analysis). Relationships between sets of many (independent and dependent) variables can be investigated using *canonical correlation analysis* (→ Factor Analysis; Structural Equation).

Variables in each set can be measured on a nominal, ordinal, or interval level (→ Scales; Measurement Theory). There is a specific correlation analysis for any combination of measurement level and number of variables in each set. Associations between ordinal variables (i.e., variables that have been measured on an ordinal level) are usually analyzed with a nonparametric correlation analysis (→ Nonparametric Analysis). All other combinations can be considered parametric linear correlation analyses and are as such special cases of canonical correlation analysis. Among the quantitative research methodologies (→ Quantitative Methodology), correlation analyses are recognized as one of the most important and influential data analysis procedures for communication research and for social science research in general. Explanation and prediction are generally considered the quintessence of any scientific inquiry. One can use variables to explain and predict other variables only if there is an association between them. One of the most established and widely applied correlation analyses is the bivariate linear correlation analysis, which will be used in the following demonstration.

## **BIVARIATE LINEAR CORRELATION ANALYSIS – PRODUCT–MOMENT CORRELATION COEFFICIENT**

Suppose the researchers are interested in the relationship between the variables “playing a violent video game” (X) and “aggression” (Y). Both variables are measured on an interval level (X in hours per week; Y in aggression scores from 0 to 10) and with standard measurement instruments. The following dataset was obtained from five research participants:

$X_1 = 10; X_2 = 16; X_3 = 13; X_4 = 19; X_5 = 20;$   
 $Y_1 = 02; Y_2 = 07; Y_3 = 03; Y_4 = 05; Y_5 = 02;$

Since the researchers are interested in the linear relationship between the two interval variables they will apply a bivariate linear correlation analysis and calculate a *bivariate correlation coefficient*. A widely used bivariate correlation coefficient for linear relationships is the *Pearson correlation coefficient*, which is also known as *product – moment correlation* or simply as *Pearson’s r*.

$$r = \frac{\text{cov}(x, y)}{s_x \cdot s_y} = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \cdot \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \bar{y})^2}}$$

$\text{cov}(x, y)$  means the covariance between the variable X and Y while  $s_x$  and  $s_y$  stand for the standard deviation of X and Y. The means of X and Y are indicated by  $\bar{x}$  and  $\bar{y}$ . Hence, the product–moment correlation is simply a standardized covariance between two interval variables, or the covariance divided by the product of the variables’ standard deviation. For calculations it is recommended to use the following formula:

$$r = \frac{n \cdot \sum_{i=1}^n x_i \cdot y_i - \left( \sum_{i=1}^n x_i \right) \cdot \left( \sum_{i=1}^n y_i \right)}{\sqrt{n \cdot \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2} \cdot \sqrt{n \cdot \sum_{i=1}^n y_i^2 - \left( \sum_{i=1}^n y_i \right)^2}}$$

Therefore, we calculate the following sums and products:

$$\begin{aligned} \sum_{i=1}^n x_i &= 78; \sum_{i=1}^n y_i = 19; \sum_{i=1}^n x_i \cdot y_i = 309; \sum_{i=1}^n x_i^2 = 1286; \\ \sum_{i=1}^n y_i^2 &= 91; \left( \sum_{i=1}^n x_i \right)^2 = 6084; \left( \sum_{i=1}^n y_i \right)^2 = 361; n = 5 \end{aligned}$$

Inserting these sums and products into the formula results in

$$r = \frac{5 \cdot 309 - 78 \cdot 19}{\sqrt{5 \cdot 1286 - 6084} \cdot \sqrt{5 \cdot 91 - 361}} = \frac{63}{\sqrt{346} \cdot \sqrt{94}} = \frac{63}{180 \cdot 344} = 0.349 \approx 0.35$$

This result indicates a positive product–moment correlation of 0.35 between “playing time of a violent video game” and aggression scores. All statistical software packages, such as SPSS, SAS, S-PLUS, R, and STATISTICA, offer a procedure for the calculation of product–moment correlations and many other correlation coefficients. The statistic software R is freely available at [www.r-project.org](http://www.r-project.org).

### INTERPRETATION OF A PRODUCT–MOMENT CORRELATION COEFFICIENT

The product–moment correlation coefficient (as most other correlation coefficients) will be a value between  $-1$  and  $+1$ . A value of  $0$  indicates that the two variables are independent, i.e., have nothing in common. A value of both  $+1$  and  $-1$  would be interpreted as a perfect linear relationship between the two variables. A correlation of  $+1$

stands for a positive or increasing linear relationship (“the more of variable X the more of variable Y” or vice versa). A correlation of  $-1$  represents a negative or decreasing linear relationship (“the more of variable X the less of variable Y” or vice versa). The closer the correlation coefficient is to either  $-1$  or  $+1$  the stronger the association between the two variables.

The squared correlation coefficient indicates the proportion of common variance between the two variables and is called the *coefficient of determination*. In the example above, the squared product–moment correlation is  $0.35^2 = 0.1225$ , or 12.25 percent. This means that the two variables “playing time of a violent video game” (X) and “aggression” (Y) share 12.25 percent of their variance. In other words, 12.25 percent of variable Y is redundant when knowing variable X or vice versa. This result, however, also means that 100 percent minus 12.25 percent = 87.75 percent of the variables’ variance is not shared and needs to be explained by other variables. This quantity is commonly called the *coefficient of alienation*.

Many authors have suggested guidelines for the *practical interpretation of a correlation coefficient’s size*. The question is whether a given correlation coefficient indicates a small, medium, or strong association between variables. Cohen (1988), for example, has suggested the following categorization of correlation coefficients for psychological research:  $0.10 < r < 0.29$  or  $-0.29 < r < -0.10$  indicates a small correlation (small effect),  $0.30 < r < 0.49$  or  $-0.49 < r < -0.30$  a medium correlation (medium effect), and  $0.50 < r < 1.00$  or  $-1.00 < r < -0.50$  a strong correlation (strong effect). As Cohen stated himself, these guidelines are, to a certain degree, arbitrary and should not be taken too seriously. Ultimately, the interpretation of a correlation coefficient’s size depends on the context. On the one hand, a correlation coefficient of 0.85 may indicate a weak relationship if one is studying a physical law with highly reliable measurement instruments. On the other hand, a correlation coefficient of 0.35 may indicate a strong relationship if many other variables intervene in the association of two or more variables, or if one has to use measurement instruments with imperfect reliability. A categorization of correlation coefficients that is comparable to Cohen’s classification and based on communication research findings is still missing.

### **SIGNIFICANCE OF A PRODUCT–MOMENT CORRELATION COEFFICIENT**

The above example of a product–moment correlation resulted in a product–moment correlation coefficient of 0.35 in a sample of five research participants. Most of the time, however, researchers are more interested in whether a result found in a sample can be generalized to a population. In other words: researchers are often interested in whether  $\rightarrow$  hypotheses that refer to relationships among variables in a population hold when confronted with empirical data in a sample ( $\rightarrow$  Test Theory). For this purpose, one has to apply a statistical significance test. The classical hypotheses of a product–moment correlation coefficient are:

Two-sided research hypothesis ( $H_1$ ; association existent):  $\rho \neq 0$

Two-sided null hypothesis ( $H_0$ ; no association existent):  $\rho = 0$

One-sided research hypothesis ( $H_1$ ; positive/negative association):  $\rho > 0$  or  $\rho < 0$

One-sided null hypothesis ( $H_0$ ; no or negative/no or positive association):  $\rho \leq 0$  or  $\rho \geq 0$

In the example above we assume a one-sided research hypothesis, i.e., we assume a positive correlation between the variables “playing time of a violent video game” and “aggression.” In other words, we expect that the more often people play a violent video game the higher their aggression levels, or vice versa. A null hypothesis test for  $r$  can be performed using a  $t$  or  $F$  sampling distribution. We obtain the  $t$  or  $F$  statistic as:

$$t = \frac{r \cdot \sqrt{n-2}}{\sqrt{1-r^2}} = \frac{0.349 \cdot \sqrt{5-2}}{\sqrt{1-0.349^2}} = 0.645; F = \frac{r^2}{1-r^2} \cdot (n-2) = \frac{0.349^2}{1-0.349^2} \cdot (5-2) = 0.416$$

As one can see,  $t = \sqrt{F}$ . If the null hypothesis is true, the  $F$  statistic is Fisher’s  $F$  distributed with  $df_1 = 1$  and  $df_2 = n - 2$  degrees of freedom, or the  $t$  statistic is student’s  $t$  distributed with  $df = n - 2$  degrees of freedom. According to the corresponding sampling distributions, the probability of finding a  $t$  value of 0.645 or an  $F$  value of 0.416 under the assumption of a true null hypothesis is  $p = 0.282$ . Since  $p$  values of greater than  $\alpha = 0.05$  (5 percent) usually do not result in the rejection of the null hypothesis, the relationship in the sample is characterized as not significant.

## THE PITFALLS OF CORRELATION ANALYSIS

The concept of correlation analysis and correlation coefficients in particular can be easily misconceived. The following three aspects are frequently a source of misinterpretations:

*Correlation Analysis and Linearity:* Most correlation analyses indicate only linear relationships among variables and will miss nonlinear associations. For example, a perfectly U-shaped relationship between two interval variables will result in a product-moment correlation coefficient of zero and, therefore, would suggest no association. Hence, it is important to test whether the relationship under examination could be nonlinear in nature before conducting a linear correlation analysis. Among various statistical procedures, one can use a simple scatterplot for this purpose.

*Correlation Analysis and Systematic Sample Biases:* A correlation analysis with a test of statistical significance assumes that we have a perfect random sample ( $\rightarrow$  Sampling, Random) at hand. Frequently, however, this is not the case. For example, samples can be composed of extreme groups, or samples may not cover the entire variation of variables in a population. While extreme group selection usually leads to an overestimation of the true relationship in a population, samples that are restricted in variation typically result in an underestimation of a correlation in a population. Another problem is that correlation coefficients are extremely sensitive to outliers in a sample which, too, lead to an overestimation of a population’s true correlation. It is recommended to check a sample for systematic sample biases before conducting a correlation analysis.

*Correlation Analysis and Causality:* The most common misconception of a correlation analysis, however, refers to the question of causality. The fact that two or more variables are correlated does not mean that some variables can be considered as cause and others as effect. Correlation is not causation! The example above stated a positive correlation between “playing time of a violent video game” and “aggression.” It is possible that playing a violent video game causes higher aggression scores (effect hypothesis), but it is also

conceivable that already aggressive personalities purposely select violent video games (selection hypothesis). A positive product–moment correlation coefficient does not provide any information about which of the two competing hypotheses is the better model. Perhaps both variables are even affected by a third variable and show no direct relationship at all. In this case the association between “playing time of a violent video game” and “aggression” would be a spurious relationship. On a basic level, three conditions define causality:

- 1 Time order must be appropriate. If X is the cause and Y the effect, then usually X antecedes Y in time.
- 2 Variation must be concomitant, as shown with a significant correlation coefficient.
- 3 The relationship among variables must not be explained by other variables, i.e., is not spurious.

Considering these three conditions, a significant correlation coefficient is a necessary, but not a sufficient, condition for causality.

## **Cost and Revenue Structures in the Media**

*Hugh J. Martin*

*University of Georgia*

Media rely on different combinations of revenue from consumers and advertisers to pay production costs and earn a profit. Reliance on either revenue source is determined by the characteristics of the media good, and by consumer and advertiser demand for the good.

Consumers select media products that meet needs such as entertainment or information for decision-making. Advertisers in turn select media that reach potential customers for the advertised products (→ Markets of the Media; Media Economics; Economies of Scale in Media Markets).

Individual consumers use a mix of media products to meet a range of needs, but the mix is dynamic (Lacy 2000). Changes in existing media products, or the introduction of new products, can change their media mix.

Consumers select media products because of *embedded characteristics*, such as speed of delivery and quantity or quality of information (Litman 2006). Different media, such as → television, → newspapers, and the → Internet, have different proportions of desirable characteristics. Consumers use these characteristics to select a mix of products that gives them maximum utility within the constraints of time and income (Litman 2006; → Consumers in Media Markets).

Changing patterns of consumption mean some forms of media lose revenue that others gain. These changes can be understood with models of media economics. These models are used below, first to examine the costs of producing and distributing media content, and strategies for raising revenue to cover those costs. Then cost and revenue interactions are examined. Third is a discussion of how interactions are affected by competition and by new media technologies.

## ECONOMIC CHARACTERISTICS

Media products – be they printed, broadcast, or published on a website – have two important economic characteristics. First, significant costs must be paid to produce the first copy. *First-copy costs* usually increase with the sophistication of the product because skilled workers must collaborate to creatively use specialized equipment.

Second, it is difficult to tell in advance how many copies consumers will demand. Many media products are “experience goods” – consumers must experience the product before they know if it meets their needs. For instance, consumers must read a book to find out if they enjoy the story. Some media products also have characteristics of “credence goods” – consumer evaluation is imperfect even after the good is experienced. Reputation is particularly important for credence goods, such as news reports.

Together, these characteristics require that media producers pay substantial first-copy costs without knowing how many additional copies consumers will actually demand. The problem is complicated by expensive production technologies, such as printing presses. These investments create substantial fixed costs which must be paid regardless of the number of copies produced.

*Total production costs* are a combination of fixed costs, high first-copy costs, and relatively small variable costs of producing each additional copy. This means average costs of production actually decline as the number of copies increases, creating economies of scale. The change in cost from producing one additional copy, or marginal cost, is less than the average cost. Marginal cost will only increase if the number of copies produced begins to strain production capacity.

Traditional microeconomic rules state that firms maximize profits by setting the price of their product equal to marginal cost. But media firms will fail if they set prices equal to

a marginal cost that is less than average production costs. Producers must either attract an audience willing to pay average production costs, or find alternative financing. Ludwig (2000) calls this “the essential economic problem of the media.”

This problem varies with the characteristics of the medium. For instance, first-copy costs are less for books than for studio films, so publishers can earn a profit with smaller audiences than film producers. Distribution costs also vary. Only one copy of a television program needs to be broadcast, but separate copies of a newspaper must be distributed to each subscriber.

Nonetheless, many media must find a *source of revenue beyond consumers* to succeed economically. This source is often → advertising (Ludwig 2000). This solution creates interdependence between demand for a media product and advertiser demand to reach the audience for that product. Media producers must balance the interests of their audiences and the interests of advertisers trying to reach potential customers in those audiences. Producers use different strategies to strike this balance and reduce uncertainty about how many copies of a product consumers will demand.

### PHYSICAL CHARACTERISTICS

All media have at least one of two physical characteristics of public goods. Nonrivalry in consumption exists if multiple consumers can use the same product without using it up. Nonexcludability exists if consumers cannot be prevented from accessing the good. Media products are nonrival, and many are nonexcludable. Determining demand for public goods is difficult because they can be consumed without payment. Governments supply *pure* → *public goods*, which are nonrival and nonexcludable, such as national defense.

Broadcasting is an example of a similar media product. Consumers cannot be excluded from radio and television broadcasts if they have a receiver, so there is no way to charge them for the product. Instead, broadcasting is supported by advertisers or by the government. The financiers determine the quantity and characteristics of broadcasts in line with their desire to reach particular audiences (→ Audience Segmentation). Expensive programs can use established formats, story lines, or actors to create mass appeal and attract support from multiple advertisers (Dimmick & McDonald 2001). Inexpensive programs can appeal to smaller audience segments because they only require support from a single advertiser.

*Mixed public goods* have only one characteristic, nonrivalry. Newspapers, magazines, and → cable television are products that can restrict consumer access. Subscriptions can be used to collect advance payments that reduce uncertainty about the future size of the audience and how many copies to produce. However, many excludable media products still rely on advertising to pay some costs.

With both pure and mixed public media goods, the degree of influence that consumers or advertisers have will vary. For instance, a product with many advertisers is less likely to be influenced by the preferences of a single advertiser because its economic success is not at stake, and vice versa.

### WINDOWS FOR CONTENT

Some media products, such as music and films, are not time-sensitive (→ Popular Music; Film as Popular Culture). Unlike → news, they remain attractive to consumers for extended

periods. If these products meet two additional conditions they can be sold repeatedly to different groups of consumers for different prices. The first condition is excludability. The second condition is that consumers can be separated into groups based on the maximum they are willing to pay for the product. This maximum is called a *reservation price*. When both conditions are met, the same product can be sold to different groups of consumers at different prices. If the sales take place in different markets, each market is called a window (Owen & Wildman 1992).

For example, films released first in theaters attract consumers with the highest reservation prices. This may be followed with a release on restricted cable television channels to viewers with lower reservation prices. Eventually, the film may appear on advertising-supported cable or broadcast channels. Additional distribution windows were created by home video and the Internet.

Foreign markets are another window for episodic television or film. However, national differences such as language or culture may reduce the utility that foreign audiences receive. For example, a movie with subtitles may attract smaller audiences than a movie using the audience's native language. Foreign windows require a *cultural discount* – producers must lower their price because audiences have lower reservation prices. Video sequences that cut across language barriers – such as chase scenes, or explosions – can reduce the size of the cultural discount.

Producers can use price discrimination in the same market if they sell different versions of a product (Varian et al. 2004). Cellular telephone providers vary prices according to the type and amount of service demanded by different groups of consumers. DVDs can offer a film, or a more expensive version with features such as extended commentary.

## BUNDLING MEDIA PRODUCTS

Bundling is used to sell groups of cable television channels, but the strategy has applications across a variety of media products. Bundling allows media producers to place consumers with different tastes and reservation prices in a group. The producer sells the group a bundle of different products for the same price.

The strategy requires low cost for supplying additional units of a media product. If one consumer has a high reservation price for films, and a low reservation price for history programs, but a second consumer has opposite preferences, sales can be increased by selling both consumers a bundle of film and history channels (Owen & Wildman 1992). This is why cable television channels are sold in tiers instead of being offered for individual sale. Newspapers and → magazines bundle a variety of information in print to attract consumers with different interests. This strategy can easily be transferred to the Internet.

## MARKET STRUCTURE

Interactions between costs and revenues are also influenced by competition between producers of substitute media products. Firms compete by reducing prices, or by differentiating products to make them less substitutable. Differentiation of media products often involves embedded characteristics such as content quality or speed of delivery. However, differentiation increases production costs and can be imitated. This means

profits from product differentiation are influenced by market structure. Firms with limited competition can set prices well above production and distribution costs, earning substantial profits that could be used for product differentiation. Firms in competitive markets must set prices close to cost, limiting their ability to differentiate (→ Concentration in Media Systems).

For example, economies of scale limit newspaper competition, allowing some newspapers to charge monopoly prices. The financial commitment model predicts that newspapers that do face competition will increase newsroom spending, improving the quality of coverage in order to make themselves less substitutable and maintain market share (Litman & Bridges 1986; Lacy 2000).

Thousands of magazines in the US compete in crowded market segments, and have little power to raise prices paid by readers or advertisers. To survive, publishers must produce articles targeting the interests of readers whom advertisers want to reach. Newspapers are adopting similar tactics as readers and advertisers migrate to newer forms of media.

Cable television and telephone providers can reach very large markets with continually decreasing average costs. These natural monopolies therefore have regulated prices and service. These firms had few incentives to differentiate before new technologies, such as satellite television and cellular telephones, threatened their monopoly status. This is part of the reason why Asian nations that lagged behind in developing telecommunications now have technology more advanced than the US.

### **ALTERNATIVE FINANCING**

Public financing offers an alternative to reliance on advertisers and consumers. Governments can make grants directly to media producers. Another alternative is financing from dedicated taxes, such as the tax on television receivers in some European nations. Public financing is used to support broadcasters, filmmakers, publishers, and other media producers.

Public financing can encourage production of content with social benefits that cannot be realized by private firms. For example, news programs that increase knowledge about complex issues may increase the efficiency of democratic political systems. Privately financed producers have no way of making consumers pay for these benefits and may focus on news stories with mass appeal to attract advertisers. Public financing is the only alternative for encouraging such production (→ Commercialization: Impact on Media Content; Quality of the News).

However, effects from these programs are hard to measure, so it is difficult to determine if public financing is providing too much, too little, or just enough of the desired content. The allocation of public funds is often subject to political influence. In extreme cases, publicly supported media are little more than government mouthpieces. In less extreme cases, they may limit content due to political considerations (→ Public Service Broadcasting: Law and Policy).

### **EVOLUTION OF MEDIA**

Media production, technology, and markets are dynamic, and changes influence interactions between costs and revenues. Firms with a monopoly or few competitors could raise prices

above production costs plus a fair return to investors who put their money at risk. These firms earned economic profits, or profits above the amount necessary to remain in business. Media in these markets financed substantial investments in plants and equipment, increasing fixed costs, by producing content with mass appeal to maximize audiences and advertisers. This created opportunities for smaller firms to serve niche audiences with specialized content not available from the larger firms.

However, competition increased as *new distribution technologies* brought more content into the markets. New production technologies that lowered first-copy costs had a similar effect. These changes allowed new firms to compete away the economic profits enjoyed by existing firms. As prices decreased, firms had to reduce production costs, accept reduced profits, try to limit new competition, or some combination of the three.

For example, in the 1950s cable television was a threat to broadcasters because cable could import signals from outside local markets. Broadcasters pressured the → Federal Communications Commission (FCC), which regulates television in the US, to limit the spread of cable (Owen & Wildman 1992). The FCC restricted cable in large markets until the 1970s. As a result, cable was not widely available in the US until the 1980s. Cable allowed viewers to receive frequencies that were difficult to acquire with a television set antenna. This, and changing regulations, encouraged News Corp (→ News Corporation) to purchase local ultra high frequency stations that became the Fox network (Thomas & Litman 1991). Costs were minimized by using programs and movies owned by Fox film studios, and inexpensive reality programs. The network targeted young viewers, eventually acquiring rights to broadcast professional (American) football, which solidified its market position.

Cable made consumers pay to watch programs that were broadcast free. But cable also offered new programs. The growth of cable is an early example of consumer willingness to pay if new technologies offer desirable features not previously available. Consumers adjusted their mix of media, revealing preferences that were not apparent before they had cable. The mass audiences for broadcast television began to fragment, and advertisers followed audiences to new channels and new media. The adoption of cable, and News Corp's successful exploitation of new markets it created, is one example of a story that repeats with increasing frequency and speed.

## DIGITAL MEDIA

Digital production and distribution eliminates large capital expenses such as printing presses and broadcasting towers. Inexpensive software replaces equipment for creating and editing content, which the audience can copy and redistribute (→ Information and Communication Technology, Development of; Digital Media, History of).

Digital producers operate with lower fixed costs and can profit with prices below what is economic for firms with higher costs. High-cost firms must cover costs with a diminishing audience or advertiser base. New technologies reduce the cost of collecting specific information about consumer preferences. Google and Yahoo! place ads beside compatible search results, track whether individuals click on the ads, and provide this information at low cost to advertisers (→ Search Engines). Advertisers only pay if someone clicks on the ad. This highly efficient technology draws revenue away from nondigital media, which must increase spending to find effective responses (→ Advertising, Economics of).

However, digital media still face the essential economic problem that reproductions cost less than the first copy. Varian et al. (2004) identify three variables that help resolve the problem. *Creating different versions* was discussed earlier. The second variable is *switching costs*, which exist when it is costly for consumers to switch from one product to another. Email creates switching costs because address changes require notification, and messages may be missed. Companies offer free email to create switching costs, then profit by selling advertising directed to email customers. Social networking sites, such as MySpace, offer free personal web pages with elaborate tools for managing online interactions. This creates switching costs for the site's users. Newspapers that offer readers free web pages and chat forums are using a similar strategy (→ Social Networks; Network Organizations through Communication Technology).

The third variable is *network effects*, which exist when demand for a good depends on how many other people use the good. Network effects can be direct; demand for social networking increases with the number of users on a site. Network effects can also be indirect; the number of DVDs increases as more people buy DVD players. Switching costs and network effects interact to increase demand for Internet media if production costs are low. As websites add content, the cost of switching to another site increases. As more people use the site, demand to place content there will also increase. YouTube makes it easy to watch or upload videos. As more videos are added, more people watch them, creating a cycle of growth. Google can then sell advertisers access to users while it tracks their activities to refine the efficiency of its operation.

## Course Organization Programs in Education

Ronald A. Yaros

University of Utah

Software programs and computer systems for organizing courses continue to grow in popularity and can be divided into two categories. The first category includes “standalone” computer hardware and software that is obtained by an institution and used onsite to deliver course-related content (intranet; → Computers and Display Programs in Education). The second category is a server environment capable of delivering content to anyone anywhere in the world via the world wide web (→ Internet). Physical absence no longer prevents students from participating in an educational experience. A 2005 survey of 2,200 colleges by the Sloan Consortium reported that nearly 3.2 million students took at least one online course in the fall of 2005, up from 2.3 million in 2004 (Carnevale 2006). Such programs can reach students who are physically or geographically unable to attend school. Some distance learners can interact with teachers and their peers on a daily basis (→ Distance Education).

Course organization programs facilitate the creation and delivery of text, graphics, and multimedia learning environments. In general, these programs deliver material that was previously only available in a traditional print-based format. Additionally, these systems provide students and teachers with instant access to email, course syllabi, calendars, discussions, blogs, live chat, collaborative conferences, galleries for publication of student work, educational communities around the world where students can learn about other cultures, and links to other relevant websites. Instructors can post student grades, comments, and progress reports.

*WebCT*, acquired by Blackboard in 2005, is one of the oldest and best-known programs, used by more than 3,700 colleges, schools, corporations, and government agencies in the US and other countries to create web-based educational content. This content can be integrated with traditional classroom instruction or can be posted for dedicated distance learning. Developed at the University of British Columbia, the WebCT program provides a customizable “shell” to post content such as text, images, audio, and video. WebCT also provides communication and testing tools, tracking of student activity online, grading, calendar, and student presentation area. The four classes of users in a WebCT course, each with its own set of privileges, include: administrator, designer, teaching assistants, and students.

Other course organization programs include *Convene* from Learning Technology Partners (LTP) of San Francisco. This program assists smaller schools with on-demand hosted academic technologies. The *FirstClass* groupware engine, produced by Embanet, is designed to foster learner collaboration at a distance for colleges, universities, corporations, and associations by providing a hosting service for learning platforms, live technical support, course development, and training services.

*IntraLearn* Software Corporation (ISC) provides technology that educators can use to create, deliver, and measure interactive learning over the Internet and intranets. More than 2,000 corporations, academic institutions, and associations use ISC's products to provide e-learning to millions of learners worldwide. The *Learning Manager*® (TLM) provides tools for development, delivery, reporting, and management of training and learning materials. Based on a modular approach, TLM allows clients to expand and tailor functionality to their current and changing needs. The *Learning Manager*® users can build the application that matches their organization's requirements.

The *FirstClass* Communications Platform, Open Text, develops and supplies schools, school districts and other educational organizations with a messaging and collaboration system including basic email and voicemail. The *ToolBook*, produced by SumTotal, is an authoring suite that organizations can use to create content and simulations for learning. The program is used to create professional, standards-based simulations, tutorials, assessments, courses, and interactive content. Finally, *eCollege* provides the technology and services for online distance programs, online degrees, certificates, and professional development programs for publicly traded for-profit institutions, community colleges, and public and private universities.

Empirical research results about the *effectiveness of courses using such technology* are mixed (→ Classroom Instructional Technology). Although some scholars found that web-assisted instruction was more effective than traditional classroom instruction (Maki & Maki 2002; Twigg 2003), others found that instruction without the use of programs produced better results (Wang & Newlin 2000; Waschull 2001). A third group of researchers found no significant differences between classroom and online instruction (Benoit et al. 2006). Limitations acknowledged by past studies include small sample sizes (→ Sampling, Random) and potentially confounding co-variables such as student age, gender, and previous computer knowledge by both student and teacher (→ Statistics, Explanatory). As students and teachers become increasingly comfortable with technology, the effectiveness of learning from course education programs could improve. Another limitation of past studies is the inability to generalize the amount of learning in one subject to all subjects using course organization programs.

## Co-Viewing

Daniel G. McDonald

Ohio State University

Co-viewing is the viewing of media content in groups. Typically, the co-viewing group is a dyad, but the term can also refer to groups of three or more. Most of the research has been conducted in regard to television viewing, but the concept has been a part of communication research since the investigation of silent motion pictures in the early 1900s (→ Exposure to Film). Generally, studies of co-viewing fall into *three areas*: co-viewing configurations (who views with whom and with what frequency), co-viewing as a socialization aspect of the family decision-making process (who controls the TV and decides what to watch), and – making up the bulk of current research on co-viewing – parent–child co-viewing as a mediation process (→ Audience).

Research on *co-viewing configurations* began with studies of the motion picture. In the early days of motion pictures, theaters were often small and dimly lit, and were generally considered unhealthy places for children (→ Cinema). Studies by Phelan (1919), Dale (1935), and others assessed the extent of the theater problem and documented the audiences for motion pictures and other social amusements, such as vaudeville and burlesque. These early studies found that children were most likely to view motion pictures with other children. Although some of the viewing was done with parents or siblings, the most common viewing situation was with peers. There was often an assumption of positive effects for parent–child co-viewing of motion pictures in these early studies; for children, co-viewing with friends drew the most attention and concern.

Few studies investigating radio seemed particularly concerned with co-listening. Kirkpatrick (1933) was one of the few reporting any data related to the concept. His report, though, suggests that, because the radio was a medium accessed at home, listening to the radio with others was a good thing. Reporting that about 3.5 persons listen together to an average radio program, he noted that radio listening “is to a certain extent a family matter.”

With the advent of television, co-viewing again became a subject and context for research (→ Exposure to Television). During the 1950s and 1960s, research focused on co-viewing configurations and *co-viewing as a context for* → *family decision-making*. As Wand (1968)

noted, researchers and broadcasters wanted to know who controlled the set. Much of the early literature focused on the idea of a dominant individual deciding when and what to watch (McDonagh 1950; Blood 1961). During the 1970s and 1980s, this stream of work continued, but researchers began to suggest that quasi-democratic processes (Lull 1978) and socialization (McLeod et al. 1982) might be better explanations. By the late 1980s, overlapping preferences as a result of socialization and physical maturation, rather than domination of the set by an individual, appeared to be the primary explanation for both the decision-making process and the most common co-viewing configuration of peer co-viewing (either parent–parent or children of similar ages; McDonald 1985; Dorr et al. 1989).

In the 1990s, most co-viewing research was undertaken within the context of what Nathanson (1999) described as a dimension of *parental mediation research* (the other two dimensions being active mediation and restrictive mediation). Parental mediation research is focused on the nature of parents' or other adults' behaviors regarding television, and the impact that those behaviors have on a child's reactions to television or other media. Co-viewing research in this context has led to mixed results in terms of whether adults' co-viewing leads to positive or negative outcomes for children. There is increasing evidence that co-viewing of content suggests to the child that the parent approves of the content, even if the content is violent (Nathanson 2001). Such a conclusion helps explain a number of negative and positive effects attributed to co-viewing of TV content (McLeod et al. 1982; Nathanson 2001; → Media Use and Child Development; Media Use by Children).

While co-viewing has become a part of the literature on mediation in recent years, research results suggest that the antecedents and consequences of co-viewing are different from those of other forms of parental mediation. Some researchers see these as different dimensions of the concept of mediation, while others suggest that parental mediation is a particular case of co-viewing – one in which a parent and child watch together. As indicated above, the earlier literature suggests that parent–parent or sibling–sibling co-viewing occurs most commonly.

A more general model of co-viewing and media effects is faint, but evident in the literature. Even the early literature suggests that anyone who views media content with another person may have an impact on their enjoyment and interpretation of that content. Such *peer effects* have been documented in televised sports and in watching sports at a stadium (Hocking 1982). More recently, McDonald and Fredin (2001) found evidence indicating a synchronization of emotional responses among co-viewers of televised content (→ Enjoyment/Entertainment Seeking).

The co-viewing literature established thus far suggests that our future knowledge of media use and media effects will hinge to some extent on how well we understand social aspects of the media. Early evidence on the proliferation of newer forms of media suggests that social uses of these media will also be an important part of their diffusion and acceptance (→ Exposure to the Internet). Some of these new media are inherently individualized or seem most likely to diffuse with dyadic use patterns (e.g., personal mp3 players, mobile phones with video capabilities), while others would appear to be very similar twenty-first-century versions of television or motion picture viewing (e.g., home digital video recorders, DVD players). Still others may emerge with differing co-use or co-viewing configurations (e.g., digital music through networks, video on demand). Our concept of co-viewing may need to be expanded to incorporate co-use of these new

media, or some other term may need to be introduced, which can incorporate new forms of media in social use situations.

## **Credibility of Content**

*Donna Rouner*

*Colorado State University*

Credibility of messages, studied in the communication, psychology, sociology, political science, and other literatures, is generally defined as a collection of attributes of messages that make the message content or their senders valued relative to the information imparted. The

attributes generally refer to either the sources of the messages' content or the authenticity of their meaning. Perceived source or message credibility, then, is generally defined as a message recipient's recognition and holding of evaluative information about these messages and their sources (→ Exposure to Communication Content).

### **CREDIBILITY MOSTLY CONCEPTUALIZED AS SOURCE CREDIBILITY**

Perhaps the most noticeable characteristic of information credibility is its source – the individual who reported it, wrote it, or was quoted in messages. This human voice of messages is one of the most studied concepts in communication research. In addition, the institutions associated with the human sources, whether government agencies, private, or not-for-profit, have been found critical in determining credibility, as have the media organizations that bring the information to the message receivers – mass media → news, → advertising, entertainment, and sports, in particular (Berlo et al. 1969; Singletary 1976).

Historically, credibility has been researched almost exclusively in → persuasion, which generally studies whether messages or speakers can change people's beliefs, attitudes, and behavior. Stemming from the classical Greek focus on credibility, typically the work of Aristotle and Plato, the study of "ethos" has distinguished the field of public speaking in examining properties of texts and judgments of audience members about characteristics of speakers during rhetorical transactions. It was well into the twentieth century before communication social scientists began a systematic look at communication, and, therefore, credibility (Hovland & Weiss 1951). Although it was one of the first communication concepts studied, credibility remains an area with many questions.

Credibility has been studied empirically relative to human social behavior as a characteristic of speakers, organizations, media (usually news media), messages, or communication contexts. *Early research* investigated the relative trustworthiness of different media presenting similar information. Research specific to rating news media sources has investigated publications, not individual communicators (Gaziano & McGrath 1986). Early on, this work found → newspapers to be the most trusted purveyors of news. Interestingly, a new medium, → radio, followed with an era when the first electronic media form became more trusted than newspapers. Later, with the innovation of → television, news on that medium became the top trusted source (Lee 1978; → Television News). Some recent work has examined new information technology in this regard.

Most of this work has used audience perceptions of credibility, not systematic inquiry into what specific attributes about these particular media were believed to garner their comparatively greater trust. Some interpretation of this literature has proposed that the more personal delivery of electronic media has made it more trusted than mere printed information, i.e., the friendly voice or face of the newscaster bringing the news to the home in a recognized, personable, consistent style. This area of research has extended beyond issues of trust to such matters as a media institution's social concerns and level of patriotism (Gaziano & McGrath 1986).

The *conceptual definition of source credibility* stems from some of the earliest social science research in communication and mass communication, where message characteristics were examined as they impact persuasion (→ Credibility Effects). The first published empirical work on credibility as it pertains to persuasion presented information in

experimental settings to message recipients about a source who was either an expert on a topic or who was trusted by audience members. Often these earlier researchers mixed the people, messages, and communication channels to represent credibility. For example, in the 1950s, pioneer researchers → Carl I. Hovland and Walter Weiss (1951) presented audience members with information from the following sources, thought to indicate a high level of trustworthiness: Robert S. Oppenheimer, the scientist who led the development of the hydrogen bomb, writing about the practicality of atomic submarines; *Fortune Magazine*; the *Bulletin of the National Resources Planning Board*; and the *New England Journal of Biology and Medicine*. These scholars used the following low-credibility counterparts: *Pravda*, the Soviet Union's state newspaper; an "anti-labor, anti-New Deal, 'rightist' newspaper columnist"; "a monthly pictorial magazine"; and a syndicated women's movie gossip columnist. Research that followed frequently focused solely on audience judgments about people sources or institutional sources. Other confounding aspects of sources, such as gender, notoriety, and political ideology have also been teased out.

### **DIMENSIONS AND MEASUREMENT OF SOURCE CREDIBILITY**

Over time, findings of source credibility that utilized similar measures to the early research distinguished two consistent dimensions of the concept: (1) expertise is the extent to which a communicator is perceived by audience members as providing correct assertions, and (2) trustworthiness is the extent to which the audience members perceive that the assertions made by a communicator or speaker are assertions that the communicator considers valid (Sterthal et al. 1978). *Expertise*, then, generally involves a communicator's knowledge, accuracy, and precision relative to the subject matter presented in messages. *Trustworthiness*, on the other hand, can be thought of as the source's intentions in the relationship between the message and the receiver of the message. For example, a source is perceived as honest, believable, sincere, and reliable by message recipients. A shift in studying source credibility as merely an attribute of a message to the perceived credibility by audiences paralleled a paradigmatic shift in mass communication research, which at the time first viewed media content as all-powerful and important, capable of massive, uniform effects on audiences – moving to the view that aspects of audiences were also important, and that sometimes audiences could resist media influence (→ Media Effects, History of). This eventually gave way to the view that audience transactions with media messages depended on various personal and contextual factors – audience characteristics like selectivity, motivation, and decision-making (→ Selective Perception and Selective Retention).

Hundreds of → scale items have been used to measure source credibility, and this concept has been studied as both an independent cause of persuasion, a contributory factor in a persuasion situation, and as the result of persuasion (Singletary 1976). Typical indicators of credibility, besides "credible" and "trustworthy," are "believable," "expert," "dynamic," "helpful," "rational," "objective," "professional," "intelligent," and "qualified." Although researchers have developed multidimensionality to source credibility, this has generated greater complexity of the concept rather than greater insight into its meaning (McCroskey 1966). Such components as dynamism, attractiveness, and professionalism have enhanced scientific understanding of how the style or presentation of a communicator

is part of that communicator's credibility, or the associated audience's perception of credibility. There has been some controversy about using traits of individuals as dominant in the study of perceived source credibility by audiences (Delia 1976). Over time, many studies have found that expertise and trust remain as useful dimensions for this concept (→ Research Methods; Validity).

### **SOURCE CREDIBILITY AS A PERIPHERAL ASPECT IN RESEARCH**

Regarding the importance of credibility in communication research, the phenomenon has taken a back seat to other critical aspects of persuasive messages. This was evident even in the first studies by Hovland and his colleagues, who initially may have been more interested in the propagandistic nature and sidedness of messages than the credibility of the message sender (Hovland & Weiss 1951; → Propaganda). They found an initial difference for high and low credibility conditions, in that people who received information from the high credibility sources, compared to the low credibility sources, were more persuaded. However, they found a delayed → *sleeper effect* about four weeks later, where the credibility of the sources were believed to be disassociated from the messages, and persuasive information from both types of sources was retained by experimental participants.

Even in recent persuasion research – indeed, in most current state-of-the-art persuasion models, like the → elaboration likelihood model in cognitive response theory (Petty & Cacioppo 1986) – source credibility is considered a peripheral cue to message processing. Although this research emphasizes message content characteristics that guide the cognitive processing of message content (→ Information Processing), understanding the actual processing mechanisms involved relative to message credibility remains elusive. In this theoretical approach audience members are thought to process central message content when they are highly motivated or involved in the message or its outcome. Conversely, audience members who are low in motivation or involvement are thought to pay attention to peripheral, less important message cues, such as source credibility.

### **MESSAGE CREDIBILITY**

This research brings to question the subject of the credibility of the message itself, as a message might also be viewed by audience members in persuasion or learning contexts as more or less credible. To a lesser extent, message credibility has been studied, particularly in experimental research (Slater & Rouner 1997; → Experimental Design). As far as message characteristics are concerned, qualities such as strong vs weak evidence, narrative vs statistical content (→ Exemplification and Exemplars, Effects of), truthfulness, number of arguments and variety of arguments have been studied. Some of this research shows a message credibility impact on source credibility, or an enhanced persuasive effect when credibility of the message and source were taken into account as to their combined effect on attitude change or behavior.

Some research documents *situational circumstances* or audience states that moderate the impact of credibility cues on either persuasion or learning. These include involvement or personal stake in a message's topic, knowledge and direct experience, and dispositional factors like incredulity and cognitive complexity. Only a few research studies have investigated the

actual nature of processing strategies associated with message and source credibility. Recent work not only continues to investigate persuasion processes but has expanded this inquiry to the study of information processing of information not meant for persuasion, such as news and public affairs media, as well as entertainment messages. Accurate reflection of social reality, believability, and message quality assessment are some more recent audience determinations that might affect source credibility (→ Reality and Media Reality).

## RESURGENCE OF CREDIBILITY RESEARCH

Recently, two research areas in the study of media have yielded a resurgence of credibility research: new information technology (→ Technology and Communication) and → health communication. Scholars have been studying message features of new information technology, for example, world wide web structural elements and message content quality, like thoroughness, complexity, and truthfulness. Combining this technology focus with health communication has become important, given the increasing use of new information technologies for health information in prevention, identification, diagnosis, treatment, and possible cures for varied health matters. Credibility of messages and their sources takes on new meaning for individuals recently diagnosed with cancer, possibly seeking more information about their illness and prognosis, available health information about future prospects, and a virtual community of cancer survivors with whom they might learn ways to cope and to share their stories.

Some additional audience characteristics found related to credibility include gender, race, ethnic similarity to the audience member, management style, and leadership. *Gender differences* have been mixed, demonstrating both research that shows males more credible than females and females more credible than males. However, recent research has found less evidence of gender differences, suggesting a time-period phenomenon that may have led to less bias against females as information sources, compared to the past, when males dominated as speakers and news deliverers (→ Feminist and Gender Studies).

The robust concept of credibility has held strong across the many years since communication originated as a field of study. It continues to be a crucial component of media content, particularly in public affairs, public speaking, politics, advertising, marketing, and public relations.

## Credibility Effects

*Nikolaus Jakob*

*Johannes Gutenberg University of Mainz*

The importance of credibility in human communication had already been recognized long before modern communication research emerged as a scientific discipline. For ancient rhetoricians like Aristotle or Cicero it was self-evident that the credibility of a communicator had an important impact on the persuasiveness of his performance (→ Rhetorical Studies; Rhetoric, Greek). At the beginning of the twentieth century credibility became a central concept in communication research, first in → propaganda, later in other areas such as → advertising or → political communication. Today, the field of research is quite complex: different research traditions have bred a considerable number of definitions, operationalizations, and findings. Three major models of credibility can be distinguished: the source model, the recipient model, and the experience model. Modern research has come to the conclusion that there is no linear relationship between the credibility of a communication source and the effectiveness of its persuasive efforts. The magnitude as well as the persistence of credibility effects depend on several intervening variables (→ Journalists, Credibility of; Credibility of Content).

### THEORETICAL APPROACHES

Carl I. Hovland (1954, 1071) stated that “*who* says something is usually as important as *what* is said in the determination of the impact of a communication.” However, the effects of both the communicator and the message depend largely on the perception of the third

core element of every communication model: the receiver. Credibility is a perceptual state, i.e., the outcome of an attribution process in which recipients of messages form judgments about their sources and therefore assess them as credible or not. The perceived credibility of a communication source depends on the perception and attribution by the receiver: a message source may be regarded as highly credible by one person and not at all credible by another.

The *source model* focuses predominantly on the communication source: credibility is considered as the result of the pre-existing or perceived characteristics of a source. A rudimentary version of this model can be found in Aristotle's ground-breaking treatise on rhetoric in the fourth century BC, in which he argued that trustworthiness, good will, and wisdom make a communicator appear credible and therefore facilitate persuasion. The concept of credibility actually first appeared in the Yale Studies, a series of psychological experiments conducted by → Hovland and his colleagues in the 1940s and 1950s: credibility was conceptualized as a composition of several (perceived) communicator characteristics – especially the communicator's *expertise* and *trustworthiness* (→ Experimental Design). Later researchers have tried to identify additional source characteristics, e.g., qualification, fairness, similarity, physical attractiveness, and dynamism (e.g. Berlo et al. 1969). Although the model provoked intense criticism (e.g., Cronkhite & Liska 1976), it gained much attention in communication research.

The *recipient model* focuses predominantly on the recipients' traits: the perception and attribution of a source's credibility are likely to differ between different recipients. Thus it depends on the recipients' predispositions whether a message source is perceived to be credible or not. Hovland and Janis hypothesized the existence of an individual predisposition called general "persuasibility" (→ Persuasion). The term "refers to a person's readiness to accept social influence from others" (Hovland & Janis 1959, 5). It was assumed that women and individuals with low levels of intelligence or self-confidence were generally more persuadable. However, no significant evidence for the existence of a general persuasibility as a personality trait could be found. Later research focused on other traits such as dogmatism which can be defined as individuals' tendency to "close off their minds to new ideas and accept only the opinions of conventional, established authorities" (Perloff 2003, 219). Research indicated that dogmatic persons were more susceptible to persuasion than others. However, until today there has been no commonly accepted empirical procedure for identifying persuadable individuals. In addition, no sustainable evidence about the existence of general persuasibility or its correlates could be found (O'Keefe 2002, 242).

The *experience model* emphasizes the interaction between message source and recipient. According to Niklas Luhmann (1989), credibility serves as a heuristic that helps to reduce social complexity. Based on positive experiences with communication sources, individuals attribute credibility to them. By this, they avoid engaging in arduous investigations to find evidence for the trustworthiness of the respective source. Credibility is defined as an outcome of frequently practiced pseudo-empirical tests which are part of every individual's life. This "inductive knowledge" (Simmel 1990) leads to experience-based expectancies toward message sources. Credibility is thus the result of learning: individuals believe in a person or institution because they have learned that they can do so without experiencing negative consequences.

## EFFECTS OF CREDIBILITY

In early research a linear relationship between source characteristics and the persuasiveness of its messages was usually assumed: the more credible a source was perceived by its users, the more effective its messages would be (e.g., Berlo et al. 1969). However, the correlation between source credibility, the persuasiveness of messages, and attitude change is not as clear as is frequently assumed. Credibility effects are neither linear nor permanent. The magnitude and persistence of credibility effects varies from one case to another, depending on a considerable number of intervening factors (→ Linear and Nonlinear Models of Causal Analysis).

When discussing the effects of credibility it has to be noted that most experimental studies compare the effects of *high- and low-credibility* sources. Hovland and Weiss (1951) found that messages from high-credibility sources created more attitude-change than those from low-credibility sources. Subsequent studies revealed that high-credibility sources were not always more effective – their influence depended on other factors such as the position advocated in the message. High-credibility sources enjoy an advantage when the advocated point of view is opposed to the audience's position. Low-credibility sources, on the other hand, are more successful when the position advocated is shared by the audience (→ Latitude of Acceptance). Therefore the impact of both the source's perceived credibility level and the position advocated by the source and the receiver have to be considered when explaining credibility effects (O'Keefe 2002).

Credibility effects largely depend on the recipient's attitude toward the issues in discussion. According to contemporary → information-processing models such as the *elaboration likelihood model* (Petty & Cacioppo 1986), the effects of persuasive communication mainly depend on the recipient's *ego-involvement*. Indifferent or uninterested recipients tend to process information superficially (→ Involvement with Media Content). They rather base their judgments on source characteristics such as the communicator's credibility. Highly involved individuals, on the other hand, search for high-quality arguments and tend to process information systematically and carefully, mostly neglecting source characteristics and focusing on the quality of the communication content. In consequence, "under conditions of low personal relevance, the communicator's credibility may make a great deal of difference to the outcome, whereas on highly relevant topics, the source's credibility may have little impact" (O'Keefe 2002, 192).

Furthermore, the effects of credibility depend on the *availability of information* about the source. The timing of the source's identification and the revelation of information about it decide whether credibility dimensions like expertise or trustworthiness have effects on the audience. When no information about the source is provided, recipients concentrate on message cues, which leads to a minor significance of source characteristics. Sources that are usually regarded as simply not credible at all can improve the persuasiveness of their messages by delaying source identification (O'Keefe 2002).

Finally, the effects of credibility seem to decay over time. Hovland and Weiss (1951) discovered that messages of high-credibility sources lost persuasiveness after some time, leading to a lower extent of attitude change. Correspondingly, low-credibility communication seemed to be more effective at a later date than it had been directly after transmission. Regardless of many unsuccessful attempts to replicate these findings, this

so-called →  *sleeper effect*  gained much attention in communication research. It is assumed that message sources become forgotten or disassociated from the message. Effects of source characteristics such as expertise and trustworthiness seem to lose ground. Accordingly, long-term effects in persuasive communication are rather a result of message content than of source characteristics. However, the persuasive effects of messages also decay, but more slowly, thereby causing the sleeper effect. Although it is doubtful whether a general sleeper effect exists, it is an important finding that credibility effects probably are short-lived.

Although many questions still remain unanswered today, and although there is much criticism focused on theory and methodology, the last six decades of credibility research have produced a considerable amount of *agreement* among scholars concerning the nature and effects of credibility (Perloff 2003). First, most researchers agree that credibility is a perceptual variable – the result of an attribution process, not a property of a communication source. Second, there is an agreement that source credibility is a multidimensional construct, though the quantity and quality of credibility dimensions is controversial. Third, there is no doubt that under certain circumstances communicator credibility has a strong influence on audiences; however, there is no linear relationship between the (perceived) level of credibility on the one hand and the magnitude and persistence of effects on the other hand. To understand the effects of credibility in human communication it is necessary to attend simultaneously to the different intervening factors. The attribution of credibility and its effects on audiences result from a complex social interaction that includes all parts of the communication process.

# Crime and Communication Technology

Paul Ekblom

University of the Arts London

Crime and communications are perennial and pervasive features of society, while equally subject to dramatic change. They have a complex and evolving relationship, covering both the communications function or service and its realization through communication technology (→ Technology and Communication). Attempts to control crime involve both conventional law enforcement/criminal justice and broader, more “scientific” approaches to prevention.

Crime is simultaneously a set of hazardous events and the expression of social conflicts, varying in seriousness from littering to terrorism (→ Terrorism and Communication Technologies); in target from property to person, organization, group, and society; in motive from materialism to sex, power and status, revenge and ideology; in organization and complexity from impulsive vandalism to international networks of people-traffickers; and pervading all of society from homes and shops to global financial systems in cyberspace. Beyond individual criminal events, *fear* of crime and distrust and avoidance of people, places, services, or systems prone to crime may have independent negative effects on social and economic life for individuals, economies, and communities – hence the interest in the role of the media in elevating fear (→ Crime Reporting; Risk Perceptions) and the wider “quality of life” concept of community safety. The *trust* necessary for secure transactions and services is difficult to establish/maintain in the absence of face-to-face contact, posing a serious problem for government, trade, financial, and other systems increasingly based on remote communications (→ E-Commerce).

## COMMUNICATION TECHNOLOGY AND CRIME

The evolving relationship between communications and crime mostly involves old crime in new forms (such as school bullying switching to cyberspace with hostile text messages or “happy-slapping” – taking movie clips of assaults for camera-phone transmission to friends). Entirely new crimes are unlikely except for contraventions of new regulations protecting communications themselves, such as anti-spam laws or those criminalizing possession of equipment for overcoming security features of mobile phones (→ Internet Law and Regulation). The crime–communications relationship can be understood using the “misdeeds and security” framework. This distinguishes generic roles which some functioning object, service, or system, or its underlying technology, can play in criminal events and processes.

For instance, communications as both a service and a technology can be *misappropriated* and act as a target of crime by being stolen or fraudulently obtained. Both can be *mis-treated*, as for example through damage via denial of service or hacking (→ Hacktivism). *Mistakes* in communications, as with accidental emergency calls to police from improperly locked and protected mobile phones, can also deny service, and *mishandling* may include improperly obtaining information in transit, or inserting false/misleading information into a message stream. *Misjustification* can take place when pedophiles or animal-rights extremists come to assume that their views and activities are widespread

and acceptable through, for example, self-selecting newsgroups (→ Network Organizations through Communication Technology). *Misbehavior* with a communication system includes putting obscene or satirical messages on it for wider transmission. Both function and technology can be *misused* in the service of crime, whether by giving false information (as in hate-crime websites); obtaining information by deception (phishing: sending emails purporting to come from the receiver's bank requesting confirmation of security details, which are used to plunder the account); fraudulent sales, or disposal of stolen goods, on Internet auctions; coordinating crimes, football riots, or terrorist attacks; spying on rivals, enemies, or sexual prey; or remote detonation of bombs. A whole series of compound criminal involvements can occur; for example, *mishandling* of signals from remote car-locking devices by illicit reception, then *misusing* the code to *misappropriate* the vehicle.

With communications *technology* and items such as mobile phones, there are empirically and theoretically based risk factors (Clarke and Newman 2005): products most likely stolen are concealable, removable, available, valuable, enjoyable, and disposable. Trends toward miniaturization, portability, and added value that drive legitimate markets in mobile phones also drive theft. Continual emergence of new products/features and fashion considerations ensure that neither legitimate nor illegitimate demand diminishes with saturated markets.

With the communications function, several aspects are important:

- *Physical constraints* affecting risk, effort, and reward ratios in real-world crimes lose their strength or relevance; for example, emails can be intercepted anywhere in the network, and Trojan-Horse software accidentally received over the Internet can turn computers into spies that reveal passwords and bank details to remote users. Vulnerabilities can be rapidly and efficiently exploited before any compromise and loss are detected and loopholes closed.
- The *identity of offenders* is often linked only tenuously to the crime "scene," and *social constraints* from empathy with personal victims are weakened if the victim cannot be seen, heard, or imagined.
- Electronic media expose children to peer and other nonparental influences in *socialization*, which may create/reinforce a criminal predisposition, though research evidence remains conflicting (→ Media Use and Child Development; Socialization and the Media).
- Technologically enabled *cross-jurisdiction crimes and criminal collaborations* inhibit enforcement through diversity of national legal systems, extradition barriers, and even what constitutes crime or what is a local priority for enforcement (as with Internet pedophilia).
- *Specialist knowledge and equipment for law enforcement* involving modern communication systems are scarce and costly, and *organized crime* especially builds itself around networks.
- *Knowledge transfer among criminals* is facilitated – the Internet and search engines make information on explosives, lock-picking, etc. readily available.

## LAW ENFORCEMENT, CRIMINAL JUSTICE, AND CRIME PREVENTION

Criminal events extend beyond offender and victim to include the infraction of formal rules and informal norms supported and enforced by society. However, these traditional

approaches to crime control have significant limitations. Their capacity is constrained and the cost-effectiveness of conventional law enforcement and imprisonment is also limited. Alternative, preventive forms of crime control with potentially greater capacity and cost-effectiveness and fewer side-effects have developed on a more rational, causal, and evidence-based footing (Sherman et al. 2002).

Crime prevention reduces the risk and potential seriousness of criminal events by intervening in their causes. Preventive interventions can broadly be classified in terms of whether they act through manipulating the disposition and motivation of the offender (usually via attempts to influence the risk and protective factors in parenting, schooling, etc., and current life circumstances such as poverty or stress), or the immediate crime situation. Practical methods of “situational crime prevention” (Clarke 1997) change the immediate environment to influence offenders’ “rational” perception of risk, effort, and reward and hence their decision to commit a crime.

Situational and offender-based causes (and equivalent preventive interventions) are combined in the conjunction of criminal opportunity framework, which has been applied to cyberspace (Collins and Mansell 2005, 64, Table 7). This describes the causation of criminal events in terms of *offenders* predisposed, motivated, and equipped to commit crime, encountering or engineering a *crime situation* with a vulnerable, attractive, or provocative target in a conducive environment. The environment may *lack* people (or intelligent, active software) that act as crime preventers and *contain* those who act as “crime promoters” such as fences, or those “criminal service providers” who circumvent security by supplying passwords or doctoring security chips on mobile phones.

## DESIGN AND EVOLUTION

Crime prevention is only one of many requirements in communications systems/technology and is often low in priority for the commissioners and users. Designers are challenged by “troublesome tradeoffs” between security and cost, convenience, privacy, fail-safety, and a range of other values. Since there is little to distinguish illegitimate from legitimate use of communications, making systems *user-friendly* while *abuser-unfriendly* demands informed creativity and subtlety of the same order as medicine requires when destroying tumors without killing healthy tissue.

Crime and crime prevention are locked in an arms race, with preventers struggling to keep up with adaptive criminals and changing circumstances. Designers of many new technological applications and systems fail to “think thief” and a vulnerable product or service appears on the market, followed by a “crime harvest” and often inefficient or awkward attempts to retrofit security. Even when the motivation to forestall crime is there, the emergent properties of complex systems mean that surprise opportunities for crime will appear. *Laws* are especially prone to lag behind new forms of crime, particularly in rapidly evolving and complex technical fields where moral/ethical issues are not entirely clear and agreement is hard to reach. Communications technology and services are one such field, with advantage continually shifting between offenders and preventers in perpetual disequilibrium – “disturbed ground” in ecological terms.

Although preventive *principles* are perennial, knowledge of what specific preventive *methods* work is thus a wasting asset. To keep crime at tolerable levels preventers must

out-*innovate* and anticipate criminals; and must apply strategies such as researching *offender capabilities*, *horizon-scanning*, built-in *future-proofing* (as with automatically downloadable security patches for computer operating systems), generating a *variety* of security features and hence maximizing *design freedom*, and developing security standards based on *performance criteria* rather than fixed technical specifications.

## TOLERATION OF CRIME

“Rational” approaches to coping with crime problems can include simple *toleration and concealment*. Politically unacceptable in the public sphere, toleration, and the passing on of costs to consumers, is a common strategy in commerce. It is more likely where the costs of criminal justice involvement and the effects on a company’s reputation for competence and security are considerable, the costs of prevention are high (and may even put off customers through inconvenience), and the costs of crime to the company are limited (profit may sufficiently outstrip loss even with a large “parasitic burden” of crime). However, such toleration and inactivity allow *collective* commercial and social costs such as mistrust to grow, and they amount to market failure. Where victims are not companies themselves but third parties (such as purchasers of goods or services that are then stolen or enable identity theft), companies’ savings on security specifications become externalized costs to users, other citizens or organizations, and the taxpayer.

In such circumstances governments have felt obliged to step in. Attempts to *incentivize* crime prevention have included “climate setting,” by encouraging the public as customers or shareholders to understand that companies have some causal and contributory moral responsibility for the occurrence of crime, and to *expect* that they will alter their products or services to reduce the risk. Market forces can be awakened or supplemented by publishing a theft index of vulnerable makes, models, or services, “naming and shaming,” providing financial incentives, or fostering pre-competitive collaborations.

## Crime Reporting

*Claire Wardle*

*Cardiff University*

Crime reporting represents a significant component of → newspapers in the western world. This is the case for both broadsheets and tabloids, although crime coverage in tabloids tends to be more sensational, in terms of the types of crime covered, as well as the use of emotive language and visual images (→ Photojournalism; Sensationalism; Tabloid Press). The most up-to-date research in the US and UK suggests approximately 25 percent of newspaper articles are dedicated to crime and justice stories (Reiner et al. 2003). Furthermore, studies have shown crime news stories are read and remembered by a greater percentage of readers than any other type of news story (Graber 1980; → Exposure to the News).

Crime news in Europe can be traced back to reports of *witchcraft trials* in the late sixteenth century. Around the same time, specific pamphlets dedicated to crime news emerged, which included regular court reports written by court clerks. The amount of crime reporting increased in a variety of printed formats, as the commercial benefits of the genre became established. In the US, crime reporting was less common, although notorious crimes often warranted special reports from the courtroom. It was only in the 1830s, however, that crime news became a staple of newspaper reporting, with the advent of the penny presses, the overtly populist daily newspapers in the major eastern seaboard cities.

Although crime reports in different newspaper types and geographic locations can differ to some extent, they have many similarities. Newspaper scholars have acknowledged the influence of a powerful set of → news values, which influence the types of crimes that are covered, and the ways in which the stories are told. The types of crimes most commonly featured in newspapers are those which display certain characteristics: serious; extraordinary; violent; sexual; include children as either the victim or the perpetrator; can be blamed on individual deviance, rather than cultural or political explanations; and include graphic or emotive visuals (→ Emotion; Emotions, Media Effects on).

As reporting became more specialized, the crime beat established itself as a central feature of newsrooms, with trainee reporters frequently starting their journalistic life covering crime, honing their reporting skills while building relationships with local police officers. These loose relationships between reporters and police officers have become

increasingly professionalized, with police forces developing media relations departments that work closely with the media, particularly during large-scale investigations (→ Journalism, History of; Professionalization of Journalism). The relationship between the press and the police works on the basis of mutual reliance, with both sides requiring the support of the other in the course of their work. It also helps to explain the relative absence of reporting about courts and prisons, as equivalent relationships between representatives of these two institutions and the press rarely exist.

The most common characteristic of crime reporting is that newspapers tend to focus on the incident of the crime itself. If a report is particularly high profile, because it meets a number of established news values, coverage of the crime investigation will be included, and perhaps even the trial in the months that follow. Information about custodial sentences is rarely included, although executions are widely reported.

There are various *explanations for the continued prominence of crime reporting* in newspapers. One is the fact that crime news sells, with readers fuelled by a fascination that “it could happen to you” (→ Affects and Media Exposure; Enjoyment/Entertainment Seeking). Second is the instinctive appeal of crime news: the good versus evil composition of reports that mirror childhood fairy tales and follow the simple narrative structures of fiction. Some have argued that crime reporting provides moral boundaries for social behavior, exposing and demonizing criminal behavior. A final explanation for the amount of coverage is the institutional influence of the crime beat system, which provides a steady stream of easily investigated, well-sourced material.

*Critics of crime news* can be found in large numbers. The most common criticism is that newspapers focus on unusual crimes, raising levels of fear, particularly about violent and sexual crimes. Many scholars point to the invisibility of other crimes, such as white-collar crime or sexual abuse within the home. Similarly, critics bemoan the disproportionate focus on the victims, and the frequent absence of any contextualization about the motive of the offender. This lack of context can lead to increasing support for more punitive punishments in society.

In 1972, Stanley Cohen wrote *Folk devils and moral panics*, which described the amplification of fear, and the knee-jerk moralistic reactions that can arise when the press concentrate their attention on a specific type of crime or deviance. Media scholars have identified the same pattern in news reports over the past 30 years, from subjects as varied as pedophilia to carjackings. Moral panics are caused by disproportionate amounts of attention given to particular crimes, and certainly the amount and type of crime news appearing in newspapers is significantly different to the crimes reported officially. Violent crimes are far more likely to be featured than property crimes, such as burglary, and while murder is the rarest crime, it is the most likely to receive coverage. Criminologists complain frequently about the effect of the coverage, believing it leads to misinformation and confusion about current crime figures.

## **Crisis Communication**

*W. Timothy Coombs*

*Eastern Illinois University*

The topic of crisis communication has attracted a great deal of attention from researchers in → public relations, → corporate communication, → marketing, and management. The ever-growing body of research is both a blessing and a curse. There is a large amount of information, which is good. However, the insights are scattered throughout a myriad of books and journals, making it difficult for crisis managers to uncover. In addition, there are some serious shortcomings to the literature.

### **KEY DEFINITIONS**

Crisis communication is usually associated with how management responds to a crisis. The emphasis is on what the organization says and does in response to the crisis (Benoit 1995; Coombs 1999; → Organizational Communication). The focus is on public statements and actions by management. The belief is that how an organization communicates during a crisis has important ramifications for how stakeholders will (1) perceive the organization in crisis, such as reputation (→ Corporate Reputation), and (2) interact with the organization in the future. However, there are important elements of crisis communication that transpire within the context of the crisis team. The crisis team must gather and process information in order to make decisions about how to respond to the crisis. Hence, crisis communication can be divided into two broad categories: public crisis communication and private crisis communication.

A “crisis” is the perception of an unpredictable event that threatens important stakeholder expectations, significantly impacts the organization’s performance, and/or creates

negative outcomes. In general, “crisis communication” is the body of messages created to address the crisis. *Public crisis communication* is composed of the messages (words and actions) directed toward stakeholders outside of the crisis team. Examples would be warning sirens, product recall notices, statements about the time and extent of a supply chain disruption, and basic details about the crisis event. Typical stakeholders involved in crises are customers, communities, investors, suppliers, government agencies, news media, and employees. Employees are part of the organization but messages sent to employees about the crisis are often released publicly and are seen by other stakeholders as well. An example would be updates posted on an organization’s website.

*Private crisis communication* is composed of messages between crisis team members and private messages sent to employees. The collection and processing of information and decision-making by the crisis team constitute the core of private crisis communication. Restricted access messages sent to employees, such as automated response systems and intranet postings, would be considered private as well. There is a natural connection between private and public crisis communication. The public statements made during a crisis are a result of private discussions and deliberations by the crisis team.

## RESEARCH LINES IN PUBLIC CRISIS COMMUNICATION

### The Origins of Crisis Communication

The vast body of public crisis communication research can be divided into *three broad traditions*: (1) practitioner lessons, (2) rhetorical, and (3) social-psychological. Each tradition brings with it certain assumptions and research methods. The limited research addressing private crisis communication focuses on information processing and decision-making.

The initial discussions of crisis communication were provided by practitioners who drew lessons from their crisis experiences. There is no research method, just observations from experience. These lessons focused on the basic form of a crisis response: be quick, be accurate, be open, never speculate, and never say “no comment.” Crisis managers should respond in an hour or less but be confident in the accuracy of the information. Being open means a willingness to field inquiries from stakeholders and report what is known about the crisis. Never speculate because speculation could be wrong and make the company look incompetent or deceptive. Avoid “no comment” because stakeholders take that to mean the organization is hiding something (Coombs 1999). These lessons make sense, and later research has shown their value. But these early lessons fail to dig below the surface and to help crisis managers understand the dynamics of crisis communication. Applied research in crisis communication developed to unpack the dynamic.

### The Rhetorical Tradition

The rhetorical tradition is rooted in apologia (→ Apologies and Remedial Episodes; Rhetorical Studies). Apologia is a genre that examines how people respond to character attacks, or self-defense. A person is accused of engaging in some inappropriate act. Apologia posits that there are four rhetorical strategies for responding to these charges: denial, bolstering, differentiation, and transcendence. Denial claims the person did not do anything

wrong. Bolstering connects the person to something others would view positively. Differentiation attempts to take the act out of its current, negative context. The idea is that it is the negative context, not the act, that creates unfavorable stakeholder reactions. Transcendence attempts to place the act in a broader context to make an event seem more favorable. Dionisopolous and Vibbert (1988) were the first to argue that organizations could engage in apologia. Their premise is that organizations have a public persona (a reputation) that may be attacked and in need of defense; organizations can experience and respond to character attacks. Their book chapter outlines the parameters of corporate apologia without specific application to crisis management (Dionisopolous & Vibbert 1988).

Keith Hearit (1994) is the researcher who developed *corporate apologia* into a distinct line of research. Hearit has articulated a unique perspective for integrating corporate apologia into crisis communication. Social legitimacy, the consistency between organizational values and stakeholder values, became a focal point. A crisis can make an organization appear incompetent (e.g., a hazardous chemical release) and/or violate stakeholder expectations (e.g., unfair labor practices), thereby threatening social legitimacy. A social legitimacy violation is a form of character attack and crisis communication can be used to defend the organization's character (Hearit 1994).

William Benoit (1995) drew upon apologia, guilt and redemption, and account analysis to create his → image restoration theory. *Image restoration theory* holds that one's → image (reputation) is important and communication can be used to defend against attacks on an image. It assumes communication is goal directed, and that maintaining a positive image (reputation) is a central goal of communication. Image restoration theory can be used when an image is threatened by an unfavorable act and the person is held accountable for the act (Benoit 1995). Image restoration theory was not designed specifically for crisis management but Benoit and others have applied it to a wide variety of crisis cases, including airlines, entertainment, and the chemical industry. A crisis is one of the situations when an organization is accused of objectionable behavior. Since such a situation can damage an organization's reputation, communication can be used to explain the behavior and repair the reputation.

Research in the rhetorical tradition tends to be → case study and qualitative in nature (→ Qualitative Methodology). The end result is that the conclusions are a suggestion and not "tested" recommendations. Image restoration theory is an example. Image restoration theory favors a public acceptance (mortification) as the response for most every crisis. Management is not always willing to do that because of the financial costs. Moreover, quantitative research indicates that mortification is not always the best option, nor are many of the suggested conclusions of image restoration theory accurate (Coombs & Holladay 1996).

The overdependence on case studies in the rhetorical tradition is problematic. While interesting, the cases shed precious little light on *how* stakeholders react to crises or public crisis communication. As Dowling (2002, 252) noted, "to date there are few published scientific studies of how a crisis (adversely) affects a company's images or reputations. Much of what (we think) we know is opinion based rather than well researched. For example, many managers believe that a good corporate reputation acts as a type of insurance policy the first time the company faces a serious crisis."

### The Social-Psychological Tradition

The social-psychological tradition is rooted in *attribution theory* (→ Attribution Processes). Attribution theory posits that people search for the cause of events, especially events that are unexpected and negative. People will attribute a cause either to the person involved in the event or to external factors. The causal attributions people make influence their feelings and behaviors toward the actor (Weiner 2006). The more we hold a person responsible for an action, the more negatively we will view that person, and it will affect our future interactions.

It is logical to connect crises and attribution theory. Stakeholders will make attributions about the cause of a crisis (a negative event) by assessing crisis responsibility. Was the crisis a result of situational factors or something the organization did? Indeed, extant research forges a link between attribution theory and crises (Bradford & Garrett 1995; Coombs 1995; Stockmyer 1996). Stakeholder attributions of crisis responsibility have perceptual and behavioral consequences for an organization (Coombs & Holladay 2005). If the organization is deemed responsible, the reputation (a key perception of an organization) will suffer. Stakeholders may also engage in negative word-of-mouth about the organization and/or sever their relationship to the organization (e.g., sell stocks or stop purchases). Attributions of crisis responsibility are a threat to an organization.

The key to using attribution theory is to understand what shapes stakeholder attributions of crisis responsibility, even when there is little information about the crisis. A variety of cues are used to make attributions of crisis responsibility. Understanding these cues helps managers to effectively respond to the crisis. Situational crisis communication theory (SCCT) offers one framework for predicting stakeholder attributions of crisis responsibility and reactions to crises. SCCT argues that by understanding the threat presented by a crisis situation, crisis managers can determine which crisis response strategy or strategies will maximize reputational protection and reduce the likelihood of negative behaviors. SCCT fuses the rhetorical and social-psychological traditions. The social-psychological tradition helps to identify the threat and the rhetorical tradition provides the communication strategies.

SCCT notes that the crisis type, crisis history, and prior reputation are the essential cues used to evaluate crisis responsibility. The *crisis type* is how the crisis is being framed. Frames are the cues stakeholders use to interpret a crisis (Coombs & Holladay 2002; Dowling 2002). The crisis type serves as a frame that indicates how people should interpret the crisis events. Was the event an accident, sabotage, or criminal negligence? Research using SCCT has found that crisis types cluster into three groups based upon assessments of crisis responsibility: (1) victim, very weak attributions of crisis responsibility; (2) accidental, minimal attributions of crisis responsibility; and (3) preventable, strong attributions of crisis responsibility (Coombs & Holladay 2002).

Crisis history and prior reputation serve to intensify the attributions associated with a crisis type. *Crisis history* refers to whether or not an organization has had a similar crisis in the past. *Prior reputation* refers to how well or poorly an organization has treated stakeholders in other contexts. A history of crises and/or a negative prior reputation will intensify attributions of crisis responsibility (Coombs & Holladay 2004). Applied to crisis management, a victim crisis will present the same threat as an accidental crisis and an

accidental crisis will present the same threat as an intentional crisis when either a crisis history exists or the prior reputation is unfavorable.

SCCT posits that the greater the threat, the more accommodative the response. The general recommendations from SCCT are as follows: for victim crises, provide instructing information (tell stakeholders how to protect themselves physically from the crisis) and express concern for victims; for accidental crises, add statements that reinforce the crisis was an accident to the instructing information and expression of concern; and for intentional crises, add either a public acceptance of responsibility and/or offer compensation to victims in addition to instructing information and expression of concern (Coombs 2006).

It would be simple to just use the most accommodative response all the time. But the costs and yields argue against that. Expenses increase as strategies become more accommodative (Stockmyer 1996). Moreover, using overly accommodative strategies produces no greater benefits than those recommended by SCCT. For example, accepting responsibility for an accidental crisis provides no greater reputational benefit than reinforcing that the event was an accident and expressing concern. Management pays more for the response but does not see a corresponding yield in reputation repair (Coombs & Holladay 2004). Furthermore, using an overly accommodative strategy may have a boomerang effect. Stakeholders may wonder why an organization has engaged in overkill. They may even wonder if the crisis is worse than they thought (Siomkos & Kurzbard 1994).

One problem with the social-psychological tradition is a failure to extend it much beyond the US. Researchers have begun to explore its application in China and the role of ambiguity tolerance in evaluating crisis responsibility. Maureen Taylor (2000) is right in arguing for the need to apply intercultural concepts, such as those of Hofstede, to crisis communication. Cultural variables such as ambiguity tolerance and power distance must be factored into the social-psychological tradition research to permit an international application of the findings.

### **PRIVATE CRISIS COMMUNICATION: INFORMATION PROCESSING AND DECISION-MAKING**

Situational awareness is the focal point of private crisis communication. In general, situational awareness is when the crisis team feels it has enough → information and knowledge to make a decision (Kolschoten & Appelman 2006). Knowledge is the end result of processing information. Information is the raw material and knowledge is the output. For the crisis team, situational awareness indicates that there is a perception and understanding of the crisis situation, and the ability to predict the effects of it and to determine what actions are needed to address it (→ Information Processing).

The crisis team must identify the information it needs and the sources that would have it, retrieve the information, and process it into knowledge. Researchers such as Egelhoff and Sen (1992) have noted the value of information processing, while Wang and Belardo (2005) emphasized → *knowledge management* as central to crisis communication. However, little research has explored the actual information processing and knowledge management of crisis teams. We know something about the problems that plague information processing/knowledge, but not much more than that. This is an area in need of further study. We

must understand in more detail the problems crisis teams will encounter in reaching situational awareness and how to overcome those problems.

*Situational awareness* is a prelude to decision-making. Once teams feel they have enough knowledge, they make decisions about how to respond to the crisis. There is a large body of work on decision-making in organizational groups. From this research emerge recommendations for vigilant decision-making. Vigilance applies critical thinking to group decision-making by emphasizing the need for careful and thorough analysis of all information related to a decision (Olaniran & Williams 2001). Four critical vigilant decision-making functions aid the decision-making process: problem analysis, standards for evaluating alternative choices, understanding the important positive aspects of an alternative choice, and understanding the important negative aspects of an alternative choice. Each of these functions helps to correct a factor that could contribute to decision-making.

Research has begun to explore how crisis teams actually make decisions, naturalistic decision-making (NDM). NDM studies decision-makers in the field. Crisis teams operate in a very dynamic information environment characterized by ambiguity, stress, risk, and time pressure. Due to the decision-making environment, crisis teams will not always be able to apply normative (ideal) decision-making models. Researchers have just begun to explore how crisis teams actually make decisions, and determine the correct course of action. Again, more research is needed to understand how crisis teams make decisions and what can be done to facilitate the team making effective decisions.

## Critical Rationalism

*James A. Anderson*

*University of Utah*

Critical rationalism is, first of all, the solution proposed by Karl Popper to the epistemological problem of the growth of knowledge. Second, it has come to be one description of the method by which science progresses. And, third, it has become an ideological position which both continues the project of the Enlightenment and celebrates the role of communication in the field of knowledge. The essence of critical rationalism is contained in four steps: (1) Through intuition, ignorance, or other circumstance, even blind luck, “we stumble over some problem” (*Myth*, p. 101). (2) We attempt a solution by boldly proposing a theory that entails material consequences that can be tested. (3) Our conjecture and tests are subjected to rigorous critical review and stringent testing by the scientific community. (4) The results of this process are used to refine our original understanding of the problem, and we return to step (1).

Critical rationalism, therefore, represents several differences from what Suppe (1989) calls the “received view” of science. First, it changes the starting place, which was and often still is considered to be careful observation. Second, it encourages dicey hypothesizing (Miller 1994). Third, it demands deductive rationalism as the basis of critique. Fourth, it requires both a review community and a community review. And last, it considers the process to be iterative and nonconclusive, although further refinement may be deemed currently unnecessary or too costly.

For Popper, the central epistemological problem was the growth of knowledge, which is best studied “by studying the growth of scientific knowledge” (*Logic*, p. 15). In crafting his argument for critical rationalism, Popper rejected inductionism, psychologism, probabilism, and verificationism, and advanced falsificationism and fallibilism (→ Deduction vs. Induction vs. Abduction).

## FOUR PRINCIPLES REJECTED BY CRITICAL RATIONALISM

### Inductionism

Inductionism supports a general principle of inductive logic by which we can move from statements of the particular (this swan is white) to statements of the universal (all swans are white). Popper rejected the possibility of inductive logic, because even a very large number of white swan sightings do not preclude the existence of a nonwhite swan. Accordingly, there is no way to move from experience (a series of singular events) to a justified hypothesis (a tentative universal statement) or from particular supporting tests of any number to a justified theoretical claim. The empirical basis of science, therefore, is not at the beginning of the process, but in the middle, within attempts to falsify a theory by demonstrating the failure of the material consequences deductively predicted from that theory.

Popper’s rejection of induction has implications for a description of science as moving in verifiable ways from observation to theory to hypotheses to confirmation, as proposed by Bacon (*Cogitata et Visa*, 1607; *Novum Organum*, 1620), and still used in standard textbooks. Popper’s starting point for science is not observation, but a problem. The goal of science is the continued refinement of that problem, which yields theory, hypotheses, as well as observations.

### Psychologism

The role of psychology in the philosophy of science is a continuing source of debate (e.g., Fuller 1992). To provide an empirical basis for scientific claims, psychology has been introduced in the form of “the doctrine that the empirical sciences are reducible to sense-perceptions and thus to our experiences . . . [This doctrine] is one which many accept as obvious beyond all questions” (*Logic*, p. 93). Popper’s rejection of the doctrine does not question that experience and its observations are central to science, but rather, he denies that experience could be the basis for accepting something as true (*Logic*, p. 98). As he points out, the ostensibly simple sensory statement, “this swan is white,” depends on the universal principles of swan-ness and whiteness. One’s unmarked experience of being

certain of the swan in sight happens only once, and is unique to the individual. Neither the experience nor the conviction can be shared except through some transformation. That transformation depends on something that is not in the experience, and is variable according to the rules adopted to govern the transformation. In making this argument, Popper rejected the various forms of positivism, accepted that theory inhabits every observation, and went on to establish a new standard of objectivity.

Positivism is a philosophical system of thought that addresses the certainty of knowledge. It is attributed in Enlightenment times to Auguste Comte, but the principles reach back to the Greek empiricists (Aristotle, Epicurus, and the Sophists). Positivism and its modern expression in logical positivism assumed the independence of theoretical statements from statements of observation – a position that Popper explicitly rejected: “Every observation and, to an even higher degree, every observation statement, is itself already an *interpretation in the light of our theories*” (*Realism*, p. 222). Critics of positivism have used this position to declare that no observation is possible without theory and that, therefore, observations made under the aegis of one theory cannot be compared with observations made under another. This doctrine – the incommensurability of theories – is often used to defend one family of theories against attacks from another. Popper, however, rejected this extreme, as well (as he must in order to sustain falsification). He pointed out that all (known) sentient beings start out with the same a priori (the material world). Consequently, all theories can be compared, although the task may be more difficult across some theories. He offered the slogan, “I may be wrong and you may be right, and by an effort, we may get nearer to the truth” (*Myth*, p. xii).

Popper finds his *standard of objectivity* in this joint effort (→ Objectivity in Science). The need for the new standard stems from his rejection of the presumed independence of observation and theory statements. Objective observations are replaced with hybrid statements that are an indivisible mixture of fact and interpretation. How, then, does science protect itself from this inherent bias? Popper’s answer is first to warn us against false expectations and then to note the work to be done: “Science has no certainty, no rational reliability, no validity, no authority. The best we can say about it is that although it consists of our own guesses, of our own conjectures, we are doing our very best to test them; that is to say, to criticize them and refute them” (*Realism*, p. 222). Popper does not expect the individual scientist to criticize his or her own theory, but does demand that the *scientific community* commit itself to the practice of critical review and refutation.

### **Probabilism**

Probabilism is the practice of assigning truth-probability values to statements. Popper rejected all forms of induction, including those that depend on probability. In this form of induction, statements are arranged along a continuum anchored by ideal (but unattainable) end points of true and false, according to their likelihood of being true. For the swan example, the form might be, “all the swans I have seen are white, therefore it is most likely that all swans are white”; or, “all the swans I have seen are white, therefore, non-white swans are rare”; or, “all the swans I have seen are white, therefore, it is most likely that the next swan I see will be white.” For Popper, all these statements are inductions because a set of experiences is used to describe a universal set without any

knowledge of the universal. In the absence of such knowledge, one cannot establish the probability of any possible subset. Our sense of the truth of the matter, thus, is a psychological condition, not an epistemologically valid conclusion (*Logic*, p. 255).

Popper spends a good deal of time on this pernicious problem in at least four different volumes (*Logic*, *Realism*, *C&R*, and *Myth*). To him, there is no way of developing the probability calculus because the degree of corroboration depends, not on the number of tests that support a hypothesis, but on the complexity of the hypothesis and the quality of the attempts to refute it. A thousand replications of one supporting protocol offers no decrease in the probability of dozens of other tests that will refute the hypothesis. Further, a hypothesis with a 90 percent chance of being true can still be false. Consequently, it remains merely a statement not yet falsified.

Finally, Popper holds that probabilism encourages scientists to test only what is known to work, to become uninspired and uninspiring: “Every interesting and powerful statement must have a low probability; and *vice versa*: a statement with a high probability will be scientifically uninteresting, because it says little and has no explanatory power. Although we seek theories with a high degree of corroboration, *as scientists we do not seek highly probable theories but explanations; that is to say powerful and improbable theories*. The opposite view – that science aims at high probability – is a characteristic development of verificationism: if you find that you cannot verify a theory, or make it certain by induction, you may turn to probability as a kind of *Ersatz* for certainty, in the hope that induction may yield at least that much” (*C&R*, p. 65).

Although Popper would not admit that a theory can have, for example, a 90 percent chance of being true, he argues that we can distinguish theories and hypotheses according to their *degree of corroboration*. This phrase may sound like a probability but, it is instead an evaluation of the quality of the refutation attempted and of the severity of the tests that have failed to falsify the theory and/or hypothesis in question. The mere accumulation of confirming instances adds no new information about or value to the theory/hypothesis. Consequently, he would reject a simple counting as in arguments beginning with “many studies have shown.” A theory advances on the basis of a complex analysis of the deductive consequences that a theory/hypothesis entails and of the quality of the tests that have demonstrated (or failed to demonstrate) their occurrence.

This argument appears to have implications for *evidence from convergence*. In convergence, a statement can be held to be true if the preponderance of evidence supports the truth of the matter. Popper would consider this an extension of the statement: “all the swans I’ve seen are white,” which itself depends on the methodology of looking at swans. He argued that the fact that a particular methodology generates consistent results simply reflects on the methodology, not on the validity of the finding as a universal statement.

### Verificationism

Verificationism in science assumes that statements are meaningful only to the extent of their empirical content. Empirical content is material phenomena that can either be experienced directly or produce a necessary link to sensory experience. Verificationists use this principle as a demarcation between scientific and nonscientific statements, so that a statement with no empirical content is scientifically meaningless. This requirement

would appear to rule out many variables that are of relevance to communication research, such as uncertainty, compliance, or apprehension. (The solution was operationalism – a contested, but generally accepted practice – by which a concept like uncertainty is defined in the methods of measurement adopted.) Verificationists also advance the argument that each hypothesis has a crucial test or series of tests that would justify its acceptance. Nearly all statistical studies in communication research can be seen to adopt this as a rhetorical, if not an epistemological stance.

Popper disagreed with verificationism on both points. He noted that atomic theory predated our ability to provide an empirical basis by several centuries. Atomic theory, nonetheless, was a worthy scientific problem that justified the effort to achieve an empirical basis. The immediate availability of empirical content, therefore, was not an acceptable demarcation criterion. His demarcation criterion was that the theory had to entail *potentially falsifiable consequences*.

Popper saw crucial tests as a return to inductionism – a point in his writings that has been lost in current notions of verification. No hypothesis or theory can ever be justified by an individual outcome or even the sum total of all supporting outcomes. No matter how many there are, outcomes can never deny disconfirming instances.

### **FALSIFICATIONISM AND FALLIBILISM**

Though one cannot verify a hypothesis, Popper's system does offer ways of evaluating a hypothesis or theory, proposing falsification both as a demarcation between science and nonscience, and as the appropriate means of assaying the possible truth content of a hypothesis. *Falsification* rests on deductive rather than inductive logic. A theory, to be scientific, must require certain empirical outcomes that can be deduced and tested to see if they actually occur. If the theory meets this requirement, it is falsifiable and meets the minimal requirements of science. The more outcomes it requires, and the more directly those outcomes can be tested, the more robust the theory. Any failure to achieve those outcomes falsifies the present theory and calls for its revision. Importantly, the occurrence of a predicted outcome does not verify the hypothesis, but simply declares it as not falsified. In the ordinary practice of inferential statistics, however, positive information is gained when the null hypothesis – a negation of a predicted outcome – is rejected (→ Statistics, Explanatory). No information is considered gained when the null hypothesis cannot be rejected. This practice, on the face of it, is a verificationist, not a critical rationalist approach.

Popper proposed *four classifications of statements about the world*: statements that can be but have currently not been tested (not yet in the active domain of science); statements that have been tested and not falsified (scientific statements under continuing review; the location of current scientific activity); statements that have been tested and falsified (statements held to be scientifically false and presumably returned for revision); and statements tested, not falsified, and no longer being tested (statements acted upon by the scientific community as scientifically classified as true). The first type of statement is perhaps uninteresting or currently intractable to testing. The second is the bulk of research. The third is where the controversies lie, and the last type of statement is part of the background knowledge of science that will be used to pose new problems and their tests.

Popper's original formulation of falsificationism has been the subject of much *critique* for its unfaithfulness to the actual practice of science (Lakatos 1970), its presumption of a common basis of comparison across theories (Feyerabend 1965), its inability to specify just when a theory has been falsified (Newton-Smith 1981; see also the Quine-Duhem thesis discussed in Klee 1997), or equally when it has been sufficiently corroborated (Salman 1978).

*Fallibilism* is the doctrine that all of science can be wrong both in the particular and in general. Popper believed that science had no special claim to authority or to certainty. While fallibilism has a long history, including the philosophy of → pragmatism, Popper's position should be understood within the cultural context in which he was writing (Germany in the 1930s, anticipating the rise of Hitler) and his personal distaste for dogmatism of any kind (*Open*). He avoided falling into unrelenting skepticism by holding that sufficient corroboration can justify classifying a claim as true, and acting on it as if it were true, without giving up the possibility that it may be false. Popper saw fallibilism as the opportunity for bold new conjectures about the world rather than as a limitation on human knowledge.

## CRITICAL RATIONALISM IN CONTEMPORARY COMMUNICATION SCIENCE

Critical rationalism has steadily advanced Karl Popper in the ranks of scholars rejecting positivism. Other key figures include Thomas Kuhn, Paul Feyerabend, Norwood Hanson, Imre Lakatos, Willard Van Orman Quine, Dudley Shapere, and Frederick Suppe. While most philosophers of science today would declare positivism dead, there remains a nostalgia for the clarity and simplicity that it provided. Positivist positions such as the unity of science, the observational basis of science, the corrective presence of an objective reality, and the mathematical framework of science still dominate discussions of communication as a science. Nonetheless, critical rationalism and its allies in the history and sociology of science have opened up spaces for practices in social science that were simply unavailable as few as 50 years ago, albeit still controversial today.

One particular appeal of critical rationalism is that it grounds science in communication practices. Science, in critical rationalism, progresses in the robust debate between contesting theories and their empirical evidence. In Popper's figuration, it was, however, an enlightened, Habermasian debate with all members situated in a common epistemology (→ Habermas, Jürgen). The continued fractionalization of the field suggests that communication researchers remain divided by epistemology as well as politics (→ Communication as a Field and Discipline).

Communication is a very young science which has yet to develop a center. The conventionalism of critical rationalism is difficult to achieve because there is little agreement regarding background knowledge and frameworks of evidence. It is not clear that there is a common community of review, or an open, public critique in the pages of our journals. There is promise and possibility, but little of a unified practice.

## **Critical Theory**

*Graham Murdock*

*Loughborough University*

The phrase “critical theory” was first promoted by the German philosopher and sociologist, Max Horkheimer, in a 1937 essay, “Critical and traditional theory.” An astute academic entrepreneur, he devised it to promote the approach to studying society and culture that he and his colleagues had been developing at the Institute for Social Research in Frankfurt, which he had headed since 1930, and which became an important influence on international media and communication research (Horkheimer 1972).

The later labeling of the group as *the Frankfurt School* with its strong connotations of a single position misrepresents both the scope and diversity of the members’ interests. The institute was a path-breaking interdisciplinary center that cut across the boundaries dividing philosophy from empirical inquiry and the humanities from the social sciences. It attracted scholars from a wide range of intellectual and academic backgrounds, including musicology (Theodor Adorno); political economy (Friedrich Pollock; → Political Economy of the Media); literary theory (Leo Löwenthal); political philosophy (Herbert Marcuse); and psychoanalysis (Erich Fromm). This heterogeneity generated novel theoretical combinations, but also disputes and disagreements – self-critical debate as a basis of social critique.

### **ORIGINS OF CRITICAL THEORY**

The Frankfurt group’s work was grounded from the outset in the *Enlightenment’s* core philosophical project of advancing human emancipation by replacing the rule of religious

dogma, hereditary privilege, and tyrannical government with the free and critical exercise of reason. Surveying the social landscape in the early 1930s, however, the Frankfurt group saw rationality increasingly used to develop technologies and administrative systems employed as instruments of domination rather than liberation – a process later reaching its terminal point in the Nazi death camps. The promise of the Enlightenment had been negated by the very forces it had set in motion. Horkheimer and Adorno set out to reveal this logic in their best-known book, the *Dialectic of Enlightenment* (1973, 1st pub. 1944).

Against the ascendancy of “instrumental reason,” Horkheimer and Adorno sought to develop a critical theory that would keep the promise of emancipation alive, identifying possible points of opposition. Marx’s critique of capitalism was central to that project. As noted in the opening chapter of Marx’s major work, *Capital*, the seductive surfaces of *commodities* concealed the dark secret of capitalism’s radically asymmetric power relations (→ Commodification of the Media). The intention of critical analysis is to reveal these hidden mechanisms, to demonstrate how they block Enlightenment principles of liberty, equality, and fraternity, and to explore ways of dismantling them. This project is critical in two senses: it proposes a comprehensive critique of prevailing systems of power; it also subjects its own assumptions to continual scrutiny – a double ambition summed up in Marx’s favorite motto, *De omnibus dubitandum* (“You must have doubts about everything”).

For Marx, capitalist power was not as secure as it appeared. In the immediate aftermath of World War I, with popular protests and insurrections across Europe, it seemed as though his prediction of mass workers’ risings was about to be fulfilled. However, only the Bolshevik revolution in Russia succeeded, and within a few years, Germany and Italy, both bastions of socialist and communist opposition, had witnessed the rise of Hitler and Mussolini and the establishment of fascist dictatorships. This reversal posed a major theoretical challenge for intellectuals of the left, prompting them to look beyond economics and politics – to culture.

## CRITIQUE AND CULTURE

For both the Frankfurt group in Germany and Antonio Gramsci in Italy, one central explanation for social developments in the first few decades of the twentieth century lay in the intensified management of cultural life and its enlistment in securing popular consent. In the Soviet Union, too, the explosion of experiments that followed the Bolshevik revolution had been replaced by socialist realism, mandated by Stalin. Nor was this tendency toward closure and centralization confined to totalitarian states. The Frankfurt group’s leading political economist, Friedrich Pollock, argued that it was becoming increasingly characteristic of the major capitalist democracies, including the US. The market-driven system of capitalism’s initial phase, with its relative openness to innovation, seemed to be giving way to *state capitalism*, in which more and more of the responsibility for managing the economic playing field passed to the state, leaving only pseudo-markets that were carefully engineered to match mass consumption to mass production. This argument strengthened Horkheimer and Adorno’s conviction that, in the absence of a radical workers’ movement, the cultural sphere was the next battleground. As Horkheimer argued, “Art breaks through the barriers” erected by “accepted forms of thought” and “the language of propaganda” and marketing (Horkheimer 1972, 279).

The idea of culture and art as a separate and autonomous realm, resistant to incorporation into the mundane worlds of economy and administration, had long been a theme in idealist German philosophy (→ Culture: Definitions and Concepts; Aesthetics; Art as Communication). For Adorno, culture in the true sense never simply accommodated itself to prevailing ideas and existing tastes – it always simultaneously raised a protest against the social relations within which people lived. His belief in the resistant power of art was at the core not only of his philosophical position, developed in graduate theses on Husserl and Kierkegaard, but also of his own creative experience. Adorno was an accomplished pianist, who had studied composition under the prominent avant-garde musician Alban Berg, and belonged to the circle surrounding the leader of the so-called Vienna School, Arnold Schoenberg. In Adorno's view, music retained an emancipatory potential, with two main characteristics. First, it was produced out of inner conviction, as an authentic expression of personal vision, rather than with an eye to sales. Second, instead of reconciling listeners to contradictions in society by offering the illusion of harmony, its formal structure should encourage a critical stance by engraving these contradictions in its innermost structure. Schoenberg's atonal string quartets met these criteria for Adorno; popular music, with its standardized formulae and routinized distribution, did not.

The relationship between popular and elite culture has remained high on the agenda of critical theory and research (→ Popular Culture). For the original Frankfurt group, this relationship was thematized in exile. As critical Jewish intellectuals in Hitler's Germany, their situation became untenable, and the institute moved, first to Paris and later to the US.

### EXILE IN POPULAR CULTURE

After a brief stay in New York, working in an uneasy partnership with → Paul Lazarsfeld on a research project investigating radio music broadcasts, Adorno joined Horkheimer in California. While there, he collaborated on a major research project on the popular roots of fascism published as *The authoritarian personality* (1950). His psychologist co-authors looked for determinants of anti-Semitic attitudes within the individual, but Adorno drew attention to the general cultural climate, and particularly to the role of mass media in molding public opinion. He explored this process empirically in 1943 with a detailed dissection of the radio broadcasts made by a right-wing Christian demagogue, Martin Luther Thomas, demonstrating how Thomas's personalized forms of address promoted an authoritarian populism and transformed religious bigotry into political and racial hatred (see Apostolidis 2000). This research was among proliferating studies of propaganda during and immediately after the war, including *Prophets of deceit*, a study co-authored by another Frankfurt group member, Leo Löwenthal (→ Propaganda in World War II).

Adorno's interest in the ideological role of media was not confined to politically motivated speech. He also explored how prevailing relations of power were bolstered by routine instances of popular culture, including the astrology column in the *Los Angeles Times*. By inviting readers to yield to invisible, pre-determined forces that paralleled the impersonal economic and administrative powers over which people had no control, he saw the daily predictions reinforcing everyday feelings of dependency. True to the

Frankfurt group's commitment to combining cultural, political, and economic analysis, Adorno developed his detailed analyses of particular media texts alongside a general structural critique of the commodification of cultural production and its consequences for the diversity of popular expression (→ Qualitative Methodology).

By the early 1940s, → Hollywood was a dominant force in world cinema; American jazz and popular music had achieved global reach; and commercial radio was an established everyday presence in American life. It was the dynamics shaping this imaginative landscape that Horkheimer and Adorno set out to investigate in *Dialectic of Enlightenment*. Subtitled "Philosophical fragments," the *Dialectic* was intended as a work in progress, and originally circulated as a mimeographed manuscript. The chapter on the → culture industry, still widely read, should be interpreted in this spirit, as an initial sketch of trends in cultural production rather than as a detailed analysis of the communications industries. In fact, the English translation conflates these two levels. In the original German, the term "culture industry" refers to the progressive transformation of cultural work, in all its forms, into commodity production, oriented to the market, while "*the* culture industry" refers more specifically to the mass media. The confusion is further compounded by Adorno's later admission that "the expression 'industry' is not to be taken too literally," and that their main concern was with the "standardization" of popular cultural forms and "the rationalization of distribution techniques, but not strictly the production process" (Adorno 1991, 87). There is little doubt, however, that Horkheimer and Adorno saw American commercial media as reproducing the stereotypical design and standardized assembly of any kind of commodity, and as prototypical of the rule of instrumental reason in the cultural sphere. "Cultural entities typical of the culture industry are no longer *also* commodities, they are commodities through and through" (Adorno 1991, 86).

The implication of such in-depth analyses was that the culture industry, specifically the drive toward standardization, was robbing popular culture of its critical potential. Adorno did admit exceptions, Charlie Chaplin's uniquely individual style, for example. He also pointed to detective novels, but noted that although they "regularly unmask" the sordid underbelly of capitalism, their "standardized schemas" would ensure that any challenge to the status quo was eventually charmed away by the "inevitable triumph of order" (Adorno 1967, 129). Even jazz improvisation was, for him, simply a collection of repetitive techniques, continually sorted out and kaleidoscopically mixed into ever-new combinations to produce the appearance of novelty, but no real innovation (Adorno 1967, 124). Returning to the relationship between popular and high culture, Adorno concluded that the creative autonomy defining genuine art was being eliminated, not because writers, performers, and musicians acted in bad faith, but because they – and their bosses – were employed in factories devoted to producing profits.

Many later commentators on Adorno and Horkheimer have assumed that they saw audiences as passively accepting the culture industry's blandishments. Horkheimer came closest when arguing that people had lost the power to conceive a world different from the prevailing system (Horkheimer 1972, 278), but in the *Dialectic*, consumers are cast as skeptics rather than dupes. They see through the promotional ploys, but nonetheless feel compelled to buy and use the products on offer (Horkheimer & Adorno 1973, 167). Audiences are not deceived, but the heartlands of popular culture offer them few

alternatives, making them informed accomplices. In Adorno's striking phrase, media users are "amphibians" moving between the solid ground of distrust and the pleasures of immersion in the warm waters of routine and repetition. This ambiguity has continued to occupy later critical communication studies.

### A CRITICAL LEGACY

With the end of World War II, the Frankfurt group dispersed. Marcuse and Löwenthal stayed on in the US; Adorno and Horkheimer returned to Germany. Despite a rapidly changing media landscape, neither pursued their analysis of the culture industry. The second generation of Frankfurt writers, led by → Jürgen Habermas, had different preoccupations. Appalled by the revelations of Hitler's "final solution," Habermas set out to construct a model for deliberative democracy, rooted in agreement through argumentation. He shared Adorno's view that the cultural resources for this project were becoming increasingly commodified, oriented to entertainment rather than Enlightenment, but offered no detailed analysis of how that general process operated in the contemporary media environment. This task was left, not least, to a disparate group of scholars in different national contexts who were developing a critical political economy of communications.

The US had survived the war unscathed by bombing, invasion, and rationing, enabling it to consolidate its strength in the film and music industries and to press forward with the major postwar medium: television. With the onset of the Cold War with the Soviet Union, the cultural industries assumed an unprecedented political significance. As the former colonies of the European empires achieved political independence, they became stakes in the struggle for global influence between the two new major powers. In accordance with the Frankfurt group's diagnosis, popular culture, again, became a key site in the battle for hearts and minds. A process of *cultural imperialism* was examined in detail by Herbert Schiller in a series of influential books, from *Mass communications and American empire* (1969) to *Culture Inc.* (1989; → Cultural Imperialism Theories). With a wealth of empirical examples, he described this dynamic as a logical extension of processes within the US that were marginalizing critique and mobilizing media around the promotion of consumerism. Although Schiller's work was indebted to the Frankfurt group, particularly Marcuse's *One-dimensional man* (1964), which achieved wide readership when they were both colleagues at the University of California, it also drew on a strong current in American critical thought running from Upton Sinclair's scathing attack on the commercial press, *The brass check* (1920), to C. Wright Mills' anatomy of "mass society" in *The power elite* (1956).

In an essay on "Art and mass culture," Horkheimer (1972, 275) had argued that the routinization and commercialization of leisure had turned it into "a kind of tail to the comet of labour." The Canadian scholar, Dallas Smythe (1994, 1st pub. 1977), took this argument one step further, arguing that since the economy of commercial television relied on selling viewers to advertisers, audience labor inevitably became commodified, and viewing became working to complete the circuit of consumption (→ Audience Commodity). Programs were the "wages" paid for the labor of attending to sales pitches.

This critique carried less resonance in Europe, where television (and radio) was organized primarily as a public service funded through license fees (→ Public Broadcasting,

History of). Identifying this system's distinctive features, and defending it against extensions of commercialism, became a major theme in critical media scholarship, particularly in Great Britain which, uniquely among major European countries, had introduced commercial television in the mid-1950s. Utilizing Habermas's notion of the → public sphere, Nicholas Garnham, Graham Murdock, and Peter Dahlgren, among others, argued that, for all its faults, public service broadcasting offered the most accessible and flexible basis for the cultivation of citizenship – within and despite a consumerist culture.

Central components of critical theory – for example, the theoretical conception of culture as a site of social struggle, and the reliance on interdisciplinary methodologies to identify power in social practices – have informed not just work in the political economy tradition, but also → cultural studies, → feminist and gender studies, → postcolonial theory, and other current research positions. Some of this work has been grounded in wider debates in the philosophy of social science, for example, Roy Bhaskar's argument for a critical realist epistemology (→ Realism). Identifying the generative mechanisms underlying everyday action and the hidden barriers to emancipation was, for Bhaskar, the first step toward encouraging action that transforms rather than reproduces existing social conditions. One influential version of such a critical project was pursued by the French sociologist, Pierre Bourdieu, in a series of studies of cultural production and consumption. His contributions have proved particularly fruitful in opening up new avenues for critical empirical research on everyday cultural practices, which had been given less attention by Herbert Schiller and other figures in the critical political economy of communications.

The critical interventions of Adorno and Horkheimer remain a starting point for contemporary studies of the concentration of media ownership, the commercialization and commodification of communication, and the consolidation of consumerism throughout culture and society. At a time when governments around the world see “the culture industries” as a driver of economic growth in the postindustrial era, it is important to revisit the history of the term and to reclaim it for critical inquiry. The Frankfurt group's legacy suggests the lasting value of an interdisciplinary approach combining the detailed analysis of texts with critical political economy, to interpret – and change – current cultural practices and institutions.

## Cross-Media Marketing

*Benjamin J. Bates*

*University of Tennessee*

Marketing refers to activities that promote and organize the distribution and sales of products to consumers (→ Marketing). Specifying “cross-media” focuses on those activities that involve multiple media. As such, the term “cross-media marketing” can be used to describe two somewhat related phenomena: general marketing and promotion activities that cross media boundaries (→ Advertising Strategies; Markets of the Media; Media Management); and efforts to increase sales of content by distributing them in a variety of media forms (→ Convergence of Media Systems; Distribution). Increasing competition and the rise of new media forms have fragmented audiences and markets (→ Audience Segmentation; Consumers in Media Markets; Digitization and Media Convergence), making cross-media marketing more critical. The changing production and distribution

cost structures brought about by technological developments have made it more viable (→ Cost and Revenue Structures in the Media; Information and Communication Technology, Economics of; Media Economics).

*Promotion* is an important part of economic activities. Promotion helps reduce uncertainty in the marketplace, by providing consumers with information about products and services. Promotion is particularly valuable for information goods and services, as new product is continually introduced, and there is always a degree of uncertainty and variability concerning the value of information goods and services to individual consumers (→ Uncertainty and Communication). Cross-media marketing, from the promotions perspective, refers to the use of multiple media for campaigns. Promotion targets potential consumers, who may or may not correspond with the audiences of specific media markets. Different media also have distinctive characteristics that may be more or less effective for particular promotional messages. As such, there was always a degree of cross-media marketing when it was appropriate for the particular product or campaign.

### TRENDS TOWARD CROSS-MEDIA MARKETING

Several trends are bringing cross-media marketing into greater use and prominence as a marketing and promotional tool. As competition and multiple media fragment audiences, utilizing multiple approaches across media becomes more critical in order to reach broad audiences. While fragmented audiences are valuable for those seeking targeted audiences, broad appeals need to reach across such fragments. Greater knowledge about the effectiveness of various techniques has allowed more sophistication in developing and using multiple message strategies across different media. The development and proliferation of *integrated marketing approaches* has also provided a focus on marketing across media (→ Integrated Marketing Communications). Increasingly fragmented audiences and increased competition has also acted to moderate the cost of media advertising. Technological developments, particularly the rise of the Internet and the world wide web (→ Internet), have opened up inexpensive alternatives for reaching audiences. These various factors have contributed to making cross-media marketing affordable, and a viable strategy.

A more competitive media environment also places a greater emphasis on promotion and → *branding in media products*. Cross-media promotions help to reach new markets and audiences, developing interest in particular channels and products. Reducing uncertainty about the value of new products and content provides a competitive advantage for media firms. Branding can contribute to this significantly, by establishing a clearer perception of the type and value of content to be provided. In addition, brands can be established across media, which facilitates cross-promotion of particular content and channels.

Increased *horizontal integration* among media conglomerates (→ Cross-Ownership; Media Conglomerates), and increased marketing of content in various media forms also increases the value and likelihood of cross-media promotions. Firms that produce and/or distribute content in multiple media forms have an interest in promoting all media forms, thus increasing demand in all markets and not just for one particular outlet. They are also in a better position to utilize open availabilities for promotional efforts among “in-house” media markets, although there is still considerable value in promoting in external outlets.

Marketing refers not only to promotional efforts, but to the goal of increasing sales. One strategy for doing this is to market products in multiple forms or versions, and in multiple markets. There are sound economic motives for doing this with media products.

### **ECONOMIC SPECIFICS OF MEDIA PRODUCTS**

One of the distinctive characteristics of media products is that they comprise both the information content and the specific form(s) in which that content is distributed to audiences and consumers. A related characteristic is that if you focus on the information portion, it is relatively costly to produce (high first-unit or fixed cost), but after that, there is very little cost involved in duplicating the information itself (low marginal cost). There also tend to be fairly high costs in fixing that idea or content in a particular media form (high first-unit or fixed costs), and often fairly low per-unit costs in making copies and/or distribution (low marginal costs). Having low marginal costs encourages wider distribution, helping to keep average costs (and thus prices) down.

Until fairly recently, media markets were thought of as generally distinctive and tended to have *limited direct competition*. Differences in media were such that translation of content across forms could be very expensive. If media forms were fairly similar, content could be ported from one media market to another fairly easily (say from hardcover to paperback books (→ Book; Paperback Fiction) or serialization in magazines, use of older movies (→ Cinema) as content for television broadcasts (→ Television), or distribution in multiple geographic markets). Content could also be marketed across more distinct media types (books turned into movies), but that often required the idea to be reproduced in the new format, incurring significant new first-unit (translation) costs in the new media form.

On the down side, new forms and markets could impact on primary market sales, if audiences viewed them as close substitutes. *Substitutability* tended to relate to similarity in media forms. Hardbacks and paperbacks are fairly close substitutes, books and movies are not (in fact, very different media are closer to complements – where consumption of one form can increase demand for the other). Firms were often more concerned about the negative impact of cross-media marketing from close substitutes on primary market sales, than the incremental revenues to be gained from entry into new markets. Media were seen as substitutes, cross-media marketing often included other versioning techniques, such as quality differences, or time delays past the point where the primary market demand has peaked. For media seen as complements, the impact of cross-media marketing was generally positive. However, the often sizable translation costs, and the fact that often the other media was owned by someone else, reduced the likely benefits of cross-media marketing as a general strategy.

*Firm and market structures* (→ Economies of Scale in Media Markets; Media Corporations, Forms of) also influenced the value and viability of cross-media marketing. Marketing across media made more sense to horizontally integrated media firms, who could engage in cross-subsidization and economies of scope, as well as more easily capture value across media outlets and markets in which they operated. On the other hand, media and market structures where content production and distribution were handled by the same firm experienced some disincentives to engage in cross-media marketing. While the production side tended to benefit, specific distribution systems might lose out to consumers choosing to access the content via alternative media.

## IMPACT OF TECHNOLOGICAL DEVELOPMENTS

Technological developments and structural market changes have made cross-media marketing increasingly viable, and it has become an important business strategy. As technological developments reduced many production and distribution costs, translation costs lowered. The same developments also contributed to several structural shifts in media markets. Changing cost structures, as well as general deregulatory policy shifts (→ Telecommunications: Law and Policy), have reduced barriers to entry, encouraging new firms to enter markets and conglomerates to expand. New technologies (→ Technology and Communication) encouraged the development of new media forms, with declining costs encouraging rapid diffusion and adoption by consumers.

For example, the once unique medium of movies has faced new competition (as well as new potential distribution markets) from a continuing litany of new media forms: television, cable systems and networks, video cassettes, DVDs, direct broadcast satellites, and on the horizon, video-on-demand, IPTV systems (not to mention digital piracy through the Internet), and cell phones, and there is probably more to come. An increasingly deregulatory policy focus encouraged these structural changes, while allowing greater horizontal and vertical integration by some media firms. Horizontally integrated firms are particularly well-positioned to benefit from cross-media marketing, as they can capture the benefits from distribution across their media outlets.

As noted earlier, technological advances have tended to reduce a wide range of production and distribution costs. *Digital technology* in particular has helped to significantly reduce translation costs, contributing to convergence of media markets and systems. Combined with telecommunications advances resulting in the Internet, distribution costs over some networks approach zero, virtually eliminate geographical boundaries, and expand the scope of markets. The changing cost structure has enhanced the discrepancy between the initial production costs of the information, and marginal costs. Reduced translation costs also reduce the average cost for secondary markets, enhancing their value. This has increased the potential to profit from cross-media marketing. The rise of digital media systems that exhibit near-zero translation and distribution costs are particularly disruptive. The ease with which content can be translated and distributed across digital media regardless of the intent of the content producers and owners has raised concerns about digital piracy (→ Piracy).

At the same time, the increase in competition within and across media has impacted on revenues within specific media markets. Many firms face shrinking sales and revenues from their primary media products, making it even more critical to develop new markets and revenue sources. Firms producing content, as opposed to those only distributing it, find the ability to market that content across as many media and markets as viable critical to their continuing success. As one example, the movie industry has shifted from having its primary revenues derived from theater ticket sales, to revenues from television and cable licensing, to the point where revenues from DVD sales provide the bulk of revenues.

Trends in technology suggest that cross-media marketing will be increasingly critical, both in terms of promotion and in the marketing of content. Old market boundaries are disappearing, and with them the ability of media firms to capture audiences and monopoly profits from exclusiveness. Competition and fragmented audiences spreading their

attention across a wide range of media (and increasingly multitasking) increase the value of promotion, and the need for cross-media promotion and marketing efforts, for many products. Changing cost structures suggest that content will be increasingly available across a range of media forms, and if producers do not market the content across those media forms themselves, they face losing that value to those who do (legally or not).

Currently, prospects for both aspects (advertising across media, and distributing content across media) look promising. Bruner (2005) notes the shift in advertising markets and the rise of cross-media advertising in his report on online advertising (→ Advertising, Economics of). The European Commission has been actively promoting the potentials of cross-media marketing in the emerging digital media marketplace, funding a variety of projects and consortia (e.g., Boumans 2004) as part of its → information society initiatives.

## **Cross-Media Production**

*David Domingo*

*University of Iowa*

Mainly used to refer to news, cross-media production is the coordinated reporting of events in several media outlets (press, radio, television, Internet, mobile phones, and other mobile

devices). The production can occur at a single *integrated newsroom* or involve collaboration among newsrooms from different media. The concept can also apply to other media products systematically designed for and delivered in different media formats. Practitioners and scholars use the term *convergence* to refer to the process of developing cross-media strategies in newsrooms.

The first newsroom-wide tests of cross-media production began as media businesses adopted digital technologies in daily news production and tended to concentrate in big multimedia conglomerates in the late twentieth century (→ Digitization and Media Convergence). The starting point in many cases was the exploration of a tighter relationship between the production of the newly developed Internet outlets (→ Online Journalism) and traditional formats (press, radio, television). The greatest challenge for cross-media production, nonetheless, is coordinating the different journalistic cultures of print and broadcast newsrooms.

Advocates of cross-media production argue that coordinated reporting may enhance the quality of coverage for an event and optimize the use of human resources in newsrooms, as each outlet provides the information that best suits it. At the same time, this global strategy facilitates cross-promoting different outlets from the same company. Their aim is to offer comprehensive, ubiquitous, and continually updated news, using the different media of the company to allow citizens to receive the best coverage at any time or place through the most convenient media device.

However, several scholars and professionals point out the risks to news quality and media diversity if reducing production costs drives the convergence process. An early case study found that journalists felt stress and considered their stories less elaborated when doing cross-media production (Cottle & Ashton 1999). Newsroom coordination may diminish the diversity of approaches that the separate media take toward a community, may ignore intrinsic differences among media formats that contribute to heterogeneous journalistic discourse, and may make immediacy prevail over analysis.

Two theoretical models attempt to differentiate cross-media efforts, although the concrete forms around the world show extraordinary variability: *coordinated newsrooms*, where each outlet retains an autonomous newsroom and a *multimedia desk* fosters strategic coordination among the teams; and *integrated newsrooms*, where a single team produces stories for any medium.

At Newsplex, an experimental cross-media production initiative, researchers in 2002 began developing four new professional roles for converging journalism (Northrup 2004). These roles are bundles of tasks in the cross-media production workflow, and one person may perform more than one role, depending on the structure of the newsroom.

- News flow managers decide what human and technical resources to devote to each event.
- Story builders coordinate reporting on a single event and decide which materials to gather (video, audio, photos, data) and the best cross-media publication strategy.
- News resource workers help journalists find and process archive and database information.
- Journalists gather information using multiple tools and skills (such as audiovisual recording, still photography, note taking, database mining) and combine multiple-format elements into a story or adapt the materials to different outlets. Multiskill roles

may give reporters more control over the final products of their work, but may also overload them with technical procedures, leaving less room for journalistic interpretation (Bromley 1997).

Successful cross-media production requires teamwork, a challenge to the individualistic work of journalists that demands training and flexibility (Deuze 2004). Companies cannot expect convergence to serve as a cost-saving strategy. Convergence may instead allow growth, resulting in better-quality and better-coordinated content in the outlets of a media group, and fostering loyalty and visibility among audiences who have new information-seeking behaviors (Quinn 2005). Another key to fluent cross-media production is adequate knowledge management (Quinn 2002), backed by efficient database software and online systems that store and retrieve the data journalists use and produce when they report events.

Empirical research has concentrated on the perceptions of professionals involved in cross-media production. General attitudes toward convergence are positive, but journalists perceive a lack of training, time pressure, and business-driven strategies as the main barriers to success and quality in cross-media production (Singer 2004; Klinenberg 2005). Media regulation, resistance from unions, physical distances between the newsrooms, lack of management commitment, and poor organizational flexibility also constrain convergence (Quinn 2005). To assess the relationships among newsrooms and the processes and consequences of convergence, research may need to use media groups as the unit of analysis (Boczkowski & Ferris 2005).

# Cross-Ownership

Marc Edge

Sam Houston State University

Cross-ownership of media occurs when a person or company owns outlets in more than one medium (i.e., → newspapers, → radio, and → television) in the same geographical market. It is a business strategy driven by advances in technology and also a public policy issue due to concerns over increased concentration of ownership (→ Media Policy). Cross-ownership is aimed at achieving economies of scope across multiple media. Costs may be reduced through the “synergy” of sharing of staff and content between outlets in different media, and revenues may be increased through the sale of multimedia advertising packages.

On the other hand, diversity of media ownership is considered crucial to ensuring diversity of news information (→ Plurality). As a federal circuit court of the US noted in 2004, “diversification of media ownership serves the public interest by promoting diversity of program and service viewpoints as well as by preventing undue concentration of economic power” (*Prometheus Radio Project v. FCC*, 373 F.3d 372, 383 [3<sup>rd</sup> Cir.] 2004; → Public Interest). Various media competition laws and regulations are widely accepted in connection with a society’s significant interest in ensuring a wide range of information and opinion for citizens through pluralistic media (→ Competition in Media Systems). That is, media cross-ownership is a matter of freedom of expression as a right (→ Freedom of the Press, Concept of).

## INTERNATIONAL FRAMEWORK

The Universal Declaration of Human Rights, the International Covenant on Civil and Political Rights, the → American Convention on Human Rights, and the European Convention on Human Rights recognize a right of individuals to receive information and opinions from a diversity of sources (→ Freedom of Information). Thus, they impose an obligation on government to ensure media pluralism. This is especially the case with the American convention in that it expressly prohibits private entities such as the news media from restricting freedom of expression through media monopolies and concentration.

Article 10 of the *European Convention on Human Rights* has been interpreted as requiring member states to take positive actions against press monopolies. In 1994, for example, the → European Court of Human Rights held that the Austrian public broadcasting monopoly was incompatible with Article 10 because it violated the freedom of individuals to communicate their ideas on the audiovisual media (*Informationsverein Lentia v. Austria*, 17 E.H.R.R. 93 [1994]). A dozen years earlier, the Council of Europe’s Committee of Ministers stated: “States have the duty to guard against infringements of the freedom of expression and information and should adopt policies designed to foster as much as possible a variety of media and a plurality of information sources, thereby allowing a plurality of ideas and opinions” (Committee of Ministers, Declaration on the Freedom of Expression and Information, April 29, 1982; → European Union: Communication Law).

## NATIONAL FRAMEWORK

The increased concentration of news media ownership through horizontal integration or multimedia integration came under heightened public scrutiny (→ Concentration in Media Systems). Consumer advocates, political activists, proponents of media reform, and most media scholars generally opposed allowing news media companies to grow larger. They perceived the increased political power that corporations could accumulate through cross-ownership to be contrary to the public interest and called for restrictions to be maintained or enacted (→ Media Conglomerates; Media Corporations, Forms of).

### Cross-Ownership Rules Relaxed

Reform and even outright repeal of restrictions on cross-ownership, however, have been broad trends worldwide, with long-running deregulation initiatives culminating in the United Kingdom in 2003 and Australia in 2006. In *Australia*, cross-ownership of media became linked with the country's limits on foreign ownership in a decade-long attempt at media deregulation that failed twice before finally being passed in 2006. The small size of the media market led to it being dominated by a few major owners, creating resistance to dropping a prohibition on cross-ownership without allowing more foreign ownership in order to prevent increased concentration. The ban on cross-ownership of print and electronic media had been introduced by the Labour government in 1987, forcing the country's multimedia owners to choose between their television and newspaper holdings. Nonetheless, the Australian government under liberal prime minister John Howard enacted a broad package of reforms in July of 2006. It abolished restrictions on foreign ownership and permitted cross-ownership starting in 2007, subject to a "diversity test" to ensure a minimum of five owners in metropolitan markets and four in regional markets (→ Australia: Media System).

In *Canada*, a prohibition against cross-ownership of newspapers and television stations was issued in 1982 by Order in Council after a Royal Commission on Newspapers recommended restrictions on ownership. The cross-ownership prohibition was allowed to lapse in 1985 following a change in government from Liberal to Conservative. Several multimedia transactions since 2000 prompted federal inquiries by committees of both Parliament and Senate. A report to Parliament on broadcasting and media ownership recommended in 2003 that the Canadian Radio-television and Telecommunications Commission (CRTC) cease issuing broadcast licenses to owners of newspapers pending formulation of a federal policy on cross-ownership. A Senate report on news media was issued in 2006, but it stopped short of recommending measures against cross-ownership, as another change in government from Liberal to Conservative earlier in the year made unlikely any regulations limiting media ownership (→ Canada: Media System).

In the *United Kingdom*, the 1990 Broadcasting Act prohibited newspaper owners with more than 20 percent of national circulation from holding more than a 20 percent interest in any Independent Television (ITV) license. A new Broadcasting Act in 1996, however, loosened regulations so large newspaper owners could also reach up to 15 percent of the audience share in television and commercial radio, but with no more than one national license in each. In 2003, the Communications Act made sweeping changes to

media regulation, including for the first time allowing foreign ownership of broadcasting. Restrictions on cross-ownership were also eased, with owners permitted to hold both national radio and television licenses. But media mergers are subject to special statutory requirements. Under the Communications Act of 2003, the Secretary of State for Industry intervenes where the public interest considerations of media mergers are involved (→ United Kingdom: Media System).

### **Cross-Ownership in the Era of New Media Technologies**

With the advent of the → Internet in the 1990s, a “convergence” of print and broadcast media was seen as inevitable (→ Digitization and Media Convergence). The traditional content of newspapers, magazines, radio, and television was thus foreseen by some as all eventually being delivered online. This technological revolution was expected to render national regulatory agencies redundant, and as a result owners sought relaxation of cross-media and foreign ownership restrictions. As an OECD study of 1998 noted, “The pressure of convergence brings into sharp focus the restrictions many OECD countries have placed in terms of cross-ownership and joint provision regulations imposed on the traditionally separate communications” (OECD 1998). Consumer advocates, however, sought to retain limits where they existed and to implement them where they did not, arguing that more concentrated ownership of news media would reduce diversity of opinion and political pluralism.

In *South Korea*, where a select group of print and broadcasting media dominates the media industry, several special statutes showcase the Korean government’s commitment to diversify the media market while reducing the actual or perceived media concentration. The Newspaper Act, for example, prohibits the simultaneous ownership of broadcasting stations and newspapers and news agencies. In 2004, to stem the print media’s concentration in Seoul, the Korean government passed the Regional Newspaper Act. By laying a healthy foundation to develop regional newspapers, it aims to promote diverse public opinions and to accomplish a balanced development of local communities. The law mandates a development fund for regional newspapers to improve their management and distribution and to support their computerized database.

To the Korean government, the broadcasting industry is no exception. The Broadcast Act forbids anyone to own more than 30 percent of stocks of a terrestrial broadcasting licensee and a news broadcasting program provider. Also, a daily newspaper cannot operate a broadcasting station or a program provider simultaneously. Further, the corporate owner of a daily newspaper or a news agency cannot own the stock or equity shares in cable broadcasting or satellite broadcasting companies (→ Satellite Communication, Regulation of). Likewise, it is illegal to concurrently operate an off-the-air broadcaster, a cable television broadcaster, and a satellite broadcaster. Moreover, the Broadcast Act proscribes an over-the-air broadcaster, a cable television broadcaster, and a satellite broadcaster from owning another over-the-air broadcaster that runs a digital multimedia broadcasting (DMB) service, another cable broadcasting service, and another satellite broadcasting service, respectively. Similarly, a broadcast program provider cannot operate another program provider or own stocks in the other provider beyond what a presidential decree permits (→ South Korea: Media System).

The government of *Singapore*, which had tightly restricted media ownership for decades, announced in 2000 the introduction of “controlled competition” through cross-ownership. Singapore Press Holdings (SPH), which for 16 years had enjoyed a government-sanctioned newspaper monopoly, was issued licenses for English- and Chinese-language television stations. Government-owned broadcaster MediaCorp was issued a newspaper license and began publishing a free commuter tabloid titled *Today* (→ Tabloid Press).

### **Liberalization of Cross-Ownership Rules in the US**

US media ownership rules as they have evolved over several decades are probably in a class by themselves. In 1970, the → Federal Communications Commission (FCC) passed the cable/broadcast cross-ownership (CBCO) rule, which disallowed a cable system from owning broadcast TV stations in its own market. At the same time, it enforced the radio–TV cross-ownership rule against ownership of a radio station and a TV station in the same market. In 1975, the FCC adopted a rule that banned a daily newspaper publisher from owning a broadcasting station in its community.

The Telecommunications Act of 1996, the most sweeping change in US broadcasting regulation since the 1934 Communications Act, has affected ownership regulations. In 2003, the FCC announced a new tiered cross-media ownership rule that would liberalize the radio–TV cross-ownership and the broadcast–newspaper rules. But a federal appeals court blocked the new rules from taking effect, reasoning that the FCC failed to prove justification of its new ownership rules. Meanwhile, there is no cross-ownership rule on satellite TV and cable in the US (→ Cable Television). Antitrust laws will apply if a cable company buys a satellite TV provider. The Department of Justice or the FCC will likely intervene (→ Antitrust Regulation).

*Germany* and *France* stand in sharp contrast to the US. Their cross-media rules are less developed. Constitutional law provided the basis for the enactment of appropriate competition rules to ensure pluralism in the media industry. In 1966, the German Constitutional Court indicated that *Pressefreiheit* (“press freedom”) obligates the government to take affirmative actions to the deleterious impact of media monopolies. Similarly, the Conseil constitutionnel in France held in 1986 that freedom of expression mandates special media merger restrictions to safeguard pluralism in media outlets (Barendt 2005, 433).

## Cuba: Media System

Jürgen Wilke

Johannes Gutenberg University of Mainz

With nearly 111,000 square kilometers Cuba is the largest island in the Caribbean Sea. It is located only 180 kilometers off Florida on the American continent. Since 1976 the *República de Cuba* has been subdivided into 14 provinces of almost equal size and one special municipality (Isla de la Juventud). The total population is 11.3 million; 2.2 million live in the capital Havana. The official language is Spanish.

For a long time Cuba was ruled by Spain, but since the end of the nineteenth century it has been under American hegemony. In 1959, the authoritarian dictatorship of Batista

was overturned in a guerilla war under the command of Fidel Castro. Subsequently a socialist government was established. Fidel Castro became president and continued to adhere to communism even in the 1990s after the systems in the Soviet Union and its satellite states had broken down. As support from the Soviet Union ceased, Cuba faced a severe economic crisis. The so-called “Período Especial en Tiempos de Paz” brought considerable restrictions. Increasing tourism led to some relief, but the temporary toleration of the US dollar as currency was abandoned. For health reasons, Fidel Castro delegated the power to his younger brother Raúl in 2006. Since then there has been great uncertainty about the political future of the country.

Even at the beginning of the twenty-first century Cuba is – in accordance with its political system – globally one of the last *media systems of the Soviet totalitarian type* (Siebert et al. 1956). Today, however, basically two media systems coexist in Cuba: one for the population that is still strictly controlled, and the other for tourists, diplomats, and foreigners living in the country enjoying greater liberties.

Art. 53 of the Cuban constitution (1976, amended in 1992) grants citizens the right to freedom of speech and of the press “in keeping with the objectives of socialist society.” The latter justify restrictions of this freedom. Mass media are considered as public and social property, and private individuals are under no circumstances entitled to own them (→ Public Goods; Freedom of the Press, Concept of).

There is *no explicit media law* in Cuba. But in the 1990s laws were enacted restricting the freedom of the media and of journalists: Law no. 80 “Reaffirming Cuban Dignity and Sovereignty” (1996), further tightened by Law no. 88 in 1999 (“Law of Protection of the National Independence and Economy of Cuba”). Based on this more than 70 opponents of the regime were arrested in 2003, predominantly journalists, resulting in international protests by human rights activists. In the 2006 Press Freedom Index published annually by the journalist organization, Reporters without Borders, Cuba ranks 165th out of 168. Only in three countries of the world were the media classified as even more inhibited.

The first → *newspaper* in Cuba was published in 1764 (*La Gaceta*). When press freedom was guaranteed in the constitution of 1812 the number of newspapers increased. Under the authoritarian governance of Batista there were still 58 newspapers, mostly receiving state subsidies. Due to suppression many illegal publications emerged.

When Fidel Castro came to power a press concentration took place (→ Concentration in Media Systems). The *newspapers* also suffered from the problems of the “Período Especial.” Hence most of the 24 newspapers in Cuba today appear only once a week. Only two of them are published nationwide: *Granma*, since 1965 the official organ of the Partido Comunista de Cuba (PCC), bearing the name of the yacht with which Castro and his followers crossed over from Mexico to Cuba in 1956 to start the revolution. The paper has a circulation of 400,000 and comes out as a tabloid. It prints the official news and the speeches and editorial articles of Castro himself (Saavedra Hurtado 2003). *Juventud Rebelde* is the second nationwide newspaper. It was originally designed for youth but is read today by a broader public. The Cuban provinces have a weekly newspaper each. Since 1996 there has been an international edition of *Granma*, intended as antidote to the US media. Besides Spanish it appears in four languages (English, French, Portuguese, German); the circulation is 50,000.

In 2002, 284 → *magazines* were published in Cuba (Massmann 2003, 425), launched mostly by organizations and unions. Before the Período Especial there were more than 600 magazine titles. Since the mid-1990s the magazine market has been growing again. This mainly concerns specialist journals (medical science, culture, etc.). The most important general magazine is *Bohemia*, which has been in existence since 1908. It is published biweekly with a circulation of 100,000.

The Americans brought → *radio* to Cuba in 1922. Thus the medium was initially operating in the private sector. After the revolution the radio stations were expropriated and nationalized, or simply disappeared. Any kind of → advertising was prohibited. Since 1962 radio has been supervised by the Instituto Cubano de Radiodifusión.

Today there are 59 radio stations in Cuba. Seven of them broadcast their program nationwide, 52 only have a regional transmission area (Saavedra Hurtado 2003, 77). The programs concentrate on information rather than on entertainment. Furthermore there are service and educational programs. There are no music stations as such, but *Radio Reloj* is purely a news station. One exception is *Radio Taíno* addressing foreigners and tourists in Cuba. *Radio Habana Cuba* is designed also to propagate revolutionary ideals internationally. In Cuba there are more than three million radio sets, one to two per household.

Before the revolution Cuba had a private-sector → *television system* with six programs. Under Castro this system was also nationalized. Today it is technologically outdated and also abstains from advertising. *Televisión Cubana* developed in 1962 and broadcasts via two channels: *Cubavisión* (channel 2) focuses on information and entertainment, *Tele Rebelde* (channel 6) on information and sports. During the Período Especial the airtime had to be reduced. In 1999 *Cubavisión* was on air for an average of 13 hours per day, *Tele Rebelde* for 16 hours. *Televisión Cubana* has 15 Telecentros, regional broadcast stations covering nearly all provinces. These Telecentros normally broadcast 90 minutes with local information via *Tele Rebelde* from Monday to Friday. Before the revolution TV was restricted to the province La Habana and only covered half of the island. In 1988 TV reached 93 percent of the population.

Another TV station is *Cubavisión Internacional*, presenting a cable program for tourists, diplomats, and foreigners. In 2005 *Televisión del Sur (teleSUR)* came along. This is a joint program of various Latin American countries. “Founding father” was the Venezuelan president Hugo Chávez, who wanted to establish an “opposite pole” to the influence of the American TV station → CNN International. Cuba holds a 19 percent stake in the station.

Although Cuba had already introduced new information and communication technologies for education and in the health sector (→ Health Communication), the government tried to obstruct the licensing of the → *Internet* because it is difficult to control. However, as the Internet is important for tourism, the domain name “cu” was allocated in 1996 (→ Domain Names). In the same year, Law no. 209 decreed that only companies, state institutions, and universities get internet access. For private individuals this is prohibited. The regulation of the Internet was put in the charge of the Ministerio de la Informática y de las Comunicaciones de Cuba (MIC), newly founded in 2000. In 1996, *Granma Internacional* was the first Cuban media outlet with an Internet presence. Today nearly all newspapers, magazines, and broadcast stations have one. Although it is

illegal, the Internet is the medium most likely to be used by people in opposition. Private and illegal news agencies use it (Cuba Press, Habana Press, Prensa Cubana). Partly these are web pages maintained abroad. Employees and users within the country have become victims of a wave of arrests and sentenced because of subversive activities.

Media extending into Cuba from outside have been in existence for decades. They are organized by exile Cubans and considerably subsidized by the American government. By these means the Cuban population can receive news other than just the filtered news in the country. Since 1985 *Radio Martí* has been the most important radio station for this purpose. Five years later *TV Martí* was added, supervised by the US American Office of Cuba Broadcasting. Critics accuse the stations of being one-sided. In Cuba, their reception is prohibited and jammed. There are no reliable data available on the spread of utilization.

## **Cultivation Effects**

*Nancy Signorielli*

*University of Delaware*

Television is the world's storyteller, telling most of the stories to most of the people, most of the time. As such it has become our most common and constant learning environment, one that very few can or even want to escape or ignore. Children today are born into homes in which most stories are told by a centralized commercial institution rather than parents, peers, schools, or the church. Television shows and tells us about life – who wins,

who loses, who is powerful, who is weak, as well as who is happy and who is sad (Weimann 2000; → Media Effects; Media and Perceptions of Reality).

Television is only one of many venues that help explain the world (→ Television; Television: Social History). What is different about television is that its version of reality bombards everyone with basically the same perspectives at the same time. These views are not much different from those found in other media or imparted by other powerful socialization agents. Yet television is unique because it provides a common set of images to virtually all members of society and because people tend to spend more time with television than other media.

Since television's inception there has been concern about its effects. The popular press and the government continue to ask: what does television do to us? Teachers and parents wonder if television makes children more aggressive or if it helps or hinders learning (→ Violence as Media Content, Effects on Children of). Although seemingly simple, these questions are complex and the answers are far from simple or straightforward.

### THE CONCEPT

Cultivation analysis is one approach that helps us to find answers to these broad questions. It is the third component of a research paradigm that investigates (1) the institutional processes that underlie the media and the production of its content, (2) the prevalent images in media content, and (3) the relationships between watching television and audience beliefs and behaviors. Simply, cultivation analysis is designed to assess the contribution television viewing makes to people's conceptions of social reality (i.e., cultivation effects). In its simplest form, cultivation analysis asks if those who watch more television have views that are more reflective of what they see on television compared to those who have similar demographic characteristics but who watch less television (→ Cultivation Theory).

The methods and assumptions of cultivation analysis differ from those typically found in mass communication research. Research on media effects often focuses on how specific media messages produce immediate change in people's behaviors or attitudes. Cultivation analysis, on the other hand, is concerned with the long-term, more general, and pervasive consequences of cumulative exposure to television's messages (→ Media Effects Duration; Media Effects: Direct and Indirect Effects). Cultivation does not imply a simple, linear, → "stimulus-response-model," or immediate short-term response to exposure. Rather, the focus is on the cumulative exposure to television's repetitive and stable messages that persist despite today's increased channel offerings available to most viewers (→ Cumulative Media Effects; Linear and Nonlinear Models of Causal Analysis). Cultivation analysis represents the independent contribution of television viewing to people's conceptions of social reality.

### DESIGN OF CULTIVATION STUDIES

Cultivation studies typically begin with identifying and assessing the most recurrent and stable patterns in television content, looking for those images and values that cut across most program genres. These findings are used to generate questions designed to uncover

people's conceptions about social reality. These questions are then presented to samples of children, adolescents, or adults using standard techniques of → survey methodology. In addition, some cultivation analyses use existing data sets (such as NORC's general social survey), with the methods of secondary analysis. A key element in these surveys is the assessment of television viewing. Questions about viewing typically ask how much time the respondent watches television on an average day. Researchers then determine which respondents will be light, medium, or heavy viewers on a sample-by-sample basis (→ Exposure to Television). Hence the analyses look for differences in amount of viewing, not specific amounts of viewing. The questions about social reality used in cultivation analysis do not mention television but rather provide answers that reflect either the dominant views or images seen on television or those found in reality. The resulting relationships between amount of viewing and the tendency to respond in terms of what is seen on television reflects television's contribution to viewers' conceptions of social reality (cultivation effects).

According to cultivation theory, those who watch more television are different from those who watch less television in many ways. Although all demographic groups have people who watch more or less television, there are overall differences between those who watch more and those who watch less in terms of sex, age, education, income, occupation, race, and other demographic and social variables. In short, cultivation analysis assumes that those who watch less television are exposed to more varied and diverse information (from both mediated and interpersonal sources) compared to those who watch more television and thus rely more upon television for their information. It stands to reason that if you spend most of your time watching television then you will have little free time to explore other options that might provide different views or information about the world. Consequently, cultivation theory predicts that the more time a person spends watching television and being immersed in this mediated world, the more likely it is that their views about reality will reflect what they have seen on television.

## **SOME RESULTS**

Similar to findings for many studies about media effects, cultivation analyses typically generate small effects. Even those who watch very little television may watch 7 to 10 hours a week and certainly interact with those who watch more television, so the cards are really stacked against finding evidence of cultivation. Consequently, even though the effects may be small, finding even small differences between light and heavy viewers may indicate far-reaching consequences. Moreover, small effects may have profound consequences. For example, a difference of one percentage point in ratings may indicate the success or failure of a program, and a difference of a few percentage points in an election may determine who wins or who loses.

### **Variations in Cultivation: Resonance and Mainstreaming**

Cultivation is a continual, dynamic, ongoing process, not a unidirectional flow of influence from television to viewers. Scholars have found two processes that reflect differences in how cultivation may work, i.e. "resonance" and "mainstreaming." First, direct

experience may be important for some viewers, and the phenomenon called *resonance* illustrates how a person's everyday reality and patterns of television viewing may provide a double dose of messages that "resonate" and amplify cultivation. For example, those who live in high-crime urban areas often show stronger relationships between amount of viewing and stated fear of crime.

Second, television provides a shared daily ritual of highly compelling and informative content for diversified viewers. Television programs typically eliminate boundaries of age, class, and region. Consequently the *mainstream effect* is a relative commonality of outlooks and values that is cultivated by consistent and heavy exposure to the world of television. The phenomenon of mainstreaming means that heavy viewing may override differences in perspectives and behavior that result from numerous factors and influences. In other words, attitudes or behaviors that would ordinarily be attributed to different social or political characteristics may be diminished or absent in groups of heavy television viewers. For example, for some topics, the beliefs of those who designate themselves as liberal or conservative are often very different when they are light television viewers. But, when heavy television viewers who call themselves liberal or conservative are asked about these same topics, those classified as liberals may give responses that are somewhat more conservative and the conservatives may give responses that are somewhat more liberal. The result is that both groups reflect beliefs that are more moderate or middle-of-the-road. In short, mainstreaming reflects the sense in which television cultivates common perspectives, a relative homogenization that illustrates how television viewing has become the true melting pot of the American people and increasingly the world.

### Evidence of Cultivation

Cultivation analysis is most often associated with concerns about *television violence* (→ Violence as Media Content). Studies of television content conducted in the cultural indicators perspective have consistently found that US television's prime-time world has had a consistent and fairly high level of violence for more than 30 years. Approximately six out of ten programs are considered to have violent components, with violence occurring at the rate of four to five acts of violence per program (Weimann 2000; → Gerbner et al. 2002). Similarly, other studies of television violence, including the content analysis of the US national television violence study in the mid-1990s, found similar levels of violence across all channels (cable and broadcast, and throughout the day, with the most similarity during the prime-time hours).

As a result of this consistent level of violence viewing, cultivation studies have predicted and found that those who watch more television tend to see the world as a more violent place. These studies have found that those who watch more television are more fearful and believe that they are living in a mean and dangerous world. These individuals are more likely to buy guns and watchdogs for protection, and to install more locks on windows and doors. Heavy viewers also tend to overestimate the likelihood that they will be involved in violence and the numbers of police and others in law enforcement and crime detection. In short, viewing tends to heighten perceptions of danger and risk and reinforce an exaggerated sense of mistrust, vulnerability, and insecurity.

Evidence of cultivation is not, however, limited to studies of fear and violence. For example, television programs consistently *underrepresent women and women's roles* (→ Women in the Media, Images of; Stereotyping and the Media). Analyses have found that those who watch more television tend to give more gender-stereotyped answers to questions about the roles of men and women in society. They also found that youngsters who watch more television tend to say that boys and girls should do chores that are gender-stereotyped, such as boys should mow the lawn while girls should clean the house. Other studies examine television's content about *aging and the elderly*. These studies have shown that those who watch more television typically underestimate the number of older people in the US and are more likely to say that the elderly are infirm. They also tend to give more stereotypical responses about how people age. In addition, cultivation analyses have been conducted in areas pertaining to people's *health and nutrition*. For example, two studies of middle-school-aged children found that those who watch more television tend to say that the types of foods often advertised to children (sweetened cereals, fast food restaurants, candy, and soda) are more nutritious than they actually are.

Knowledge of cultivation and the cultivation process is by no means complete. Scholars are currently looking at the conceptual and methodological implications of cultivation on numerous levels. Cross-cultural studies are helping us to understand the → generalizability of cultivation on a worldwide basis. New technologies also are increasingly relevant for cultivation effects research, although the continued concentration and interdependence in media industries (→ Concentration in Media Systems), continued imitation of successful formats and genres (→ Cross-Media Production), as well as greater competition for media audiences should continue to enhance rather than fragment television's contribution to people's conceptions of social reality.

# Cultivation Theory

Michael Morgan

University of Massachusetts Amherst

Cultivation theory, developed by → George Gerbner and his colleagues, proposes that television viewing makes an independent contribution to audience members' conceptions of social reality. The central hypothesis guiding cultivation research is that the more time people spend watching television, the more their beliefs and assumptions about life and society will be congruent with the most stable and repetitive messages found in television's dramatic entertainment programs.

## HISTORY

Cultivation theory was devised as one component of the *Cultural Indicators project*, a long-term research program that began in the late 1960s. The project follows a three-pronged research strategy. The first, called "institutional process analysis," investigates power roles in media industries and the pressures and constraints that affect how media messages are selected and produced. The second, called "message system analysis," quantifies and tracks the most common and recurrent elements in television content (→ Content Analysis, Quantitative). The third, cultivation analysis, studies whether and how television viewing relates to viewers' conceptions of social reality (Gerbner 1973).

The theory of cultivation has been prominent in communication research, and the Cultural Indicators project has generated over 300 scholarly publications. Although early cultivation research was especially concerned with television violence, over the years the investigation expanded to include sex roles, images of aging, political orientations, environmental attitudes, science, health, religion, minorities, occupations, and other topics. Replications have been carried out in Argentina, Australia, England, Germany, Hungary, Israel, the Netherlands, Russia, South Korea, Sweden, Taiwan, and elsewhere.

The methods of cultivation analysis were designed to correct for specific blind spots in previous mass communication research. Most earlier studies looked at whether individual messages or genres could produce some kind of change in audience attitudes and behaviors; in contrast, cultivation sees the totality of television's programs as a coherent *system of messages*, and asks whether that system might promote stability (or generational shifts) rather than immediate change in individuals. Whereas most research and debate on, for example, television violence has been concerned with whether violent portrayals make viewers more aggressive, Gerbner and his colleagues claimed that heavy exposure to television cultivates exaggerated beliefs about the amount of violence in society, along with a sense of insecurity, victimization, and interpersonal mistrust. This cluster of outlooks is referred to as the "Mean World Syndrome" (Gerbner & Gross 1976).

## THEORETICAL FRAMEWORK

Cultivation theory is not concerned with the impact of particular program(s) or genre(s). It does not address questions of artistic quality, realism, or individual viewers' "readings"

of media messages. Rather, cultivation emphasizes aggregate patterns of images and representations to which entire communities are exposed over long periods of time (→ Cumulative Media Effects).

Cultivation does not deny the existence or importance of selective viewing, individual programs, or differences in interpretations; it just sees these as different research questions. It focuses on what is most broadly shared, in common, across program types and among large groups of otherwise heterogeneous viewers. Thus, cultivation theory argues that the systemic consequences of *television* as technology and institution cannot be found in terms of isolated fragments of the whole. The project is an attempt to say something about the broad-based ideological consequences of a commercially supported cultural industry celebrating consumption, materialism, individualism, power, and the status quo along lines of gender, race, class, and age. None of this denies the fact that some programs may contain some specific messages more than others, that not all viewers watch the same programs, or that the messages may change over time (Gerbner et al. 2002).

The theory of cultivation emphasizes the role that *storytelling* plays in the lifelong process of socialization (→ Storytelling and Narration). One basic difference between human beings and other species is that we live in a world that is created by the stories we tell. The stories of any culture constitute lessons that reflect and cultivate that culture's most basic, fundamental, and often invisible assumptions, ideologies, and values. Great portions of what we know, or think we know, come not from personal or direct experience, but from many modes of storytelling. Stories – myths, legends, soap operas, cop shows – tend to express and reproduce (i.e., cultivate) a culture's central beliefs about what exists, what is real, normal, good and bad, and what different types of people can expect in life.

Mass communication is the mass production, distribution, and consumption of cultural stories. Over much of human history, stories were told face to face by parents, teachers, or the clergy. Mass media, especially television, transform the cultural process of storytelling into a centralized, advertiser-sponsored system that now tells most of the stories to most of the people, most of the time. Most of the stories we now consume are not hand-crafted works of individual expressive artists, but mass-produced by bureaucracies according to strict market specifications. The commercial imperatives of television require it to produce stories that reflect – and thereby sustain and cultivate – the “facts” of life that most people take for granted.

## METHODOLOGY

Each year, starting in 1967, the Cultural Indicators project content analyzed a week-long sample of US network television drama in order to delineate selected features and trends in the overall world television presents to its viewers. In the 1990s, the analysis was extended to include new networks, channels, and genres. Throughout, message system analysis focused on the most pervasive content patterns that are common to many different types of programs but characteristic of the system of programming as a whole, because these hold the most significant potential lessons television cultivates. The coding instrument covers a wide range of themes, actions, and demographic representations, and is subjected to extensive reliability analysis.

The findings from the message system analyses are used to formulate questions about people's conceptions of social reality, often contrasting television's “reality” with some other

real-world criterion. Survey questions are posed to samples of children, adolescents, or adults, and the differences (if any) in the beliefs of light, medium, and heavy viewers, other things held constant, are assessed. The questions do not mention television, and respondents' awareness of the source of their information is seen as irrelevant. For the analysis, respondents are divided into groups of relatively light, medium, and heavy viewers on the basis of the distribution within any specific sample (→ Interview, Standardized; Survey).

### **MESSAGES AND IMPACTS**

The prominent and stable over-representation of well-off white males in the prime of life pervades prime time. Women are outnumbered by men at a rate of two or three to one and allowed a narrower range of activities and opportunities. The dominant white males are more likely to commit violence, while old, young, female, and minority characters are more likely to be victims. Crime in prime time is at least 10 times as rampant as in the real world, and an average of five to six acts of overt physical violence per hour involve well over half of all major characters.

Cultivation researchers argue that these messages of power, dominance, and victimization cultivate relatively restrictive and intolerant views regarding personal morality and freedoms, women's roles, and minority rights. Rather than stimulating aggression, cultivation theory contends that heavy exposure to television violence cultivates insecurity, mistrust, and alienation, and a willingness to accept repressive measures in the name of security, all of which helps maintain the prevailing hierarchy of social power (→ Cultivation Effects; Violence as Media Content, Effects of).

Cultivation is not a linear, unidirectional "effect," but part of a dynamic, ongoing process of interaction among messages and contexts. Television viewing relates in different ways to different groups' life situations and worldviews. For example, personal interaction with family and peers makes a difference, as do real-world experiences. A wide variety of socio-demographic and individual factors produce sharp variations in cultivation patterns. These differences often illustrate a phenomenon called "mainstreaming," which means that heavy television viewing may erode the differences in people's perspectives which stem from other factors and influences. Mainstreaming represents a relative homogenization of otherwise divergent viewers (→ Mainstreaming).

### **CRITIQUES**

Cultivation theory has been a highly controversial and provocative approach; the results of cultivation research have been many, varied, and often contested. The assumptions and procedures of cultivation analysis have been vigorously critiqued on theoretical and methodological grounds; extensive debates and colloquies continue to engage the scholarly community, and have led to a wide variety of refinements and extensions (Newcomb 1978; Gerbner et al. 1980; Hirsch 1980; Shanahan & Morgan 1999).

Some researchers have sought cognitive explanations for how television's images are processed, stored, and retrieved within viewers' heads. A broad range of intervening processes has been examined (e.g., the role of perceived reality, active vs passive viewing,

the family and the social context of exposure). Some have criticized the assumption of relative stability in program content over time and across genres, and emphasized the differential and specific impacts of exposure to different programs and types. The spread of nonbroadcast alternative delivery systems such as cable, satellite, and VCRs has been taken into account, and cultivation has been adapted to the virtual worlds of video games. Increasingly complex and demanding statistical tests and analytical models have been applied.

The literature contains numerous failures to replicate its findings as well as numerous independent confirmations. The most common conclusion, supported by meta-analysis, is that television makes a small but significant contribution to viewers' beliefs about the world (Shanahan & Morgan 1999; → Meta-Analysis) Given the pervasiveness of television and even light viewers' substantial cumulative exposure, finding observable evidence of cultivation at all is remarkable. Therefore, a systematic pattern of small but consistent differences between light and heavy viewers may indicate far-reaching consequences.

### NEW TECHNOLOGIES

Cultivation theory was developed when television viewing in the United States was dominated by three broadcast networks. Yet, in the early twenty-first century, all US broadcast networks combined attract under 50 percent of prime-time viewers, and the audience is divided among dozens of specialized cable and satellite channels devoted to specific interests. With the spread of VCRs, digital video recorders, digital broadcasting, video-on-demand, and pay-per-view, along with the ability to download programs on the Internet, mobile phones, and portable music players, audiences now seem to be able to choose from an extraordinary range of diverse content, watching whatever they want whenever they want, in ways that contradict many assumptions of cultivation.

Yet these new delivery systems alone do not fundamentally change the dynamics that drive program production and distribution. There has been little reduction in exposure to "network-type" programming; many new channels mainly offer more of the same types of programs. Concentration of ownership is increasing as the traditional barriers among networks, stations, studios, syndicators, cable operators, cable networks, and advertisers dissolve (→ Concentration in Media Systems). Further, key aspects of the earlier media system are amplified; e.g., premium cable channels have much higher levels of violence than do broadcast networks. Available evidence indicates that new technologies intensify cultivation; for heavy viewers, new media mean even greater exposure to more of the same messages. Thus, technological developments alone will not diminish cultivation if the messages do not change.

In sum, cultivation theory is concerned with the most general consequences of long-term exposure to centrally produced, commercially supported systems of stories. Cultivation analysis concentrates on the common consequences of living with television: the cultivation of stable, resistant, and widely shared assumptions and conceptions reflecting the institutional interests of the medium and the larger society. Understanding the dynamics of cultivation can help develop and maintain a sense of alternatives essential for self-government in a media-dominated cultural environment.

## **Cultural Appropriation**

*Marian Bredin*

*Brock University*

Cultural appropriation describes the use and exploitation by a majority or dominant group, of cultural knowledge or expressions originally produced by a minority or dominated group. It is applied to media and popular communication when ideas, images, sounds, and narratives produced by one group are appropriated for personal, professional, or commercial gain by members of a more powerful social group. Linked to colonial histories, racist discourses, and disparate access to power and resources, cultural appropriation can occur within and across specific national communities and within a range of popular communication practices (→ Communication Inequality).

### **THEORETICAL CONCEPTS**

#### **Distinguishing Cultural Appropriation from Related Concepts**

Cultural appropriation must be distinguished from other types of → popular communication and cultural exchange. Cultural appropriation bears some relation to processes of

assimilation, acculturation, hybridity, and cosmopolitanism, but is distinctive in important ways (→ Acculturation Processes and Communication). The term “cultural appropriation” came into widespread usage in communication studies in the late 1980s and early 1990s. Its theoretical development marked a shift away from the anthropological concept of *acculturation*; the gradual adoption of majority norms, values and practices by a minority or subordinate social group. The concept of acculturation as a model of cultural contact presupposes a degree of cultural essentialism and lacks an analysis of global structures of power (Born & Hesmondhalgh 2000). Postmodern influences in anthropology led to revised understandings of cultures as undergoing continuous transformation through intercultural contact and exchange (→ Postmodernism and Communication).

Cultural appropriation must likewise be distinguished from cultural *assimilation*. As Ziff and Rao (1997) suggest, assimilative practices occur when cultural minorities are encouraged or obliged to adopt the cultural forms and practices of dominant groups. Appropriative practices involve the reverse process; borrowing of cultural forms originating with subordinate groups. By the early 1990s scholars situated both these processes within theoretical analyses of power. Cultural appropriation developed as a negative concept to describe the exploitation of forms and expressions borrowed from other cultures by western societies without acknowledging their origins.

Cultural appropriation can also be compared to notions of *cultural hybridity* and *cosmopolitanism*. Within → postcolonial theory, hybridity is understood as both the transaction between past and present within a particular culture, and as the emergence of new cultural identities in periods of extensive contact between different cultures. This reinterpretation and mixing of cultural traditions is sometimes presented in a celebratory manner that obscures the histories of colonial violence from which hybridity emerges (→ Hybridity Theories). Contemporary theories of cultural cosmopolitanism suggest that global citizens should reject narrow attachments to national cultures. This view resists the notion that cultural identities are exclusively linked to specific cultural knowledge, rather it encourages forms of cultural sharing and borrowing. These concepts of cultural hybridity and cosmopolitanism neglect to consider how cultural difference is hierarchically ordered within → international communication flows. In the realm of popular communication, critics have suggested that postmodern notions of “crossover” and pluralism in music, art (→ Art as Communication), → fiction, film (→ Cinema), and → television disguise inequalities in the status and legitimacy of cultural production. This conceals practices of cultural appropriation behind appeals to aesthetic choice and cross-cultural exchange (Born & Hesmondhalgh 2000; → Aesthetics).

### **Disciplines and Areas of Study**

Because cultural appropriation occurs in a wide variety of domains, it has been studied by scholars in communication, → cultural studies, anthropology, history, art history, sociology, ethnomusicology, literary studies, political science, and law. Studies focusing on popular communication have examined appropriation in music, art, narrative, performance, popular film and television, sport and → advertising. Groups experiencing cultural appropriation can be defined in terms of ethnicity, race, and nationality. Researchers must define these groups according to their common identification with specific cultural

values, forms, and objects. Thus, approaches to cultural appropriation depend upon the initial conception of culture employed (→ Culture: Definitions and Concepts).

As Rosemary Coombe (2004) suggests, culture is defined in two main ways in discussions of appropriation: either as the universal and common heritage of humankind, or in the plural anthropological sense in which different cultures have different properties. When culture is seen as universally shared and equally available to individual artists, musicians, or media producers, cultural appropriation is viewed more positively, especially if the borrowing is acknowledged and done respectfully. If cultures are conceived in relativist terms as collective entities with common traditions and shared identities, appropriation is viewed less favorably. This distinction is further problematized in the realm of popular communication because those cultures more often seen in the anthropological sense are indigenous, colonized, and minority cultures. Perceived as existing in a traditional and “natural” state, elements of these cultures are more likely to be used as a resource for western artists. Popular musicians such as Paul Simon and Moby, for example, have been criticized for producing commercially successful recordings that adapt the work of African performers or use samples from early African-American recordings. While the resulting commercial work is protected by the multinational recording industry and → copyright law, the source material and samples originating in other cultures are implicitly viewed as a “free” cultural resource to be exploited (Taylor 1997; Hesmondhalgh 2006).

The analysis of cultural appropriation in popular communication must be situated within an understanding of colonial discourse and racist ideologies and stereotypes in the media. Where cultures have come into contact with each other through colonial and neo-colonial relationships, aspects of the colonized culture are appropriated by the dominant one (→ Social Stereotyping and Communication; Stereotypes; Stereotyping and the Media). In the North American context, “playing Indian” in a variety of popular practices, from summer camp tribes and rituals, images of Indian princesses in brand-name logos and advertising, and New Age “shamans,” is an example of cultural appropriation (Root 1995; Deloria 1999). These practices demonstrate the ahistorical use of images and identities from indigenous cultures in ways that disown origin or authorship and reproduce stereotypical and one-dimensional perceptions (Lutz 1990). Even when the appropriation of a minority cultural form is well-intentioned and more direct, as is the case when contemporary hip hop or bhangra artists sample original African or South Asian music, the authorship of the musicians sampled is often erased or obscured (Hesmondhalgh 2000). Using the example of “pygmy pop” to demonstrate how musical communication is shaped by colonial contexts, Steven Feld (2000, 262) argues that this case of appropriation marks “the historical moments and contexts where oral performance and cultural participation are transformed into material commodity and circulable representation.”

## **MOTIVATION FOR AND EFFECTS OF CULTURAL APPROPRIATION**

Cultural appropriation is an aspect of institutional power that allows western media practitioners and cultural producers to objectify, reify, and authenticate nonwestern cultures. The motivation to appropriate has been traced to different needs and impulses

within the dominant society. In the case of appropriation of African-American musical styles and sensibilities, Perry Hall (1997) argues that white musicians are attracted to the innovative rhythmic and aesthetic sensibilities emerging from marginal black communities. This attraction triggers a form of cultural dissonance in the face of racist attitudes and values. The initial social rejection of new popular musical genres like jazz, blues, rock, and rap is overcome once these genres have been adopted by white performers and penetrate the white-dominated mainstream. The attraction to exotic and marginalized minority cultures might also be understood as a metaphor for the rejection of bourgeois western norms and values. The popular appeal of stereotypical Native Americans in Hollywood Westerns and popular television drama may reflect the viewer's desire to identify with the fictional victimized and "vanishing" Indian and avoiding the implications of real political struggles over indigenous rights (Root 1997). What might initially be perceived as a valorization of marginal and minority cultures can also be read as a desire to contain and control cultural difference and gloss over the unsavory details of the past.

Cultural appropriation in popular communication often takes the form of → fetishization of the cultural other, the reduction of living cultures and social groups to a means of social and spiritual redemption for members of the dominant society. Thus, advertising campaigns like the "united colors of Benetton" that code cultural and racial difference as an exotic commodity are also a form of cultural appropriation. The mass appeal and commercial success of yoga studios and fashions in major North American and European cities involves the appropriation of South Asian culture emptied of its original spiritual meaning and reconstructed as a form of upscale urban stress-relief. In postcolonial terms, members of the dominant society become "touring subjects" in Asian, African, and indigenous cultures (→ Tourism and Popular Culture). In each of these instances, cultural appropriation must be seen as a systemic attribute of communication practices rather than merely the result of individual acts by cultural producers and performers.

Not all researchers agree that cultural appropriation is always related to unequal power relations and modes of subjugation. Goldstein-Gidoni (2003) studied the appropriation of Japanese culture in Israel through the commercialization of activities like origami, martial arts, mask-making, dance classes, and flower arrangement. Though she suggests that these activities involve the production and consumption of an essentialized and objectified "people-less" culture, she argues that they are not ultimately harmful to Japanese culture. Other scholars defend cultural appropriation because even though it is offensive to some members of the appropriated culture, it is not always wrong. James O. Young (2005) suggests that when cultural appropriation produces works whose social value outweighs the offense (giving the example of Shakespeare's representation of Jews in the *Merchant of Venice*) it can be defended. Distinguishing between collaboration and appropriation, between mutually productive cultural exchange and exploitation, is sometimes difficult.

Although cultural appropriation includes the acquisition and use of cultural objects, its relevance in the study of popular communication is focused on the appropriation of intangible cultural forms. James O. Young (2005) distinguishes between *subject appropriation*; when outsiders represent members or aspects of another culture or make the culture or lives of others the subject of an image, story, film, or television production, and *content appropriation*; when artists, musicians, writers, or media producers use the cultural

forms, expressions, music, images, styles of another culture in the production of their work. Young suggests that people are offended by cultural appropriation because of the derogatory nature of the image or content represented, because consent to use or adapt cultural elements and expressions should have been sought and was not, or because appropriation is perceived as misusing something sacred or private (→ Ethics of Media Content).

The *effects of cultural appropriation* on subordinate groups are social, economic, cultural, and political. *Socially*, cultural appropriation is experienced as offensive, insulting, and sometimes violating. Stereotypical images of the Native American warrior or chief used as “mascots” by sports teams or in advertising logos are viewed as demeaning to indigenous people. The appropriation of religious imagery such as the eroticization of Hindu religious deities at a major gay and lesbian social event in Sydney, for example, is experienced as a form of disrespect and violation (Velayutham & Wise 2001). In the domain of *economics*, cultural appropriation exploits and commodifies aspects of subordinate cultures while diverting financial compensation away from its members. The case of jazz is a compelling example. Musical innovations in African-American communities in the 1930s were appropriated and commercialized by white musicians to the extent that black performers received little exposure in the market, were rarely rewarded with recording contracts, and were ultimately unable to support themselves by playing the music they had created (Hall 1997). The *cultural* impact of appropriation lies in the misrepresentation of subordinate cultures by stereotyping, simplifying, and silencing them. In the American context, while images of indigenous people appear frequently in many domains of popular culture, and indigenous languages are used to name regions, cities, and streets, most people know little or nothing of the original inhabitants’ history or cultures. In European cultures, representations of formerly colonized African and Asian peoples abound in literature, art, music, and popular media, but contemporary inhabitants of the former colonies have limited access to current global communications and cultural industries. Finally, cultural appropriation has a *political* impact that flows from the relationship between power and representation. Appropriation is compounded by other exclusions from education, financial support, and access to the media, and has the end result of displacing, containing, and controlling subordinate cultures.

*Responses to cultural appropriation* have emerged from debates amongst scholars, critics, media practitioners, and cultural activists. While critics of cultural appropriation have sometimes been accused of promoting → censorship, their goal could more properly be described as demanding respect and accountability in processes of cultural exchange. Both legal and ethical solutions have been considered to contain the negative effects of cultural appropriation. Legal debates have raised the problem of extending intellectual property rights to cultural forms and expressions whose ownership or origin may be collective rather than individual (→ Intellectual Property Law). Ethical questions have focused on shifting the balance of power in representation through cultural funding programs and media access policies. By this means, members of subordinate, indigenous, and minority cultures would have the resources to produce and circulate their own cultural forms to counteract appropriative processes.

# Cultural Imperialism Theories

*Nancy Morris*

*Temple University*

The cultural imperialism thesis states, broadly, that a powerful country uses cultural means to achieve or support the political and economic ends of imperialism that were historically attained through military force and occupation. In this view, the tools of culture can smooth the way for domination by exposing people to lifestyles to aspire to, products to desire, and even new sources of allegiance (→ Culture: Definitions and Concepts).

Overall, the notion of cultural imperialism appears embedded in critiques of the substantial US export of media programming to other countries. Those lodging the charge of cultural imperialism – found mainly in scholarly, political, activist, and diplomatic realms – have asserted that western films, TV shows, and commodities serve as → propaganda for a consumerism-based capitalist model of society (→ Consumer Culture). Gaining adherents for this model, the argument goes, would create overseas markets and political environments favorable to western – particularly US – interests (→ Americanization of the Media). In the process, the autonomy of receiving countries, as well as their cultures, values, and identities, would be weakened or destroyed.

## ORIGIN AND HISTORY OF THE CONCEPT

This idea is not limited to the contemporary setting: it has been applied to practices of, for example, Britain, Japan, the Ottoman Empire, France, Spain, and other imperial powers throughout history. The phrase “cultural imperialism” appeared in late-1940s discussions of the nascent United Nations Educational, Scientific, and Cultural Organization (→ UNESCO), expressing trepidation about the potential activities of countries with technologically advanced media systems. Although the term is not new, it first gained wide attention in the 1970s, in the context of the expansion of the US and western European mass media export industries.

The intellectual roots of the cultural imperialism thesis lie in world systems theory (Galtung 1971; Wallerstein 1974), which categorizes the countries of the world by their degree of development and of trade domination. It sees the developed countries – the “center” – dominating the non-industrialized countries – the “periphery” – in ways that do not allow the peripheral countries to establish their own paths. Dependency theory, a Latin American outgrowth of world systems theory that attained prominence in the 1960s and 1970s, elaborated the notion that underdevelopment was not simply a matter of some countries’ progress lagging behind others, but rather conferred structural advantages on developed countries (→ Communication as an Academic Field: Latin America; Dependency Theories). Therefore it was in the interest of powerful countries to maintain their domination. During the same period, analyses of the global trade in entertainment products, particularly film and → television programs, confirmed that the US was by a large

measure the world's principal exporter of audiovisual material, while importing very little (Nordenstreng & Varis 1974). Together, these concepts – of center and periphery, of the advantage to industrialized countries of domination, and of the “one-way flow” of audiovisual material internationally – contributed to the charge that in their search for worldwide markets and ideologically sympathetic populations, states and transnational corporations were practicing cultural imperialism (→ Free Flow of Information).

The name most prominently associated with the cultural imperialism thesis is Herbert Schiller. In *Mass communication and American empire* he stated that, “Directly by economic control, indirectly by trade and a foreign emulation effect, communications have become a decisive element in the extension of United States world power” (1969, 163). Schiller set forth a fundamental claim of cultural imperialism exponents: that activities labeled as cultural imperialism constituted a threat to “the cultural integrity of weak societies whose national, regional, local or tribal heritages are beginning to be menaced with extinction” (1969, 109).

In his later book *Communication and cultural domination*, Schiller employed the term “cultural imperialism,” defining it as “the processes by which a society is brought into the modern world system.” Mass media, he contended, are the principal vehicle for “shaping social institutions to correspond to, or even promote, the values and structure of the dominating center of the system” (1976, 9). In Schiller's view, this was intentional – US government and business sectors were attempting to mold developing countries' values and institutions to benefit US objectives.

### RELATED CONCEPTS AND LIMITATIONS

Other analysts modified and adapted the notion in various ways, often focused on political and institutional relationships. The terms “media imperialism” (Boyd-Barrett 1977) and “electronic colonialism” (McPhail 1981), for example, were coined to describe phenomena recognizable as variants of the cultural imperialism thesis, drawing attention with the labels to the centrality of mass media in the analyses.

Another approach to these questions focused on media content. *How to read Donald Duck*, a seminal study by European scholar Armand Mattelart and Latin American author Ariel Dorfman, was first published in Chile in 1971. This book parsed Disney → comic books distributed in Latin America and found messages of native inferiority that the authors maintained were designed to induce readers to discard their own values and cultural identities, and to accept US superiority.

These diverse analyses both paralleled and intersected international debates about the regulation of media imports in the interest of national development. This controversy pitted the US/UK conception of the “free flow of information,” which promoted unregulated markets in news and entertainment, against many other countries' insistence on the need for balance in media exchanges, particularly of → news. This position was expressed in the UNESCO-based call for a → new world information and communication order (NWICO), which centered on concerns recognizably related to cultural imperialism claims. Exemplifying these concerns, the 1980 report of the UNESCO International Commission for the Study of Communication Problems signaled the problems caused by “certain powerful and technologically advanced States [that] exploit their advantages to

exercise a form of cultural and ideological domination which jeopardizes the national identity of other countries” (MacBride Commission 2004, 37).

There exist few explicit formulations of cultural imperialism as a theory. John Tomlinson has noted that cultural imperialism is a “generic concept” that has been used as an umbrella term for various propositions that, while related, do not share a precise meaning (1991, 9). Critics have argued not only that the concept lacks a clear definition, but also that it overlooks the complexities of culture and cultural interaction, and disregards the role of → audiences in interpreting media texts. Overall, the specific claims of proponents of the cultural imperialism thesis have not been supported by empirical research. As a → critical theory, however, cultural imperialism has provided a framework for thinking about global media flows and the power of state and commerce.

In the twenty-first century, the term “cultural imperialism” has been eclipsed. As a way of conceptualizing and analyzing multidirectional cultural interactions, the concept of hybridity has gained attention. Ongoing international trade liberalization and the advent of the → Internet have also brought the notion of “globalization” to the fore (→ Globalization Theories). The latter has largely supplanted cultural imperialism in discussions of international media flows, with analysts stressing that the concept of media globalization lacks the intentionality implicit in the cultural imperialism thesis.

# Cultural Patterns and Communication

*Peter B. Smith*

*University of Sussex*

The concept of culture was first found useful by social anthropologists in studies of tribal societies. More recently, it has also been used to analyze differences between industrialized societies. A culture can be said to exist when a number of persons interpret the events around them in relatively similar ways. These shared interpretations typically include the meanings of both the behaviors of other persons and the physical entities that are present in a particular setting. Thus, attributes of a culture might include agreement that a certain building is to be thought of as a school and perceptions that certain students are more able, attractive, or industrious than others. Culture is a concept that can be applied to marriages, teams, tribes, organizations, and nations. There is obviously less consensus between the members of a nation than there is between members of smaller groupings, but cross-cultural psychologists have found value in studying nations as cultures.

By comparing survey responses of business employees from over 50 nations, Hofstede (2001) identified *five dimensions describing cultural differences* between nations. He named these as Individualism–Collectivism, Power Distance, Uncertainty Avoidance, Masculinity/Femininity, and Long-Term Orientation. First identified in the 1960s, these dimensions can still predict how many aspects of behavior relevant to communication vary between nations. In particular, the contrast between individualism and collectivism has been confirmed by later studies. Within the (mostly western) nations categorized as relatively individualistic, most persons define their identity in terms of personal attributes and see their linkages with others as based on individual choice (→ Communication Modes, Western). Thus, although relationships, marriages, and jobs can be long-lasting, they can also be terminated if they do not meet one's goals in life. Within nations categorized as more collectivistic, most persons define their identity in terms of long-term commitment to groups such as family, tribe, or organization. An individual leaving such groups would find it difficult to locate new sources of identity, because alternative groups would not be open to new members.

Nations cannot be categorized simply as individualistic or collectivistic, but can be arrayed along a *spectrum* from one extreme to the other. Individuals also vary in their orientation toward individualism and collectivism, so that one may find some individualists within a predominantly collectivist culture and some collectivists within a predominantly individualistic culture. This has been particularly true recently, due to extensive migration from collectivistic to individualistic nations.

The types of communication that are most prevalent in different cultures reflect the priorities of those living within them. In individualistic settings, it is important to establish one's credentials as someone who is attractive, coherent, competent, and trustworthy. In collectivistic settings, a stronger priority is to preserve harmony within one's group and to maintain the integrity of its boundaries. Even the languages spoken in different cultures reflect these priorities: those spoken within collectivistic nations mostly permit the omission of the personal pronoun "I" from a sentence, while those (such as English) spoken in individualistic nations do not (Kashima & Kashima 1998).

For members of a collectivist culture, preferred communication styles will depend upon whom one is communicating with more than for those in an individualistic culture. Among one's ingroup, concerns with face and harmony will predominate. In dealing with those outside one's group, communication may be as direct and as confronting as is favored by members of individualist cultures, in order that the integrity and honor of one's group may be upheld. Research studies (Smith et al. 2006) now show that individuals' orientation toward individualism or collectivism predicts directness of communication (→ Communication Modes, Asian), nonverbal aspects of communication (→ Nonverbal Communication and Culture), expression of emotions, politeness strategies, concern with one's own face rather than with others' face (→ Intercultural Conflict Styles and Facework), embarrassability, receptiveness to individual- or group-focused feedback, styles of negotiation, and response to different types of advertisements. Communication style even affects how individuals respond to research surveys: members of collectivist nations show a stronger tendency to agree with positively worded questions, so that cross-national comparisons can be invalid if no correction is made for this (Smith 2004).

The other dimensions of cultural variation identified by Hofstede have been less intensively investigated. Power distance, defined as relative acceptance of hierarchy, affects styles of address in different nations. Preference for high or low levels of uncertainty avoidance is associated with variation in the types of emotion most frequently reported. More recent studies have shown that nations can be distinguished in terms of distinctive profiles of beliefs, in addition to the values upon which Hofstede focused (Bond 2004).

Conceptualizations of culture are important because communication can only be fully understood as an interaction between individuals' dispositions and the broader context within which they are located. To become effective, individuals must learn to express themselves in ways that convey desired meanings within the interpretive system in which they are located. While cultural transmission occurs normally in the family and at school, it becomes problematic for the increasing number of those who move from one cultural context to another, whether as students, tourists, business persons, refugees, or migrants (→ Acculturation Processes and Communication). Learning another culture entails more than learning a new language: it requires a grasp of the ways in which that language is used to interpret local meanings.

## **Cultural Products as Tradable Services**

*Kenton T. Wilkinson*

*Texas Tech University*

In the communication field, the term “cultural product” refers to media artifacts such as → books, → newspapers, → magazines, recorded music, films, → television programs, and related audiovisual materials. “Cultural product” succinctly conveys the juxtaposition that renders these artifacts controversial: they express cultural values of societies that produce them, yet are economic goods created, distributed, and engaged by → audiences under market conditions (→ Culture Industries; Music Industry; Markets of the Media). Because of their power to influence a society’s aesthetic and ideological environments, as well as its economy, the exchange of cultural products across political, cultural, and linguistic boundaries can be quite sensitive. Efforts to promote cultural products’ creation and dissemination – and also to control their importation and circulation – have been undertaken by a variety of organizations in diverse contexts (Hesmondhalgh 2007). Historically this has involved less developed nations restricting importation of cultural products from more developed nations, although despite moves toward free trade, more developed nations have resisted cultural imports from their peers.

### **HISTORY**

Cultural products have been assumed to carry the political, economic, and social ideals of their societies of origin since the beginnings of mechanized print media (→ Printing, History of). As western economies became more intricate and specialized under European colonial expansion and the Industrial Revolution, markets for cultural products grew more robust, and the products themselves more complex. A translation industry developed to increase their market reach across cultures. Concerns over the impacts of imported cultural products mounted during a period of accelerated technological innovation that began in the mid-nineteenth century and continues today. As cultural products assumed a more central position in cultural and economic relations among nations and social groups, national governments elaborated and began to enforce cultural policies (→ Media Policy). Political advocacy organizations also began monitoring media content and wielding political and economic power to press for change. A North American example is illustrative.

During the first half of the twentieth century, the US government supported the export of US-produced films through currency exchange rate guarantees, suspension of antitrust rules for international business, tax breaks, and other programs (Guback 1985). In the 1910s and 1920s, US studios produced so-called “greaser” films that depicted Mexicans

and Mexican Americans as unwashed, lascivious criminals. These portrayals led to public outcry and theatre boycotts in the southwestern US and Mexico. In 1922 Mexico's government threatened to block distribution of all films from an offending studio if representations did not improve. The filmmakers quickly developed a production code, and an industry organization, the Motion Pictures Producers and Distributors of America, began reviewing films prior to export so as to avert such confrontations. This example clarifies who are the major players in cultural products trade: media industry participants (including industry organizations), government agencies, advocacy groups, and the → public. Other key players would emerge later: supra-national organizations such as GATT and WTO.

### INTELLECTUAL ROOTS AND THE ISSUES OF THE 1970S

Cultural products and the organizations that create them, cultural industries, initially received theoretical attention from members of the Frankfurt School in the 1930s through 1950s (Horkheimer & Adorno 1996, 1st pub. 1944; → Critical Theory). The Frankfurt scholars joined analyses of media ownership and control with critiques of mass cultural products' content to discuss their impact on economic conditions as well as aesthetic values (→ Ownership in the Media). This scholarship brought attention to the multifaceted influence of cultural production and stimulated subsequent research along these lines (→ Political Economy of the Media). Midway through the twentieth century as many newly independent nations struggled to cast off the yoke of political, economic, and cultural dependency, discussions of a new world information and communication order occurred in the United Nations Educational, Scientific, and Cultural Organization (→ Dependency Theories; New World Information and Communication Order [NWICO]; UNESCO). The content, dissemination, and impact of cultural products were directly linked to arguments about the commodification of mass media and communication's role in maintaining global inequities.

An empirical study of international television flow by Nordenstreng and Varis (1974) summarized the lopsided distribution of programs from more developed nations to less developed ones – typically following former colonial trade routes – and highlighted the advantaged position of the US among more developed nations. This study, among others, invigorated the cultural imperialism thesis asserting that western culture displaces local culture in less developed nations where cultural products are imported and engaged by audiences on a large scale, thereby overshadowing locally produced media content (→ Cultural Imperialism Theories). A widely read UNESCO report on the international communication status quo called for reforms to make media production and dissemination more equitable, and underscored the combined cultural and economic character of cultural products (MacBride Commission 2004).

### RECENT CONCERNS

More recent concerns about cultural products as tradable services have focused on their inclusion in *regional trade agreements*. Although North America and Europe pursued different methods of economic integration, the inclusion of cultural products was contested

in both regions. As the 1988 *Free Trade Agreement* (FTA) was negotiated, Canada's historic sensitivity to cultural domination, resulting from high volumes of imported US media, clashed with the US preference to treat cultural products like any other economic good. Canada insisted that cultural products be excepted from the FTA, and the US countered by reserving the right to retaliate in other industries should Canada restrict distribution of its cultural products. In 1994 Mexico joined an expanded North American Free Trade Agreement, with little public discussion of the agreement's potential impact on the cultural sector, though concerns were raised by Mexican intellectuals (McAnany & Wilkinson 1996; → NAFTA and International Communication).

*Europe's* integration efforts date from the 1940s and display deep traditions of direct government involvement in media production and dissemination through state-subsidized publishing, film production, and public service broadcasting (→ Public Service Broadcasting: Law and Policy; Public Broadcasting Systems; Public Broadcasting, History of). These traditions have complicated the emergence of additional commercially supported media systems since the 1980s. The European Commission's goal of establishing a vigorous regional exchange in cultural products is also challenged by considerable diversity in numbers of language speakers, the size and wealth of national economies, and the uneven productivity of media industries among European Union (EU) members. Equity and balance in the cultural product trade is at issue within the EU system since half a dozen languages and production centers predominate among more than 25 nations. As concerns the external trade in cultural products, the EU endeavors to promote the export of regionally produced media and curtail the heavy importation of outside content, especially from the US (→ European Union: Communication Law). In 1993, as the deadline to sign the General Agreement on Tariffs and Trade (GATT) drew near, the EU, under France's guidance, advocated specifying limitations for US films on European screens. The heated disagreement over this provision threatened to derail the entire agreement before a last-minute compromise was reached.

The *Southern Common Market* (MERCOSUR) among Argentina, Brazil, Paraguay, and Uruguay was created in 1991. The agreement contains little specific language concerning the trade in cultural products, yet it should be noted that Argentina and Brazil are prolific producers of music, film, and television, especially telenovelas (→ Soap Operas), which are exported throughout Latin America and beyond (Galperin 1999; → Communication Law and Policy: South America). In *Asia*, the Association of South East Asian Nations (ASEAN) has left cultural trade issues for its member nations to address; some have successfully slowed the importation of cultural products while developing their own multicultural, multilingual media (Lent 1990; → Communication Law and Policy: Asia).

The *World Trade Organization* (WTO) is the supra-national organization administering the trade in cultural products since 1995, when it took over the GATT negotiation process. Several sub-agreements negotiated under WTO auspices address specific trade issues related to cultural products. A general agreement on trade in services (GATS) established a framework for facilitating trade and investment in the "services" sector, including → advertising, business, computers, finance, insurance, and market research, among others – industries that experienced tremendous growth due to digitization and diminishing costs for international telecommunications since the 1980s. The GATS annex provides that private telecommunication firms may gain adequate access to national infrastructures.

It has opened many domestic telecommunication systems to international competition, and institutionalized the → “free flow of information” principle long at issue in international communication (Thussu 2006). As various types of communication content move across myriad distribution systems, the definition of cultural products and the analysis of their exchange have become more complicated. It is also increasingly difficult to control → piracy as digital technology facilitates the rapid and economical reproduction of cultural products with no degradation of quality for each subsequent “generation” produced. This challenge is addressed by the WTO agreement on trade-related aspects of intellectual property rights (TRIPs), a treaty establishing minimum standards for intellectual property regulation. TRIPs is strongly endorsed by the US as a means of bringing order and dispute-settlement procedures to intellectual property protection through the multilateral trading system.

A key area of dispute over intellectual property rights has been *file sharing*, the practice of making computer files available for downloading by other users on a computer network (→ Internet, Technology of). A computer file containing the cultural product is transferred from a remote computer to a local computer’s hard drive or other storage medium (e.g., CD) or playback device (e.g., MP3 player). In the late-1990s concerns focused on file-sharing systems such as Napster, used for downloading music without paying royalties to the copyright holders (→ Copyright). By the mid-2000s, concerns had expanded to audiovisual content, including television programs and feature films that computer users could download and view without paying fees. In 2007 the media conglomerate Viacom filed suit against YouTube, a popular video-sharing website where users could upload, view, and share videos they had produced themselves or recorded from other media. The presence of commercially produced, copyrighted cultural products on servers that also stored home movies and other amateur productions challenged conventional approaches to intellectual property rights enforcement.

The easy access to volumes of content among people who have computers, the → Internet, and the knowledge to use them tends to obscure the vast majority of the world’s population who remain disconnected (→ Digital Divide). In 2004 the G8 countries were home to only 15 percent of the world’s population, but represented nearly 50 percent of the world’s total Internet users (World Summit on the Information Society 2005). A movement to address this and related problems emerged in the early 2000s with the World Summit on the Information Society (WSIS; → Internet: International Regulation; Internet Law and Regulation). A series of international meetings sponsored by the International Telecommunications Union (ITU) began in 2003 to “build a people-centered, inclusive, and development-oriented Information Society, where everyone can create, access, utilize, and share information and knowledge . . .” (Building the Information Society 2003). Although some indicators suggested a *narrowing of the digital divide* in limited sectors by the mid-2000s, a clear pattern had emerged: slower uptake and fewer benefits derived from new technologies in the less developed nations. The WSIS concerns were reminiscent of calls for a NWICO, though with an emphasis on new, interactive technologies (→ Interactivity, Concept of). It must be emphasized that these new technologies are often used to engage cultural products that are still traded as economic services and simultaneously carry cultural values from the societies that produce them.

## **Cultural Studies**

*Lawrence Grossberg*

*University of North Carolina at Chapel Hill*

Cultural studies is a recent, innovative, and interdisciplinary project that has had a significant presence in the field of communication since the late 1970s, as well as in other

humanities and social sciences (→ Communication and Media Studies, History since 1968). Cultural studies is concerned with describing and intervening in the ways in which texts, discourses, and other cultural practices are produced within, circulate through, and operate in the everyday life of human beings and the institutions of society.

Unlike some other interdisciplinary fields, cultural studies is not defined by a single object (e.g., an identity, as in women's studies) or a geographical region (e.g., area studies). Moreover, there are several versions of cultural studies. Although some commentators locate its origins in Britain in the 1960–1970s (especially at the Birmingham Centre for Contemporary Cultural Studies), it actually emerged independently, as an interdisciplinary and international project, in multiple geographical locations. While communication was perhaps its first and most sympathetic host, at least in the US, today it has a presence in many disciplines and fields. This diversity – theoretical, methodological, political, and empirical – can make it difficult to discern the project of cultural studies.

The common project involves a particular way of doing intellectual work that is responsive and responsible to its changing context, whether geographical, historical, political, or institutional (→ Critical Theory). Without giving in to relativism, cultural studies seeks new and more modest forms of expertise. Its modesty is based not on any failure of scholarly rigor, but on a realization that knowledge and the tools of its production are always, unavoidably, contextually bound. If people make history, but in conditions not of their own making, as Karl Marx suggested, cultural studies explores this process as it is enacted through cultural practices.

### KEY CONCEPTS

Two pairs of concepts ground the project of cultural studies: culture and context; power and belonging. Cultural studies starts from a recognition that *culture* has several meanings (→ Culture: Definitions and Concepts). While other disciplines may study one aspect, cultural studies aims to hold together the different dimensions of culture in a productive tension: (1) culture as a set of privileged activities, texts, and rituals, ranging from the highly valued (e.g., art) to the common (mass and popular culture), through which people express complex relations to the world in which they live; (2) culture as the uniquely human, symbolically mediating activities through which human beings make sense of that world; and (3) culture as the whole way of life of a group of people in the world, linking everyday life to the totality of social relations and institutions.

Cultural studies, thus, addresses the interrelations among the aesthetic-expressive-ritual, the symbolic-constructionist-hermeneutic, and the socio-anthropological dimensions of culture. It is the concrete totality of these relations that constitutes the uniqueness of human life in any particular time and place, for any particular group of people. To put it simply, cultural studies scholars believe that every aspect of human life is in part (but never only) cultural. This is different from a frequent, but mistaken identification of cultural studies with the application of humanistic or literary methods of interpretation and judgment to all of culture or society, or as the study of academically and socially marginalized forms of culture (e.g., media culture, popular culture, or subaltern cultures).

The second key concept is *context*. Cultural studies believes that any element or aspect of human life can only be understood relationally; what something is, is less the product

of its own internal essence than the sum total of its relations with other elements of the context of the lived social reality of a group of people. Cultural studies is an effort to think contextually about contexts; context defines both the object and the practice of research. Many of the core and unique features of the project of cultural studies derive from this concept. If academic work is commonly characterized as moving from the complex to the simple, from the concrete to the typical, cultural studies insists on describing and theorizing the complexity of the specific contexts. Instead of the disjunctive and reductionist logic that attempts to find the one thing that will explain something, cultural studies adopts an anti-reductionist and conjunctive rhetoric: “yes (it is that), and that . . . (and that . . . and that).” And, partly as a result, cultural studies work has to be interdisciplinary, establishing culture’s relations to everything that is not culture; for example, economics, the state, or various social institutions. The diverse versions of cultural studies normally operate within a broader theoretical framework – such as → pragmatism, historical materialism, or postmodern materialism – that embraces a radical contextualism. Cultural studies, however, does not have a general theory of culture per se.

This contextualism is expressed in the key notion of *articulation*, which refers to a theoretical model as well as a methodological practice. Articulation is the making, unmaking, and remaking of relations according to a logic of contingency, what Stuart Hall (1983) called a theory “without guarantees.” If some theories treat the shape and structure of social contexts as inevitable, other theories tend to deny any stability or reality to the structures and relations of social life. Cultural studies operates in the space between, on the one hand, absolute fixity and determination, and, on the other hand, absolute freedom and indetermination. Cultural studies is committed to the reality of relations that have determining effects, and attempts to construct politically relevant descriptions of how contexts are continuously being made, unmade, and remade.

The third key concept defines context as a material configuration of *power*. While avoiding a reduction of all social relations to matters of power, cultural studies approaches contexts as sites of a struggle over power. Here, power is understood not necessarily as domination, but as the ongoing production of structures of inequality, and as a temporary balance in the field of social forces and interests involving multiple dimensions. One dimension of power (e.g., class) does not necessarily explain another (e.g., gender), nor will changing one necessarily change the other. Similarly, there is no singular mechanism through which a given dimension of power (e.g., race) is produced, organized, and performed. Instead, power operates at different levels, including the state, civil institutions, discourses, everyday life, emotions, and the body.

In this process, culture is a crucial agent configuring, consolidating, and resisting power. Exhibiting fissures and fault lines that may become active sites of struggle and transformation, power can be seen as always contradictory and incomplete. Cultural studies examines how power infiltrates, contaminates, and limits the possibilities that people have of living their lives in humane, dignified, and secure ways; it also explores the possibilities for change through an analysis of the existing fields of power. Cultural studies, then, investigates how people are empowered and disempowered by the particular discursive practices through which their everyday lives are articulated in relation to the wider structures of social, economic, and political power.

The final key concept addresses how people experience everyday life and its contexts of social power: *belonging* points to the forms of affiliation, identification, and differentiation by which people locate and invest themselves in particular social groups, cultural identities, geographical and symbolic spaces. Whether understood in terms of national formations or local communities, shared identities or structured differences, belonging is closely connected to a notion of the popular: this is not some subset of culture, but the full set of maps, logics, and languages within which people understand themselves, calculate their values and commitments, and decide on the necessary stabilities and possible mobilities of their lives.

### KEY FIGURES

The actual shape of any version of cultural studies is determined by a number of choices and circumstances: the particular local or regional setting of the work; the specific cultural ensemble of media and discourses being examined; the theoretical tools and key concepts that lend themselves to the domain of study; and the (political) questions being addressed. The literature in cultural studies from different regions of the world and in different languages bears witness to the viability and diversity of the project within various national and regional settings. While some of these traditions emerged as a result of an encounter and conversation with English-language work in cultural studies, others, especially in Asia and Latin America, emerged out of their own traditions of cultural and political analysis in the context of developments following World War II (→ Communication as an Academic Field: East Asia; Communication as an Academic Field: Latin America; Communication as an Academic Field: South Asia). For example, the founding work of Néstor García Canclini and Jesús Martín-Barbero, drawing upon a long history of cultural criticism, has made important contributions to the cultural studies of communication in both the Latin American and global contexts. In the English-language literature within the field of communication, the two most important and influential figures have been James Carey in the US and Stuart Hall in Great Britain (→ Communication as an Academic Field: USA and Canada; Communication as an Academic Field: Western Europe).

Carey's contribution was driven by a pragmatic concern for the role of communication in community and democracy. Influenced by the anthropological semiotics of Clifford Geertz and the materialist history of → Harold Innis, Carey's research examined the ways in which the social appropriation of various technologies (e.g., the telegraph, railroads) and of cultural forms (e.g., journalism, the novel) gave expression to, shaped, and sometimes undermined the maps of meaning, modes of belonging, and structures of experience that are shared across culture, including not least people's experience of themselves in social space and time. Carey described culture as the symbolic realm through which human beings create representations of reality, and then live within those representations. He took the fundamental challenge facing cultural studies to be the growing influence of science as a model of research, embodied, for example, in a transmission view of communication as opposed to his own ritual view (→ Models of Communication). Carey argued that a reduction of human reality to the parameters of scientific knowledge was partly to blame for the growing weakness both of a sense of

community and of a commitment to democracy in the United States. A consistent underlying theme in his work, which became more evident toward the end of his career, was the historical processes by which societies themselves are made, unmade, and remade. He was particularly concerned with how the university was giving up its critical role in describing and judging larger social and cultural changes.

Hall's work began from an ambivalent relation to Marxism, and was also influenced by poststructuralism and postmodern materialism, especially as represented by Jacques Derrida and Michel Foucault. Hall's research has moved from analyses of the ideological messages of media content to broader accounts of the active cultural agency of media audiences and their symbolic resistance, as stated in his encoding–decoding model of communication. While continuing to explore more complex, circulatory models of the production and consumption of culture, his major writings since the 1980s have focused on the reorganization of national politics and the rise of a new conservatism in Britain. Theorizing such political developments as cultural struggles for hegemony over the definition of “the popular,” Hall's attention was turned to identities and subjectivities (particularly aspects of race and ethnicity), again not as analytical categories regarding individuals, but as dimensions of culture and society as such.

### RESEARCH ISSUES AND PROBLEMATICS

Despite their diversity, different versions of cultural studies define themselves as answering particular questions that derive not from academic protocols, but from the world of lived realities. At least four such problematics can be identified: knowledge, agency, subjectivity, and modernity. While different research formations may address these questions – whether alone or in combination – one has to remember that the form of the questions themselves will be differently articulated in relation to the specific context.

The concept of *knowledge* raises questions not just of how to assess the claims of, but of distinguishing between competing forms of, knowledge. Cultural studies generally places itself in opposition to the universalizing claims of “scientific” or reductionist approaches. It interprets the variety of cultural messages in a given society as maps of the structures of meaning and belonging. Such interpretations may approach culture critically, as ideological representations in the service of dominant interests, or more sympathetically, as rituals of belonging that reaffirm the shared meanings and values of a social group.

The question of *agency* is directly connected to the concept of power as described here. Cultural studies seeks to understand not only the organizations and institutions of power, but also the possibilities for resistance, struggle, and change throughout society. It takes contestation for granted, not as a reality in every instance, but as a potential and a precondition for the existence of critical work, political opposition, even historical change. People are not considered simply passive objects being manipulated by dominant messages, or cultural dopes. Cultural studies examines how people attempt to assert themselves in the face of power, the determinations that constrain and empower them, and the possibilities available to them.

The problematic of *subjectivity* arises primarily from two developments within cultural studies: first, the influence of poststructuralist theory, which argues that discourses produce the positions (subjectivities) from which individuals both experience the world and become speakers of the discourse (→ Postmodernism and Communication;

Structuralism); second, the organization of political struggles around a series of identities relating to gender, race, ethnicity, etc. This consideration of subjectivity challenges the common assumption that there is an authentic way of experiencing the world, which may have been distorted by ideological representations. The problematic is radical because it suggests that the very possibilities of human experience and agency are determined by the structures of discourse. One further implication is that any identity – understood now as a place within language from which people speak and live the world – is always and only constructed negatively, as differences. The everyday understanding of identity as positively defined is, accordingly, the result of a constant differentiation within and among the members of a social group. This helps to explain why cultural studies scholars have often championed notions of a hybridity and complexity of identities.

The final problematic – *modernity* – is the broadest, involving social formations in their entirety; it addresses, for example, not the question of race, but that of national formations that can be described as raced. In such cases, cultural studies analyzes the interrelations of state, economy, and culture. The aim is to understand the place of culture in the ongoing transformation of contemporary societies, whether in a national or a colonial perspective, and the particular processes, such as globalization, that are redefining the contours of modernity in both cultural and social terms.

The future of cultural studies is uncertain, in part because much of what makes cultural studies unique contradicts the demands of traditional universities. Neither the academy nor the “real” world of politics is a very sympathetic home for the kind of work that cultural studies proposes. Its commitment to studying relations and, hence, to an interdisciplinary project means that cultural studies cannot sit comfortably in any discipline. Even more important, while cultural studies is committed to the necessity of what Marx (1973) called a “detour through theory,” its commitment is to theory as a resource to be used strategically to respond to specific questions of relevance. Cultural studies measures the truth of a theory by its ability, first, to enable a better understanding of the context in question and, next, to open up new possibilities for changing that context. Theory, then, should not become a way of avoiding the risks of research, or of reducing the possibility of surprise and discovery. Therefore, cultural studies does not identify itself with any single theoretical paradigm or tradition.

Similarly, cultural studies seeks not to give priority to particular political stakes and constituencies, nor to take the appropriate goals and forms of struggle for granted; such assumptions might substitute political commitment for intellectual work. Therefore, cultural studies has no single politics. While it puts knowledge in the service of politics, it also attempts to make politics listen to the authority of knowledge. Cultural studies is a modest proposal for a flexible and contextual, intellectual and political practice that tries to make the connection between politics and culture.

# **Cultural Studies: Feminist Popular Culture**

*Jane Arthurs*

*University of the West of England*

The question of what counts as “feminist popular culture” arises from an engagement with foundational debates within → cultural studies as to the primary site for cultural reproduction and contestation (→ Culture: Definitions and Concepts). These debates are reflected in the competing definitions of → “popular culture” that circulate in the literature, namely: (1) the ideological products of mainstream commercial culture addressed to the mass audience, (2) an alternative, negotiated culture based on a “lived” sensibility of subordination and marginalization, and (3) an oppositional culture developed through the political consciousness necessary for a radical critique of the status quo (→ Critical Theory).

### **COMPETING VIEWPOINTS**

These three sites are connected through the hegemonic processes by which resistant meanings are co-opted into the mainstream in an attempt to neutralize their power, and thereby maintain the status quo. Thus it is argued that the more radical implications of contemporary feminism have been side-stepped by the incorporation into mainstream culture of the demands for greater female visibility, autonomy, sexual freedom, and economic equality through the figure of the “independent career woman” who takes on many of the attributes of the successful middle-class man while remaining sexually

alluring and feminine in appearance. Nevertheless, the performance of gender in contemporary culture allows for a much wider range of legitimate identities as a result of the questioning of gender norms that feminism has provoked (→ Identity Politics).

There are also differing views among feminist producers and critics about how cultural representations can adequately address political questions about *women's place in society* and, crucially, what those political goals should be – different strands of feminism have different ideas about what their utopian society would be like, ranging from the liberal feminist goals of integration and equal rights, for example, to the more separatist implications of radical feminist valorization of women's distinctive identity and culture.

There is also a *diversity of methods*: from an initial concern with textual issues of gender equity drawing on semiotics, psychoanalysis, theories of ideology, the analysis of mainstream → stereotypes, and “progressive texts” (→ Text and Intertextuality), feminist studies of popular culture soon took on a wider cultural agenda with research into audience pleasures, the politics of taste, the integration of popular media into the routines of everyday life, and the influence of feminist cultural critique on everyday gendered → discourse (→ Research Methods). An integrated approach researches feminist influences on textual meanings through the political, economic, and cultural contexts of their production and reception. Feminist critical discourses are themselves influenced by the portrayal of feminism in popular culture – they are “part of the same social and cultural struggles over the meaning of feminism” (Hollows & Moseley 2006, 15).

### PROGRESSIVE TEXTS

One of the outcomes of feminist studies of popular culture has been the identification of a “canon” of feminist texts, whether found in mass-produced culture or on the margins. A range of criteria has been used by commentators to identify them; it has been argued, variously, that they must (1) be female authored, (2) be produced and distributed outside mainstream patriarchal institutions, (3) be ideologically unambiguous and politically radical, (4) represent women's experience and subjectivity accurately, (5) deconstruct the codes of patriarchal culture, (6) provide positive images of women, (7) express female desire and fantasy, and (8) be addressed to and give pleasure to women.

There are some obvious contradictions in this list that reveal *divergent values and purposes*. For instance, calls for a realistic portrayal of women's lives imply a very different approach than required for utopian expressions of women's desires and fantasies. Similarly, it is difficult to reconcile the demand to accurately portray women's suffering and powerlessness with the desire for “positive images of women” (→ Women in the Media, Images of). It is also clear that, while calls for female authorship and alternative institutions of production and distribution have helped to deconstruct the embedded sexism of established cultural forms and working practices (→ Sexism in the Media), the effect of working on the margins has limited the impact of women's oppositional cultural production. Nor can female authorship guarantee a feminist perspective. Increasingly, interventions into mainstream media have been seen as equally significant for political change, and a popular feminist culture has emerged that engages with and pragmatically adapts familiar generic forms to express the social and political impact of feminism on women's experiences and perceptions. But there is a two-way permeable relationship

between the mainstream and the margins, with feminist artists, for example, producing work that both draws on and influences the more popular cultural forms addressed to wider audiences.

To tease out some of the difficulties that arise in designating texts as “feminist,” *Thelma & Louise* (1991), a film about two women escaping from capture after one of them shoots a rapist, provides a useful example as it has been extensively discussed in these terms in both the popular press and academic articles (Projansky 2001, 121–153). Its popular success was regarded as either surprising given its feminist perspective, or simply evidence that it was not really feminist at all in that it conformed to Hollywood conventions of narrative and visual pleasure and was made by a well-known male director, Ridley Scott. Yet it was scripted by a woman who reworked the road movie genre so that two women were the central characters in control of the masculine technologies of the gun and the car. The film was not marketed as “feminist” and so avoided the liberal dislike of → propaganda, remaining sufficiently ambivalent to be read in divergent ways. It fitted into a changed context where selected feminist ideas had become more generally accepted and the use of “role reversal” as a textual strategy was already well established. The film has been claimed for feminism on the basis that it offers empowering images of strong, independent women and produces an intensely pleasurable response in women audiences. It is celebrated as a fantasy of revenge for the disempowerment and injustices that women experience in their everyday lives. But equally it is condemned as anti-feminist for promoting violent masculine values and relying on masculine visual pleasures of technological excess to draw its audience in. In this view, the women take over the male hero’s role without really transforming it and their death at the end is a punishment for their transgression of acceptable femininity. In this reading, their driving over the edge of the Grand Canyon when pursued by the police is a confirmation of the women’s subjection to patriarchal law, but for other viewers it offers the ultimate escape fantasy as the women are suspended in mid-air in the final shot, a confirmation of their assertion that “there’s no going back” to their lives under patriarchy.

These diverse interpretations of the film’s textual politics highlight the problems with the concept of the “progressive text” that relies not only on an assumption of shared political values but also on shared interpretations of the meaning of a text. This difficulty intensified as feminist academics turned their attention to the increasingly ambivalent texts of what came to be known as “postfeminist” popular culture, in which contradictory discourses are rendered open to interpretation by an aesthetic of irony, parody, and excess that celebrates as well as critiques the established forms of popular culture and their gendered conventions (→ Postfeminism). The ideological work performed by these texts in undoing or reconfirming the disciplinary norms of femininity is therefore undecidable, except as an empirical question in local contexts using ethnographic techniques of research.

### **FEMINIST MODES OF RECEPTION AND PARTICIPATION**

When feminist popular culture is studied as a sensibility rather than as a set of texts, the focus turns to the ways in which people participate in cultural activities in their everyday lives. Feminist scholars seeking to validate women’s enjoyment of romance novels or

television melodramas argue that they have value in the face of a dominant hierarchy of taste in which they are labeled as “trash,” but there is a problematic gap between the tastes of the majority of women and their own politically motivated criteria of value (→ Exposure to Communication Content). One approach has been to maintain the political importance of women “carving a space” for their own pleasure through consumption of escapist fantasies when their role requires prioritizing other people’s needs. A case has also been made for “*Oprah*-style” confessional talk shows (→ Broadcast Talk), which focus on the problems of women’s lives rather than the “happy ending” of the romance, offering a means to convert painful personal experience into a politicized consciousness of how to overcome shared experiences of oppression.

Ethnographic studies (→ Ethnography of Communication) in countries undergoing rapid → modernization have shown that both global and locally produced female-centered television serials play a significant role in mediating women’s everyday negotiations of traditional and feminist conceptions of female identity (Mankekar 1999; Kim 2005). The empowering potential of popular culture has also been studied in “fan” communities in which the pathologized passivity of feminine consumption of “trash” is reconfigured as active appropriation. A well-known example is the production of “slash/fiction” by female fans of *Star Trek* who circulate homoerotic stories based on the series that subvert the patriarchal ideology of the original narrative. Internet communication has enabled fan activity to escalate to a new level in response to cult television series such as *Buffy the Vampire Slayer* or *Xena: Warrior Princess*. The presence of female action heroes and explicit or implied lesbian relationships in these series encourages feminist and queer interpretive pleasures that spill over into imaginative and critical writing (→ Exposure to the Internet).

Feminist activists have wanted to educate taste, to develop *new cultural competences and communities of practice*, through formal courses in women’s studies or informal exhibition or workshop spaces, for example, that teach women to read “against the grain” of hegemonic patriarchal meanings and build their confidence to engage with (and produce) alternative feminist cultures (→ Feminist Media). But new feminist practices also emerge in sub-cultural contexts such as the predominantly masculine cultures of rock music, digital gaming, or hip hop, for example. Studies of youth sub-cultures as a “site of resistance” hold a privileged place in the development of cultural studies, but few initially gave any attention to the way in which young women carve out a space for expressive resistance in the home or the more masculine spaces of the street, school, or club.

More recent “*third wave*” *feminist studies* have emphasized the positive effects of young women’s entry into previously male-dominated cultural activities. The “riot grrrl” network, for example, seeks to subvert the masculine codes of rock culture through performing hard rock alongside an assertive expression of female difference derived from girlhood experiences. Work on women and girls playing digital games reports on how they learn to negotiate their enjoyment of the masculine pleasures of competitive game play and technical prowess alongside the more traditional pleasures of cooperation and communication that playing affords. “B-girl” break dancers challenge their own sexualization within hip hop sub-culture by adopting a masculine style of dress and learning the dance skills required to participate as equals in a culture that Ogaz considers to be “a powerful third space of play, resistance and creative achievement” (2006, 180), which not

only empowers them as women but forges an alliance with male break dancers in their resistance to the dominant racist culture.

## **Cultural Topoi in Public Relations**

*Greg B. Leichty*

*University of Louisville*

A topos is a line of argument that can be adapted to a variety of subjects and audiences. Since Aristotle's time, communicators have used lists of topos to generate arguments relevant to their persuasive tasks (→ Argumentative Discourse; Persuasion). In addition to introducing the cultural topos perspective, this entry describes a set of topos that are widely used: cultural premises about the social world and how human relationships should be organized (see Leichty & Warner 2001 for a detailed description).

Mary Douglas (1997) characterized culture as an accounting system (→ Culture: Definitions and Concepts). "Think of culture as essentially a dialogue that allocates praise

and blame. Then focus particularly on the blame” (1997, 129). The cultural system consists of five voices or competing “ways of life”: fatalism, egalitarianism, hierarchy, autonomous individualism, and competitive individualism (Thompson et al. 1990). Each voice has a distinctive cultural topos that it uses in the competition of praising and blaming.

The *fatalist* voice considers the world to be capricious and unpredictable. It is characteristically cynical and suspicious of the motives of others. It routinely disparages calls for collective action. The *egalitarian* voice privileges the value of social equality. It seeks consensus in decision-making in order to maintain group solidarity. Anything that breaks down the primary group boundary, or increases social inequality in the group, is vociferously criticized.

The *hierarchical* way of life privileges harmonious relations among a differentiated set of roles and ranks. Defined relationships between ranks, often specified by tradition, make social order and social harmony possible. The *autonomous individualist* way of life stands aloof from constrictive commitments that would bind self and other. It favors the spontaneity of the present moment over reflecting on the past or contemplating the future.

The *competitive individualist* way of life is a confident and future-oriented voice. It focuses on the opportunities it may miss rather than concerning itself with avoiding mistakes. It celebrates competition and scans the horizon for clues about future trends.

The “ways of life” are interdependent. Each needs “its rivals, either to make up for its deficiencies, or to exploit, or to define itself against. To destroy the other (way of life) is to murder the self” (Thompson et al. 1990, 4). Ordinarily, one or two voices dominate the discussion and the remaining cultural voices are marginalized or pushed to the periphery.

In cultural disputes the egalitarian and competitive individualist voices tend to clash the most vociferously. The egalitarian way of life represents the simplest form of social organization, while the competitive individualist mode of organization provides the most complex form of social exchange and organizing (Fiske & Tetlock 1997). The egalitarian voice resists putting a cash value on many things, while the competitive individualist voice insists that everything should have a price (e.g., donor organs).

The cultural topoi perspective provides a parsimonious framework for describing the competition of praise and blame that constitutes culture. It enables us to trace cultural change. It also allows us to identify instances where groups operating from different premises may be able to collaborate.

People interpret a text differently when they apply premises from different cultural topoi to the message. Message credibility depends on how closely it aligns with the receiver’s underlying premises (→ Credibility of Content; Credibility Effects). If we know which cultural topos a person applies to a message, we can anticipate how a message will be interpreted.

Public relations (PR) is enmeshed in the cultural clashes of contemporary culture. PR practitioners interpret culture for organizational management, and represent the views of management to relevant publics. Tacit knowledge about cultural topoi enables PR practitioners to interpret multiple perspectives and encode messages that appeal to people who adhere to different cultural premises.

Communicators often deploy arguments grounded in different cultural topoi in order to broaden their appeals. For instance, when debating a proposal to raise cigarette excise taxes, tax-increase advocates predominantly used egalitarian premises (e.g., raising excise taxes saves children’s lives), whereas tax opponents predominantly used competitive individualist warrants (e.g., raising cigarette taxes is a politically correct tax scam). Each

side, however, also developed arguments that represented different cultural topoi. Tax opponents voiced egalitarian themes by claiming that the excise tax would damage the livelihoods of small retailers and small tobacco farmers. Tax advocates developed a competitive individualist theme by arguing that the excise tax was really a user's fee that reimbursed the state for treating sick smokers (Esrock et al. 2007).

Public relations itself is a culturally constituted system (Leichty 2003). Different versions of PR practice are advanced and criticized in → discourse about PR. A hierarchical model of PR and a competitive individualist model have long vied for disciplinary dominance (Leichty 2003). This cultural competition is visible when communicators: (1) identify problems with PR practice, (2) predict future trends in PR, or (3) make recommendations for collective action regarding the discipline. The hierarchical voice portrays PR as a science that applies its incrementally growing body of knowledge systematically and deliberately. In contrast, the competitive individualist model portrays PR as an art that requires continual adaptation to rapid changes in society and communication technologies (Leichty 2003).

# **Culture and Communication, Ethnographic Perspectives on**

*Donal Carbaugh*

*University of Massachusetts Amherst*

Studies of culture have been conducted in a variety of productive ways in several academic fields; one might say the same about studies of communication, while also

saying as much for ethnographic studies (→ Cultural Patterns and Communication). Adding this variety, that is, all three of these, together can create an unwieldy assortment of theories and research reports. Saying something about them all would be a difficult task, indeed. However, examining a subset of these that stand at the nexus of all three concerns, that is, identifying studies of communication that highlight cultural variability, and do so ethnographically, is a more manageable pursuit, and one that this entry undertakes, with special attention to intergroup and intercultural dynamics. It will be shown that this type of study has provided a very detailed and deep look at actual intercultural encounters.

We begin by assuming that communication and culture are inextricably tied, and, further, that the relationship between them can be studied through ethnographic theory and methodology. This brings several assumptions with it: (1) communication is a situated practice, and process, that is formative of social life; (2) communication is in some sense distinctive in its cultural scenes and communities; (3) ethnographic study of the social situations and communities in which communication occurs can indeed unveil the cultural features in communication conduct. In this way, ethnography provides a general way of studying communication that is not simply the implementation of a set of specific methods (such as interviewing and participant observation), but also a theoretical orientation to the subject matter of communication and culture (→ Communication: Definitions and Concepts; Ethnography of Communication).

## **DIMENSIONS IN ETHNOGRAPHIC STUDIES OF COMMUNICATION AND CULTURE**

Ethnographic studies of communication and culture involve systematic observations of socially situated practices. For example, Bailey (2000) has noticed that service encounters in Los Angeles convenience stores are conducted differently by African-Americans than they are by Korean-Americans; Chick (1990) has observed that communication in educational settings is conducted differently by native speakers of English and of Zulu; Wilkins (2005) has investigated similarly Finnish and American enactments of speaking, and silence, in educational settings; my own work has explored how communication among people from different regional and national communities is coded differently (Carbaugh 2005).

Each such study is conducted through these basic modes of inquiry: *describe* the communication of concern in exacting and detailed ways; *interpret* the meaningfulness of that communication to those who have produced it; *comparatively analyze* the practices so described and interpreted; and occasionally, *critically assess* the resulting intergroup, or intercultural dynamics at play in these interactions. Each of these analytical tasks involves different yet complementary procedures. However, when put together, the set creates robust ethnographic accounts of communication and culture.

Ethnography involves living with the practices one is concerned with, seeing them first-hand, and feeling how they work (or do not work) for particular people. More formally for ethnographers, this involves carefully creating a detailed, *descriptive record of the practices* being investigated. This is done in the form of electronic recordings (audio and visual, if possible), detailed field notes, and recorded interviews (Gumperz 1992). These

materials are subsequently analyzed in order to create a documentation of the actual occurrences of the practice being investigated. This is the empirical bedrock of ethnographic inquiry, and involves claims of the form: "This practice indeed occurred, in these social contexts, in exactly these ways." Detailed accounts like those cited in the studies above involve exacting transcripts, for example, of communicative phenomena. These provide the necessary toe-holds of ethnographic inquiry in real-world events. A collection of these creates a descriptive record, a corpus of data, from which features of patterns are analyzed.

To describe a practice, pattern, or event is not necessarily to interpret its meanings. In other words, one can describe how a woman addressed a man, yet not be able to interpret the social meaningfulness of that form of address in that community. A further dimension in such study thus involves *interpretive analyses*, claims about the meaningfulness of the communication to participants. For ethnographers, this type of analysis focuses on cultural meanings, that is, those that are shared, common, and publicly active during the performance of the practice (e.g., Geertz 1976). In Bailey's (2000) study, he was able not only to describe exactly how Korean- and African-American participants engaged in service encounters, but also to interpret how these encounters activated different meanings in what constituted "respectful" (and disrespectful) interaction for each. While African-American customers enacted a high degree of verbal interaction as a way of showing appropriate interactional concern, Korean shopkeepers enacted verbal reserve as a way of showing proper distance between themselves and their customers. Efforts to become more verbally engaged by African-Americans led to further reserve from the Korean shopkeepers. In the process, each interpreted their own practice as appropriate, and respectful, but the other's practice as being improper, and disrespectful. Interpretive claims are thus built on the back of a descriptive record in order to establish the patterned practices of concern, while unveiling the socio-cultural significance in, and importance of, those practices when done in that way.

Intergroup dynamics such as these involve *comparative and cross-cultural analyses*. These help establish two complementary types of findings: what is distinctive to one group's practices relative to another, and what principles are held in common across different groups' practices. Given adequate fieldwork, ethnographers are thus positioned to analyze more deeply the unique qualities of, for example, respect in each group's practices, but also to understand what is common among those practices and others elsewhere. For example, addressing others or taking turns may be patterned in different ways in different speech communities, and these may hold different meanings; or the same or similar meanings, for example, of respect, may be active, but these may appear in different practices. Note, then, how ethnographic studies such as these employ comparative analyses in order to work toward the dual objectives of understanding what is particularly distinctive in a people's communication practices, and what is general across them.

At times, ethnographers describe and interpret how one set of practices may disadvantage, subvert, or in some ways harm others. For example, the way courses are taught in some classrooms can privilege some while disadvantaging others. Chick's (1990) study demonstrates this point, as others have done (e.g., Carbaugh 2005). The nature of some intercultural and intergroup dynamics thus warrants critical analyses,

judgments based upon an explicated ethical or normative stance. This is especially the case when asynchronous dynamics create outcomes such as the misattribution of intent, negative stereotyping, misinterpretations, misunderstandings, and/or discrimination (→ Intercultural Conflict Styles and Facework; Social Stereotyping and Communication). Ethnographers have identified and can identify these as aspects of interpersonal and mass communication, they can document in detail how these outcomes have occurred, interpret the meanings of these dynamics for participants, even link them to historically transmitted trends, and thus critically assess the ways communication is thus formative of such circumstances.

### PRIMARY THEORETICAL CONCERNS

Ethnographic studies of communication and culture have examined many current, major theoretical concerns. These have included the role of one's first language in learning and using a second language, the role of key terms in discourse systems, the relationship between visual and verbal signs in specific communicative situations, the relationship between speaking and silence as means of communication, and the ways in which electronic and face-to-face media are used, with all such concerns exploring the variability of each in cultural systems of expression.

A major concern in these studies has been the *relationship between communication practices* and identity (→ Interactional Sociolinguistics; Speech Codes Theory). A strong link has been examined in several cases between one's identity and the structuring of communication (Lehtonen & Sajavaara 1984; Wieder & Pratt 1993; Hester & Eglin 1997; Hastings 2000; Philipsen 2002; Katriel 2004). Variability in the focal interactional concerns has been examined in some televised and interpersonal events, revealing the importance of truth-telling for some, the espousal of a collective ethic for others (Carbaugh 2005).

A second set of concerns focuses on the cultural shaping of communication acts, sequences, and forms: whether one should speak or remain silent; if one should talk, who should speak; whether speaking should be done alone or together, and to what degree; how long one should speak, and in what ways; what the rules are for opening social events; how turns are exchanged, pauses managed (→ Conversation Analysis); what rules there are for departing encounters; and so on. The investigation of responses to each question begins an understanding of the cultural shape and meaning of communication acts, sequences, and forms. Various responses to each question suggest cultural features in the patterning of communication practices, such that communicative actions vary in culturally significant ways (Carbaugh 1990; Milburn 2000; Wierzbicka 2003). How social relations are structured, and indeed how interpersonal life should be conducted, have also become focal concerns (Fitch 1998; Milburn 2000; Philipsen 2002; Wilkins 2005).

Over the past few years, new theoretical concepts and perspectives on communication and culture have been developed. Some works have proposed a discourse-centered approach to culture (Sherzer 1990), with one program of work, indeed, developing a theory of cultural communication (Philipsen 2002). While not all of this work focuses on actual instances of intergroup and intercultural communication, some have set this as an

agenda for communication studies (Tannen 1986), with some work already done in exploring, ethnographically, the cultural role of communication in intergroup dynamics (Bailey 2000; Carbaugh 2005; Wilkins 2005).

# Culture: Definitions and Concepts

Paul Cobley

London Metropolitan University

Since at least the nineteenth century, culture has been one of the most difficult, richly connotative concepts to define. While it is widely accepted that its roots are to be found in the Latin verb *colere*, among whose associated meanings is “to cultivate,” this has been all but forgotten in ordinary language. Being a web of meaning in which social life is suspended, culture most commonly goes unnoticed, and requires detailed inquiry, or what the anthropologist Clifford Geertz (borrowing from the philosopher, Gilbert Ryle) called “thick description.” Geertz used Ryle’s example of two boys in a room, rapidly contracting their right eyelids: is this a wink, a twitch, a deliberate message, to someone in particular, coded, without cognizance of the rest of the company? These and other preparatory questions have to be addressed before any analysis can reach an understanding of the “piled-up structures of inferences and implications” (Geertz 1993, 7) that characterize communications in any culture. Culture, thus, can be said to consist of all the structures and processes of → meaning in which communication takes place.

## ELEMENTS AND DIMENSIONS OF CULTURE

In the nineteenth and the early part of the twentieth centuries, anthropology, relying on ethnography as its “method” or approach, came to interpret the communications of diverse peoples in order to reach an approximation of their culture. Ethnography, further, provided a template and inspiration for understanding not only so-called primitive peoples, but also cultures in the industrialized west and, indeed, the broader concept of culture itself. As argued by Marcus and Fischer (1986, 20), much anthropology in this period involved a “salvage motif,” or a determination to capture cultural diversity, mainly of non-western peoples, coupled with a cultural critique of “ourselves” in the west. The implication was that “primitive” culture is somehow “authentic” in comparison to the “mass” culture that has grown in the west during the past two centuries. If culture resides in communication, societies with mass communication will have increasingly diverse and diffuse cultures, and no common cultural core (→ Communication: Definitions and Concepts). In modernity, then, the definition of culture has been made more difficult by the global proliferation of media and messages. In the second half of the twentieth century, anthropology responded, in part, by transforming its methodology: “thick description” of multiple and complex cultures could only be achieved through a melange of interpretive approaches from the humanities, complementing the methodologies of the social sciences. As media and communication research took shape during this same period, it imported several of the lessons and legacies of anthropology.

Summarizing elements of prevalent conceptions of culture across the humanities and social sciences, Jenks (2003, 8–9) offered a *fourfold typology*. First, culture is a cerebral or cognitive capacity (→ Cognition). This notion considers culture the product of a uniquely human consciousness, an exemplification of the status of humans as “chosen.” Although

culture may thus be considered the pinnacle of human achievement on earth, the concept of culture as cognition also feeds into ideas of false consciousness, as found in varieties of Marxism – an unrealized human potential. Second, culture is embodied and collective. Culture can be seen as evidence of moral development, indeed, an evolutionary feature of humans as group and species. However, this understanding of culture also informed the civilizing process that was foisted on to “savage” or “primitive” societies as part of imperialism and colonialism. Third, culture is a descriptive category: it refers to a body of work, “the best which has been thought and said in the world” (Arnold 1869) – special knowledge, training, and socialization whose products are commemorated in museums and archives. Yet, any account of which insights are special or best is not just descriptive, but normative. Fourth, culture has been understood as a social category. This is the idea, widespread in contemporary research, that culture constitutes the whole way of life of humans generally and of specific social groups and peoples.

The breadth of such a typology re-emphasizes the open-ended status of culture in modernity. Mass communication has produced a proliferation in the number and types of texts and other cultural artifacts; it has also, in extending their availability, resulted in a blurring of the boundaries between texts intended for the elite and those for the “masses.” Still, despite reports and debates concerning a collapse of the high-culture/low-culture distinction, it remains important to assess cultural practices in the context of other social structures. Jenks (2005) has suggested that the modern understanding of culture unfolds along a dimension involving tensions between *absolutist* and *relativist* tendencies. In the former case, attempts will be made to establish and maintain a given cultural formation while eschewing traces of others; in the latter case, the inclination is to see cultures and cultural artifacts as functionally equivalent and even, sometimes, essentially equal. If this first dimension captures the qualities of cultural products and processes in themselves, another related dimension addresses the interrelations between cultural forms and their social uses. This other dimension involves tensions between *elitism* and *egalitarianism*: culture can either be considered either the preserve of the few or, alternatively, the possession of many or all. Within a matrix of such dimensions, culture can be defined and practiced in different ways with specific social implications. For example, egalitarianism may be compatible with absolutism if the public at large is educated to gain access to, and to accept, one cultural canon. And relativism may feed elitism if the capacity to appreciate multiple or rapidly shifting cultural styles becomes a mark of social distinction.

### **CULTURE AS AN ESSENTIALLY CONTESTED CONCEPT**

Within a matrix of absolutism/relativism and elitism/egalitarianism, culture stands as an essentially contested concept (Gallie 1956), having a consensual core meaning, but also a series of connotations that give rise to continuous scientific as well as social debate. These connotations can be traced to the conceptual root of culture in cultivation and, especially, the extended metaphor of *horticulture*, i.e., the enhancement of gardens or natural environments. In use as early as 1837, when it was employed by the British poet Samuel Taylor Coleridge, the notion of culture as horticulture can be seen as absolutist (there is a state of cultivation against one of non-cultivation), relativist (there are different kinds of

cultivation), and elitist (only some could or should have the power of cultivation), as well as egalitarian (everyone can, potentially, cultivate). The connotations of culture in the sense of meaningful communication, similarly, are traversed by absolutism, relativism, elitism, and egalitarianism. One connotation of culture is *civilization*, the idea that participation in a culture qualifies the individual for membership and, even, status within a community. Further, at the community level, culture as ongoing cultivation suggests dynamism, emergence, and potential *change*, partly in opposition to the static implications of “tradition,” especially in a modern context. In summary, culture generally connotes *process* and *movement*: a process of educating and socializing people within specific webs of meaning, and a movement of meanings within and, perhaps, beyond a given community. In the last case, culture may amount to a colonizing process, complementing political and economic imperialism, or extending a national monoculture, for example, through elite adoption and transformation of popular culture.

Even the distinction between culture and its etymological opposite – *nature* – contributes to contested definitions. The root of “nature” is the Latin verb *nascere*, “to be born,” suggesting a contrast between qualities of innateness and processes of cultivation. This distinction has been emphasized within elitist and absolutist conceptions in an attempt to delineate culture as the height of achievement by human consciousness. The position was typified in Romanticism’s ambivalent relation to nature, celebrating the union of humans and their natural environment, while simultaneously elevating the work of the artist as the cultivator of such a union. In the wider history of ideas, the notion of *Kultur* as a privileged domain of human activity established itself contemporaneously with Romanticism in the late eighteenth and early nineteenth centuries in Germany, anticipating subsequent anthropological research on cultures in the plural and the very concept of culture. An elitist/absolutist conception of culture has remained influential in theories of communication and society, including, perhaps curiously, neo-Marxist analyses by the Frankfurt School from the 1920s to the 1970s. Here, an elitist definition of culture served to exclude popularly consumed artifacts produced by the industries of mass communication. Although Marxist and other critical work might be expected to pursue egalitarianism, or an alternative culture of the proletariat, an absolutist conception of culture may have been attractive across ideological divides in social theory as a representation of what societies might become in contrast to a state of nature.

## CULTURE, COMMUNICATION, AND SOCIETY

### Culture as Social Practice

Contemporary research on culture, communication, and society, while diverse, commonly addresses culture as an integrated constituent of social practice. The idea of culture as *a whole way of life*, associated primarily with the work of Raymond Williams, has been adopted by sociologists, anthropologists, and communication researchers as a framework for investigating the bewildering variegation of communications in modernity. Williams (1981) envisaged culture as an object to be studied by sociology rather than, say, art theory, because culture is a product of broader social formations, institutions, organizations, and ideologies, which make up particular historical means of production and reproduction.

His works (see especially Williams 1965) stressed that culture is a *process* whose continual movement and development are checked only by the vicissitudes and conflicts between those other social factors that make up its context. Unlike other egalitarian conceptions of culture that frequently have an absolutist tinge, holding that fine art should be the province of all, Williams's premise was that the practices of all people in a society are eligible to be considered parts of culture. Countering any relativist overtones in this position, Williams instead sought to erase the line between elite and popular culture, stressing not their relativity but their commonality.

Another influential body of work on culture as social practice is that of Pierre Bourdieu. Two of his concepts have passed into general usage in cultural and communication theory. First, Bourdieu (1986) conceived culture in terms of the specific *habitus* that different groups in society rely on as they orient themselves in, interpret, and act on everyday contexts. The *habitus* is at once an embodied predisposition and a socially patterned space of evaluative positions. It comprises "both the generative principle of objectively classifiable judgments and the system of classification . . . of these practices" (1986, 170) – a person's *habitus* generates value judgments, and these judgments bear witness to the place of that person in the larger social space. Accordingly, "taste" is an expression of how social groups – stratified by income, occupation, education, etc. – pursue different variants of language, art, and style. Second, Bourdieu described the distribution of such cultural resources across the social space in terms borrowed from Karl Marx; depending on the amount of *cultural capital* that individuals have accumulated, they may, or may not, be able to participate in particular aspects of social and cultural life. Even when practicing an egalitarian conception of culture, for instance, making museums accessible to all classes, Bourdieu noted, a society will tend to reproduce the elitism inherent in its stratification.

### **Subcultures**

The boundaries of culture are frequently challenged from both within and without. In the second half of the twentieth century, it became increasingly clear that western culture was producing a number of distinctive "subcultures" internally. These are generally thought to consist of communities of people who come together to pursue practices and observe customs (sometimes recently developed) that are somehow divorced from or in opposition to "mainstream culture." Frequently, though not exclusively, subcultures have been associated with youth tastes and pastimes, not least popular music. Facilitated and amplified by the mass media, subcultures form within as well as across national boundaries.

The relation of subcultures to culture in general, however, remains ambiguous. On the one hand, mainstream culture may integrate and co-opt subculture in an ultimately elitist fashion; on the other hand, subcultures may transform mainstream culture in an egalitarian direction as subcultural vocabularies and styles become naturalized forms of communication in the culture.

### **Intercultural Communication**

While subcultures may transform a culture "from within," cultures are also affected by communication "from without." Intercultural communication has usually been understood

in research as subject to difficulties and limitations (→ Intercultural and Intergroup Communication). Growing out of anthropological work in the first half of the twentieth century, the *Sapir-Whorf hypothesis* has been influential, if debated, since the 1950s: it states that communication between different cultures is impeded by the distinctive languages and other → codes on which they are based, so that cultures can never be fully communicative with each other. Put briefly, the language you speak places you firmly within one culture and at a distance from any other culture.

Nevertheless, mass communication, globalization, and intensified commerce have meant that different cultures are increasingly exposed to diverse communicative practices and traditions – both verbal and nonverbal – far beyond translation in any traditional sense. The idea of monocultures is being challenged by notions of cultural hybridity. For example, → postcolonial theory has suggested that only mental and physical repression have enabled particular cultures to maintain a mythical monocultural status. Similarly, research on imperialism has noted that western cultures, in addition to imposing themselves on those being colonized, were changed in the interaction (Bhabha 1985). In the case of commercial exchanges, cultures can be seen, over time, to enter into a more consensual process of hybridization. Intercultural communication, thus, occurs not just through specific acts of translation, but through interactions in all areas of social life.

## SEMIOTICS OF CULTURE AND NATURE

The inclusive conception of culture as social practice has been developed further in research on the *semiotics of culture*. Semiotics has commonly been concerned with interpersonal communication (→ Semiotics), whether technologically mediated or not, but has also addressed interspecies or interorganism communication, seeking to reorient the culture/nature distinction. Thomas A. Sebeok summed up this position when referring to culture as that “minuscule part of nature compartmentalized by some anthropologists” (1986, 60). Communication can be said to take place across nature and culture, comprising both verbal and nonverbal signs (→ Sign Systems). Whereas the signs of the known universe are predominantly nonverbal, a small number are based on the uniquely human capacity for language, which is the primary source of culture. Contemporary semiotics has described language as a *modeling system*, following the work of the Moscow–Tartu school and Sebeok (1988), and conceives culture as the outcome of three distinctive processes of modeling in humans. The primary modeling system is language as a cognitive capacity for differentiation, ontogenetically and phylogenetically manifested in nonverbal communication. The secondary modeling system is the capacity for verbal communication, manifested in speech and writing. Culture is the tertiary modeling system, in which complex and metaphorical manifestations of the primary and secondary modeling systems are circulated (Sebeok and Danesi 1999).

One ambition of the semiotics of culture is to avoid the pitfalls of egalitarianism/ elitism and absolutism/relativism, in consonance with Williams’s (1981) conception of culture as a whole way of life. Another ambition, comparable in certain respects to that of → cognitive science, is to renegotiate the culture/nature dichotomy, which has been on the interdisciplinary research agenda since, in 1959, C. P. Snow lamented the divergence of the humanities and the sciences.

# Culture and Health Communication

*Matthew W. Kreuter*

*Saint Louis University*

It is widely recognized that cultural norms, values, beliefs, and practices vary among population sub-groups, and influence how members of a group seek, understand, process, communicate, and act upon information about health. Ignoring these cultural differences during health and medical system interactions can have serious consequences that lead to or exacerbate disparities in health status between population sub-groups.

Critical reviews examining the relationship between cultural competence and health disparities recommend a wide range of communication-based strategies to help eliminate disparities (→ Health Disparities, Communication in), including improved patient–provider communication, interpreter services, → health literacy enhancement, clearer signage and forms, and culturally appropriate health education materials and health promotion and disease prevention programs (Brach & Fraser 2000; Betancourt et al. 2003; Institute of Medicine 2004). Yet surprisingly little is known about whether, or the extent to which, taking culture into account in such planned health communication efforts increases their effectiveness (→ Culture: Definitions and Concepts). A 2002 Institute of Medicine report on health communication strategies for diverse populations concluded that there is an urgent need for comparative studies of the effects of health communication interventions that address and ignore diversity factors, like culture (Institute of Medicine 2002; → Health Communication).

## **APPROACHES TO ACHIEVING CULTURAL APPROPRIATENESS IN HEALTH COMMUNICATION**

Although evidence for their effectiveness may not be clearly established, at least five approaches are commonly used to achieve cultural appropriateness in health communication (Kreuter et al. 2003).

### **Peripheral Approaches**

Peripheral approaches “package” health information in ways likely to appeal to a given group. The term “peripheral” is used in reference to the → elaboration likelihood model’s explanation of the non-central route of → information processing, which suggests that characteristics such as the superficial elements of culture described here can, under certain circumstances, lead to attitude change when included in a persuasive communication (→ Persuasion). Specific tactics include integrating colors, images, fonts, pictures of group members, or declarative titles (e.g., “A guide for African-Americans”) into health communication materials designed for a given group. By reflecting culture in the design elements of programs and materials, health communication developers hope to attract attention and convey relevance. Peripheral approaches tend to focus on expressions of culture that are visible and accessible to those outside the culture, like social rituals, traditional dress, language patterns, and cuisine.

Effective use of peripheral approaches should enhance receptivity to and acceptance of health communication materials (Resnicow et al. 1999). Although a mechanism for this effect has not yet been demonstrated empirically, → graphic design and visual literacy scholars propose that the language of colors, images, and pictures is immediately perceptible, and to the right audience will feel familiar and comfortable, be trusted, and may generate interest in or attention to the information.

### **Evidential Approaches**

Evidential approaches to cultural appropriateness in health communication seek to increase the perceived relevance of a health issue by presenting population-specific evidence of its impact to members of the group. Usually such evidence takes the form of statistics and/or probability statements. For example, health information designed to motivate lesbians to be screened for breast and cervical cancer might emphasize that lesbians have lower rates of mammography and Pap testing than other groups of women, and higher rates of breast and cervical cancer.

Evidential statements are generally designed to raise awareness, concern, and/or perceived vulnerability to a particular problem by showing that it affects a group to which a person belongs. Research based on Weinstein's precaution adoption process model lends support to this explanation, showing that those who perceived a problem to affect others like them were more likely to think about the problem, decide to take preventive action, and actually make plans to do so. But using certain types of group-specific evidence may have unintended and detrimental effects. Compared to exposure to the same evidence framed in a positive way, exposure to evidence that one's group is doing worse than another group can elicit more negative and fewer positive reactions to health information, and lower the group's intent to prevent the problem.

### **Linguistic Approaches**

Linguistic approaches seek to make health information more accessible by providing it in languages spoken or read by different cultural groups. Because language is so fundamental to effective communication, linguistic accessibility is arguably the most fundamental dimension of culturally appropriate health communication. In clinical health-care settings, linguistic approaches may involve providing translator services or hiring multilingual providers. Similarly, creating culture-specific health communication programs or materials can involve adapting existing content or developing original content. When translating existing health information to another language, maintaining the meaning and effectiveness of the original (i.e., fidelity) is a particular challenge, and can be difficult to achieve reliably in a straight translation task. Linguistic approaches also include efforts to incorporate into health communication the specific terminology, colloquialisms, and figures of speech used by a cultural group, even if they are not in a foreign language.

### **Constituent-Involving Approaches**

Constituent-involving approaches seek to assure cultural appropriateness by drawing on the experiences of members of a cultural group to be reached. Adhering to principles of

community participation and audience involvement is fundamental to health communication planning, and requires identifying substantive, decision-making roles for members of the cultural group during all phases of communication development. It may also include hiring staff members indigenous to the cultural group and training paraprofessionals or “natural helpers” from the group. Involving constituents can provide insight into deeper levels of culture such as underlying rules and assumptions that are known and understood by members of the group, but seldom shared with outsiders or accessible to communication scientists and practitioners from outside the culture. Their ideas, involvement, and commitment can often be applied to optimize the other four approaches to achieve cultural appropriateness in health communication.

### **Socio-Cultural Approaches**

Socio-cultural approaches present health information in the context of cultural values and beliefs held by the intended → audience. When key elements of culture can be identified and incorporated into health communication messages, sources, and channels, they can convey salience to the group’s members. For example, framing the benefits of a given health action in terms of faith or family may make the information more meaningful to those in cultures that value collectivism and spirituality. Thoughtfully executed socio-cultural approaches to health communication will reflect an understanding of culturally normative practices and beliefs – the inner workings of culture rather than the outward appearances emphasized in peripheral approaches.

There is some recent evidence that socio-cultural approaches enhance effectiveness of traditional health communication interventions (→ Health Campaigns, Communication in). In a randomized trial among lower-income African-American women from urban public health centers, those who received health information tailored to their behavioral beliefs and cultural values were more likely to get mammograms and increase daily fruit and vegetable consumption than those who received information tailored to behavioral beliefs or cultural values alone, or a usual-care control group (Kreuter et al. 2005; → Tailoring, Communication and).

### **OUTLOOK**

A summary of each approach and its proposed effects on communication outcomes is provided in Table 1. Further development and empirical testing of these hypotheses will enhance our understanding and application of culturally appropriate health communication. For intervention planners, the question may not be which of these approaches to use, but rather how best to integrate multiple approaches in a single health communication program. At present, however, this does not appear to be a normative practice. In a recent review of injury prevention interventions targeting racial or ethnic minorities, only 11 percent used three or more approaches to cultural appropriateness (Parks et al. 2006). Constituent-involving approaches were used most often (in 61 percent of interventions), but only one in four interventions used peripheral, evidential, linguistic, or socio-cultural approaches. While the review identified exemplars of multidimensional cultural appropriateness in interventions conducted in New Zealand and the US, these stood out as exceptions.

**Table 1** Description of five approaches to cultural appropriateness and proposed effects of each

Approach	Description	Proposed effects
Peripheral	Using colors, symbols, fonts, pictures, or titles that overtly convey relevance to those in the group	Captures attention, generates interest, is trusted, feels familiar and comfortable
Evidential	Providing evidence, often in the form of data, that a given problem affects members of the group	Increases awareness, concern, perceived susceptibility; may also offend some
Linguistic	Providing health information in the dominant or native language of the group	Increases accessibility of health information
Constituent-involving	Drawing on experience and knowledge of group members when planning and delivering information	Provides insight, builds commitment, establishes ownership, enhances credibility
Socio-cultural	Integrating cultural norms, values, beliefs, and behaviors of a group into health information	Conveys salience, provides context

Although progress has been steady since the 2002 Institute of Medicine report, there remain substantial gaps in the science of culture and health communication and significant need for applying evidence-based approaches to cultural appropriateness in health communication practice. Both represent excellent opportunities for current and future health communication professionals.

## Culture Industries

C. Michael Elavsky

Pennsylvania State University

The study of the culture industries has become increasingly more complex in the field of communications in light of the ways in which expanding research into their organization, activities, and logics connects with questions and arguments concerning culture, commercialism, and social control. Largely originating in Theodor Adorno and Max Horkheimer's *The Dialectic of Enlightenment* (1944), the term "culture industry" was initially utilized to critique the proliferation of commercial mass culture and what the authors perceived as the increasingly routinized techniques employed in the processes of cultural production (→ Critical Theory).

### THE ORIGINAL CONCEPT

In trying to explain why the working class revolution predicted by Karl Marx failed to materialize, Adorno and Horkheimer posited that a new, more subtle form of *social domination* had emerged which operated through the mass appeal and production of standardized leisure commodities and amusement culture which served to keep the population docile and distracted from recognizing the real conditions of their labor and exploitation under capitalism. Calling this process "enlightenment as mass deception," the authors suggested that administrative techniques within advanced capitalism played upon societal myths regarding scientific enlightenment, essentially curtailing the development of any revolutionary impulses toward systemic change from below. Consequently, the ideas and ideology (the "superstructure") of the ruling classes are able to condition and shape the material and historical impulses for change within the sets of economic (the "base") and social relations. In turn, individuals are "conditioned" and society is "structured" toward reproducing and expanding the relations of capital (→ Entertainment, Effects of).

In their analysis, the culture industry and its approach to cultural production was responsible for the "commodification" of culture, making the "exchange" value of cultural objects more important than their "use" value, and cultural products themselves, assembly-line commodities (→ Commodification of the Media). Through these processes, culture became *pseudo-culture*, where a surfeit of meaningless and unnecessary information and

products gratified people while impeding their ability to experience and understand phenomena on deeper levels. The information, technology, and organized rituals of pseudo-culture thoroughly mediated their ability to think through their “false consciousness,” keeping the masses oblivious to the monotony and meaninglessness of their lives. Advertising contributed to these processes, creating false needs and fostering and promoting “lifestyle” choices which implicitly disciplined work and leisure practices in ways that directly supported and reproduced the networks of capitalism (→ Advertising; Advertising as Persuasion). Consequently, market interests trump cultural considerations in society, citizens become enamored with and enslaved to consumerism, the mechanisms for ideological control induce uniform thinking and behavior within the population, and the masses are kept obedient to the system through their devotion to mass culture.

This sharp and pessimistic attack on mass culture, its mode of production, and the ideological control its instrumental and technological rationale imposed sought to highlight the detrimental social impact of commercial logics on cultural production. Moreover, it sought to underscore how these logics masked social domination, which occurred subtly in the manner by which mass-produced culture distorted the proper role of art in society – namely to challenge thinking and enhance cognitive development, rather than to entertain, gratify, and ultimately deceive the population.

Although often simplified and misinterpreted, this critique does not posit that all cultural products are necessarily homogeneous, that the logics of cultural production necessarily produce certain outcomes (and are simply matters of class domination), or that individuals are merely passive subjects readily controlled by the ideology of the culture industry. As such, the authors leave a space for the concept of agency and the development of an oppositional social politics to emerge, at least in theory.

### **FROM CULTURE INDUSTRY TO CULTURAL INDUSTRIES**

Since the late 1960s, the critique of the culture industry has become more detailed in light of developments in critical-cultural theory, insights from other disciplines, and the increasing recognition that significant differences separate the various types of content, systems, and processes related to cultural production (→ Media Production and Content). In turn, the plural term *cultural industries* has emerged as a way of speaking about investigations into institutions that produce symbolic objects/commercial products related to the construction of social → meaning. The core institutions of the cultural industries have subsequently been distinguished as advertising, → marketing, the broadcasting industries (radio, TV [cable, digital, and satellite]), the film industry, the → Internet, the music industry, print and electronic publishing (→ newspaper, → magazine, and → book), and video/computer games (→ Computer Games and Reality Perception). This shift from the singular to the plural has opened new avenues for exploring the processes related to cultural production and the dynamic variation among the institutions invested in integrating cultural objects and ideas into the realm of capital.

Scholarship utilizing integrated and interdisciplinary → *research methods* began to emerge in the 1970s and 1980s, serving both to extend and to nuance the perspectives of Adorno and Horkheimer, which had come to be known as part of the Frankfurt School critique of mass culture. Employing insights from political economy, sociology, and cultural

studies, several scholars (Kaarle Nordenstreng, James Halloran, Armand Mattelart, Nicholas Garnham, Herbert Schiller) began to consider the ways in which the cultural industries – through the dynamics of their economic and cultural power, institutional networks, and transnational influence – were implicated in new forms of cultural imperialism related to the emergent global political economy and ideas of globalization (→ Political Economy of the Media; Cultural Studies; Cultural Imperialism Theories; Globalization of the Media).

*Bernard Meige's* (1989) insightful sociological examination of the diverse logics of production and varied modes of labor organization in the cultural industries, however, challenged many of these ideas within the “cultural imperialism” thesis. By collectively considering a wide array of economic and sociological variables, Meige outlined the distinct plurality of the “social logics” of production within the cultural industries, underscoring not only how cultural production occurs across various sites of contestation, but also the extent of ambiguity involved in assessing the processes and outcomes related to cultural commodification. His work strongly suggested that media institutions and products have political and cultural dimensions and implications beyond the economic relations of their production. And despite the fact that critics have challenged Meige’s analysis on the grounds that it accomplishes little beyond description, it nonetheless deepened how the communication industries, their structures, employee activities, and the range of processes that constitute their activities have subsequently been conceptualized. These ideas have been further developed in the work of Bill Ryan, Keith Negus, and Jason Toynbee.

*Pierre Bourdieu's* empirical work, which examines how social relations within the processes of cultural production enact and reproduce networks of social meaning, power, and domination, has increasingly been incorporated in recent studies of these industries, complementing and extending the theoretical trajectories that seek to reconcile the tensions between structuralism and agency that often arise in considerations of the cultural industries and their impact upon individuals and society (especially in developing ideas about “cultural capital” and “cultural intermediaries”).

Although less concerned with distinguishing the plurality of the cultural industries or addressing the Frankfurt critique directly, the work of *Robert McChesney* has nonetheless been instrumental in identifying how the policies, practices, and organization of these institutions are specifically linked to questions involving macro-social power, democracy, and social justice. In the interest of nurturing media policy and grassroots activism, his critiques of corporate cultural production have been particularly effective outside the scholarly community, illuminating in plain terminology the links between institutional power, politics and media policy, and the negative impact commercial imperatives have with regard to the media’s role in fostering conceptions of citizenship, democratic governance, and civic society (→ Media Policy). In many ways, McChesney’s work pragmatically extends the call to arms that Adorno and Horkheimer’s essay initially put forward regarding reclaiming our media culture from the industries and logics that produce it.

### SHIFTING TERMS AND OVERLAPPING TERRAINS

Since the 1980s, a number of terms – i.e., “cultural industries,” “media industries,” “production of culture,” “the production of culture/cultures of production,” “creative industries,”

“cultural work,” “cultural economics,” “cultural economy” – have been employed by various disciplines (economics, organizational sociology, media studies, etc.) to examine the cultural industries from different perspectives. These investigations have both broadened understandings of the organization, activities, and influence of the cultural industries, and caused confusion with regard to exactly how they differ in their theoretical and methodological approaches. Only recently has an *interdisciplinary dialogue* begun to emerge, allowing popular communication scholars to draw from a wide range of insights in investigating the mutually constitutive relationship between culture and economy, examining cultural production as a series of interconnections between production, consumption, identity, texts, regulation, and discourse.

These dialogues (which increasingly include input from practitioners as well as scholars) range in their optimism/pessimism regarding the impact of the cultural industries and their products upon the development of society. Nonetheless, a consensus is emerging which recognizes “the complex, ambivalent, and contested” nature of the cultural industries, the texts they produce, and the social relations of symbolic creativity that constitutes activities within them, while simultaneously acknowledging the very real power they wield as networks of logics and forces (Hesmondhalgh 2002, 3).

Recent theoretical explorations from Manuel Castells, Michael Hardt & Antonio Negri, and Scott Lash & John Urry have considered how the logics and forces of capitalist production are reproduced micro-socially in ever more complex organizational configurations within macro-social formations of power. These studies are particularly relevant when considering how the cultural industries are implicated in extending commercial logics ever further into all aspects of modern life, understanding how economic organization and power impacts social practices and the construction of textual meaning, and how the transnational development of neoliberal policies and practices are advanced and sustained.

Consequently, many of the original charges raised within the Frankfurt School critique still resonate and remain relevant, valid, and pressing concerns today for scholars examining the operations of the cultural industries and their relationship with society. Future research will most certainly continue to explore the links between institutional organization, technological innovation, cultural development, the implementation of power, and the role of agency as they relate to the cultural industries and upholding democratic principles, enacting egalitarian practices, and reproducing social and cultural justice within the expanding realm of global capitalism.

## Cumulative Media Effects

David Fan

University of Minnesota

The mass media can be the major influence on the adoption of an idea after the general public begins to become aware. Initially, an idea spreads through limited → social networks, with members exchanging information in formats ranging from face-to-face discussions to blogs on the → Internet (→ Blogger). Such interactivity means that participants are actively engaged in the topic. The spread will be more rapid if the adopters are more vocal, more influential, and have the other traits that → Rogers (2003) ascribes to innovators and to early adopters for the diffusion of innovations (→ Diffusion of Information and Innovation).

If an idea has features of interest to the general population, it can enter the mass media with its wider audience of people with diverse interests. This population heterogeneity leads to homogeneity in one important respect: most members of the general public will be disengaged and dispassionate about the idea.

Idea adoption can be modeled using survival analysis if this population homogeneity is further accompanied by homogeneity in mass media penetration, meaning that all members of the public have the same chance of being exposed. *Survival analysis* is a broad class of mathematical models applicable to phenomena as diverse as radioactive decay and the death of people. In survival analysis, there are two key components: (1) a hazard

or force causing change, and (2) a collection of unconverted individuals who respond by undergoing a one-way conversion. For human survival, the hazard is the “force of mortality,” and transition is from life to death. A survival-based model for ideas is “ideodynamics,” in which the force for change is a persuasive force and the responding population is the fraction of the public that does not accept the idea.

The mass media contributors to the persuasive force include media messages with each one assumed to have its maximum force at time of its release, and with the magnitude of that force declining exponentially over time with a rate characterized by a *persistence constant*. People can convert without learning about the message directly from the media. Instead, they can receive the information through interpersonal communications (→ Media Effects: Direct and Indirect Effects; Two-Step Flow of Communication; Opinion Leader; Interpersonal Communication). The effective result is to prolong the persistence of the media message.

The other constituent of survival analysis is the non-adopters of the idea who are the potential targets of the persuasive force. The persuasive force will convert some fraction of the non-adopters with a probability given by a *persuasibility constant*. Survival analysis only considers the one-way transition from unadoption to adoption. Ideodynamics extends survival analysis by also including the reverse conversion from adoption to unadoption in response to opposing information (Fan & Cook 2003).

The validity of the ideodynamic model can be tested by its ability to use both favorable and unfavorable mass media messages to predict the time trend of the adoption of an idea. Theory assessment through time-dependent predictions is also the key to astronomy, for which it is also impractical to perform controlled experiments. Empirical studies show that the news media content can indeed capture the dominant forces for behavior change, because the ideodynamic model can use media coverage to predict behavior percentages over time with accuracies close to that of survey error (→ Survey; Statistics, Descriptive). The behaviors have included not only such actions as cocaine use by teenagers (Fan & Holway 1994) but also opinions, such as the University of Michigan’s index of consumer sentiment (Fan & Cook 2003).

The persistence constant of a media message is typically much less than a single day. Thus a message and its interpersonal repetitions must change a behavior almost immediately or it will be forgotten. In other words, people act on new and not old information. If, instead, old information has a major effect, then behavior change would be more sluggish than actually observed due to the time needed to flush prior messages from memory. Nevertheless, prior persuasion can have a long-lasting effect by bringing an individual to a current behavior. After that behavior has been acquired, the individual might even forget the earlier information that had been the cause, but that does not contradict the prior media effect. If no new information is available, the prevalence of the behavior will stay unchanged. However, if new messages do arrive, then changes from adoption to unadoption and vice versa will occur following the ideodynamic processes based on survival analysis.

The *ideodynamic equations* can use media values at time  $t$  to predict behavior at time  $t + 1$ . That predicted behavior can then be used to predict behavior at time  $t + 2$ , and so on in a recursive manner. A potential danger in such an iterative calculation is that errors in media measurements will grow with each computation cycle, leading to expanding

uncertainty in the predictions. However, formal statistics shows that this is not the case. Instead, the variance stabilizes, thereby justifying the recursive method that does not have the autocorrelation and missing data problems of autoregressive models (Fan & Cook 2003; → Time Series Analysis).

The Bass model for the diffusion innovations (Mahajan et al. 1990) is a special case of ideodynamics, with the special assumptions that the persuasive force from the mass media is constant over time and that the persuasive force from the social network is proportional to the adopters. This model is prevalent in marketing and related disciplines and assumes no idea unadoption. Given the satisfactory performance of the ideodynamic model, there is no need for the Rogers (2003) postulates of population and communication heterogeneity.

## **Curriculum Studies**

*Ann L. Darling*

*University of Utah*

Questions and discussion about the most appropriate goals for and organization of educational experiences in communication drive the area of curriculum studies. Curriculum studies are projects that examine the content, structure, and organization of communication curricula. These projects have focused on each level of educational endeavor from the elementary school classroom to the graduate seminar at a research university. Perhaps because formal degree programs in communication are rare outside of US universities, most of the work reviewed in the area of curriculum studies has been done by US scholars focusing on US curriculum issues.

Work reviewed in the area of curriculum studies includes both conceptual essays and empirical explorations. Examinations of communication curricula have been targeted

toward professional communication educators and administrators seeking to understand better ways to argue for and guide communication instruction. While a great deal has been studied and written about the nature of communication curricula, very little consensus exists (Morreale & Backlund 2002). Because the nature of communication phenomena is so complex and sometimes elusive, and because the discipline has evolved as an interdisciplinary amalgamation, widespread agreement as to the content and organization of communication curricula is difficult to find.

### ELEMENTARY AND SECONDARY CURRICULA

A large body of work has examined the goals, standards, and appropriate outcomes of an education in communication at the elementary, middle or junior high, and high school level. The *goals* for communication instruction from kindergarten to 12th grade setting (“K-12”) focus on the idea that communication skills are important elements of an elementary and secondary school experience (→ Communication Education, Goals of). The *goal of skill development* can be seen in the amount of attention given to specific sets of skills in speaking, listening, and media participation. This focus on skills (as distinct from knowledge or disposition) was first initiated by the 1983 publication of *A nation at risk: The imperative for educational reform* (a report by the US Department of Education’s National Commission on Excellence in Education), and steered most recently by US President George H. W. Bush’s *Goals 2000* (Morreale & Backlund 2002). Given this public and widely publicized mandate, it is unsurprising that much of the work in communication curriculum studies has focused on the development, organization, and adoption of standards and outcomes of communication instruction.

The National Communication Association (NCA, previously the Speech Communication Association; → Speech Communication, History of) sponsored two conferences (widely known as the Memphis conference and the Flagstaff conference, respectively) and published a wide variety of documents in an effort to direct and guide the development of *standards*, competency statements, and assessment guidelines for instruction in communication in the K-12 setting. The outcome of these efforts is considerable. Two of the NCA-published documents are landmark resources for parents, teachers, and administrators, each representing considerable research by and dialogue among a number of communication scholars. At one point at least 60 communication scholars were involved in this endeavor. The first publication is a listing of 23 K-12 standards in four categories: fundamentals of effective communication, speaking, listening, and media literacy (→ Media Literacy; Student Communication Competence). The second publication serves as a companion tool and articulates grade-appropriate competency statements that are derived from the 23 standards.

In addition to content standards such as those composed by the NCA, efforts have been made to identify standards that describe the ways in which students will behave differently as a result of instruction. These *performance standards*, composed by a US agency known as the New Standards, are intended to be used in conjunction with content standards. To date, standards relevant to communication have been developed within the English language arts curriculum for grades 4, 8, and 10. Two areas of distinction are important to note. These performance standards identify expectations for specific develop-

mental changes in communication skill proficiency. They also highlight opportunities for cross-disciplinary reinforcement of communication skill development (i.e., giving oral presentations on science projects).

Questions have also been raised about the degree to which national standards such as those written by NCA and New Standards are put to use in curriculum development in individual school districts and classrooms. Some evidence suggests that national standards influence curriculum development at an abstract level (e.g., in the titles of state curriculum documents) but that state standards are much more relevant to the more concrete dimensions of state standards, (e.g., in statements of outcome measures; Goulden 1998; Hall et al. 1999). All of the work that examines the relationships among state standards and practices and national level articulation of standards appears to reveal that when communication instruction is included in the K-12 setting it is done so within the English and language arts curriculum; it does not, in other words, have standing as a curriculum unto itself (Witkin et al. 1996).

A second, and much smaller, body of work has focused on the goals and benefits of elective courses in communication. Targeting largely the middle and high school levels, this body of work describes the ways in which experiences in debate, forensics, and journalism can enhance the educational experiences of students as well as prepare them in meaningful ways for civic engagement in college or careers (→ Journalism).

## UNDERGRADUATE CURRICULA

Among the first claims that must be extended about studies of communication curricula is that there is consensus neither about a *core* communication curriculum nor the particular ways in which a communication curriculum might contribute to general education.

Up until the mid-1960s, examinations of communication curricula revealed a tendency toward helping to forge useful relationships between individuals (students) and society. During this time courses in public speaking, rhetoric, and argumentation and debate were guided by the goal of preparation for democratic participation (→ Rhetorical Studies; Argumentative Discourse). Beginning in the late 1970s a focus toward helping individuals (students) develop skills and capacities for working with each other began to evolve. These courses were guided by goals of helping to enhance relationships, families, and productivity in working environments.

Contemporary surveys of undergraduate communication curricula reveal some areas of relatively strong consensus. Repeatedly, four different courses are identified as either required for the major and/or necessary to fulfill general or liberal education requirements: communication theory (→ Communication Theory and Philosophy), public speaking, → interpersonal communication, and a survey or hybrid course (Smith & Turner 1993; King 1998; Morreale & Backlund 2002). For departments that include a degree in mass communication, courses in introduction to broadcasting (→ Radio; Television), broadcast news (→ Radio News; Television News), radio production, and public relations constitute the most frequently identified core or required courses. Other communication courses regularly included in the curriculum, but not with the consistency of the “top four,” include the following: rhetoric and public address, communication theory, organizational communication, persuasion, and small group communication (→ Group Communication).

At the end of a series of meetings (annually from 1985 to 1999) on the undergraduate communication curriculum, a group of scholars involved with the Hope College conference reached a consensus decision that the curriculum should be guided by competencies rather than specific courses. They identified eight different competencies, including: theoretical approaches, sensitivity to diverse others, presentation, media literacy, influence processes, systematic inquiry, ethics, and human relational interaction (Rosenthal 2002).

Curriculum studies have explored the contribution that communication makes to a liberal (or general) education. On the premise that communication is the basic building block of literacy and that an education in communication contributes to an understanding of the history and character of our culture, several essays have advanced arguments for the role of communication in liberal education. Communication is also included in the liberal education curriculum because the basic skills in communication are consistently identified as necessary building blocks for successful learning throughout undergraduate education (Allen 2002). As such, the NCA has identified specific competencies in speaking, delivery, interpersonal skills, and listening at both the basic and advanced levels as important elements of a liberal education (Morreale & Backlund 2002).

In addition to surveys and articulations of competencies, a number of essays have been published using a case study approach in order to provide detailed descriptions of curricular innovations as well as the benefits to learning that can be demonstrated. Examples of this type of contribution include the following: civic usability in Internet journalism classes (→ Internet; Internet News), experiential education in communication, communication research in the undergraduate curriculum, organ donation awareness campaigns in the PR campaigns course, and cornerstone and capstone courses.

Instruction in communication also plays an important role in the educational mission of disciplines other than communication. Some of this contribution has been recognized in discussions of general or liberal education. However, increasingly special attention has been paid to the unique role that communication plays in learning and performing disciplinary subject matter, especially in the context of professional education (e.g., engineering, law, and education). This body of work, commonly referred to as *communication across the curriculum*, has been the focus of numerous curriculum studies. These studies have primarily investigated questions about different models for structuring communication skill development within other disciplinary curricula. Cronin & Glenn (1991) in an excellent review of this body of work provide descriptions of programs that depend on standalone communication courses, courses that include a communication module or special communication assignments within an existing disciplinary course, and programs that take advantage of a speech laboratory or consultation service in order to help students who are not communication majors develop targeted communication skills. A recent evolution of communication across the curriculum focuses attention on unique types and functions of communication practices within disciplines (Dannels 2001). Referred to as *communication in the disciplines*, this work argues in favor of embedding communication instruction deeply within the epistemological structures and performance expectations of individual disciplines.

Curriculum studies at the two-year college offer two important dimensions of distinction from the four-year institution. First, two-year colleges frequently have a mission to

provide traditional job skills or vocational education. To recognize this responsibility, they frequently offer a greater number of courses geared toward specific vocational applications like business speaking or interpersonal communication for health-care providers than is commonly seen in four-year institutions. Second, two-year colleges have a mission to prepare students to transfer to four-year institutions. In response to this mission, many of the course offerings mirror those offered at four-year schools. Students who are following this educational path are likely to encounter courses in public speaking, introduction to interpersonal communication, and a hybrid course. Several essays by Wolvin and his colleagues (e.g., Wolvin & Wolvin 1999) describe the unique curriculum features of the two-year college.

Essays describing methods or approaches to teaching specific communication courses (like public relations, media ethics, and research methods) exist in abundance (→ Ethics in Journalism). A complete listing of these sources is beyond the scope of this entry but interested readers might examine the following for such work: BEA syllabus project (Broadcast Education Association 2005), *Teaching communication* (Vangelisti et al. 1999), and the journals *Communication Education* and *Journalism and Mass Communication Educator*.

## GRADUATE CURRICULA

Studies of the graduate curriculum in communication have become more pronounced with the widespread attention given to graduate education in general (see Andersen 1997; Salmon 2006). Beginning in the early 1990s, concerns were raised about the potential “glut” of PhDs in a labor market not prepared to support an already unprecedented number. In response to these concerns presidents of both NCA and the association for education in journalism and mass communication (AEJMC) established task forces charged with examination of the graduate curriculum in communication. Like similar task forces established to study the undergraduate curriculum, this group of scholars published reports and held a summer conference on the topic of graduate education (see Applegate et al. 1997 for a summary). Curriculum studies of graduate education have tended to hover around issues of theory vs application, culminating pedagogical projects, and preparation for the faculty role.

Reports from both task forces have issued recommendations that doctoral education focus on a structured curriculum that assures development rather than use of theory. These reports cite the increasing need for a complex and theoretically sophisticated understanding of how communication technologies and practices are influencing global economics, politics, and sociologies.

Work on theory development is supplemented with increased attention on an alternative view of the MA degree. With increased need for and opportunities to attain professional applied advanced degrees, there has been effort on the part of many communication scholars to develop applied graduate degrees in communication. Such applied degrees, it is argued, should be offered as alternatives to the traditional theory-driven path to graduate education. To date, several such programs have been developed and are offered (Powers & Love 1999). Discussions of appropriate culminating pedagogical projects are a natural extension of this discussion. Programs offering applied MA degrees

in communication also report a flexible range of culminating projects from theses, to exams, to applied projects. Debate about the proliferation of PhD degrees led to concern about the extent to which graduate students were well prepared for the full range of duties expected of a faculty member at a variety of types of institutions. These concerns led to suggestions that PhD programs ought to include teaching methods courses and teaching supervision more systematically in their curricula (Nyquist & Wulff 1992). Salmon (2006) suggested that graduate students need to be as well prepared for teaching in online and virtual environments as they are for more traditional classroom settings.

## INTERNATIONAL STUDIES

As early as 1954, essays exploring international perspectives on communication curricula appeared in a variety of journals. These essays explored the various ways in which communication topics were integrated into primarily European educational settings. The focus of attention was on performance skills, like voice and diction, and the most common curricular “home” for communication instruction was in theatre departments. Recently, increased attention has been devoted to the study of international issues related to communication education. The BEA syllabus project, for example, provided an analysis of international media studies courses, and an entire issue of *Journalism and Mass Communication Educator*, Winter 2005, explored communication education from a variety of international perspectives, including an internship program in Ghana and multi-cultural journalism education in the Netherlands.

## Cyberfeminism

Jenny Sundén

Royal Institute of Technology

Cyberfeminism as feminist theory and practice has grown out of an emergent use of digital media and new communication technologies. The concept was used for the first time by Australian artists' group VNS Matrix in their *Cyberfeminist manifesto for the 21st century* (1991), and soon after by British cultural theorist Sadie Plant. Cyberfeminism refers to a wide range of feminist practices, ranging from high theory to political techno-art, science fiction writing, game design, and activism. Cyberfeminist projects can usually be mapped in relation to two intersecting axes, one running between “theoretical” and “practice-based” cyberfeminism, the other between “third wave” and “second wave” feminism.

Theoretically oriented cyberfeminism, aligned with third wave feminism, operates primarily on a sophisticated theoretical level of feminist theory and technoscience studies,

in relation to which feminist historian of science Donna Haraway's (1991) cyborg is an emblematic figure (→ Cybernetics; Cyborgs). But in contrast to the use of the cyborg in, for example, mainstream science fiction as an illustration of hardened masculinity, Haraway uses the cyborg to represent transcendence of dichotomies such as mind/body, organism/machine, culture/nature, civilized/primitive, and, centrally, man/woman, implying movement toward a society where gender has ceased to matter, or at least matters differently.

Another strand of the theory-driven, cyberfeminist paradigm is inspired by thinkers such as Sandy Stone and Sadie Plant, who have envisioned the → Internet as a realm of re-embodiment, and/or a space in which a feminist utopia could be realized. Stone (1995) uses her transsexual body as an argument in the area of political transgressions. According to Stone, cyberspace is a place in which the unexpected compositions of the cross-dressed or transgender body are the norm (→ Gay, Lesbian, Bisexual, and Transgender Media Studies). Through the ever-present possibility of radical performance and play with gender and identity online, the problematic position of the transgendered body can potentially be turned into a starting point. Even though cyberspace provides environments where, momentarily, bodies can be virtually altered, Stone simultaneously highlights all the skills and requirements that are necessary for online participation.

Plant (1997), in turn, suggests a cyberfeminism in which there is an intimate and maybe even subversive element between women and machines. Her main argument is that women in the shadow of male culture have been the ones who did the ground-breaking work: from the very first computer program to the latest incarnation of virtual reality. She argues that in typing as well as telecommunicating women have, through their bodies, provided the male world with a living interface with machines. Her idea is that women have been the machine parts in a male culture, by reproducing both the species and the communication. When machines get more autonomous, women go the same way, and between them a sexually charged alliance is developed.

In contrast to cyberfeminists such as Stone and Plant, who emphasize that the use of new communication technologies carries utopian and emancipatory potential, feminist philosopher Rosi Braidotti (1996) argues for a "cyberfeminism with a difference" and points at the risks for women in buying into the notion of cyberspace as a place for subversive identity performances, freed from the limitations of the physical body. According to Braidotti, rather than liberating women, this repeats the Cartesian fallacy of separating mind from body. The dream of getting rid of the body reflects an understanding of masculinity as abstraction and of men as physically disconnected and independent, which, she argues, is being remapped onto cyberspace discourses.

Between the poles of third wave feminism and practice-based cyberfeminism, there is the online equivalent of feminist groups like Guerilla Girls and Riot Grrrls. In the field of artistic practice and with considerable ironical force, "grrrls" have come together transnationally to join in the fight over representation. Braidotti defines their position in terms of "the politics of the parody," which points at the irony of treating femininity as a set of multiple options to play with. This online politics takes shape among grrrls on the web through a mixture of putting up active resistance, having fun, and doing it all their own way. They are the bad girls, smart, and proud of having tech skills, guiding other women online to express, empower, and encode themselves.

In a similar location on the cyberfeminist map to that of the online grrrls, there is the Australian artists' group VNS Matrix, shuttling between art, politics, and theory through strategies of irony, parody, and appropriation of sexual obscenities. Even if VNS Matrix shares with Plant the idea of technology as feminine and sexual, they have used quite literal efforts to contaminate technology with corporeality. Sentences like "The clitoris is a direct line to the matrix," from their manifesto, have not only been interpreted as bad girls talking dirty, but can also be seen as female appropriation of computer technologies that traditionally have been viewed as belonging to a masculine domain.

Positioned between the poles of second wave feminism and practice-based cyberfeminism, there is another kind of cyberfeminism with significant awareness of information inequality, searching to network between women worldwide to create special women's spaces of resistance online. One such formation is an alliance between → UNESCO and the Society for International Development called "Women Working on the Net." This project considers how to expand online opportunities from women in academic, activist, and professional circles in industrial countries to other women, particularly in developing countries (→ Digital Divide). If theoretically oriented cyberfeminism has been critiqued for excluding women who do not belong to the inner circle of white, western, middle-class, theoretical cyberfeminists, this version of the cyberfeminist movement seeks to integrate women of many different ethnicities and cultures.

# Cybernetics

*Klaus Krippendorff*

*University of Pennsylvania*

Heron of Alexandria (first century AD) was the first chronicler of a peculiar mechanism capable of holding the flame of oil lamps steady. Later, similar mechanisms were found in water clocks. In the eighteenth century, they reappeared in the regulator of Watt's steam engine, which drove industrial production. Since 1910, engineers have called them servomechanisms. Norbert Wiener (1948, 1950), mathematician at MIT, realized that the theory underlying them had far wider applications, linked them to communication, and called the study of these phenomena "cybernetics . . . the science of control and communication in the animal and the machine" (→ Communication: History of the Idea). He derived "cybernetics" from the Greek *kybernetes* or "steersman." Before him, Ampere had used the word to designate a science of government, without, however, developing the idea.

Cybernetics became established during a series of interdisciplinary meetings held between 1944 and 1953. It brought together some of the most important postwar intellectuals, including Wiener, John von Neumann, Warren McCulloch, Claude Shannon, Heinz von Foerster, Ross Ashby, Gregory Bateson, Margaret Mead, and Alex Bavelas, and became known as the Macy Conferences on Cybernetics (Heims 1991). Erving Goffman presented his early sociological ideas at these meetings as well. Cybernetics quickly expanded its conceptions to embrace neural networks (McCulloch), communication patterns in groups (Bavelas), anthropological concerns (Mead), mind (Ashby, Bateson), management (Stafford Beer), and political systems (Karl Deutsch).

Cybernetics did not establish itself as a discipline with its own academic institutions. It remained an interdiscipline that gave birth to numerous specializations; for example, mathematical communication theory, control theory, automata theory, neural networks, computer science, artificial intelligence, game theory, information systems, family → systems theory, and constructivism. Many of its revolutionary ideas – feedback, digitization, simulation, autonomy, networks, homeostasis, and complexity – are now embraced by established disciplines. In the 1970s, cyberneticians shifted gears, recognizing that the known reality cannot be separated from the process by which it is explored and constructed. This gave rise to second-order cybernetics, fundamental to the social sciences.

The use of the prefix "cyber-" in popular literature about intelligent artifacts, digital media, and globalization of communication – fueling a sense of liberation from authorities, geography, and technological determinisms – is evidence for how well the fruits of cybernetics are growing in contemporary culture, if in a somewhat shallow soil.

## CYBERNETIC EXPLANATIONS

Initially, cybernetics explored models of phenomena, such as mentioned above, without reference to their materiality, ultimately favoring impersonal mathematical formulations. The power of computer programs, for example, does not depend on who uses them and on which machine they run. Their virtue lies in their reproducibility. The a-materiality of early cybernetic concepts fertilized many fields.

Ashby (1956) characterized cybernetics as the science of all possible systems, which is “informed” when some of them cannot be built or evolve in nature. This definition departs from the traditional preoccupation of science with generalizations from observational data. Bateson (1972) related this characterization to the theory of evolution.

*Second-order cybernetics*, or the cybernetics of cybernetics, the control of control, and the communication of communication (von Foerster 1996), by contrast, acknowledges that all explanations reside in language, the language of a community – cyberneticians, for example. It amounts to a shift from the earlier preoccupation with disembodied models to constructions that recognize the observer as a participant in them, embodied knowing.

Cybernetic explanations can be described as resting on four conceptual pillars: *circularity*, *information*, *process*, and *participation*. These are not separate ideas. They join in the cybernetic project of overcoming numerous orthodoxies of contemporary science.

## CIRCULARITY

Just as arguments proceed from premises to conclusions, Newtonian science proceeds from causes to effects. Cyberneticians, by contrast, are fond of circular causalities such as when A affects B, B affects C, and C affects A in return. They include linear causalities as less interesting cases. In systems that embody such circularities, every part affects itself via others, causes and consequences are no longer clearly distinguishable, and a dynamics is set in motion that resists outside interventions.

## Feedback

Circular causality is familiar in home heat control. The thermostat does not respond to room temperatures, but to the difference between actual and desirable temperatures. This difference determines another difference, whether a heater is on or off. When it is off, the room slowly loses heat. When it is on, the heater increases the room temperature up to the point where the difference has disappeared and room temperature stays where it is set. Feedback loops reside in more complex technologies (target-seeking missiles, automated production), biology (regulation of bodily functions), economics (supply and demand of goods and services), and in social life (the giving and taking required to maintain friendships). In human communication, feedback is explicit in verbal comments to what one said, and implicit in responses to differences between observed and expected consequences of one's actions. Feedback is a necessary condition for learning and for maintaining homeostasis, whether within organisms, families, or social organizations.

Systems with feedback loops either converge on a stable state, or diverge, leading to meltdowns, fights, and breakups. The former is called negative feedback, as deviations are reduced. The latter is called positive feedback, as deviations become amplified. While most technical devices are designed to converge on a preferred state, social interactions often escalate, unintentionally as in arms races, or intentionally, to achieve various kinds of growths, for example in business or individuals in therapy. Circular causalities underlie all purposive systems and explain their capacity to compensate for variations in their environment, control themselves, and display a “will of their own.”

### Self-Application

Tools usually are engineered as open functions, a means for humans to control something else – driving a car or influencing an audience. To understand systems with loops, including feedback, their output must re-enter their input, at least in part. The functions that enable self-application are called recursive. Examples of self-application are copying a document repeatedly, which eventually results in a version that resists what the copier can do to it, or taking the square root of any positive number over and over again, which converges to 1.000. Fractal geometry utilizes recursive functions by repeatedly inserting a figure into its own parts, generating a complex configuration. Individuals converge to their identity by recursively using their name, developing behaviors that are uniquely traceable to them, and interacting with others consistently.

Self-application ushered in the computer revolution. Early ideas of computation maintained a clear distinction between the data and the operations transforming them. It occurred to von Neumann to store programs in the same memory as the data to which they were applied. This opened the possibility of programming computers so that programs could call on other programs, including on themselves (→ Information and Communication Technology, Development of). He also theorized a special case of self-application, the ability of machines to reproduce themselves. While his work did not create self-reproducing robots, his ideas resurfaced in communication theory (reproducibility), and recently informed Richard Dawkins's memetics.

### Self-Organization

A self-organizing system is one that develops in its own terms, without instruction from, copying of, or adapting to features of an external environment. The biological makeup of living organisms, for example, cannot be explained from where they live. Their history is their best explanation. While social organizations may well learn from each other, they also develop indigenous forms. Ashby's *law of self-organization* specifies two properties. First, to the extent the parts of a system engage in recurrent interactions, they converge on stable regions – or attractors – in the process of which their networks of communication become increasingly orderly. Second, by moving from one attractor to another, the freedom to move is transformed into indigenously orderly conduct. Von Foerster demonstrated that systems are self-organizing by decreasing their entropy (increasing order) inside, or increasing entropy (decreasing order) outside, or both. He also showed that random perturbations can speed up self-organization, and called this phenomenon the “*order from noise*” principle.

Fundamental to all self-organizing systems is that they defy control from their environment as well as understanding by external observers. This is due to their constitution as relatively closed circular networks of communication. Conversations, for example, are self-organizing, and it is hard indeed to know what is going on in one without joining (→ Interaction; Interpersonal Communication; Language and Social Interaction). This difficulty is magnified when seeking to understand social organizations, which cyberneticians describe as networks of conversations. Self-organization presents profound methodological challenges to the study of communication.

### Autopoiesis

Autopoiesis or self-production is a process that Humberto Maturana and Francisco Varela (1987) identified as the condition for living systems to practice their living. Autopoietic systems consist of *recursive networks of interactions* among components that produce all components necessary for such a network to operate, maintain a boundary within which their autonomy is practiced, and thus continually regenerate themselves under conditions of continuous perturbations from their outside. Reproduction, cognition, purposiveness, the efficient use of energy, and even survival are epiphenomena of the autopoietic organization of a living system. Autopoiesis explains, for example, that humans continuously change their organic makeup without losing their identity as human beings. Allopoietic systems, by contrast, produce something other than their own components. A bakery, for example, may feed its owner metaphorically but does not produce what it takes to bake. Autopoietic systems can distinguish among perturbations and compensate for them by changing their structure, but have no access to the nature or sources of these perturbations.

For Maturana, autopoiesis is embodied in the components that constitute the self-generating networks of production. It cannot be separated from where it is embodied. Therefore, he distanced himself from sociological theorists like Niklas Luhmann, who appropriated the term in his disembodied conception of social systems.

### INFORMATION

Cybernetic conceptions of information emerged in studying purposive systems, which must respond appropriately to deviations from their goals. Bateson observed that circular systems, from simple feedback loops, to manifestations of mind and social systems, do not respond to physical stimuli but to differences between them. They are triggered by differences, process differences and differences of differences, and may in turn affect the differences that triggered the process. He defined  $\rightarrow$  information as the differences that make a difference at a later point. This places information on a logical level higher than the physical phenomena it relates, and therefore it cannot be explained or measured in physical terms. To highlight that information is created within a system, not representative of realities external to it, Varela proposed to write the words as “in-formation.”

Shannon introduced binary digits (bits) as the unit for measuring the extent to which messages from one point are reproduced at another point. His information calculus gave rise to several concepts, such as *noise*, the extent to which *entropy* surreptitiously enters a communication channel and inexplicably pollutes messages; *equivocation*, the extent to which messages lose their details in the course of transmission; and *redundancy*, unused or wasted channel capacity. His tenth theorem asserts that the effect of noise can be eliminated by adding an amount of redundancy to the channel that is equal to or larger than the measure of noise. Redundancy has made contemporary information technology extraordinarily reliable. Language is said to be about 70 percent redundant, allowing people to understand verbal expressions even when barely audible, mispronounced, or containing spelling errors.

Ashby explored the complement of communication. Purposive systems, he noted, must counteract the entropy in their environment, for example, reducing the effects of external

temperature fluctuations on the room temperature, and to accomplish this requires internal variability. To remain competitive, business organizations need to respond to environmental changes and must have uncommitted organizational variety at their disposal. Ashby's *law of requisite variety* states that effective regulators or, more generally, purposive systems, must possess an internal variety equal to or larger than the variety of the disturbances of that system; in short: "only variety can destroy variety" (Ashby 1956, 207). Ashby's Law includes Shannon's tenth theorem as a special case. They merely pursue opposite aims of information processing.

## PROCESS

Philosophically, cyberneticians' preference for processes favors ontogenesis over ontology, accounting for processes of evolution rather than its products, constructing reality rather than describing what exists. An example from early cybernetics is the development of algorithms. Adding time to propositional logic, which is limited to stating facts, creates an algorithmic language, capable of describing processes and essential to programming computers. Shannon's celebrated MIT thesis enabled networks of relays – radio tubes in the case of ENIAC, the first operational computer – to be treated algebraically and hence far easier to program efficiently. He concluded before von Neumann did that anything that can be stated logically can be converted into an algorithm and hence becomes computable.

Adding time also led Varela to his calculus of self-reference. Self-references had threatened the consistency of logical systems for centuries. Whitehead and Russell identified them as the chief culprit of problems in logic, considered them an abnormality of language, and proposed a "theory of logical types" to rule them out of the language of science. Yet Zen Buddhism has employed paradoxes as powerful teaching devices for centuries, and psychotherapy has recently learned to use them in the treatment of psychopathologies. Human communication scholarship, especially by Bateson (1972) and the Palo Alto School that elaborated his ideas, developed its own responses to Russell's problem, for example, in the concept of meta-communication and the distinction between content and relational communication (Ruesch & Bateson 1951; Watzlawick et al. 1967; → Communication: Relationship Rules; Communicology). Utilizing Spencer Brown's *laws of form*, Varela dissolved the "viciousness" of such paradoxes by describing their eigen-dynamics – from assuming Epimenides is telling the truth, it follows he is lying, it follows he is telling the truth, it follows he is lying, *ad infinitum*. Dissolving paradoxes in time renders them analyzable, no longer threatening. Varela characterized self-reference as "the infinite in finite guise." Shifting from the study of writings to processes of communication did much the same for communication research.

Explaining systems in terms of what they do rather than what they are is also reflected in efforts at verbing nouns, like speaking of observing instead of observers, languaging instead of language, governing instead of government, or processes of living instead of life – but verbing may not be enough.

Contemporary computers are serial machines – characterized by changing from one state to the next. Social phenomena, by contrast, involve massively parallel processes: different things happen simultaneously, raising doubts about the ability of serial models

to help understanding of social processes. The parallel computer is a promising alternative. Heralded as a recent idea, it goes back to early cybernetic conceptions, for example in McCulloch's neural nets, Frank Rosenblatt's perceptron, and von Foerster's pattern recognizer.

Digital computers also are nonlinear machines. Many social theories, especially of the effects of mass communication, are still conceptualized in terms of linear functions – relating changes in one variable to changes in another. Although digital computers can be tamed to compute linear functions, this is not their strength. Recently, social scientists have discovered that nonlinear models can offer powerful simulations of social phenomena.

The cybernetic preoccupation with processes and ontogenesis also prepared the ground for its → *constructivism*, an effort to understand reality not as given but as brought forth in the process of enacting one's constructions of reality. Invoking actions that create realities implies that realities could have been otherwise, liberates scientific explorations from the determinism of causal explanations, and opens the possibility of changing what is undesirable.

## PARTICIPATION OR SECOND-ORDER CYBERNETICS

Werner Heisenberg's *uncertainty principle* asserts a limit to observing a system's states whenever the act of observation affects them. This principle troubled the idea of knowing by detached observation, celebrated since the Enlightenment, fundamental to the natural sciences, and emulated by social scientists as well. The shift from first-order to second-order cybernetics takes note of Heisenberg's epistemological challenge.

This shift was gradual. Early cyberneticians, while building models, already reflected on their own role. Shannon theorized his ability to design error-correcting codes that would resist noise in communication channels. Ashby explored the difference between what he, as the designer of a system, knew about its internal working and what he could learn about that system by observing the consequences of experimenting with it – describing that system without knowledge of its history or makeup, as a black box. The idea of a black box became the paradigm for studying systems that have no designer or cannot be taken apart, such as a living brain or an economy. In modeling such systems, cyberneticians soon became aware that their models defined, if not created, the conceptions of the modeled. This rendered the human modeler a key to understanding what was to be known. Following up on such threads, the anthropologist Mead (1968) suggested that cyberneticians apply cybernetic principles to their own work, a suggestion that von Foerster (1996) formulated as the inclusion of the observer in the observed and called “second-order cybernetics.” However, Mead went further, asking cyberneticians to explore systematically how societies organize themselves around cybernetic ideas and to assume responsibility for what the language of cybernetics brings forth – in effect, asking cyberneticians to acknowledge their role as unwitting change agents or designers. This prompted Klaus Krippendorff to define second-order cybernetics as *the cybernetics of participating in systems under continuous reconstruction by their constituents*, invoking a participatory epistemology.

Second-order cybernetics highlights the *use of language* – language not as a system of representations of an objective reality, which Richard Rorty (1979) aptly criticized, but as a Wittgensteinian language game or as Maturana's coordination of coordination of

action. Coordination is already evident, for example, when people kick a ball to each other. However, it is in language that soccer is distinguished from other sports and its rules are invoked to determine the progress of the game. In this conception, language brings forth consensual coordinations, in the process of which people acknowledge each other and direct their constructive attention to phenomena conceptualized in language. Conversation is one such language game. Second-order cybernetics takes conversation as the site where realities are co-constructed.

In the *social domain*, unless the products of communication research are purely academic or concern necessary causes, the very act of publishing social theories and making them available to interested parties, especially to those theorized therein, encourages people to respond. Whether people take advantage of such theories, and if applicable to themselves, conform to their claims, or act to counter them, any of these responses invariably change the theorized reality right in front of its theorist's eyes. The communication of social theories can affect what they theorize, change their own validity, and create new realities. This renders social theorists constitutive participants in the very realities they are describing. (Without realizing his own culpability in that constructive circularity, Anthony Giddens referred to this process as double hermeneutics; → Communication Theory and Philosophy.)

We know many constructive circularities of this kind. One example is self-fulfilling prophecies (or hypotheses), dreaded by sociologists like Robert Merton, who prefer that the truth-value of their theories be objectively verifiable, not changing in the course of their dissemination. Another well-known example is → Elisabeth Noelle-Neumann's → spiral of silence, which takes effect when citizens are informed of where they stand relative to a political majority. Economic crises, the growth of social movements, and many psychological problems can be explained in linguistic terms, as consensual coordination of understanding and actions. Herbert Simon realized the effects of publishing polling results on voting behavior, and suggested that valid election predictions must build these effects into whatever is published.

Mead realized that upholding the illusion of detached observers is no longer an option for cyberneticians when cybernetic principles begin to transform society (→ Objectivity in Science). To the extent that scientific findings are socially relevant, scientists need to see themselves as participants in the very systems they claim to describe but unwittingly influence if not create. The "god's eye view" that scientists have enjoyed since the Renaissance reveals itself as a convenient way to avoid responsibility for the inevitable circularity of scientific involvement. Second-order cybernetics can be likened to an insider's, not a meta-, perspective.

In the *domain of cognition*, McCulloch's work on neuronal networks, Maturana's experiments on the circularity of perception and action, and his and Varela's biology of cognition are embraced by what Ernst von Glasersfeld (1995) calls radical constructivism (Watzlawick 1984). It acknowledges that humans cannot leave their own nervous system and enter an external world to determine what they are seeing. Our nervous system does not map the Cartesian "universe" but constructs realities suitable for living and interacting with others. In enacting them, constructions of reality may be retained when they lead to what one expects, revised or expanded when they are seen as improvable, lessons to learn from, but when they prove fatal, the constructions and their beholders

vanish. Thus, constructions of reality are subject to evolution. They are what can bring down the autopoiesis of living systems.

Second-order cybernetic epistemology accepts Maturana's injunction against theorizing what violates human bodily capabilities. Its application to social phenomena leads to the study of embodied social phenomena, grounded in practices of living and communication, each enacting their own understanding, responding to their understanding of others' understanding, and generally expanding the possibilities of living together.

As an interdisciplinary, cybernetics continues to create challenging conceptions and takes responsibilities for the realities that follow from them.

# Cyborgs

*David Mertz*

*Freelance Writer*

The term “cyborg” was coined in 1960 by Manfred Clynes and Nathan Kline as a portmanteau of Norbert Wiener’s (1965) “cybernetics” with “organism.” A cybernetic organism (cyborg) is a biological creature – generally a human being – whose functioning has been enhanced through integration of mechanical, electrical, computational, or otherwise artificial components.

Many concepts now associated with the cyborg pre-date the term’s usage: antecedent or similar terms include robot, android, replicant, bionic human; stories of human–machine hybrids date back to myths such as Daedalus’ artificial wings. Presentations of human–machine hybrids have frequently acted as tropes in social arguments and literary imaginations that attempt to conceive the proper roles, and deeper meaning, of humans themselves, of machines, of the moral worth of each, and of the interactions among them.

Following the popularization of the term “cyborg,” especially in science fiction of the 1960s and 1970s, a number of further neologisms with the cyber-prefix developed that chiefly refer back to cyborgs, rather than directly to → cybernetics. These include cyberpunk (fiction), → cyberfeminism (theory), cyberspace (electronic networks), and cybersex (shared fantasy). Indeed, ad hoc usage of the prefix is common in journalism and popular writing.

Organic capabilities enhanced in cyborgs vary in kind as well as in extent. The enhancements addressed in fiction or essays – or, indeed, by practiced technologies – follow both the rhetorical or literary purposes of their creator and the evolving state of societal technical capabilities. Early examples of cyborgs generally centered on mechanical enhancements to motion; the growing prevalence of electronic sensors and computers led to discussion of cyborgs that improve human perception, → cognition, and communications channels (→ Cognitive Science). With inventions in genomics and nanotechnology at the start of the twenty-first century, visions of cyborgs often discuss augmentation of human health and longevity.

Diverse thinkers set very different boundaries for what artificial additions make a human into a cyborg. In a broad sense, all humans in the last several thousand years have been intimately shaped by the utilization and presence of technologies around them, or physically manipulated or attached to them. A spear, or even a stick, extends human capabilities for hunting or warfare; writing extends human memory, cognition, and information transmission. Inclusive thinkers, including those embracing the label transhumanism, focus on this broadest sense, usually with the intention of extending human–machine interactivity (→ Human–Computer Interaction).

In a stricter conception of the cybernetics stem, a cyborg’s machine elements must have a meaningful feedback mechanism with its biological aspects. For example, a continuity exists between a wooden leg that, indeed, enhances motility, and a hinged, weighted, and carefully balanced artificial leg, and further between these and a servo-mechanical prosthetic that actively responds to posture and muscle conductivity.

A prominent trend in the literary portrayal of cyborgs has been distinctly dystopian, seeing cyborgs as extensions or symbols of socially destructive industrial or postindustrial

technologies. An early and prominent entry in this genre was Shelley's (1831) *Frankenstein*. Many subsequent works demonstrated a similar but updated anxiety over the violation of the moral dignity and integrity of human beings, ranging in the twentieth and early twenty-first centuries from Fritz Lang's *Metropolis* to melodramatic portrayals of cyborgs as powerful evil beings in popular films such as the *Terminator*, *Star Wars*, *Star Trek*, or *Matrix* series. With the increasing feasibility of genetic or other biological manipulation of humans, many criticisms of such genetic cyborgs arise from ethical – and often religious – perspectives, which largely recapitulate the set of concerns suggested by Shelley. Many of these are, in turn, represented in dystopian fiction portraying the emergence of a new eugenics.

In contrast to negative portrayals, several literary or intellectual trends praising or advocating cyborgs have occurred over a similar time frame. Cyborgs have acted as superheroes, from Jean de la Hire's *Nyctalope* at the beginning of the twentieth century, through numerous mid-century American comic book heroes, on to late twentieth-century television heroes such as *The Six Million Dollar Man* and *The Bionic Woman*, or the *Robocop* film series.

Beyond the cartoonish heroes or villains of some popular fiction, a number of intellectuals – who have generally conceived cyborgs in their expansive sense – have seen liberating potential in cyborgs. For some, such as Haldane (1923) or Wiener (1965), cyborgs simply represent an extension of the positive capabilities of technologies (→ McLuhan, Marshall); most practicing doctors and medical researchers probably share this attitude, albeit infrequently naming medically assisted humans as cyborgs. Another trend in social thought, however, puts a positive light on cyborgs in that they can break down normative roles of gender, class, race, or other subaltern status (perhaps as much by compelling metaphor as by direct intervention). This tradition largely follows Michel Foucault's (1998) conception of *biopower*; Haraway (1991) is a prominent thinker in this tradition (→ Technology, Social Construction of).

Recent fiction around cyborgs, particularly that labeled cyberpunk, both takes a morally ambivalent attitude toward what it conceives as more-or-less inevitable cyborg technologies, and also tends to focus on cognitive and communicative enhancements over physical ones.

## Czech Republic: Media System

*Barbara Köpplová*

*Charles University*

*Jan Jiráček*

*Charles University*

The Czech Republic is located in the central part of Europe, with over 10 million inhabitants, Czech as the main official language, and a two-chamber parliamentary system. The state was founded after the split of former Czechoslovakia in 1993, which had belonged to the Soviet bloc after World War II. The current media system, established and developing since 1989, can be characterized as a liberal, pluralistic system operating within the framework of constitutionally guaranteed freedom of expression. The media in the country operate in a market-driven environment with no or very limited regulation regarding both content and ownership. Audiovisual media operate within a dual system of both public-service media and private (mostly commercial) broadcasting. The system is close to the so-called “democratic corporatist model” (Hallin & Mancini 2004). The typical characteristics of the system are a high level of both horizontal and vertical concentration of ownership, with wide influence of foreign owners, especially in print media (→ Concentration in Media Systems); a strong tendency toward commercialization (with a remarkable shift toward → tabloidization and → infotainment); a comparatively weak and politically dependent position of public-service media; and dynamic development of Internet media.

The media system of the Czech Republic is based upon developments and changes that took place during the period of former Czechoslovakia (1918–1992) and, before that, in the period of the Austro-Hungarian monarchy. The *first periodical newspaper* in the Czech language was published in 1719, but even before that periodicals in German were published in the area now known as the Czech Republic. During the second half of the nineteenth century, the big quality or liberal papers and the structure of the political party press were established (→ Partisan Press). The serious interest of the general public in national and political issues slowed down the commercialization of the media, and sensational papers did not appear before the 1920s.

After the foundation of Czechoslovakia in 1918, a liberal approach to the media was adopted and the structure of the media was developing. The coexistence of both Czech and German written periodicals, as well as the rise of big publishing houses, the development of political quality press and cultural/political magazines, on one hand, and

sensational press on the other, and the establishment of a national press agency (1918) and radio broadcasting (1923) are main features of the changes in Czech media between the wars. After World War II, Czechoslovakia was incorporated into the domain of influence of the Soviet Union, and its media system was accommodated to it. All of the media were supposed to serve the goals of the leading party and ideology. Most prewar periodicals were canceled or redesigned, and new titles were launched. The content of the media was under strong and systematic control (→ Censorship). However, the system itself was developing, and television was introduced in 1953. With the short interruption of the so-called “Prague Spring” (in the broadest sense, the period 1967–1969), when the media were allowed to operate more freely, the system can be characterized as nondemocratic, centralized, and nonpluralistic.

At the end of 1989, developments in Czechoslovakia led to the establishment of the media as independent of the state, market driven, pluralistic, and mostly nonregulated (Jakubowicz 2003). The media and advertising market became established as a new feature of the developing market economy of the country. Both print and audiovisual media were transformed. This development was adopted by the Czech Republic in 1993.

One of the main features of the media transition was the *change of media ownership*. Private publishers were allowed to enter the segment where only political parties, governmental bodies, and quasi-nongovernmental organizations had been licensed before 1989. During 1990, the structure of ownership of dailies and magazines was stabilized, with substantial presence of foreign ownership. The main dailies are owned by publishers based in other countries. Among the leading dailies, only one is still owned by a Czech publisher (→ Globalization of the Media).

New *newspapers* were published soon after 1989 but most of them did not survive. Some pre-1989 newspapers were transformed, and some have survived until today: for instance, *Právo*, the successor of the former communist daily *Rudé právo*; *Mladá Fronta Dnes*, the successor of the former daily *Mladá fronta* published by the Union of Socialistic Youth; the weekly *Hospodářské noviny* has been changed into a daily; the *Lidové Noviny*, a daily with a long liberal and quality tradition, established at the end of the nineteenth century, banned during the pre-1989 period, and published as a *samizdat* since 1988, was re-established and got its place on the market. Among new titles that survived on the market, mostly sensational papers can be found, e.g., the *Blesk* (“Flash”) daily was founded in 1992. The structure of the regional and local daily press was re-established completely, as well as the structure of magazines. The mainstream magazines are mostly domestic versions of international magazines.

State-run *radio and television* were transformed into public-service media, the *Český rozhlas* (Czech Radio) and *Česká televize* (Czech Television). Private commercial broadcasting was established (the first private radio in 1991; the first private TV broadcasting in 1993 and 1994). The leading TV station is a private commercial one, *TV Nova*, which started in 1994 and quickly achieved the position of market leader.

The newly established → advertising market is one of the most dynamic segments of the economy in the region. The amount of money fueled into the media via advertising has been increasing constantly, starting at less than 400 million Czech crowns in 1990 and increasing to more than 21.3 billion Czech crowns (0.75 billion euros) in 2006.

The new network media (→ Internet connections and mobile phone networks) have developed rapidly since the mid-1990s. There are three international mobile phone providers present in the Czech Republic (including Telefónica and Vodafone). The penetration of the Internet into the population was over 48 percent in 2006. All main traditional mass media are present on the Internet and some have developed specific i-products (e.g., the *Hospodářské noviny* daily produces [www.iHned.cz](http://www.iHned.cz); the *Právo* daily offers [www.novinky.cz](http://www.novinky.cz)). New Internet media (radios, news servers, etc.) have been developed as well (e.g., [www.aktualne.cz](http://www.aktualne.cz), an Internet news server; *Leonardo*, a radio station provided by public-service radio).

## Dance

*Adrienne L. Kaepler*

*Smithsonian Institution*

Dance is a complex visual form that communicates through movement in time and space, often in conjunction with music and poetry. Dances convey → meaning through culturally understood conventions within social contexts (→ Culture: Definitions and Concepts; Symbolic Interaction; Visual Communication).

Dances are produced as a result of creative processes that move human bodies through time and in spatial layouts. They are transient in performance, visual manifestations of socio-political relations, and may be the subject of an elaborate → aesthetic system. Often the process of performing is as important as the cultural form produced. Dances and dancing are surface manifestations of the deep structure or underlying philosophy of a society. That is, as presentations for an audience, dances may be admired as art or work; they may be participatory and enjoyed as entertainment, they may make political or social statements, they may bring religious ecstasy or trance, or they may be performed as a social duty (→ Art as Communication).

It is misleading to assume that dance is a universal language, as many have done in the past. Except on a most superficial level, dance cannot be understood or communicated cross-culturally without an understanding of the individual dance traditions within a culture (→ Ethnography of Communication). However, some dance types, such as ballet and Hawaiian hula, have been imported across cultural boundaries and can be considered → discourses on globalization (→ Globalization Theories). The places of origin, cultural traditions, and “communicative competence” of these now globalized performances have become nearly irrelevant as particular dance forms have attained a status of “international languages,” variously understood, admired, or viewed simply as → spectacle.

Dances consist of grammatically structured movements that in performance are usually part of some larger activity or activity system (→ Sign Systems). The grammar of a dance idiom, like the grammar of any language, involves structure, style, and meaning; one must learn the movements, how they can be stylistically varied, their syntax (rules about how they can and cannot be put together to form motifs and whole dances), and what meanings are ascribed to them. Movements may have been given originally by the gods, ancestors, or historic figures, but are retained and perpetuated in contemporary life as cultural artifacts and aesthetic performances. These movements are important, even if

their meanings have been changed or forgotten, as a reference point for ethnic or cultural identity.

Meaning is not inherent in movement but is ascribed to dances by groups of people at specific points in time, and these visual dimensions of performance need to be decoded (→ Code). In order to communicate as a cultural and aesthetic artifact, performers and observers must have communicative competence in an evolved Chomskyan sense. *Competence* or knowledge about a specific movement tradition is acquired in much the same way as competence in a spoken language is acquired. Competence relates to the cognitive learning of the shared rules of specific movement traditions, as *langue* is acquired in a Saussurian mode (→ Structuralism; Structuralism in Visual Communication). Competence enables the viewer to understand a grammatical movement sequence that he or she has never seen before. *Performance* refers to an actual rendering of a movement sequence, *parole* of Saussure, which assumes that the performer has a certain level of competence and the skill to carry it out (→ Semiotics). Only after one has competence in this enlarged sense is it possible to compose, dance, or view performances in a culturally appropriate manner.

Dance, like all symbolic systems, creates new meanings by combining old forms in new ways. The product and process interact dialogically, relying on shared understandings among composers, performers, and viewers. As in spoken language, understanding the meaning of movement requires understanding structure and style, which are learned by watching and participating. Such knowledge is passed from generation to generation in a more or less formal manner, and absorbed by experiencing how the meanings of motifs, choreography, and style are communicated in context. Most important is knowledge about the culture in which a dance tradition is embedded, such as male and female roles in movement, social status, social structure, and especially socio-political discourse (→ Gender and Discourse; Spectator Gaze). *Methods and theories* currently in use for analyzing dance include “form analysis,” which originated in eastern Europe (Giurchescu and Kroschlova 2007; “emic analysis,” which uses linguistic analogies (Kaeppler 2007); and “semasiology,” which is concerned with the semantics of body languages (Williams 2004).

# Dating Relationships

Laura Stafford

Ohio State University

Dating relationships have no uniform defining characteristics. They have romantic or sexual overtones, occur between two people who are not married to each other or to anyone else, typically do not share a residence, have not formally acknowledged plans to marry, and may or may not expect continued involvement. These relationships vary in expectations for and level of commitment, intimacy, exclusivity, and sexual activity. Dating relationships have often been equated with “premarital” relationships or are considered part of “courtship,” though it is recognized that most “premarital” relationships do not result in marriage, nor are they intended to. Dating as a relational form emerged in the US and has received limited research attention in nonwestern countries.

## THE PHENOMENON OF DATING RELATIONSHIPS

In the US, the primary type of romantic involvement among unmarried individuals has shifted from courtship as a precursor to marriage to dating as a recreational activity with little emphasis on commitment (Rollin 1999). In addition to courtship or mate selection and recreation, reasons for dating include socialization (getting to know each other), status grading (increasing one’s social status by dating popular or attractive individuals), sexual experimentation, satisfaction, and intimacy (Roscoe et al. 1987).

Some report that “dates” as formal preplanned activities are becoming less frequent (Glenn & Marquardt 2001). This has led some to proclaim that dating is becoming extinct. Others argue that dating and dating relationships simply continue to change (Surra et al. 2007). *Dating forms* vary from exclusive committed relationships to “getting together,” “hanging out” alone or in a group (Rollin 1999), “hooking-up” (sexual encounters between acquaintances or strangers without commitment), “speed-dating” (meeting individuals via fast-paced round robin interactions), and “pre-dates” (meeting potential dates via online interaction; → Mediated Social Interaction).

Many stage models of dating have been offered (Cate & Lloyd 1992). In the US, the most common reasons for initial attraction/interaction are physical attraction, similarity, reciprocal liking, and proximity. Reasons for breaking up include social incompatibility, low relational quality, and influence of social networks (Sprecher 1998). Relationships often develop and deteriorate at a similar pace; the more quickly partners become involved, the more abrupt the termination, whereas the more prolonged the development, the more prolonged the termination (Cate & Lloyd 1992). Scripts and expectations for dates have been examined, as have ways of ending dating relationships (→ Expectancy Violation; Relational Termination; Scripts).

Recently, dating relationships have been studied as one context for the numerous relational processes such as self-disclosure, abuse, power, and trust that are universal in close relationships (Surra et al. 2007).

### **DATING FROM 1880 TO 1960**

Dating emerged in the US during the 1920s, as did the term “date” (Bailey 1988). *From 1880 to 1920*, “courting” was the predominant romantic form among unmarried individuals. Courting was formal. After an introduction, a man could “call on” a woman in her family home. Among the upper and middle classes, courtship was a step toward marriage. Working-class families did not have homes large enough for courting so it occurred in public. Upper-class youth adopted the idea of “going somewhere” as part of courting, and an early form of dating was born (Bailey 2004a).

*In the 1920s* dating, as a recreational activity separate from courtship, was established. Dating and courtship coexisted but had different objectives. The term “date” was coined and was understood as “an occasion where a boy asked a girl to join him for an afternoon’s or evening’s outing, for which he generally paid” (Rollin 1999, 54). Dating was about fun and popularity. Courting was about selecting a marital partner. Despite this distinction, a series of dates with the same person over a period of time (keeping “steady company”) was expected to result in marriage.

Into the *1930s and early 1940s* the principal purpose of dating was recreation devoid of commitment (Burgess et al. 1954). “It was about competition within the peer culture” (Bailey 2004a, 35). In efforts to boost their popularity, individuals often had multiple dates with different people during the same week; the most attractive or popular dating partners were sought. Though this “rating and dating complex” (Waller 1937) did occur, the extent to which it was widespread has been questioned (Whyte 1990).

With the depression and World War II “rating and dating” waned, and arguably dating served as preparation for marriage. During the 1950s “going steady” took center stage. It involved “a whole new set of rituals” (Cate & Lloyd 1992, 26). Girls might wear boys’ class rings or “get pinned.” Going steady was an exclusive relationship, even if only for a brief period of time. Though going steady took on a semblance of preparation, this relational form was not expected to culminate in marriage. A person might “go steady” with several different individuals prior to engagement.

### **DATING RELATIONSHIPS AS PRECURSORS TO MARRIAGE**

Two relevant areas of study are the progression toward marriage (→ Relationship Development) and the prediction of marital success. In the former, trajectories and stage models from initial attraction, first date or encounter, through “serious dating,” engagement, and marriage have been plotted (Cate & Lloyd 1992) and facets surrounding decisions to marry, marriage markets, timing, and social, political, and economic influences examined.

Larson and Holman (1994) summarize research on premarital factors associated with lower marital quality and/or instability. These include: divorced or low-quality marriage of parents; dysfunctional family backgrounds (e.g., parental mental illness); lack of support for the marriage from parents; young age; less education; lower income; premarital childbearing; depression; an unsociable personality; holding dysfunctional beliefs about marriage; and cohabitation prior to marriage. When decisions to marry are made with external pressures such as job/career concerns, economic depression, or war,

success is less likely. Success is more likely the more homogeneous the partners are in terms of race, age, religion; the more similar in attitudes and beliefs; and the better partners know each other before marriage, often assessed as the length of time partners date and their ability to engage in positive communication (→ Marital Communication).

Early research suggested that premarital sex and cohabitation were associated with divorce, but according to recent research neither is associated with divorce when limited to a future marital partner. Thus sex and cohabitation are becoming part of a courtship progression. However, multiple sexual and/or cohabitation partners prior to marriage have still been found to be predictive of divorce (Teachman 2003).

### DEFINITIONAL ISSUES

A problem with research on “dating relationships” is the *lack of a conceptual definition and loose operationalizations*. No one definition or widely shared cultural norm exists. A couple in a dating relationship might or might not go on “dates,” and a couple who are going out on dates might or might not consider themselves in a dating relationship. Even the same event or relationship might be defined differently by the two individuals involved (Chornet-Roses 2006).

Studies of dating relationships often inquire whether participants are in a dating relationship, but provide no definition. Sometimes “dating relationship” is broken into categories of “casual” and “serious.” Some might argue that participants are only in a dating relationship (or in a casual as opposed to a serious relationship) if they believe they are; so this definition serves research well. Such participant-driven definitions can result in both partners in a couple disagreeing about whether they are in a “dating relationship” (e.g., one cohabiting partner considers the relationship to be a “dating relationship,” whereas the other does not). Such definitions also make integration of studies difficult; without stated criteria, the reader has little knowledge of the nature or characteristics of the relationships under study. Collapsing into one group individuals who are in a casual relationship as well as individuals seriously and exclusively committed to each other obscures variations within dating relationships.

Also, dichotomizing relationships as “marital” or “premarital” (or marital versus single) does not allow for consideration of nonmarital romantic relationships such as civil unions and cohabitation without marriage. Though it is unlikely that researchers or relational participants will come to a consensus on what a dating relationship is, given the amount of research conducted on “college dating relationships” studies might be improved by providing conceptual definitions. Such definitions could be based on factors such as level of commitment, intimacy, exclusivity, and sexual involvement. To understand the phenomenon better, it might be fruitful to break dating relationships down into the “activity” of going on a date, the “process” of dating, and the “status” or “role” of the relationship, and to consider these aspects separately and in conjunction with each other.

Most knowledge about dating relationships comes from never-married heterosexual college students in western cultures. Clearly, more heterogeneous populations and the types of dating and dating relationships formed warrant attention. Some research on relationship formation (e.g., arranged marriages, preferences for a mate) exists. Western views of mate selection, including dating, are gradually infiltrating other cultures, though

many traditions have also been maintained. Yet scholarly consideration of nonwestern dating relationships is virtually nonexistent. The limited research outside western cultures focuses almost exclusively on romantic involvements as related to marriage. Comparisons among preferred characteristics of mates, means of mate selection (e.g., free choice and parent-arranged), and beliefs about marriage (e.g., the role of love and fate) have received the most attention.

## Death, Dying, and Communication

*Cecilia Bosticco*

*University of Dayton*

*Teresa L. Thompson*

*University of Dayton*

Death is considered a taboo topic in most cultures. The lack of willingness to talk about the issue reflects discomfort with the subject and attempts to deny the reality of death. Instead of talking openly about death, most people use euphemisms and metaphors to maintain distance from it. This communicative avoidance then defines death as an even more taboo issue. The topic of death was not even studied extensively by scholars until the 1970s.

Death anxiety affects both terminally ill individuals and those who interact with them. The fear of death can stem from thinking about one's own end and about the uncertainty of what lies beyond death – the unknown and unknowable. Being afraid of death can contribute to anxiety about aging; however, experiencing the deaths of others may help to lessen an individual's fear of death, especially when the dying person and those around him or her accept and cope with death directly. While initially causing a heightening of fear, death education reduces denial, allows for expression and discussion of fears, lessens anxiety, and eventually leads to greater comfort for health-care providers who deal regularly with dying people (Servaty & Hayslip 1997). Death anxiety is also reduced by having a relationship with a higher power.

People who are facing impending death need as much information as possible, whether positive or negative (Jenkins et al. 2001). Knowing allows hope, while not knowing allows the imagination to create scenarios often worse than reality. In cancer patients, *less than honest information* results in anxiety and adjustment disorders. In patients with inoperable tumors, lack of honest communication has been found to cause very high levels of drug use, anxiety, and depression. Accurate information allows people to be more actively involved in decision-making about their treatment, although some patients do prefer a more passive role.

Most dying people want to talk openly with their loved ones, friends, and caregivers about their death (Servaty & Hayslip 1997). Talking about death helps people deal with it and the emotions it causes in them. Those communicating with someone who is dying do best to listen as the person talks about his or her life, tries to make sense of it, and brings it to a close.

Health-care providers should talk with patients and/or their relatives to determine the level of awareness of the person's condition and its likely results (especially if it is a fatal diagnosis) and then gently confirm the bad news. Most patients (and their families) want to know if death is imminent (Seale 1991), although some may feel that loved ones or friends might not be able to handle such information. Patients who are not told the truth about their prognoses, yet perceive it from verbal and nonverbal messages that are disparate from information they have been told, are placed in a difficult double-bind and cannot properly deal with the impending death. People want to know they are dying so they can say goodbye to family and friends, maintain a sense of dignity, and secure God's forgiveness for their mistakes.

*Denial* can exist at the same time as an awareness of impending death. Some people report not remembering that they had been told of their fatal diagnosis, even when it had been clearly explained to them previously. Denial can help people deal with fear, can help them cope with the coming of death, and can protect interpersonal interactions that the nearness of death could diminish or extinguish (Beilin 1981–1982).

For the most part, interactions with those who are terminally ill are characterized by social distance and social death – treating people as if they are already dead. *Reluctance to interact* with the dying reflects both the death anxiety noted above and perceptions of a lack of knowledge about how to interact with someone who is dying – a lack of a response repertoire for dealing with the terminally ill. Negative attitudes toward death and dying also lead to less aggressive medical treatment for terminal patients, especially if the patients are older or of lower social status (Timmermans 1998). In addition to differential treatment from health-care providers, the terminally ill are also treated differently by their friends and families than are nonterminal patients. Family members and friends experience anticipatory grief prior to death; while it may make bereavement easier, this also leads to increased social distancing and social death prior to demise. It can rupture already fragile social bonds. Some research has shown that only a third of spouses openly discuss impending death, and another third discuss it in a limited fashion. The last third do not discuss it at all. Open communication from health-care providers, however, does positively impact openness of family communication. More open communication prior to death facilitates the grieving process after death.

Uncertainty about how to communicate with the dying is based on the assumption that there is a correct way to interact in this situation, when the research demonstrates that there is no correct way to communicate with the dying. There is nothing that can be done to make terminality more acceptable. The most effective interaction is that which just communicates caring and presence – that the other person is there for the dying or bereaved individual. There are no magic words that can be used to make the situation better.

Research in this area has also examined *bad news delivery* from health-care providers (→ Bad News in Medicine, Communicating). In general, providers receive very little and wholly inadequate training in this area. Bad news delivery is relevant in terms of the announcement of impending terminality in those cases where it can be anticipated and the indication to family and friends that a loved one has died (→ Doctor–Patient Talk). The anxiety and uncertainty experienced by care providers typically leads them to overwhelm the terminal patient with information when announcing the diagnosis rather than providing the empathy that is more appropriate in such a context. Patients cannot

process high levels of information when they are trying to comprehend terrible news. When making the death announcement to family members, care providers generally do not communicate the sympathy that is needed. Law enforcement personnel and physicians are less effective at such announcements than are nurses, whose training emphasizes more interpersonal sensitivity.

## **Deception Detection Accuracy**

*Timothy R. Levine*

*Michigan State University*

Much research attention has been devoted to identifying the factors that affect people's ability to detect others' deceptive acts. Communication researchers typically have focused on the accuracy of judgments based on the verbal and nonverbal behaviors of a message source, unaided by technological devices or extra-interaction information. In general, results show that people are not very good at detecting deception, that people overestimate their ability to detect deception, and that people are more likely to believe that others are honest than deceptive, independent of the other person's actual honesty.

Deception occurs when one person intentionally misleads another person. The most frequently investigated type of deception is the *lie*. Lying involves knowingly presenting false information. Other forms of deception include *omission*, *evasion*, and *equivocation*, but most deception detection research focuses exclusively on the ability to distinguish outright lies from complete truths (McCornack 1997; → Deceptive Message Production). People are considered to be accurate when they judge truthful messages to be honest and deceptive messages to be dishonest.

Deception detection experiments usually involve showing research participants a series of truths and lies, and having them identify which are which. Judges are typically exposed to an equal number of truths and lies, and accuracy is most often calculated as a percentage correct averaging across truths and lies. More recent research also reports separate accuracy scores for truths and lies.

Three consistent findings are evident in the literature. First, people are significantly, but only slightly, above chance levels of accuracy (50 percent). Second, people overestimate their ability to detect others' lies. Third, people are more likely to judge a message truthful than deceptive, independent of actual message veracity. Many research findings are counterintuitive, and common sense and conventional wisdom are often proven wrong in the realm of deception accuracy research.

People are, on average, 54 percent accurate in deception detection experiments (Bond & DePaulo 2006). This value is significantly greater than the 50 percent chance base rate, and is very stable, with few studies reporting values below 45 or above 65 percent. Although a number of variables affect detection accuracy rates, the impact of most of them is small in absolute terms. Nonverbal training improves accuracy only slightly. Judges tend to be slightly more accurate when presented with audio-only, audiovisual, or text-based messages than when only visual information is presented. Sender motivation actually improves accuracy. That is, the more motivated a liar, the more transparent the lie. Alternatively, variables that have little impact on accuracy include source expertise/occupation, source–receiver relationship, extent of interaction, question-asking, and whether honesty values are scaled or dichotomous (Bond & DePaulo 2006).

There are several reasons why people tend to be inaccurate lie detectors. First, there do not appear to be any strong, cross-situation behavioral cues that make high accuracy possible. Although statistically reliable cues to deception are observed across studies (DePaulo et al. 2003), these cues are too inconsistent to be of much use in detecting specific instances of deception. Second, people pay attention to cues that lack diagnostic utility. For example, there is a widely held belief that liars do not look other people in the eye, yet truth-tellers and liars do not differ in eye behavior, and eye gaze has no diagnostic utility (DePaulo et al. 2003). Third, research procedures preclude much potentially useful information for detecting lies. Research indicates that when people do detect lies in everyday life, it is often done well after the fact, and on the basis of information other than at-the-time source verbal and nonverbal behavior (Park et al. 2002). Instead, detection is often based on inconsistencies with prior knowledge, information from third parties, and physical evidence. Such information is not available in most deception detection experiments. Finally, people are generally truth-biased, and often fail to even consider the possibility of deceit (Levine et al. 1999).

Truth-bias refers to the tendency to believe another person independent of actual message veracity. Truth-bias likely stems from how people mentally represent true and false information and from tacit assumptions that guide communication (Levine et al. 1999; McCornack 1997). Truth-bias is more pronounced in face-to-face interaction, when communicating with a relationally close others, and when people are not primed to be suspicious. Because people are more likely to judge messages are truthful than deceptive, people are more likely to be correct at judging truths than lies. Accuracy for truthful messages is often well above 50 percent, and accuracy for lies is often below 50 percent.

Further, so long as people are truth-biased, the greater the proportion of honest messages judged, the greater the percentage of judgments that are likely correct (Levine et al. 1999).

The major research challenge facing detection research is making the experiments more realistic while maintaining ground truth (→ Deception in Discourse). Ground truth means the actual truthful or deceptive nature of the message must be known so that accuracy can be determined. The need for ground truth leads most researchers to laboratory experiments. This makes studying realistic, higher-stakes, unsanctioned lies challenging. There is a growing recognition that the distinction between everyday lies and high-stakes lies is a meaningful one, and different methodologies may be needed to study different types of deception.

## **Deception in Discourse**

*Dariusz Galasiński*

*University of Wolverhampton*

The “truth-bias,” the expectation that, normally, one tells the truth, is proposed to be the cornerstone of humanity (Bok 1978). Yet, it is the skill of displacement – speaking of things which are not present – and thus also the ability to deceive that is the basis of human language (Aitchison 1996). A society of truthfulness, to highlight the downside of truth-telling, would be a society of hurtfulness. The discursive status of an act of deception has been the subject of some considerable debate. It focuses upon questions: (1) What is the act of deception? (2) What are its kinds? (3) What is its discursive and social status?

Discussions of the *definition of an act of deception* focus upon truthfulness of the proposition of the act and the beliefs of the speaker and of the addressee. There is widespread consensus that falsity (or other misrepresentation) of the act’s proposition, whether explicit or implicit, is not sufficient for the act to be deceptive. Thus, commonly, an act of deception is held to be one in which the speaker conveys information with the

intention to induce false beliefs in the addressee. There are, however, attempts to reposition deception in terms of accuracy of the speaker's beliefs (Ng & Bradac 1993), covert violation of Gricean maxims (→ Linguistic Pragmatics) – i.e., covert failure to be truthful, to say as much as needed, or to be relevant or clear (McCornack 1992) – or manipulation (Galasiński 2000).

There are many *classifications of acts of deception*. Regardless of the actual categories, classifications are based on a number of axes of comparison. Acts of deception can be monologic or dialogic (as in covert evasion where the speaker pretends to answer the question, e.g., A: *Do you want a tougher regime in these secure places?* B: *I want a regime that helps them [inmates] face up to their responsibilities . . .*); they can be active or passive (by withholding a message); they can be done via explicit or implicit proposition (implicatures, presuppositions, e.g., the infamous *Have you stopped beating your wife?*); and, finally, they can vary with regard to the way they misrepresent reality (they can falsify, but also only distort by making stronger or weaker claims, or take words out of context). Other important aspects of acts of deception are the relevance of the act and the accountability of the speaker (Bradac et al. 1986). The final distinction is whether the act of deception focuses upon the extralinguistic reality or the message itself (see Galasiński 2000).

The status of deception as a discursive act is relatively less explored. Deception is not a speech act in the same way statements, promises, or questions are (→ Questions and Questioning), nor is it related to any linguistic form. Rather, it is a characteristic of speech acts. Thus, lies are mendacious statements, and evasions are covertly uncooperative answers. Deception is parasitic on other uses of language in that speakers use conventional speech acts to further their social goals.

Even though morally condemned, acts of deception are sometimes accepted (the so-called “white lies”), and expected. There is a plethora of discursive activities in public, semi-public, and private discourses in which deception can be expected. Discursive practices in politics, in advertising, in storytelling (→ Storytelling and Narration), or in contacts with insurance companies are often assumed to be economical with the truth.

*Methodologically*, research into deception as a discursive action is fraught with problems, the main one being that of basing it upon naturally occurring data. As deception is inextricably linked to the intention to mislead, which is covert, socially unaccepted, it is therefore empirically inaccessible. Thus, it is possible to argue that research based on researchers' instructions for the participants to lie or deceive, which dominates in the field, or asking participants to remember their deceptions, explores social constructions of deception rather than deception itself. The way forward might be collection of data in which one has access both to the “act of deception” and the reality it is designed to represent and so it is research focusing on misrepresentation that might be part of the solution (Galasiński 2000; Miller and Stiff 1993).

*Future research* into the discourse of deception should, first, more clearly locate deception within the family of strategic, nonovert acts of discourse, such as manipulation, persuasion (→ Persuasion and Resistance), and others. Second, and related, it should more clearly locate discursive deception in relation to visual and other kinds of deception. Third, it might look into the linguistic workings of deception, its relation to the context as well as its various social configurations, and especially its relationship to power

relations as well as gender (→ Gender and Discourse), ethnicity, age, or disability, as well as other axes of social status.

## **Deceptive Message Production**

*Judee K. Burgoon*

*University of Arizona*

*Lauren M. Hamel*

*Michigan State University*

Deceit is part and parcel of daily life. It not only frequents news headlines in conjunction with political chicanery, corporate scandals, campus cheating, telemarketing scams, identity theft, online predators, and terrorist plots but also permeates the fabric of everyday conversation (→ Deception in Discourse). People who complete diaries of their communication report 20 to 33 percent of their interactions include some form of deceit and they average two lies per day (DePaulo et al. 1996; Hancock et al. 2004). Biologically, deception is regarded as adaptive, as a part of natural selection that improves chances of survival for animals that are most successful at it. Thus, deceit is not limited to humans. Other species have developed very sophisticated forms of deception ranging from camouflage and mimicry to misdirection, bluffing, and hiding of resources.

*Definitions of deception* vary but most emphasize that it is an intentional act in which senders knowingly transmit messages intended to foster false beliefs or conclusions by recipients (Knapp & Comadena 1979). Self-delusions are excluded, as are mistaken representations or role-playing in which the audience willingly suspends disbelief. This

definition broadens the scope of the concept beyond outright lies to include such forms as omissions, intentional ambiguity, evasions, exaggerations, and the like. Human deception also includes not just deception for self-benefit but also deception intended to benefit others or the interpersonal relationship between sender and receiver. White lies intended to spare another's feelings, for example, are considered deception just as are blatant falsehoods intended to bilk targets of their fortune or to cover up treasonous acts.

### THEORIES OF DECEPTION

Research on deception has centered largely on one of two issues: deceptive message production and deception detection (→ Deception Detection Accuracy). Here we focus on theories that relate to message production – converting thoughts into verbal and nonverbal messages – and the message features that have been shown to be reliable indicators of deception.

The *Leakage Hypothesis* (see Ekman 1985) focuses on the neurophysiology, emotions, and cognitions of deceivers and how changes in these internal states due to deceptive attempts become apparent in behavioral displays. Involuntary signs – referred to as “leakage” because they “leak” out of the body unbidden – act as telltale signs to the actor's true intentions or state of affairs. Originally, leakage and deception cues were considered to be separate indicators, the former referring to signs of the true emotional state of the deceiver and the latter as signs that one was in fact attempting to deceive. However, all involuntary behaviors are now typically called leakage. This perspective, which partly harks back to Freudian psychology and psychiatric views of human behavior, drives much of the quest for lie-detection tools like the polygraph or vocal stress analyzers that are intended to detect physiological arousal and emotional states.

The *Four-Factor Theory* (see Zuckerman et al. 1981) is an extension of the leakage hypothesis and attempts to refine the origins of telltale nonverbal indicators of deceit. This theory proposes that (1) arousal, (2) affective reactions, (3) cognitive difficulty, and (4) attempted control all affect deception displays. Deceivers are thought to experience higher levels of arousal that will result in changes such as faster blinking, higher vocal pitch, and more speech dysfluencies. Deceivers also may experience emotional reactions such as guilt and anxiety that are evident in their behavioral displays, often in the form of micromomentary facial expressions – fleeting indications of negative emotions that are seldom recognized by the naked eye. Deception is assumed to require more cognitive effort than does truth-telling. This effort should be reflected in such indicators as more pauses in speech, dilated pupils, and fewer speech-related gestures. Lastly, this theory proposes that deceivers will try to control their leakage, resulting in overly rigid and stilted nonverbal behavior.

*Interpersonal Deception Theory* (IDT; see Buller & Burgoon 1996) advances a series of propositions (general statements) intended to predict and explain the causes, processes, and consequences of deception in interpersonal interaction. In contrast to the psychologically oriented theories, it distinguishes between strategic and nonstrategic components of messages. The former refer to purposeful features of speech and the latter refer to nondeliberate behaviors including leakage and other forms of impaired performance. This theory argues that because deceivers connive and plan and adjust to accomplish their deception and to avoid detection, deceptive message production must

look at these intentional strategies as well as at unintended and involuntary behaviors. Three classes of strategic activity identified by IDT are information management, which concerns the verbal content and style of messages; behavior management, which concerns the nonverbal behaviors that accompany a verbal message and are meant to create a normal communication style; and image management, which concerns general efforts to make oneself appear believable. A strategic perspective is consistent with viewing deception as a persuasive or self-presentational activity (→ Impression Management; Self-Presentation). Other key principles of IDT are that deception is adaptive and dynamic. Deceivers do not display the same behaviors constantly; they change in response to feedback from their targets. This means that there are no profiles of deception that can be counted on to remain stable over time. Lastly, deception is interdependent, meaning that what deceivers do is partly dependent on what co-interactants do. If a person questioning deceivers becomes very animated and involved, they will too, which can make them appear truthful. How deceiver and deceived interact and adapt to one another's behaviors over the course of an interaction is a major focus of IDT.

*Information Manipulation Theory* (IMT; see McCornack 1992), like IDT, recognizes the strategic nature of interpersonal deception. Drawing upon Grice's theory of conversation, IMT discusses four maxims that deceivers can violate to achieve their desired outcome. People can say less than is usually expected (the maxim of quantity), they can give untruthful information (the maxim of quality), they can say things that are irrelevant (the maxim of relevance), or they can say them in an unclear, ambiguous fashion (the maxim of manner). Deceivers rely on people's assumptions that others' messages are complete, truthful, relevant, and easily understood and they may covertly violate any of the four maxims to produce messages that are deceptive. *Information Management Theory* (see Burgoon et al. 1996), though similar, is a part of IDT that was developed independently of IMT. It adds a fifth dimension to IMT and elaborates on the semantic and syntactic tactics deceivers can use to intentionally alter the veridicality, completeness, relevance, clarity, and personalism of verbal messages.

The *Motivation Impairment Effect* (see DePaulo & Kirkendol 1989) hypothesizes that when deceivers try harder (i.e., are motivated), they end up with impaired nonverbal performance but also improved verbal performance, which should affect how detectable their deception is to observers. Challenges have been posed to this hypothesis in part because deceivers may show improved nonverbal performance and impaired verbal performance when they are highly motivated. In other words, motivation sometimes helps and sometimes harms performance but it need not have opposite effects on verbal versus nonverbal behavior.

## INDICATORS OF DECEPTION

Investigations of message features associated with deception have taken two approaches. The first has sought the behaviors that people *perceive* to be deceptive. Invariably, the number one answer worldwide to the question of how to tell when someone is lying is to look at their eyes. Yet research has confirmed that the eyes are *not* a good indicator of deceit (DePaulo et al. 2003), partly because skillful deceivers know to look their questioner in the eye. Other widely held stereotypes such as nervous gesturing are also not good indicators. The second approach is to identify *actual* verbal and nonverbal

behaviors that separate truth-telling from deceit. These can be grouped according to IDT's classifications of nonstrategic and strategic indicators and the division of strategic behavior into information, behavior, and image management.

*Nonstrategic behavior* includes all the telltale, nonverbal leakage cues of arousal, emotional states, and cognitive effort or difficulty (Vrij 2000; → Nonverbal Signals, Effects of). Arousal is the psychological activation in the autonomic nervous system, central nervous system, and/or limbic system. Examples of deception-triggered arousal are fidgeting, self-adaptors (self-touching), pupil dilation, blinking, pitch rise, postural rigidity, and a tense voice. Emotional states are overt reactions that signal discrete and transitory psychology feeling states. Examples include fewer authentic smiles, more forced smiles, and less vocal pleasantness. Micromomentary facial expressions of fear, guilt, or contempt are also purported by some to signal deceit.

Cognitive difficulty is associated with shorter utterances, longer delays in responding, more hesitations, looking away, and temporary cessation of gesturing. Greater cognitive effort need not signal deception, but deception may lead to greater cognitive difficulty. Other cognitive indicators may relate to memory processes and whether senders are accessing real versus fabricated or imagined memories of people and events. Unintended indicators of making up answers rather than reporting real answers include saying less and giving fewer details.

IDT also identifies impaired speech performance as nonstrategic activity. It includes more speech dysfluencies such as stutters, hesitations, and incoherent sounds; fewer punctuating head movements to accompany speech; more stilted posture; reductions in overall conversational involvement; mismatches between verbal and nonverbal channels; and behaviors that are unusual or “fishy-looking.”

*Linguistic and content features* of deceptive messages are understudied relative to nonverbal features. Deception has been associated with use of fewer words, sentences, and content details; simpler and less complex language; greater uncertainty shown through modal verbs and modifiers; and less personalism (e.g., use of first-person pronouns) and more language that instead refers to others. However, these patterns can reverse under many circumstances, making content and linguistic features very dependent on the specific context.

## **BEHAVIOR AND IMAGE MANAGEMENT INDICATORS**

*Behavior management* is directed toward approximating normal conversational patterns. *Image management* strategies are more global changes in demeanor intended to preserve a credible image and evade detection. Deceivers may attempt to increase postural, gestural, facial, and vocal involvement. This may include a shift from psychological “distance” to closeness signaled through forward lean, increased eye contact, and direct facing. Deceivers may attempt to become more expressive facially, gesturally, and vocally while simultaneously conveying that they are composed and unstressed through postural stillness while listening and postural relaxation. Efforts to achieve fluid conversational coordination may include fewer pauses, smoother switches in turns between speakers, and more synchronization of behavior between sender and receiver (→ Interaction Adaptation Theory). Deceivers may also strive to appear and sound pleasant. Finally, deceivers may adjust their levels of dominance and formality. They may opt to be submissive, meek, and

overly formal if caught off guard but become more dominant and formal if they have time to plan or rehearse their deception. Dominance may include use of a loud, deeper-pitched, more variable voice; more expansive gesturing; and more asymmetrical, relaxed posture.

# **Decision-Making Processes in Organizations**

*Marshall Scott Poole*

*University of Illinois at Urbana-Champaign*

*Iftekhhar Ahmed*

*Texas A&M University*

Organizational decision-making is a primary process in organizations. It has been the subject of much research, and numerous prescriptive frameworks have been advanced. A

facile analogy with individual decision-making makes organizational decision processes seem relatively straightforward, but research has shown it to be complex and problematic.

In its simplest form, decision-making is the process of reaching a conclusion or resolution after consideration. Herbert Simon (1976) defined decision-making as choice based on analysis, and divided the decision process into the sequential tasks of intelligence, problem analysis, solution search, and choice. Henri Mintzberg (1979) defined organizational decision-making as making a commitment to action.

An important question is: “Who makes the decision?” In common expression decisions are often attributed to organizations (for example, “GM announced today that it has decided to close XYZ plant”), but decisions are made by people within organizations, and understanding of organizational decision-making processes is closely linked to the role attributed to participants in the decision process. One perspective treats organizational decisions as *unitary actions* taken by a single individual – a manager or leader – or by a group. Scholarship in this perspective focuses primarily on how the decision is made. It takes the classic rational model of decision-making as a reference point, whether as an ideal that decision processes should follow or as an unattainable standard that should be replaced by more realistic models. This perspective treats communication as a medium through which decisions are made and attempts to develop normative models for improving decision-making effectiveness.

A second perspective takes the *organizational context* of decision-making into account. Theories or models in this perspective focus on the role of different people, groups, or organizational units in the decision process, on how the process moves through the organization, and on how it is influenced by organizational structure and processes and by politics. This perspective has often focused on how the decision process departs from the rational ideal due to the organizational context. The organizational context perspective treats communication as a medium through which decisions are made, and emphasizes the role of communication processes in the shaping of decisions through formal and informal networks and argumentation concerning decision premises.

A third perspective focuses on the *social construction of organizational decisions* through communication. It is concerned with how decision premises and rules for making decisions are constructed by those making the decision as the process unfolds. The social construction perspective problematizes the other two by arguing that the elements of decisions they take for granted – problem definitions, solutions, decision rules, stakeholders – are constituted by communication during the decision process.

A range of outcomes is relevant to organizational decision-making, including effectiveness – as indexed by decision quality, return on investment, and other “bottom line” measures – timeliness, acceptance of and support for the decision, degree of implementation, degree to which the decision builds the capacity of the organization to make effective decisions, impact on morale, and degree to which the decision meets member needs. Different outcomes are emphasized by the three perspectives.

### **ORGANIZATIONAL DECISION-MAKING AS A UNITARY PROCESS**

An important goal of modern organizations is predictability and control, and in organizational decision-making this can be achieved through careful analysis and calculation. The

*rational decision model* aspires to systematize analysis and maximize the returns a decision will yield for the organization. A rational decision-maker gathers complete information about the situation and choices confronting the organization, generates all feasible decision options, evaluates each option thoroughly using an array of criteria that represent the various benefits and costs that the options might yield, and chooses the option that maximizes return. Decision scientists have developed models and decision-support systems that formalize various schemes for rational decision-making (→ Meeting Technologies).

The rational model assumes that the decision-maker(s) can gather all relevant information about the situation and options; that criteria are clearly defined; that the probability that the benefits and costs will actually materialize for a given option is known; and that the decision-maker can assign precise values to (or rank order) the various benefits and costs. Generating this information requires thorough and complete analysis, which is likely to ensure that the decision-maker exercises due diligence.

Herbert Simon (1976) and others criticized the classical rational model on the grounds that it sets too high a bar. They observed, among other things, that decision-makers can rarely obtain complete information about a situation; that criteria for evaluating options are often fuzzy and may change as the decision unfolds; that the likelihood of realizing benefits and costs from a given choice is impossible to estimate accurately; that preferences among criteria, benefits, and costs are unclear and change over time and across situations; and that the cognitive load involved in managing all the information that the rational model requires is far beyond the capacity of human information processing. Hence, it is literally impossible to be rational in the classical sense. While the rational model is a worthy ideal, these scholars argue, it is unattainable in practice.

Herbert Simon advanced an alternative model of *bounded rationality* that better captured the process by which decision-makers operate. Rather than the complete information and analysis demanded by the rational decision model (the maximizing principle), decision-makers operate according to the principle of satisficing. In making decisions based on satisficing, decision-makers acquire an understanding of the situation that is sufficient to enable them to proceed and search through available alternatives until they find one that satisfies the criteria that are most important to them in the situation at hand. To the extent that decision-makers actually find the most important information about the situation, generate a reasonable number of alternatives, and devote time and care to analysis, satisficing can yield effective decisions which approximate the benefits attainable through the exhaustive process demanded by the rational model.

While the bounded rationality model implicitly takes the individual as the focal decision-maker, organizational decisions are often made by groups (→ Group Communication), and group decision-making models analogous to bounded rationality have been advanced. One important model of group decision-making communication is the functional model of group decision-making (Gouran & Hirokawa 1996). Functional theory posits that effective group decision-making and problem solving are most likely to occur when group members attempt to meet five requirements of the decision-making task: (1) understand the issue to be resolved; (2) determine minimal characteristics of an adequate solution (criteria); (3) generate or discover a realistic and relevant set of alternatives; (4) evaluate positive and negative aspects of alternatives carefully; and (5) select an alternative that analysis reveals most likely to satisfy the criteria (→ Group Decision-Making,

Functional Theory of). In addition, members should be vigilant for and counteract a number of biases or constraints on group communication that undermine the group's ability to meet the requirements.

### **THE ORGANIZATIONAL CONTEXT OF THE DECISION PROCESS**

A limitation of the unitary perspective is that it focuses primarily on the process of decision-making per se and gives less import to the effects of organizational context on decision-making. In organizational context, a decision is not just an isolated action. It is one of a stream of past decisions that provide precedents and context for the decision at hand and of future decisions. Moreover, the choice aspect of decision-making is just one stage in a longer process. Mintzberg (1979) described the continuum of control over decision-making extending through several steps: (1) collecting information about the decision to pass on to the decision-maker(s) without comment; (2) processing the information to generate advice for the decision-maker(s); (3) making a choice; (4) authorizing that the choice be executed by the organization; and (5) actually executing the action decided upon. Different individuals from various organizational units may contribute to one or more of these steps, and their particular beliefs, attitudes, and interests (which are influenced by organizational structure and culture) will shape information passed on, advice given, and other aspects of the process. This introduces constraints and biases into the decision process.

Organizational decisions differ widely in terms of scope, participants, and temporal horizons. They range from routine, immediate operating decisions made by line workers, to longer-term decisions about coordination or organizational activities and exceptions by middle managers and staff, to long-term strategic decisions by top management that set high-level policies and general directions of the organization.

The organizational decision-making process can be described as a set of "flows" involving a mix of the decision types that move through the organization to the various involved departments and parties (Mintzberg 1979). For instance, a problem detected at the operational level and given an immediate "fix" may then become an object of an exception decision if the fix does not work, and then involve a coordinative decision to handle future cases. If the problem is important enough it may be involved in a strategic decision, which is then implemented through coordinative and operational decisions. This complex process is influenced by various actors and departments, which introduce constraints and assumptions that bound the rationality of the entire process (sometimes too narrowly, leading to ineffective decisions).

Decision flows may operate in ways that differ from the unitary models, yet still generate adequate decisions. Cohen et al. (1972; see also O'Connor 1997) advanced a "garbage can model" of organizational decision-making, which argued that organizational decision premises are made up of problems looking for solutions, solutions looking for problems, goals, and decision opportunities. The organization is a rich soup of these premises and a decision is made when all four components – problem, solution, goal, and decision opportunity – link up. The garbage can model allows for decisions that fit the unitary model when the first component of the process is goal or problem, then opportunity, then solution. However, when solution or opportunity comes first, the

decision process is quite different from the unitary model. Poole (1983) described a similar pattern in his multiple sequence model of group decision-making.

Studies have identified typical patterns of stages and phases through which the organizational decision process unfolds. Nutt (1984), for example, described five phases of organizational decision-making – problem formulation, solution concept development, solution detailing, evaluation, and implementation – and identified five decision-making patterns that activated different combinations of phases in particular orders. In each pattern, organizations tended to emphasize solutions very early in the process, thus going against the tenets of the rational model. Of the five patterns, those that emphasized locating established solutions, evaluating them and tailoring them to the organization were more effective and better accepted than those that emphasized creating novel solutions.

With this emphasis on the variety of decision processes and on the bias introduced by limited perspective and politics comes attention to what can go wrong in the decision process. Nutt (2002) noted that more than 50 percent of over 350 decisions he studied had negative or disappointing outcomes, a figure that is in line with other sources. He identified several blunders that contributed to decision-making debacles. These include accepting premises (claims) uncritically, ignoring barriers to action posed by key stakeholders in the decision, providing ambiguous direction and goals, limiting search for options and alternatives, using evaluation to bolster a preferred decision or as window dressing that conveys false rigor to external audiences, overlooking ethical questions, and failing to learn and revise plans over the course of the decision process.

Participation is a critical parameter in organizational decision-making (→ Participative Processes in Organizations). Actively participating in decision-making or implementation of decisions has been shown to increase participant satisfaction with the decision and decision process and acceptance of the decision, although it has not been shown to be related to effectiveness. In terms of organizational context, Mintzberg (1979) notes that participation is a complex phenomenon and distinguishes between vertical decentralization, in which formal power is distributed to those lower in the organizational hierarchy, and horizontal decentralization, in which authority for decisions is delegated to experts or nonmanagerial members. Organizations may have varying degrees of each for different decisions (→ Organizational Structure).

## **THE DECISION PROCESS AS SOCIAL CONSTRUCTION**

Karl Weick (1995) exemplifies the social constructionist position in his argument that people and organizations often act before they think (→ Sense-Making). Many organizational “decisions” are post hoc rationalizations of actions that members of organizations have taken routinely or as “experiments,” tentative tests of viable action. Decision-making serves a symbolic purpose as a justification and cover for organizational members so that they can appear rational.

Some studies of communication in organizational decision-making emphasize the enactment and construction of decision premises and procedures. Studies show that participants actively construct, modify, and reinterpret proposals and their own positions over the course of the deliberation in order to achieve a desirable self-presentation as they achieve their objectives (Castor 2005). Other studies inquire as to the basis of heuristics

and decision rules, suggesting that they are not the traditional logical shortcuts described in unitary research, but rather are based on narratives about the organization and grounded in emotion rather than reason (Oliver and Roos 2005).

Another group of studies focuses on the unique narratives that various participants create during decision-making, and on how these narratives reflect different takes on the decision (O'Connor 1997; Eisenberg et al. 1998). Narratives may present an integrative view of the decision consistent with the unitary decision model, different viewpoints suggesting that the decision did not reflect the views of all participants, or a fragmented view of the decision that stresses substantially different viewpoints and interpretations of the same decision. The narrative approach suggests that the decision process is neither unitary nor ultimately singular, but an occasion to observe the fragmentation of organizational processes.

### **VALUES AND ETHICS IN DECISION-MAKING**

Conrad (1993) highlights the role of values in organizational decision-making processes that are often treated as neutral by the scholars in the three perspectives (→ Organizational Ethics). For the three perspectives, values enter into the process primarily as decision premises that influence the assessment of options and choice. Typically ignored are the value premises underlying the decision process itself or the organizational context. Members of organizations are taught implicit values of the organization through socialization and the organization's culture (Tompkins & Cheney 1985). These values are usually hidden within other premises. For example, "the customer is always right" carries an embedded valuation of the profit the organization receives from its business. These values serve as the unspoken term in enthymemes used in justifying decisions and so exert a form of unobtrusive control over the decision process (→ Control and Authority in Organizations).

Deetz (2003) critiques the larger governance schemes that frame organizational decision-making. He argues that these schemes incorporate a narrow set of values that reflect the interests of stockholders, top management, and elites. Such value judgments include the presumption that ownership rights pre-empt other social rights, the valorization of managerial knowledge over other types of knowledge, and the belief that the market economy is always superior to other approaches to economics and social allocation. For organizational decision-making to be truly responsive to stakeholder concerns, it is important that all stakeholders participate in the decision process without the presumption that some are superior to others, and that all premises be open to consideration on their own merits.

### **COMPARING THE PERSPECTIVES**

The three perspectives (unitary action, organizational context, social construction) are in part complementary and in part antagonistic to one another. The unitary perspective's emphasis on the activity of decision-making provides the basis for adding complexity in the move to the organizational context and the social construction perspectives. The rational model provides a foil for both perspectives, while bounded rationality is a foundation of the organizational context and a foil for the social constructionist

viewpoint. The organizational context perspective provides a “full-bodied” view of decision-making that is an important supplement to the unitary perspective. The social constructionist perspective shows how bounded rationality and organizational factors operate in the micro-level interaction that constitutes decisions.

This literature provides a complex picture of decision-making, but always the classic rational model stands in the background as a key reference point. The bounded rationality and functional models treat it as a desirable but unattainable standard, due to limitations in human information processing and group processes. The organizational context perspective treats it as a desirable, but unattainable standard due to the constraints imposed by organizational structures and processes. The social constructionists treat it as one way to construct and make sense of decision-making processes. Those concerned with organizational values treat it as a tyrannizing image that could be useful if it did not exert such dominance over decision-making that it forecloses other modes of reasoning and valuation. This underscores the importance of normative standards in the understanding of organizational decision-making and the need to explore multiple standards in a pluralistic world.

In terms of the outcomes of organizational decision-making, it is noteworthy that effectiveness and acceptance are by far the most common in extant research. Other important outcomes, such as building organizational capacity, social justice, impact on morale, and satisfaction of member needs have received far less attention. As a multifaceted phenomenon, organizational decision-making should be judged using multiple criteria.

## Deduction vs Induction vs Abduction

*Klaus Bruhn Jensen*

*University of Copenhagen*

Deduction, induction, and abduction are three basic *forms of inference* that inform the methodologies of communication research as well as other fields and disciplines. Whereas the most familiar forms are inference from a general principle or law to individual instances (deduction), or from several instances to a law (induction), abduction is an equally important constituent of scholarship, serving to identify possible explanations for a set of observations. Different traditions of communication research can be seen to rely on distinctive variants and combinations of deduction, induction, and abduction.

Aristotle had identified abduction as a type of inference; it was reintroduced in modern philosophy by Charles Sanders Peirce in an 1878 article. An inference can be said to consist of three components – a rule which, when applied to a single case, produces a result or conclusion. These components yield three possible combinations (adapted from Peirce 1992):

### DEDUCTION

*Rule.* All the beans from this bag are white.

*Case.* These beans are from this bag.

*Result.* These beans are white.

### INDUCTION

*Case.* These beans are from this bag.

*Result.* These beans are white.

*Rule.* All the beans from this bag are white.

### ABDUCTION

*Result.* These beans are white.

*Rule.* All the beans from this bag are white.

*Case.* These beans are from this bag.

Strictly speaking, only the deduction is a valid inference. When the rule is applied to the case, the result follows from the meaning of the constituent terms. In the induction, the implication is that, if one examines a sufficient number of beans from the bag in question (cases), one may be willing to conclude that they are all white. The point of the abduction is that it introduces a rule which may explain why one encounters particular facts (white beans) in a particular context (the bean bag). While the bean example is trivial, such a newly devised rule can represent an exceptionally bright idea, as in Sherlock Holmes's solution of crime mysteries (Sebeok & Umiker-Sebeok 1983) and major scientific discoveries such as Charles Darwin's conception of the origin of the human species by natural selection.

### AN INDUCTIVE HERITAGE

Induction has a long heritage in human history and evolution. The capacity for generalizing from single events presumably has been a key instrument of human adaptation and survival. Also commonsense or lay theories (Furnham 1988) that guide people through their everyday activities have important ingredients of induction.

Despite David Hume's argument, in the mid-1700s, that an induction from "some" to "all" is never logically valid, an inductive ideal of science remained attractive throughout the nineteenth century. Notably, John Stuart Mill's *A system of logic* (1843) detailed how inferences could be accumulated in various scientific fields. In the early twentieth century, an inductive ideal of science rose to new prominence in the shape of logical positivism.

Taking its general cue from Mill's contemporary, Auguste Comte, and his call for a "positive philosophy" that would be nonspeculative and applicable to real human concerns, logical positivism developed into an influential school of thought between the two world wars. Much of the inspiration came from the so-called *linguistic turn of philosophy*, which took the structure of sentences to correspond to the structure of facts in reality. Logical positivism, further, upheld an absolute distinction not only between facts and values, but between empirical observations and theoretical conceptions of reality. Accordingly, any meaningful statement about the world is either elementary in itself (reducible to sense impressions in a given space and time), or may be decomposed into such elementary propositions, which are either true or false.

Within such a reductionist conception of knowledge, most of the questions of both social scientific and humanistic research fall outside the realm of science. In response, these disciplines and fields have fundamentally questioned the view of science as the identification of *universal laws*, or context-independent regularities; the grounding of science in *elementary sensations*; and the requirement that all scientific research proceed according to the *same methodological principles* (Hammersley 1989, 17). Re-emphasizing deduction and abduction, much contemporary theory of science has specified principles and procedures for producing knowledge concerning communication, culture, and society (→ Idiographic vs Nomothetic Science; Verstehen vs Erklären).

Inductivism does figure prominently in at least two kinds of current communication research. First, probably the majority of all media studies are of the descriptive and administrative (and often commercial-confidential) variety, including marketing studies of

media audiences and evaluation research informing industry or government policy decisions. Importantly, although the aim is not to state or test particular theories, the approaches and findings are still theory-loaded (Hanson 1958). Second,  $\rightarrow$  grounded theory has advocated generating explanatory categories from the field and its informants – inducing theory from data. This position, in turn, has been questioned since grounded data collection and analysis may be guided by unacknowledged theoretical frameworks.

### A DEDUCTIVE MAINSTREAM

The quantitative mainstream of international communication research is sometimes described as *hypothetico-deductive*, testing hypotheses that have been deduced from some general theoretical principle ( $\rightarrow$  Quantitative Methodology). In a first step, deduction ensures that a hypothesis is neither logically inconsistent nor tautological. Next, a relevant hypothesis may contradict or specify an accepted principle, calling for further study. Again, it is deduction that serves to predict what the researcher will find under specified circumstances. If, finally, the findings correspond to the prediction, the hypothesis is confirmed.

Confirmation, however, does not equal verification. The hypothetico-deductive approach, as elaborated especially in Popper's (1972) *critical rationalism*, stipulates that scientists must seek to *falsify* their hypotheses ( $\rightarrow$  Critical Rationalism). Only if falsification fails is one justified in still holding the hypothesis, and only preliminarily. Further studies may end up falsifying it – which readmits inductivism through the backdoor.

In formal terms, the prototypical quantitative study will pose a *null hypothesis*, which suggests that any relations between the variables, as anticipated by the theory and documented by the data, are due to chance fluctuations or random error. If this is the case, as defined by a conventionally agreed level of probability, the original hypothesis has been falsified. The quantitative research process thus operates on a principle of deduction, even if the mechanisms in question are ascertained in probabilistic terms (see Hempel & Oppenheim 1988, 13–18).

The practice of critical rationalism has been challenged for not living up to its principles. A key problem relates to the notion of probability, which gradually acquired an ambiguous meaning in modern philosophy and empirical sciences (Hacking 1975). On the one hand, *stochastic* probability has to do with stable relative frequencies; the purpose is to rule out, beyond a reasonable doubt, that the particular configuration of empirical data could have occurred by chance (the null hypothesis). *Epistemological* probability, on the other hand, concerns “the degree of belief warranted by evidence” (Hacking 1975, 1). The distinction is sometimes summed up in the dictum that “correlation does not equal causation.” In other words, statistical measurements do not in themselves warrant conclusions about causality and other empirical phenomena. Ritchie (1999), for one, suggested that much current empirical media research fails on this crucial point. The fact that the null hypothesis is sufficiently improbable (statistically) is mistaken for evidence that a *specific* alternative hypothesis, namely, the one deduced in the study, is more probable (epistemologically). The logic of hypothesis testing, then, may contribute to a conflation of two distinct levels of scientific analysis and argument.

## **AN ABDUCTIVE SUBSTREAM**

Following the demise of positivism as well as other inductivism, qualitative and interpretive approaches to research have sought to specify an alternative to the hypothetico-deductive model ( $\rightarrow$  Qualitative Methodology). In opposition to Hempel and Oppenheim's (1988) "covering-law model," Dray (1957) argued that historical events cannot be examined as a variant of natural events (which may all be "covered" by one law), but require a different type of "rational explanation." In another influential contribution, Danto (1965) suggested that narratives provide a model for studying historical events and human actions. And Ginzburg (1989) identified an "evidential paradigm" in Sigmund Freud's and Sherlock Holmes's uncovering of underlying structures, respectively in dreams and crimes.

While no consensus comparable to the hypothetico-deductive model has yet emerged in communication research, abduction presents itself as a major candidate for a qualitative theory of science. Since Peirce's early formulation, its relevance has occasionally been considered in both philosophy and other disciplines, including mainstream sociology (Merton 1968, 158). It was reasserted by, among others, Hanson (1958) as part of the post-1945 questioning of both inductive and hypothetico-deductive prototypes of research. More recently, abduction has been reintroduced to social and cultural research, as an alternative to the inductivist self-understanding of grounded theory (Alvesson & Sköldbberg 2000), as a strategy of interpretive social science (Blaikie 1993), and as a distinctive characteristic of qualitative media research (Jensen 1995).

In qualitative research projects, the category of abductive inference can explicate and formalize various contextual and empathetic forms of interpretation. One quality of formalization is that it facilitates a systematic comparison of different kinds of reasoning in empirical research. Abduction is at the core of that interchange between researcher and informants that serves to establish – infer – relevant categories and concepts. Qualitative studies gain a resource, first, for structuring key moments of the analytical process and, second, for deciding who (informants, researchers, both) originates which abductions.

In conclusion, the three types of inference point to several different types of relationship between empirical analysis and theory development. In this regard, two main varieties of media and communication research can be identified – hypothetico-deductive reasoning in combination with quantitative data analysis, and abductive reasoning employing qualitative data analysis. And yet many, perhaps most, actual research projects include aspects of abduction, deduction, as well as induction in configurations still to be explored in further research. To exemplify, the prototypical form of social scientific study departs from a relatively specific hypothesis, as derived from a more general premise (deduction), which is tested against a large number of concrete instances (induction). The findings may be only partly in accordance with the hypothesis, giving rise to a new rule (abduction) to be investigated in further research. The original premise of the study might itself have been the outcome of a bright idea or bold conjecture – abduction.

## **Definition**

*Benjamin Fretwurst*

*Free University of Berlin*

The meaning of a term is determined by a definition. Definitions are, therefore, conventions of a language. Terms are words that describe, for example, objects, processes, characteristics of objects or persons, or notional content of our imagination.

The language that we learn forms the foundation for every definition. Terms are attributed to phenomena, which science investigates, if our day-to-day language is capable of describing them, however inadequately. Definitions enrich and concretize the basic vocabulary of our day-to-day language. This language consists of words the meaning of which we learn essentially during childhood and adolescence. Words that possess content are linked by recurrent attribution of words to phenomena (objects, processes, and ideas). In this manner, we learn the general usage of day-to-day vocabulary. We learn the meaning of scientific terms not by recurrent examples; we determine their meaning through known words from the day-to-day language by means of a definition.

Because various disciplines of science are specialized and go deep into the core of every subject, a conceptual differentiation is necessary. For this purpose, new words are coined or borrowed from other (living or extinct) languages. Naturally, even words from the day-to-day language are attributed to scientific terms, but, in most cases, their meaning must be redefined in order to achieve the required degree of precision. Since the language of science also aims to facilitate proper comprehension, there must be unanimity about the usage of the terms. If new or inaccurate terms are introduced without a prior definition, their meaning will remain ambiguous or completely obscure. Nevertheless, comprehension is also lost when new definitions are formulated instead of using established terms or simple descriptions (→ Research Methods).

### NOMINAL DEFINITIONS

Nominal definitions interlink terms (nouns) – nouns are attributed to other nouns. That is to say, a word is defined as a term by equating it with other known words. The meaning of a term (*definiens*) to be defined is determined as synonymous with the description of a fact through known words (*definiendum*). For example, “mass media” (*definiens*) are defined as “institutions that periodically present communication content to an open public” (*definiendum*; → Media). This example makes the problem of nominal definitions clear: the usefulness of a nominal definition depends on the usefulness and the clarity of terms with which the *definiens* is determined. Also, the terms of the *definiendum* would have to be defined (in the example, particularly: “institutions,” “communication content,” and “open public”). Any attempt to give a “complete nominal definition” is doomed to fail, because terms are always explained with terms that, in turn, need to be defined through terms. This problem is called an *endless definitional regress*. Nevertheless, as a rule, such chains of definitions can be broken if we can assume that the terms of *definiendum* are generally known.

A definition becomes useless if it is circular. Circularity is always present if the *definiens* is contained within the *definiendum*. When terms of the *definiendum* are later defined in stages, the risk of hidden circularity increases. To illustrate this: a “journalist” is defined as a “person who possesses a journalist’s identification”; in the next step, a “journalist’s identification card” would be defined as a “document to identify a journalist” (→ Journalism).

In principle, nominal definitions cannot be incorrect or false; they can only be either useful or useless. Moreover, there must be certain unanimity about the usage of terms. Normally, generally known terms from the day-to-day language or established terms from the disciplines of science are analyzed for their usage (explicated) and, if necessary, more precisely defined. Whenever a term occurs even in the natural language or, as a rule, if it is already established in the discipline, it must be verified whether the given definition covers all that it is expected to cover. Only when a new object or phenomenon is described and a new term is coined for it, an absolute sovereignty of definition is present with the definer.

For example, if a definition needs to be formulated for the term “journalist,” this existing day-to-day term must be explicated. Similarly, we must take into account various definitions that have already been created in the communication research. One first attempt to define a word could sound like this: “Journalists are persons who work for the media of → radio,

press ( $\rightarrow$  Quality Press; Tabloid Press), or  $\rightarrow$  Television.” Now we must verify if instances are possible that are covered by the definition but generally *not* considered to be journalists, and also if others are not covered but, nonetheless, are considered to be journalists. According to the present definition, a printer of a publishing house would be a journalist. An agency journalist would not be a journalist.

Then we must try an extended definition: “Journalists are persons who work for the media and collaborate with their fellow journalists on the editorial content of media products.” In this case, what is decisive is particularly the term “media product.” Even the simple and ordinary terms like “collaborate” are after all not unambiguous. The latter condition must be further refined: “. . . who draws at least one half of his income through his work for the media products . . .” This would solve other problems concerning the demarcations, but it could also pose new problems.

In this process, examples that generally do not belong to the term should be included in the same way as those that belong to the term. Whether an explication of a term covers all and only that which needs to be covered, remains always a  $\rightarrow$  hypothesis. Erroneous attributions cannot be ruled out with absolute certainty.

### REAL DEFINITIONS

By real definitions, the researcher attempts to determine the essence – the “true meaning” – of a term. There cannot be such real definitions, because no word has a meaning by itself. First of all, a link must be established between a word and its meaning. Often, explications of a term are hidden behind the supposedly real definitions, which – as explained earlier – are analyses of nominal definitions. Even if science does not have the sovereignty of definition over a term, the existing convention of meaning does not revert to something “real” but to the established usage of the term. These established conventions of language do not have, in terms of their validity, any higher precedence over the nominal definitions.

A similarly misleading argument for real definitions is the reference to acquisition of language prior to the age of  $\rightarrow$  comprehension among children. After all, a child’s first words are not based on any known terms. But yet there is an arbitrary definition that has no higher validity than the nominal definitions. To illustrate this: using a nominal definition, a “stool” can be defined as an “object that is about knee-high and has a seat but no backrest.” Or whenever a child sees a knee-high object that has a seat but no backrest, someone would say, “stool” ( $\rightarrow$  Language Acquisition in Childhood). Also, every linguistic circumscription of a phenomenon is based on nouns and is, therefore, a nominal definition.

Another typical case of assumptive real definitions is the recourse to the history of the word; that is to say, the attempt to trace the meaning of the term from the etymology of a word. Apart from the change of meaning of words, an old definition is also based on an (obsolete) nominal definition, which, by no means, can claim a higher validity than the current one.

### OPERATIONAL DEFINITIONS

In the empirical research, terms must be determined so that they are measurable ( $\rightarrow$  Operationalization). We must decide how a characteristic should be precisely measured.

This process is called operationalization and the outcome “operational definition.” For example, if we are to find out from a man how long he reads newspapers daily, we can ask him: “How long do you read newspapers on average per day?”. The possible answers (“none at all”; 1–2 hours; 2–3 hours . . .) belong to the operational definition. If we wanted to know if someone is a journalist or not, we could ask him, for example, if he possesses a journalist’s identification. The characteristic “journalist” could be a trait if, for example, we are to ascertain whether journalists read more newspapers than all others. If I intended to conduct a journalist survey, I could use the same definition. So, we need operational definitions to determine the object of an investigation and to decide how the characteristics relevant to the investigation need to be gathered.

How do operational definitions differ from nominal definitions? Nominal definitions are expected to abridge elaborate descriptions through indicative terms, whereas operational definitions determine the measuring operations by means of which terms or constructs can be empirically obtained.

### UNAMBIGUITY AND PRECISION

A definition is good if it is unambiguous and precise (→ Reliability). If, on the basis of a definition, we can decide whether a person, a group, an object, or an event is covered by the defined term or not, the definition is unambiguous. In principle, definitions always deal with a demarcation and, for that, necessary and adequate conditions need to be defined. The necessary conditions are meant for exclusion: any object that does not fulfill the necessary conditions of a definition does not belong to the defined term. If, on the other hand, the adequate conditions are met, the object is attributed, in any case, to the term. In this, the adequate conditions always cover the necessary conditions. Therefore, we must verify which conditions are applicable.

We have three options: (1) the necessary conditions are not applicable and the object will not be attributed to the term; (2) the adequate conditions are applicable (consequently, the necessary conditions are met) and the object will be attributed to the term; (3) the adequate conditions are not applicable, but the necessary conditions are: the object cannot be unambiguously attributed; it is placed in a gray area. The quality of a definition increases if the gray area between attribution and demarcation becomes narrower.

### VALIDITY

The operationalization is always measured on a parameter of ascertaining if it credibly covers what was meant by the nominal definition. This criterion of quality is called → validity. If the operational definition defines measurement processes that unambiguously cover whatever is expected to be covered by the nominal definition, the operationalization is then valid. Validity is an assumption about the validity of a research operation. For example, if we were to ascertain if a person we are questioning is a journalist and, therefore, ask him if he possesses press identification, in the background the following assumption of validity is present: “every journalist obtains press identification and none other.”

If we intended to examine violence on TV (→ Violence as Media Content), an operational definition could sound like this: “Whenever a person intentionally causes physical or

emotional pain to another person, that is ‘violence.’” This definition may be adequate in many cases. Supposing we analyze TV news items where there is a report about fighter planes destroying bridges and roads. According to the present operationalization, no violence would be encoded here, but the group of researchers might agree without hesitation to extend the definition to “wanton destruction of property.” But then, we face a problem with medical drama on TV: doctors often cause physical pain to their patients in order to make a diagnosis or even during the therapy itself. The definition must be refined further. The validity of an operational definition can always be improved but it will always remain an assumption: exactly that and only that will be measured which needs to be measured.

## **Deliberative Polls**

*Mark Lindeman*

*Bard College*

The phrase “deliberative polls” most often refers to political philosopher James Fishkin’s conception of a multi-stage opinion poll that incorporates systematic deliberation on policy issues (→ Public Opinion Polling). As such, Fishkin has trademarked the phrase “deliberative polling.” It can refer to other methods of introducing a deliberative component to public opinion research, some of which are touched on below.

Deliberative polling addresses the relationship between public opinion and policy outcomes. Many political philosophers believe that in a representative democracy, policy should be responsive to considered public preferences (→ Deliberativeness in Political Communication). Many empiricists conclude that policy *is* responsive to public opinion as expressed in conventional surveys – but whether such opinion is “considered” is another matter. Survey researchers agree that citizens do not typically form considered opinions on policy issues (→ Public Opinion). As Anthony Downs (1957) has argued,

citizens tend to practice rational ignorance: they expend little effort informing and refining political opinions that, individually, will have vanishingly little impact on outcomes. In consequence, conventional opinion surveys often tap what Philip Converse (1964) called “nonattitudes”: opinions made up on the spot (→ Survey). As such, not only are individuals’ responses often unstable, but the aggregate results can be distressingly inconsistent (for instance, influenced by substantively trivial changes in wording) and, arguably, irresponsible.

Deliberative polling seeks, in Fishkin’s words, to establish “the conclusions people would come to, were they better informed on the issues and had the opportunity and motivation to examine those issues seriously” (Fishkin 1997, 162). Fishkin proposes that the results have a “recommending force”: they indicate to political leaders and the public at large what the public’s view of an issue would be if citizens were to form considered opinions.

Deliberative polling begins with a baseline survey administered to a random sample of the relevant public (→ Sampling, Random). Many of these respondents – typically several hundred people – then convene to learn about the specified issues, through carefully vetted briefing materials, and to discuss the issues in moderated discussion groups. At the end, a post-deliberation survey measures possible changes in attitude induced by the process. For instance, the (US) National Issues Convention in January 1996 convened 460 participants (about half of the initial respondents) for three days of discussion on three broad issues: the US economy, the US role in the world, and the state of the American family. Participants discussed the briefing materials in small groups of about 15 apiece, and then posed questions to diverse panels of experts. The final survey elicited, *inter alia*, substantially less support for a “flat” (rather than progressive) tax, and considerably more support for current US levels of foreign aid, compared to the baseline. Follow-up surveys indicate that such changes in aggregate opinion tend to weaken, yet persist, well after the initial study.

Deliberative polls under Fishkin’s trademark have been conducted in the United States and elsewhere. They were originally conducted under the auspices of the Center for Deliberative Polling, University of Texas at Austin (often in cooperation with other organizations), and since 2003 by the Center for Deliberative Democracy at Stanford University. Most deliberative polls focus on substantially narrower issues than the National Issues Convention described above. Various polls have considered foreign policy priorities, public utility policies, criminal justice, and adoption of the euro.

Deliberative polls can be conjectured to improve *opinion quality* in various ways. Factual knowledge questions often evince substantial information gains (→ Political Knowledge). Some studies show marked gains in opinion constraint – for instance, larger correlations among responses to arguably related policy questions – although there is little evidence that deliberative polls actually narrow prior differences in constraint. Deliberative polls could evoke more stable expressed opinions (e.g., larger correlations over time), but available data do not permit stringent tests. Some evidence indicates that deliberative polls may reduce the likelihood of preference cycles (in which distinct majorities prefer outcome A to B, B to C, and C to A). More subtly, deliberative polls can be hoped to increase majorities’ willingness to accept the costs and risks of their preferred policies. It is unclear how such willingness could be measured systematically.

Deliberative polling combines values of standard social scientific research and democratic theory, creatively but not without compromise. In comparison with conventional surveys, deliberative polls resist replication due to their scope and expense, especially in national studies entailing long travel. The attempt to present balanced information is inevitably problematic. The group dynamics are inherently unpredictable; the use of multiple small groups does provide for measurable variation (→ Group Communication). The survey instrument limits participants' ability to express their views. Some critics argue that any change induced by deliberative polls amounts to a *Hawthorne Effect* – participants' response to knowing they are being watched – with no normative relevance. Advocates reply that the Hawthorne Effect classically refers to improved performance; if people deliberate more effectively and responsibly because they are conscious of being watched, so much the better. Observers must decide for themselves whether the results merit “recommending force.”

Deliberative polling bears comparison with other modes of deliberative research. These include, among many others, the “Citizens’ Juries” designed by Ned Crosby, citizen panels convened by the Public Agenda Foundation, Alan F. Kay’s public interest polling, and Holland’s “General Social Debate” of the early 1980s. These methods vary among many dimensions, including the number of participants involved; the efforts to assure representative participation; the length of the program; the scope of the agenda, and whether participants can have any influence; the amount and form(s) of information provided; the opportunities to discuss the issues and to ask questions; and the means by which final opinions are assessed. Arguably, given Fishkin’s reasoning, various methods should tend to converge upon qualitatively similar outcomes. This provocative possibility has been little explored.

# Deliberativeness in Political Communication

Hartmut Wessler

University of Mannheim

Deliberativeness denotes a specific quality of political communication that centers around argumentative exchange in a climate of mutual respect and civility. Empirically, deliberativeness is a variable feature of political debate or discussion. From a normative point of view, the standard of deliberativeness can be used to evaluate political communication processes and settings, and to suggest possible ways to improve them. Deliberativeness has been studied in very different communicative settings, including parliamentary debate (Steiner et al. 2004), news media content and television talk shows (Ferree et al. 2002; Wessler & Schultz 2007), online discussion forums (Price et al. 2002), civil society organizations (Ryfe 2002), as well as everyday political talk among citizens (Mutz 2006). When deliberative discussion is not confined to arcane settings, such as decision-making behind closed doors, or private settings, such as the family, it is also called public deliberation or public discourse (for an overview of the empirical literature, see Delli Carpini et al. 2004; Ryfe 2005).

## NORMATIVE STANDARDS AND MODELS

Standards of deliberativeness are an important ingredient in normative theories of deliberative democracy (for an overview, see Fishkin and Laslett 2003). Although it is by no means a uniform body of theory, deliberative democratic theorists agree on the central value of argumentative exchange in order to foster both the cognitive quality of political judgment as well as mutual respect and social cohesion between deliberators. If applied to the role of the news media in political communication, deliberative media content can be theorized to have salutary effects on both political decision-makers and citizens (Wessler, in press). Vis-à-vis decision-makers, political deliberation can foster active justification of political claims and decisions, and thereby at least help to avoid egregious mistakes. Vis-à-vis ordinary citizens, deliberative media content can serve as a repository of arguments and justifications as well as a model for deliberative behavior in everyday political talk (→ Political Language).

Conceptions of deliberative democracy contrast with other normative conceptions that are either less demanding in their normative standards or focus on different normative elements in political communication, or both (→ Journalism: Normative Theories). Habermas (2006) distinguishes (1) a *liberal model*, which places particular emphasis on equal rights for citizens and fair representation, (2) a *republican model*, particularly favoring political participation by active citizens, and (3) a *deliberative model*, prizing the formation of considered public opinions and the responsiveness of decision-makers to such opinions (→ Habermas, Jürgen). Ferree et al. (2002) present a similar typology, adding a fourth variant called *constructionist theory*, which aims at privileging and empowering oppressed or marginalized groups and nondeliberative forms of communication (also

called “agonistic pluralism”). It must be noted, however, that the assignment of individual theorists to these traditions is by no means unambiguous. For example, John Stuart Mill (1806–1873) has been claimed for the “representative liberal” theory by Ferree et al., while in his work we find numerous remarks on the epistemic and social benefits of deliberation. This shows that the traditions are not as mutually exclusive as they are sometimes portrayed for didactic purposes.

Still, there are important differences centering around three issues. First, a deliberative model of political communication demands more than providing a mirror image of pre-existing positions (as in a strictly representative liberal model) and asks for an actual exchange of positions and justifications. Second, due to the expected benefits of such exchange, a deliberative model tends to place more emphasis on argumentative exchange than on maximal popular inclusion and maximal levels of participatory activity (such as a strictly participatory model would suggest). Empirical research suggests that deliberation and participation can indeed not be maximized at the same time but that a tradeoff exists between them (Mutz 2006), and deliberative theory places a comparatively higher premium on innovation and creativity in public discourse than on strict equality (Peters 2008). Finally, a deliberative model privileges civil and “literal” modes of exchange over purely strategic, strongly impassioned, or rhetorical forms (as in the agonistic or “constructionist” tradition) in order to secure chances for considered opinions to emerge from public exchange (→ Political Discourse).

## **CONNECTING NORMATIVE THEORY TO EMPIRICAL INVESTIGATION**

In connecting normative theories or models to empirical investigation, three basic strategies can be employed. First, one can try to measure the normative concepts in order to find out which normative model approximates social reality best. While this tells us something about social reality, such investigation cannot serve to bolster up or discard the normative claims, which can only be supported or contested on the level of normative theory itself. A second strategy attempts to test implicit or explicit empirical claims in the normative framework; in the case of deliberativeness, this pertains particularly to the putative benefits of deliberative media content (see below). A third strategy, finally, tries to ascertain the degree to which different normative conceptions guide social action in the real world. This can be studied, for example, by asking to what degree journalists subjectively or in their meta-communication endorse elements of the deliberative model (Gerhards et al. 1998, 163–177).

### **Measurements of Deliberativeness in Media Content**

For all three strategies, valid → operationalizations of deliberativeness are needed. In print media content, elements of deliberativeness have been studied on four different levels of analysis, ranging from an entire page or edition down to the level of an individual idea expressed by a particular actor (in direct or indirect quotation; see Table 1). Ferree et al. (2002) find no consistent differences in the level of deliberativeness between Germany and the USA. Such cross-national differences have not been studied on a larger scale, but it is likely that deliberation in print media will take different forms in different countries,

**Table 1** Measures of deliberativeness in print media content

Level of analysis	Measure	Operationalization
Idea	Justification	Presence of a justification for an idea expressed
	Rebuttal	Presence of an idea that refers to and argues against an idea that it opposes
Utterance	Conflicting ideas	Co-presence of separate conflicting ideas or policy positions in the same utterance
Article	Civility	Absence of “hot button” language (i.e., inflammatory speech)
	Responsiveness	Presence of a direct response by one speaker to a claim made by another speaker in the same article
Page/edition	Response articles	Presence of a direct response by one speaker/author to another speaker/author on the same page/in the same edition

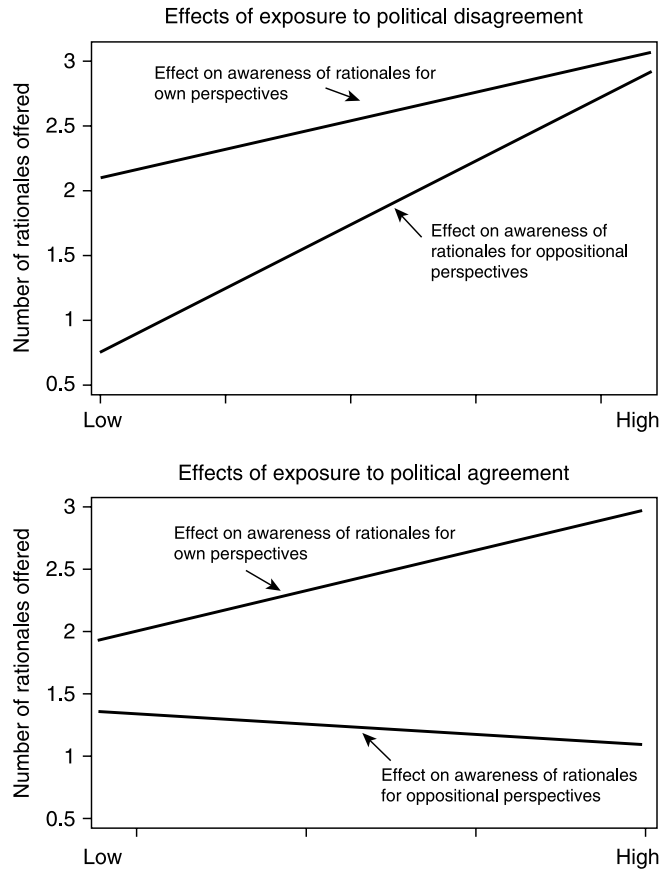

depending on, for example, journalistic traditions as well as the degree of political parallelism in the media (→ Party–Press Parallelism) and the degree of polarization in political discourse (Wessler, in press).

Similarly, the deliberativeness of political talk shows on television has been measured by the extent to which participants, in their contributions to the debate, engage in justification, explicitly weigh arguments, directly relate to other participants’ utterances, or directly attack and vilify their opponents (→ Broadcast Talk). Schultz (2006) has shown that levels of deliberativeness are generally higher for experts and journalists than for politicians, lobbyists, artists, and celebrities. Participants addressing others directly in talk-show discussion seem to be more prone to also engage in justification but do not necessarily weigh arguments more in their contributions. In public debate in front of large audiences, dialogue thus fosters justification but not argumentative integration. In addition, talk-show hosts have been studied with respect to their propensity to confront participants with questions eliciting justification or challenging participants to react to others’ contributions. Hosts differ in these respects and have considerable latitude in making a talk show more or less deliberative. In general, research has shown that deliberative features do exist in media content to a degree that merits close scrutiny but that they are not dominant in most media and most formats.

### Measurements of Deliberativeness in Citizen Talk

In citizen deliberation, the degree of deliberativeness has been measured by citizens’ argument repertoires, i.e., their awareness of rationales for their own positions as well as for possible counter-positions (Price et al. 2002; Mutz 2006; → Language and Social Interaction). Both elements of argument repertoire have been shown to increase with increased exposure to political disagreement in citizens’ personal networks. Conversely, exposure to political agreement (homogeneous networks) increases awareness of rationales for one’s own position but decreases citizens’ knowledge of reasons for opposing positions (Fig. 1).

These results lend support to one central empirical element in the normative deliberative model as described above, namely that “hearing the other side” does contribute to the

**Figure 1** Effects of exposure to political agreement and disagreement on awareness of rationales for own and oppositional political perspectives  
*Source: Mutz (2006, 73)*

formation of considered opinions. Network heterogeneity has also been shown to be related to more intense public affairs media use as well as to better factual → political knowledge (Scheufele et al. 2006, → Political Media Use). One crucial question remains open, however; namely, whether the news media can serve as a substitute for heterogeneous individual networks and thus also foster deliberative opinion, and whether they do so to varying degrees in different countries. More precisely, even, the deliberative model would suggest that it is not the news media as such, but deliberative features of news media content, as described above, that serve to enhance deliberative opinion. While this claim seems plausible from a deliberative perspective, more research is needed to substantiate it empirically.

## Delivery and Rhetoric

Merete Onsberg

University of Copenhagen

As rhetoric originally was closely tied to the oral presentation of a speech, delivery, understood as the best management of voice and body, was naturally of interest to the art. Thus, in the traditional rhetorical system, the so-called rhetorical *canon*, delivery made up the fifth and last part (Greek *hypokrisis*, Latin *actio* or *pronuntiatio*) (→ Rhetoric, Greek; Rhetoric, Roman).

Of the five canonical parts, comparatively little has been written about delivery. The subject has been given rather uneven attention in books on rhetoric, from antiquity till today. Apparently Aristotle – perhaps under the influence of a Platonic distrust of rhetoric – only reluctantly accepted delivery as part of the art. In their turn, Cicero and Quintilian, the two major Latin rhetoricians, both evidenced their interest in rhetoric’s practical and educational aspects by including delivery as one of the public speaker’s duties. In John Bulwer’s *Chirologia* and *Chironomia* (Bulwer 1974) we have one rhetorical example of the compartmentalized interest in the body typical of the Renaissance, namely a treatise of the natural and the rhetorical hand’s gestures, respectively. Bulwer’s plans for a similar book about the head were never carried out. The high point of interest in delivery was in the eighteenth century, when the elocutionists equated delivery with rhetoric.

Throughout Europe books with rules for the proper management of voice and body, written in the national languages, were published for a growing reading public. The inspiration came from France, and the rules applied to the public speaker of many trades (→ Rhetoric in Western Europe: France). Gilbert Austin, an Irish-born educator and clergyman, even introduced a notation system for the proper and polite movements of head, arms, hands, and feet. For the elocutionists delivery had several venues. Besides delivering a speech it also encompassed reading aloud, reciting, and stage acting. For the private learner, assorted collections of literature in prose and verse equipped with delivery rules were published well into the nineteenth century in Europe as well as in the USA.

Delivery is predominantly a *tacit knowledge* because it does not easily lend itself to description or prescription. Apart from cautions against offensive behavior, such as picking one’s nose in public, it proved to be very cumbersome to describe the speaker’s voice and body in detail. The proper body language of any given time would be known to the majority of rhetorical practitioners, or at least to those inside the establishment, for those outside to emulate. The social mobility starting in the eighteenth century gave more people opportunities to speak in a political or an occupational setting. Some of these speakers lacked rhetorical education and therefore felt the need to acquire the skills in other ways. This may be part of the elocutionists’ success and perhaps also explains the demand for modern popular books on body language and voice production.

Present-day rhetorical textbooks still include some commonsense advice for good delivery; however, delivery is first and foremost an integral part of the teaching of public speaking. In the classroom students develop a suitable delivery through practice, often with the aid of visual recording. Philosophically, rhetorical delivery is phenomenological: through delivery speakers signify audibly and visibly to an audience their commitment to the issue at hand.

## Delphi Studies

*Stefan Wehmeier*

*University of Greifswald*

The main objective of Delphi studies is to collect expert knowledge for decision-making. In Delphi studies experts' ideas and opinions are systematically surveyed. The data are gathered through a series of questionnaires interspersed with controlled and anonymous feedback (Häder & Häder 2000). The goal of most Delphi studies is to create a group consensus in future tasks. Although the method originates from the *modus operandi* of the Greek oracle at Delphi, it is a young research method. The modern Delphi was a spin-off from defense research conducted by the Rand Corporation in the early 1950s at the beginning of the Cold War (Gordon & Helmer 1964). The authors wanted to “obtain the most reliable consensus of opinion of a group of experts” (Linstone & Turoff 1975, 10).

The principle of Delphi studies is based on panel → surveys; however, in contrast to such surveys, participants in Delphi studies are confronted with feedback from all participants. Two main assumptions are central: first, the judgment of a group is claimed as superior to judgments of individuals, and, second, the multilevel process of opinion forming is preferred as more valid than the single-level process (Häder 2002). The classic design uses formalized questionnaires that are submitted to experts in the fields analyzed (pencil and paper or online version). The experts are anonymous; the feedback is sent in an averaged form and the questionnaire is repeated at least once. One main aim of the anonymous answering is to bypass the disadvantages of conventional group questionnaires or committee action where social orientation through the identification of communicative or rhetoric leaders has an impact on the result.

As Delphi is a young method its research design can take many forms. Most of these differ in two ways: the number of questionnaires and the number and selection of participating experts. Meta-analysis of Delphi studies shows that a consensus is often established after the second questionnaire (→ Meta-Analysis). A satisfying result is achieved after the third round at the latest (Häder & Häder 2002). The number of experts

varies: huge Delphi studies, as, for example, the 1993 study of the German Federal Ministry of Research and Technology, have more than 3,000 participants. However, many scholars prefer a maximum of 30 participants. Duffield's (1993) analysis demonstrates that comparable results were produced from two Delphi studies on the same topic but with different numbers of experts (16 and 34). The selection of experts is one of the major problems, as experts need to have not only knowledge but also influence in changing procedures and structures in the relevant field (Duffield 1993). Some authors suggest a standardized pre-questionnaire to determine the level of expertise of the candidates. However, such costly tests are rarely done.

Given that mass communication pertains to a field of rapid technological change, Delphi studies can be seen as having a kind of tradition in this discipline. Krüger, for example, was an early adopter of this method in the field of communication (1975). Nowadays the Delphi technique is applied in the field of new communication technologies (Beck et al. 2000) as well as in the field of → public relations (van Ruler et al. 2004; *Technology and Communication*). Despite the beneficial attributes of Delphi and its application in the field of communication, the method has its critics. The main criticisms are that (1) the outcomes of Delphi studies are mere opinion; (2) the method is not rigorous enough to be part of the serious research methods in the social sciences (Sackman 1974); (3) participants feel pressured to find a consensus; and (4) Delphi tends to simplify the complex tasks of forecasting. To judge the quality of the method, more comparative studies would be needed. These could also make valid statements on different aspects of the design such as the number and structure of the expert groups and/or the usefulness of Delphi as opposed to other foresight techniques like environmental scanning, → simulation studies, scenario technique, or trend extrapolation (Häder & Häder 2000).

## Dependency Theories

*Joseph Straubhaar*

*University of Texas at Austin*

Even after they formally become independent, many developing countries still depend on the industrialized world for many resources, including technology, financing, models, and even media content, such as films or television programs. This is a structural legacy of imperialism, with which many countries with former colonies have struggled. Only a few countries have completely overcome it (→ Cultural Imperialism Theories).

For a long time, these post-independence issues were analyzed in terms of world systems theory and dependency theory. In *world systems theory*, a core of industrial nations controls the essential dynamics of the world capitalist system. A large number of nations, i.e., most of the developing world, are peripheral or essentially dependent, and a smaller number of nations, which Wallerstein (1979) calls “semiperipheral,” achieve some growth and development. Semiperipheral states include the partially industrialized states of the third world and eastern Europe, and, at least before World War I, also included Russia. In all of these cases, the world economy, still controlled by the core nations, expands and penetrates new states to draw in new raw materials, cheap labor for manufacturing, and potential markets for goods. The peripheral or developing countries depend on the industrialized world for capital, technology, and most manufactured goods, while tending to export low-cost primary products or cheap manufactured goods that add little benefit to the local economy.

### BASIC ASSUMPTIONS OF DEPENDENCY THEORIES

*Dependency theory* makes a similar analysis, but more from the point of view of developing countries, which even after obtaining political independence, often saw themselves entangled in a series of dependent relations with either their former colonial rulers or with competing international powers, such as the US or Great Britain. These lines of dependence tended to center on the following dimensions.

*Finance*: many countries depended on outside powers for either investments or foreign aid; *trade*: many countries remained locked in unfavorable trade relations with dominant countries, selling their raw materials cheaply and buying manufactured goods for high prices; *politics*: countries often had to accept subordinate political alliances to obtain

foreign aid or other benefits; *culture*: countries often imported television, films, and news from either their former colonial ruler or the US; *education*: national elites often spoke the languages of either former colonial rulers such as France or of emerging global powers such as the US.

Dependency varied greatly in regions of the world. The term itself was created by Latin American theorists, e.g., Cardoso (1970), to describe the experience of Latin American countries after becoming independent in the 1820s, then forming powerful new relationships of dependency on Britain, France, and the US. Most other developing countries became independent of colonialism much later, after the 1940s. However, the Latin American experience provided a useful set of prototypes and precedents for understanding dependency among other newly independent countries in other regions (→ Development Communication: Latin America). However, regional experiences differed, and dependency developed and transformed in different ways around the world.

The reach of the industrialized nations continued to expand after World War II and to draw the newly independent nations into dependency. Even though the US had been a literal colonial ruler in only a few countries, for example, Cuba and the Philippines, it now became a logical economic partner for developing country elites around the world. Both the US and the USSR actively pursued *alliances with elites in developing countries* as part of the Cold War, so political and military concerns often overlapped or even opposed economic interests of the elites in both industrialized and developing countries.

Almost all national elites, whether in the economy, politics, or cultural industry, were seen as strongly linked to the economic interests of the core countries. These elites had been educated by the colonial rulers, had learned the colonial languages, had often worked in or been trained by their companies, and often saw their economic fortunes as linked to the corporations and governments of the major core countries, even after independence. So as these elites created political systems, economic groups, and cultural industries, they often saw profit and stability in continuing ties to the core countries. A key example is the television broadcasting personnel in various countries, who were trained in how to produce television and, implicitly, what television is or should be, by the BBC or other dominant media groups. Cultural industry elites, in television or elsewhere, were particularly interested in creating and guiding markets both in their economic role and in their ideological role in reproducing the systems of culture and information.

Many saw the *ideological role of* → *television* under dependency as making third world residents content with their lot as lower-paid consumers of first world products. The core nations saw advertising and the subsequent *consumerism* it promotes as key vehicles of both economic and ideological expansion. However, some elites in politics, economics, and media were interested in increasing their own national power and reducing dependency. So a great deal of policymaking came to focus on reducing dependency by addressing issues such as enabling countries to produce more of their own media content and reducing imbalances of cultural imports, as in UNESCO's MacBride Report in 1980 (→ New World Information and Communication Order [NWICO]).

The continuing results of conditions of dependency, such as low income resources, lack of industrial infrastructure, lack of support by weak governments, inappropriate models for production, and lack of trained personnel, have kept a number of poorer countries from developing much local or national production, even if their audiences

might prefer more national programs. This is particularly true for the smallest and poorest of nations, such as those in the English-speaking Caribbean.

Over time, however, even as postcolonial dependencies in developed world countries sorted out and shifted, an asymmetrical replication persisted of core capitalist country structures, especially those of the US. Although some countries originally modeled British or French colonial systems, many moved increasingly toward the US model because it reflected an increasingly dominant, essentially capitalist, economic model. This took place in part because of direct economic dependency on the US and US firms. The US model spread well beyond its area of direct primary influence in Latin America, however, because as more countries shifted toward greater integration with the world capitalist economy, both policymakers and would-be media owners saw the US model as a highly functional and commercially successful way of organizing television. That view was powerfully reinforced by both foreign and domestic advertisers, who wanted to see television become an advertising vehicle open to them (Fox 1975).

When related to cultural dependency, particularly in television, most observers add → *advertising* to the foreign economic influences observed by the dependent development paradigm in the general economy. Fejes (1980) emphasized the influence of multinational advertising on television industries throughout Latin America, both currently and historically. He noted that “it was the demands of advertising, particularly the advertising of multinational corporations, that shaped the commercial development of television in Latin America” (1980, 25). Others observed that the television industry still depends on foreign financing in the form of advertising revenues from multinational corporations and advertising agencies (→ Advertising, Cross-Cultural).

## DEPENDENCY AND OWNERSHIP

Direct foreign investment in media ownership first followed lines of colonialism and then dependency (→ Global Media, History of). For example, the logic of regional proximity led US companies to become involved in Latin America from the nineteenth century on, first with resource extraction and trade, later with direct investment for manufacturing. So radio and television developed in Latin America in the context of a region that had already moved from mercantilist capitalism under Spain and Portugal to a capitalism dependent on trade, capital, investment, and corporate models from the US and Europe. American advertisers and advertising agencies promoted commercial radio and television elsewhere because they wanted to have commercial media with which to work.

The US, Britain, and France also made a considerable direct investment in colonial and other third world newspapers in the 1920s, in movies in the 1920s and 1930s, in radio in the 1930s and 1940s, and in television in the 1960s and 1970s. Early in the twentieth century, as today, many local elites have found it convenient to grow their national industries through cooperative links with global corporations. For example, Brazil’s *TV Globo* is now one of the largest media corporations in the world outside the core industrial countries. But when Robert Marinho started it in Brazil in 1962, he was unsure of his own capabilities in a new medium. In classic industrial strategy, he sought to minimize his risk with an alliance for technology, capital, and management advice with Time-Life, which invested in *TV Globo* and advised him until 1970, when it was forced

out by the government pressure and by its own frustration with lack of profit (→ Brazil: Media System).

There was one initial wave of investment in foreign television companies in the 1960s, particularly by the US in Latin America. However, most countries enacted laws that prohibited or limited direct foreign investment in television, even if it meant forcing out some of the investments made in the 1960s. “With a few minor exceptions, nationalism would prompt foreign governments to deny outsiders control of the sensitive and powerful medium of television” (Duarte 2001, 21).

Local families, often those already involved with print media, started most radio and television operations in Latin America, but they took these initiatives within a context of a capitalism that might be characterized as dependent. These cultural industries were also hybrid. They blended national characteristics, such as family ownership and strong ties to the state, together with typically US characteristics such as commercialization, professionalization of network management, production, and the development of truly national advertising markets with strong ties to national and global advertising agencies. Of the influences exerted on Brazil’s *TV Globo* by Time-Life, for example, the most lasting were the reorganization of its production system, its network/affiliate management, and its relations with advertisers and ratings firms. In contrast, Time-Life’s programming advice was almost immediately rejected as useless within the Brazilian cultural market context, and program decisions were made by a combination of Brazilian advertising executives who knew the national market and program producers hired from other networks who knew which genres worked in that market (Straubhaar 1984).

# Desensitization

*Rena M. Rudy*

*University of California, Santa Barbara*

*Daniel G. Linz*

*University of California, Santa Barbara*

Media desensitization is a reduction in emotional, physiological, cognitive, and/or behavioral reactivity resulting from extensive media exposure. Communication researchers have primarily used the term “desensitization” to label the effects of repeated media violence exposure on violence tolerance, meaning both a decrease in empathy and concern and also an increase in callousness toward victims of violence (→ Violence as Media Content, Effects of; Violence as Media Content, Effects on Children of).

The rise in popularity of media desensitization research starting in the 1960s roughly coincided with the development and popularization of exposure treatments for phobias of various kinds (→ Media Effects, History of). In systematic desensitization therapy, patients are exposed to anxiety-provoking stimuli (real, imagined, or mediated) at gradually increasing levels of intensity. Flooding therapy rejects graduated hierarchies in favor of immediate introduction to intense anxiety-evoking stimuli (→ Fear Induction through Media Content). Research has established the effectiveness of both approaches in dulling adverse emotions; regardless of the precise sequence, exposure to a previously aversive object reduces fear and anxiety. The predominant theoretical reasoning behind exposure treatments is that pairing aversive stimuli with relaxation reinforces positive associations with the stimulus, leading to an extinction of the phobia. The same mechanism appears to operate in the context of media exposure to aversive stimuli (→ Exposure to Communication Content).

The earliest frequently cited media desensitization studies are those by Lazarus and colleagues (e.g., Lazarus et al. 1962), who determined that physiological and self-reported stress waned upon repeated (albeit short-term) exposure to scenes of Australian aboriginal sub-incisions. Several widely reported incidents of bystander apathy among Americans, including the murder of Kitty Genovese and the My Lai massacre, fueled research into media desensitization in the 1970s. Researchers discovered that violence exposure led to decreased physiological reactivity during subsequent nonfictional televised depictions of riots and car accidents. Children are also susceptible to desensitization; various researchers (e.g., Cline et al. 1973; Drabman & Thomas 1975; Thomas et al. 1977) found that compared with children who watched little to no media violence, children exposed to high levels of media violence demonstrated low levels of physiological reactivity and high levels of behavioral tolerance of other children’s aggressive acts.

With the advent of video tapes and → cable television in North America in the 1980s, and the concomitant increase in anonymous access to pornography (→ Pornography Use across the Life-Span), legislators and feminist writers focused scholars’ attention on the effects of violent, sexual, and degrading depictions of women (→ Pornography, Media Law on; Pornography, Feminist Debates on). A field experiment by Malamuth & Check (1981; → Experiment, Field) established that exposure to a film portraying violence against women as positive and justified increased men’s attitudinal acceptance of violence against

women. Linz and colleagues (e.g., Linz et al. 1988) conducted multiple studies demonstrating that a decrease occurred in self-reported depression as well as in physiological and self-reported anxiety between the first and last day of exposure to violent sexual films, and ratings of the films' violence and degradingness also decreased. In addition, indifference toward victims of violence generalized to a mock sexual assault trial, in which male participants who belonged to a high violent-sex exposure condition demonstrated less sympathy toward the rape victim in the trial and toward rape victims in general, compared with men in a no-exposure condition (→ Habituation). Later studies suggested that women demonstrate some, but not all, of the same responses to violent sexual films, and that audiences' callousness toward violence victims dissipates in the days following exposure, provided that they avoid further exposure to violent sexual media content.

Current concern about the *increasing realism* of video-game violence has recently led researchers to study the desensitizing effects of video games (→ Video Games). These effects are indeed evident; for instance, the men who played a high-violence video game in a study by Deselms & Altman (2003) assigned more lenient prison sentences to violent criminals than did men who played a low-violence game, even an hour after exposure, and among children in another study (Funk et al. 2003), self-reported long-term exposure to violent video games was negatively associated with empathetic responses to vignettes.

Desensitization may be *rooted in changes in the brain*; recent research using event-related brain potential data (Bartholow et al. 2006) suggests that the aversive motivation system is less activated in habitual violent video-game players than in others, and that this decreased activation predicts greater behavioral tolerance for aggression. Further evidence, gathered by Funk and colleagues, suggests that the relationship between heavy exposure to violent video games and low levels of empathy may be stronger than are the relationships between empathy and violence on television, on the Internet, in film, and in real life.

Some areas of media desensitization research have yet to be explored in depth, including the apparent gender differences in desensitization; the interactions among cognitive, emotional, physiological, and behavioral domains of desensitization; and the precise mechanisms that govern media desensitization. Nevertheless, mounting evidence demonstrates that extensive exposure to media violence decreases depression, anxiety, empathy, physiological reactivity, and attitudinal and behavioral opposition to acts of violence by others, especially among males.

## Design

*Richard Buchanan*

*Carnegie Mellon University*

Design is the human power to conceive, plan, and make all of the products that serve human beings in the accomplishment of their individual and collective purposes. It is a cultural art and a practical art, supporting all forms of activity in the human community by providing a high degree of forethought for communications, artifacts, actions, and organizations. The practice of design provides the subject matter and examples upon which the arts and sciences of communication base a significant portion of research and theory. In turn, the exploration of rhetoric and the arts and sciences of communication deepens awareness of the dimensions of communication in design and human-made products (→ Art as Communication; Rhetorical Studies).

### ORIGINS

The origins of design are prehistoric, since one of the signs of the emergence of human culture is the images and artifacts created by the first humans (→ Culture: Definitions and Concepts). However, the beginning of formal discussion of design and human-made products may be traced to the ancient world, in philosophical and technical writings in both Greece and China. The earliest technical writings were about architecture, instruments for measuring time, and weapons of war. In the west, those discussions were shaped by a broad conception of rhetoric as an intellectual art of invention and communication (→ Rhetoric and Philosophy; Rhetoric and Visuality). In the east, they were related to dialectic as well as rhetoric, placing communication in a context of social hierarchy and duty.

The *origins of modern design* are traced to the Renaissance and the Industrial Revolution, because it was in this period that a significant division of labor distinguished the conception and planning of products from the manufacture of products by machines. Before this, both designing and making were in the hands of artisans. Craft remains a part of design, particularly in developing countries, as a popular art form in industrialized countries, or as an aspect of design practice, evident in the crafting of prototypes. But from the eighteenth to the twentieth centuries, design evolved from a craft activity into a *trade activity* and then into a growing body of professions, based on new disciplines of design thinking and more explicit methods of practice.

The *new disciplines of design thinking* emerged in a variety of places in Europe and the United States, but the Bauhaus (1918–1933), a school established in Germany during the Weimar period, is widely regarded as the place where these disciplines emerged around a single coherent vision. It was Walter Gropius, director of the Bauhaus, who expressed the idea of a “modern architectonic art” that would be all-embracing in its scope, creating all of the products and buildings that were designed for industrial production. With Gropius and the Bauhaus, we have the beginnings of design as a new liberal art of technological culture, with diverse forms of professional practice but also providing a broad intellectual and practical perspective on the human-made world that all men and women may use in understanding products and technological developments.

The history of design in the twentieth century took shape around a sequence of fundamental problems that represent a coherent practical inquiry into the human-made world, which continues to affect virtually every aspect of daily life. This is reflected in the *expanding concept of “product.”* At the beginning of the twentieth century, product usually meant a physical artifact – the result of industrial design. By the twenty-first century, product means any result of the creative work of designers. Designers and design theorists often recognize four broad classes of products, sometimes called the “four orders of design,” representing different kinds of design problems and different aspects of communication.

## **AREAS OF MODERN DESIGN PRACTICE AND RESEARCH**

### **Mass Communication**

Early in the twentieth century, the problems of design were identified in two great areas of collective enterprise: mass communication and mass production. The first area, mass communication, focuses on symbols and images, yielding a class of products whose explicit purpose is communication (→ Symbolism). It uses words, numbers, drawings, paintings, diagrams, and photographs to achieve the diverse ends of communication in daily life. Work in this area gave rise to → graphic design and its allied professions, including modern typography, book design, newspaper and magazine design, early forms of information design, and advertising (→ Media History). The evolution of the term “graphic design” into → “visual communication” and, most recently, “communication design” indicates the field that emerged. It is a field of *communication and demonstration*, presenting information and arguments for audiences in all areas of culture. It began in the medium of print but expanded with the technological development of new media such as film, sound recording, television, and digital communication.

## Mass Production

The second area of design problems, mass production, focuses on physical artifacts, yielding the class of tangible goods, objects, buildings, and technological marvels that are often regarded as the most visible sign of modern technological culture. Work in this area gave rise to industrial design and product design (the branch of industrial design primarily concerned with consumer goods), as well as new developments in engineering design and architecture. It also extended into other areas such as textile, clothing, and → fashion design, and led to the exploration of a vast array of new materials based on advances in physics, chemistry, and biology.

It is a *field of construction*, concerned with the conception and fabrication of the physical artifacts of everyday life, based on knowledge of the natural world and of the human and cultural context of products. Communication in this class of products begins with control features and the interface between the product and the person who uses or operates it. It also includes operating instructions, service manuals, and packaging. Finally, it includes the subtle, indirect communication that comes from forms and materials, with the complex symbolism and cultural associations that these have in different human communities (→ Cultural Patterns and Communication).

Work in the first and second orders of design continues to yield a flood of good and bad products that influence daily life around the world. However, in the latter decades of the twentieth century, two new problem areas emerged with revolutionary importance for design thinking and human culture, yielding the third and fourth classes of products.

## Actions and Activities

The third class of products focuses on actions and activities. It involves the *design of activities for living, working, → playing, and learning*. Work in this area gave rise to new professional divisions of design practice such as interaction design, service design, strategic planning, game design, and new forms of information design. Though prompted by the development of new digital technologies in the 1960s and 1970s, where designers were asked to support the dynamic, time-based flow of interface and interaction with computers, this area has expanded in many directions (→ Digitization and Media Convergence). It has led off the “flat land” of computer screens into the design of activities that support a wide variety of human experiences.

In this broad class of products, communication serves the advancement of specific human activities; → information is no longer regarded as a static subject to be presented in printed form but is understood as part of the temporal progression of experience toward some goal. Designing the progression of an activity is the central concern, though often supported by graphics and artifacts. From the earliest times in history, human beings have attempted to plan their activities, whether in battle or politics, education or law, religion or governmental administration.

Today, however, the planning and execution of human activities is increasingly understood as a design problem, requiring a designer’s forethought and communication skills to make the activities more effective in serving the goals of individuals and groups. This is evident in many areas of commercial life, but it is also evident in efforts to improve

the delivery of government services and education. The design of human interactions and services is one of the most important ways in which the real intent and values of an organization are communicated to its participants.

### **Creation of Environments, Organizations, and Systems**

The fourth class of products focuses on the creation of environments, organizations, and systems. It involves the context in which human activities take place and the values and principles upon which human-made environments are based. This class of products typically integrates many activities as well as products from the other classes into a system or whole with many interacting components. Designers working in this area often regard themselves as facilitators of organizational or community process. They organize conversations and debates among all of those who have a stake in the outcome, focusing on the values of a community and how those values may be implemented in concrete plans and actions (→ Environment and Social Interaction).

Work in this area is an emergent design practice with a wide variety of applications. Examples include the design of nature parks and amusement parks, businesses and governmental agencies, complex technological and information systems, and any other human environment, whether for medical care, education, entertainment, or some other purpose. What distinguishes this kind of design from earlier efforts to conceive of systems and environments is typically the designer's use of specific methods of practice and communication, as well as explicit recognition that a concrete product is the intended outcome. Significantly, work in this area has helped to raise consciousness of the issues of sustainability and interdependency in the natural and human-made world.

### **METHOD OF DESIGN**

Many people regard design as an art of styling and aesthetics, concerned primarily with the visual appearance of products. This is a serious misconception of the nature and discipline of design thinking. The "visual" in "visual communication" captures only part of the work of the designer. Designers create products to solve problems, and the central feature of their work is the discovery of the ideas and arguments upon which products are based.

The method or *practice of design* typically begins with an understanding of the function or purpose to be served by a product, including the social, economic, and cultural context. Next is the development of suitable form and content, based upon the subject matter of the product, the needs and desires of the intended audience, and the most appropriate quality of "voice" or "ethos" that will be influential and persuasive with that audience, inducing identification with the product.

Then comes the embodiment of form and content in appropriate materials, with determination of the styling and appearance of the product that will make it attractive and desirable for the intended users or → audience. Finally, there are considerations of the manner of production and distribution of the product. Design thinking integrates all of these factors in the final product, and variation among the factors serves to distinguish the wide range of products that are available in contemporary life.

## DESIGN AS A RESEARCH FIELD

The study of design encompasses history, criticism, and theory, including empirical investigation as well as philosophical speculation. In general, there are three *broad topics of investigation*: the nature of products and their creation in varied circumstances; the nature of the arts, methods, and techniques of design practice and product development; and the “career” of products in individual, social, economic, and cultural life. These topics are explored in three broad strategies of inquiry. First, *dialectical* inquiries (idealist, materialist, and skeptical) seek to place design in the context of larger systems of philosophical or cultural understanding. Second, the inquiries of *design science* search for basic underlying mechanisms in the workings of the mind and the material world. Third, *inquiry*, in the precise meaning of the term, is the exploration of human experience through analysis and synthetic or creative action, involving either rhetorical inquiry or productive science, known in the ancient world as “poetics.” In all of its variety, design research represents a pluralism of perspectives, reflecting the pluralism of practicing designers (→ Design Theory).

*Ethics* plays a significant role in design thinking because the problems of design are often “wicked problems,” involving conflicting values and visions that require careful consideration of the consequences of products in natural, social, and cultural life. However, many designers and design scholars would agree that design is fundamentally an affirmation of human dignity. It is an ongoing search for what can be done to support and strengthen human rights and the dignity of human beings as they act out their lives in responsible ways in varied natural, social, economic, political, and cultural circumstances.

# Design Theory

Mark Aakhus

Rutgers University

A central puzzle that people face is how to make possible communication that is otherwise difficult, impossible, or unimagined. Communication design is a response to this puzzle. It happens when there is an intervention into some ongoing activity through the invention of techniques, devices, or procedures. Such interventions redesign interactivity and thus shape the possibilities for communication. Design is evident in the choices made about how people in relationships, groups, organizations, and communities will speak to and interact with each other. The purpose of design theory is to open up the intentional design of communication as an object of inquiry in order to advance knowledge about communication.

## KEY FINDINGS

Design theory is most immediately a response to the accelerated capacity for communication-by-design ushered in through advances in communication and information technology. Communication becomes an object of design when, for instance, people build web-based services such as forums for buying and exchanging goods and services, finding relational partners, or engaging in specialized discussions. Design theory also addresses the more generalized concern with the broad range of interests in the structuring, shaping, and disciplining of communication practice. Communication becomes an object of design across a range of settings such as when people determine the participants, topics, and decisions to be made at a meeting or when people decide who reports to whom about what so that an organization can run most effectively.

Aakhus and Jackson (2005) identify *seven key insights* from theory and research in language and social interaction that provide resources for investigating, understanding, and engaging in communication design: (1) turn-taking formats vary in the methods provided for generating and displaying relevant contributions; (2) participant identity and face concerns affect participation in any interaction format (→ Politeness Theory); (3) speech is a kind of action with collateral commitments; (4) speech act sequences are indefinitely expandable (→ Linguistic Pragmatics); (5) coordinated action depends on repair; (6) the consequences of design for practice are interactionally emergent; (7) communication is subject to culturally shared assumptions about communication (→ Ethnography of Communication).

Design theory is interested in what an intervention presupposes about communication and with what consequence the intervention is taken up in communicative practice. Interventions embody “hypotheses” about communication evident in choices about affordances and constraints for speaking and interacting such as turn-taking, turn types, topics, and the sequencing of acts. The communicative successes, failures, and surprises that result from interventions on speaking and interaction provide material for reflecting upon and theorizing communication. The accumulation of successful and unsuccessful interventions is a form of knowledge-building about communication.

## COMMUNICATION AS DESIGN

Communication design is often implicit in the work performed in society and taken for granted in the procedures and formats used by technologies, institutions, organizations, and communities. Design theory opens up the design of communication for inquiry in two general ways: (1) through the investigation of the communication design work that takes place in society and the designs for communication that emerge in society, and (2) by engaging in the practice of communication design and the development of design methodology.

Communication design work is evident in the interventions people make to realize preferred forms of interactivity and avoid non-preferred forms. For example, Jacobs and Aakhus (2002) examined the transcripts of divorce mediation sessions by looking at how the mediators treated the arguments made (or implied) by disputants. Their discourse analysis found that what mediators do with their words tends not to articulate the argumentative potential of what disputants say. Rather than resolving differences of opinion based on facts and shared values, disputes were managed in terms of the possibilities of striking a bargain or repairing identities. The mediators used their tools of practice (e.g., questions and summaries) to construct different types of discussion (e.g., bargaining, therapeutic, and critical discussion) as a way to manage the conflict among the parties.

Investigations of communication design work pay attention to the often taken-for-granted design work performed by people in a position to shape the communication experienced by others. These investigations make use of interviews, observations, and transcripts to articulate the tools, ideals, and knowledge of practitioner work. The analysis reconstructs the practical theory of communication evident in the conduct of intervention and the type of knowledge about and practice of communication cultivated in various forms of work and professional activity.

Designs for communication are evident in the procedures and formats available through technologies, organizations, institutions, and communities that provide affordances and constraints for interaction. These designs are solutions to communication problems and each solution varies in terms of its presumptions about how communication works and how it ought to work. For example, Aakhus (1999) examined the *Science Court* approach to resolving the disagreements that arise among experts and then complicate policy decision-making by non-experts. The analysis found that *Science Court's* design-for-communication altered the way experts and non-experts interacted in policy decision-making but did not relieve decision-makers from the predicament of dependence on expert authority. The design recreated the dilemma of authority, ignored facilitating reasoning across domains of expert practice, and encouraged rational discussion on potentially trivial matters. When the *Science Court* was used to facilitate learning about science policy issues in public settings rather than as a tool for rendering a policy decision, however, its design was more relevant and effective.

There are, in principle, an unlimited number of designs for communication and these designs are distinguishable by considering what any procedure or format implemented by an institution, technology, organization, or community presupposes about communication. Investigations of designs for communication articulate the affordances and constraints of various designs by examining artifacts, observing implementations, interviewing

developers, and collecting user assessments. The analysis reconstructs what the design presupposes about communication and how this resonates with the communicative practices and communication values of those participating in the social setting.

The study of design work and designs for communication uses the insights of language and social interaction theory and research (→ Language and Social Interaction). It draws from approaches such as micro-ethnography, ethnography of speaking, → discourse analysis, and → conversation analysis to examine how communication is made an object of design and with what consequences. While the focus is on micro-matters, a direction that design theory could develop is understanding the formation, maintenance, and dissolution of broader patterns and structures in society such as networks of influence, political communication, media systems, and organizational communication.

### **REFLECTIVE PRACTICE AND DESIGN**

The reflective practice of communication design involves a designer using communication concepts, theories, and methods to work out how to make forms of communication possible in particular circumstances through intervention and invention. For example, Jackson (2002) developed web-based instructional support using argumentation theory to devise formats that facilitate learning. The structured online protocols were created based on research demonstrating that the expression and management of disagreement facilitates learning. The key design features of these protocols were developed using the concepts of “repair” and “preference for agreement” from conversation analysis and the theory of conversational argument. The protocols help participants in the online discussion overcome various argument suppressors such as authority dependence, peer pressure, and passivity.

Communication design is a *reflective practice* that uses communication concepts, theories, and methods to conceptualize design, examine the context of intervention, and analyze outcomes for redesign. When approached as a reflective practice, communication design ascertains the value of communication concepts, theories, and methods by discovering whether these aspects of communication theory help solve actual problems experienced in the world. Communication concepts realize their value when the concepts enable designers to determine relevant interventions and inventions. Communication research methods and techniques realize their value when the method or technique enables the designer to reflect on the situation at hand to detect surprises, flaws, and opportunities for redesign.

### **DESIGN METHODOLOGY**

Communication design as a reflective practice also develops design methodology. A design methodology is a strategy for operating in any circumstance of intervention from a design stance. For example, Aakhus (in press) describes how he developed a web-based system to support experiential learning in the workplace. The methodology involved several steps. First, he observed and assessed current communication practices relative to the educational goals. Second, he developed an idealized model of interaction – the conversation for reflection – that, in principle, would realize the educational goals. The

model was based on a theory of reflective inquiry and on empirical research on accounting behavior and disagreement management. Third, he used the model to determine the specific types of communication support needed, such as the types of turns and roles of participation required for the interaction. Fourth, he created a web-based support system to realize the idealized model in the practical circumstance. Finally, the implementation was monitored to identify opportunities for redesign and ways to better conceptualize and model the required interaction.

Methodologies for communication design address the relationship between ideals for communication and knowledge about how communication works. Since much communication theory and research either focuses on how communication ought to work or on how communication works, design theory addresses an important gap in the discipline. Design theory draws on two related approaches to methodology from the area of language and social interaction that engage both the empirical and normative dimensions of communication. Jackson (2002) has worked out the components of a *normatively pragmatic design methodology*: an empirical examination of discourse practices, a critical analysis based on comparison of practices with an ideal model, a specification of designable features, and a proposed redesign. Tracy's (2005) → action-implicative discourse analysis is a related alternative for integrating normative and empirical insights. This approach seeks to articulate normative beliefs, rather than starting with a given normative model, and aims to generate reflection on those beliefs and their consequences for action.

Engaging in design and developing design methodology draw upon the insights of language and social interaction research to formulate design processes for communication. Design theory is a unique complement to the traditional empirical and critical modes of theory in the communication discipline. Design theory brings communication studies into contact with the broad interdisciplinary area of design studies such as that found in architecture, urban planning policy, human–computer interaction, and computer-supported cooperative work.

## Determination Theory in Public Relations

*Juliana Raupp*

*Free University of Berlin*

Studies under the heading of determination theory focus on the question of how media content is produced (→ Media Production and Content). The main assumption is that news releases and other public relations material play a critical role in news-gathering activities.

Public relations (PR) as a source of media content has been analyzed in communication studies since the 1970s (Sigal 1973). In English-speaking research the relationship between → journalism and → public relations is examined in terms of → agenda-building processes. In 1982, Gandy used the expression “information subsidy” to describe media access to information. PR professionals provide information subsidies to the media in order to systematically distribute information on their behalf (Turk 1985). In German-speaking research the term “determination theory” was coined after an initial study by Baerns (1979; 1991, 1st pub. 1985). Based on the results of an extensive content analysis, Baerns stated that PR determines issues and timing of media coverage. The term “determination hypotheses” was coined with regard to this statement, and communication scholars began for the first time to take PR seriously as a possible determining factor in media content (→ Public Relations: Media Influence).

### **ASSUMPTIONS, METHODS, AND RESULTS OF DETERMINATION STUDIES**

Determination theory is inspired by a paradox. On the one hand, there is the social responsibility of journalism that is also expressed in the guise of investigative journalism (→ Investigative Reporting). Independent and investigative journalism should result in a plurality of topics and opinions in mass media. On the other hand, media coverage is characterized by a high degree of concurrence (→ Consonance of Media Content). This observation leads to the question of journalists’ perceptions and selection modes

concerning what is → news. Research on news values, gatekeeping studies, studies examining the internal structure of media institutions, and studies on news bias all try to address this question from different angles (→ News Values; News Factors; Gatekeeping; Bias in the News). They have in common their focus on the journalist's decision on what to publish, and on structural influences of media institutions. Determination theory offers an alternative perspective to this media-centered orientation: it focuses on the question of how extra-media information enters the news media and thereby becomes news itself. Thus, the use of PR material as extra-media information by news media becomes apparent.

Determination theory is based on a functional distinction between journalism and PR. While the latter is seen as self-perception and presentation of an individual's particular interests, journalism is considered a function of the public interest. The relationship between PR and journalism is described in terms of influence. Baerns formulated what later became known as the determination hypothesis that states: the more influence PR exerts, the less influence journalism exerts, and vice versa.

The main methodology of determination theory is content analysis (→ Content Analysis, Quantitative). As an example of the design of subsequent determination studies, Baerns's original study will be briefly presented. In 1978, Baerns analyzed all news related to state politics in North Rhine-Westphalia in print, radio, and television coverage. Alongside this, she analyzed the corresponding releases of the main → news agencies. The study also encompassed all press releases of the legislative and executive bodies of North Rhine-Westphalia, all official publications of the regional state parliament, and protocols of press conferences. In total, more than 3,500 news items were analyzed to determine whether the news items relied on identifiable PR sources, other sources, or the journalist's own investigation. A main result of the study was that more than two-thirds of all news items appeared to be based on information provided by PR. The issues in the news were identical with the items of political PR. Obviously, journalists did not check for additional information as more than 80 percent of all news items relied on only one source (→ News Sources). Only 10 percent of all news items appeared to be produced by active investigation of the issue by the journalist. All in all, independent inquiry and further investigation were largely neglected. The involvement of journalists was mainly limited to cutting the PR material. Also, Baerns's study shows a fast dissemination of PR material. News agencies, → radio and → television distributed the PR-based information the same day they got the material; print media used the information the next day.

Furthermore, Baerns's results indicate an absence of disclosed PR sources. A disclosure of sources was indicated when phrases such as "statement in front of journalists . . ." or, "a ministry informs that . . ." were mentioned in the news item. Sources were mentioned most often by news agencies; more than 50 percent of all news agencies' releases referred to the origin of the information. In television, on the other hand, the source was mentioned least. In addition, the mentioning of sources in the news reports was misleading. Articles based on news releases were marked as agency reports in more than half of all articles in daily papers; the rest of the articles were published under the name of the journalist or anonymously. From this Baerns concluded that absence of reference to PR sources is possibly one reason why even researchers all too readily ascribe to journalism what is in fact a product of PR activities.

### EXTENSION OF DETERMINATION THEORY

The notion of PR and journalism as antagonists competing for influence, and the assumption of a largely passive journalism, provoked considerable follow-up research. This research tried to verify the quantitative influence of PR on media coverage. The studies come to different results: in fact, the amount of PR-based news articles ranged from 7 to 78 percent. This wide range of results is due to *methodological differences* in determination studies. First, the quotas differ depending on the definition of PR influence: is influence a literal adoption of PR messages, must the source be referred to or is it sufficient when there is an indication that PR information was the reason why a certain item was reported?

Second, a systematic comparison of determination studies reveals that there are two different ways to define media output: one way is to analyze all media coverage on a specific topic and to compare it with the PR input on the topic. This is the original design of determination studies and calls for use of determination quotas. Alternatively, all news articles based on PR material can be analyzed using selection quotas that show how successful news releases are in generating news stories. Selection quotas inform on PR's effectiveness to get its messages published in the news media while determination quotas give evidence on PR's capacity to influence the agenda of the news media.

Alongside differences in methodological design, the wide range of determination and selection quotas is explained by *situational variables*. Some studies identify the status of the PR organization as critical. Official sources are quoted more frequently (Hallin 1993) because governmental sources are assumed to be more reliable, more informed, and easily accessible (Sigal 1973). Other studies show the critical role of news agencies. They serve as a kind of catalyst for PR releases; media are more likely to publish information that is distributed by news agencies (Donsbach & Meißner 2004). PR information that is considered newsworthy (prominent actors, relevant topics, and timely information) is more likely to be used by journalists (Turk 1985; Schnitzmeier 1989; Saffarnia 1993; Gazlig 1999; Donsbach & Wenzel 2002). Determination studies indicate that press releases have an impact on media coverage, especially in routine situations. In crisis situations, however, journalists tend to become more investigative, questioning PR messages (Barth & Donsbach 1992; → Crisis Communication). Studies also suggest that the section makes a difference. Determination research initially focused on political journalism and excluded local pages. Further research suggests that local reporters make less use of PR material. Another variable that influences the use of PR material is the possible bias of news media. A partisan perspective in news media appeared to determine the way news releases of political parties were treated by different news media (Knoche & Lindgens 1988; Donsbach & Wenzel 2002; Kepplinger & Maurer 2004, 123). Finally, determination theory was combined with frame analysis. According to a study by Fröhlich and Rüdiger (2004), setting the issues is a PR activity, while framing the issues is a function of journalism (→ Framing of the News).

### LIMITATIONS OF DETERMINATION THEORY IN PR

Studies based on determination theory are not homogeneous. But most of them have a certain method in common: they use an input-output analysis and compare systematically media content and PR material. From this comparison, conclusions are drawn with regard

to the determining influence of PR on journalism. The advantage of this nonresponsive method is that conclusions regarding the interaction between PR and journalism can be drawn on the basis of the *result* of this interaction (→ Measurement Theory). This delivers a more accurate picture than → surveys and expert → interviews with journalists, because journalists tend to routinely underestimate the degree of influence of PR activities (→ Journalists' Role Perception). The disadvantage of content analysis is that much research is limited to the use of printed PR material by print media. In addition, determination effects have been shown mostly in quality papers. Compared with this, media coverage in tabloids seems to be less influenced by PR material (Donsbach & Wenzel 2002). Determination theory in PR is conclusive mainly with regard to the possible influence of news releases from relevant political sources on political journalism in quality papers.

The assumption of determination effects on journalism does not implicate PR efforts as reprehensible. In fact, determination theory is not so much about PR success as about journalism's performance (→ Media Performance). It challenges the normative image of journalism as an objective, neutral, and critical force (→ Objectivity in Reporting). Determination theory confronts this image with a highly influential PR practice that exerts its influence mainly in obscurity. Thus, determination theory has given proof of PR's ability to set the agenda in the news.

## Deutsche Welle

Ingrid Volkmer

University of Melbourne

Deutsche Welle (DW) is a German news and information broadcasting channel that explicitly targets a worldwide audience. DW cannot be received within Germany.

Deutsche Welle → radio service is distributed via shortwave, → Internet, and satellite, and its → television service is delivered by satellite to relay stations as well as to households in various world regions (→ Radio Technology; Television Technology). In addition, DW distributes content through an Internet platform (including weblogs). According to DW studies, DW radio reaches a 65 million audience and DW television 28 million viewers weekly worldwide (Bettermann 2005, 10). DW radio and television rebroadcasts programs from various public service channels and has its own production studios in Brussels, Moscow, and Washington, DC.

Although operating internationally, DW is a typical German public service broadcaster (→ Public Broadcasting Systems; Public Service Broadcasting: Law and Policy). It is governed by two “public” commissions (broadcasting board and administrative board), to which the director general reports, is funded by public funds provided by the German foreign office, and is regulated under federal law through the Deutsche Welle act (*Gesetz über die Rundfunkanstalt des Bundesrechts “Deutsche Welle”*). As other public service channels in Germany, DW is also allowed to sell limited commercial airtime. Today, DW has a high reputation as a German international → news and → information program. However, its history, program profile, and journalistic approach are quite distinct from other internationally operating news and information channels.

During the 1930s, radio emerged as a household medium across Europe, throughout North and South America, and in some Asian countries such as Japan. Shortwave radio emerged in this era as the first “globalizing” medium, being able to deliver signals terrestrially across vast distances and across borders. This was when the first international radio services were launched. National shortwave radio services were seen as a way of extending “sovereignty” to a worldwide sphere by targeting audiences in other countries (1) in order to provide additional news sources, (2) for → propaganda purposes, or (3) for the shaping of a national “imagined” community (Anderson 2006) by means of reaching expatriate audiences.

In this first phase of shortwave journalism, the Voice of Russia (VoR) was formed in 1929 (the first program targeting Germany with a program called “Hier ist Moskau”), the → BBC World Service began its transborder program as the “Empire Service” in 1932, the BBC’s European Service began in 1940, and → Voice of America (VoA) began in 1942 (also with a German program). Deutsche Welle was established much later, on May 3, 1953, in the early Cold War period.

The BBC and VoA already had a clear focus on so-called “public diplomacy.” However, in its early days DW’s program was restricted by the Allied German government, the High Commission, which banned international distribution of programs in languages other than German. For this reason, DW’s early program was only aired in German and simply aimed to “connect” German expatriates living in North America.

In 1954, as soon as the Allied Government ban was removed, radio transmissions in English, French, Spanish, and Portuguese began. At this stage DW was also established as a federal public service institution.

Throughout the 1960s, when radio and television were not only “household” but rapidly becoming “mass media,” and mass-produced radio technology allowed easy access to shortwave in many world regions, DW also began to expand its international reach and diversify its program. The radio program was aired in a variety of additional languages

such as Farsi, Spanish, Turkish, Russian, and Polish, and also delivered by satellite to regional relay stations in Australia, East Asia, and Africa (→ Satellite Communication, Global). This expansion of the radio program into the international sphere, by focusing on specific cultures worldwide, continued throughout the 1970s.

DW's program philosophy changed in the mass media age of the 1970s when international radio stations began to compete for local audiences worldwide. During this time, DW attempted to increase the number of regional relay stations and aired information programs in local languages (such as Dari and Pushtu for audiences in Afghanistan). DW's overall goal was to represent and promote a new postwar Germany as a modern European country. News and information programs covered the latest political and nonpolitical events from Germany. In addition, German language courses were launched in cooperation with the Goethe Institute.

DW underwent major restructuring in the context of German reunification. The former international radio station of the socialist German Democratic Republic, Radio Berlin International (RBI), had been explicitly launched in 1959 to compete with DW's worldwide audiences and had in particular targeted the east European region. In 1990, what remained of RBI was merged with DW, forming a more powerful broadcasting organization. DW incorporated the RBI agreements in the territory of the former Soviet Union, such as with Radio Moscow.

Throughout the 1990s, DW strengthened its position internationally by launching DW-TV, Deutsche Welle Television, in 1992 in Berlin, programming 16 hours a day, delivered via satellite and relay stations in German, English, and Spanish. The launch of DW-TV (and also of the pan-European channel, Euronews) was a reaction to → CNN's dominance in the 1990–1991 Gulf War.

The objective of DW has been further refined since then. Globalization and the increasing number of public service (BBC World), commercial (CNN, Fox Cable News), and privately owned international broadcasters (Al Jazeera Arabic, Al Jazeera English; → Arab Satellite TV News) have influenced the program strategy. Today's DW mission is → media diplomacy (Gilboa 2000), which is viewed in a broad sense. Since 2004 a DW academy provides training programs for journalists of developing countries and crisis regions, especially focused on young journalists, as well as intercultural training (→ Journalism Education).

The new program philosophy is clearly defined in the amended Deutsche Welle act (2004). This act defines the public role of DW as no longer promoting a modern Germany and German viewpoints on world affairs but conveying a broader spectrum of perspectives on world events. This objective represents a new approach to international journalism, by including a variety of local viewpoints and making them transparent to a world audience. A recent study has analyzed audience reactions in the Arab world to this “dialogue” journalism and concludes that one of the key parameters of “dialogue” is to build trust among the audience (Zoellner 2006). The Internet will definitely help DW to reach out and extend this dialogue by including the audience interactively. The Internet is not defined as an additional version of radio and television, but as a standalone unit that provides specific content.

## **Development Communication**

*Karin Gwinn Wilkins*

*University of Texas at Austin*

Development communication refers to a process of strategic intervention toward social change, initiated and engaged by organizations and communities. Development itself encompasses participatory and intentional strategies designed to benefit the public good, whether in terms of material, political, or social needs. While the more broadly defined field of development communication incorporates mediated as well as interpersonal channels, more particular approaches of media development specifically include mediated technologies, such as television, radio, and computer systems.

### **HISTORICAL CONTEXT OF DEVELOPMENT COMMUNICATION**

Historically, the notion of development has been accorded to the domain of developing countries, meaning those with comparatively fewer resources than the wealthier countries supporting bilateral and multilateral development institutions. More recently, the field of development has been merging into a *more broadly defined interest in social change*, applicable to any group, regardless of material base or geographical setting, actively engaged in promoting economic, political, social, or cultural progress. Social change may be

occurring as a result of a variety of factors, such as long-term shifts in policies and political leadership, economic circumstances, demographic characteristics, normative conditions, and ideological values: development communication intersects with social change at the point of intentional, strategic, organized interventions.

Following World War II, development communication emerged as a *foreign aid strategy*, designed by northern, western institutions to promote → modernization among less wealthy countries. Early approaches articulated by → Daniel Lerner, → Wilbur Schramm, and others advocated the promotion of media toward modernization, through individual change (such as empathy, advanced by Lerner) as well as structural change (addressed by Schramm). According to these scholars, through individual attention to mediated news as well as fiction, consumers would become more modern, meaning capitalist and democratically inclined, constituents. These early efforts were also more focused on rural development. Everett Rogers expanded upon the individual process of social change through his articulation of diffusion of innovations, charting a path across the projected rate of adoption of new practices (→ Diffusion of Information and Innovation; Rogers, Everett).

These theories equating development with modernization were advanced mostly from US-based academic and development institutions. From the mid-1970s, scholars in Latin America and Asia initiated critiques, joined by others, of these models of development, for being ethnocentric, linear, acontextual, and hierarchical. These critiques were grounded in broader concerns with *cultural imperialism* and *dependency*, drawing attention toward global conditions rather than the internal national contexts highlighted in earlier models (→ Cultural Imperialism Theories; Dependency Theories). The processes of development, along with media production and distribution, were then recognized as privileging those with political and economic capital to the detriment of those without these resources.

Emerging from these critiques came a profound stance advocating participation, in opposition to hierarchically and narrowly defined terms of development. Overall, participatory approaches center their attention on the people engaged in and affected by social change interventions. Development is accorded to communities over nations, while communication is envisioned as dialogic rather than linear. Multiplicity refers to the aspect of participatory communication that recognizes diversity in approaches to development, as opposed to assuming social change occurs along one universal path. The role of the development communicator then becomes one of facilitator rather than outside expert, such that local knowledge is privileged over external advice.

## THE CONCEPT OF PARTICIPATORY DEVELOPMENT

Conceptualizations and justifications for *participatory development* have varied greatly, encompassing recognition of the processes as well as the consequences of social change (→ Participatory Communication). Development institutions interested in creating efficient and effective projects understand participation as a necessary tool toward achieving a defined end. For example, → social marketing projects may involve extensive interviews and conversations with intended beneficiaries in project planning stages. A television advertisement would be created only after beneficiaries had been consulted in their understanding of the problem and possible solutions, and in their reactions to types of

messages, sources, visuals, and other aspects of the campaign. These types of interventions utilize participation as a means toward an end, defined by the institution itself.

Other development institutions concerned with the ethical aspects of participation are more likely to conceive of participation as an end in itself, regardless of project outcomes. Community members are encouraged to define their own social problems, and to engage actively in their resolution. Some projects, for example, teach video production skills, so that local participants can create their own mediated texts, building on what came to be known as the “Fogo process” after Canadian development strategies implemented in the mid-1980s. Radio, the Internet, theater, and other venues of communication can function in dialogic capacities, contingent upon how the processes of production and distribution are organized. Participation can be built around concerns with access to the means of cultural production, as well as to the technologies of distribution. Key to this approach is centering control within communities rather than large development institutions.

Participatory goals may be constrained, however, by resistant power structures. In this view, participation may be a necessary though not sufficient condition toward social transformation. Substantive long-term change would require institutional, normative, and political-economic support. Positioning local community efforts within broader contexts of social change allows attention to the possibilities for resistance.

Moving participatory approaches toward more resistant strategies to fight oppressive conditions finds grounding in dialogic communication, inspired through Freire’s and others’ work in liberation theology. Building on a foundation in praxis, in which thoughtful reflection grounds political engagement, this dialogic approach sees the value of communications in illuminating oppressive conditions in order to inspire collective action. The locus of control then is situated within the collectivity of the oppressed group, determining both the reasons for problems as well as their potential resolutions. Moreover, the contribution of liberation theology to development recognizes the importance of addressing those who are suffering the most, not only in terms of lack of material resources but also in terms of human rights and dignity.

These concerns resonate with recent attention in development to the importance of social movements in the broader context of social change. *Social movements*, like development organizations, engage in strategic social change, using communications processes and texts to facilitate their goals (→ Social Movements and Communication). Their origins and compositions, however, differ from those of the more formally constituted development organizations, being created through interests and acts of collective groups and advocating potentially more resistant strategies. Although there are many different types of social movements in the development realm, they have the structural potential to advocate against groups with power, through recognizing historical conditions privileging certain groups over others.

Although the focus of development communication has changed over time from concerns with modernity, to dependency, cultural imperialism, globalization, participation, and resistance, these shifts have not evolved in a linear fashion (→ Globalization Theories). Many underlying concerns with power, whether conceived within political-economic structures or within community contexts, or whether posited as hegemonic or pluralist processes, remain.

Development communication typically addresses programs designed to communicate for the purposes of social change, or what can be called “communicating for development.” Other terms that resonate with this approach include “development support communication” and “participatory communication.” More recent critical approaches of development concern “communicating about development,” questioning the way that social change projects articulate assumptions about problems, solutions, and communities. These are not mutually exclusive endeavors: ongoing critique and dialogue engaged through communicating about development should contribute toward improving strategies for communicating for social change.

### COMMUNICATING FOR DEVELOPMENT

Communicating for development engages processes of mediated as well as → interpersonal communication designed to promote socially beneficial goals. Development problems often addressed through these projects can be found in health, agriculture, governance, population, nutrition, sustainable development, and other sectors. These projects address a variety of goals, such as facilitating economic liaisons between consumers and businesses, promoting transparent governance, asserting cultural identities and practices, and creating social spaces for interpersonal exchange and community dialogue.

Media and communication technologies might include radio, television, film, print, telecommunications, mobile phones, computers, and more. Interpersonal forms of communication might be manifest in the form of discussion groups, folk media, theater, and personal interviews, as well as other approaches. *Radio for development* projects have been quite popular in the field, particularly with rural and illiterate populations (→ Radio for Development). Evolving with the field historically, early radio projects were designed to advance the path of modernization, whereas more recent efforts are more concerned with issues of access and dialogue. *Television* has also been employed in development projects, with early efforts distributing information through satellite programming. More recently, → *telecenters* have been supported in order to offer public access to information provided through information and communication technologies. Many projects use other communications technologies as well, at times in concert with broadcasting modes.

Communication intervention for social change may help to mobilize support, create awareness, foster norms, encourage behavior change, influence policymakers, or even shift frames of social issues. The goals themselves vary with the underlying approach taken to development.

Communication projects focusing on media tend to employ social marketing, → entertainment education, or media advocacy interventions. What unites these approaches is an intentional, organized strategy toward a specific, noncommercial goal. These types of projects differ, however, in terms of the types of groups they address and the nature of the social change process assumed. Some projects integrate more than one of these types of interventions in broader programmatic efforts. Therefore, these are not proposed as independent types of interventions, but as a variety of approaches that can be employed in the process of strategic social change.

*Social marketing*, for example, targets individual consumers to change their behavior, whereas media advocacy directs attention toward policymakers who have the potential to

change structural conditions. Social marketing remains a frequently employed approach to communication for development, particularly in health, nutrition, and population projects. Typically, the ultimate goal of social marketing is to induce behavior change among individuals through mediated messages, through more intermediary goals, such as knowledge and attitude change. Built along the parameters of commercial models of → advertising, social marketing focuses on changing behavior, as a consequence of exposure to messages and knowledge gained (→ Communication and Social Change: Research Methods).

Entertainment education programs also incorporate socially beneficial messages into mediated texts, typically, though not always, through longer narratives in comparison to the shorter segments often used in exclusively social marketing campaigns. Popular cultural formats are used, such as songs and fictional narratives, distributed through radio, television, film, theater, and other venues. Capitalizing on audience interest in the entertaining draw of these texts, producers incorporate educational messages they hope will influence audiences. Social learning theory, building on projected positive and negative role modeling of fictional characters, guides the composition of these projects. Some of the topics addressed include fertility and gender equity, as engaged by the Indian television program *Hum Log*, as well as subjects of health, sexual and reproductive health, political and civic engagement, and education. Entertainment education strategies are at times combined with social marketing efforts, integrating intervention strategies in order to promote social change.

While prominent development organizations may be more likely to fund extensive social marketing and entertainment education campaigns, *media advocacy projects* tend to be promoted more by social movement organizations engaged in social change. Media advocacy is designed to foster change at a structural rather than individual level, through attempting to influence policy and decision-makers as well as normative climates. Media advocacy strategies are more likely to employ news media than the other approaches described above, which rely more on popular culture as a vehicle toward reaching audiences.

Some development institutions also address *structural issues* through investing in media systems and facilities. Rebuilding radio and television systems in countries devastated by conflict and war focuses on the need to build media infrastructures in order to bolster economic growth, democratic governance, and civic engagement. These projects tend to be expensive in nature, and thus promoted by the larger of the bilateral and multilateral development organizations. With these projects, the immediate goal is to establish the infrastructure needed for the system to function, with the intention that long-term sustainability will follow.

Whereas many of the large-scale infrastructural projects tend to be funded through the auspices of bilateral and multilateral development organizations, other media systems are engaged at a more local level, building on participatory processes. With some participatory media projects, people are involved in the creation of the texts themselves, such as through the use of video to document critical social issues. Other participatory efforts build and foster the media systems themselves, such as community radio, in addition to the production of texts. The terms → activist media, → citizens' media, and → community media share a concern with participation and control over media production and distribution. Community and citizens' media assert the importance of empowerment within local

venues to create cultural texts, focusing on the importance of the processes of production. Activist media identify the outcome of their strategies as a central feature, utilizing resistant strategies to oppose politically and economically privileged groups. Some of these media centers concentrate on the process of production, emphasizing participatory aspects of engagement, whereas others privilege the content produced, toward creating high quality texts designed to attract and compel particular responses. Funding structures and resources of these media centers, to the degree they rely on a concentration or multiple donors, commercial or nonprofit financing, volunteer or paid support staff, guide and constrain the possibilities for these processes and products. While their primary concern with process or outcome may diverge, these approaches connect in their interest in active participation among community members in the process of articulating problems and enacting solutions, as well as the more resistant possibilities of the strategies engaged.

Development journalism shares some of the concerns inspiring activist, citizens', and community media, attempting to offer democratic, public spaces for political engagement (→ Development Journalism). The value of development journalism lies in a need to chronicle the path of socio-economic development as well as to offer an independent critical voice. Whereas development journalism emerged through the ideas and practices of professionals in less wealthy countries, there are some critical links to a recently emerging → media democracy movement within the US. Both movements are concerned with establishing venues for critical dialogue and active engagement. The media democracy movement combines an interest with democratic engagement and a concern with corporate power in media industries, whereas the development journalism model has been more centered on political concerns.

## **RESEARCH METHODS AND APPROACHES**

Communicating for development builds on a variety of research approaches that inform the design, implementation, and assessment of projects. Formative research contributes to decisions made in the planning of communication interventions, such as the selection of problems engaged, media employed, messages devised, and audiences approached. This type of research can be used to promote participatory practices that might contribute toward more effective or efficient interventions. Monitoring research analyzes the ongoing implementation of projects, in order to understand how the project has worked in the event of future replication in other sites. Summative evaluation research allows an assessment of the consequences of the project, in order to contribute to improving future projects. The knowledge gained from summative work can inform the future development practices (→ Research Methods).

Participatory action research (PAR) resonates with the broader evaluative concern in acquiring knowledge for the sake of social gain (→ Participatory Action Research). Research engaged in the interests of development should be considering the broader interests of society, not implemented for commercial gain or for individual accomplishment. In addition to a concern with how research is used, PAR incorporates attention to research processes, advocating the active involvement of local constituents, rather than relying on external research experts.

Many projects focus their applied research on short-term indicators of success, such as audience exposure, knowledge gained, or behavior changed. There is a critical role, however, for more long-term consequences of social change interventions. Research of this nature serves as a valuable resource, for participants in the immediate intervention as well as others who might be interested in replicating similar projects.

In addition to assessing the degree to which projects have achieved their institutionally defined goals, research might also question the content of communication interventions, in terms of the efficacy or appropriateness of the source or message, or in terms of the relationship between the mediated representations and larger social circumstances. Relying on stereotypical images of gender roles, for example, may hasten short-term acceptance of campaign objectives in children's health or population projects, but may also curtail more progressive long-term goals toward shifting gender roles (→ Gender: Representation in the Media).

Although quite different in strategies implemented and theories engaged, these approaches are united in their attempts to build on communication processes and technologies toward social change. Sharing a profound concern with devastating conditions worldwide, critical scholars and advocates broaden the vision of development communication to encompass concerns with the development industry more broadly, in terms of what visions of social change and communities are articulated.

## COMMUNICATING ABOUT DEVELOPMENT

A complementary approach within the broader field of development communication addresses the topic of communication about development. Critical of a development industry that appears to channel resources yet with worsening rather than improving consequences, some scholars position development as a particular → *discourse* that communicates problematic assumptions about the nature of the problems addressed, appropriate solutions, and communities at risk (→ Development Discourse).

The *ideological assumptions of development*, as an industry and as a particular institutional practice, are deconstructed and critiqued in this approach. For example, when groups are described as suffering from a particular problem, they are framed in particular ways. Women may become subject to population projects designed to lower fertility rates, in projects that reinforce the idea of contraception as a female responsibility. When women are targeted in children's health interventions, women's central role in infant care is confirmed. Similarly, characterizing Egyptian development problems as a natural result of too many people on too little arable land confirms dominant development approaches that privilege geography and demography as points for intervention, rather than raising political questions regarding social and economic inequality or the role of development institutions in influencing national policies. In addition, when development institutions partner with commercial organizations, profit-driven processes are legitimized as a central part of efforts designed for the public good. Development institutions and social movement organizations create and act on these social categorizations as definitions of problems and solutions (→ Development Institutions).

This approach to development questions the discourse of the industry, through examinations of institutional rhetoric and practice. The underlying issue questions how

development communicates particular ideological assumptions, and, moreover, what the implications are in terms of *understanding power*. Power can be understood as a negotiated and fluid process through which some agencies have the economic, cultural, and other resources to dominate and advance their agendas, whereas other groups have the potential to subvert and resist. The power to situate a problem at an individual or structural level, for example, has serious long-term implications. Providing clean water, for example, could be framed as requiring individual change (such as boiling water) or structural change. Promoting automobile safety could be positioned as necessitating individual (such as wearing a seatbelt) or regulatory (such as fining people for non-compliance with seatbelt laws) acts. The group able to define these conditions and solutions is able to control the process of strategic social change.

Some development strategies explicitly take on the goal of “*empowerment*,” advocating the rights and responsibilities of particular communities (→ Communication Strategies for Empowerment). Women’s empowerment in some gender programs, for example, may be facilitated through promoting gender equity in governance, education, and micro-enterprise. Empowerment can be conceptualized at individual, community, or even organizational levels, as a way of establishing control over social, economic, or political conditions. With reference to communications processes, empowerment might also refer to an ability to communicate one’s own stories.

Apart from the intentional objectives of particular projects to promote empowerment, one can understand development as implicitly enacting the broader power dynamics of society, engaging state as well as commercial institutions. Focusing on structure, power refers to the ability to shape the contexts within which interventions are conceived and engaged. These projects take place either through the direct coordination or the tacit approval of the state. Moreover, some projects explicitly incorporate commercial organizations in the implementation of their programs. Partnering with corporations may enhance the overall reach of a project through shared financial, material, and human resources. This form of partnership may be critiqued, though, for narrowing a vision of social change to one that benefits particular enterprises as well as more normative capitalist values.

*Critical approaches to development* have raised a number of other issues as well. While historically, development primarily referred to economic prosperity and growth, recent attention to issues of cultural identity, spirituality, and political governance broadens the scope of development to include non-material components of social change (→ Spirituality and Development). Recognition of human rights, freedom of expression, reproductive rights, and other concerns contribute to a more holistic vision of development (→ Freedom of Communication). Concerns with the spiritual aspects of development are based in part on Freire’s approach to liberation theology. But even with the emergence of these non-material interests within the development community, concerns with poverty and inequity remain.

Classic conceptualizations of development have divided up nations according to their relative wealth, though not in terms of disparity in income or basic needs. These divisions generally operated on a national level, classifying some as “developed” and others as “developing” countries, or aligning countries as in first, second, third, and fourth worlds. Critical approaches again contribute toward reshaping interest in social change across and within national boundaries, recognizing pockets of elite as well as poverty stricken

regardless of geographical positioning. Highlighting experiences of oppression and dominance, a reframing of the *geometry of development* shifts the landscape of development from nation-states in north/south orientations toward a more fluid sense of transnational collectivities and agencies (→ Development, Geometry of).

A central concern within the genre of communication about development work is with the ideological foundations of the development industry. Attention to women, gender, and feminism helps illustrate how these issues become articulated in the course of development practice (→ Development, Gender, and Communication). Early concerns with women's role in development highlighted their previous absence in discussions of agricultural and economic projects. Offering visibility then brought women's contributions into sharper focus. Subsequent concerns with gender dynamics questioned the ideological tenets of women and development work, in that the very goals and structures of development were not questioned, but rather assumed. Instead, gender concerns recognized the ways in which gender dynamics contributed to the potential for social change. Feminist critiques further broadened the scope of ideological critique to subsume attention to the political and economic structures constraining the possibilities for material, cultural, and political gain.

Understanding development as an industry within a global context also includes recognition of social movements, particularly in terms of their potential to resist dominant global forces. Communication strategies may facilitate the process of social mobilization toward resistance, but may also serve as a target for activists attempting to increase visibility and induce sympathy for particular causes.

This vision argues for a phase of → “postdevelopment,” positing social movements as radical alternatives to dominant development structures and ideologies. In this regard, social movements are seen not as a way to transform or improve development, but as a channel for resistance. The potential for social movements to engage in resistance is quite varied, given the complexity of their conditions, with varied access to powerful agencies and resonance with dominant discourse. Opening our gaze to the possibilities of more resistant strategies, though, means advocating a more inclusive understanding of development and social change. Individual projects need to be analyzed not only in terms of their defined objectives, but also as they relate to broader programmatic strategies, such as structural adjustment programs of multilateral and foreign policies of bilateral institutions.

Building on interdisciplinary theories and methods, development communication advances applied work through thoughtful reflection and critique. Development communication continues to offer an increasingly holistic and far-reaching framework for engaging in dialogue and action toward social change.

## **Development Communication: Africa**

*Andrew A. Moemeka*

*Central Connecticut State University*

“Development” refers to the process of social change that has as its objective the promotion of physical and material progress (→ Development Communication). The “silent engine” that drives this development endeavor is communication. In the developed world, development communication is geared toward addressing the dysfunctions of physical and material progress. In the developing world, it is concerned with the provision of physical and material infrastructure. But it is also concerned with social change in the form of inspiring hard work, eliciting self-help, and providing education, health facilities, and other critical conditions. Africa is one of the regions in the developing world where development seems to be occurring slowly. As a result, there has been great concern about how to stimulate development and social change.

## AFRICAN COMMUNICATION MODE

The act of exchanging views, opinions, and ideas on how to bring about this stimulation of development is the key thrust of development communication. Although it is often not engaged as such by governments, this process works best through the → participatory communication processes critical to substantive social change. However, the way this exchange of views for the purposes of community improvement is done and the underlying cultural and philosophical base that give effect to such exchange differ from society to society. In traditional Africa, communication was and still is largely seen as a matter of human interrelationships: what a person said, to whom, when, and how, was guided by certain cultural imperatives, giving effect to the cultural belief that the society takes precedence over the individual. This is summed up in the principle: “I am because We are!” (→ Communication Modes, African; Interpersonal Communication).

In such a cultural environment, development was in the past seen not so much as perpetuating movement beyond existing boundaries, but as creating stability within the culture by not allowing what had existed to decay or be destroyed; insuring that elders showed good examples; teaching the young; providing communal help to those who needed it; and avoiding conflict in the community (→ Community Integration). Although focusing on maintaining the status quo may have worked in the past, this process became problematic. While it was good to insure that material and socio-cultural heritage did not deteriorate, it was even better to move communities toward growth socially and economically. To do so demanded looking beyond the boundaries of their culture and thinking beyond their existing accumulated knowledge.

## MINIMAL IMPACT OF EXTERNAL AID

Development communication practice typically involves a transfer of resources from wealthier agencies or countries to those with fewer resources (→ Development Institutions). In the African region, western European agencies initiated some of these processes through colonial rule. The continent was exposed not only to what the Europeans said, but also to what they had and did. In addition to exchanges of ideas, discussions, and coercive actions, there were material goods and services as well as standards of living that opened the eyes of Africans to new ways of thinking and living (→ Social Mobilization).

This created not only widespread rising aspirations but also set in motion a spate of discussions that led to the formation of development unions, age grade groups, youth associations, development committees, and so on – all geared toward efforts to improve community socio-cultural and economic circumstances. Footpaths were widened, feeder roads were built, schools were constructed, environmental sanitation was encouraged, dispensaries and health rooms were established, and scholarships were bestowed on children. But these were all self-help efforts at the local level; shortage of resources did not allow these efforts to grow to appreciable levels. Rising frustration soon set in among many of these groups. People felt that what it would take to get them out of their existing conditions was more than they could handle, and many gave up. This was not a surprise because research has shown *that four unheralded and unwritten imperatives* are always at work in development communication. These are: (1) knowing what to do; (2) knowing

how to do it; (3) having the willingness and ability to do it; and (4) having the resources to do it. If any one of these is missing, development efforts are hampered. The fortunes of the self-help initiatives of rural Africa represent a case in point.

In the 1960s, newly independent countries faced with the task of developing their nations sought help from the west, especially from the UK and the US. They also sought help from international organizations, including → UNESCO, the United Nations Food and Agriculture Association (FAO), UNICEF, and the United Nations Development Program (UNDP). The first major help came from the US, which had, through its *Marshall Plan*, turned war-devastated Europe into thriving societies almost overnight. Because of this success, it was thought that rapid development of any society was possible if adequate international financial and technological assistance were forthcoming. So the Marshall Plan was transplanted into Africa. But it became a failure not because resources were not forthcoming, but because a pre-existing socio-cultural structure oriented toward industrial organization and activities that obtained in Europe was nonexistent in Africa. Three very relevant cultural values identified by the British cultural anthropologist Radcliffe-Brown as basic to European social order – protestant work ethic, achievement motivation, and economic pragmatism – were foreign to the African social order.

The last factor that badly affected the Marshall Plan was a *disregard of the socio-cultural realities* of the target social system. This policy of bypassing what Inayatullah has called “the intractable local social structure” did extensive harm to the expected goals of the plan. Many people were suspicious of the plan because it was imposed; they regarded the behavior of the agents of the plan as ethnocentric. And they responded to the ethnocentric attitude with cultural pride, explicitly touting the values of their culture and accumulated traditional knowledge (→ Culture: Definitions and Concepts). Cooperation of government officials with the agents was not effective enough without the cooperation of the people. In spite of these hindering facts, agents of the plan did not effect any changes in operation. The same was true of succeeding generations of European development agents in Africa. Not only did they not understand the people and their socio-cultural contexts, they in fact did not allow African development agents on contract with them to build local content into their work.

The impact of this failure to “know the people” before planning any development activity was so great that the then President of Tanzania – Julius Nyerere – had to warn that you cannot develop a people – people develop themselves. Sure enough, the people needed financial resources, technical advice, and technological knowledge. But these were expected to have been used, working with the people, not without them. Unfortunately, this tactic of working for the people without working with them did not end with the failure of the Marshall Plan; it continued in many development efforts of international organizations.

### **APPROPRIATE STRATEGY**

In addition to the extension and community development strategy described above, the other strategy mostly used in Africa in the 1960s up until the 1980s was *advocacy*. This strategy has the tendency to very easily become what is now known as “benevolent power strategy,” providing facilities and amenities for social change for a people but without involving the people in the discussions for the project, or in its planning and execution.

This is based on the principles that the government knows what the people want and need, and that consulting with the people would add extra cost, in time and money, to total expenditure. Examples abound of completed development projects that crumbled soon after they were put into use. Such projects failed because of one or a combination of the following: the people did not sufficiently appreciate the value of what was provided for them and so treated amenities carelessly; they did not have enough know-how to manage the projects efficiently, or, following the way the projects were brought to them, they did not feel it was their responsibility to maintain the facilities.

During this time, development communicators warned against working for the people without working with the people. Since the 1970s, Inayatullah, Ake, Somavia, Freire, Chikulo, and Grunig, among others, had, each in his own way, stressed the importance of not dumping development information and projects on target social systems. By the 1980s, the voices for involvement and participation were heard with increased strength and regularity. The Xavier Institute of Social Service in Ranchi (India) was particularly forceful in saying that development efforts should be anchored in faith in the people's capacity to discern what is best for them as they see their liberation, and how to participate actively in the task of transforming their society (Xavier Institute 1980, 11). People's intelligence and their centuries of experience should be taken into account. This view agrees with what the role of development is, that is, to inform, discuss with, and motivate the people and create an enhanced environment, in which target social systems can feel the need for – and demonstrate commitment to – development activities, thus raising the level of their participation in development projects (→ Communication Strategies for Empowerment).

It is gratifying to note that since the beginning of the twenty-first century, development organizations would appear to have had a change of heart and of tactics. The United States Agency for International Development (USAID), UNESCO, UNICEF, UNDP, and of course, the FAO and the British Government's Department of Overseas Development and many others, have not only shown committed to "getting the people involved," but have changed from using only foreign agents, to using African agents – people who know and understand the target social systems. African governments, too, seem to have seen the need for development agents to enter into the socio-cultural contexts of target social systems, learning from them and building on what they have. One concrete way of showing governments' resolve in this regard is permission given for the establishment of *local radio stations*, focusing on local participation in the production of programs to insure truly community-based projects built on the interests of the people (→ Radio for Development).

Many of the 194 *universities in Africa* have departments of communication. Many of these departments teach courses in development communication at both the undergraduate and graduate levels. A few have full-fledged departments of development communication. In addition, international organizations such as USAID and UNICEF do organize regular seminars and teach-ins to discuss how to incorporate development communication techniques and procedures into courses taught at the university and secondary school levels. Nongovernmental organizations around the continent are also setting up institutes for research and study of development communication. Examples include the Research Institute for Development Communication and School Partnership in the Cameroon,

and Soul City Institute for Health and Development Communication in South Africa. The African Council on Communication Education has a development communication division charged with the responsibility of keeping an eye on development communication initiatives on the continent, and making suggestions on how to insure that their activities are relevant to the needs of the people (→ Communication as an Academic Field: Africa).

## **Development Communication: Asia**

*Wimal Dissayanake*

*University of Hawaii at Manoa*

Development and communication in Asia is a vast and complicated topic for two main reasons. First, Asia comprises a substantial portion of the earth's land mass and population. Second, the direction as well as the velocity of economic development in Asian countries varies profoundly. Economists have divided Asia into five categories, including Japan, People's Republic of China, East Asia, South Asia, and Southeast Asia. The term "East Asia" here refers to the newly industrialized economies of Hong Kong, Korea, Singapore, and Taiwan. South Asia consists of Afghanistan, Bhutan, Bangladesh, India, Maldives,

Nepal, Pakistan, and Sri Lanka. Brunei, Cambodia, Indonesia, Laos, Malaysia, Myanmar, Philippines, Thailand, and Vietnam form Southeast Asia. This categorization is premised not necessarily on topography, but on such important economic variables as per capita income, structure of the economy, openness to trade, engagement with the imperatives of globalization, and policy directions.

Currently, development is vitally connected with the newer information and *communication technologies* (→ Communication Technology Standards; Communication Technology and Development). Email, mobile phones, semiconductors, etc. are becoming increasingly important in data transmission, database management, and in communication in general. It is evident that there is a glaring gap in Asia in the availability and use of information and communication technologies. There is, as development planners in Asia maintain, a → digital divide in Asia. Countries such as Hong Kong, Korea, Singapore, Japan, Malaysia, and Taiwan are at the top of this digital divide while the other countries are at the bottom. The term “development” is used here in an expanded and inclusive sense, to include attention to a process of social change that has as its objective the improvement in the quality of the lives of people without causing damage to the natural and cultural environment in which they exist. In this understanding, development seeks to involve people as closely as possible in this enterprise, making them the masters of their own destiny. Communication plays a highly significant role in this process.

*Five models of development and communication* have guided Asian societies. *The first model* pertinent to the Asian context is the oldest and the most dominant among them. It emphasizes rapid economic growth by means of industrialization. Heavy emphasis was laid on capital-intensive technologies and centralized planning. The guiding thought seems to have been that productivity is the key to development and that the most productive sector of modern society is the industrial sector. Mass media such as newspapers, radio, and television were deployed for the purpose of creating a more conducive climate for rapid modernization and industrialization (→ Radio for Development; Television for Development). This was evident in countries like Japan, Korea, Hong Kong, and Singapore. It was also felt that for rapid modernization to take place, a modern elite needed to play a crucial leadership role. It was felt that the weight of communication policies should be on the side of protecting the freedom of these leaders and fortifying their influence in society. This model of development and communication was very powerful in the 1950s and 1960s (→ Lerner, Daniel). By the 1970s certain doubts regarding the efficacy of this model were expressed by communication scholars and policy planners in countries such as India, Sri Lanka, Philippines, and Bangladesh. Critiques of this model pointed to the inappropriate replication of western models to Asian and other regions (→ Development Communication).

All these perceived deficiencies of the first model resulted in the emergence of a *second model* of development and communication, particularly advocated in India, Philippines, Sri Lanka, and Bangladesh. It emphasized both capital-intensive and labor-intensive technologies, centralized and decentralized planning, and exogenous and endogenous factors of development. The advocates of this model raised a number of important questions related to development and communication: how can distributive justice be achieved? How can the ideals of self-reliance, self-development, and popular participation be attained? How can the power of the old and new media of communication be

purposefully combined? How best can we make use of culture as an ally and facilitator of development? How can we come up with more historically conscious and society-specific models of communication? This shift of emphasis regarding the meaning of development was accompanied by a parallel shift of emphasis in the meaning of communication. The old mechanistic, linear, one-way model of communication was replaced by a process-oriented two-way approach to communication (→ Participatory Communication). The emphasis was now on the facilitation of information exchange related to development through mass media and interpersonal channels.

A *third approach to development* focused on centralized planning within nations, emerging in communist countries like China, North Korea, and Vietnam. This model has to be understood against the backdrop of socialist ambitions and agendas, which placed emphasis on centralized planning and command economies. Capitalist individualism and private entrepreneurship were shunned and collective activities encouraged. In this model, media of communication played a propaganda role in mobilizing the people behind this set of goals. As is now evident, after the fall of the Soviet empire and the increasing globalization of the world, this model has lost much of its luster.

An alternative, *fourth approach* to communication and development was encouraged by communication scholars in countries such as Japan, Korea, and Taiwan, who were in some ways disenchanted with the development in their respective countries. Their approach focused on the interdependence of the developed and developing countries, and how developed countries are responsible for the underdevelopment in the poorer countries (→ Dependency Theories). The advocates of this approach demonstrated the futility of discussing communication and development in a national setting, when the global experience influences the possibilities and constraints for social change in nations and communities (→ Globalization Theories).

Prominent within Asian development was attention to self-reliance as a *fifth and last model*. Here the focus was on grassroots development, integrated village development, use of appropriate technology, productive use of local resources, maintenance of the ecological balance, and culture as a mediating force for development. NGOs across Asia played a critical role in the propagation of this model. In countries such as India, Indonesia, Sri Lanka, Thailand, Philippines, Bangladesh, and Nepal, it was easy to see the way that this model was being popularized. The emergence of the concept of → sustainable development in recent times has strengthened this model.

With the increasing velocity of globalization and the spread of satellite communication (→ Satellite Television) and the strengthening of the forces of neo-liberalism, the first model has received additional impetus. Even countries like China, which were fiercely opposed to this capitalist model, are increasingly embracing it. Development and communication in Asia is a multi-faceted topic.

# **Development Communication Campaigns**

*J. Douglas Storey*

*Johns Hopkins Bloomberg School of Public Health*

The use of → strategic communication has an ancient history dating back at least to Aristotle's *Rhetoric* (→ Rhetoric, Greek). But technological and theoretical advances beginning in the twentieth century, most notably the growth of electronic media and media studies, have resulted in dramatic improvements in the scale, sophistication, and effectiveness of purposive communication and in the rise of contemporary communication campaigns. Billions of dollars are spent globally each year on commercial, political, and public service campaigns aimed at influencing consumer decisions, mobilizing support for political candidates, changing unhealthy behaviors and reinforcing healthy ones, advocating for social issues and policy changes, and much more.

## **ORIGINS**

Contemporary communication campaign theory and practice owe much to public health movements (→ Health Campaigns, Communication in), such as Benjamin Rush's efforts to promote smallpox immunization during the American revolution (Artenstein et al. 2005), and to the abolition of slavery movement in America and Britain beginning in the late eighteenth century, both of which are early examples of large-scale organized attempts to influence mass publics through the use of communication. Fears about the effects of Nazi propaganda during World War II launched decades of primary and applied research on the social psychology of persuasion, establishing a conceptual foundation from which commercial and political campaigns still draw for inspiration (→ Propaganda in World War II; War Propaganda).

Beginning in the 1950s, post-World War II reconstruction efforts took full advantage of national broadcasting media to encourage such things as agricultural innovation, childhood immunization, and contraception; and national independence movements used national and local media to create or renew identities based on new political boundaries and mobilize populations to support political agendas. Mixed success with these large national communication campaigns drew attention to structural, political, and economic factors – particularly inequities in access to resources and control over them – that constrain or facilitate access to and use of campaign information. Beginning in the 1970s, these concerns pushed campaigns to re-assess the relationship between campaign designers and

their audiences, resulting in more participation by beneficiaries in the design, implementation, and evaluation of campaigns and more integrated, multilevel campaigns that address individual, as well as structural, change (Rogers & Storey 1987).

Commercial → advertising and → marketing campaigns build on similar foundations, but focus on influencing consumer behavior and promoting the purchase and use of products. So-called *social marketing campaigns* (Kotler et al. 2002) redefine behaviors, such as recycling glass or plastic, or condom use to prevent HIV transmission, as “products” and apply the principles of marketing to the promotion of behaviors that have personal or social but little or no commercial value for the adopter (→ Social Marketing). Worldwide, commercially oriented campaigns draw inspiration from popular culture and build on social and political structures and trends in order to make their products appealing and relevant to consumers.

Paisley (2001) argued that successful public communication campaigns historically have used some combination of what he called the “three Es of public communication campaigns” to achieve success: engineering, enforcement, and education. *Engineering* refers to planned technological change that facilitates a change in behavior, such as requiring car manufacturers to provide seatbelts. *Enforcement* refers to planned policy or law enforcement systems that sanction noncompliant behavior, such as creating and enforcing fines for non-use of seatbelts while driving. *Education* refers to informing people about desirable practices, how to perform them or reasons for doing so. Engineering and enforcement strategies almost always require some educational support, such as advocacy for technological change or communication to motivate the public to use a technological innovation or to comply with regulations.

### CHARACTERISTICS OF COMMUNICATION CAMPAIGNS

Although there are many variations, Rogers and Storey (1987) identify four attributes that characterize communication campaigns. They intend to generate (1) specific outcomes or effects, (2) in a relatively large number of individuals, (3) usually within a specified period of time, (4) through an organized set of communication activities.

Campaigns are *purposive*. The desired outcomes of campaigns can range from individual cognitive changes in knowledge, attitudes, or behaviors to societal-level structural changes in political systems or the distribution of resources. Individual-level behavior change continues to be the most common type of outcome sought, but campaigns increasingly seek to change or support collective behavior.

Campaigns typically target *large audiences*. Large is a relative term that serves to distinguish campaigns from smaller interpersonal efforts to communicate or persuade (→ Audience; Persuasion). Because considerable financial, technological, and human resources can be required to design and carry out communication campaigns, campaigns usually justify themselves in terms of the number or variety of people they are able to reach.

Campaigns typically have *defined time limits*. Because campaigns are results-oriented, they often specify a time period within which those results should be achieved. While it may seem that campaigns begin with the launch of campaign messages, the launch is almost always preceded by a period of systematic needs assessment or formative research and strategy development before messages can be produced, pre-tested, and disseminated.

Campaigns typically end with some kind of formal or informal impact assessment that determines whether or not they have achieved their stated goals, how the results were achieved, and what might be done differently in the future. The period of time between start and finish varies greatly from one campaign to another. An advertising campaign for a weekend sale or the promotion of a national immunization day may last only weeks from beginning to end, while an HIV/AIDS stigma reduction campaign or a national political campaign might unfold over a period of a year or more. Some commercial or national development campaigns may be better characterized as communication programs composed of a series of carefully sequenced campaigns designed to achieve change in stages or to change and then maintain behavior over time.

Campaigns consist of *an organized set of communication activities*. Communication activities refer not just to the dissemination or exchange of information, but also to the other support functions that make campaigns run smoothly and effectively. The P-Process (Piotrow et al. 1997) describes one such set of activities ranging from systematic audience research, needs assessment and situation analysis, through strategic design, message development and pre-testing, implementation, and monitoring of campaign activities, to campaign evaluation and replanning. The most effective campaigns also involve their audience, beneficiaries, and stakeholders in many – if not all – of the steps in the campaign. Some social change or development campaigns go a step further and work to strengthen the capacity of beneficiaries and stakeholders to design, carry out, and evaluate communication campaigns themselves in order to increase the sustainability of pro-social communication.

Another aspect of campaign organization is the use of integrated mutually reinforcing messages and communication activities, rather than relying on one form of communication – for example, a poster or a television advertisement – to achieve the desired outcomes. More sophisticated campaigns use multiple messages and activities to reach audiences in a variety of ways. For example, a sport drink marketing campaign might reinforce television messages with outdoor advertising and giveaways at sporting events, as well as point-of-purchase advertising or discounts at the supermarket. Similarly, pro-social hygiene campaigns might reinforce radio messages about handwashing with community-based activities about the upgrading or maintenance of community water sources and safe water handling in the home (→ Advertising Strategies).

## OBJECTIVES OF COMMUNICATION CAMPAIGNS

Variations in the ways campaigns are organized and conducted can be described in terms of three broad dimensions: the level of objectives, the locus of desired change, and the locus of benefit (Rogers & Storey 1987).

*Level of objectives* refers to the type of effect sought, ranging from relatively simple awareness or knowledge gain (e.g., creating brand awareness for a new commercial product) to relatively complex mobilization and maintenance of behavior (e.g., motivating and sustaining community recycling practices). Many hierarchies of this sort are identified in the literature (see, e.g., Rogers 2005). Higher-level objectives typically build on lower-level changes.

*Locus of change* refers to whether changes are sought at higher or lower levels of social aggregation from the individual level to the group, community, institutional, or societal

level. Often individual behavior change is directly sought in a campaign, but the ultimate locus of intended effect may be at the community or societal level. For example, a smoking cessation campaign might attempt to motivate individual smokers to quit, but the ultimate intended effect is lower smoking-related morbidity and mortality at the societal level.

*Locus of benefit* refers to whether successful achievement of campaign objectives primarily benefits the campaign designers or the campaign audience. Commercial campaigns are generally thought to benefit advertisers or producers of consumer goods through product sales, although marketing and advertising are often described in terms of an exchange process in which consumers voluntarily give money or other resources in exchange for a product of value to them. In comparison, health or environmental campaigns are often considered to benefit members of the audience or society at large in the form of better health or a cleaner and more stable environment. Little direct benefit may accrue to the designers of a health campaign in a government agency, except in the sense that a healthier populace means lower burden of disease and fewer demands on public health resources.

## **CAMPAIGN EFFECTIVENESS**

How effective are communication campaigns? Given the enormous variety of campaigns and campaign objectives, it is difficult to generalize. If expenditures on campaigns are an indicator, they must be effective. Commercial advertisers paid up to \$2.6 million for 30 seconds of television airtime during the 2007 Super Bowl football championship. Impact data from commercial advertising tends to be proprietary, but → meta-analysis (synthesis of findings across studies) of health mass media campaigns provides some estimates of average effect sizes. For example, Snyder and Hamilton (2002) analyzed 48 health campaigns conducted in the US for which impact evaluation data could be found in the published literature. Overall, they found that health communication campaigns using mass media achieved on average an eight percentage point change in behavior among members of the targeted population, with greater effect sizes achieved by campaigns that targeted larger audiences. The size of the effect varied by type of behavior, with seat belt use, oral health, and alcohol abuse reduction campaigns being the most successful. Greater effects were found for campaigns focused on adoption of new behaviors compared with prevention or cessation of problem behaviors (→ Advertising Effectiveness; Advertising Effectiveness, Measurement of).

A number of planning and implementation steps, if followed, make campaigns more likely to succeed. Most campaign designers conduct at least some formative research to understand the campaign context and audience characteristics and they carefully pre-test messages with members of the target audience before the campaign is launched. Because most people are exposed to hundreds of communicated appeals every day, novel and creative messages are more likely to stand out from the information clutter and be noticed. The use of theory to guide campaign strategy and *message design* also increases the likelihood that the program will have desired effects (→ Message Design Logics).

When audiences are large and diverse, audience segmentation techniques (Grunig 1989) are often used to identify meaningful sub-groups that may benefit from individually tailored message strategies or message treatments. Messages should be placed in channels

that are widely used by the audience at times and places when they are most likely to be seen or heard. Even within the same campaign multiple channels may be used to reach the same audience segments with multiple reinforcing messages, or to reach different audience segments that have different media use habits. And because campaigns play out within a larger social environment, many campaigns design messages that encourage interpersonal discussions (e.g., within the workplace or the family) and try to mobilize interpersonal influence (e.g., of co-workers on each other or of wives on their husbands) to support campaign goals (→ Audience Segmentation; Segmentation of the Advertising Audience).

Finally, depending on the length of the campaign, its scale, and the need to justify expenditures or to learn from experience and improve future efforts, many campaigns conduct monitoring and impact evaluation research. Monitoring research includes the collection of data on the campaign implementation process: are the activities going as planned, on schedule, on budget, and reaching the intended audience? Many campaigns also monitor other events and activities occurring simultaneously with the campaign (e.g., policy changes, presence of other campaigns, disease outbreaks) that may affect outcomes either positively or negatively. Impact evaluation of campaigns refers to the collection of data that indicate if change occurred and whether or not the change can be attributed to the campaign.

## **Development Communication: Latin America**

*Luis Ramiro Beltrán*

*Bolivian Catholic University*

A universally valid and widely accepted definition of the field does not exist, but three conceptualizations have prevailed in the western world, the first two emanating from the US and the third from Latin America. The first, development communication, is the notion that mass media are capable of creating a public atmosphere favorable to change, which is assumed to be indispensable for modernizing traditional societies through technological advancement and economic growth. The second is → “development *support* communication,” i.e., the idea that planned and organized communication – massive, interpersonal, and mixed – is a key instrument for the accomplishment of the practical goals of national development-seeking institutions (→ Planned Social Change through Communication). The third is the concept of alternative communication for democratic development. This assumes that, by expanding and balancing people’s access to, and participation in, the communication process – at both mass media and interpersonal grassroots levels – development should secure, in addition to material gains, social justice, freedom for all, and the majority’s rule (→ Communication Strategies for Empowerment).

## PRACTICE CAME FIRST

The practice of communication for development began considerably before the inception of its theory. During the last quarter of the 1940s three events occurred simultaneously in Latin America, two of them native and the third coming from the US, all of them pioneering endeavors but emerging through divergent paths.

A parish priest in a remote Andean village of Colombia established a rudimentary broadcasting facility, *Radio Sutatenza*, with evangelical purposes. He rapidly turned it into the centerpiece of a cleverly conceived educational communication strategy that he called “*radio school*.” It consisted of a number of small groups of peasants who met periodically to listen to programs specially produced for them to teach them literacy and, later, farming and health care. A trained local leader stimulated and assisted each group to discuss the lessons and applied them to undertaking community improvement activities. So successful was this endeavor that within about a decade it had grown into *Acción Cultural Popular (ACPO)*, a Catholic rural development agency endowed with a number of powerful broadcasting stations serving hundreds of “radio schools” across the country supported by a team of teachers, three leader-training institutes and a print shop to publish a weekly paper and teaching materials. The format corresponded to “development communication” and to “development support communication” (→ Radio for Development).

To break the isolation and silence to which they were confined, workers’ unions in the rich tin mines of Bolivia established very modest broadcasting stations across a vast territory through contributions their members made from their meager salaries. In about a decade these *Radios Mineras* were to grow to about 30, operating at times as a network (→ Radio Networks). This transformed downtrodden and often repressed citizens into protagonists of mass communication. The main characteristic of the miners’ radios was their “*open microphone*” policy that gave participants free and ample opportunity to become active sources of messages instead of remaining passive receivers. To that end, these radios not only welcomed people into their tiny studios but also went into the depths of the mines; in addition, much of their broadcasting was done through dialogue with people in their homes, churches, schools, marketplaces, and sports fields. They thus enabled people to speak out, even to criticize the unions’ positions and performance. Unknowingly, the Bolivian workers of the mines were the pioneers of the practice of what many years later became known as “alternative communication for democratic development.”

In the early post-World War II period, the government of the US launched an international program of development with emphasis on assistance for agriculture, education, and health (→ Health Campaigns for Development). Cooperative services specialized in those fields were established in Latin American countries. Each service focused on a particular line of communication activity such as agricultural extension information, audiovisual education, or health education. In the 1950s and 1960s, the program was to train hundreds of individuals in the principles and skills of communication for development so as to increase and improve the design, production, and distribution of educational messages through multiple media. And soon many other international agencies, such as FAO, → UNESCO, and UNICEF, were to do likewise. Over many years millions of dollars were thus applied, with different degrees of achievement, to hundreds of projects in this

commendable endeavor eminently corresponding to the development support communication and development communication formats.

### THE ADVENT OF THEORY

In 1958, US sociologist → Daniel Lerner published a 50-country study of what he regarded as the extinction of traditional society to make room for → modernization. He found this process was taking place in four stages: (1) urbanization, (2) people's participation in mass communication, (3) literacy, and (4) participation in politics. In 1962, US rural sociologist → Everett Rogers formulated the theory of diffusion of innovations as the engine for society's modernization (→ Diffusion of Information and Innovation). In 1964, US communication scientist and journalist → Wilbur Schramm (1964) published a major study on development and mass communication. Perceiving the latter as "watchman," "teacher," and "policymaker," he stipulated a set of roles for it in helping people meet these needs.

Throughout the 1960s these conceptualizations born in the US were received with interest in Latin America by communication specialists in universities and development agencies. No criticisms were recorded at that time. On the contrary, some conducted research based on the propositions, especially those of Rogers, notably in Colombia and Brazil. Others just proceeded to attempt to apply what they learned from the readings to their field operations. Many seemed to have even come to share with enthusiasm the faith in the mass media as endowed with powers to virtually generate development by themselves.

### REMOVING BLINDFOLDS

The theory and the practice of communication in general and of communication for development in particular came into question in Latin America at the start of the 1970s. This decade was plagued by dictatorships, by the failure of the development undertaking, and by the collapse of the region's economy due to the effects of a grave oil crisis in the developed nations. A movement of young communication scholars committed to radical social change to build a real democracy emerged during the first quarter of the decade. They criticized the classical model of communication in general, formulated by → Lasswell in the US in the late 1940s and expanded in the mid-1960s by Schramm and Berlo (S-M-C-R, i.e., source, message, channel, and receiver). It was regarded as unidirectional (monological) and impositive (vertical) as well as conservative, mechanist, and effects-oriented toward securing manipulative persuasion.

The pioneering propositions of Lerner and Schramm were also somewhat challenged, but the most criticized was Rogers's theory of diffusion of innovations. The main objection was that this model ignored the determinant influence of the archaic power structure, which in Latin America made possible the exploitation of the oppressed masses, especially the peasantry, by the oligarchy. Some critics argued that, in fact, it was that structure that defined who was to be an "innovator" and who would have to be a "laggard." And they added that the concept of leadership in the model hid the reality of the elite; that the notion of cosmopolitanism disguised the linkage between the powerful of the urban and

the rural areas; and that the use of the term “reference group” could dilute the reality of internal domination that victimized the peasants in Latin America.

### **TOWARD “HORIZONTAL” COMMUNICATION**

Brazilian educator Paulo Freire (1969) gained international celebrity as of the early 1970s for his proposal of an “education for liberation” through “conscientization” based on dialogue. Extrapolating from this, Frank Gerace, an American living in Bolivia, was the first to suggest the notion of horizontal communication. Paraguayan specialist in educational communication Juan Diaz Bordenave (1982) soon engaged in creative reflection on the matter, which made him a chief proponent of theoretical bases for the democratization of communication for development.

Francisco Gutiérrez (1973), Daniel Prieto (1987), and Mario Kaplún (1978) were also prominent in this effort. And many other scholars of the region produced proposals for alternative communication, also understood as “dialogical,” “participatory,” and “popular.” Chilean journalist Fernando Reyes Matta (1977) advanced a scheme for “communication with active social participation,” in which he emphasized instrumental organization and education (→ Participatory Communication).

At the end of the 1970s, taking into account the critiques of the US-oriented models and seeking to conjugate the Latin American propositions to replace them, Beltrán formulated a set of bases for a model of horizontal communication, defined as follows: “Communication is the process of democratic social interaction based upon exchange of symbols by which human beings voluntarily share experiences under conditions of free and egalitarian access, dialogue, and participation. Everyone has the right to communicate in order to satisfy communication needs by enjoying communication resources” (Beltrán 1980, 3).

### **LIGHTS AND SHADOWS**

The era of neo-liberalism, globalization, and the “information society” started in Latin America with a catastrophic and paralyzing economic crisis in 1982. This seriously curtailed state development programs and, consequently, their communication components. By contrast, activities of alternative communication recorded considerable growth and improvement. Although multiple media were a part of this evolution, radio was by far the favorite for many grassroots organizations, especially in Bolivia, Peru, Ecuador, Mexico, Costa Rica, Honduras, and the Dominican Republic. Films were used in Bolivia and Nicaragua, and video in many countries. Puppet shows, street theatre, dance and songs festivals, “mini-papers,” and even circus-type presentations were successfully used for various educational purposes. Along with the numerous Catholic educational broadcasting stations, modest but highly participatory “community radio” activities proliferated across the region, sometimes suffering repression.

The decade of the 1990s saw the intensifying of health communication activities, especially for family planning and for the struggle against AIDS, as well as programs to prevent adolescent drug use, to inhibit violence against women in the family, and to promote environmental protection.

## **Development Communication: Middle East**

*Nabil H. Dajani*

*American University of Beirut*

This entry offers an overview of → development communication in the region that the west calls the Middle East, but which in Arabic is known as “al-Mashrik al Arabi,” or the Arab East. The area comprises three Arab regions that fall between the eastern Mediterranean, the Arabian (Persian) Gulf, the Red Sea, and the Indian Ocean. Located in an area where Africa, Asia, and Europe meet, these regions are: Egypt, which is in Africa; Bilad ash-Sham (sometimes referred to as the Fertile Crescent or Greater Syria), on the eastern shores of the Mediterranean Sea, which extends from Turkey and Iran in the north to Egypt in the south and the Arabian peninsula and the Red Sea to the east (including the present states of Syria, Lebanon, Jordan, Iraq, and Palestine); and the Arabian peninsula, or Arabian Gulf, which is largely a desert area that includes the present states of Saudi Arabia, Yemen, Oman, Qatar, Bahrain, the Arab Emirates, and Kuwait.

While the first two regions rely on aid funds for development (mainly from the west) and consequently are economically dependent on the west, the Arabian Gulf region generally enjoys more material resources. Thus the region includes development recipients as well as donors in development practice (→ Development Institutions).

### COMMONALITIES OF THE AREAS

Although the regions differ in economic wealth and political systems, they all suffer from social and economic inequalities as well as from similar structural development “diseases.” Bureaucracy enables politicians and senior state officials not to be accountable to communities, while corruption remains common. The absence of strategic planning and incompetence often means that “growth” or “development” have become synonymous with the accumulation of wealth by the rich and powerful while the support of the poor and deprived is seen as the responsibility of nongovernmental bodies. There is a notable similarity in the kind of development problems faced in the Arab region and in developing countries in Latin America and Africa (→ Development Communication: Africa; Development Communication: Latin America). They all seek social change but lack clear overall objectives or a vision of what this change might mean. They also lack a proper understanding of the process of communication and, while they admire the new communication technologies, are not usually aware of how they can be used to support development projects.

Functional social change is based on national development strategies, which are lacking in the Arab East regions due to the absence of agreement on the objective of this change, at regional and national levels. While there is relatively good awareness of the new technologies, this is based more on an enthusiasm for imitating the west than on how they may be relevant to their societies’ needs. Consequently, communication technology is usually regarded as a source of prestige, often at the expense of weakening or eliminating the support of traditional media institutions in the development process (→ Communication Technology and Development).

In short, development communication approaches have by and large failed in the Arab East because they often reflect western development approaches, are planned by experts who are not familiar with the local culture, and are mainly technology-oriented.

### THE STATE OF DEVELOPMENT COMMUNICATION IN THE ARAB EAST

The field of development communication is relatively new. In the Arab East it is often mistakenly regarded by officials and organizations as the act of promoting development projects. As in many other regions this approach focused on the public relations of government projects rather than engaging the broader process of social change. Communication for development or social change never took off as a specialized field in the Arab regions.

The most serious obstacle to development communication in the region is that communication is not regarded as a transactional process that aims at grassroots participation and behavior change, but rather as an act of informing and of increasing awareness, mainly a *top-down type of informing* (→ Participatory Communication). The issue of development is complex. It cannot be pinned down to a single variable, but attention

tends to be paid to economic variables to the neglect of other (such as social and political) variables. Arab development communication efforts often lack professionalism and strategic planning as well as the ability to function securely within the present world order, which suffers from corruption, and where the development agenda is usually set by the powerful and the rich. In this age of globalization development policies are mainly drafted and controlled by international superpowers and by regional powers (→ Globalization Theories).

Development projects often fail in the Arab East regions and in most developing countries because strategic communication is not integrated into development projects (→ Development Communication, Planning of). The communities that need development are often not involved, because the authorities either do not allow them or do not see the need for them to be involved. Dialogue and debate are not an option and freedom of expression is not guaranteed. Vertical projects (that come from above) are usually not sensitive to social change and cultural realities.

There seems to be a consensus among Arab development communication practitioners that failure in Arab development efforts is due largely to: a *lack of adequate structures* to support development efforts and facilitate popular participation; corruption of the social/political system (nepotism and political priorities over national societal interests); and ignorance by officials and decision-makers and their lack of vision for the role of development communication in the overall social and political processes.

The Arab East does not *lack qualified personnel* who are properly trained in development communication. The problem is that these personnel are usually not employed and most of them end up migrating to the west. Recommendations by regional and international organizations relating to development matters are frequently shelved, usually after ceremonial welcome. The author served on a panel of experts forming a National Population Council for one of the Arab states. In the two years of his service on the council none of the plans proposed were adopted or even taken into account by the authorities concerned when making decisions, although the minister responsible regularly attended the council meetings. Consequently, the present Arab national development organizations and nongovernmental organizations are *staffed by non-professionals*, most of whom are either well-meaning but unskilled social preachers or those who seek material gain.

Additionally, development projects that qualify for funding by United Nations organizations and most other regional and international development funding organizations require an application by the concerned governments. Competent nongovernmental groups often do not benefit from such development funds because of their inability to get endorsement by their governments.

In general there is a tendency in Arab development communication efforts to *focus on the adoption of information communication technologies* with little or no attention to their effect on actual community needs, or to the cultural factors that are essential for community involvement in development efforts. And while there has been a recent upsurge in the information channels in the Arab East these are not utilized to enhance participation but rather employed either to support official political positions or as entertainment channels. People need to be informed in order to participate meaningfully in development, and the media need to be utilized as instruments of information. Instead they are utilized more as instruments of propagation or agitation.

The *Arab media* do not play a meaningful role in advancing or developing awareness for development needs or good governance, in accelerating poverty reduction, or in stimulating debate about aspects of accountability. By providing individuals with material that bears no relation to their society, the media contribute to their alienation instead of facilitating their participation in society. Nor is any effort made by the media in terms of the socialization of children, for example, in helping children accept differences and in teaching social habits. Children's messages in the media and school curricula usually lack vision or coordination, and are often counter-productive. In general, the Arab media fail to serve the genuine development interests of their societies (→ Radio for Development; Television for Development).

The Arab East also *lacks solid academic programs* that address the subject of communication for development and social change. The teaching of this subject is scattered among different academic programs: in agricultural extension and public health programs, as well as in a few communication programs (→ Rural Development; → Health Campaigns for Development). Specialized study in communication for social change is urgently needed, in spite of opposition from traditionalists (both academic and political). The various curricula of communication programs in Arab universities do not address the social and development communication needs of the Arab regions. Academic training is mainly in the areas of journalism, radio, and TV as well as in public relations. The academic area of communication for development and/or social change is almost disregarded as are the important areas of communication policies, communication research, and even communication theories. Communication in rural contexts is nonexistent except within agricultural extension programs.

## NEW COMMUNICATION EFFORTS FOR DEVELOPMENT

This rather bleak overview of the state of development communication in the Arab East region is not the whole picture, however. There have been frequent, though scattered and uncoordinated, efforts toward development and social change. However, such efforts are not part of a comprehensive plan nor can they be ends in themselves.

Among the promising efforts in this direction are some of the *new tele-dramas* and → soap operas (→ Entertainment Education). While there are marked variations among the Arab countries in their efforts to adopt development messages in their tele-dramas and soap operas, Egypt and Syria have excelled. Syrian and Egyptian media reflect a new visual dynamic and a real effort to communicate development messages in their drama. For example, Syrian drama has used popular culture to deal with current social problems in bold historical dramas and clever satire, showcasing an abundance of technical and artistic talent.

Other established areas of Arab development efforts are in communication to improve people's *health and agriculture*. Health communication and agricultural extension can have a great impact on development outcomes in the Arab East. These areas are perhaps among the most successful in development efforts in the Arab East. However, most of the efforts are based on either individual initiatives or projects implemented by local, regional, or international organizations. They are not usually followed up and do not form part of a national development plan. Efforts in these areas are the public health and agricultural

extension work carried out by universities in the regions, notable among which are those of the University of Cairo and the American University of Beirut. There are also development projects carried out by UNDP in Syria and Jordan, as well as agricultural extension work by the International Center for Agricultural Research in the Dry Areas (ICARDA) in Syria.

Arab *higher educational institutions* can have an impact in the field of development communication. New academic institutions, many of which include communication programs, are being set up and are attracting well-trained professionals. While most of the new communication programs do not focus at present on development communication, the area is beginning to attract Arab communication scholars. The new Arab Gulf States are investing considerable funds in developing their higher education sector and are setting up promising communication programs.

A field that is in an early stage of development in the Arab regions, but has a good potential of growth, is that of *information communication technology* (ICT). According to El-Hage et al. (2003) the Arab region represents less than 1 percent of the world's Internet users and there are marked variations among the Arab countries in their efforts to adopt ICT tools and grow their networked economies. Yet, according to this study, by working together "Arab countries can build on each other's experiences to . . . position themselves on a common competitive platform, [and] they can improve their combined standing in the world ICT market."

The strategic goal of development communication in the Arab East needs to be a change of structure, that will produce an institutional system positively oriented to development goals as well as capable of allowing the enhancement of such positive orientations. A new outlook to development is needed that will encourage the Arab individual and official to build up positive development habits that stress participation, good governance, and transparency.

To reduce the Arab gap in development, Arab organizations and institutions need to focus on development projects that contribute to active citizen participation. There is a need for projects that are founded on qualitative and critical research and that are policy- and problem-oriented. These projects need to tackle the role of the state, the role of the people, and the role of the media in development.

The Arab regions need a development strategy that will involve citizens in development projects as well as in the evaluation process of these projects. This requires that communication theory feed into media strategies and social change. And the economic and policy transparency of development projects needs to be appraised according to constructs that recognize Arab cultural practices and not merely western constructs. What is needed is more attention to transparency at the policy formulation level and not merely at the level of local execution of projects. Policy transparency should be given as much weight as economic transparency.

## **Development Communication, Planning of**

*J. Douglas Storey*

*Johns Hopkins Bloomberg School of Public Health*

Effective development communication programs require a clearly defined strategy with specific goals established in advance. Communication goals may range from relatively short-term changes in individual behavior (for example, improving health or environmental practices) to relatively long-term changes in social or structural conditions (for example, increased economic opportunity, increased gender equity, improved environmental quality). Goals must align with → audience or stakeholder needs and achieving this match usually requires the involvement of stakeholders in the program planning stage, if not all stages of program implementation, monitoring, and evaluation (→ Stakeholder Theory). Unlike many other types of communication programs, development communication demands greater attention to social structural factors (Wilkins 2000) because change typically is sought at the societal level, not just the individual level. Also, longer-term and macro-structural changes usually require greater attention to self-sustainability of communication activities, engaging whole communities and organizations (not just individuals) and creating mechanisms for ongoing participation by and coordination among stakeholder groups at multiple levels of social organization from the international and national level to the local and community level (→ Participatory Communication).

Consequently, successful development programs, even more than other types of communication programs, need to follow a systematic, rather than ad hoc, planning process. Numerous approaches, manuals, and toolkits exist as guides to program planning (see, for example, Mody 1991; Piotrow et al. 1997; or McKee et al. 2000). Although details vary somewhat from one system to the next, all describe a similar sequence of planning and implementation decisions.

### **ANALYSIS**

Before attempting to design communication activities and materials, planners need to understand the context within which a program will operate and the audience or audiences that will be involved in and benefit from the program. *Situation analysis* describes the existing context and status of issue(s) that the program will address: How prevalent or

severe is the problem? What causes it? What social, cultural, political, and economic factors inhibit or constrain change from happening? Situation analysis typically draws on existing data, survey results, and other study findings but may require additional research if gaps in knowledge exist.

*Audience and communication analysis* consists of identifying primary and secondary audiences and describing their current status in terms of their knowledge, attitudes, skills, behaviors, and access to resources relevant to the development issues at hand (→ Audience Segmentation). Other aspects of the audience that may be useful to understand include the presence of → social networks, socio-cultural norms, and community dynamics that influence individual and collective action. At this stage, planners also analyze audiences' media access and use and the capacity of local media, traditional media, nongovernmental organizations, and communication agencies to participate effectively in development communication programs (→ Audience Research; Exposure to Communication Content).

## STRATEGIC DESIGN

The second stage of systematic planning involves setting objectives, developing program activities to achieve those objectives, and specifying how the activities will be implemented, monitored, and evaluated. Participation in this stage by stakeholders increases the likelihood that the program will address needed changes. The first step is to *establish communication objectives* that are SMART (specific, measurable, appropriate, realistic, and time-bound). Many programs falter because their objectives are too broad, unmeasurable, or unrealistic within the limits of time and resources available. Programs should avoid the mistake of setting too many objectives, as this dilutes focus and overburdens available resources. SMART objectives also specify precisely who and what will change as a result of program activities.

Next, planners should *specify a causal model* for the program by drawing on relevant theories to define why and how the program is expected to result in change. This will help to focus communication activities precisely on factors or processes that are most likely to result in desired changes. Even before messages are designed, planners should *determine channels* that can be used to reach primary and secondary audiences. The most effective programs (even those that operate at a localized level) typically use multiple channels to achieve change on a larger scale.

For example, mass media can be used to encourage and reinforce community mobilization and interpersonal communication among family, friends, community members, peer networks, professionals, and policymakers. Once objectives and strategies are clear, planners *develop an implementation plan*, which includes a management plan, budget, and work schedule with regular benchmarks established to monitor progress. The implementation plan should include a list of indicators and data sources that will be used to monitor program implementation and audience reaction to it, as well as a study design to measure program outcomes and to assess impact (→ Communication and Social Change: Research Methods).

## DEVELOPMENT AND TESTING

Only after the strategic plan is clear and agreed to by key stakeholders should the program move on to the development of communication materials and messages. *Message and*

*materials development* is most effective when key stakeholders (managers, fieldworkers, and members of the intended audience) are involved in the process to insure that communication meets their needs. It is unlikely that one message can achieve more than one objective; more often than not a single objective may require more than one message or communication activity, which is another reason not to overburden a program with too many objectives.

As the materials and messages begin to take shape, it is essential to *pre-test communication concepts and messages* with stakeholders and representatives of the intended audience(s). Even if messages are designed with the participation of key stakeholders, formal pre-testing can still help to avoid costly errors and loss of time. If pre-testing reveals – as it usually does – that some adjustment or redesign is needed, then messages and materials should be *revised and retested* to insure that they match audience needs before final production of materials or implementation of activities occurs.

### **IMPLEMENTATION AND MONITORING**

As for all other stages, involving stakeholders in the implementation and monitoring stage helps insure that the program is responsive to local needs and conditions and increases local ownership of and buy-in to the program. The first step in this stage is *production and dissemination of messages and materials*. Successful programs formally assign responsibility for communication and dissemination activities and may enlist a variety of groups to assist in this process, including local governments, civil society organizations or community groups, private sector organizations and the media, with the aim of achieving maximum reach among those who need to receive materials or participate in communication activities.

*Training* may be needed to insure that communication activities and distribution of materials are carried out according to plan. In the case of longer-term social change programs, it may be necessary to design ongoing efforts to institutionalize capacity for program communication. Sustaining communication beyond the initial launch of a campaign requires ongoing *mobilization of key participants* and sharing information, results, and credit with partners, allies, and communities in order to keep everyone motivated toward the strategic goal. In order to insure that the program is on track and being implemented according to plan, it is important to design a system to *manage and monitor program implementation*. This involves such things as checking program outputs to insure quality, consistency, and timeliness; tracking existing service statistics; and conducting special studies using surveys, focus groups, observation, and other techniques to track audience reaction to the program. Programs need to be prepared to *adjust implementation activities based on monitoring results*. It is usually less costly to make mid-course corrections or adjustments in activities, materials, and procedures based on monitoring data than to let an inefficient program proceed unchanged.

### **EVALUATION AND REPLANNING**

The final stage of program planning is evaluating how well a program achieves its objectives. Evaluation can explain why a program is effective (or not), including the effects of different activities on different audiences. Sound program evaluation stimulates program

improvements and redesign, guides cost-effective future funding allocations, supports advocacy and fundraising, and can motivate continued involvement by stakeholders. Many programs *measure outcomes* to determine if the desired changes have occurred. More rigorous study designs *assess impact*, which links changes in outcomes to one or more intervention activities.

*Dissemination of results* is an important part of evaluation because it helps everyone involved to be aware of the program's impact, whether or not it is positive. Impact results should be shared and discussed widely with partners, allies, key stakeholders, the media, and funding agencies. Finally, because most development communication programs are part of a larger agenda for social change, evaluation results from one phase of a program should help to shape plans for future activity. Good evaluation designs help development communication planners *revise or redesign programs* by revealing program strengths to be replicated and weaknesses to be corrected. Again, key stakeholders, decision-makers, donors, and all interested parties should be involved in reviewing the results of the program evaluation in order to determine what the follow-up should be. New follow-on programs may have to start over at the analysis stage if the situation changes markedly or if new causes are found for the development issues being addressed.

## **Development Discourse**

*Young-Gil Chae*

*University of Texas at Austin*

Development discourse refers to the process of articulating knowledge and power through which particular concepts, theories, and practices for social change are created and reproduced (Escobar 1995; 1999; 2000; Crush 1996). Historically, the approach to development in terms of discourse has evolved out of debates on → modernization and

Marxist dependency theory rooted in social evolutionism (→ Dependency Theories). Departing from the linear models of social progress, this approach to development seeks to articulate the processes and meanings of more nuanced social control and challenges. Epistemological premises are grounded in poststructuralist concepts asserting language and discourse of development as systematically organizing power through the subjectivity of social actors and their actions (→ Power and Discourse).

Attention to development discourse emerged in the 1990s, building upon critical approaches to → development communication studies. Development discourse studies tend to view dominant models of development as a highly contested domain in which dominant groups attempt to assert control over marginalized groups of people (→ Power in Intergroup Settings). Studies of development discourse tend to examine *strategic communicative intervention* of → development institutions for social change in terms of the constructed problems and solutions designated toward concerned communities (→ Strategic Communication). The issues of the exploitation of the rainforest region of Colombia in the Pacific coast, for example, are formulated around the discourse of “biodiversity” insuring manageable generic resources and effective controls of intellectual property of genes. Systematically organized “facts” were created, mostly through the networks of experts associated with international agencies and the northern environmental NGOs supported by G-7 countries, to provide scientific prescriptions for the defined goals. The created knowledge carefully submerges the identities and cultures of the Afro-Colombian and indigenous communities in the region.

Discussions of development discourse often parallel the concept of → postdevelopment (Escobar 1995), because they attempt to shift the analytical frame of discourse analysis to envision the popular resistance of local communities. Instead of reinscribing dominant development projects, they intend to critique the logics and devices constructed by and for development industries. Thus, they value the knowledge and experiences of local, self-reliant participatory, and collective actions as the fundamental sources for alternative social change, both at local and global levels (→ Participatory Communication).

Some critics question the feasibility of dominant development discourse to envision an alternative approach to social change (Pieterse 1998; 2000; 2001). Dominant development discourse fails to offer a venue for restructuring processes of social change, instead providing an “ideological platform” that benefits the work of the development industry and the logic of the global capitalist system. Critics of dominant development discourse stress the importance of → community media and alternative media in promoting collective and resistant approaches to social change (→ Activist Media).

## Development, Gender, and Communication

*H. Leslie Steeves*

*University of Oregon*

Development communication addresses issues of gender in a variety of ways. Communication projects designed to address social problems, such as health, agriculture, population, nutrition, education, democracy, and other topics, may either target women or consider gender as a way of understanding the social context in which the issue might be best addressed (→ Development Communication Campaigns). In addition, → development communication also refers to the way that → development discourse communicates particular assumptions made about groups of people, such as women and men, as responsible for social problems and subsequent change. The history of development communication has transitioned from no attention to women, to a recognition of women in development (WID), to gender and development (GAD), to more recent concerns raised that are pertinent to global feminism.

Following little attention to women or gender issues by early development communication scholars such as → Daniel Lerner, *women in international development* (WID) approaches emerged in the early 1970s. Notably Boserup (1970) used data from Sub-Saharan Africa to show how women's economic status was harmed by colonial and postcolonial aid policies favoring men. Development increased women's workload, as men's work was redirected to cash crops or urban employment. Women, who had traditionally farmed with the assistance of men, became almost solely responsible for food production and childcare, in addition to being forced to earn cash in the informal market.

From Boserup's and others' research, WID scholars argued for integrating women in economic development, an argument that catalyzed the 1975–1985 UN Decade for Women and the implementation of women-specific programs in most aid agencies. Many studies show, however, that these changes were cosmetic and did not alter the

capitalist-patriarchal basis of modernization. They affected a small minority of projects and most women remained marginalized (e.g., Staudt 1985).

The liberal feminist strategies of WID have been critiqued not only for their failures, but also for ignoring women's reproductive work, exploiting their labor, and neglecting gender relations (Mohanty 1991). Hence, while adding women to development has helped address an affirmative action problem, it has not necessarily improved women's lives. After a half-century of development aid, women remain poorer than men, with the greatest gender disparities in the poorest developing countries. This affects development, as improvements in women's employment and education have been correlated to virtually all indicators of positive social change (UNDP 2007).

These findings led to the gender and development (GAD) framework, which is more sophisticated than WID in addressing the *gendered* context of every situation, including the ideology of male superiority and men's control over resources. Especially instrumental in this shift was DAWN (Development Alternatives with Women for a New Era), a group of activists, researchers and policymakers formed during the Decade for Women (Sen and Grown 1987). GAD challenges the distribution of power in societies. GAD's objective of empowering women by transforming patriarchal socio-economic structures threatens donor agencies that seek improvements in economic indicators but oppose fundamental social change. Nonetheless, agencies such as the US Agency for International Development (USAID) have embraced the rhetoric of GAD. However, as with WID stipulations, GAD applies only to some projects, and evidence thus far indicates little change in USAID practice (Wilkins 1999). Despite decades of research and dialogue on development communication, gender remains inadequately addressed.

Media and information and communication technologies (ICTs) have the potential to reinforce as well as resist women's secondary status (→ Technology and Communication; Communication Technology and Development). For example, the → Internet, mobile phones, and other interactive technologies may facilitate the sharing of information, but may also exploit women through limited and harmful representation (→ Interactivity, Concept of). Hence, media monitoring and women's media projects constitute a key area for scholars and activists (Gallagher 2001).

In addition, the spread of ICTs is widening information gaps, often referred to as the → digital divide. Cybercafés and mobile phones require discretionary resources, less available to women than men. As literacy is essential for the Internet, extending women's access requires improvements in their education (Hafkin 2006).

At the level of project communication, there is consistency between those who advocate grassroots, participatory, project planning and implementation and those who agree with GAD ideology (→ Participatory Communication). Critical and feminist examinations of large-scale → modernization-based projects, particularly → social marketing and → entertainment education campaigns, are needed to expose biases that may neglect and harm poor women, while privileging men and commercial interests. While these projects are often associated with large bilateral and multilateral aid agencies, they are increasingly sponsored by nongovernmental organizations (NGOs) as well, many of which receive funding from government-affiliated agencies (→ Development Institutions). In addition, more projects aligned with community media practices (→ Alternative Journalism; Citizens' Media) are being engaged by women's collectives (Steeves 2007).

In sum, attention to both communication and gender in development are necessary for women's political, economic, and cultural empowerment, as well as successful outcomes in vital areas such as health, education, and income (→ Communication Strategies for Empowerment). The spread of new information and communication technologies intensifies this mandate.

## **Development, Geometry of**

*Hemant Shah*

*University of Wisconsin-Madison*

*Karin Gwinn Wilkins*

*University of Texas at Austin*

Geometries of development refer to the spaces, shapes, and arrangements underlying the idea and practice of development. Similar to a classic definition of “geometry” as a physical arrangement of forms, discourses of development describe the arrangement of

various actors within a global system. As used within development discourse, geometries of development describe the relationship among three elements: spaces, key points, and vectors. Boundaries demarcate the “edges” of various kinds of spatially based actors in a global system – such as nation-states, regions, and transnational configurations. Points refer to key institutional sites where development policies and programs are formulated and implemented, such as government ministries and intergovernmental organizations (IGOs), but also where policy may be resignified and resisted (e.g., social movements, nongovernmental organizations [NGOs], local governing bodies). Vectors are linkages among institutional and spatial actors characterized by directions of the flow of resources and benefits and by the strengths of the exercise of power. These relationships help create divisions of various kinds among actors and determine the overall shape of the structure of development. Thus, in the geometry of development framework, structural shape is somewhat contingent and fluid, created by the spatial boundaries and coordinates of actors in a global system. Further, the structural shape is characterized by hierarchically arranged actors whose places are formed historically by the vectoral relationships among those actors.

### **PURPOSE AND ORIGINS OF THE APPROACH**

The geometry of development approach offers a flexible analytical tool for analyzing development processes (see Shah & Wilkins 2005). The abstract concepts within the geometry of development framework are not bound by nation-states as the key unit of analysis, though they are recognized as important actors. Also, the geometry of development approach is not limited to viewing the flow of development aid in a “West-to-Rest” fashion. The nomenclature involving space, points, and vectors allows not only critique of various arrangements of development geometry, but also consideration of alternative development arrangements that are open to incorporating a wide range of actors and in which there are no predetermined roles.

The contemporary, neo-liberal geometry of development has been dominant in global development relations since the end of World War II. Grounded in a Cold War context, this geometry of development created spatial distinctions between west and east, rich and poor, and first and third worlds. The underlying principle of the Cold War-era development approach involved the transfer of financial, technical, and human resources (vectors) among spatial and institutional actors and functioned within a set of categories that distinguished, with each transaction, donors from recipients. The current global geometry of development articulates a vision of development that compartmentalizes communities divided along various types of boundaries. The Cold War-era development thinkers divided the world neatly along political (communism in the east vs democracy in the west), economic (industrialized north vs agricultural south), cultural (modern vs traditional), and hierarchical (first = west, second = east, and third = south) lines.

The emergence of the dominant geometry of development can be traced to the late 1940s. While preparing his 1949 inaugural address, US President Harry Truman’s staff agreed upon three central points regarding foreign policy: to continue support for the United Nations organization; to maintain commitment to the Marshall Plan; and to create a joint US–European defense organization. Almost as an afterthought, a mid-level

civil servant suggested a fourth point: to expand existing Latin American technical assistance programs to the poor countries of Asia, Africa, and the Middle East, thereby expanding an existing vector between the United States and countries of the “south.” Point Four received massive attention from the press and policymakers around the world. As a result, government efforts in this area were intensified and over the course of several decades, new international actors were created, such as the forerunners to the United Nations Development Program (UNDP), regional development banks, and the United Nations Conference on Trade and Development (UNCTAD). Consequently, Point Four established in a very public, very global way the idea of underdevelopment as a synonym for what had been called “economic backwardness,” and demonstrated in a dramatic way the position of power held by the United States in defining the status of other nations.

At the time this framework emerged, the idea that development could be strategically planned and stimulated was notable for shifting away from the idea of intransitive social change. Importantly, the Point Four configuration of international relations eliminated (at least rhetorically) the colonizer–colonized relationship by erasing discussions of unequal relations of power among nations. Underdevelopment was now a stage in an inevitable, linear process toward development that all nations went through. This development–underdevelopment continuum created the possibility of recognizing intervention as a humanitarian mission rather than one of colonization or imperialism (→ Cultural Imperialism Theories). Finally, mass media were assumed to operate as an appropriate and relevant means toward inspiring people in the “underdeveloped” world to emulate those in the “developed” west (see Lerner 1958; → Lerner, Daniel). Many of these basic principles still serve as the foundations for development practice today, as international development institutions allocate resources to transfer knowledge and technologies to communities in nations with few material resources (→ Communication Technology and Development).

### **CRITIQUE OF THE DOMINANT GEOMETRY OF DEVELOPMENT**

The dominant geometry of development has been criticized from several directions. As has been suggested in many other reviews of dominant development models, the approach inappropriately justifies the positioning of wealthier states as a normative model and therefore legitimizes their intervention in “underdeveloped” areas. The model has been critiqued also for its ethnocentric vision, collapsing diverse communities of the south with a wide range of cultural histories into a single monolithic space for development intervention. According to some scholars, even the seemingly innocuous assumption that technologies themselves are inherently “neutral” belies an ethnocentric approach.

The dominant geometry of development also implies a vectoral relationship whereby interventionist policies and programs, created at various institutional points in countries of the north, are posed as being in the best interests of their target communities in the south. Such views allowed many academics and policymakers in the north, without a trace of self-doubt or self-consciousness, to craft blueprints for “developing” the south in the image of the north. The dichotomization of the entire global structure of

development into modern and traditional spaces (even with a transitional category in between, as evidenced in Lerner 1958) obscures the intersections between and within practices in historical contexts. These broad generalizations miss distinctions within countries, essentialize groups into homogeneous categories, typically at the level of nations rather than communities, and assume that experiences of poverty, gender, and other social conditions are similar across historical and cultural contexts. This kind of “spatial will to power,” as Escobar (1995) puts it, allowed domestic elites in southern countries in the postcolonial era to represent their specific self-interest as a class as equivalent to the general interest of the nation-state as a whole. More often than not, however, the interests of domestic elites in southern countries actually were identical to the interests of development policymakers in the north’s countries. As such, the south’s country elites replicated the dominant international geometry of development within the boundaries of southern nations. This process has, in many cases, resulted in the abuse of minority and indigenous rights.

Another problem with this dominant geometry of development is that it conceptualizes the development–underdevelopment continuum in a way that fetishizes geopolitical boundaries. Postdevelopment critiques have illustrated the processes through which the development industry constructs “third world” spaces through planning and implementing strategic intervention. The dominant bilateral and multilateral development institutions are premised on a notion of stable geopolitical boundaries, and the development “target” becomes operationalized as the “third world.” Even in participatory models of development, despite the best intentions and dedicated work of many practitioners and scholars, “participation” serves more often to fulfill administrative needs of the industry than as an alternative to dominant development approaches.

In the geometry of development created by Point Four, since the primary unit of analysis was the nation-state, five-year plans, data-gathering protocols, communication systems, infrastructure building, bureaucracy creation, and other activities were all conceived as national projects. While these data may have been useful for certain large-scale planning and policy purposes, they missed recognizing the inequities in resource distribution among segments of a country’s population. A tremendous amount of energy was expended on mapping territories and constructing borders of newly independent states. Again, this information may have been valuable for building infrastructure, facilitating some forms of social interaction, and creating certain kinds of economic growth (all with unequally distributed benefits), but another purpose of these activities was to monitor and constrain the movement of minority and indigenous communities.

With regard to communication issues in the dominant geometry of development, the operative assumption was that nationally based media systems were necessary to distribute information efficiently and to mobilize people to become modern in the national interest.

Lerner and others assumed that identities fostered through national media systems would transcend other identifications within and across national boundaries, and that these larger media systems would be more efficient and sophisticated than other, smaller media systems. Even current development discourse, perpetuating this geometry, seems incapable of dealing with the contemporary vectoral realities of specialized transnational media networks created by diasporic communities.

Many writers are uneasy with the vocabulary of the dominant geometry of development, employing quotations and footnotes to signal their critical use of terms such as “third world” and “development.” These scholars and practitioners are attempting to distance themselves from an ethnocentric vision of a hierarchical distinction between the northern west as “first” and others as somehow “lagging” behind, in “third” or even “fourth” place. However, even these critical usages can evoke a more-or-less traditional understanding of geopolitics. For example, the term “third world” was first posed during the 1789 French Revolution as a way to refer to a “third estate,” or people in poverty lacking political power, and since then has been critically used to denote spatial actors, such as communities united through shared experiences of oppression based on race, ethnicity, class, or gender hierarchies; of economic distance from or dependency on the global capitalist economy; or of anti-colonial political struggles. The dominant, Point Four-inspired geometry of development typically essentialized diverse groups of donor and recipient nations into broad geopolitical categories. An alternative geometry of development framework can accommodate a variety of social groupings (i.e., new spatial and institutional actors), along local and regional lines, that resonate more clearly with cultural histories and contexts.

## **Development Institutions**

*Jacob Groshek*

*Indiana University*

*Christine Ogan*

*Indiana University*

At present, there are over 50,000 international organizations with a total budget easily over US\$250 billion devoted to improving social, economic, political, and health conditions around the world, specifically in less developed countries (Directory of Development Organizations 2007; → International Communication Agencies). The current status of

modern international development organizations can be traced back to the end of World War II and the official launch of the United Nations. Indeed, while other organizations pre-date the UN, including religious and political bodies, it was the formation of the UN and its many subsidiary programs and funds that helped catalyze international → modernization efforts.

## MODERN HISTORY OF DEVELOPMENT INSTITUTIONS

This launch also coincided with the establishment of the World Bank, the International Monetary Fund, and the Bretton Woods System in 1944. While the Marshall Plan for post-World War II recovery focused on bilateral agreements made with individual European countries, Bretton Woods created a multilateral system that provided economic aid to developing countries through loans that were tied to changes in economic policies in the recipient countries (Spero & Hart 2003).

In the *United States* the first bilateral assistance to developing countries began with the Truman Point Four program (a Marshall Plan for the third world), which provided skills, information, and equipment from 1950 onwards, and other legislation that led to short-term assistance. But it was the Foreign Assistance Act of 1961 that sought to address long-term world development needs through a bilateral system of loans and grants to be administered through the US Agency for International Development (USAID). To this day, USAID is the primary federal US agency for assisting developing countries. It employs a wide range of communication strategies to support its programs of disaster relief, poverty eradication, and democratic reform (Melkote & Steeves 2001).

During the Cold War era from 1947 to 1989, development aid was offered according to east/west ideological principles. One of the most obvious examples of this was the *Peace Corps*, initiated by John Kennedy in 1960. During this period, political rhetoric was often part and parcel of communication strategies employed by development agencies. The US development efforts closely followed foreign policy objectives, frequently tying aid to US technology, experts, and communication systems.

In *Europe*, the Organization for Economic Cooperation and Development (OECD) was one of the earliest organizations to establish a goal of supporting economic development both within and outside its 30 member countries. Established in 1948 to coordinate the Marshall Plan as the Organization for European Economic Cooperation, OECD has emerged to offer its assistance to more than 70 developing countries. One of its major programs is in the promotion of information and communication technologies in sustainable economic growth and social welfare (→ Telecenters).

Once the Soviet Union began to fragment in the early 1990s, communication research and development organizations experienced a substantial paradigm shift. Largely absent from the communist/capitalist geopolitical framework, international development organizations lost their status as central to governmental policy focus, and hence the economic support for many of their activities. However, nongovernmental organizations, now grouped with trade unions, faith-based organizations, community groups, indigenous peoples' organizations, and foundations under the umbrella title of civil society organizations, have increased their activity in development assistance (Mody 2003; → Transnational Civil Society).

## MISSIONS OF DEVELOPMENT INSTITUTIONS

Many of these organizations use communication strategies and support communication projects in their work. These organizations operate at the international, regional, national, and community levels (see Table 1). A far-reaching group of organizations have made it their priority to develop media organizations and work for a western-style free press. These efforts include funding for infrastructure, training for the use and maintenance of such networks, and education for journalists and citizens alike in creating and using media for democratic ends (Wilson 2004; → Development Journalism). Additionally, some organizations work to insure that journalists who speak or write against the government are not treated unfairly, imprisoned, or executed.

*Civil society organizations* focusing on communications, such as Panos (working with journalists and other communicators) and CFSC (Communication for Social Change Consortium), were created as networks of smaller organizations in order to increase the potential impact across more countries and with greater resources addressing a wider range of development issues. Other groups organized around networks of faith, like the World Association for Christian Communication, made up of a range of ecumenical Christian funding partners, focus on communication as a human right.

Since the diffusion of communicative technologies, most recently the → Internet, has been shown to be linked to advances in education, health, and income, many international development organizations began to re-emphasize the importance of communication in their strategies. The United Nations made the information society the theme of one of its major world summits in 2003 and 2005, thus pointing other international development agencies in this direction and drawing in technology-based organizations, such as the Computer Professionals for Social Responsibility and various countries' Internet societies, to focus on development issues (Carpentier & Servaes 2006; → United Nations, Communication Policies of).

Another common mission is to effect *social change in health-care and practices* and in education, and to reduce poverty. In some instances, local programming is created in an effort to match cultural needs and norms (→ Health Communication; Health Campaigns, Communication in). These efforts, such as the → UNESCO-sponsored *Sara campaign*, directed to the education needs of young girls in Sub-Saharan African countries, are to be lauded, but may exceed their target audiences and reduce their effectiveness when exported multinationally. Many international organizations focus on solving particular problems, such as AIDS, illiteracy, or child welfare. Others support particular groups, such as migrants or indigenous peoples. Some of these organizations cross national borders, while others work at local levels within particular countries, such as the Rainforest Action Network (→ Migration and Immigration; Activist Media).

Still others operate only at the national or local level. One such organization in India, the Self-Employed Women's Association, established in 1972, grew out of a trade union for textile workers. In order to promote the rights of women workers, this organization has used a range of communication technologies to disseminate information and tell the stories of women workers' successes to other workers. Based on its successes in India, SEWA organizers have helped spread the movement to South Africa, Yemen, and Turkey. Though SEWA was begun as a gender-based organization, it has widened its

**Table 1** International development organizations and communication

<b>Mission</b>	<b>Representative organization</b>
Develop media and establish free press	International Press Institute
Social change in health, education, and poverty	Academy for Educational Development
Social justice for women and oppressed groups	United Nations Population Fund
Send economic aid, enhance free trade	Organisation for Economic Co-operation and Development
Several of the above goals	Organization of American States
<b>Type of organization</b>	<b>Representative organization(s)</b>
NGO and civil society	World Congress on Communication for Development

Late (1996–present)	International Institute for Communication and Development (1997)

focus to home workers and vendors in other countries (→ Development, Gender, and Communication).

Finally, there are a number of international development organizations with goals that encompass all, or a number of, the above-mentioned areas and using a wide range of frameworks in their approaches. These supra-mission organizations are usually well funded and have great discretion in choosing projects and locations as well as extending or restructuring their overall mission. Private foundations are able to change their focus frequently, and many organizations within the UN often have sub-programs or organizations under one umbrella to achieve larger goals such as gender equity or access to education (Servaes 1999).

## **Development Journalism**

*Hemant Shah*

*University of Wisconsin-Madison*

During the 1970s and 1980s, the United Nations Educational, Scientific, and Cultural Organization (→ UNESCO) was the site of vociferous debate about global communication. Collectively, these arguments have come to be known as the → New World Information and Communication Order (NWICO) debate. Nations of the south, many of which had relatively recently emerged from colonial domination, demanded a restructuring of the flows, distribution, and practice related to global information and communication. Many nations of the west, led by the United States and Great Britain, resisted any restructuring, arguing that such changes would have to be mandated by governments and would amount to undermining sound universal principles such as the free flow of information. Among the most contentious issues in the debate was development journalism – a term referring to the role of the press in the process of socio-economic development, primarily in countries of the south (→ Development Communication).

Development journalism was conceived in the 1960s at the Press Foundation of Asia (PFA), where Filipino journalists Alan Chalkley and Juan Mercado were concerned that news organizations were inadequately covering socio-economic development. Journalists were reporting government press releases and quotes but giving little attention to detailed analysis, interpretation, or evaluation of development projects, policies, or problems. Their concerns led Chalkley and Mercado to organize seminars at the PFA to train journalists in the art of development journalism.

### **THE DEBATE ABOUT DEVELOPMENT JOURNALISM**

Development journalism, as conceived at the PFA, implied an adversarial relationship between independent news media and the government in which reporters offer critical

evaluation and interpretation of development plans and their implementation. Development journalism challenges traditional → news values, gives priority to the needs of ordinary people, and recognizes that objectivity is a myth (→ Objectivity in Reporting). Development journalism results in news that provides constructive criticism of government and its agencies, informs readers how the development process affects them, and highlights local self-help projects (Aggarwala 1980; Golding 1974).

Even as the *concept* of development journalism gained a following in Asia and beyond, the *practice* of development journalism was quickly appropriated by national leaders to justify government control of mass media and to promote state policies, often as part of larger campaigns of repression (Domatob & Hall 1983). Sometimes this appropriation was called “developmental journalism” (Sussman 1978), indicating a form of reporting and writing that viewed the task of news media as explicitly and uncritically supporting the government in achieving its development goals. Critics of developmental journalism said it opened the door for government control of the press (→ Communication and Law; Freedom of the Press, Concept of). The result of such control, said the critics, was an emphasis on government success stories and uncritical government say-so journalism, not investigative and thorough development news as proposed by development journalism advocates such as the staff at PFA.

Critics such as Stevenson (1988) and Sussman (1978) proclaimed the failure of development journalism despite recognizing the vast differences between how development journalism was originally conceptualized and how the term was appropriated (as developmental journalism) to serve as a rationale for state control of national media. By suggesting that development journalism is inevitably controlled by government ministries and officials, the critics’ declarations of failure hurt even the development journalism projects taken on by independent media.

Thus, “debate” over development journalism often boiled down to a simplistic dichotomy: western commercial media were free while third world mass media were strictly controlled and manipulated by political elites. This questionable formulation gained a measure of acceptance among some academics and journalists as a “developmental” theory of the press (Hachten 1993), even though it could not be consistently supported empirically since some western governments also owned and controlled national media (particularly broadcasting) while many third world countries had independent and even oppositional media.

Further, others pointed out that even though developmental journalism might indeed uncritically emphasize government success stories, it did not mean that such reporting has no potential to contribute to development. Whether a government elected to control the media and use it for developmental journalism or the media freely reported development news in the way defined by PFA, development news contributes to development only if it possesses certain characteristics.

The *criteria for development news*, i.e., determining whether or not a news item can potentially contribute to development, should not be based on the source of the message (i.e., independent media or government-controlled media) but rather on the characteristics of the message itself. Aggarwala (1980), Shah (1996), and others have described the characteristics of effective development news. It should critically examine, evaluate, and interpret the relevance of development plans, policies, and programs. It should indicate the disparities between plans and actual accomplishments and include comparisons with how development

is progressing in other countries and regions. It should also provide contextual and background information about the development process, discuss the impact of plans, projects, and policies on people, and speculate about the future of development. And development news should make reference to basic needs of the population. News items that do not refer to some of these features cannot be considered development news.

### RELATIONSHIPS BETWEEN MASS MEDIA AND SOCIETY

To highlight the unique features of development journalism, the concept should be distinguished from three similar ideas about the *normative relationship between mass media and society*. These are the social responsibility theory, articulated by the US Commission on the Freedom of the Press (1947); the democratic-participant perspective, summarized by McQuail (1987); and communitarian journalism detailed by Christians et al. (1993).

*Social responsibility theory* calls for journalism that emphasizes interpretation and analysis tempered by a devotion to fairness and neutrality. The theory suggests that journalists have an obligation to provide citizens with thorough, incisive, and useful information. In exchange, the press is provided with freedom from pressures and constraints that could be imposed by government and business interests. Development journalism also calls for comprehensive reporting with a critical edge. But while social responsibility theory supplements neutral reporting with an interpretive and analytical approach, development journalism requires not only provision of socially relevant information, but also journalistic advocacy in challenging oppression of all kinds.

The *democratic-participant model* features media that are small-scale, decentralized, and owned and operated by their users. The model assumes that certain audience needs are not adequately met by large, centralized, commercially oriented media and that professional communicators should have a minimal role in the communication process. The primary emphasis of this model is providing individuals and groups with access to channels of communication through which their voices can be heard. However, media access seems to be the ultimate goal. Although McQuail (1987, 122–123) claims that the model is informed by an eclectic “mixture of theoretical elements, including libertarianism, utopianism, socialism, egalitarianism, environmentalism, and localism,” there is no explicated theoretical or practical link between gaining access to media and movement toward alternative social organization. In development journalism, individuals are also given a means of voicing critique and articulating alternative visions of society. But then, the professional communicators disseminate the voices from the grassroots in forms and formats that can mobilize action to force policymakers to institute reforms.

*Communitarian journalism*, in its call for changing journalism’s preoccupation with dualism, scientism, and individualism, represents a model with several elements in common with development journalism. For example, both models urge journalists to assume a central role in helping construct community identities and critiquing unequal power relations and distribution of resources. Both models also encourage journalists to abandon the role of neutral observer while reporting in a manner that is thorough, deeply researched, historically and culturally grounded, and oriented toward progressive social change. However, community building takes place, in communitarian journalism, by “engender[ing] a like-minded philosophy among the public,” a problematic proposition

because it implies a fixed and universal understanding of community that exaggerates harmony and homogeneity (Calhoun 1993). From the perspective of development journalism, on the other hand, a primary focus is on specific and locally defined views of identity and community that recognize differences among and within marginalized groups (→ Journalists' Role Perception).

### FIVE PRINCIPLES OF DEVELOPMENT JOURNALISM

Shah (1996) has summarized development journalism as comprising the following five principles. The first three are related to the practice of reporting and writing while the last two concern the role of journalists themselves.

- 1 Development journalism is concerned with *social, cultural and political aspects of development*, not just the economic. Development journalism promotes and contributes to humane development, which focuses on helping people meet their basic needs, empowering people to articulate their concerns and manage their development, and ameliorating poverty and inequality.
- 2 Development journalism is *democratic* and emphasizes communication from the “*bottom up*.” Bottom-up reporting results in news that includes the voices and perspectives of people most adversely effected by modernization. By prioritizing the views of people at the grass-roots level, development journalism allows them access to mass audiences and policy makers.
- 3 Development journalism is both *pragmatic and unconventional* in its approach to reporting. While traditional journalism reports facts perceived to be true and makes a conscious effort to remain detached from the subject of the story, development journalism makes explicit efforts to promote reform and encourage social action.
- 4 Development journalists take on the *role of professional intellectuals*, providing energy for social movements and helping create awareness about the need for action. Journalists can help “articulate the concerns of emergent forms of protest, putting them into broader frameworks,” and showing their “deeper meaning and significance.”
- 5 Development journalists encourage the *production of development journalism at multiple sites*, both geographically and within the overall structure of the news industry. The global concentration of → ownership in the media industry has left little space for cultural products that question the status quo, and even less space for material that forcefully advocates even limited structural change. Thus development journalists should advocate for “both the development of alternative, usually localized, media and a critical monitoring, intervention in, and sometimes use of mainstream media.

### DEVELOPMENT JOURNALISM AND PUBLIC JOURNALISM

Finally, it should be noted that development journalism is similar to the → *public journalism* approaches to reporting developed in the United States in the 1990s by academics and journalists concerned with a crisis of media and democracy. Gunaratne (1996) perceptively pointed out that public journalism advocates typically refused to acknowledge the similarities of their model of reporting to the conception of development

journalism. Nevertheless, the similarities between development journalism, born in the south at a precarious moment when many newly independent countries struggled to establish democratic, accountable governmental institutions, and public journalism, born in the west at a precarious moment when people were losing confidence in the media and other democratic institutions, reveal that all democracies are inherently unstable and that journalism assumes a key role in creating and maintaining democratically accountable government that is legitimate in the eyes of citizens.

## **Development Support Communication**

*Srinivas R. Melkote*

*Bowling Green State University*

A cursory examination of halo terms used on the world stage in the last 50 years will surely unearth the term “development.” *Development* is commonly understood to mean a process by which societal conditions are improved. However, there is much disagreement

on what constitutes improvement. Consequently, the term *development* has been continually contested. Development communication, a special focus of this entry, often refers to a linear process of information exchange, resulting in knowledge acquisition or persuasion toward some objective related to development. This term too has been actively contested, especially with the changing interpretations of *development*. Today, many emphasize *communication* as a process of shared meaning that takes place in a cultural, political-economic, and geographical context, and is inseparable from that context (→ Development Communication).

Development in its modern form dates back to World War II. The early decades since World War II witnessed the dissolution of the colonial empires and the concomitant political emancipation of most of the countries in the third world, and the birth of the United Nations. This marked the formal beginning of development work and assistance primarily targeted at the developing countries in Asia, Africa, the Caribbean, and Latin America, or more often known collectively as the third world (→ Development Communication: Africa; Development Communication: Asia; Development Communication: Latin America).

The label “*third world*” will be used often in this text. There are a plethora of interpretations of this label. Most often the term is used to refer to countries considered less technologically advanced, economically poor, and less endowed with good infrastructures in the sectors of education, health-care, agriculture, etc. Other labels often used interchangeably with *third world* are: *developing countries*, *less developed countries*, *underdeveloped countries*, and *south*. Geographical connotations have been overemphasized over other factors, and consequently countries in Asia, Africa, the Caribbean, and Latin America are commonly considered as constituting the third world.

## DEVELOPMENT AS MODERNIZATION

Modernization propelled a powerful set of forces at work, especially in the third world. A dominant paradigm of development influenced by the techno-social biases of → modernization guided intellectual thinking and practice in the decades that followed World War II (Lerner 1958). It had enormous social, cultural, political, and economic consequences for the developing economies of the third world. The concept and practice of modernization were based on liberal economic theory. It was grounded in the grand project of Enlightenment, namely reasoning, rationality, objectivity, and other philosophical principles of science of the western-hemisphere developed countries (→ Modernity). In the modernization theories, the definition of a modern nation resembled western industrialized countries in all areas of society, including political and economic behavior, attitudes toward technology and science, and cultural norms. Thus, implicit in this discourse of modernization was a philosophy of what development in the third world should be, and how it should be facilitated.

The modernization paradigm was also influenced by a social evolutionary theory (Portes 1976). In these theories, the third world countries were usually considered as traditional societies and placed at one end of a development continuum, while the industrialized countries in the west signified the modern counterpart and occupied the other end of the same continuum. Unlike the developed countries, the third world nations were regarded as being limited in their capacity to cope with problems or crises

and even to master their environment. At the micro-level, individuals in the developing countries were considered as traditional, uneducated, unscientific, and irrational in their thinking, and generally inimical to modernization. Theories of individual psychological attributes stressed that attitude and value changes among these individuals were prerequisites to the creation of a modern society. These theories argued that modernization of the third world was dependent on changing the character of individuals living there to resemble more closely the attitudinal and value characteristics of people in western Europe and North America (Lerner 1958; Inkeles 1966; McClelland 1966; Rogers 1969).

The development process in the third world countries did not follow the assumptions implicit in the dominant paradigm of development. The paradigm worked better as a description of social change in west Europe and North America than as a predictor of change in developing countries. The neo-classical economic model in the modernization paradigm that suggested a trickle-down approach to development benefits started losing credibility in the 1970s (Seers 1977). The promised trickle-down of benefits did not occur. The worldwide recession of the 1980s and the economic reforms forced by multilateral institutions such as the World Bank on the third world countries left them further behind. The modernization paradigm was also criticized for its negative view of cultures (Singer 1972), especially the religious cultures in the nonwestern world, for its patriarchal biases and for its andocentric views (Braidotti et al. 1994). In the mainstream view, local cultural traditions and living arrangements had to be displaced with attitudes and value sets of people in the industrialized west if the third world nations and people wanted to modernize. This idea no longer has overt supporters (→ Development Discourse).

A universal model of techno-social development as articulated in the modernization paradigm has been increasingly questioned and criticized. Alternative approaches to development that have been posited in the last few decades tend to be pluralistic and indicate varied goals for meaningful and real development in the third world. The concerns in the alternative approaches have included the articulation of development models that are relevant to the local contexts (→ Community Media). The newer approaches have argued for more local people involvement in development initiatives. Grassroots activists have argued for a regeneration of local people's space and local cultures in the developing countries of the third world. In these approaches, goals of individual and community empowerment are usually central. Concerns with spirituality (→ Spirituality and Development), and with cultural and grassroots organizations provided a sharp contrast to the exogenous models of the modernization paradigm and its near-exclusive concerns with the technical and economic systems as the principal drivers of modernization.

## **DEVELOPMENT SUPPORT COMMUNICATION**

The earliest models of → media effects conceptualized the impact of mass media as direct, powerful, and uniform on individuals living in modern, industrial societies termed *mass societies* by sociologists in the early twentieth century. The early models conceptualized communication as a linear and one-way process flowing from a powerful source to a passive receiver. However, more recent research conducted after World War II showed the mass media as weak in effecting important behavioral and attitudinal changes (Lazarsfeld et al. 1948). Communication scholars suggested that the mass media were

more agents of reinforcement than of direct change (→ *Media Effects, History of*). This shift in emphasis made little difference to formulations advocating the use of mass media for development in the third world countries. Here, uses of mass media for transmission of information and for persuasion were transferred to fields such as agricultural extension, health, and education (Diaz-Bordenave 1977; → *Rural Development; Health Campaigns for Development*). The mass media were perceived by administrators and policymakers as important tools for bringing about quick behavioral change, particularly in favor of the modernizing effects of the state (→ *Development Journalism*).

Thus, mass media were considered to be ideal vehicles for transferring new ideas and models from the developed nations to the third world and from urban areas to the rural countryside. The mass media were entrusted with the task of preparing individuals in developing nations for rapid social change by establishing a climate of modernization. They were thought to have powerful, uniform, and direct effects on individuals in the third world. Research in this tradition generated high expectations from the mass media. They were considered the magic multipliers of development benefits in third world nations (Lerner 1958). Information was thus seen as the missing link in the development chain. The quality of information available and its wide dissemination were a key factor in the speed of development. Adequate mass media outlets and information would act as a spur to education, commerce, and a chain of other related development activities.

By the 1970s, it became increasingly clear in Asia, Africa, and Latin America that socio-economic structural constraints greatly diminished the power of mass media in overcoming problems of development (Beltran 1976). The process of development was not as straightforward and clear-cut as conceptualized earlier. And the mass media, far from being independent factors in the change process, were themselves affected by many extraneous factors. The top-down nature of the mass media models and their exogenous orientation were increasingly criticized by scholars and practitioners. Increasingly, it was felt that if development is to have any relevance to the people who need it most, it must start where the real needs and problems exist, namely in the rural areas, urban slums, and other depressed sectors. People living in such peripheries must perceive their real needs and identify their real problems. To a large extent, these people have not been able to do so due to a lack of genuine participation in development strategies ostensibly set up to ameliorate their problems (Mody 1991). Many scholars and practitioners since the 1970s have favored active participation of the people at the grassroots in development planning and execution (Ascroft & Masilela 1994; Jacobson & Kolluri 1999). Other practitioners have favored a more liberating type of communication education that would contain more dialogue and would focus more on the receiver and his/her social context (Freire 1970). In this approach, communication channels are used to generate dialogue, helping people to understand each other and identify their collective problems. Communication is thus used as a vehicle for liberation from mental and psychological shackles that bind people to structures and processes of oppression. Consequently, the changing nature of communication in development was labeled “development support communication” by critical scholars and practitioners. With this term, the emphasis changed from viewing communication as an input toward greater economic growth to visualizing communication more holistically and as a support for people’s empowerment, especially in marginalized groups (→ *Participatory Communication; Communication Strategies for Empowerment*).

## EMPOWERMENT

Sustainable development is not possible unless we deal with a crucial problem in society, namely the lack of economic and social power among individuals at the grassroots and other marginalized groups (Steeves 2000; Wilkins 2000; → Sustainable Development). Individuals are impoverished or sick or often slow to adopt useful practices not because they lack knowledge or reason, but because they do not have reasonable access to appropriate or sustainable opportunities to improve their lives. This is an issue of unequal power. The focus on unequal power dynamics has a direct consequence for development support communication. The transmission approach or the delivery of new information and technology innovations will be insufficient for the task. Empowerment requires more than just information delivery and diffusion of technical innovations (→ Diffusion of Information and Innovation). The objective of the development support communication professional should be to work with individuals and communities at the grassroots and other marginalized groups so that they eventually enter and participate meaningfully in the political and economic processes in their societies. This calls for grassroots organizing and communicative social action on the part of people at the grassroots, meaning women and others who have been marginalized in the process of social change. Greater importance will need to be directed to the use of communication in empowering citizens. The new focus in development support communication then should be to move away from facilitating development toward assisting in the process of empowerment.

Communitarian theory emphasizes preservation of community and emancipation from oppression at all levels (Tehrani 1994). Liberation, feminist, environmental, and some third world social movements have made arguments consistent with communitarian theory. It appears that communitarian theory offers potential as a general framework that could ground participatory and empowerment-oriented perspectives in communication and development. For development support communication, the goal is no longer just information delivery and diffusion of technical innovations but rather to work with individuals and groups at the grassroots or at the peripheries of a society so that they eventually have a voice in political, economic, and ideological processes in their societies.

## Developmental Communication

*Jon F. Nussbaum*

*Pennsylvania State University*

*Carla L. Fisher*

*Pennsylvania State University*

In the last two decades of the twentieth century, communication scholars began to adopt a perspective that recognizes the dynamic and evolving nature of behavior. Termed “developmental” or “life-span” communication, this approach mirrors its sister disciplines, psychology and sociology, in the study of change across time. Communication scholars became interested in this perspective after the 1979 National Communication Association, led by Carl Carmichael and Robert Hawkins, included a caucus on communication and aging (Nussbaum & Friedrich 2005). Just over 10 years later, notable scholars including

Nikolas Coupland, Howard Giles, John Wiemann, Jon F. Nussbaum, and Mark Knapp responded to this surge of interest with a summer conference, a Fulbright International Colloquium, and numerous books that not only showcased a developmental approach to communication scholarship but illuminated the need to more fully appreciate change when examining communicative behavior (Nussbaum et al. 2002; Nussbaum & Friedrich 2005). To date, developmental communication research – with interdisciplinary studies in relationships, media effects, entertainment, education, and health – has produced invaluable knowledge on the individual, relational, and societal levels of how communicative behavior changes over time. Developmental communication has become an increasingly important part of the communication discipline.

## **DEVELOPMENTAL COMMUNICATION: INFLUENCES AND CONSIDERATIONS**

### **The Life-Span Perspective**

Developmental communication is an area of study grounded in psychological as well as sociological research. Influenced by Baltes et al.'s (1988, 4) definition of life-span developmental psychology, developmental communication involves “the description, explanation, and modification (optimization) of intraindividual change in behavior across the life span, and with interindividual differences (and similarities) in intraindividual change.” Communication scholars have adopted and modified this description as well as other life-span scholars' perspectives to create a more communication-specific developmental approach to social science (Nussbaum et al. 2000; Williams & Nussbaum 2001; Nussbaum et al. 2002; Pecchioni et al. 2005). An exploration of these past and present influences reveals the undeniable utility of a life-span perspective when examining human interaction.

Baltes's (1987) *five assertions of the life-span perspective* explain the usefulness and stance of this approach in behavioral studies and have markedly influenced developmental communication research. His first assertion states that life-span developmentalists *refute* the commonly held belief that aging equals decline. His assertion means that we do not necessarily lose communication competence over time. In fact, the opposite is often true: many communication skills actually improve as we age (Bergstrom & Nussbaum 1996; Fingerman 2003). Baltes's second assertion recognizes that development is *not* a predetermined, non-influential form of change. Rather, our development varies in speed and is influenced by a multitude of factors. With this in mind, we can claim that communication development may vary due to different life experiences. Baltes's next assertion states that developmentalists must appreciate the gain–loss dynamic inevitably encountered over time. In other words, as some behavioral skills decline, others may increase in efficacy. Hence, while aging adults may lose abilities that impede their daily living activities, to compensate for such losses they may simultaneously cultivate a more supportive social network that provides assistance in these areas (Nussbaum et al. 2000). Finally, Baltes's fourth and fifth assertions acknowledge the unquestionable fact of diversity in human life. His fourth assertion acknowledges that behavior varies intra- *and* interindividually over the life-span. Our communicative behavior can vary from situation to situation (intraindividual variance) and from other individuals' interactive

skills (interindividual variance). Baltes's fifth assertion further recognizes such diversity: behavioral development is impacted by environmental influences, and vice versa. Therefore, when examining how communication changes over time, it is important to account for relational, social, contextual, and technical factors necessary to fully explain behavior.

Developmental communication scholars have modified Baltes's assertions to reveal the implications this approach has for communication research. One notable modification was presented by Pecchioni et al. (2005) in their text, *Life-span communication*, which was published to update Nussbaum's (1989) book, *Life-span communication: Normative processes*. They modified the above-mentioned definition of life-span developmental psychology to define life-span communication as a perspective that "deals with description, explanation, and modification of the communication process across the life span" (p. 10). They also outlined five propositions exemplifying the need for this approach to answer many communication-related inquiries.

First, they note that it is important to recognize that communication is, by nature, developmental. In other words, communication is a process over time rather than a single event. Second, like Baltes, they advocate acknowledging multiple influences in order to obtain a comprehensive understanding of interactive behavior. Their third proposition asserts that when scholars examine communication change over the life-span, they must appreciate both quantitative and qualitative change because quantitative changes are useful in depicting "a difference in degree" whereas qualitative changes display a "fundamental departure in the meaning of an event or a relationship" (Pecchioni et al. 2005, 12).

In their final two propositions, they address theory and method. The fourth proposition advocates including all theories that are testable. Most communication theories lack any consideration of development, yet life-span scholars fully appreciate that any theory may be useful in expanding knowledge of communication behavior. Moreover, this perspective does not exclude any theory of behavior or development. As a result, developmental communication studies have been firmly grounded in communication theory (Nussbaum & Friedrich 2005). Finally, Pecchioni and colleagues address the need to entertain numerous diverse methodologies in order to gain real knowledge of communication change over time. Although cross-sectional designs are a favorite and are certainly helpful, they lack the ability to make causal inferences, observe change over time, or assess interindividual variation. Therefore, developmental communication scholars must learn the strengths and weaknesses of their methodologies and aim to use those that are of most value.

These guiding principles from past and present experts not only offer ways effectively to examine the dynamic nature of our interactive experiences, but also clearly depict the need for communicative behavior to be examined developmentally. Researchers need to know these basic principles and should also bear in mind the two critical factors that influence the substance and worth of any scientific study: theory and method. As Pecchioni et al. (2005) note in their five propositions, theory and method must be carefully considered when exploring communication change.

### **Incorporating Communication Theory**

Developmental communication studies can incorporate theory from all paradigms of thought (Pecchioni et al. 2005). Pecchioni et al. note that, at one end of the spectrum,

interpretive and critical theories are useful in attributing meaning to social interaction as well as in unveiling factors that influence these experiences. For instance, an interpretive perspective – such as Fisher’s (1989) narrative theory – is useful in examining how we communicatively make sense of our social experiences across time through the use of stories. Similarly, critical approaches, such as power and language studies, aid in illuminating factors, like power, that impact communication over the life-span (→ Power, Dominance, and Social Interaction). At the other end of the spectrum, scientific theories enable scholars to examine more universal communicative patterns by using scientific methods to control variables in order to reach more generalizable conclusions from multiple data sets (Pecchioni et al. 2005). The latter approach is more common in the communication discipline as communication theory has typically been generated from this approach. For instance, expectancy violation theory can be used to examine how people react differently over time when their expectations of other people’s behavior have been violated (Burgoon 1994; → Expectancy Violation). In addition, Hirokawa & Poole’s (1986) functional approach is useful for scholars interested in communication development during group decision-making processes (Pecchioni et al. 2005; → Group Decision-Making, Functional Theory of).

In addition to the above-mentioned scientific theories, → communication accommodation theory (CAT) has greatly contributed to developmental communication research as well as to the communication discipline as a whole (Ryan et al. 1986; → Intergenerational Communication). Like many life-span studies, CAT views age as a marker related to change. In this case, age is a group identifier that influences behavior leading to generational differences in attitude and behavior. CAT posits that younger adults influenced by negative age stereotypes will over-accommodate their speech with elderly adults. As a result, older adults may encounter negative social experiences with younger generations, which may lead to their avoidance of future interactions. Scholars have also used CAT to advance various models of communication and aging stereotypes. Ryan et al. (1986) introduced the communication predicament of aging model (CPA) to demonstrate that in social interactions, age-related cues (i.e., physical appearance, age, behavior, and socio-cultural signs) activate age-related stereotypes that negatively affect intergenerational interactions, leading for example to over- or under-accommodation results (Coupland et al. 1988).

Even though many intergenerational interactions are influenced by negative stereotypes, Hummert et al. (1994) discovered that some stereotypes are positive (→ Social Stereotyping and Communication). Hummert (1994) extended CPA by proposing the age stereotypes in interactions model to include a stereotype activation cue that is influenced by the perceiver’s self-system, the context, and the physical characteristics of the older person – cues that can lead to either positive or negative outcomes. According to this model, when elderly adults are characterized positively, they are perceived to have fewer communication problems; therefore, we proceed with normal adult communication. Conversely, elderly adults who are characterized negatively receive age-adjusted communication. The communication enhancement model of aging (CEM) also extends the CPA model by considering the conditions that are necessary for positive intergenerational communication to occur (Ryan et al. 1995). This model recognizes that social partners must concentrate on individual needs in addition to group characteristics, in other words, not solely relying on age stereotypes. Recently, Barker and Giles (2003) presented a model that integrates the above-mentioned models and includes intragenerational communication

– an often ignored component, even though older adults reportedly stereotype against their own age group (Hummert 1994). Like Hummert's and Ryan's models, interaction outcomes can be either positive or negative. For positive outcomes to occur, we must accommodate differences in regard to communication effectiveness rather than just assumptions based on the other person's social identity.

By integrating communication theory and appreciating all paradigms of thought, developmental communication research can continue to be produced by well-guided means and studies can be replicated and compared by researchers today and in the future. Moreover, by generating knowledge grounded in theory, scholars have the groundwork to establish theories – and models – specific to developmental communication – an element of the discipline that is significantly lacking and, as is seen with research grounded in CAT, incredibly valuable (Nussbaum et al. 2002).

### **Capturing Communication Development over Time**

While developmental communication scholars should be attuned to integrating theory in their investigations, they must also choose methodologies that enable them to capture change over time (Nussbaum et al. 2002; Nussbaum & Friedrich 2005; Pecchioni et al. 2005). Life-span research, by its nature, is methodologically more difficult as studies must be designed in a manner that enables change actually to be captured rather than just suggested. This is challenging, but experts in various disciplines have already provided guidance to help scholars make better methodological choices.

A critical area of concern frequently discussed in the developmental literature is the issue of capturing intra- versus interindividual change. To date, most life-span communication research has examined interindividual change. These researchers typically utilize cross-sectional designs to compare communicative behavior between age groups. By doing so, scholars can only *suggest* behavioral change over the life-span. For instance, scholars examining adolescents' conflict communication can show that they behave destructively (Comstock 1994). They can compare such findings with data collected from older age groups, such as elderly adults, whose conflict management skills are more constructive, and hence, competent (Bergstrom & Nussbaum 1996). Hence, we can conclude that conflict communication becomes more competent with age. However, when and how these changes manifest is not captured. Consequently, cross-sectional studies often produce findings that lead to misinterpretations of intra- versus interindividual changes over time (Schaie & Hofer 2001; Nussbaum et al. 2002; Pecchioni et al. 2005), illustrating the point that in order to fully appreciate, examine, and interpret communication change, designs and methodologies need to *capture* change, not just suggest it. Scholars need to consider using new methodologies and data from multiple methodological approaches, and to re-evaluate results across time (Pecchioni et al. 2005). In addition, life-span scholars need to utilize a design that enables them to produce the most valuable data. Currently, scholars in various disciplines are recommending longitudinal designs (→ Longitudinal Analysis). Although this design is not immune to validity threats, it remains the best approach in comparison to others (Schaie 2005).

To support this idea, scholars refer to Baltes and Nesselrode's (1979) five rationales for longitudinal approaches when examining development over the life-span. They argue in

favor of this approach because it enables scholars (1) to directly identify intraindividual change as well as interindividual variance within intraindividual change, (2) to appreciate complex phenomena (such as communication) that require knowledge about multiple variables as they occur concurrently, (3) to recognize that development does not always occur in a continuous or same-speed process, and (4) to consider that while behaviors may remain the same for an individual over time, the causes of these behaviors may differ. In essence, these rationales exemplify the critical issue at hand: the need for scholars to capture intraindividual change – an element that has virtually been ignored due to researchers' preference for cross-sectional designs. According to Schaie (2005), data from a conventional cross-sectional design is limited as it only enables scholars to assess interindividual change. Moreover, it is often based on or contributes to the assumption that development is linear. On the other hand, longitudinal designs offer more realistic portrayals of development. They account for the reality that behavior may develop differently. Thus, these designs portray a nonlinear growth curve that encompasses both intra- and interindividual change. In light of this, scholars must formulate longitudinal studies to obtain data over time that takes into consideration inevitable elements of variability (e.g., cohort differences, an unstable environment), and in turn, depicts change more realistically (Schaie 2005).

Although longitudinal research is rare in the communication discipline, other fields – namely human development, psychology, and sociology – have produced studies that can be used as exemplars in constructing future communication studies via this design. These studies include the USC 30-year study of generations (Bengtson et al. 2002), the PAIR project (Huston & Vangelisti 1991), and the Seattle longitudinal study (Schaie 2004). In addition, Schaie (1965) produced a useful tool, the general developmental model, which combines both longitudinal and cross-sectional designs. In the model he also outlines three data collection methods (cross-sequential, cohort-sequential, and time-sequential) in which data is collected with the same participants over time (e.g., time 1, time 2, etc.). Communication scholars have recognized that this model is also an excellent resource to utilize to produce more longitudinal research (Pecchioni et al. 2005).

While methodological choices are a difficult and critical consideration, scholars also need to employ better statistical analyses. This improvement is being sought by developmental scholars across disciplines. According to Schaie (2005), developmentalists using longitudinal design and multiple methods have begun to alter how they measure change because it is now possible to apply very powerful statistical models that enable them to separate patterns individually rather than just assess group averages. Communication scholars are also backing this claim. Nussbaum et al. (2002) note that powerful statistical resources, such as multilevel modeling, are valuable in testing longitudinal hypotheses of developmental change. They note that linear  $\rightarrow$  *structural equation modeling* (SEM) allows researchers to consider variances and co-variances rather than just mean differences from t-tests or MANOVAs, the typical statistical procedures. Like SEM, confirmatory  $\rightarrow$  *factor analysis* can assess differences in communication phenomena within as well as across samples of different age groups (Schaie 2005). Thus, as new, more appropriate methods are utilized in developmental communication research, so too should scholars employ more sophisticated tools to analyze their findings ( $\rightarrow$  Statistics, Explanatory).

## SIGNIFICANT AREAS OF DEVELOPMENTAL COMMUNICATION RESEARCH

To date, experts in life-span communication have integrated theory into many areas of research using various methods. These studies support the need to examine communicative behavior developmentally, and simultaneously highlight the multidimensional nature of communication. According to these scholars, cognition, language, communication competence, relational change, and media effects are key areas of concern in developmental communication studies (Nussbaum et al. 2002; Nussbaum & Friedrich 2005; Pecchioni et al. 2005).

### The Foundation of Communication: Cognition and Language

Cognition and language are foundational roots of communicative behavior. Yet, as Pecchioni et al. (2005, 41) point out, neither is more important than the other. Rather, “the development of language, cognition, and communication are intertwined.” Hence, communication scholars must consider cognition and language in order to accurately explain and interpret the short- and long-term consequences of behavior.

*Cognition* refers to any thought process that involves the use, storage, and retrieval of knowledge (Nussbaum et al. 2002; → Cognition). Cognitive aging, itself, is a discipline that investigates changes in memory, learning, and intelligence as a function of age (Schaie 2004). These processes impact our social experiences, more specifically our communication efficacy, as early as infancy. Child development studies clearly depict a massive development in cognitive abilities early in life that directly impact children’s capacity to communicate effectively (Haslett & Samter 1997). While it was originally believed that this cognitive development was biologically driven (e.g., Piaget’s theory of early cognitive development), theorists today consider environmental influences, and hence, view cognitive and communication development as bidirectional (e.g., Vygotsky; see Haslett & Samter 1997). Yet, the trajectory of our cognitive development is clear. While this development is significant early in life, it levels off in midlife, followed by a slow decline in later life and a sharper decline after the age of 80 (see Schaie & Hofer 2001). Even though cognitive abilities decline over time, these declines (such as processing speed and retrieval of information) do not significantly impair our social interactions until they are very pronounced, either due to old age or mental pathologies. In addition, people often compensate for these losses by adopting other strategies in order to continue to thrive in their social world.

Like cognitive development, language skills also develop considerably during early life (→ Language Acquisition in Childhood). Moreover, language aptitude develops over the life-span and impacts social interaction. Reportedly, children show great variance in this area of development, likely due to both biological and environmental influences (Nussbaum et al. 2002). By the time children reach the age of 5, they have acquired basic language skills that affect interaction (sound, meaning, grammar, and discourse). By the end of early childhood, language skills slowly decline with the exception of vocabulary, which can continue to expand over the life-span. However, by later life, we begin to lose linguistic skills, primarily those related to syntactic and discourse processing (Ryan et al. 1991). By the age of 70, older adults may even lose competence in verbal fluency, vocabulary,

and verbal performance (Schaie & Hofer 2001). As a result of these declines, older adults are more likely to experience social interactions that may negatively impact their self-esteem (see CAT research).

Language and cognition enable us to transmit information and are a part of our social world. Communication scholars have the challenge of carefully considering these foundational elements of behavior – and how they overlap – while assessing communication change over time. As scholars continue to recognize the importance of this interplay in communication development, future studies will continue to enhance our understanding of interactive behavior.

### **The Development of Communication Competence**

Research in communication competence has been instrumental in capturing the developmental nature of communicative skills (→ Interpersonal Communication Competence and Social Skills; Communication Skills across the Life-Span). According to Parks (1994, 595) communication competence is “the degree to which individuals satisfy and perceive that they have satisfied their goals within the limits of a given social situation without jeopardizing their ability or opportunity to pursue their subjectively more important goals.” While communication competence is related to cognitive and linguistic capacities, acquisition and refinement of these skills is inherently linked with age and experience – in other words, time. Although developmental research in communication competence did not take off until the late 1980s and 1990s, developmental scholars asserted long before this that such skills were learned and cultivated with age. Thus, life-span communication scholars should be concerned with how these communication competencies develop over time.

To date, research in communication competencies has centered on specific points in time, namely child development. As communication competence is linked with linguistic competence – skills typically acquired during infancy and adolescence – this focus on youth is not surprising. Much of the research centers on two areas of communication development: verbal skills and communication knowledge. Haslett and Samter (1997) note that most verbal skills (e.g., word production, initiating conversations) are learned from birth up to the age of 5. From birth up to the age of 3, children learn that communication is interpersonal. Between the ages of 3 and 5, conversational competence begins, and after the age of 5 more complex verbal skills are learned, such as monitoring, evaluating, and repairing messages. With time, individuals also learn to integrate these skills into social experiences (i.e., communication knowledge). These competencies accumulate as early as one year from birth, and like verbal skills, continue to develop with age.

Although less prominent than research focused on child development, scholars have also examined communication competence during middle childhood (see Stafford 2004). During this period of life, children learn communication competencies in nonliteral language, code switching, appropriateness of roles, conversation rules, and more complexity in language organization, vocabulary, abstractness, and syntax (Stafford 2004). In other words, linguistic competence coincides with the development of communication skills. Similarly, cognitive growth is also linked to communication competence. As we age and

our cognitive skills become more sophisticated, so too do our interactive strategies. For instance, older children have more competence in perspective-taking, adapting messages, message design, counterarguing, as well as in attending to listeners' needs (O'Keefe 1988; → Message Design Logics). In addition, Stafford (2004) notes that social growth occurs as children learn to communicate more competently in a variety of settings (e.g., school, family, peers). During this time, they acquire skills such as caring behaviors, argumentation skills, and emotional/affective display rules – skills that have been found to develop further in later periods of life.

In sum, the findings indicate that communication competence develops over the life-span. Various areas of communication competence demonstrate this growth. Emotional support skills first emerge in middle childhood when the parent–child separation and adolescent struggle for independence begins (Burlison & Kunkel 2002). As we become more cognitively complex (or age), we become more competent in our ability to support others emotionally (→ Social Support in Interpersonal Communication; Support Talk). This development is also exhibited in conflict communication. Children begin to learn argumentation skills in middle childhood, such as persuasive messages and situation-specific arguments (Stein & Albro 2001). By later life, older adults prefer and utilize more solution-oriented or cooperative conflict strategies, and hence, are more communicatively competent (Bergstrom & Nussbaum 1996; → Conflict and Cooperation across the Life-Span).

Clearly, with age, our communication skills become more competent. Hence, communication competence is a developmental phenomenon and should be examined as such. In addition, it is crucial that scholars take into account the interplay of cognition and language, as communication is grounded in these phenomena. By doing so, scholars can better examine how we develop and refine our communicative behaviors to adapt to life changes over time.

### **Relational Change**

Communication scholars have also produced a multitude of studies on relationship change (→ Relationship Development; Relational Maintenance; Relational Termination). Ultimately, due to cognitive growth alone, relationships are bound to change over time (Cohen 1981). Nonetheless, relationships are also influenced by life events that alter roles, dynamics, and expectations (Pecchioni et al. 2005). For these reasons, relationships are not stable phenomena, and the communicative behaviors used to adapt to relational changes are also not stagnant. Research to date illustrates the dynamic nature of relational communication in both family and nonfamily bonds. Therefore, it further supports the need to examine relationships and communication developmentally.

Studies across disciplines show that families change over time as relationships evolve or cease; members are born, welcomed, or lost; and the structure as a whole is altered. Family scholars have been examining family changes for the most part of the twentieth century. They have termed this approach the family life cycle (Duvall 1957), family development (Rodgers & White 1993), life-span (Hagestad & Neugarten 1985), and life course (see Price et al. 2000). Today, communication scholars also examine family from this perspective and have provided insight into how relationships and communication

change over time in the following bonds: parent–child; sibling; marital; and grandparent–grandchild (→ *Family Communication Patterns*).

The parent–child bond has been examined developmentally during the child’s adolescence (Haslett & Samter 1997), during midlife (Putney & Bengtson 2001) and during the parent’s old age (Fingerman 2003). During these time periods, the bond experiences role changes, variation in closeness, struggles of power and control, and at the same time encounters normal and non-normative transitions that alter the nature of relationships, such as health crises, divorce, marriage (Pecchioni et al. 2005). During these changes, parents and children are challenged to cope by adapting the way they communicate. For example, during the child’s adolescence, parents must learn to adjust communicatively to the child’s desire for independence and simultaneously manage their own midlife changes, such as “juggling” multiple roles and encountering unexpected transitions such as divorce (Fingerman et al. 2004). In later life, aging parents may have to adjust to being cared for by their adult children by communicatively adapting to changes in power dynamics and independence (Fingerman 2003).

Siblings also experience incredible change over time, and yet display a life-span of closeness that significantly impacts their lives (→ *Sibling Interaction*). Cicirelli’s extensive work has shown that siblings experience several relational changes in closeness. The relationship begins with a high level of closeness in early life, there is then a loss of closeness in midlife, and finally, closeness resumes in later life (Cicirelli 1983, 1991). Early in the life-span, siblings encounter life events, such as leaving home, that may lead to distance in their relationship; however, during later life, when siblings have more in common, they often become a significant source of social support to one another (Nussbaum et al. 2000). Although even less studied, research also indicates that the grandparent–grandchild bond experiences communication change in response to transitions. For instance, when parents divorce, grandparents and their grandchildren may lose contact or see one another less frequently (Noller & Fitzpatrick 1993). As a result, they may employ new communication strategies to maintain the relationship. Age also plays a role in how this bond develops. For instance, older grandchildren perceive their grandparents’ role differently in comparison to younger grandchildren, which ultimately impacts how they communicate (Pecchioni et al. 2005). In addition, younger grandparents tend to be closer to their grandchildren than older grandparents; consequently, cohort differences may impact this bond’s development.

Though not widely studied, bonds outside the family also experience dramatic changes over time. Of these voluntary relationships, friendships have received the most scholarly attention (→ *Friendship and Communication*). Though little is known about friendships on the macro-level, these studies highlight how the meaning of friendship evolves, how conversations with friends change with time, and how friendships play different roles at various stages of life (Pecchioni et al. 2005). Like other bonds, the friendships are influenced by cognitive, linguistic, and communicative development (Haslett & Samter 1997). Patterson et al. (1993) found that the meaning of “best friends” becomes more complex with age. In pre-adolescence, friendships are based on play or shared activities (Haslett & Samter 1997). By adolescence, friendships influence identity formation (Haslett & Samter 1997). From young adulthood through middle adulthood, the number of friendships decreases as other aspects of life (e.g., career, marriage, and children) influence the nature of the bond (Pecchioni et al. 2005). Yet, by later life, older adults’

friendships are often considered a critical component to successful aging as they become a significant form of social support. Research shows that friendships in later life provide a critical source of social contact, offer a context in which to manage health decline both emotionally and physically, and act as a primary source of emotional comfort not received from family (Nussbaum et al. 2000).

Thus relational changes are evident across time. Likewise, communication changes within voluntary and nonvoluntary bonds occur as the relationship evolves and encounters new circumstances. It is evident that communication scholars need to approach such studies from a developmental perspective that takes into account the dynamic trajectory of change both relationally, communicatively, and individually.

### **Media Effects**

Media exposure has greatly increased in recent years, which heightens the need to examine media influences on communication over the life-span (→ Advertising: Responses across the Life-Span; Attention to Media Content across the Life-Span; Educational Television, Children's Responses to; Media Use across the Life-Span). Wilson and colleagues' studies reflect how media exposure leads to short- and long-term consequences (see Strasburger & Wilson 2002; and Wilson 2004 for reviews). A notable media influence, television, plays a large part in how we formulate and evaluate our social world, and even impacts development into adulthood (Strasburger & Wilson 2002; Wilson 2004). Rather than just being influenced by friends, peers, family, and real-life social experiences, children are now noticeably impacted by what they see on TV. According to Wilson (2004), media shapes behavior, views, and expectations of family life behavior. Studies show that family communication patterns predict media habits and that media exposure can lead to conflict and power struggles between family members (see Wilson 2004). Moreover, these exposures affect perceptions of beauty and health, violence and aggression, and can even endorse stereotypes (see Strasburger & Wilson 2002). Additionally, more TV viewing in children is associated with negative long-term outcomes such as the potential for aggression and violence (see Strasburger & Wilson 2002; → Violence as Media Content, Effects on Children of).

Ultimately, these media effects are related to cognition. As children cognitively develop in youth, they utilize these skills to interpret their social world, as well as what they view on TV (Strasburger & Wilson 2002). Recently, Valkenburg & Cantor (2001) produced a typology that descriptively characterizes cognitive development in accordance with media consumerism. During the first stage (infancy), primary information concerns are centered on the senses: smells, colors, sounds, and objects. During the second stage – preschool years – cognitive processing is still unsophisticated as children cannot distinguish between advertisements and sitcoms and also cannot identify the intent of programming. Interestingly, however, social relationships do influence our consumerism during this stage. For instance, when preschoolers are accompanied by an older sibling while watching a suspenseful program, they are less likely to experience fear (Weiss & Wilson 1998). During the third phase or elementary years, cognitive aptitude increases, and by the end of this stage, the foundations of consumer behavior are set (Valkenburg & Cantor 2001). Children can categorize information into schemas and are better at information processing (Strasburger &

Wilson 2002). Their perspective on what they see on TV affects how they behave and perceive real-life events (Strasburger & Wilson 2002; Wilson 2004). For instance, during these years, children perceive that families on TV are realistic, even though studies show that TV programming typically portrays families too idealistically (Weiss & Wilson 1998). Hence, by the time children enter elementary school, exposure to media has cultivated an unrealistic view of the social world, which ultimately influences interaction (Wilson 2004). In other words, part of our interactive learning comes from unrealistic representations on TV. As a result, scholars have recently been advocating mediation, suggesting that families should exercise more control over children's media exposure (Wilson 2004; → Parental Mediation Strategies). According to Wilson, by producing more studies, particularly longitudinal research, scholars can gain a more comprehensive understanding of the long-term effects of media on interaction.

### FUTURE DIRECTIONS

Today, developmental communication scholarship has expanded and enhanced the stature of the discipline by contributing theory-grounded knowledge of human interactive behavior as a dynamic process. However, it should be noted that research has predominantly centered on communication at certain points in time (youth or later life). Consequently, a lack of knowledge of communicative behavior over the entirety of the life-span still persists. In addition, outside of life-span research, communication as a developmental phenomenon is still rarely integrated into studies. According to Pecchioni et al. (2005, 14) it is not an understatement that "communication as a developmental phenomenon has been systematically ignored in the discipline."

Nussbaum & Friedrich (2005) note that advances in this area of research should continue with the following two issues in mind: (1) expand the scope of the life-span to include it in its entirety; and (2) utilize the most appropriate and optimum methodologies to capture change. For instance, communication scholars need to pay more attention to overlooked areas in the life-span (midlife and young adulthood) and become more familiar with methodologies such as longitudinal design and multilevel modeling. In doing so, scholars can help contribute to our understanding of communication as a developmental phenomenon and continue to extend knowledge of the dynamic nature of communication in our social world.

## Dialogic Perspectives

J. Kevin Barge

Texas A&M University

Multiple intellectual traditions exist within a dialogic perspective toward organizational communication. These intellectual traditions share a common set of theoretical inclinations that distinguish a dialogic perspective by focusing on discourse, holism, and tensionality (Stewart et al. 2004). First, dialogic approaches emphasize the *centrality of discourse*. A dialogic perspective focuses on both “little d” and “big D” discourse, with the former centering on language-in-use and the latter spotlighting enduring systems of thought, feeling, and action that structure the way organizational members make sense of and act in their social worlds (Fairhurst & Putnam 2004). Second, dialogic approaches are *holistic* as they emphasize the interplay among communication, context, action, and meaning. Third, dialogic approaches view human systems as riddled with *tensionality*, which requires theorists and researchers to articulate the tensions constituting a system and how individuals attempt to manage them (→ Organizational Discourse).

Dialogic perspectives are also marked by difference, as some intellectual traditions use dialogue as a descriptive term and others employ it as a prescriptive term (Stewart & Zediker 2000). A *descriptive approach* to dialogue views all human life, communication, and meaning-making as dialogic whereas a *prescriptive approach* views dialogue as a particular type or style of relating and communicating. Three intellectual traditions toward dialogue have emerged within organizational communication: (1) dialogue as a form of critical thinking and deliberation, (2) dialogue as a form of relational practice, and (3) dialogue as a form of discursive coordination (→ Deliberativeness in Political Communication).

Dialogue as a *form of collective thinking* and deliberation is best reflected in the work of David Bohm (1990) and the MIT learning organization project (Senge 1990). Dialogue is conceptualized as a special form of meeting that occurs at particular moments when people gather to explore how their thought patterns control their interactions. Dialogue as a form of collective thinking allows individuals and groups to explore how each makes meaning in situations, to become aware of the incoherence in their thoughts, and to establish a common pool of meaning that facilitates learning. Dialogue is a prescriptive phenomenon that emphasizes the importance of setting ground rules to create safe space for conversation and mastering the abilities of inquiry and advocacy (Isaacs 1999). Organizational

members who wish to create dialogue maintain a tension between accepting and rejecting their own thoughts, beliefs, and feeling through a process known as suspension.

Dialogue as a *form of relational practice* is best reflected in the work of Martin Buber. Buber (1998) characterizes dialogue as an ability to stand one's own ground while being profoundly open to the other. Dialogue facilitates organizational members creating I–Thou relationships where they enter into authentic communication with one another. Dialogue is a prescriptive form of interaction that emphasizes individuals being authentic, present, and accepting with others while communicating. Buber's work has been particularly useful for exploring the notions of otherness and spirituality within organizational communication processes and how organizational members can create genuine meeting with one another (Black 2005).

Dialogue as a *form of discursive coordination* is highlighted in the work of → Mikhail Bakhtin as well as Kenneth Gergen. Bakhtin (1981) is concerned with the dialogic qualities of language where dialogue is used as a descriptive term to highlight interrelatedness among self and Other in language and being. Dialogic practices are aimed at furthering meaning-making and creating patterns of coordination by managing the tensions among multiple voices and Discourses. Organizational members must learn how to make wise choices about how to structure their discourse and what Discourses need to be foregrounded and backgrounded if they are to orchestrate successfully working relationships (Barge & Little 2002).

Most recently, Gergen et al. (2004) contend that all communication is dialogic, involving relational coordination as people organize their activity from within the flow of communication. Gergen et al. have developed a descriptive approach that articulates different patterns of dialogic interaction. Generative dialogue occurs when the meaning-making potential of a previous communication is elaborated by subsequent communications, whereas degenerative dialogue occurs when the meaning-making of a previous communication is negated by successive communications. Generative dialogue is the basis for successful organizing because the process of successive affirmation creates a stable, yet fluid, image that individuals can co-orient around and so sustain their activity. One important exemplar of dialogue in Gergen et al.'s approach is an appreciative approach to organizational development and management that emphasizes picking up and spotlighting life-generating qualities of previous organizational activity and leveraging them to create new forms of meaning-making and action (Barge & Oliver 2003).

## Diffusion of Information and Innovation

*James W. Dearing*

*Kaiser Permanente Colorado*

*Do Kyun Kim*

*Northeastern University*

### THE DIFFUSION PARADIGM

*Diffusion* is a multifaceted perspective about social change in which people, innovations, and the media environment affect how rapidly change occurs. Scholars dating back at least to the German social philosopher Georg Simmel and the French sociologist Gabriel Tarde theorized about imitative behavior at the level of small groups and within communities, and the relation between these micro-level processes to macro-level social change. In the 100 years since, researchers have tended to conceptualize diffusion either at the macro sociological level of sector, system, national, or state change (Dearing et al. 2006), the social psychological or communicative level of local relationships and how those linkages affect adoption patterns as in the classic studies by Katz & Lazarsfeld (1955) and by Rogers & Kincaid (1981), or the psychological level of how individuals perceive innovations in the form of a codified set of pros and cons (Manning et al. 1995). Beginning in the 1960s, diffusion concepts have been operationalized and used to purposively spread pro-social innovations through → development communication in Colombia, Pakistan, Brazil, Nigeria, India, Finland, Korea, Tanzania, Bolivia, and Vietnam (see, e.g., Puska et al. 1986).

Since 2000, diffusion studies have traced and explained the spread of kindergartens across cultures throughout the world, the spread of schools-of-choice policies among the 50 states in America, the diffusion of tobacco-control policies back and forth between Canadian and US political jurisdictions, the adoption of participatory approaches in

community health system planning, the spread of e-commerce, and the online spread of social norms among adolescents. Studies such as these form the basis of the generalized codification of key concepts and the general over-time pattern of diffusion from a literature of more than 5,500 publications as best synthesized by the communication scholar → Everett Rogers in his successive editions of *Diffusion of Innovations*. Diffusion concepts have also contributed importantly to theoretical and conceptual development of social learning theory, technology transfer, dissemination strategy, → social network theory, → entertainment education, and now the science and practice of translational studies (Singhal & Dearing 2006).

### MAIN ELEMENTS OF DIFFUSION

Rogers (2003, 5) defines *diffusion* as “the process in which an innovation is communicated through certain channels over time among the members of a social system.” An *innovation* is anything that potential adopters perceive to be new, inclusive of new ideas and beliefs, explicit and tacit knowledge, processes and protocols, tools and technologies, even value belief systems. The first 2.5 percent of adopters are *innovators*; the next 13.5 percent *early adopters* (a category that includes the subset of *opinion leaders*); followed by the *early majority* (34 percent), *late majority* (34 percent), and *laggards* (16 percent). Diffusion conceptualizes individuals as progressing through stages of change as they first confront, make sense of, and then routinize that which was new to them (→ Stages of Change Model).

Newness is key in diffusion processes, since the perception of newness creates uncertainty in the mind of potential adopters about what they should do or how they should respond to the opportunity presented to them about the innovation. Uncertainty, in turn, leads to a feeling of discomfort or → cognitive dissonance, which propels the individual to seek out, first, descriptive information about the innovation (typically through efficient mediated communication channels such as the Internet), and then evaluative information about how well the innovation performs (most often through nonmediated and mediated interpersonal discussion and observation of others’ behaviors). It is at this point that perceptions of the attributes of innovations become important. Simplicity, low cost, effectiveness, how observable the results of an innovation are, and how trialable an innovation is are all attributes positively related to individual-level adoption and system-wide diffusion.

Thus, in diffusion processes, communication of information through mass and specialty media often precedes the communication of personal influence through informal communication networks, especially local networks. Because people tend to communicate with others whom they recognize as similar to themselves, real and perceived heterophily slows diffusion. Innovations can spread rapidly within one clique or network of like individuals, and then take years to achieve acceptance in other networks where members differ in terms of demographics, ethnicity, behavior, and situation.

### LINKING MACRO- WITH MICRO-PHENOMENA

Many diffusionists take a macro-structural perspective on diffusion, especially those in population planning, demography, economics, international relations, anthropology, and

**Figure 1** Diffusion is a nonlinear over-time process of social influence

linguistics. Such scholars conceptualize waves of innovations washing over societies, and serving as the means by which social change occurs, as in → agenda building or → agenda setting. Their units of adoption are countries or cultures. A macro-orientation to diffusion is highly enticing to scholars because of its deductive and parsimonious potential based in a simple mathematical law of nature that describes a logistic (S-shaped or exponential) growth curve (see Fig. 1). Marketing scientists, epidemiologists, demographers, and political scientists create and test mathematical models of diffusion, based on this predictive potential and eloquence (→ Marketing).

Other scholars, including many in communication studies, conceptualize diffusion at a micro level of analysis of focusing on the predictors of positive adoption decisions of individuals or organizations, or interpersonal relations and how they mediate the effects of information exposure about innovations, or local social networks and how network position is related to adoption decisions (→ Interpersonal Communication).

The diffusion paradigm is noteworthy, especially in the work of Rogers (2003), for deliberately offering explanations based on empirical studies of how macro-change processes are linked to micro-individual- and group-level processes. The explanations offered show both how micro-level units of adoption (usually people) are influenced by system norms, as well as how system change is dependent on individual action. Diffusion is one of the very few social theories that persuasively links macro- with micro-level phenomena.

### **MASS MEDIA, SPECIALTY MEDIA, AND NEW MEDIA**

Mass communication channels are the most efficient means for spreading awareness of innovations that have popular or broad appeal. When the innovation in question is only an idea, as in knowing something new, awareness equates with adoption. Often, however, agencies or organizations have objectives that require more of adopters. To adopt, they

must engage in a new practice, buy a new service, or commit to learn a new routine. In these cases, mass communication functions to raise awareness and, for some, produce information-seeking behavior. For innovations with specialized appeal, such as new medical procedures or disease-prevention interventions, specialty media in the form of targeted magazines, industry newsletters, and conference presentations function to spread awareness.

The promise of new media, especially the Internet and portable telecommunications, is high, and not only for speeding up the awareness of innovations. New media, especially formats such as tailored interactive web pages that allow for portrayals of innovations, can be designed to encourage choice and a sense of ownership among potential and actual adopters, to show social modeling of the innovation, and to increase efficacy. Customized websites can, for example, increase the likelihood that modifications made during the implementation of adopted innovations will not be counter-productive. Insisting on innovation fidelity by discouraging or prohibiting adaptation is negatively related to adoption. Portable digital assistants and cell phones can be used to reinforce decisions in diffusion-based health campaigns (→ Health Campaigns, Communication in).

### **INNOVATION QUALITY AND DIFFUSION**

Many people assume that high quality, especially when paired with low cost, will result in rapid diffusion. This expectation is often not met. Many innovations that have a tangible basis spread because of other factors, such as bandwagon effects in which managers or administrators are afraid of lagging competitive rivals, or because the decision to adopt is decoupled from responsibility for implementation. In both cases, diffusion can be extensive, but implementation and use can be quite limited.

The diffusion literature includes many examples of advantageous innovations that do not achieve widespread use, even after many years, and even when campaigns are conducted to publicize them. This is so even for highly effective “best practice” innovations that have demonstrated, empirical advantages compared to alternative ways of achieving the same ends, and it is so even when studying diffusion within the same organization, where the rate of adoption might be expected to be more rapid than the adoption across separate organizations. Concerning innovation diffusion, what is best and what is used are frequently different. For example, in the field of health promotion, a computer simulation by Stover et al. (2002) found that if proven programs in HIV/AIDS prevention were actually adopted worldwide, 29 million new infections could have been prevented by 2010.

Cases from the diffusion literature do not stop at highlighting effective innovations that do not diffuse; we also have cases of innovations with very important implications for adopters that spread prior to the communication of any information about their effectiveness, such as in the rapid imitation of strike behavior by eighteenth-century coal miners as studied by Conell & Cohn (1995). Fads and fashions occur regularly; having an innovation received by potential adopters as fashionable can be highly desirable. Yet other studies have documented the diffusion of ineffective innovations.

In sum, while effectiveness is typically positively related to positive adoption decisions, the correlation can be weak, with other factors more highly correlated with adoption. Social influence is one of those factors.

## DIFFUSION AS A SOCIAL PROCESS

Opinion leaders influence the decisions that others make about innovations that are communicated to them (Weimann 1994; → Opinion Leader). Opinion leaders are the reason why diffusion can be such a very efficient process to jump-start: an innovation source or sponsor need only communicate an innovation to a special small subset of all possible adopters for the innovation to spread through a social system. Their existing influence and the extent to which followers monitor the attitudes and behaviors of opinion leaders can do the rest as long as opinion leader attitudes are favorable toward the new practice, and followers positively identify the opinion leader with the innovation. The social influence of opinion leaders either by talking or by example-setting is what drives the diffusion curve up, giving it its characteristic “S” shape. Opinion leaders are also responsible for innovations *not* diffusing, by ignoring an innovation (passive rejection) or speaking out against it (active rejection). Studies of higher-order aggregates demonstrate opinion leader effects through interorganizational networks, and among counties and nations (→ Interorganizational Communication).

Different people take different lengths of time to adopt innovations. For some, only one or two people in their personal networks or “reference groups” are required to adopt before the focal individual then adopts; for others, nearly all others in their personal networks or reference groups must adopt before the focal individual finally converts. These differences are *thresholds* that vary from person to person for any particular innovation.

Beginning with the empirical results of Ryan and Gross (1943), diffusion has been understood to be a social process. While knowledge is often gained through the largely one-way communication of information, especially with the increased information search capabilities of new communication technologies, persuasion occurs through the two-way communication of social influence, most commonly in the form of local informal opinion leaders who are already in place and who already influence the decisions of others. Information alone, whether in one-on-one counseling, training workshop, website, brochure, etc., is insufficient to move the individual toward a positive decision or even serious contemplation of innovation costs and benefits when the innovation in question is perceived to be consequential by the potential adopter.

Opinion leaders are perceived as expert and trustworthy, influential, credible, popular, a near-peer friend, and accessible. The trait of *opinion leadership* tends to be stable across time, and operates consistently across social systems such as hospitals, schools, towns, and distributed networks. In intervention work, opinion leaders are especially effective when they are not asked to do too much. Asking opinion leaders to advocate, persuade, promote, or educate in ways they normally would not with their colleagues is asking them to risk their status within the system in question by formalizing what is an informal role.

## **Digital Divide**

*Sandra J. Ball-Rokeach*

*University of Southern California*

*Joo-Young Jung*

*University of Tokyo*

“The digital divide” terminology is often used in policy discourse to refer simply to access to information and communication technologies (ICTs). It is a misnomer in at least two ways. First, it suggests that there is something new and different about the particular information and communication inequalities that surround digital technologies, whereas it is just the most recent case of inequality spawned by the advent of new ICTs (→ Information and Communication Technology, Development of). Hence, we should include a historical perspective in our examination of communication technologies and inequality (see, e.g., Marvin 1988). Second, it is the definite article *the* in “the digital divide” that

falsely suggests a single dimension dividing people into haves and have-nots when it comes to ICTs. *Digital divides* are better conceived as occurring at multiple levels of analysis and as a multidimensional phenomenon (Norris 2001).

### MULTIPLE LEVELS OF ANALYSIS: INDIVIDUALS, COMMUNITIES, AND COUNTRIES

One of the first things that researchers do when a new technology emerges is to track its diffusion through the population to note differences between the people who have early access and those who do not. The idea of a divide comes with the belief that access privileges people in some way; for example, people with access can communicate farther, more quickly, more easily, and less expensively than people without access (→ Access to the Media). With respect to ICTs, there are continuing large-scale survey research efforts to track patterns of access and utilization. These are generally at the *individual or household level of analysis*. Some of the better known are the Pew Internet and American Life Project which began its reports in 2000; the US Department of Commerce (2004) which began reporting in 1995, a series of reports by German public stations ARD and ZDF since 1997, and the World Internet Project, an international collaborative project looking at the impact of ICTs. These and other micro- or individual-level studies produced a familiar pattern. Those with relatively early access to ICTs tend to be relatively well educated (Howard et al. 2002), at higher income levels (Chakraborty & Bosman 2005), younger (Loges & Jung 2001), and members of a majority race or ethnicity (Kim et al. 2002; → Exposure to the Internet).

While the majority of studies are done at the individual or household level, ICT inequalities are also meaningfully analyzed at the *level of community* or residential area. There are, in other words, divides between communities that are or are not able to take advantage of resources that are available in digital form; for example, resources offered by institutions that concern quality of everyday-life dimensions such as health, transportation, leisure, education, and political representation. Communities that have integrated the → Internet and other ICTs into their indigenous → communication infrastructures (Matei & Ball-Rokeach 2003) are prepared to engage the digital worlds in and around them. There are many efforts to close community-level digital divides (e.g., Hayden & Ball-Rokeach 2007; → Community Integration). Researchers have found that interventions to close community-level digital divides are most successful when they take into account the existing and particular communication infrastructure of a community and adjust their efforts accordingly (Borgida et al. 2002). For example, some communities may benefit more from building a local network, while an Internet cafe may be more beneficial in others (Ferlander & Timms 2006).

In addition to the individual/household (micro) and community (meso) levels of analysis, there are studies of *digital divides between nation-states* (macro). According to a report of the International Telecommunication Union (2006), the average level of Internet penetration in the world was 13.3 percent in 2004. In this instance the haves are generally the developed world and the have-nots are the developing nations. For example, Europe and the Americas had penetration rates of 31 percent and 28 percent, respectively, while Asia and Africa had lower rates of Internet penetration – 8 percent and 3 percent, respectively.

The study of ICT digital divides has also been grounded in the context of larger issues of globalization. An important aspect of these inquiries is attention to the active negotiations of technologies by developing countries and marginalized populations. These often overlooked groups may create rich networks of association and commerce utilizing inexpensive versions of ICTs such as Internet cafes, prepaid phone cards, or mobile phones. Cartier et al. (2005), for example, refer to such negotiations by rural-to-urban migrants in China as the activities of “the information have-less.” Wilkin et al. (in press) observed that even in a global city like Los Angeles, it is possible for some new immigrant groups (e.g., Latinos) to have very low rates of Internet connection, relying on lower-tech technologies to maintain their networks of association.

### THE MANY DIGITAL DIVIDE DIMENSIONS

In addition to the vertical dimension of ICT access (haves/have-nots, have-less) that are of primary concern in the early diffusion of digital technologies, horizontal dimensions of digital divides emerge as people go beyond access to consider qualitative dimensions of how ICTs are employed in daily life. For example, the technological quality of connection is likely to affect people’s Internet use. In terms of broadband penetration rates, there are significant differences across countries. In 2006, South Korea led all countries with 83 percent broadband penetration, followed by Hong Kong (81 percent), Iceland (74 percent), Israel (69 percent) and Taiwan (65 percent) (Cox 2006). The speed and ease of connecting to the Internet is likely to affect the frequency of Internet use and the range of Internet activities (US Department of Commerce 2004).

Hargittai (2002) speaks of a *skills divide* or a “second-level digital divide.” Among those with relatively good ICT access, there are profound differences in the skills people develop when they engage ICTs. Generally, the people who develop higher-level Internet skills are well-off (Jung et al. 2001) and better educated (Bonfadelli 2002). Socio-economic differences have been observed in the adolescent population, again with higher socio-economic status being associated with a higher skill level (Jung et al. 2005). Given the importance of ICT skill level to issues of education and employment, studies are beginning to examine students’ educational achievement as a function of Internet skill level (Huang & Russell 2006).

As with any other communication technology, there are wide variations in what people do with ICTs in the course of seeking to achieve everyday-life personal and social goals. What people do on the Internet, for example, may reflect individual differences (e.g., skill level or personal goals), but often these differences are grounded in their socio-cultural and ethnic orientations (Kim et al. 2002). Another important source of variation is age (Loges & Jung 2001). Age, of course, reflects the widely varying histories of cohorts or people with respect to their information and communication practices. The socio-cultural differences associated with gender (Kennedy et al. 2003) and occupation (Thompson 1998) have also been found to affect the ways in which people engage ICTs in everyday life.

There are substantial divides or differences in *how people go online*, and these may affect what they are willing and able to do online. For example, whether people go online mainly on a home computer or on a computer at another location, or whether they go online with personal computers or with mobile devices, are important factors that are likely to affect

what they can or will do online. How people go online can depend upon individual choice, but it is also largely affected by the national ICT infrastructure. A case in point is Japan where, because connection to the Internet via mobile phones developed earlier than Internet connection via home computers, more people go online via their mobile devices than via home PCs (Ito et al. 2005). For example, 33.5 percent of Japanese Internet connectors access the Internet exclusively via mobile phones (NICT 2005), fewer people (28.3 percent) access the Internet exclusively via PCs, and 38.2 percent use both mobile phones and PCs.

Another horizontal or qualitative difference that might be viewed as a divide is the *relative importance of the Internet and other ICTs vis-à-vis other media*. This issue bears upon the position of ICTs in a larger media and communication ecology. Researchers have examined variations in people's Internet behavior in context of their home environment where many other media are present (Beentjes et al. 2001). Another approach to this issue is to ask people how much they would miss the Internet if it were unavailable (Jung et al. 2005) or by asking people to choose which media they would give up if forced to do so (USC Annenberg School Center for the Digital Future 2005).

It is important to examine multilevel and multidimensional digital divides in the light of Castells' observation: "The fundamental digital divide is not measured by the number of connections to the Internet, but by the consequences of both connection and lack of connection" (Castells 2001, 269). Discussions of the digital divide need to be grounded in their historical context and within the larger issue of communication technology and inequality. In the scholarly literature, discussions about the digital divide have become increasingly critical of this terminology and have begun to contextualize various kinds of divides within the broader contours of society. Nevertheless, this terminology continues to be widely used in policy settings, often being juxtaposed with debates about "digital opportunities." Future research will continue to be focused on the many dimensions of these divides, on the reasons that this language maintains its currency in national and international policy debates, and on the social, political, and economic consequences of failures to adequately address the complexity of the issues in this area.

# Digital Imagery

Paul Messaris

University of Pennsylvania

Two distinct processes can give rise to digital images. On the one hand, they can be created entirely by computer, as → animations or as single computer-generated images. On the other hand, they can be produced photographically, through digital cameras and camcorders, or through the digital scanning of photographs originally recorded on celluloid (→ Photography). When a real visual scene is photographed digitally, the scene's pattern of light and color is translated into a rectangular grid of pictorial elements, known as pixels. Variations in brightness or color from one pixel to another are recorded in terms of discrete, fixed units – hence, “digitally” – instead of the continuous gradations employed by analog media.

These properties of digital photographs, which are also characteristic of wholly computer-generated images, have substantial technological consequences. Digital images can be copied repeatedly with no significant loss of information between one generation and the next. Likewise, they can be transmitted without significant loss across computer networks. Perhaps most notably, from a communications perspective, digital images that started out as photographs can be manipulated and altered by computer.

## POTENTIALS OF DIGITAL IMAGERY

Because of the dominant position of Adobe Photoshop in the market for photo-manipulation software, the term “photoshop” has now entered the dictionary as a synonym for the act of computerized photographic manipulation. The term is also commonly used to refer to the manipulated image itself. However, software for the manipulation of photographs had been in use for at least a decade before the commercial release of Photoshop in 1990. A notable early instance was the February 1982 cover of *National Geographic* magazine, in which the position of an Egyptian pyramid was shifted in order to create a more pleasing design. Popular media portrayals of computerized photo-manipulation often paint an exaggerated picture of what it can accomplish. For example, in the 1998 movie *Wag the Dog*, a single tap on an editing keyboard instantly transforms one object into another in a news video.

The actual capabilities of Adobe Photoshop and similar software are much better represented by the *National Geographic* example. As far as substantive changes in an image are concerned, the *capabilities that matter* most are the following: (1) the ability to detach an object in the image from its background more precisely and more efficiently than was typically the case through traditional cut-and-paste methods; (2) the ability to selectively resize portions of an image relative to the rest of the image; (3) the ability to clone parts of an image and paste the cloned patterns, colors, or textures elsewhere in the image; and (4) the ability to change an image's brightness, contrast, and/or color values in a much less cumbersome manner than that entailed in traditional photographic darkroom work. In one combination or another, these four types of operations have been

responsible for a series of photo-manipulations that have periodically raised public concerns about the social implications of digital imaging. The first two are exemplified by the notorious post-9/11 hoax entailing the insertion of an incoming airliner in a photograph of a tourist on the observation deck of the World Trade Center (an image subsequently rumored to have been retrieved from a camera that was found in the buildings' ruins). During the Israel–Hezbollah war of 2006, cloning was used to amplify the smoke over Beirut in a news photograph that led to the dismissal of a Reuters stringer. And, following O. J. Simpson's arrest on suspicion of murder, the fourth type of manipulation was used to darken a *Time* magazine reproduction of his booking photograph (→ Picture Magazines).

### PROS AND CONS

Two somewhat contradictory tendencies recur in scholarly analyses of this aspect of digital imaging. On the one side are those writers who are concerned about the *erosion of the evidentiary value of photography*. In a book originally published in 1990, Fred Ritchin (2006) describes the sense of dislocation and rupture that he felt when he realized that a news image of Tom Cruise and Dustin Hoffman was actually a digital composite and that the two actors had never been in the same physical space when the original photographs were taken. As Mitchell (1992) has argued, during a century and a half of traditional photography, the chemical basis of image creation had underwritten public belief in a causal link between photographs and reality. According to Mitchell, the advent of digital imaging has severed that link and ushered in a new, "post-photographic era," in which photographs are now no closer to reality than handmade pictures or other non-photographic images are.

In seeming opposition to such views, though, other writers have argued that the *idea of photographic truth* has always been an illusion and that concerns about digital lying are misplaced (Kember 2003). According to the authors of a theoretical treatise on new media, "Digital photography poses a . . . threat for those who believe that the traditional photograph has a special relationship to reality. . . . But in any case photographic 'truth' was not unassailable even in the nineteenth and early twentieth centuries" (Bolter & Grusin 1999, 106).

Indeed, photographs that were recorded on celluloid and printed on paper have always been subject to alteration through cutting and pasting. Moreover, as photo-editor Kenneth Brower has pointed out, such darkroom manipulations as "burning" or "dodging" – i.e., selectively over- or under-exposing portions of a photographic print so as to emphasize certain features and suppress others – were considered routine, unremarkable elements of standard photographic practice (Brower 1998) .

Finally, since every photograph is the product of an inevitable act of selection as to where and when to record an image, there is a sense that no photograph can avoid manipulating reality (Lang & Lang 1971). With these considerations in mind, writers such as Julie Newton (2001) have argued that, far from representing a radical departure from earlier photographic culture, what digital images have brought about is a heightened appreciation of the complex nature of photographic truth and falsehood. This awareness is reflected in the work of professional photojournalists and editors, who are reportedly more attentive to certain practices, such as cropping, which might previously

have passed without comment (Gross et al. 2003), and it is also evident in the writings of academic authors with photojournalistic experience, who have invested considerable effort in the delineation of the boundaries and contexts separating acceptable from unacceptable forms of visual manipulation (Wheeler, 2002; Lester, 2005; → Image Ethics). In a related development, the systematic detection of digital manipulation has received increasing attention from such writers as Brugioni (1999), and Hany Farid has developed a substantial body of computerized techniques for that purpose (Lyu & Farid 2005; Popescu & Farid 2005; Farid 2006).

What is less clear is how the broader public views these matters. Vicki Goldberg has noted that, even as early as the post-Civil War period in the US – i.e., barely 25 years after the introduction of photography – the use of photographs as evidence in a courtroom trial was felt to require corroboration by expert witnesses who testified as to the photographs' authenticity (Goldberg 1991, 24). Since the advent of digital imaging, several instances of computer manipulation – for example, *Time's* O. J. Simpson cover – have received considerable attention in the mass media. After it was revealed that *TV Guide* had pasted Oprah Winfrey's head onto the body of actress Ann-Margret for a cover photo, the magazine published a humorous apology, in which Oprah's head was superimposed on the bodies of a number of other celebrities. Moreover, increasing numbers of nonprofessionals have direct experience with image-editing software.

These circumstances suggest that the general public is not entirely naïve about digital imaging technology. As far back as the 1990s, surveys by Messaris (1997, 156–160) and Huang (1999) point to widespread knowledge about the digital manipulation of images, together with relatively nuanced views about the acceptability of such practices. Moreover, research by Greer & Gosen (2002) suggests that greater understanding of the technology is associated with increased likelihood of its acceptance. Of course, these trends do not preclude the possibility that substantial numbers of people may still be deceived by any one instance of digital tampering. Awareness of a principle is not the same thing as being able to detect all of its applications. For example, in a study of college students' ability to discern the superimposition of one person's head on another person's body, about a third of the sample failed to detect a manipulated image, and about two-thirds incorrectly imputed manipulation to an image that had not been altered (Wheeler 2002).

Although issues of photographic truth and falsehood have received the lion's share of attention from writers concerned about the implications of digital imaging, such concerns should not blind us to other important ways in which digital images have affected the nature of visual communication. The fact that digital images can be manipulated by computer may have substantial social consequences even when the manipulation is transparently obvious and freely acknowledged. Moreover, the other characteristics of digital imaging – their *replicability and ease of distribution* – are significant in themselves, even when an image has not been manipulated in any significant way. Both of these possibilities figure prominently in studies of nonprofessional users of digital imaging technology (e.g., Cohen 2005; Majid 2005; → Amateur Photography and Movies). Because the market for digital media has experienced the same trend toward lower prices that has occurred in other sectors of the computer-related economy, the development of digital imaging has led to unprecedented levels of public access to the technologies of visual production, post-production, and distribution. These developments, in turn, have nourished a widespread

belief that digital technologies may loosen the grip that large corporate media have historically exercised over the flow of public communication.

### THE USE OF DIGITAL IMAGERY IN JOURNALISM AND FILMMAKING

Emblematic instances of this putative trend are not hard to find. In the realm of visual journalism, the Iraq war has provided several notable examples of photographs that achieved wide circulation despite the fact that they were taken by nonprofessional photographers (Griffin 2004a; Perlmutter 2006; → Photojournalism). A study by Frank (2004) has also drawn attention to amateur web posters' extensive use of Photoshop and related software to create composite images that comment on the news in a manner somewhat similar to that of traditional editorial cartoons. Focusing specifically on visual reactions to the terrorist attacks of September 11 – for example, a picture of Osama Bin Laden superimposed on the center of a urinal – Frank argues that such amateur image-making may be seen as a corrective to the restraint of the professional press and, at the same time, a protest against that restraint (→ Ethics in Journalism).

A parallel widening of the scope for amateur creativity is also taking place in the world of film and video, whose production practices have been affected radically, at all budgetary levels, by the advent of computer-based editing. Since the late 1990s, a number of movies produced entirely on consumer-level digital video have entered into commercial distribution, beginning with *The Last Broadcast* (1998) and *The Blair Witch Project* (1999). The latter is notable for its innovative use of the Web as a means of generating advance publicity (→ Digitization and Media Convergence).

According to Holly Willis, the fact that *The Blair Witch Project* grossed \$140 million on a production budget of \$40,000 “helped spark an avalanche of interest in digital filmmaking, and along with it, a renewed rhetoric of transformation” (Willis 2005, 30) – i.e., a belief that digital technology would enable a renaissance of independent filmmaking in the US and elsewhere. However, Willis herself approaches such claims with caution. She notes that similar aspirations have been ignited repeatedly by previous waves of technical innovation – for example, analog video in the 1970s – only to be extinguished by the inertial power of existing institutional and economic arrangements. While it may be true that technologies of digital production and distribution have made it possible for a number of individual filmmakers and other creators of images to break out of obscurity, it does not necessarily follow that these technologies will lead to any enduring changes in the flow of information and ideas through the mass media. As Griffin (2004b) has observed in a study of newsmagazine visuals about US military operations in Afghanistan and Iraq, the broad patterns of pictorial coverage adhered to established narratives despite the publicity given to “spontaneous” images from the field. The established media industries have a history of absorbing or out-competing independent operators, and it should not be taken for granted that this historical trend will cease to operate in the case of digital media (→ Media History).

One issue that is often overlooked in discussions of the transformative powers of digital media is the fact that the wide availability of photo-manipulation technologies has not been matched by the other major category of digital imaging, namely, *computer generated imagery (CGI) and computer animation*. The ability to create photorealistic images

entirely by computer, and to make them move in a naturalistic manner, is still largely confined to the professional media industry and, most prominently, to special-effects houses (→ Special Effects). Scholarly analyses of special effects have noted their role in enhancing the visual spectacle of Hollywood movies and providing a measure of insulation against competition from television and independent cinema (Darley 2000; Pierson 2002). Dalianis (2005) has argued that digital effects are analogous to the spectacular visual creations of baroque art, whose function was also to bolster the social position of its patrons (→ Spectacle).

On a more metaphorical level, Bukatman (2003) has interpreted F/X scenes of flying superheroes as compensatory reactions to the anxiety-producing dislocations of rapid technological change. Within the media industry itself, however, the trend toward digital effects may also serve another function. To the extent that effects become major sources of movies' commercial appeal, they may contribute to wresting control of production away from powerful stars and returning it to producers and directors (Messaris 2006; → Film Production). Such a development would indeed constitute a transformation in the distribution of media power, although not of the sort that most digital-media enthusiasts have been hoping for.

## Digital Media, History of

Wendy Hui Kyong Chun

Brown University

Digital media, also known as “new media,” comprise content created, disseminated, and/or stored using digital computers or mobile devices (video games, blogs, etc.), as well as their physical embodiment (DVDs, flash memory sticks, etc.). Digital media are often defined in contrast to “analog media,” new media in contrast to “mass media.” The history of digital media documents the move of computers from glorified calculators to devices for human communications, entertainment, and creative production, linking digital media to earlier interactive machines and media.

Central to this move and to computers more generally is memory: one of the definitions of digital media is *digital storage device*. The first clear articulation of computer memory

to store both data and instructions was John von Neumann's 1945 *First draft of a report on the EDVAC*, in which he compared vacuum tubes to human neurons. More concretely, J. Presper Eckert developed a mercury signal delay tube to produce "regenerative memory." Static magnetic memory – based on recording technology developed in Germany during World War II – was first used in 1952 for an MIT test machine. The term digital media, however, does not simply mean digital storage: not only do early forms of digital storage (CRTs, ferrite magnetic coated tapes, and so on) not register now as digital media, the emergence of digital media effected the notion of medium as storage device. The term digital media encompasses broader definitions of medium as a form of circulation, dissemination, and communication. These understandings emphasize algorithms and human use over storage and thus the difference between technology and media. Important to these definitions are the development of higher-level programming languages, real-time and graphic user interfaces, and networked communications – all of which rely upon discrete hardware.

### **DIGITAL, REAL-TIME COMPUTATION, AND HUMAN AUGMENTATION**

Higher-level *programming languages*, which enable language-based exchange between man and machine, depend on the programmability of discrete computation. Because digital machines treat ranges of signals as one value, they allow for the precision necessary for solving equations numerically, and for ensuring that instructions, stored in computer memory, are accurately read and executed. The first implemented higher-level language was Short Code for the UNIVAC (1950); the first widely used language FORTRAN, developed by IBM (1954–1957). Stemming from the desire to use the computer to program itself, higher-level programming languages hide the specificities of hardware and memory allocation from the programmer, and focus the programmer's attention on questions of problem flow and data relations. Computers are thus part of the drive within media development to offer a highly technologized, equipment-free reality (Benjamin 1968).

Software as a mediating entity also requires *real-time interfaces*, where real time means computation that occurs "in conjunction with instruments receiving and responding to stimuli from the external environment" (OED). The first real-time digital computer was the WHIRLWIND, a post-World War II project initiated by the US Navy and MIT to produce a universal cockpit simulator. It eventually evolved into an Airforce-funded, continent-wide missile detection system known as SAGE, already obsolete by the time it was first fully implemented in 1963 (Edwards 1996). Real-time interfaces are the basis for time-sharing interfaces such as UNIX, developed by Bell Labs in 1970, that make the user feel as though he or she controls a shared machine and are thus considered the basis for personal computing (Campbell-Kelly & Aspray 1996). Real-time interfaces also make possible graphic user interfaces (GUIs), in which computers respond in real time to user input framed as an intervention on to a graphical surface.

*Graphic user interfaces* – along with a concerted commercial effort to turn computers from industrial to personal commodities – have helped to make computers personal multimedia machines. GUIs are part of a series of attempts to make the computer a vehicle of empowerment and mastery, rather than an object of grudging acceptance and resentment. Douglas Engelbart, who demoed the first mouse in 1968, argued as early as

1962 for the development of computer interfaces to augment human intellect. Such systems, he argued, would enable the type of associative linking (and thus human progress) advocated by Vannevar Bush in his highly influential “As we may think” article (1945). Theodor Nelson, who coined the term “hypertext” and was also influenced by Bush’s ideas, similarly argued “Responsive computer display systems [that] can, should and will restructure and light up the mental life of mankind” (Nelson 1987). Whether or not such displays could or would effect, or have effected, such results, GUIs have been a key component to the spread of desktop computers and the automation of office work.

### INTERNET COMMUNICATIONS AS MEDIA

The → Internet has provided a means of circulation that makes digital media mass media. Like the technologies described above, the Internet was a military creation designed to augment human intelligence and turn humans into more creative producers. The Internet stems from ARPANET, a US military-funded network designed to link together several research sites. The main impetus behind its development was the belief that time-sharing computer networks could bring about a “man machine synthesis” (Licklider 1960). The most popular use of ARPANET was an unforeseen one: electronic mail, an application that would also drive widespread civilian use of the Internet. In 1983, with the formal adoption of TCP/IP, the Internet proper – as a network of networks, based on an open protocol to link differently configured local area networks – would emerge.

Commercial transactions were prohibited on the Internet until 1991, and before 1991 popular forms of communications were email (→ Electronic Mail), newsgroups (1979), Internet Relay Chat (IRC, 1988), and multi-user text-based games (1978), such as MUDs and MOOs. Access to the Internet backbone was limited to academia, the government, and the military, although there were some public bulletin board services run by organizations such as the WELL in San Francisco. Communications were mainly text-based, although image files could be downloaded.

The Internet as popular mass medium coincided with its commercialization, the privatization of its backbone (early 1990s) and the development of the *world wide web* (WWW) by Tim Berners-Lee in 1990. The WWW enabled the mass sharing of linked files and provided an easy to use, readily accessible way to post personal and commercial content. At first, the WWW was populated by personal and institutional homepages, designed with a distinctly amateur DIY aesthetic (now perpetuated as an indicator of “authentic” digital content). Soon flashy “push” media (content delivered to users whether or not they had requested it) were developed for the WWW. With the frenetic laying down of fiber optic cable in the late 1990s, high-bandwidth media such as video and music became available and “real time” referred less to synchronous computing and more to synchronous transmission. Massively Multiplayer Online Role Playing Games (MMORPGs) also emerged. Technology, however, does not guarantee use: fiber optic cable was initially laid down in the 1980s in anticipation of demand for the video phone (→ Internet, Technology of).

During the mid- to late 1990s, the Internet was conflated with William Gibson’s “cyberspace” and was viewed as an alternative space that belied government regulation, big business, and intellectual property (Chun 2006). The information superhighway was

to fix all our political problems, from racial discrimination to the ills created by the mass media. The Internet was supposedly uncensorable, since it allegedly treated censorship like a network outage and thus routed around it. It was also a fundamentally anonymous and participatory medium. According to Janet Abbate (1999), “the culture of the Internet challenges the whole distinction between producers and users.” Information, the hacker ethic argued, wanted to be free (Levy 1984). This did not mean, however, that all of the utopian discussions around the Internet were non-commercial. New companies, such as amazon.com, seemed to threaten the continued existence of brick and mortar companies. Digital media were also sold as the medium of convergence and soon, it was prophesied, all mass media would converge into one narrow-casting digital form (→ E-Commerce).

### VIDEO GAMES AND OTHER “MEDIA”

Video games are a crucial form of digital media, and their history intersects with and diverges from the history of communications media. Video games underlie literary conceptions of cyberspace (Chun 2006; → Video Games).

The first *computer game* is widely accepted to be *Spacewar*, developed by Steve Russell for the PDP-1 minicomputer at MIT in 1962; the first major hit the arcade game *Pong* in 1972. The development of microchips in the late 1970s enabled more graphically complex arcade games and the development of relatively affordable digital home game consoles. Japan has a strong game machine tradition and in 1978, Taito’s *Space Invaders* was the first computer game to be more popular than local *pachinkos* (Malliet and de Meyer 2005). It and *Pac-Man*, introduced in 1980, were cross-continental hits. During this period, pre-assembled personal computers such as the Commodore-64 (1982) and the Macintosh (1984), on which computer games could be played and copied, were also introduced, and these multi-use computers threatened the game console business.

The game console, however, came back in the 1990s with new machines by Nintendo, Sega, and Sony, and later Microsoft. Made possible by the globalization of computer production, which led to cheaper microprocessors and memory, the return of the console signaled a move away from the personal computer as the universal machine, toward ubiquitous computing: from Ipods, introduced in 2001, to smart phones. SMS text messaging, first developed for GSM phones in Europe, is extremely popular globally and has started to penetrate the US market (Lee and Keeter 2006). Digital media have thus not simply signaled a convergence in hardware, but also a proliferation of it.

Digital media have also *penetrated other forms of media*. For instance, digital special effects have made animation and stop-image photography a more prominent factor in the practice and history of cinema (Manovich 2001). Devices and services such as Tivo have also affected normal television watching practices, making it possible to skip through commercials and to post recorded television shows on the Internet. This change in audience behavior is most distinct in fan sites and blogs, linked to early print fanzines, on which users post their own narratives based on the shows and stars of interest, and share information about the show. These have impacted the development of various series, with directors reputed to visit fansites regularly. Television shows have also produced official websites, which offer teasers for shows to come, episode summaries, photo galleries, and so on. The question is: what now is not digital media?

## CURRENT USAGE

New media have become both more and less than expected. They are used by over one billion users worldwide, and commercial transactions are now commonplace. Their very existence, however, has not eradicated older institutions and governmental regulations. The Internet, after all, is a networking protocol, and hence can be changed: policy-based routing protocols used by cable providers, for example, have challenged the equal treatment and circulation of data. As well, intellectual property laws, introduced by the US government, make “fair use” of digital media difficult. The Motion Picture Association of America (MPAA) has launched an aggressive anti-piracy campaign directed against content-sharing sites, as well as individual end users. The use of the Internet to prosecute people, from terrorists to journalists, and its use in commercial forms of surveillance have belied its status as an “anonymous medium.”

All this has not meant the demise of digital media DIY culture and free circulation. New networking sites, such as gnutella, are truly distributed and thus cannot be easily shut down. Sites such as Youtube.com enable users to post their own videos, and blogs, and indymedia sites have come to rival news sites as a source of credible information. More damningly for local newspapers, sites such as Craigslist, in which people can freely post classified ads, have taken away an important income source. Many popular sites, such as facebook.com and myspace.com, herald a return to homepages, albeit in an extremely standardized but easier to use form. Myspace and blogs are part of the much heralded Web 2.0 centered around these social networking sites, which enable the quick and easy posting of micro-content.

## Digitization and Media Convergence

*Tanja Storsul*

*University of Oslo*

*Anders Fagerjord*

*University of Oslo*

From the 1980s onward, media technologies have gone through a phase of *digitization*. CDs and digital music media replaced records and tapes in the 1980s and 1990s, and movies are increasingly being produced and distributed digitally. Newspaper production has become computer based and the news is distributed not only on paper, but also digitally on the web. Satellite television is completely digitized in many countries, cable networks are partly digitized, and in several countries terrestrial networks for television are being digitized. Furthermore, various models for digital radio are being tried out. And new digital media services, based on platforms like the web or the mobile phone, have become important in many parts of the world.

Digitization is the process of coding signals as numbers. When signals are digital, computer technology can be and is involved in all stages of production, as well as in distribution and media use. One single computer can be used to create and consume variants of all media. An important aspect of digitization is that the boundaries between different media have been brought into question and a presupposition has developed that we are in an era of *media convergence*.

According to *Webster's Dictionary*, convergence literally means “the act of . . . moving toward union or uniformity,” and is used to describe a number of phenomena: in physics, math, and geography, as well as in the media. Early concepts about media convergence were presented in the 1970s, but it was in the 1990s that the concept really impacted debates about media developments. From the 1990s onward, media convergence became a key issue in academic texts, policy documents, and industrial papers. The concept has had a strong influence in political and industrial circles. It communicates a media landscape

undergoing significant changes and has been instrumental in convincing politicians, regulators, investors, and other market players that they needed to adapt their strategies. The concept is, however, not always clear. There are a multitude of interpretations of what media convergence is, focusing on different entities that converge. Nevertheless, a few dominant interpretations may be singled out, emphasizing both the general arguments about convergence, and some more critical perspectives on the employment of the concept of convergence as a general description of media developments.

### **NETWORK CONVERGENCE**

The concept of network convergence implies that when digitized, any network can be used to transmit all kinds of digital signals – provided speed and bandwidth are high enough. There is no difference between sound, text, and images in digital networks, as they are all transmitted as bits and bytes, in contrast to analog signals. Consequently, possibilities are opened for integrated networks and seamless communication between networks that had earlier been used for separate purposes (e.g., voice telephony networks, cable, satellite and terrestrial television, and data networks; → Satellite Television; Cable Television). For consumers, an easier future has been imagined where each household could have one network for all communication purposes.

These predictions were particularly strong in the mid-1990s. A decade later, we find that most networks are digitized, and most are used for multiple purposes. The copper networks formerly used for telephony only have now been digitized, and in many areas enhanced to DSL (digital subscriber line) standards, implying that the same network can be used in communicating sound, text, and images. Similarly, cable television networks are in many areas upgraded to not only transmit television, but also enable telephony and IP (Internet Protocol) access (often called triple play). Most households are, however, connected to even more networks than before with recent additions such as wireless local area networks (WLAN), mobile networks, and DSL and broadband services, as well as broadcasting networks. The main reason for this is partly that people rely on electronic communication for more and more purposes, and partly that even if the networks are digital and potentially can transmit any services, many networks (such as terrestrial television) are still specialized for certain services.

### **TERMINAL CONVERGENCE**

Digitization means that computers could be used in the production and use of all kinds of media services, and several voices have predicted that this would lead to terminal convergence, meaning that different media terminals would be reduced to one – the “überbox.” As stated by George Gilder in the early 1990s: “The new system will be the telecomputer or ‘teleputer,’ a personal computer adapted for video processing and connected by fiber-optic threads to other teleputers all around the world. Using a two-way system of signals . . . the teleputer will surpass the television in video communication just as the telephone surpasses the telegraph in verbal communication” (Gilder 1994, 45).

The most radical versions of such scenarios were obviously too extreme. Although personal computers, advanced mobile phones, and other hand-held devices are multi-use

terminals, we see the number of terminals created for specific media types or user situations is growing. There are more and more kinds of terminals, not fewer. The mechanisms of capitalism ensure that we are unlikely to see the full convergence into one “übe-box” (if anyone ever truly believed that) – simply because the industry has very high stakes in always selling new and diversified gadgets.

### **SERVICE AND RHETORICAL CONVERGENCE**

Another aspect of media convergence has been the convergence of services. As digitization enabled the transmission of all digital media services over the same networks, and the use of different kinds of services on the same terminals, the services themselves were expected to converge. The services would become increasingly integrated with each other, and new multimedia services would develop. For television, cross-media formats, in which television shows are integrated with emails and/or text messages from mobile phones directly on the screen, are gaining importance. And on the web, audiovisual services are combined with text services that allow for chat, instant messaging, and network building.

The more radical versions of this line of reasoning have suggested that we will see not only the integration of services but also a rhetorical convergence in which expressions and genres would no longer be distinct, but grow into one unified language. This is a much more contested assumption than the integration of formats and services across media. Studies of new media show that what we do see is a growing number, and a differentiation, of genres in digital media. Each of these genres may be seen as a convergence of traits from one or more earlier genres, but the total number is growing (Fagerjord 2003).

### **MARKET CONVERGENCE**

A convergence of networks, terminals, and services was further expected to lead to a convergence of markets (→ Media Economics). It would no longer be self-evident where the telecom markets ended and the media markets started. The distinctions between infrastructures and services, software and media content, would become increasingly blurred. Thus ICT (information and communications technology), telecom, and media companies would merge or form alliances and we would, to an increasing degree, see the development of multimedia companies.

In the 1990s and early 2000s, we have seen large fluctuations in the communications markets, including new alliances across the value chain, the most prominent example being the merger between the Internet service provider AOL and the media house → Time Warner Inc. in 2000. There are many similar examples of alliances and mergers between telecom and content companies in both national and regional contexts. Nevertheless, this is only one aspect of the market changes. Parallel to this there are several examples of divestitures, of breakups of alliances, and of companies scaling down to “core business.” Thus, in addition to the tendencies toward vertical integration and blurred boundaries between old sectors, there is also a development toward new and highly specialized sub-markets (→ Consolidation of Media Markets).

## **REGULATORY CONVERGENCE**

The above perceptions of convergence between communication networks, terminals, services, and markets has had a strong impact on political discourse. In the 1990s, several governments, as well as the EU, produced consultation documents about the regulatory impact of convergence. It was argued that many of the old regulatory instruments were outdated, as they were related to specific technologies that were now converging – a development that produced inconsistencies in the regulatory framework.

This is illustrated by the 1997 EU green paper arguing that lack of action would prevent countries from taking full advantage of the possibilities convergence enabled. “If Europe can embrace these changes by creating an environment which supports rather than holds back the process of change we will have created a powerful motor for job creation and growth, increasing consumer choice and promoting cultural diversity. If Europe fails to do so, or fails to do so rapidly enough, there are real risks that our businesses and citizens will be left to travel in the slow lane of an information revolution which is being embraced by businesses, users and by Governments around the world” (EC 1997, 35).

It was argued that a new regulatory regime was necessary in which the regulations were horizontal. This implied that all electronic networks would exist within one framework – and all media services and contents would be in one framework. Such views were also supported by academic writers who pointed at the inconsistencies between the technological and the regulatory levels (e.g., Cuilenburg and Slaa 1993).

Following these debates, in many countries, regulations that used to be separate for different networks (e.g., voice telephony, cable television, and broadband services) have been integrated into common regulatory frameworks for all electronic networks. But, for media services and contents, regulations are usually still separate for different media. Generally, broadcasting, press, telephony, and web services have been and still are subject to different regulations. The reason for this is not only that institutional legacies are slowing regulatory reforms. The convergence processes have also been less pervasive than predicted. Media are much more than technology. Many, maybe even most differences between media are not due to technological factors, but are grounded in social codes, economy, rhetoric, and even our cognitive faculties. Thus, even if digitized, different media still vary in their characteristics, usages, and purposes. Different media play different roles in society, and politicians and regulators still perceive the need for regulation to be different (→ Communication and Law).

## **DIGITIZATION AND DIFFERENTIATION**

Digitization has enabled significant changes in the media – such as the blurring of boundaries between media that earlier were more distinctly different. Media convergence may be a description of how networks and terminals are used for multiple purposes, services integrate elements from audiovisual and text media, and media and telecom corporations form vertical alliances. At the same time, a number of closely related, yet quite opposite developments are taking place. There is an increasing diversification of products and terminals; new categories of services and genres develop, and new specialized companies and sub-markets. Thus, digitization contributes to the blurring of

boundaries between media, but this does not always imply media convergence. There are also developments toward stronger differentiation of media in which elements from earlier separate media and sectors are combined in new ways.

## **Direct-to-Consumer Advertising**

*Peter C. Verhoef*

*University of Groningen*

*Janny C. Hoekstra*

*University of Groningen*

Marketing communication is often equated with mass advertising using media such as television, radio, and print (→ Marketing; Advertising; Television; Radio). This is often referred to as above-the-line advertising. Besides these media, organizations can also use more directly targeted media, which include direct mail, telephone, email, etc. (→ Electronic Mail). This is referred to as below-the-line advertising or direct-to-consumer advertising. Remarkably, spending on below-the-line advertising more than doubles spending on above-the-line advertising in the US (V12 Group & Winterberry Group 2006). Moreover, below-the-line advertising spending has increased by 7.5 percent per year, while spending

on above-the-line advertising increases at a lower rate of 5.5 percent per year. These figures emphasize the importance of below-the-line advertising.

Traditionally, direct marketing has been the field that mainly focused on the use of direct-to-consumer advertising. In the early days, direct marketing was mainly associated with firms almost solely relying on direct media, such as *Reader's Digest*. The US-based Direct Marketing Association (DMA) defines direct marketing as an interactive system of marketing that uses one or more advertising media to effect a measurable response and/or transaction at any location. According to McDonald (1998), there are three key issues in this definition: (1) direct marketing is interactive, (2) all direct marketing actions are significantly more measurable than traditional mass advertising, and (3) activities connected with direct marketing communication can take place at any location.

European scholars have advocated a broader definition of direct marketing. Both Tapp (1998) and Hoekstra (2003) have emphasized the relationship dimension of direct marketing. Tapp (1998) defines direct marketing as a way of acquiring and keeping customers by providing a framework of three activities: (1) analysis of individual customer information, (2) strategy formation, and (3) implementation such that customers respond directly. It has also been acknowledged that direct marketing can be viewed at three levels (Hoekstra 2003): (1) direct marketing at the firm level: direct marketing drives the business (e.g., ING Direct, Capital One); (2) direct marketing at the marketing strategy level: direct marketing drives part or all of the marketing strategy (e.g., British Airways, Tesco); and (3) direct marketing at the tactical level: direct marketing is used within the communication mix (e.g., Albert Heijn).

Within direct marketing, multiple media are used (→ Marketing: Communication Tools). These include: telephone, direct mail, catalog, television (direct response commercials, home shopping), print media (coupons in → magazines, → newspapers, specialty print media advertisements), direct response radio. The upcoming of the → Internet has increased the potential of direct marketing dramatically. Consumers now use it as one of their primary information channels, while in certain product categories, such as travel and leisure, the Internet is the dominant channel. The field of → e-commerce focuses on the Internet channel. E-commerce is defined as the process of buying, selling, or exchanging products, services, and information via computer networks (Turban et al. 2004).

Direct marketing is closely related to other terms often used, the most important being *database marketing*. Verhoef and Hoekstra (1999) defined database marketing as that which uses individual customer and/or prospect data from a customer database and transforms these into information that supports marketing decision-making by applying statistical analysis and/or modeling techniques. Thus, database marketing focuses on the analysis of individual customer data.

The scientific marketing community has mainly studied direct marketing from a customer selection perspective. Research mainly focuses on predicting which customer or prospect is most likely to respond (i.e., response to a mailing). Direct marketing practice often uses the so-called *RFM-methodology* (recency of last purchase, frequency of purchase, and monetary value of purchase) to select customers. Marketing scientists have proposed sophisticated statistical models, such as logit models and decision trees. Another relevant topic is the prediction of *customer lifetime value*, which is defined as the expected net present value of all customers' future earnings. This concept is being used to value,

segment, and rank customers. High-value customers might be treated differently from low-value customers. Research in direct marketing practice is mainly concerned with testing the content and presentation of the media. For direct mailings, simple rules for the presentation of the envelope, the characteristics of the letter, brochure, and reply device have been developed based on expertise. For example, it has been recommended that they use short words, short sentences, and short paragraphs, and that they look easy to read (Roberts & Berger 1999).

Since the end of the 1990s, there has been much attention given to customer relationship management (CRM). This concept is clearly related to both direct marketing and database marketing. CRM is defined as a strategic approach that is concerned with creating shareholder value through the development of appropriate relationships with key customers and customer segments. CRM unites the potential of relationship marketing strategies and IT to create profitable, long-term relationships with customers and other key stakeholders (Payne & Frow 2005). Due to the focus on CRM in many firms, the proposed relational aspect of direct marketing is often nowadays ignored. Direct marketing is now usually again equated with its instruments, such as direct mail. The economic impact of direct marketing is, however, very large (DMA 2006).

Overall, direct marketing is an interesting and relevant discipline within marketing, which requires sufficient attention both in marketing practice and in marketing science.

# Directives

*Kristine Fitch*

*University of Iowa*

Directives were described by Searle (1975) as one of five basic *speech acts*. In his approach, taken from linguistic philosophy (→ Linguistic Pragmatics), speech acts were defined by a particular fit between words (propositional content) and the world. Directives are the class of speech acts that attempt to fit the world to the words; they are attempts by a speaker to get a hearer to do something. The class of directives as Searle proposed it encompassed a wide range of action verbs in English – command, request, plead, invite, permit, and many others – without distinguishing among them in any way. He left aside such issues as the fact that words for directives would vary across languages, that contextual variables such as magnitude of the desired action and relationship between speaker and hearer would affect which kind of directive might be used, and the varied responses hearers might have to directives. The basic definition of directives as attempts to get people to do things does, however, lend itself to a connection with compliance gaining and persuasion in the field of communication (see Fitch 1994).

## RESEARCH QUESTIONS

Searle did, nonetheless, take directives seriously as examples of how people made sense of indirectness. Because directives tend to be made indirectly, he claimed (an observation since confirmed among middle-class North Americans and contrasted with many other speech communities), they provided useful examples for understanding how hearers could recognize utterances as directives even when they seemed to be phrased as something else. “Can you pass the salt?” was a common example, as a question that no competent hearer could fail to recognize as a request for action rather than for information.

Rosaldo (1982) posed one of the most influential challenges to speech act theory based on analysis of directives among the Ilongot tribe of the Philippines. She observed that pervasive direct commands within this group upheld, rather than contradicted, a strikingly egalitarian interpersonal ethos among persons. She proposed that the failure of speech act theory lay in its assumption that language use could exist separately from social structure: “[I]t fails because it construes action independent of its reflexive status both as consequence and cause of human forms” (1982, 204). This inseparability of language use from social interaction is the central premise of the ethnography of speaking more generally (→ Ethnography of Communication), and much subsequent work on directives has proceeded as culturally situated case studies in that vein.

Before elaborating on the ethnographic work on directives, however, a strand of investigation more in line with Searle’s original formulation bears mention. Language pragmatics can be construed as the study of how people do things with words. *How to do things with words* (Austin 1962) was, in fact, the title of the seminal work from which Searle’s proceeded, and directives have received considerable attention from that direction. Politeness theory (Brown & Levinson 1987) developed Searle’s observations about

indirectness by pointing out the face threat inherent in nearly all directives (→ Politeness Theory). To try to get someone to do something they were not already doing (or to stop doing something they were doing) by definition constrains their autonomy or interferes with their freedom of movement, i.e., threatens their negative face. Directives may also threaten positive face if they concern something the hearer could already be expected to know they should or should not do. Telling a parent that their child is hungry and should be fed, for example, threatens the hearer's positive face as competent to know and meet their child's needs.

### FACE THREAT IN DIRECTIVES

The presumed face threat inherent in directives creates in many cases a social need to mitigate such threats, leading to the pragmatic question, what kinds of utterances can count as directives, being a complicated one. Commands, when formulated in conventional ways, are unmistakable: "Sailor, swab the decks." "You will clean your room this minute, young man." Hints, by definition, are far less transparent as to their status as directives. Rushforth (1985) gives an example of an Athabaskan saying, to an assembled group of kinfolk, that if he had a dog he would go hunting. This utterance, perhaps formulated within a sequence of general conversation about dogs or hunting, was understood to be a request to borrow a dog. Similarly, many North American speakers of English have little difficulty understanding the utterance, "I'd love to see you when I get to town, but if I take the bus from the airport I'm not sure I'll have time," as a request for a ride from the airport.

Some pragmatics research has thus examined the tradeoff in such indirect formulations of directives: a straightforward command is clear but is likely to be face threatening. An indirect request saves face but risks being unclear, to the point that it may not be understood as a directive at all (see Blum-Kulka 1987; Blum-Kulka et al. 1989, for extensive discussion and empirical support of this point). Beyond variation in cultural norms regarding circumstances under which clarity is more important than face threat, the pragmatic complexities of directive formulation have provided rich terrain for exploration of intention and interpretation of language use, and of construction of meaning more generally.

Ethnographic work on directives proceeds from the assumption that the need for people to influence the actions of others exists in every culture, such that directives must exist in every language. Directives have thus been widely studied as an index of culturally distinctive systems of beliefs about persons, relationships, and communication (see, e.g., Hollos and Beeman 1974; Katriel 1986). Because compelling the actions of another person implies some basic need or right to do so on the part of the person who does the compelling, directives also reveal cultural understandings and enactments of power and social structure.

### NAMING SPEECH ACTS

Fully apprehending the scope of directives' meaning as an index of cultural codes (→ Speech Codes Theory) more generally has been elaborated in various ways in the ethnographic case studies just mentioned. One line connecting directives with cultural codes incorporated speech acts with names (Fitch 1994). Speech events, as part of the basic set of categories proposed by Hymes (1972) through which language was integrated with

social life, are actions accomplished through language use recognizable within a particular culture. A speech event that has a native term associated with it can be assumed to be significant by virtue of the name itself, which identifies an action common enough to have a term of reference. Often, the distinctions between speech events are the richest source of cultural meaning and evaluation of action. “To sweet-talk someone,” for example, is recognizable among North American English speakers as a specific form of request – one “sweetened,” for example, with flattery or with promises of reciprocated effort. “To brown-nose someone,” although bringing to mind the same kind of flattery and perhaps promises of future payoffs, carries a much more negative connotation because of the assumption that the brown-noser is engaged in an often distasteful form of self-promotion (see Hall & Valde 1995), rather than merely posing a localized request in an overtly palatable way.

Names for speech events differ from the original list of performative verbs considered by Searle to distinguish directives from other speech events (commanding, for example, was a different form of action than promising or declaring) in that they incorporate culture-specific norms and premises about persons, relationships, and the nature of communication itself. To approach the meaning of utterances as inseparable from the social groups in which they are produced is one kind of departure – the same kind as Rosaldo’s, who much earlier insisted on this inseparability – from Searle’s approach that sought to specify a limited number of logical relationships between *language* – an abstraction of all human languages – and *the world* – an abstraction of all particular social worlds. A different kind of departure from that approach that nonetheless conserved the central idea of directives as Searle defined them sought to show that utterances counted as directives partly by virtue of the sequential environment in which they occurred. In the following exchange between a preschool teacher and a child, for example, the first utterance can only be clearly established as a directive by the response to it:

Teacher: Michael, I see someone throwing dirt.

Child: Oooo-kay. (sighs, drops handful of dirt) (Fitch 1994, 199)

Conceptually, then, the notion of a directive which began as an abstraction has expanded through research and theory in several disciplines to stimulate inquiry into a wide range of questions about the nature of language and its many constitutive relationships to social worlds.

## Disability and Communication

*Ellen Bouchard Ryan*

*McMaster University*

*Selina Bajorek*

*McMaster University*

*Ann P. Anas*

*McMaster University*

Specific communication disabilities affect the ability to understand and produce language. The most common hearing disabilities are congenital deafness and age-related hearing impairments. The primary causes for difficulties with the production of spoken language are traumatic brain injury, stroke, and dementia (Alzheimer's and related diseases). Of additional relevance is the impact of visual impairment on reading and writing and on following nonverbal cues in conversation. Disability of any type creates psychosocial issues associated with personal and social adjustment, identity, and interactions with others.

This entry focuses on the intergroup aspects of disability and communication. It acknowledges the importance of congenital disabilities, but emphasizes the challenges

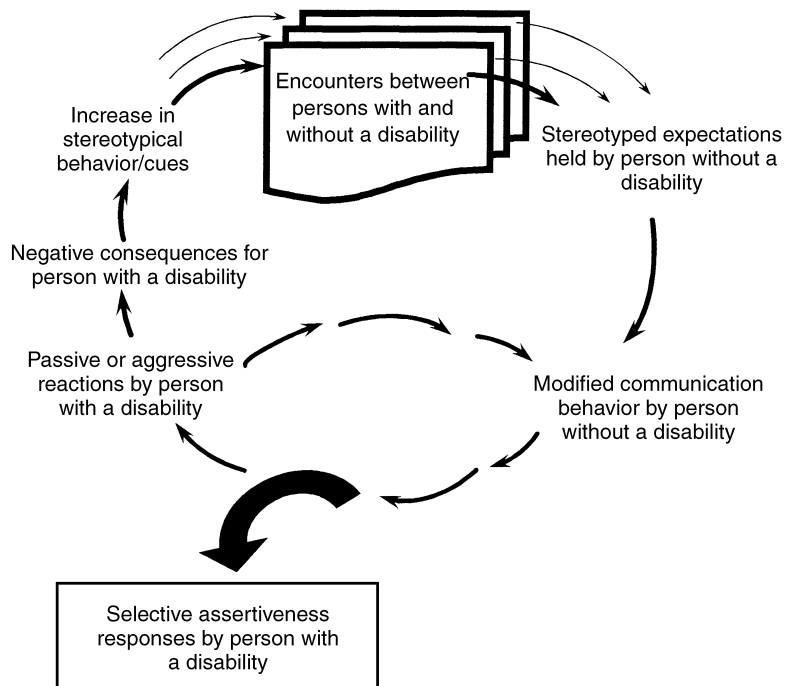

faced by the many individuals with acquired disability, where adjustment to major changes is required for the individuals and their social partners (→ Intergroup Contact and Communication).

### STIGMA AND COMMUNICATION PREDICAMENTS OF DISABILITY

As with many other social groups, societies create disability by categorizing human variation and building the boundaries through interpersonal, organizational, and societal activities (Higgins 1992). Negative stereotypes associated with disability include traits such as dependent, sick, unattractive, incompetent, burdensome, hypersensitive, and bitter. The *stigma* of disability is sustained by unquestioned societal values such as independence, beauty, and marketability (Hebl & Kleck 2000; Susman 1994; → Social Stereotyping and Communication).

Goffman (1963) highlighted the different issues faced in everyday interactions by persons with visible versus invisible disabilities. Those with visible disabilities (“discredited”) must deal with the anxiety resulting from their disability being public knowledge, while those with invisible disabilities (“discreditable”) contend with the burden of concealing information and of managing disclosure of their disability.

Based on → communication accommodative theory, the *communication predicament of disability model* (Fig. 1) summarizes the negative feedback loop within which persons with

**Figure 1** The communication predicament of disability model: interrupting the cycle with selective assertiveness

Source: Reprinted from Ryan et al. (2005, 120); with permission of the publisher

acquired disabilities often find themselves (Braithwaite & Thompson 2000; Emry & Wiseman 1987; Ryan et al. 2005). Negative stereotypes lead able-bodied conversational partners to modify their behavior in ways that stifle real communication and reinforce expected behaviors from the person with disability. As with other intergroup situations, the expectation of homogeneity among individuals with disability is pervasive and particularly harmful. Persistent experiences of this nature (from family and friends as well as strangers) can lead to social withdrawal, lessened personal control, conformity to disability stereotypes, and to a reduced sense of self. Eventually, the person's disabled identity contributes to more and more disabling communication situations in their *interability* interactions (→ Intergroup Accommodative Processes; Social Identity Theory).

Modifications in communication toward persons with disability include changes in manner, language, and nonverbal behavior. The *patronizing*, paternalistic manner may be depersonalizing, impatient (or excessively patient), overhelping without consultation, or non-listening and dismissive. Talk can include simplified grammar and vocabulary, superficial topics, invasion of privacy, and high-pitched, exaggerated tone of voice. Gestures and facial expressions can support paternalistic language or undermine appropriate language choices. Being talked about or ignored in a three-person conversation is frequently experienced.

### **REFRAMING DISABILITY AND CONSEQUENT REDUCTION IN COMMUNICATION BARRIERS**

Models of disability have traditionally been medical- or rehabilitation-oriented, while newer social models reframe the notion of disability. In particular, disability is now thought of as created largely through barriers in the environment rather than in the person, and living with a disability need not emphasize the traditional rehabilitation value of "normal." *Ableism* is a term used by persons with disabilities themselves to emphasize the value of individual differences and to create the broadest context within which to thrive individually and as subgroups (Rauscher & McClintock 1997).

*Selective assertiveness* is featured in the model in Figure 1 as a conversational strategy for interrupting the automatic negative cycle created by stereotype-driven communication. Assertiveness is characterized by calm, confident, tactful, straightforward expressions of feelings and desires. As with stereotype-based communication, an assertive style is as much tone of voice and other nonverbal features as it is the direct, non-aggressive language used. Successful *impression management strategies* used by persons with disability include establishing normalcy by emphasizing similarities, using modeling behavior, limiting attention to assistive devices, limiting responses to overly personal questions, and managing the able-bodied tendency to overhelp. When empowered with a sense of equality as a human being, the person with a disability can more effectively manage the communication predicaments which are a part of everyday life. Since assertiveness takes energy and has its societal costs, persons with disability choose their battles – when to go along, when to get what one needs at the moment, and when to educate or advocate more generally (Fox & Giles 1997; → Communicative Strategies for Empowerment).

Intergroup communication strategies have also been used selectively by persons and groups with disability to meet the *social identity* goals of social creativity and social

competition. The disability community has contributed actively towards redefining models of disability, such as ableism and the independent living model (Rauscher & McClintock 1997). This latter emphasizes the competence of persons with disability to make their own decisions regarding care and emphasizes equal social access to needed resources. The disability community is also active in the shaping of terminology for reference to persons with disability of various types and in developing ingroup language to enhance solidarity. With regard to social competition, disability groups have succeeded in North America in establishing disability acts to eliminate barriers in buildings, streets, transportation, and law.

### COMMUNICATION TECHNOLOGY AND IMAGES IN THE MEDIA

*Communication devices* need to be learned and have their own influence on conversational interactions (e.g., blowing or eye movement technology to run a synthesized voice). A key issue for the future concerns how the rapidly burgeoning improvements in assistive technologies will affect interability communication (Braithwaite & Thompson 2000).

*Computer-mediated communication* offers persons with visible disabilities the opportunity to connect with others on an equal footing since their disability disappears in this medium. In addition, many individuals and disability organizations take advantage of computer-mediated self-help/mutual aid groups to build ingroup solidarity, plan advocacy, and support each other in their interability interactions (→ Personal Communication by CMC; Human–Computer Interaction).

With regard to *media images of disability*, autobiographical writings by persons with disability have a powerful impact in individualizing the disability experience. Writers with many types of disability (e.g., visual and hearing impairments, physical paralysis or weakness, vertigo, cognitive impairment, mental illness, spinal cord injury, chronic disabling illnesses) are expressing their emerging identities by selecting to be assertive through publishing books or articles aimed at others with their specific disability as well as education and advocacy directed toward caring professionals, policymakers, family members, and the general public (Ryan 2006). Similarly, images of persons with disability incorporated recently into major films and documentaries can counteract the societal lack of understanding about specific disabilities and about how well individuals can adapt to major functional restrictions. Disability advocates argue strongly for involvement of persons with disability in producing these media images – with the slogan “Nothing about us without us” (→ Media and Perceptions of Reality).

Persons with acquired disability can use oral or written communication to reclaim their voices and to reshape their identities. As in all social interactions, the process of expressing their emerging identities contributes reciprocally to the reshaping of identity and changes in societal images of disability.

## Disasters and Communication

Matthew W. Seeger

Wayne State University

Crises and disasters are increasingly common in their occurrence and increasingly widespread in their impact. Events such as the Indian Ocean tsunami and Hurricane Katrina illustrate the potential devastation caused by natural disasters, particularly as they interact with human development. Technology-based disasters, sometimes called accidents, such as the Chernobyl nuclear plant explosion, the leak of toxic material over the sleeping community of Bhopal, India, or the *Exxon Valdez* oil spill, can also create widespread devastation. In addition, the outbreak of diseases such as acquired immune deficiency syndrome (AIDS), sudden acute respiratory syndrome (SARS), or H5N1, avian influenza, represent yet another kind of disaster. Finally, terrorism, as witnessed in the 9/11 attacks and the London transportation system bombings, has become an increasingly prominent and insidious form of disaster (O’Hair et al. 2005).

### CRISES AND DISASTERS: DEFINITIONS AND TYPOLOGIES

In general, *disasters* are “nonroutine events in societies or their larger subsystem (e.g., regions or communities) that involve social disruption and physical harm” (Kreps 1989,

34). The United Nations Committee on Humanitarian Relief defines a disaster as “a sudden, calamitous event that seriously disrupts the functioning of a community or society and causes human, material, economic, or environmental losses that exceed the community’s or society’s ability to cope using its own resources” (2006).

*Crises* are usually conceptualized as more limited in scope involving “a specific, unexpected, and nonroutine organizationally-based event or series of events, which creates high levels of uncertainty and threat or perceived threat to an organization’s high priority goals” (Seeger et al. 1998, 233). Karl Weick argues that crises are “low probability/high consequence events that threaten the most fundamental goals of the organization. Because of their low probability, these events defy interpretations and impose severe demands on sense-making” (1988, 305). During crisis and disasters, established routines, relationships, norms, belief systems, and sources of information and order break down or no longer function. Thus, these events are often characterized by confusion, disorder, misunderstanding, and uncertainty (→ Crisis Communication).

Disasters and crises include a wide variety of types such as intentional or unintentional, human-made or natural, and sudden in their onset or slow to evolve (Quarantelli 1988; Seeger et al. 2003). In general, disasters are seen as dramatically abnormal events that create widespread disruption and suspension of the status quo, and that require some organized, often governmentally based, response to contain and mitigate the harm. Disasters and crises are associated with *three defining characteristics*: high levels of uncertainty, surprising or unanticipated occurrences, and short response time (Seeger et al. 2003).

Disasters have different scopes. In general, those disasters labeled “natural” are the most devastating. In terms of modern disasters, the July 1976 Tangshan quake in China was estimated to have cost 250,000 lives. Floods also create widespread destruction. In 1939, floods ravaged northern China and may have claimed as many as 500,000 lives. Some estimates for the Indian Ocean tsunami of December 26, 2004 suggest 300,000 deaths. Disasters involving specific outbreaks of infectious disease account for untold numbers of deaths. The 1918–1919 influenza pandemic, known as the Spanish flu, is estimated to have killed as many as 100 million people worldwide, including 500,000 in the US.

### **COMMUNICATION FUNCTIONS AND PROCESSES IN DISASTERS**

Communication scholars and practitioners have described a number of instrumental functions of communication during crises. In fact, communication is frequently described as a core function of crisis and disaster management and response. *Functions include*: (1) clarifying risk and encouraging preparedness; (2) issuing evacuations and warning; (3) enhancing coordination, cooperation, and logistics; (4) facilitating mitigation on the part of the public and affected communities; (5) helping make sense of the disaster; (6) reassuring, comforting, and consoling those affected; and (7) recreating order and meaning, facilitating renewal, and learning and disseminating lessons (Auf Der Heide 1989; Seeger et al. 2005).

In a number of cases, *failure to communicate effectively* was a significant factor in the onset of a disaster. In the case of the Red River flood of 1997 in Grand Fork, North Dakota, for example, failure to communicate correct information about the expected crest of the river meant that makeshift levees were too low (Sellnow et al. 2002). Scholars have

suggested that the disaster of the space shuttle “Challenger” was a consequence of failed communication at NASA. In other cases, ineffective communication has significantly enhanced the level of harm. Following the World Trade Center attack, for example, fire fighters, police, and other emergency personnel were unable to communicate with one another due to incompatible equipment. Some emergency personnel did not receive the order to leave the collapsing World Trade Center. This event has led to a major push toward communication interoperability among emergency personnel.

During a disaster, established channels of communication are often disrupted or inaccessible. A significant proportion of the telecommunication capacity for Lower Manhattan, for example, was located on the World Trade Center. At the same time, the abnormal conditions of a crisis or disaster increase the importance of information. This accounts for the condition of high uncertainty or what has sometimes been described as an information vacuum; where there is an intense need for information at the very time when information is scarce.

### THEORETICAL CONCEPTS

Disaster communication is a diverse, interdisciplinary field that spans political science, anthropology, sociology, and public health, among others. In addition, disaster communication has roots in applied issues and practices. Recently, several useful theoretical frameworks have emerged that are helping to unify this body of diverse research.

Apologia or image restoration involves a comprehensive body of research detailing the *post-crisis communication strategies* available to organizations (see Benoit 1995; Coombs 1999). These → image restoration strategies are most often associated with organizations perceived to have caused or contributed to a crisis or those organizations that have somehow failed to mount an effective response (→ Organizational Image; Corporate Reputation). These strategies are grounded in “the belief . . . that communication (words and actions) does affect how stakeholders perceive the organization in crisis” (Coombs 1999, 121). Benoit (1995) offers the most comprehensive and widely applied typology of image restoration strategies. His five image restoration strategies include: (1) denial, (2) evading responsibility, (3) reducing offensiveness of the event, (4) corrective action, and (5) mortification.

A concept known as the *discourse of renewal* has recently been offered as an alternative to image restoration. Grounded in larger notions of organizational responsibility and the opportunities inherent in any crisis, renewal is a more provisional response to many crises and disasters in that it is guided by values and a natural response to the crisis (Seeger & Ulmer 2001, 2002; Ulmer et al. 2006; → Corporate Social Responsibility). The guiding impetus is to recover, rebuild, and learn. Image restoration, in contrast, is guided by a strategic position designed to minimize cost and harm, and repair image. *Adaptations of chaos theory* to crisis and crisis communication have resulted in powerful insights about the role of communication and about the behavior of complex, nonlinear systems (Sellnow et al. 2002). Chaos theory is also closely aligned with Perrow’s (1999) *normal accident theory* of systemic crisis. In both, the assumption is that systems reach a level of complexity where severe failure, or bifurcation, becomes programmed into system operations. Chaos theory, however, also suggests that underlying factors, called attractors, serve to reconstitute the organization following these bifurcations. Attractors may take many

forms, including proximity variables, social values, shared goals, and communication processes. Some tenants of chaos theory also view crisis as a natural or evolutionary force, allowing for the emergence of new higher-order structures and processes. Some scholars have built upon this notion, emphasizing the opportunities inherent in a crisis or disaster. A forest fire may create widespread devastation, yet create room for new growth. In fact, some species of tree require fire for their seeds to become viable. In the same way, a crisis may call attention to longstanding social problems and create new opportunities for change.

*Developmental approaches*, or stages of disasters and crises, have been described by a number of scholars (Pauchant & Mitroff 1992; Coombs 1999). These approaches describe crisis and disaster events as series of interrelated phenomena occurring developmentally over time and moving through relatively discrete and predictable stages or phases.

Developmental models have been outlined by a number of researchers and represent one of the most common tools for crisis analysis. These models range from simple three-stage models of pre-crisis, crisis, and post-crisis, to much more detailed stages. Turner (1976) identified six stages: (1) normal starting point, (2) incubation period, (3) precipitating event, (4) onset, (5) rescue and salvage – first stage adjustments, and (6) full cultural adjustment. Some of these approaches have linked communication activities directly to specific stages (Coombs 1999; Reynolds & Seeger 2005). The Center for Disease Control and Prevention has developed a crisis and emergency risk communication five-stage model (CERC) that matches specific health communication strategies to specific developmental stages (Reynolds & Seeger 2005; → Risk Communication; Risk Perceptions). Developmental models also capture the time-sensitive nature of these events. Disasters compress the interval between decision, actions, and antecedent conditions on the one hand and outcomes, reactions, and consequences on the other. Time compression is associated with high levels of decision-maker stress and the need to move quickly to limit harm during a disaster.

An additional body of work has applied the *organizational theory of enacted sense-making* to crises and disasters. This work focuses on how individuals and groups lose important social and behavior references during crisis and how communication may help reconstitute sense-making (Weick 1988, 1993; Seeger et al. 2003). This reconstituted ability to make sense may include a new fundamental understanding of what is customary or routine. Some scholars have used the term *new normal* to describe the ways in which crises and disasters may fundamentally alter a sense of normalcy (Sellnow et al. 2002).

## RESEARCH FINDINGS

Much of the research on disaster evacuations and warnings has adopted and expanded the risk communication literature and focuses on the *effectiveness of warning messages*. Mileti and his colleagues (Mileti & Sorenson 1990; Mileti & Fitzpatrick 1992; Mileti & Peek 2000) have suggested that warnings require six components: (1) hearing, (2) understanding, (3) believing, (4) personalizing, (5) decisions, and (6) actions. A variety of factors has been demonstrated to impact this warning process. Content of the warning message may include information about the nature of the hazard, what locations may be affected, guidance about what to do, timing of responses, and factors associated with the source (Mileti & Peek 2000). In addition, Mileti suggests that the style of the larger communication is also related to

message effectiveness. This includes the relative specificity of the warning, consistency, certainty, clarity, perceived accuracy, sufficiency of the information, and the channel selected.

Some research has suggested that these style variables may operate in more complex ways. Overly certain messages such as, "We have everything under control, we know exactly what is happening, and there is no risk," for example, have been shown to reduce credibility and message effectiveness under conditions of very high uncertainty and may impact message accuracy (Sellnow et al. 2002; → Message Effects, Structure of).

Finally, *receiver characteristics* are very important determinates of warning message effectiveness. These include: environmental cues, such as rain as the condition of flood warnings; social settings and social structures, such as a family being physically unified at the time of the warning; social ties, such as family cohesion, social structure, including demographic variables; psychological factors, such as cognitive features; and finally, pre-warning perceptions, including pre-existing attitudes toward hazards. Riad et al. (2001) have added gender differences, social influences and support, and prior evacuation experience to the list of receiver characteristics. Women have been consistently found to be more willing to evacuate. Social influence factors include observing others evacuating. In addition, prior evacuation is a strong predictor of future evacuation (→ Audience Segmentation).

Recent episodes, including the 9/11 terrorist attacks and the devastation caused by the 2005 hurricane season, have generated additional investigations of disaster communication. Although very wide-ranging, many of these investigations have focused on diffusion of information, uses and gratifications of disaster information, and media use.

A series of studies has examined *media usage and the diffusion of information* during crises and disasters (see Greenberg 2002). Several studies concluded that television is the most widely used channel for disaster information, followed by radio. Both radio and television are very immediate forms of communication, and radio in particular is a very robust technology that can be easily adapted to crisis conditions (Sellnow et al. 2002; → Television Technology). One study of media usage following 9/11 found that on average, individuals engaged in 8.4 hours of television viewing that day. Interpersonal channels of communication, however, are also important particularly as individuals seek out very specific kinds of information. In fact, word of mouth played a very important role in disseminating initial news about disasters even though subjects tended to disassociate their attribution of the initial source over time.

Work on diffusion of disaster information has generally supported the established *S curve of information dissemination* associated with the dissemination of more general news (→ Diffusion of Information and Innovation). In general, information disseminated through the media is diffused slowly at first, reaches a point where more rapid diffusion occurs, then reaches a plateau, at which stage a secondary surge occurs. One exception seems to be the speed of dissemination. Generally, news of disasters spreads very quickly and may flatten this S curve somewhat (Greenberg 2002).

The → *uses and gratifications* model of mass media has formed the basis of a series of studies on 9/11 and Hurricane Katrina. These studies have focused on the needs, preferences, and uses of information reported by individuals. In general, these studies have concluded that information needs and uses vary by gender and by the relationship individuals have to an event. The closer the psychological or physical proximity to the event, the greater the need for information. Women may prefer information about

mitigation and management, while men appear more interested in information about consequence and response. Needs and uses may also vary by race, social-economic class, and by perceived vulnerability.

Disaster and crisis communication is a robust, interdisciplinary field that has received a great deal of attention in recent years. The field not only includes an important research tradition, but is also an important area of applied work. Research thus far has benefited from powerful theoretical frameworks and identified a number of fundamental concepts that impact the effectiveness of these messages. Much more work is needed, however, in part because disasters are such dynamic events and new threats and implications of threats are constantly emerging.

## Disclosure in Health Communication

*Béatrice Godard*

*University of Montreal*

Much has been written in recent years about the issues of disclosing and communicating health information (including genetic information) in biomedical research and medical practice. Various guidelines and policy statements have been adopted internationally, but these are contradictory and the criteria they set out sometimes vague. Given the complexity of the ethical landscape surrounding this topic, particularly in regard to genetic risk and predictability of disease, guidance is undeniably needed on this issue.

In fact, the proliferation of tests to identify individuals with an increased risk of genetic disease has led to a re-evaluation of the duties of researchers, physicians, and other health-care professionals. Considering the speed at which genetic technologies are moving from bench to bedside, the questions of (1) whether researchers should communicate research results, (2) whether physicians should recontact patients concerning new information that might be useful to them, and (3) whether physicians should inform family members of relevant genetic information are becoming increasingly important (→ Bad News in Medicine, Communicating; Health Communication, Ethics in). These questions correspond to the current changes taking place in the spheres of knowledge, social and cultural values and norms, and individual life experience.

Currently, changes in professional attitudes are reflected in the increased level of communication and involvement in relationships with patients and research participants.

Fully informed communication and the presentation of choices and alternatives are now heralded as indispensable to ethical care. Patients are seen as full partners in the process of informed and involved decision-making. Debate surrounding the principles of confidentiality and beneficence has led to a re-examination of the Hippocratic oath and the sacrosanct principle of confidentiality. Yet there are still few therapies in the field of medical genetics. Once treatment does become available, however, a whole range of new questions arises, in the areas of access to care, the choice and costs of treatment, and the facilities available. The question is: ought we to disclose? In previous practice the wishes of the patient were paramount, but with the rapidity of genetic discoveries, research results might change over time, or the shifting of the significance of genetic diagnosis might prompt the recontact of a patient, or, finally, relatives may wish to receive information for their own benefit. This could mean telling the patient or even a third party against the express wishes of the patient.

These issues point to the need to respond to new developments in relation to existing ethical issues. An ethical framework for the practice of genetics may thus introduce new professional responsibilities in the existing duty of care, which includes the duty to inform, to provide appropriate care, to follow-up, to refer, and to refrain from abandoning a patient (Hunter et al. 2001, 270). To this, should we add the duty to communicate results in the research setting, the duty to recontact patients, and the duty to warn relatives (→ Research Ethics)?

## **MAJOR DIMENSIONS AND CHANGES OVER TIME**

### **The Communication of Results in Research Settings**

To clarify the discussion on the communication of results in research settings, there is a need to distinguish between the established ethical obligation to communicate general basic research results and the eventual return of specific findings that may be relevant to individuals. By their very nature, most research results are usually in the aggregate form and not at all “individual.” As stated by the World Health Organization (2003), in most cases genetic research data will remain of abstract significance.

Nevertheless, a suggested avenue is to communicate results in basic research if and when they have been scientifically and clinically validated and when they have implications for the health of the participant. The Consortium on Pharmacogenetics (2002, 6) considers that researchers should “offer the research subject the option of disclosure of research information when its reliability has been established and when the disclosure is of potential benefit to the subject.”

Turning to results in clinical trials, international guidelines for good clinical practice stipulate that investigators as well as institutions involved in trials “should ensure that adequate medical care is provided to a subject for any adverse events, including clinically significant laboratory values, related to the trial” (ICH 2001, 4.3.2). The communication of research results in clinical trials may occur when test results are relevant to the patient’s health: the patient has the right to receive information and to be fully informed about her or his health status, including the medical facts about her or his condition (World Health Organization 1997; World Medical Association 1995).

Ethical considerations require health professionals to evaluate the specificity of research results, differentiating between the obligations of a researcher, who usually only has general results, and those of the physician vis-à-vis their patients involved in clinical trials. Failure to provide information about study results may be one of the many factors that adversely affect accrual. Providing results to study participants or patients might maximize the good, i.e., respect for the person, quality of life, although no empirical data support this premise. The communication of research results might lead to better patient–physician communication, which would in turn lead to greater satisfaction with medical care.

### **The Duty to Recontact in Clinical Settings**

In addition to the communication of research results, do physicians have a duty to recontact patients when confronted with new genetic information, more precise tests, or new therapies? A physician may consider that recontact is needed following the discovery of preventive measures or treatment for a specific condition, or when the patient requires immediate and continuing treatment or management. The degree of uncertainty surrounding genetic risk notification warrants guidelines for determining the circumstances in which recontact efforts should be undertaken. It is important to remember that novel ethical questions come into play, as it is doubtful that consent to be recontacted could be autonomous since patients do not know in advance what kind of information might be disclosed. While recontact may be attempted if treatment or prevention is available, professionals should consider the emotional impact of communicating new sensitive information. They must, above all, ensure that the patient’s privacy and familial interactions are protected (Fitzpatrick et al. 1999; Hunter et al. 2001). The Canadian College of Medical Geneticists stresses that the disclosure process in testing “should avoid needlessly informing individuals who do not wish to learn their genotype or informing one family member of another family member’s genotype” (Hall et al., 1991).

Most professional bodies, however, have no policies requiring physicians to disclose new relevant information, except in the case of adverse events or medical incidents. This may be changing: ethical guidelines are directed at empowering patients to assume ownership of their ongoing care and to use new findings and therapies to improve their quality of life. According to the American College of Medical Geneticists (1999):

It is the medical geneticist’s responsibility to provide clinical updates to those patients to whom they provide an on-going service. However, since this represents the smaller percentage of the caseload, it should be incumbent upon the primary care physician to alert his/her patient to the need for a recontact as necessary. The patient should also be included in the process by being adequately counseled to contact the primary care physician or genetics unit as relevant changes in their lives occur.

The duty to recontact may be crucial because failing to disclose relevant updated information undermines public trust in medicine. Failure to recontact not only involves deception, but hints at a preservation of professional interests over the well-being of patients. It may cause harm if patients are injured further by the failure to disclose; moreover, it may also undermine efforts to improve the involvement of patients in their

care. And because it impinges on a patient's right to know, failure to disclose relevant genetic information could be deemed a breach of professional ethics.

While there are benefits to recontacting and to communicating new clinical data, there remain considerable disadvantages. Patients might not want to be recontacted or receive new information. Clinicians need to anticipate negative reactions and be prepared to provide the necessary support. Disclosure necessitates the use of substantial resources: participants may want more or less information and it could become quite time consuming. How should professionals recontact for new tests or treatments? The processes for both the communication of research results and for recontact should be built into the informed consent process and, if acceptable, re-offered to the individual at the recontact. And by engaging the individual in a comprehensive discussion of what disclosure entails (and always estimating the perceived benefits conservatively), physicians must insure a balance between harms and benefits. Provisions for anticipatory follow-up have to be made explicit. Patient advocacy groups, who lobby for the protection of patient rights, may prove very helpful in this process.

### **The Duty to Warn Family Members**

The personal and familial nature of genetic information further complicates confidentiality and privacy issues. It may be important for an individual to be informed of a family member's genetic test results and thus of their own risk when it comes to potentially preventable or treatable conditions. Hence, the duty to warn family members could arise when the warning is necessary to avert serious harm for treatable or preventable conditions. A Code of Ethics prepared by the Canadian Medical Association (2004) maintains:

Disclose your patients' personal health information to third parties only with their consent, or as provided for by law, such as when the maintenance of confidentiality would result in a significant risk of substantial harm to others, or in the case of incompetent patients, to the patients themselves. In such cases take all reasonable steps to inform the patient that the usual requirements for confidentiality will be breached.

Thus, health professionals must determine whether the family member is at a high risk of serious harm; they must also decide if, in the event where a patient has repeatedly refused to disclose the information, a breach of confidentiality is necessary to prevent or minimize this harm. How is a physician to resolve the competing ethical mandates of autonomy and beneficence and non-maleficence? This requires an evaluation and comparison of the actual risk of a genetic disease, the efficacy of potential preventive interventions, and emerging legal considerations and potential liabilities. The physician should strive for a balance between the right to confidentiality, the right to know, and the right not to know, including that of others who are not even his or her patients.

More detailed advice concerning the duty to warn relatives urges physicians to assist patients in their communication with relatives. Physicians, according to the American Medical Association *Code of medical ethics*, "should make themselves available to assist patients in communicating with relatives to discuss opportunities for counseling and testing, as appropriate" (2006). Advocacy groups, meanwhile, recommend asking the patient's

consent in advance of genetic testing for permission to disclose genetic information to relatives (Genetic Interest Group 1998).

### **CURRENT EMPHASES IN WORK AND FUTURE DIRECTIONS**

In the joint-account model elaborated by Parker and Lucassen (2004), it is assumed that genetic information should be available to all account holders (health professionals, relatives) unless there are good reasons to do otherwise. The justification in favor of a joint account adheres to the ethical principles of justice and reciprocity; there are also benefits to be gained by sharing genetic information. Seeing as physicians in medical genetics work with families, the chosen approach appears to be consistent with the very nature of practice in genetics. However, more often, a case-by-case approach is chosen. This approach enables professionals to intervene when the disease is fatal if diagnosed late but treatable if diagnosed early. On the other hand, in cases in which the disease is untreatable, the duty to warn would be tenuous, except for reproductive decisions. Some diseases would fit in between, such as hereditary breast cancer, which is treatable by aggressive surgery.

Ultimately, emerging responsibilities in genetic risk notification require an over-expansion in the duty of care for professionals. Duties to communicate research results and to recontact with clinical findings affect the concept of an “ongoing duty of care” in order to include patients’ informational needs. The duty to warn creates a shift from “individual therapy” to one that is “family-and-future-generation oriented.” The importance of this issue seems unlikely to diminish in the future. As public awareness grows and new technologies develop, the pressure for greater clinical services and information is inevitable. Individuals at risk push for research that is more process oriented and patient oriented. Consequently, requirements of informed consent and confidentiality may be modified relatively to other forms of medical care. These issues, along with that of non-maleficence, the duty to do no harm and yet also to prevent harm, are omnipresent. The current socio-cultural context and pressures of the “promise” of genetic information cannot be ignored.

A fair process in health-care ethics remains a priority. This approach is more likely to be successful and useful than agreement on a set of principles. A fair process would be one in which there was transparency about the grounds of the decisions to return results, recontact, or warn based on prior discussion. Appealing to rationales that all can accept as relevant to meet health needs fairly, it would allow procedures for revising decisions in the light of challenges to them.

## Disclosure in Interpersonal Communication

*Sandra Petronio*

*Indiana University-Purdue University*

Disclosure, as a type of interpersonal communication, means revealing private information that individuals believe they own and have a right to control. Disclosure builds romantic and friendship relationships, although there is a possibility of disclosing too much information, or telling information when a relational partner is not ready to hear the disclosure, thus hampering relational growth. Therefore we know that disclosure has both a positive outcome and the potential to have unwanted outcomes for interpersonal relationships (→ Interpersonal Communication).

Historically, the concept of disclosure is attributed to Sidney Jourard (1971). His work on “self-disclosure,” defined as “the act of making yourself manifest, showing yourself so others can perceive you” (Jourard 1971, 19), focused primarily on opening up the self to others (→ Disclosure in Health Communication). Much of the early research on disclosure accepted Jourard’s assumption that self-disclosure is unequivocally positive. In fact, Jourard argued that self-disclosure was the key to a healthy personality. From this early

work, we learned that there are some *gender differences* in self-disclosure. For example, women disclose more than men to others of the same sex. We also know that issues such as status, age, and attractiveness affect whether a person discloses. The research also showed that men conceal information because they fear loss of control, while women avoid disclosure to prevent hurt and problems with relationships (Rosenfeld 1979). A focus on the issue of *reciprocity* (whereby people disclose to others and those individuals respond with disclosures) revealed that people reciprocate disclosures early in a developing relationship, but as people come to know each other, self-disclosure occurs less often. Reciprocity does not have to occur immediately. When disclosure occurs, the recipient might wait days or weeks to reciprocate the disclosure. Altman and Taylor (1973) initially conceptualized disclosure reciprocity in their “social penetration theory.” Their theory explains how interpersonal relationships develop. They argued that reciprocal disclosure occurs along two dimensions: *depth*, meaning the level of intimacy of the disclosure, and *breadth*, meaning the number of topics discussed. Through these processes, people develop significant relationships with each other (→ Social Support in Interpersonal Communication).

Although early researchers argued for the unequivocal positive effects of self-disclosure, others cautioned that disclosure may not indisputably end in a positive outcome. As research began to illustrate that disclosure could be both positive and negative, it became clear that a new way to conceptualize disclosure was needed. One of the ways researchers expanded the notion of disclosure is seen in a theoretical perspective called Communication Privacy Management (CPM) (Petronio 2002). The research from this theory shows that people simultaneously need to reveal and conceal private information (→ Privacy). Disclosure helps people to connect; however, keeping information to themselves helps them to sustain autonomy. CPM illustrates how people manage the ebb and flow of these concurrent needs by placing private information within a privacy boundary. People manage the flow through privacy rules. Once people disclose, they make the recipients shareholders in the information, extending the boundary to include the recipients (→ Bona Fide Groups). In a perfect world, each person privy to the disclosed information negotiates the rules allowing third-party disclosures. But we do not live in a perfect world, so people make mistakes and inappropriately disclose or intentionally violate privacy (→ Relational Dialectics).

The CPM perspective helps us understand many interpersonal communication issues that were not clear in the past. We now have a better idea about stepfamily difficulties when children feel caught between both families (Afifi 2003). We know that there is a chilling effect in families when members apply pressure to conceal secrets by insisting on using certain privacy rules (Afifi & Olson 2005; → Family Communication Patterns). The management of secrecy and privacy is a powerful source of control for adolescents (Frijns 2004). Further, physicians use very specific management rules to preserve their integrity when it comes to disclosure about medical mistakes, but they suffer the consequences for doing so (Allman 1998; → Bad News in Medicine, Communicating). We also know that parents and children use privacy rules to avoid disclosing certain topics, leading to dissatisfying interpersonal interactions (Caughlin & Afifi 2004). People also use certain privacy rules to guide disclosing about HIV status to relational partners (Greene et al. 2003).

As the current thinking about disclosure suggests, we find that people manage a balance between wanting to connect through telling private issues, and also wanting to protect themselves from possible unwelcome or unexpected outcomes resulting from disclosure. Thus there appears to be a calculus that we use to traverse the complicated informational world we live in and still manage to establish, sustain, and repair our interpersonal relationships when it comes to disclosure of our private information.

## **Discourse**

*Paul Cobley*

*London Metropolitan University*

As a common term in English, discourse means any extended verbal communication, such as Jesus's discourse with the people (John 6: 22–71) or, "The Disinherited Knight then addressed his discourse to Baldwin" (Scott, *Ivanhoe*). Discourse is lengthy but targeted speech between individuals or between an individual and a group. As a theoretical term,

discourse gained in importance during the twentieth century, both in the relatively new discipline of → *linguistics* and in the newer discipline of communication study (→ Communication as a Field and Discipline), taking on two distinct meanings. First, it refers to stretches of communication beyond the small units that are examined with the traditional methods of linguistic analysis. Second, discourse directs attention to the social origins and consequences of communications (→ Communication: Definitions and Concepts).

### HISTORY OF THE CONCEPT

Discourse has a Latin root in *discurrere*, which itself is related to *currere* (“to run”). French derives the terms *discourir* and *cours* from these roots; English similarly derives “discursive,” “excursion,” “current,” and “courier.” The core meaning is movement of one sort or another, or running around. This idea is embodied in current uses of “discourse” to refer to communication as social interchange, and was also reflected in older occurrences of the term. Famously, Descartes’s *Discourse on method* (1637) is envisaged as a journey round the philosophical issues with which he was concerned.

After the Renaissance, “discourse” was employed in philosophy to suggest a laying out of and meditation on theoretical matters. This usage echoes the idea of rhetoric as the moving back and forth between intellectual positions in order to communicate effectively (→ Rhetorical Studies). From the classical period onwards, rhetoric had been established, on the one hand, as a practical means of identifying and studying longer forms of human communication than individual signs – for example, *exordium*, *narratio*, *argumentatio*, *refutatio*, *peroratio* (MacCabe 1979). On the other hand, these forms of communication lent themselves to persuasive or strategic uses. In envisaging *movements* between each of these forms or stages of communication, and between study and practice, rhetoric served to develop categories of discourse for scholarly as well as other social communication.

### DISCOURSE AND LANGUAGE

In his *Cours de linguistique générale* (*Course in general linguistics* 1916; translated into English in 1959 and 1983), Saussure projected “a science which studies the role of signs as part of social life” (1983, 15; → Semiotics). Despite his focus on the linguistic sign as such and the system by which specific utterances are underwritten (*langue*), he articulated a need to open up linguistics for analyses beyond individual signs and sentences. Following work by the Danish linguist, Louis Hjelmslev, Saussure’s *Cours* became applied outside linguistics and outside the domain of spoken discourse. Hjelmslev’s resolute systematization of approaches to the different levels of language, its elements and rules, made Saussure’s framework even more amenable to other structuralist thinkers (→ Structuralism) such as Claude Lévi-Strauss and Roland Barthes (→ Barthes, Roland). Both of these theorists sought to explicate the components and possible combinations of language, further applying these as general categories to various other media and modalities of communication (→ Modality and Multimodality). While such work did not focus explicitly on a conception of discourse, it delineated an approach to the social uses and implications of signs as rule-governed, discursive sequences.

In the American structuralist tradition of the 1930s, Zellig Harris also explored rules beyond the sentence by developing the concept of *transformation*. Whereas this notion has been developed in various ways, within the theory of discourse it was elaborated especially in the area of *sociolinguistics*. For example, through extensive ethnographic work, Dell Hymes found that speech acts and other communicative events followed certain well-defined parameters within a given cultural context: discursive and social patterns were precisely aligned (→ Ethnography of Communication). The capacity to communicate, then, is not simply a matter of being able to produce an infinite number of syntactically correct sentences. Rather, communication depends on what current research would call a discourse – a frame of reference including practical knowledge of when one can speak, to whom, with what purpose, and in what circumstances.

Other sociolinguists such as William Labov and John J. Gumperz worked to cement the understanding of language as part of the social world, with reference to a similar, nascent notion of discourse (→ Interactional Sociolinguistics). One of the most influential sub-fields of sociolinguistics, → *conversation analysis*, concerned itself with *turn-taking* in discursive interaction and the protocols governing this, often highlighting the seemingly marginal aspects of linguistic communication such as interjections, intonations, pauses, and overlaps that inevitably feature in everyday talk. Next, conversation analysis would focus on these features as formal representations bearing witness to the social roles of the participants in a given interaction. The implication is that discourse – communication bearing a close relation to speakers' and hearers' roles – should be understood as an encompassing system of social interaction that constitutes any particular group of speakers in terms of a periphery and a core, and which comprises both their verbal and nonverbal communication.

## DISCOURSE AND SOCIETY

The first meaning of discourse – units of communication larger than sentences – tends to imply the second meaning – communication as embedded in society – which requires more than a descriptive account of language. Austin's (1962) notion of *speech acts* has been one of the key influences on theories of discourse in this respect (→ Linguistic Pragmatics). While demonstrating that certain statements, in certain circumstances, have a *performative* function rather than a descriptive (*constative*) one (e.g., naming a ship, pronouncing a verdict), Austin went on to suggest that all statements tend to be performative – even if they might be portrayed otherwise. This insight underlies contemporary discourse studies: discourse has a rhetorical purpose, constituting speakers and hearers as ingroups or outgroups, while simultaneously delimiting those social fields to which reference can legitimately be made.

As a rhetorical form and a social practice, the concept of discourse further relates to two other conceptions of communication beyond the sentence level. *Text* is a theoretically neutral concept that refers to a string of verbal or nonverbal signs – written paragraphs, paintings, films, dance performances, gestures, etc. (→ Text and Intertextuality). An analysis might determine that such texts are part of a larger rhetorical form, or that they enter into discursive practices with ideological implications. *Genre* denotes a group of texts that share particular features, and which have been shaped for specific audiences and purposes

(→ Genre). As such, genres, in addition to being discourses in themselves, may frame specific social discourses – drama, debate, → journalism, → advertising, etc.

As social discourses, texts and genres ultimately entail the exercise of power (→ Power and Discourse). While implicit in earlier understandings of discourse, power was defined as its key constituent following the works of Michel Foucault. Today, it provides a reference point for the social understanding of discourse, the second meaning above. Foucault (1980) suggested that a particular manifestation of communication leads to an embodiment of power in discourse. Because the state cannot be omnipotent, power is often exercised (in an apparently nonstate fashion) through discourses. Although discourses open up possibilities for what may be said or thought, their very organization also delimits what can in fact be said or thought in a particular social sphere. Such discourses include those addressing the body, education, gender, public health, etc. Moreover, each discourse, according to Foucault, is maintained by specific technologies facilitating, not least, the surveillance of individual subjects.

This understanding of discourse, further, implies a constructionist position (→ Constructivism). A discourse not only delimits what can be communicated about an object, but *produces* the very objects of knowledge. A social constructionist position on discourse is traceable at least to Vološinov's work of the 1920s (Vološinov 1973), emphasizing that verbal communication is more a matter of what people want to get out of a situation than of information exchange. Discourse encompasses goal-orientated acts of *representation*, effectively creating what is being represented. Because theories of discourse consider discursive representations so powerful in constituting the social world, the concept of discourse has sometimes replaced that of ideology.

## DISCOURSE ANALYSIS

While building on earlier work on language and society, → discourse analysis proceeds from a Foucauldian perspective on power as circumscribing discourse, and on discourse as constructing social reality. In empirical studies, discourse analysis sheds further light on how discourse is constituted in practice. Conversation analysis focused on turn-taking between people but, ultimately, surveyed the workings of power as discourse organizes membership roles for some while excluding others. Communication between humans is not merely a matter of attempting to reflect the world; rather, it is a form of social action.

Discourse analysis, despite variations, is committed to the general idea that meaning and social roles are produced in interaction. This is true, for example, of frame analysis, conversation analysis, and critical discourse analysis. One variant, → *discursive psychology*, seeks to demonstrate that people's very existence is constructed through their communications. Discursive psychology examines the detailed workings of discourse, especially how people use discourse to *do* things, constructing the social world for themselves and others. Such studies uncover, for example, the many disregarded stakes and interests that people pursue in everyday communication (see, e.g., Potter 1996; Edwards 1997; Edwards and Potter 2005).

Much discourse analysis has been predicated on verbal communication, but is increasingly conducted with reference also to nonverbal signs (→ Nonverbal Communication and

Culture). The multimodal communications of electronic media serve as one reminder that texts and genres are frequently part of a broader discourse, emanating from an industry, an artistic practice, a historical epoch, or a mode or reception. Also in → *interpersonal communication*, analysis has shown that the discourses pertaining to, for instance, occupational practices are constituted as much by nonverbal as by verbal communication (see, e.g., Goodwin 1994 on court proceedings and archaeological digs; see also Sidnell & Stivers 2005). Discourse is also operative in the myriad nonverbal communications that make up everyday life – the regularities of gesture, kinesics, and proxemics (→ *Gestures and Kinesics*; *Gestures in Discourse*; *Proxemics*) that people employ implicitly while enacting social roles for themselves and others.

# Discourse Analysis

*Bertram Scheufele*

*University of Jena*

Like qualitative content analysis and → Grounded Theory, discourse analysis can be conceived as a qualitative empirical method of analyzing mostly recorded human communication (→ Content Analysis, Qualitative). The term itself was first introduced to the public by Zellig Harris in the early 1950s, but used rather unsystematically. In general terms, discourse analysis serves for analyzing written or spoken language use within a society or in public – like public discourse about abortion in Germany and the United States or like the anti-Semitism discourse in postwar Austria. As one can tell from issues like abortion or racism, discourse analysis quite often implies a normative element. For instance, the critical discourse approach (e.g., Ruth Wodak, Teun A. van Dijk) asks about social hierarchies by studying language as a form of social practice. This approach is thus convinced that social and political domination is reproduced by speech, talk, and discourse.

## DEFINITION AND ASPECTS OF DISCOURSE

There are different approaches of discourse analysis in several scientific disciplines. In this respect discourse approach is truly interdisciplinary. Some forms of discourse analysis refer to poststructuralism (e.g., Michel Foucault), some are based on socio- or psycholinguistics (e.g., Wodak, van Dijk) and some more or less belong to communication research (e.g., William A. Gamson). The historical or critical discourse analysis combines sociological aspects and linguistic elements, as well as aspects of cognitive psychology in a coherent research program. While qualitative content analysis or Grounded Theory can be applied to different text material from different theoretical perspectives, discourse analysis is tied to the theoretical core construct of discourse. Discourse is defined in different ways. Gamson, for instance, defines it as “a particular set of ideas and symbols that are used in various public forms to construct meaning about it.” Jürgen Habermas defines discourse as a form of argumentative communication in which legitimacy that has been called into question is being restored (→ Habermas, Jürgen). Many researchers follow the definition of discourse as an argumentative form of “public conversation.”

Despite all their differences, most definitions share four crucial aspects. First, discourses refer to political or social issues which are relevant for society or at least for a major group of people. In this respect one can distinguish between a “drug discourse,” an “anti-Semitism discourse,” a “migration discourse,” a “nuclear energy discourse,” or an “abortion discourse,” for example.

Second, the elements of discourses are called speech acts. Following speech act theory, a statement is not only a statement in the sense of speaking (e.g., saying “thanks”), but also a form of social acting (e.g., actually “thanking” someone). There are different opinions about the elements of speech acts. For example, some researchers look at arguments, others focus on metaphors and neologisms, and some look at key words. These elements are conceived as patterns of discourse and are a focus of discourse

analysis. The role of speech acts in discourse can be exemplified by social movements: participants in a social movement make statements in order to emphasize their concerns, to tell the public about what they claim to be an injustice, and mobilize others to participate in the movement. Thus speaking is not only a verbal act but also a type of social acting or social interaction.

Third, discourses can be analyzed by studying text corpora like party political programs, official documents, transcripts of parliamentary debates, or historical sources. In most cases, however, researchers rely on media coverage as an indicator for public discourse. Therefore, a discourse can be conceived as a political or public debate covered by the mass media. Yet, one should then speak of “media discourse.” Mass media can be conceived as producers of discourse as well as an arena, forum, or platform for discourse participants. In this sense Gamson uses the image of discourse participants “speaking from a gallery.” Nevertheless, mass media or – more precisely – journalists, reporters, and commentators should themselves be considered participants in a public discourse.

Fourth, discourses are processes of collectively constructing social reality. Participants of such processes make use of activities called “discourse practices” (Foucault) or “sponsor activities” (Gamson). Since discourse participants try to establish their point of view as collectively binding, any discourse implies some element of hierarchy, domination, or conflict. Socio- and psycholinguistic researchers (Gamson, van Dijk, Wodak) share further assumptions. They assume that all knowledge is organized in the form of cognitive schemata, frames, or scripts, and that this knowledge is applied to and transformed within social discourse. Thus, this cognitive structure can be perceived in social contexts like using language and making statements.

### **AIMS OF DISCOURSE ANALYSIS**

As mentioned above, discourses comprise speech acts and their elements. These elements serve as discourse devices – a notion going back to George Herbert Mead’s “significant symbols” of social interaction (→ Language and Social Interaction). The main task of discourse analysis is to examine and interpret discourse devices in terms of social hierarchies. On the one hand, one can distinguish different forms of discourse analysis according to theoretical backgrounds like sociology, → linguistics, or psychology. On the other hand, one can differentiate between different versions of discourse analysis according to the discourse devices under examination.

The poststructuralist version of discourse analysis (Foucault), for instance, aims at discourse practices, discursive content, elites, and formations. Socio- and psycholinguistic versions of discourse analysis (Wodak, van Dijk) rather examine argumentative structures and linguistic patterns, or focus on metaphors and neologisms. Some studies analyze these devices for a limited number of, for example, newspaper reports. Others decompose a single article in every syntactical and semantic detail. Those versions of discourse analysis dealing with public or media discourses (e.g., Gamson) focus on so-called “idea elements.” These can be categorized as “frames,” which are also called “packages of interpretation.” Although the above-mentioned researchers claim to do something different than an argumentation analysis, the idea elements are in fact simply explanations for a certain standpoint and thus a sort of “incomplete” argument. And the frames or

interpretive packages are comparable to global arguments. The process of identifying idea elements is explained rather vaguely in most studies. Yet, this also holds true for generating argumentative structures and linguistic patterns in socio- and psycholinguistic versions of discourse analysis. Some researchers seem to make a more or less hermeneutic or impressionistic categorization of the text material. Others rather do a qualitative content analysis in order to identify and describe discourse patterns more systematically.

Most studies carrying out a discourse analysis are more interested in the specific qualities of a discourse than in quantifying these qualities. For instance, critical discourse analysis is interested, say, in identifying different anti-Semitic rhetorics in political speeches or newspaper articles as well as in describing and discussing them in a wider social and political context. But there is no quantitative analysis in most studies. In contrast, a conventional content analysis would measure quantitatively by counting the appearance of such discourse elements for a large number of speeches or articles (→ Content Analysis, Quantitative). Besides, considering the social or political context would be rather an aspect of data interpretation than an inherent aspect of a conventional content analysis. Most studies in discourse approach are qualitative work. Nevertheless, public or media discourse studies are also quantifying the idea elements and frames identified before. Thus, as with categories obtained in qualitative content analysis, the elements being identified in discourse analysis (e.g., neologisms, metaphors, arguments) can be incorporated into a codebook for a quantitative content analysis. So discourse analysis and quantitative content analysis do not necessarily exclude each other, but can be integrated into a larger research project.

# Discourse, Cognitive Approaches to

*Robert E. Sanders*

*State University of New York at Albany*

Most Language and Social Interaction (LSI) researchers would agree that their findings about the social functionality of details of language use and social interaction have potential value for cognitive science. Schegloff (2006) cites evidence that people have cognitive capabilities for managing, detecting, and processing the socially consequential details of expressive acts whose complexity exceeds what cognitive science has recognized to date (→ Information Processing; Cognition).

But LSI researchers are not concerned with the value of their findings for cognitive science. They are only concerned with cognition insofar as taking it into account helps us understand how language use and social interaction work. This involves an issue on which there are differing positions. At the one end, there is the position that opposes a concern with cognitive content, except for the way cognition-related talk functions in language use and social interaction. At the other end, there is the position that we can and should assess how cognitive content influences or is influenced by language use and social interaction – what people perceive, believe, value, want, or feel at the moment. In between these poles there is a concern with what people must “know” about language use and interaction to have a systematic basis for composing and interpreting socially functional expressive acts. From several recent publications in which these issues are addressed, four distinct approaches can be distilled regarding what aspects of cognition are relevant in LSI research, and for what purpose (Fitch & Sanders 2005; te Molder & Potter 2005; van Dijk 2006).

## THE ANTI-COGNITIVIST APPROACH

The anti-cognitivist approach arises mainly in → conversation analysis, → discursive psychology, → ethnomethodology, and sometimes → ethnography of communication. This approach has roots in the work of sociologists in the 1960s, especially Herbert Blumer, → Erving Goffman, and Harold Garfinkel. They attribute persons' actions and the personal qualities they exhibit to external social demands exerted on them, not internal cognitive states – to what is required of persons in situations to achieve coordination with others and sustain social order. Empirical work associated with this approach emphasizes the postulate in LSI that expressive acts and interactions are co-constructed by the participants, rather than products of any one person's cognitions.

An additional reason given for this anti-cognitivist approach is that – apart from what actors say – it is generally not possible for either analysts or interacting persons to detect any specific influence that someone's actual cognitive content exerts. This ties to the observation of what happens when persons do publicly manifest actual cognitive events; for example, when someone utters the “change of state” token *oh*, or engages in self-repair, or reports uncertainty or confusion. It seems to be the social relevance and meaning of the indicated cognitive event that occasions such expressive acts, not the cognitive event itself.

Talk about cognition has been examined from two main perspectives. One perspective is that matters attributed to cognitive events are for all practical purposes matters of language use and interaction. For example, Lynch (2006) considers that what is nominally the cognitive activity of “looking for” something actually involves social coordination with others as to what to look for and how to look for it, as does “counting” things. He also considers that the nominally cognitive event of “failing to recall” something (as in court) often has a social basis and social meaning independent of any cognitive state.

The other perspective focuses on the fact that talk is the primary medium through which individuals’ cognitions are made known, whether in interviews, on questionnaires, or in interaction. Because of the inherent *social functionality of such talk*, it cannot provide a faithful record of cognition. Much attention has been given to the way our knowledge about another’s cognitions – what the other perceives or knows, or what his or her intentions are – depends on the accounting and interviewing practices used to present or obtain such knowledge, not interviewees’ actual cognitions. Attention has also been given to the way cognitive states are reported so as to justify an action that was taken. In addition, some research attributes practices in institutional settings to “distributed cognition,” where the basis for what people know and think about on a task depends on the social distribution of effort within a community of practice, rather than their independent cognitive states and content.

### THE “COMPETENCE” APPROACH

In contrast to the anti-cognitivist approach, analysts in language pragmatics (→ Linguistic Pragmatics), some in ethnography of communication, and others scattered across other LSI sub-fields are concerned with a different aspect of cognition. They are concerned with the “knowledge” that people must have about what makes situated expressive acts meaningful that enables them to achieve and to detect social functionality in the details of language use and interaction. Finding out what has to be known reveals the systematicity of language use and social interaction, as well as the basis for culture learning, children’s communication development, and the source of differences in individual proficiency.

One approach involves *rules*. For example, an early formulation of the concept of “communicative competence” by the sociolinguist Dell Hymes involves knowledge of “rules of speaking” within a speech community that enables speakers and hearers to produce socially meaningful acts and understand them as such. The conversation analysts Harvey Sacks, Emanuel Schlegoff, and Gail Jefferson formulated procedural rules that people orient to in taking turns and selecting next speaker in conversations. In language pragmatics, John Searle proposed that persons know constitutive rules that specify what the content of an utterance must be, the social conditions of the utterance, and the speaker’s intention, for the utterance to count as a particular speech act.

Another approach involves *formal relations between expressive acts* by which they are interpreted and interconnected. H. P. Grice’s cooperative principle and associated conversational maxims specify ways utterances are presumed to be connected that guide the way people interpret (and are counted on to interpret) them. Politeness theory draws on Grice’s thinking to model how persons reason in composing expressive acts so as to reduce the face threat that the act poses to the hearer (→ Politeness Theory). Sanders

(1987) has proposed principles by which utterances are relevant to each other on the basis of alternate possible interpretations. “Knowledge” of these principles would enable speakers to project the interactional consequences of their expressive acts. Such projections provide a basis for composing and interconnecting expressive acts to promote desired social results, and also a basis for inferring the social goals of others.

### THE ETHNOGRAPHY-IDEOLOGY APPROACH

This third approach is common to the sub-fields of the ethnography of communication and discourse analysis, with ties to critical theory and cultural studies. Work in these sub-fields has in common an interest in the cognitive content (beliefs and values) that is publicly expressed – presupposed and affirmed – by the texts and communal practices people produce, independent of the beliefs and values persons have privately. Ethnographies of communication start with communal or ritual practices that one finds community members engaged in regularly that are distinctive for the underlying beliefs and values they affirm for natives. These practices comprise not just texts but other materials of social expression and performance, including setting, participation structure, dress, nonverbal manner, equipment, and so forth. Discourse analysis starts with texts that individuals produce in relevant contexts, and inferentially specifies the underlying ideology that substantively interconnects the text’s components. In both cases, “native” informants may guide and correct inferences of the cognitions – the cultural code or ideology – underlying the materials of practices and texts.

There are two kinds of cognitive content that these sub-fields cite. Although not usually put this way, one of these is *schemas of the whole* that are the basis for the interconnections and functionality of particular component acts (→ Schemas, Knowledge Structures, and Social Interaction). Another kind of cognitive content is the ideological value placed on specific acts by which they are hierarchically ordered, sometimes expressed in terms of rules. At times this approach merges with the anti-cognitivist approach when the public expression of cognitions is regarded as a separate matter from the cognitions persons actually have. At other times, it merges with the “competence” approach in identifying “knowledge” that speakers and hearers must have to produce socially functional expressive acts and interpret them as such. And at other times, this approach merges with the social psychology approach (below) that is concerned with the way actual cognitive states in the moment shape expressive acts and the response to them.

Philipsen and Coudu (2005) and Leeds-Hurwitz (2005) survey diverse studies by ethnographers that have identified *beliefs and values* about reciprocal entitlements and obligations among neighbors, married couples, public officials, and the like that rationalize diverse communal practices. These include conceptions of masculinity inferred from men’s speaking practices in a blue collar, urban US neighborhood; the value given to social connections in such practices as seeking favors, issuing and complying with directives, and managing social asymmetries in urban Colombian society; the cultural codes underlying wedding rituals that intercultural couples try to preserve in hybrid wedding rituals they devise; the value placed on symmetry and directness in conflicts by native Israelis evident from a ritual practice for setting aside social asymmetries during disputes with one’s superiors; the knowledge that is needed to be considered a member

and to participate in the reviving culture of Osage Indians; and conceptions of self that are codified and enacted in diverse activities, ranging from being a spectator at a sporting event to an advocate in a community dispute.

Tracy (2005) and Edwards (2005) have surveyed current thinking about discourse analysis in particular institutional and social contexts. This work owes a debt to Michel Foucault's thinking about the way institutional ideologies are embedded in the presuppositions of lexical categories and their interconnections in discourse. However, LSI analysts do not generally take a critical stance. Some work focuses on presuppositions embedded in members' discourse about the institution's and members' goals and how those guide and constrain practical action, for example in discourse about the research colloquia of an academic department, or in coordination problems in interactions between 911 emergency call-takers and callers. Other work has focused on the details of persons' reports of personal experience that represent their perceptions and biases, for example the descriptions of the conduct of members of a stigmatized ethnic group, or descriptions of the appearance and conduct of a passing stranger that made him seem "suspicious" and justified reporting him to the police.

### THE SOCIAL PSYCHOLOGY APPROACH

There is consensus in the sub-field of language and social psychology that aspects of actual cognition (perceptions and attitudes) are directly relevant to certain details of language use and social interaction. Researchers investigate either what details of language use and bodily action have particular effects *on* cognition (principally, perceptions of and attitudes toward the other) and what details of language use and interaction result *from* certain cognitions (attitudes) regarding the other.

Much of the research in this tradition has been done on phonological, lexical, and syntactic aspects of speakers' style that are evaluatively (attitudinally) differentiated, as well as their nonverbal expression. These elements have been found to affect evaluative perceptions of the speaker including perceptions of speaker power, and perceptions of gender difference. In addition, a substantial body of research has been done in relation to the central tenet of communication accommodation theory that the language spoken, accent, lexical choices, and rate of persons will converge or diverge, depending on whether they have positive or negative attitudes toward the other (Bradac & Giles 2005). This general pattern of convergence and divergence and its consequences have also been investigated in the context of interviewing in organizations, and in doctor-patient interactions.

The differences among sub-groups within LSI about what aspects of cognition are relevant to examining the way language use and social interaction work do not indicate conflicting ideas about language use and social interaction. There is general agreement in LSI that the phenomena of interest are not the conduct of individuals except with reference to their coordinated interaction and the discursive practices that achieve that. When attention is given to one aspect of cognition or another, it is always in terms of the part that cognition (or talk about cognition) plays in the social functionality of expressive acts in social interactions.

## **Discourse Comprehension**

*Donald G. Ellis*

*University of Hartford*

Discourse comprehension is the act of interpreting a written or spoken message by integrating the incoming information into the memory or knowledge structures of the interpreter. As such it involves social and pragmatic knowledge as well as grammatical and logical knowledge.

Consider an example from Schank and Abelson (1977): (1) “John went into a restaurant. He ordered a hamburger and coke, paid the check and left.” The statement is simple enough and comprehension of the word “check” in (1) above was probably effortless and automatic. But how does a participant in communication come to the correct meaning of the word “check”? There are other possibilities. The word (phonetic expression) “check” could have meant (a) a particular mark on a page (✓), (b) a piece of paper for depositing money into a bank, (c) to leave a hat and coat in a coatroom, (d) to restrain, (e) to examine, or (f) a move in hockey.

People are able to arrive at the correct meaning for the word “check” because they rely on prior knowledge structures such as → scripts. When you encountered the word “restaurant” in (1) above a “restaurant” script was activated that contains considerable experiential knowledge about typical roles (waiters, cooks, customers), objects (menus, tables, silverware, cash register), goals (get food on time, waitress brings check), and activities (be seated, order food, get served, pay the check). This restaurant script was the interpretive frame for the word “check” (→ Framing Effects). It provided the world knowledge necessary to correctly understand the meaning of the word “check.” This world knowledge includes justifiable expectations and typical inferences. Thus, the restaurant was probably not a sophisticated and expensive gourmet restaurant because one does not usually order a hamburger and a coke in such places. That would be a justifiable inference based on pragmatic knowledge of the world, but certainly not a guaranteed truth condition.

*Functionality* is a first principle of discourse comprehension. Functionality means that all language accomplishes something. Its expression performs some “work”; it is language *in use* or language that cannot be restricted to structural forms but must be related to the purposes, goals, and designs of human affairs. Consider this conversation:

(2) Randy: “What are you up to tonight?” Sue: “I’ve got an exam tomorrow.”

Here it is apparent that the sequence is an identifiable question and answer, but there are also interpersonal and social goals being realized. We might speculate about the specific meaning of the sequence but would require more knowledge to be precise, knowledge such as history of the relationship, communicative intent, settings, cultural patterns of interaction, as well as conventional routines such as “going out with someone.” Randy’s question might be a simple and genuine inquiry, or it might serve as pre-request for information in order to avoid potential rejection from “asking Sue to go out.”

Functionality is contrasted with *structural* approaches, which are more concerned with language as a formal autonomous system (e.g., Chomsky 1957). Structuralists are concerned with grammar and small constituent units of language that can occur in a restricted number of arrangements. In Chomsky’s well-known example – (3) “Colorless green ideas sleep furiously” – the statement is meaningless but structurally well formed. The main comprehension processes are (a) speech act assignment, (b) the coherence mechanisms that assist with tracking information, and (c) the interpretive codes used by communicators.

### SPEECH ACT ASSIGNMENT

A speech act is the performative aspect of an utterance that produces action so the utterance (e.g., “I am sorry for missing the meeting”) is the genuine accomplishment of certain action (to apologize). The goal of discourse comprehension is to use real-time subjective experience to assign conventional meanings to speech acts. If a speaker says “Put the book over there” and wants it to count as an order, then the listener must be able to actually place the book in the designated location and accept the position of authority required to utter an order. The utterance is partially processed as an order because it includes an understood “you” and an imperative structure. Lexically, the utterance is simple and denotes actions “put” and a deictic pronoun (“there”) that refers to a mutually

understood place in the environment. All interpreters get some assistance in assigning meaning to speech acts from deictic movements (e.g., pointing to an object), facial gestures, tone and stress, bodily movements, and interaction history.

Whether or not the interpretation of speech acts is unproblematic from one context to another is a controversy in discourse comprehension. Is an “apology” from a government official the same as from a family member? Some data (Rosaldo 1982) indicate that individual communities develop subjective differences in interpreting speech acts. These data support modifications to the analysis of speech acts by making them more sensitive to sociological and interactional constraints. Work by Labov and Fanshel (1977) is an applied example of how the nonstandard assignment of meaning to speech acts can have important implications in a therapeutic setting.

## COHERENCE

Rendering a discourse as coherent is another central task for both a producer and consumer of communication if they are going to successfully accomplish the act of comprehension. All language users develop pragmatic competence which includes the mechanisms and strategies in a language code for making sequences of messages sensible or coherent. This is an interactional achievement. There is a distinction between coherence and cohesion. *Coherence* refers to the general organizational patterns that lend order to discourse. *Cohesion* has to do with relations among surface linguistic forms. Cohesion is a tie between two linguistic forms that assists a text with its wholeness. In the following sentence the relationship between “papers” and “them” is a cohesive tie:

(4) “Bundle the papers with string. Then place them on the curb.”

The function of “them” is to refer to “papers” and makes it possible to interpret the two sentences as related. The term “them” presupposes “papers” and makes no sense otherwise.

The issues in coherence are separated into local coherence and global coherence (see Ellis 1999). *Local coherence* is related to cohesion and is termed “local” because the linguistic terms are properties of the text and not a larger structure. The cohesive tie in (4) above is local. Halliday and Hasan (1976) describe five major cohesive ties: reference, substitution, ellipses, conjunction, and lexical cohesion. Local cohesive devices are a natural part of the linguistic system and communicators use them to process information. Their use varies by social constraints on language. Studies by Villaume and Cegala (1988) and Ellis et al. (1994) are direct tests of the relationship between the quality of communication and cohesive devices.

*Global coherence* is produced by interpreters who apply a general organizing scheme to a series or sequences of statements. It is a macro framework that provides the overall management and interpretation of local connections. For example, the headline of a newspaper story provides a global frame for all of the sentences that constitute the story. After reading the headline, everything in the story will be understood within the global frame of the headline. Scripts as described in example (1) above are global coherence mechanisms that direct the comprehension of the language.

Topicality is essential to notions of global coherence and discourse comprehension. It is the primary organization principle of a message. The *topic* is the theme or subject

matter of what is being written or talked about. Speeches, essays, paragraphs, and discourses of all types have a topic that organizes the language. The first sentence of a paragraph may be connected sensibly to the last sentence according to topicality rather than local cohesion devices. All discourses have a global semantic structure that explains the relevant information in the discourse as a whole.

Speakers and writers direct the fluid nature of topic changes and focus. Comprehending a discourse involves proper focusing and foregrounding of information. Information is focused and foregrounded when it is established in consciousness and other information is backgrounded. Line (5b) below makes sense because line (5a) foregrounds puppy (Tyler & Marslen-Wilson 1982):

- (5a) "The puppy stepped on a wasp"
- (5b) "He was very upset"

Line (5c) below is awkward because it is responsive to information that is not foregrounded:

- (5a) "The puppy stepped on a wasp"
- (5b) "He was very upset"
- (5c) "It started to buzz furiously"

The skillful use of foregrounding and focus is important for producers of messages who want to assist interpreters with the task of discourse comprehension.

Discourse comprehension involves the computation on the part of interpreters of communicative function. The sequence in (2) above is understood as coherent and communicatively sensible because the assumption of rationality on the part of communicators presupposes that the participants are cooperating (Grice 1975) and Sue's utterance in example (2) is a genuine response to the previous utterance that is expressed for an action performed in communicating.

## INTERPRETIVE CODES

At the highest level of generality, communicators use codes to comprehend discourse (→ Speech Codes Theory; Code). No description of discourse comprehension would be complete if it did not account for subjective and cultural experiences of language users and how these inform the comprehension process. A *code* is an orientation toward the production and interpretation of language. It is a set of interpretive frames formed on the basis of individual cultural experiences and is used to understand specialized group meanings. They are powerful to the extent that they are responsive to particular subjective experiences.

Philipsen (1997) and Katriel (1986) developed a widely recognized research program on communication codes and how members of a culture share orientations toward communication. A communication or speech code is a way of speaking that is culturally distinctive and results from the unique psychology and sociology of the culture. Discourse is interpreted on the basis of the cultural knowledge of the code. Katriel's (1986) research on *dugri* and *musayara* shows how Israeli-Jews and Arabs have ways of speaking that emerge from their respective cultures and is sometimes responsible for

problems and misunderstandings. Thus, the *dugri* code for example is direct, pragmatic, and assertive where the *musayara* code is more indirect and accommodating. One must have cultural experience in order to fully comprehend the discourse of the other. These codes are a sort of blueprint shared by members of the culture. It is interpretive information acquired in the experience of the culture and not abstractly. Linguistics had tended to ignore this aspect of comprehension in favor of more abstract cognitive processing rules for language. Recent work in communication directs the focus of discourse comprehension more toward communicative competence and language in use that includes the ability to interpret language in situated cultural contexts.

## **Discourse in the Law**

*Pamela Hobbs*

*University of California, Los Angeles*

The law operates primarily through language. Legislative bodies enact statutes and ordinances, judges hand down decisions, juries issue verdicts, and people enter into a

wide variety of contractual relationships; in each case, a legal effect is produced through language. Nevertheless, until recently, the study of legal discourse was not well developed. Since the 1980s, however, an increasing number of scholars have addressed aspects of the relationship between law and language.

The language of the law, with its specialized vocabulary and technical subject matter, is largely inaccessible to the lay public. Accordingly, a major focus of legal education is the socialization into the discourse practices of the legal profession. American law school pedagogy is based on the Socratic method. The students read and “brief” decisions of appellate courts in order to prepare for a daunting classroom exercise in which an arbitrarily selected student is presented with a series of questions which aggressively challenge the reasoning of each prior response, thus training the student to recognize, isolate, and respond to the legal issues that are presented – that is, to “think like a lawyer.”

Much of the study of legal language has focused on courtroom discourse and, particularly, on criminal and civil trials. A trial is structured by speech events – voir dire (jury selection), opening statements, witness examination, closing arguments, jury instructions, and announcement of the verdict – and Stygall’s (1994) detailed analysis of the trial of an automobile accident case demonstrates the interrelationship of these discourses in producing legal outcomes. Other studies have limited their analysis to specific aspects of courtroom interaction.

The examination of witnesses has been extensively analyzed and discussed. In an early study, Atkinson and Drew (1979) examined the interactional effects of the structuring of testimony as a series of questions and answers, resulting in a fixed order of speaking in which the lawyer controls the topics to be addressed. They also detailed the manner in which lawyers can undermine a witness’s testimony by questions which construct a damaging version of the facts. Woodbury (1984) noted that questions posed in statement form (“The light was green?”) act to signal their expected answer, and can thus be used to suggest that the witness is lying (→ Questions and Questioning). Woodbury also noted that questions that call for a “yes” or “no” answer can be used to transform the lawyer’s question into evidence. These observations have been replicated in a number of case studies. For example, Matoesian (1993) shows how a cross-examining attorney can allocate blame by constructing a particular version of an event through a series of questions. Similarly, Chang (2004) demonstrates how prosecutors and presiding judges in Chinese criminal trials use coercive questioning to accuse defendants, invalidate their exculpatory testimony, and impose discursive punishment through shaming.

A number of scholars have commented on the narrative structure of trials. Both Stygall (1994) and Cotterill (2003) describe the trial as constructed of competing stories, while Woodbury (1984) notes that the story is elicited from the witnesses through the lawyer’s questioning. The narrative structuring of trial discourse was extensively examined in the late 1970s by Lance Bennett (→ Storytelling and Narration), who argued that the story form aids in the evaluation of conflicting versions and interpretations and allows ordinary people to make sophisticated judgments about complex issues. He notes that jurors will abstract information elicited from question-and-answer sequences during the trial and arrange them in story form in the course of their deliberations.

The lawyer’s restructuring of the evidence in closing arguments has been the subject of a number of studies. Cotterill (2003) describes the use of → metaphor in the prosecution’s

and defense's closing arguments in the O. J. Simpson murder trial in order to reframe the relevant events. Similarly, Hobbs (2005) details how the defense team's closing argument in the murder trial of millionaire Robert Durst acted to direct the jury's attention to a single event in order to effect a shift in focus that would allow the attorneys to argue that the prosecution had not met its burden of proof.

In comparison to the language of lawyers, the language of judges remains underexplored. Robertshaw's (1998) examination of "summing up," the practice by which English and Welsh judges summarize the trial evidence for the jurors, and Philips's (1998) study of how judges' political ideologies impact their conduct of guilty-plea hearings demonstrate the impact of language on the outcome of cases. In addition, Hobbs's (2007) analysis of the United States Supreme Court's majority opinion in *Rasul v. Bush* describes the discursive processes by which the Court presents its decision as grounded in existing law. However, given the power of judges and, particularly, the role of appellate judges in the development of the law, much work remains to be done.

## **Discourse Markers**

*Yael Maschler*

*University of Haifa*

Using language – “linguaging” (Becker 1988) – is possible at two levels of discourse. Generally, when we use language, we look through it at a world we believe to exist beyond language. However, we can also use language for *metalinguaging*, i.e., in order to look

through it at the process of using language itself (→ Linguistics; Conversation Analysis). Discourse markers can be viewed as linguistic elements employed for metalanguaging – languaging about the interaction, as opposed to languaging about the extralingual world. In other words, rather than referring to the world perceived by speakers to exist *beyond* language, discourse markers refer to the text itself, to the interaction among its speakers, or to the cognitive processes taking place in their minds during verbalization (Maschler 1994).

Discourse markers have been investigated from a multitude of linguistic approaches. The terms used to refer to these elements vary greatly, e.g., pragmatic particle, pragmatic operator, pragmatic expression, discourse particle, discourse connective, discourse operator, marker of pragmatic structure, cue phrase, parenthetical phrase, and even mystery particle.

Discourse markers can be classified into *three major types*: (1) those operating in the realm of the structure of the text, signaling relationships between the conversational actions taking place (“textual discourse markers,” e.g., *and, but, so, because, first of all, anyway*); (2) those functioning in the realm of the interaction among text participants (“interpersonal discourse markers,” e.g., *yeah, no, look, really?, wow!, great, mhm*); and (3) those referring to (in the sense of attesting) the cognitive processes taking place in the speaker’s mind during verbalization (“cognitive discourse markers,” e.g., *uh, uhm, oh*, Hebrew *ke’ilu* (“like” recognizing the need for self-rephrasal; Maschler 2002). Of course, since all utterances are always constrained by the various contextual realms shaping discourse, discourse markers often function in more than one realm, and they often do so simultaneously (e.g., English *okay*, which can be both textual and interpersonal, Hebrew *’oy* (“oh no”), which can be both cognitive and interpersonal). Often, however, one of the realms is more pronounced, warranting a broad classification such as that above (cf. Schiffrin 1987).

In his influential study of grammaticization, Hopper conceives of grammar as a product of structuration, “an unintended outcome of communicative behavior . . . , rather than a bounded object to be thought of as structure” (1998: 158). The emergence of discourse markers from longer metalingual utterances, as well as their multifunctionality in several discourse realms, motivates studies investigating their grammaticization.

Common to all of these metalingual utterances is their function in negotiating a frame shift (Goffman 1981), or conversational action boundary in interaction (Maschler 1997). Studies of bilingual discourse show that bilinguals consistently switch languages in verbalizing discourse markers (e.g., Maschler 2000). This strategy suggests that discourse markers are perceived as a distinct and unified category – the category of utterances employed to metalanguage conversational action boundaries – constituting evidence that the category “Discourse Marker” is not merely a linguist’s construct, but rather a substantial and meaningful category for speakers.

Discourse markers constitute a system exhibiting two more types of patterning involving: (1) the moments at which discourse markers are employed in interaction, and (2) their structural properties. As for (1), in general, the higher the boundary between conversational actions, the more linguistic material necessary for its construction. “arger packages,” such as the beginning of a new episode in a narrative, typically open with more discourse markers – and particularly more *clusters* of discourse markers (e.g., *anyway, uhm, listen*) – than “smaller packages,” such as the beginning of a “second” in an adjacency pair.

In terms of their *structural properties*, discourse markers have developed from a variety of parts of speech: adverbs, interjections, conjunctions, deictics, verbs of saying, verbs of perception, nouns, adjectives, quantifiers, and even clauses. Besides having the semantic property of metalinguality, discourse markers share a prosodic property: 94 percent of the discourse markers in a spoken Israeli Hebrew corpus were found to occur at intonation-unit initial position, either at a point of speaker change, or, in same-speaker talk, immediately following any intonation contour *other than continuing intonation* (unless they appear in a cluster of discourse markers). For example:

... we talked a lot,  
 .. about this whole thing,  
 .. about compliments.  
 .... because,  
 ... to me,  
 ... that was really  
 .. that's something,  
 .. that I can't stand.

The discourse marker *because* appears here in same-speaker talk following final intonation (marked by the period following *compliments*). The remaining 6 percent of the discourse markers function at lower-level conversational action boundaries, such as introducing a voice “of second order” of the same speaker. For example, in

'amarti la *tir'i*,  
 I told her look,

*tir'i* occurs intonation-unit internally (Maschler 1997, 2002). The system of discourse markers punctuating interaction, then, constitutes part of a larger, iconic system of grammatical, prosodic, and kinesic features, helping participants distinguish higher-order frame shifts from those that are more subtle in nature.

## Discriminant Analysis

Andreas Fahr

Ludwig Maximilian University of Munich

The main aim of discriminant function analysis is to predict group membership of an object or a person by using as few characteristics (or set of predictors) as possible. Additionally, discriminant analysis is used to classify elements according to their characteristic properties (→ Statistics, Descriptive). So if you know the answers a subject might give to a crucial set of questions and/or the scores that subject might achieve on an important set of characteristics, discriminant analysis enables you to predict whether the subject is or will likely be a voter or nonvoter, buyer or nonbuyer, college dropout or graduate, researcher or lecturer, master or servant, winner or loser, television viewer or nonviewer, opinion-leader or follower, etc.

For example, a product manager is interested in the critical characteristics of the target group that distinguish the buyers of the product from the nonbuyers. The question is: what makes a person a buyer or a nonbuyer? What are the relevant factors that are responsible for paying money for the product or not? And which of the factors is mainly responsible for the difference; which are more important than others? Do buyers differ from nonbuyers predominantly in their socio-demographic background, their psychological profile, their attitudes, or their personal interests? If the answers a subject might give to the crucial questions are known, the product manager is able to predict the subject's group membership. In addition, the product manager knows the general probability of classifying a "new" element into the "right" group (→ Marketing).

### APPLICATION IN COMMUNICATION RESEARCH

A well-known example of the application of discriminant analysis in communication research is the attempt to *differentiate television viewers from nonviewers* by means of numerous variables (e.g., Tankard & Harris, 1980; → Exposure to Television; Audience Research). A list of more than 200 variables was reduced first to 43 and then to 11 by using discriminant analysis. The 11 variables succeeded in classifying television viewers and nonviewers correctly for 74.6 percent of the cases in a sample from a national US survey. Nonviewing was associated with less satisfaction from family life, greater happiness in general, fewer young children in the household, greater participation in groups and organizations, more time spent in active military service, lower family income, stronger view of self as religious, less frequent attendance at religious services, more frequent

socializing with friends outside the neighborhood, and so on (→ Media Use by Social Variable).

Another example of the advantages of discriminant analysis taken from the field of → political communication revealed that *supporters of various political parties* (in South Africa) could more easily be differentiated in terms of their support for internal harmony and equality than in their support for national strength and order (Heaven et al. 1994). Research on *opinion leadership* showed that, in addition to personal involvement and product familiarity, public individuation was the most important variable in distinguishing opinion leaders from non-leaders (→ Opinion Leader; Involvement with Media Content). Risk preference, open-mindedness, and mass media exposure, though correlated with opinion leadership, were not found to be important predictors of opinion leadership (Chan & Misra 1990).

## ORIGIN

The famous statistician, Sir Ronald A. Fisher, originated the concept of discriminant analysis. It is sometimes called *Fisher's linear discriminant*, although Fisher's original article (1936) described a slightly different discriminant, which does not make some of the assumptions of discriminant analysis such as normally distributed classes or equal class co-variances (see below). Technically speaking, discriminant analysis asks which (linear) combination of properties can best predict the discrimination of groups, and which of these independent variables has the largest predictive power, i.e., how much variance can be explained by each of the independent variables. The resulting linear combination of features is often used for dimensionality reduction before later classification.

Hence, discriminant analysis can also be related closely to principal component analysis (PCA) and → *factor analysis* in the attempt to find linear combinations of variables that best explain the data. While discriminant analysis explicitly tries to model the difference between the classes of data, PCA does not take into account any difference in class, and factor analysis builds the dimensions based on differences rather than similarities. Nevertheless, discriminant analysis can be employed as a useful complement to principal components analysis and also to → cluster analysis in order to judge the results of these analyses.

## STATISTICAL BASIS

The statistical technique (→ Statistics, Explanatory) underlying discriminant analysis is closely related to → *regression analysis and analysis of variance*, which also attempt to express one dependent variable as a linear combination of other measures. However, in the two latter procedures, the dependent variable is continuous, while for discriminant analysis it is categorical (i.e., group membership). In contrast to procedures like multivariate analysis of variance (MANOVA), in discriminant analysis group membership is explained and predicted by two or more metric independent variables. The set of these predictors could be all kinds of measures (→ Measurement Theory) – answers to questions in a → survey, test scores in psychological tests (→ Test Theory), → observation data, etc. The choice of predictors is usually made on the basis of theory about which variables provide information about group membership.

Because in MANOVA we ask whether group membership is associated with significant mean differences on a combination of dependent variables, MANOVA and discriminant analysis use similar mathematical algorithms. But discriminant analysis is putting cases into groups using a classification process – which is a significant extension of MANOVA. Moreover, adequacy of this classification can be evaluated. Adequacy reveals how many cases or subjects are classified correctly, that is, actual and predicted membership are identical (as shown in the above mentioned example where 74.6 percent of the cases were classified correctly). In addition, discriminant analysis allows for interpreting the pattern of differences among independent variables to differentiate among groups. Discriminant analysis may thus have a descriptive *and* a predictive objective. On the one hand, if the researcher is simply interested in a decision rule for classifying cases into groups, the number and meaning of the dimensions is of minor interest. On the other hand, interpreting the results of discriminant analysis in terms of the *combination* of predictors is usually of high value for research, as shown in the characterization of the “nature” of television nonviewers in the example outlined above.

Discriminant analysis can equally well be univariate as multivariate. Univariate discriminant analysis consists of only two groups that are separated through the linear combination of factors, represented by one linear discrimination function. If there are more than two groups, the number of discriminant functions is the number of groups minus 1 (degrees of freedom). In general, classification procedures such as discriminant analysis make fewer statistical assumptions (according to sample size and distribution) than inferential procedures. However, the sample size of the smallest group should at least exceed the number of predictor variables. Nevertheless, classification is optimal if requirements on data are met, such as absence of outliers and homogeneity of variance/co-variance matrices. If group sizes are unequal or distributional assumptions are unsustainable, logistic regression can answer some of the same questions that discriminant analysis answers.

# Discursive Psychology

*Hedwig te Molder*

*Wageningen University*

Discursive psychology examines how psychological issues are made relevant and put to use in everyday talk. Unlike traditional psychological perspectives, discursive psychology does not approach the question of what psychology comprises and explains from an analyst's perspective. Instead the focus is on how psychological characteristics are made available, ascribed, and resisted by people *themselves*, as part of the social actions performed in and through talk.

The step from assuming that talk *reflects* to looking at what talk *does* is paramount. Discursive psychologists analyze how direct and indirect appeals to mental states *do* things in the interaction, such as accusing, defending, building expertise, complaining, and complimenting. Rather than determining the truth value of what people report – by looking at what a person really wants, thinks or feels, or what the world really looks like – discursive psychology focuses on the *interactional business* performed with these descriptions. Limited memories may, for instance, account for a forgotten action, while displays of anger may enhance the genuineness and spontaneity of an explanation. The *action-oriented approach* to language makes discursive psychology radically different from cognitivist traditions in psychology that treat mental states as the source or cause of what is being said (Edwards 1997; Edwards & Potter 2005).

The book *Discourse and social psychology* by Jonathan Potter and Margaret Wetherell (1987) marked the beginning of a research tradition that first emerged as a discourse-based alternative for traditional social psychological work. The notion of an *interpretive repertoire* was coined to capture the ostensible inconsistencies in people's accounts of mind and reality that were not explained by the classical attitude concept. The early work on repertoires has its roots in diverse disciplines such as Wittgensteinian philosophy, ethnomethodology, and poststructuralism (→ Ethnomethodology; Communication Theory and Philosophy). Its most direct origin, however, lies in the discourse analytic approach that has been developed within social studies of science.

Derek Edwards and Jonathan Potter (1992) are the founders of what is currently associated with the term discursive psychology. While still drawing from different disciplines, this tradition is increasingly influenced by the perspective and method of → *conversation analysis*. Like conversation analysts, discursive psychologists are interested in close empirical investigation of naturally occurring data. They work from detailed transcripts of audio or video recordings, derived from a variety of “natural” settings such as phone calls between friends, adolescents' talk, counseling sessions, or police interrogations.

Discursive psychology shares the conversation analytic focus on so-called *activity sequences* as the core concept for understanding what people do in interaction. Actions such as countering blame, establishing the normality of what happened, or rebutting the assumed motivated nature of what is being said are not performed on the basis of single sentences but embedded in a series of turns. The emphasis on turns and sequences rather than isolated spates of talk is both a theoretical and a methodological starting point. People use the turn-by-turn development of a conversation as a resource to make sense of

the social activities that are accomplished. These publicly displayed and continuously updated understandings of what is being said and done are an important “proof procedure” for the analyst.

People also talk rhetorically, in that they routinely resist or deny actual or potential alternative versions of what is being said. Inspecting stretches of discourse for these alternative versions helps the analyst to make sense of the actions performed. It is the combination of a sequential and a rhetorical analysis, focused on people’s practical psychology, that forms the basis of discursive psychological work.

Recently, Edwards and Potter (2005) distinguished three *major strands in discursive psychology* that are strongly interrelated. The first strand concerns the reworking of traditional psychological topics such as attitude, causal attribution, memory, and → scripts into discursive practices. The notion of a script, for example, is not approached as the expression of underlying cognitions. Scripting is studied for what it *does*, as a participants’ concern, such as explaining an event in scripted, dispositional terms (“he is always jealous”) instead of constructing it as a “one-off.” The second strand involves studies of how psychological terms are deployed in everyday talk (intent, motive, remembering, seeing, etc.). The phrase “I don’t know” may not simply refer to a lack of knowledge but also be used to display indifference about one’s ostensible stake precisely at the point where an accusation could be made (“she would say that, wouldn’t she?”; Potter 1996). The third strand of research focuses on psychological themes as they are drawn upon in the interaction in less overtly labeled ways. Attributions of agency and intent are typically performed not by explicit imputations but through apparently straightforward descriptions of the “world-as-it-is.”

All three areas show a salient interest in the triangular relationship between facts, interests, and accountability. A pervasive feature of participants’ discourse is the construction of reports in such a way that they avoid appearing invested or biased, thereby establishing factually robust versions of mind and world. The focus is on how talk routinely resists accusations of stake and interest, and how it therein attends to issues of agency and accountability.

Discursive psychological research has identified a variety of *discursive practices* in a heterogeneous set of fields, ranging from Bill Clinton’s testimony to the grand jury to racial discourse and mealtime conversation. While recent work (Hepburn & Wiggins 2007) bears a strong resemblance to conversation analytic research, there are also differences, such as the status of cognition in interaction (te Molder & Potter 2005).

## Disney

*Janet Wasko*

*University of Oregon*

Though the Walt Disney Company began as an independent production company producing → cartoons distributed by other companies, the company has developed into one of the largest entertainment conglomerates in the world (→ Media Conglomerates).

### EARLY HISTORY, 1923–1960

Walt Disney began cartooning in Kansas City with a series called *Alice's Wonderland* (1923). Not long thereafter he and his brother founded the Walt Disney Studio, in → Hollywood. In 1927, the company developed an all-animated series called *Oswald the Lucky Rabbit*. After losing the rights to the character, Walt and his chief animator (→ Animation), Ub Iwerks, developed Mickey Mouse, who became the firm's staple product. Mickey's cartoons utilized synchronized sound. The company also began producing another series to feature sound and animation innovations. In 1932, the studio produced the first full-color cartoon (*Flowers and Trees*), winning the first → Academy Award for Best Cartoon. Disney continued to win the award throughout the 1930s and most other years thereafter. Disney also developed merchandising connected to its cartoon characters, beginning with a \$300 license to put Mickey Mouse on writing tablets in 1929. Other products quickly followed, including dolls, toys, dishes, etc., generating fresh revenue for new productions.

The company expanded into feature-length animation with *Snow White and the Seven Dwarfs* (1937), the highest grossing film until then. Although the company continued to produce animated cartoons, it also made feature films (e.g., *Pinocchio* and *Fantasia*). The small company's resources were strained, especially during World War II. During the war, Disney produced two films for the State Department, as well as films for the military. After the war, the company repackaged some into features, as well as developing such live-action films as *Song of the South* (1946) and *So Dear to My Heart* (1949), both with animated segments. Disney's *True-Life Adventure* series introduced a new style of nature films, attracting numerous awards.

1950 saw Disney's *Treasure Island*, the animated feature *Cinderella*, and the first Disney television show. Disney moved further into → television with the *Disneyland* anthology series in 1954, which eventually appeared on all three → television networks under six different

titles. *The Mickey Mouse Club* debuted in 1955, introducing the popular Mouseketeers. These shows promoted Disney products and developed an outlet for new products.

The 1955 Disneyland theme park, featuring Disney characters and stories, continuously added fresh attractions from new Disney films, as well as providing a major outlet for Disney products. The company also started its own distribution company (Buena Vista Distribution) during the 1950s, and released *20,000 Leagues Under the Sea*, the comedy *The Shaggy Dog* (1954), and a TV series about Zorro. Disney also developed Audio-Animatronics and pioneered amusements with the Enchanted Tiki Room at Disneyland and at the 1964 New York World's Fair. Walt Disney died in 1966, not long after the release of *Mary Poppins* (1964).

### AFTER WALT: THE SIXTIES THROUGH THE DISNEY DECADE

By the 1960s, the Disney brand was firmly established in live action, animation, television, theme parks, and merchandise. The firm also re-released its already amortized feature films every few years: *Snow White and the Seven Dwarfs* was re-released in 1952, 1958, and 1967, amassing an additional \$50 million. Roy Disney, Donn Tatum (previously, vice president of administration), and Cardon E. Walker (formerly in marketing) served as the executive team until 1971. Film releases included *The Jungle Book* (1967), *Winnie the Pooh and the Blustery Day* (1968), and in 1969 the beginnings of an especially lucrative franchise, *The Love Bug*. Roy Disney saw Orlando's Walt Disney World opened in 1971, but died a few months later. Tatum became chairman and Walker president. By then, however, the company was even more oriented to recreation and real estate than entertainment. Tokyo Disneyland opened in 1983.

Meanwhile, the film division was mainly turning out perhaps formula-driven box-office duds. By the early 1980s, Disney's box-office share was under 4 percent, and was only slowly moving into new media outlets. The company did launch the Disney Channel in 1983, and an adult-oriented film label, Touchstone, in 1984. However, most analysts agreed the company's management was basically "sitting on its assets." In 1984, the management was challenged by a group of outside investors and eventually lost control of the company. A group of corporate raiders started accumulating huge blocks of Disney stock and jockeying for position to take it over. In the end, Bass Brothers Enterprises invested nearly \$500 million in Disney, preventing a hostile takeover, and ended up with nearly 25 percent of the Disney stock, enough to control the company and to appoint their own managers.

The new management team (dubbing itself "Team Disney") was led by Michael Eisner, former Paramount head, as CEO, along with former Warner Brothers' vice chairman, Frank Wells, president and chief operating officer until his death in 1994. Jeffrey Katzenberg (also from Paramount) became head of the film division. Immediately the team proceeded to break a Disneyland strike and fire 400 employees. Other cost-cutting measures and strategies were introduced. From 1983 to 1987, annual revenues more than doubled, profits nearly quintupled, and the value of Disney's stock increased from \$2 billion to \$10 billion; by 1994, it was worth \$28 billion. By 1999, company revenues totaled nearly \$23 billion, assets were over \$41 billion, and net income was \$1.85 billion.

The Disney empire now revived the classic Disney (repackaging existing products and creating new animated features), modernized some Disney characters, implemented fierce cost cutting (especially on features), introduced dramatic price increases at the

theme parks, and deployed new technological developments (such as computer animation). Team Disney also emphasized corporate partnerships, limited exposure in new investments, diversified expansion, and further developed its corporate synergy. The company linked its different business endeavors under the Disney brand (and, more recently, the ABC and ESPN brands). So not only was Disney busy diversifying, but the company became perhaps the quintessential master of synergy. During the early years of the Disney Decade, the company continued to expand and prosper utilizing these strategies. In 1991, the company ranked in the top 200 US corporations in terms of sales and assets, was 43rd in terms of profits, and stock was worth \$16 billion.

Despite this, a shadow fell over the Magic Kingdom in 1994. Wells died in a helicopter accident, Eisner had heart surgery, EuroDisney (which had opened in 1992) was suffering huge losses, and a proposal for a new historical theme park was getting hammered by nearly everyone. Then in 1995, the company dramatically spent \$19 billion to take over Capital Cities/ABC. This greatly enhanced the company's position in television, sports programming (→ Sports and the Media, History of), and international marketing, in addition to publishing and multimedia components. For a short while Disney was the world's largest media company, with \$16.5 billion in annual revenues.

### **DISNEY IN THE TWENTY-FIRST CENTURY**

The Walt Disney Company was made up of several divisions: Studio Entertainment, Consumer Products, Parks and Resorts, and Media Networks. The *Studio Entertainment* division produces a wide range of products, including animated and live-action films, as well as the Touchstone, Hollywood, Miramax, and Dimension labels. The company also distributes adult and foreign films that are not associated with the family-oriented, "parent guidance"-rated Disney brand. The division contributed over \$8.7 billion of the company's revenues for 2004. Buena Vista Home Entertainment manages Disney's home video business and interactive products globally. Disney has diversified its television offerings as with its film products, under the ABC, Buena Vista, Touchstone, and Walt Disney labels. It produces theatrical versions of animated films through Buena Vista Theatrical Productions and is highly visible in Manhattan, not only by way of its stage productions and the Disney store in Times Square, but through extensive real estate holdings, including ABC's headquarters.

Musical products offered further opportunities to feature Disney properties and are especially lucrative for animated features. Buena Vista Music Group coordinates Disney's various recorded music businesses, which include Walt Disney Records, Buena Vista Records, Hollywood Records, and Lyric Street Records.

The *Consumer Products* division was certainly the foremost merchandising company in Hollywood and produced or licensed a seemingly endless array of products, contributing over \$2.5 billion of the company's revenues in 2004. One of the largest licensors in the world, it was divided into Disney Hardlines, Disney Softlines, and Disney Toys, whose merchandise was marketed globally via its own outlets at the theme parks, through online sites, by way of the Disney catalogue, and at Disney stores worldwide.

The division also produced a wide range of printed material, ranging from comic books and children's magazines to adult-oriented magazines and books. At the end of

1998, the company reported that its print products were published in 37 languages and distributed in over 100 countries, ranking above other global publishers in children's → books and → magazines. In addition to publishing under the Hyperion banner, including ESPN Books, Talk/Miramax Book, ABC Daytime Press, and Hyperion East, the company published the number one US children's magazine, *Disney Adventures*. Consumer Products also included Buena Vista Games, which turned Disney content into interactive gaming products, and the Baby Einstein Company, which produced developmental media for infants.

As of 2007 the *Parks and Resorts* division operated or licensed 11 theme parks on three continents, along with 35 resort hotels, two luxury cruise ships and a wide variety of other entertainment offerings. The parks included Disneyland (embracing hotels, shopping, dining and entertainment venues and a new addition, California Adventure); Walt Disney World Destination Resort (including four different theme parks, numerous hotels, recreational activities, and shopping outlets); Tokyo Disneyland (with Tokyo DisneySea, since 2001); and Disneyland Paris. It contributed over \$7.7 billion of the company's revenues in 2004.

Disney Regional Entertainment operated across eight ESPN Zones (restaurant entertainment centers), featuring sports-themed dining and entertainment. The Disney Cruise Line featured voyages from the Florida complex to the Bahamas. The company also masterminded Celebration, the neo-traditional planned community south of Disney World. A number of sports properties supplemented the company's strong sports media holdings, including the Mighty Ducks (hockey), as well as extensive Florida facilities.

Through acquiring Capital Cities/ABC in 1995, Disney firmly established itself as one of the dominant US media industry players. The ABC television network provided abundant opportunities to promote Disney-produced programming and other businesses, as well as exploiting the more popular ABC programs throughout the rest of the Disney empire. In 2004, the *Media Networks* division attracted over \$11.7 billion, more than any of the others. The ABC Television Network included ABC Entertainment, ABC Daytime, ABC News, ABC Sports, ABC Kids, and the Disney-owned production company, Touchstone Television. In addition, Disney owned 10 television stations (affiliated with ABC) that reached approximately 25 percent of the nation's households, as well as 72 radio stations, including Radio Disney, ESPN Radio, and ABC News Radio.

Disney's ownership of ESPN was through ABC, which owned 80 percent of ESPN Inc. in partnership with the Hearst Corporation. The franchise included four domestic cable networks, regional syndication, 21 international networks, radio, → Internet, retail, print, and location-based dining and entertainment. At the end of 1999, the flagship network reached over 77 million subscribers domestically, while ESPN International was claimed to reach more than 152 million households in 190 countries. The ESPN franchise diversified its activities even further, adding ESPN Magazine, ESPN Radio, ESPN Zones, ESPN Skybox on Disney cruise line ships, and ESPN merchandise. Meanwhile, ESPN.com was claimed to be the most popular sports site on the Internet.

Disney's other cable holdings included the Disney Channel, ABC Family, 37.5 percent of the A&E Network, 37.5 percent of the History Channel, 50 percent of Lifetime Entertainment Services (including Lifetime and the Lifetime Movie Network), 39.6 percent of E! Entertainment Television, Toon Disney (with recycled Disney programming), and SoapNet (a 24-hour soap opera channel; → Soap Operas). The segment also operates

Walt Disney Television Animation and Fox Kids International, as well as Buena Vista Television and Buena Vista Television International.

Meanwhile, the Walt Disney Internet Group managed the company's Internet business. The company's Internet site was consistently rated as one of the most popular, while *The Daily Blast* served as a subscriber-based website, including various features from Disney-owned enterprises. While the company was plagued early in the twenty-first century with a series of highly visible controversies pertaining to executive compensation, the composition of its Board of Directors, and Eisner's replacement, the conglomerate still held valuable assets that continue to pay dividends. The company reported revenues of over \$30 billion for 2004, with nearly \$4.5 billion income and \$1.12 earnings per share.

## **Disowning Projection**

*Daniel G. McDonald*

*Ohio State University*

In a *projection*, a person attributes certain aspects of him or herself to others (→ Attribution Processes). The process is closely tied to → identification in the psychology of personality. A *disowning projection* involves attributing negative aspects of the self to others, such as “selfish motives, evil intent . . . [or] stupid attitudes” (Cameron 1947). Cameron includes the exclusion of those characteristics from the self as part of that projection (hence the *disowning* portion of the name). Theoretically, a disowning projection should be contrasted with an *assimilative projection*, in which a person similarly projects his or her own qualities onto others. Although both are projections, the content and effects of the projections are quite different. When negative characteristics are projected, the person who is projecting disassociates him or herself from the characteristics. When positive

characteristics are projected, no such disassociation occurs. Instead, the person who is projecting maintains the view of him or herself as being described by these characteristics, and, after projecting them onto others, sees him or herself as similar to those others.

When facing a group of people who have been brought together for a particular purpose, such as a political meeting, a person may assume they are very different from him or herself, and so react very negatively to the group (a disowning projection), or see them as sharing certain positive characteristics, and so affiliate with the group (an assimilative projection). Cameron (1947) describes mental illnesses such as schizophrenia and paranoia in terms of a chronic disowning projection – with these mental patients reacting to their own behavior as if it were the behavior of others.

It is most likely that we all engage in both disowning and assimilative projections at one time or another. Despite the general nature of the phenomenon, the term has found little use in the literature. In the field of communication research, O’Gorman and Garry (1976) suggested that respondents to their survey projected their own ideas about racial segregation on to the general public. Glynn et al. (2004) suggest that the phenomenon may apply to the general public, and that the disowning projection may in fact be recognized and studied quite often under the label of → social desirability. In these researchers’ view, in a controversial social issue, respondents may often give what they believe to be a socially acceptable answer, but, when asked about what others may think, those same respondents may provide an answer that reflects a projection of their own view onto the general public (→ False Consensus; False Uniqueness; Pluralistic Ignorance, Pluralistic Ignorance and Ideological Biases; Social Perception; Third-Person Effects).

Although this is an interesting hypothesis, it has not been rigorously tested in the literature. In the psychological view of projection, the “disowning” portion is a real aspect of the phenomenon. Much of the social desirability literature points to a recognition among respondents as to what their own opinion actually is, and that it is one that is not socially acceptable, hence suggesting that this is the majority viewpoint, or the view of the average person provides a method for providing one’s own opinion without feeling social disapproval from the researcher who asks the question. As such, a social desirability phenomenon is a very rational method of expressing a deviant opinion; a disowning projection should reflect something less rational and voluntary. This suggests that further work on a test of the link between social desirability and the disowning projection needs to focus on awareness and ownership of one’s own opinion to establish whether social desirability responses are rational forms of communication or reflect some sort of defense mechanism in which one’s opinions are actually detached from one’s self.

## Dissent in Organizations

*Jeffrey W. Kassing*

*Arizona State University*

Employee dissent occurs when employees express their disagreement or contradictory opinions about workplace policies and practices to various audiences. The most notable and obvious cases of dissent occur when employees engage in whistleblowing by dissenting to industry regulatory bodies, the media, or both. However, not all employees feel the need to voice their concerns in this manner. Rather, employees often express their dissent within organizations either directly to their supervisors, often referred to as upward dissent, or to their co-workers, known as lateral dissent. Additionally, employees may choose to speak with family and nonwork friends about their concerns, by engaging in displaced dissent (Kassing 1997, 1998).

Initial conceptualizations differentiated *personal-advantage dissent* from *principled dissent*, with the former referring to dissent expressed as a means for some personal gain and the latter as dissenting in order to correct some matter of ethical or moral concern (Graham 1986). Further exploration into these distinctions revealed that the two were not as discrete as previously thought and in fact often overlapped or coexisted (Hegstrom 1999). Later models of dissent moved away from a content focus and toward an audience focus by recognizing that employees could dissent to various people besides managers (Kassing 1997). This body of work considers the factors that shape employees' choices about expressing dissent to different audiences by considering individual, relational, and organizational influences.

*Individual influences* include employees' predispositions and demographic characteristics, their attachment to or affinity for their respective organizations, and their organizational position. To date, a constellation of communication and personality traits that appears to influence the expression of dissent has been identified. These traits include argumentativeness, verbal aggressiveness, and locus of control. Workplace attitudes – such as commitment, satisfaction, and organizational identification – also influence dissent, as do additional factors such as workplace experiences and organizational position. *Relational influences* concern the type and nature of relationships employees possess within organizations. When employees develop high-quality relationships with their supervisors they are more likely to express upward dissent. In contrast, employees in low-quality relationships choose to express more lateral dissent to their co-workers. Additionally, research indicates that employees regularly dissent to management in response to other-focused dissent that triggers events that concern the well-being of their co-workers.

Organizations vary tremendously in the extent to which they allow for and embrace employee dissent. Findings repeatedly demonstrate that → *organizational cultures* and climates foster or impede dissent. For example, employees report expressing more upward dissent and less lateral dissent when they perceive that comparatively more freedom of speech exists in their organizations. Organizational tolerance for dissent also has an impact on the topics about which employees choose to dissent. When organizational climates suppress dissent, employees tend to remain silent and choose to dissent almost exclusively about clearly unethical issues. However, when managers create opportunities for employees to share their dissent, dialogue between management and employees improves.

Research on organizational dissent has also considered the nature of messages used in the dissent process (Kassing 2002). *Direct-factual appeal* entails supporting one's dissent claim with information derived from some combination of physical evidence, knowledge of organizational policies and practices, and personal work experience. Similarly, *solution presentation* calls for providing solutions to address the dissent-triggering issue. *Repetition* involves continued and repeated efforts to draw attention to one's dissent claim across time, whereas *circumvention* involves expressing one's dissent to someone higher in the chain of command than one's immediate supervisor. Finally, *threatening resignation* entails using the threat of resignation as a form of leverage for obtaining responsiveness and action from one's supervisor. Clearly, some of these strategies will be more effective and appropriate than others. Indeed, recent findings revealed that direct-factual appeal and solution presentation were deemed the most competent upward dissent strategies, whereas circumvention and threatening resignation were seen as the least competent.

Concepts that overlap with and inform our understanding of employee dissent include: employee resistance, upward influence, employee voice, boatrocking, and whistleblowing. Some of these concepts are much broader than dissent, others defined more narrowly. For example, employee resistance, which concerns the ways in which employees react to and defend themselves against systems and structures of domination (→ Control and Authority in Organizations; Organizational Communication: Critical Approaches), would encompass dissent. Similarly, upward influence would include dissent, but also other types of influence processes such as adhering closely to the contractual obligations of one's position or fostering personal discussions with one's supervisors (→ Supervisor–Subordinate Relationships). Likewise, employee voice involves all efforts employees make to have their concerns heard, not just their disagreement (→ Participative Processes in Organizations). Boatrocking aligns most closely with employee dissent in that it involves expressing dissent internally within an organization, whereas whistleblowing is a specific type of dissent, as noted above, that involves seeking the attention of regulatory bodies or the media. Conceptually, employee dissent should be thought of as a form of employee resistance, upward influence, and employee voice, which includes boatrocking and whistleblowing as specific means for expression.

## **Distance Education**

*Terre H. Allen*

*California State University, Long Beach*

Distance education refers to teaching and learning that occurs when students and teachers are in different physical and/or geographic locations. Although many people believe that distance education is a recent development made possible by the → Internet, it actually began in the late 1800s. Distance education has its roots in correspondence courses, which began around 1870. In fact, the first home study division of an American university was established in 1882 at the University of Chicago. Home study programs flourished in the early 1900s, and the National University Extension Association established a Correspondence Study Division in 1915. Correspondence programs provided written educational materials leading to the completion of programs, certification, and college degrees to students via mail services. Generally, early distance education programs were targeted toward adults living in rural areas who did not have access to education otherwise.

During the 1930s, → *radio broadcast* became a popular medium for providing distance education in the US, and by 1952, the → Federal Communications Commission (FCC) had established public broadcasting with the primary objective of providing instructional television (Portway 1992; → Educational Media; Instructional Television). Telecourses became a mainstay in distance education throughout the latter half of the twentieth century. Some colleges provided entire programs of study via distance education telecourses. Video-tape technology expanded the opportunities for distance education, and telecourses had their most extensive use during the late 1970s and early 1980s. The Internet and world wide web revolutionized distance education, once again, during the 1990s and into the twenty-first century (see Portway [1992], for a complete review).

Today, distance education is *defined more broadly* as a formal learning activity that occurs when students and instructors are separated by geographic distance or by time, supported

by communications technology such as → television, video tape, computers, → electronic mail, mail, and/or interactive video conferencing (→ Computers and Display Programs in Education). Distance education has become commonplace in higher education and is particularly appealing to adult learners who wish to enter college for the first time or re-enter college for degree completion, advanced training, certification programs, or professional development. Contemporary institutions of higher education offer variations of distance education in the form of web-based seminars and hybrid instruction (part face-to-face, part distance education). Recently, mobile phone technology has been added to the list of popular devices that are used to provide distance education to college students.

Corporations also make use of distance education as a *cost-effective way* to provide online training, web-based training (WBT), and computer-based training (CBT) to employees. Webinars and just-in-time training modules are also popular distance education models used in corporate institutions to provide employee training and professional development. WBT and CBT are less costly alternatives to face-to-face training; furthermore, employee time-on-task and learning outcomes can be easily monitored and measured. Additionally, employees may access these learning opportunities at home or from their offices. The flexibility provided by web-based distance education makes it an attractive option for corporate training and development. The term e-learning is used by corporations and by higher, elementary, and secondary education to refer to a wide range of learning materials accompanying learning technologies.

The concept of distance education can no longer be viewed as a separate category of instruction. Few colleges provide faculty and students with exclusively in-person access to university and course-related information. In fact, distance access to course-specific learning material, even in face-to-face only courses, is commonplace. *Learning management systems* (LMS) are used widely to provide students with access via the Internet or mobile phone to course-specific learning material, communication with faculty, communication with classmates, class group communication venues, virtual office hours, electronic submissions for course assignments, grades and graded assignments, and online testing and evaluation (→ Classroom Instructional Technology; Course Organization Programs in Education).

Perhaps the most important distinction in contemporary education is how communication takes place in distance education. Historically, communication in distance education was defined by its asynchronous nature. In fact, the term asynchronous learning emerged from the distance education context to describe learning where interaction is delayed over time (student-to-learning interface, student-to-student, and student-to-instructor). Emerging technologies have allowed for the *rapid growth of synchronous learning* in distance education. Synchronous learning refers to any learning event where interaction happens simultaneously in real time (student-to-learning interface, student-to-student, and student-to-instructor). As such, distance learning communication can be categorized by its asynchronous or synchronous nature. Asynchronous communication, then, is characterized by communication that does not occur in real time, while synchronous communication occurs in real time (Roblyer & Ekhaml 2000).

Teleconferencing or video conferencing has become a popular method for delivering synchronous distance education. Teleconferencing uses a combination of television, telephone, and Internet technology to provide instruction and learning from one point of

service to another in real time. The instructor is in one location and students may be in any variety of other locations as long as they have appropriate access to the communication devices being used for real-time instruction. Students may ask questions, talk with, or instant message the instructor and one another, all in real time. Pedagogically, synchronous learning and communication are preferred over asynchronous learning and communication.

Given the ubiquitous nature of distance learning in higher education, considerable interest has also evolved in the *effectiveness of distance education* over face-to-face instruction. Contemporary pedagogical approaches to distance education focus on links among student learning outcomes and the student-to-learning interface, student-to-student communication, and student-to-instructor communication. The student-to-learning interface focuses on how much time on task (asynchronous and synchronous) a student spends interfacing with the course learning material. Student-to-student communication focuses on how much time (asynchronous and synchronous) students spend communicating with one another (Phipps & Merisotis 1999).

Finally, the common disadvantage that is tied historically to distance education is *student retention*. Even with advancements in synchronous communication and learning, most distance education classes and programs suffer from alarmingly high dropout rates. Dropout rates for distance education courses at brick and mortar colleges are significantly higher than for courses taken on campus (Carr 2000; Pittinsky 2003). To date, the problem of student retention in distance education has not been sufficiently questioned, examined, or researched. Nonetheless, universities across the globe are moving from *brick and mortar* to *brick and click*, cementing the role of distance learning in the landscape of education and training.

# Distribution

*Benjamin J. Bates*

*University of Tennessee*

Communication requires the distribution of information from its creator to audiences, through some medium (→ Diffusion of Information and Innovation). This may occur in simple ways, such as talking (→ Interpersonal Communication), through broadcast networks (→ Radio; Television), or through the production and physical distributions of fixed forms such as → newspapers or → books. Distribution systems can be thought of as networks connecting senders and receivers, with structural limitations that can impact on what information can be sent, and to whom. It is the “channel” in Shannon and Weaver’s information theory model (1963; → Models of Communication; Communication Networks). While the concept of distributing information can be broadly applied, the characteristics and economics of distribution are of particular importance to mass communication, where the economic and technological features of distribution systems influence the definition of media and their markets (→ Markets of the Media). Media can be defined and differentiated, in fact, as specific distribution technologies for information. Media markets can be defined in part by the reach and scope of a particular distribution system for a media good or service. And the viability and function of media and markets depend on the economics of particular distribution systems.

The economics of distribution systems impact on media operations and organizational structures. Networks are designed or developed to take advantage of particular cost structures of their various components. Changes in technology and component markets can change costs and contribute to shifts in network structures, and have contributed to market convergence and globalization.

## ECONOMICS OF DISTRIBUTION

Media markets distribute information goods. Information goods have some interesting and distinctive characteristics, and are often identified as → public goods. One feature is that the information good combines the idea (or information) with the distribution systems, and while duplication of the idea is essentially costless, distribution of that content is not. Moreover, the costs of distribution depend more on the nature of the particular distribution network than on the nature of the information (although the nature of the information may constrain which networks can be used for distribution) (→ Information and Communication Technology, Economics of).

Distribution systems can incorporate a *wide range of structures*. While the particular technologies and structures employed have important implications for the specific economics of that network, there are a few general features that can be identified. First, before distribution can occur, the distribution network structure must be in place. As such, networks require an initial investment in developing, designing, and building an infrastructure, mandating at least some degree of fixed, or sunk, costs. The degree of sunk costs can depend on the costs of technology, the size and scope of the infrastructure

required for distribution, and the costs of fixing information goods and services in the appropriate formats that can be handled by the system. In addition, actual distribution of goods and services may incur variable costs tied to the particular amount distributed. These costs can change depending on the overall amount of goods distributed, the degree of duplication costs, and the costs of operating the network. If variable costs decline as production and distribution increases, the system is said to exhibit positive scale and scope economies (→ Economies of Scale in Media Markets). If variable costs rise as supply increases, negative economies (or diseconomies) result.

Another important characteristic, from a distribution perspective, is that information goods and distribution systems can exhibit *consumption externalities*. Consuming information goods and services takes time and attention, and may require access to costly equipment or networks, and acquisition of relevant literacy skills. Information goods may also have complements (other products used in conjunction with the information good) and substitutes (products used instead of the information good), which can influence demand levels.

Networks can exhibit what are termed *network, or adoption, economies*. This occurs for many types of networks (particularly interactive networks), when the value of the network increases with its reach. On the other hand, networks can also experience congestion effects (diseconomies), if the amount of information to be distributed approaches or exceeds the capacity of the network. Here, the value of the network is reduced due to the inability to deliver content effectively.

As distribution systems, or networks, develop, they encounter various *design decisions* involving tradeoffs among a variety of costs. Certain types of information products and services may require different types of distribution technologies and systems in order to be effective. Higher quality makes production and reproduction more costly and can incur higher distribution costs; the size of scale economies versus delivery costs impacts on network structure and centralization; policy can favor localism or national markets; balances must be sought between distributor costs and related consumption costs faced by audiences (time, receivers, etc.). While some older distribution systems evolved as a consequence of market forces, many were designed to achieve specific capabilities through the setting of standards and policy. In both cases, distribution systems tend to be tied to media and market characteristics, making it difficult to generalize.

In considering how distribution systems function, it is important to differentiate between systems that distribute physical copies of information goods, and those that do not distribute information in a physical form. There tend to be very different cost structures at work, in large part due to the different nature of, and cost structures for, physical goods, telecommunications-based networks, and information itself.

## **DISTRIBUTION SYSTEMS FOR PHYSICAL INFORMATION GOODS AND SERVICES**

Distribution of physical products constrains networks in several ways. In other ways they can be more flexible. A key distinction is that producing physical goods is inherently costly. Once the information is produced in a fixed form in a particular medium, raw materials must be consumed in the production of physical copies. Production of physical goods also tends to exhibit limited scale economies, as the physical components are ruled

by scarcity. And once produced, those physical goods must be distributed. Distribution of physical goods requires physical transport and delivery, tying costs to distance and product characteristics such as size, weight, and susceptibility to damage. Physical distribution costs are distance-sensitive, which tends to limit geographical markets. Physical distribution also takes time. For products that are time-sensitive (perishable), where their value declines over time, the time required for distribution can dictate the limits of the market. Of course, the use of multiple production sites can reduce distribution costs at the expense of added fixed costs and possible loss of scale efficiencies.

As a general rule, physical distribution networks seek to *achieve a balance* between minimizing production costs by taking advantage of scale economies and holding distribution costs to a level that keeps the product affordable. One advantage of physical distribution systems is that they can often “rebalance” and adapt to changes in production and distribution costs or shift to different systems without disturbing the basic product. Similarly, the distribution network can fairly easily adapt to variations in the physical characteristics of media products. Another advantage to using physical forms for information products is that having physical copies provides a degree of exclusivity for media products, as they are costly to duplicate. This can make it easier to restrict access, and to charge for access to, or acquisition of, the physical good.

Another “balance” issue facing physical distribution networks is *estimating product demand*. As producing copies is expensive, and must occur before they can be distributed and consumed, losses can occur if copies are overproduced and remain unsold. On the other hand, underproducing copies also results in lost potential sales. The perishability of the content can minimize potential losses, as unsold copies can be shifted to secondary markets, and new production runs can provide additional copies.

A recent development is the rise of *on-demand production and distribution* systems, where the production of the physical copy occurs at the point of sale or acquisition, in response to a purchase. This solves the problems related to estimating demand, and by using nonphysical networks to distribute the fixed form to the production site, can also reduce distribution costs to the site of production. However, economies of scale have yet to reach the point where on-demand production is competitive for mainstream distribution.

## **DISTRIBUTION SYSTEMS FOR NONPHYSICAL (ELECTRONIC) INFORMATION GOODS AND SERVICES**

Unlike physical goods, duplication of information in nonphysical forms is essentially costless. This type of information must still be distributed, and in some fixed form, which does impose some cost. While nonphysical forms can include media such as speech and signing, the idea of distribution systems and networks is more often associated with electronic forms such as broadcasting and telephony, i.e., telecommunications systems or networks (→ Technology and Communication). In telecommunications networks, the information or content is translated (fixed) as a particular type of electronic signal.

To distribute these effectively requires standardization of the translation process so that transmitting and receiving equipment can be produced, and the development of a system designed for the purpose of distributing just that type of electronic signal (→ Communication Technology Standards). This entails a generally greater level of development costs,

and perhaps more importantly, tends to fix the resulting system to the initial design standard. Policy often plays a role in setting standards, or defining markets and goals for telecommunications networks. Since systems are generally designed to deal with a particular level of service, telecommunications networks are more likely to experience congestion effects as demand and use increases. In addition, design limits restrict the ability to adapt to significant changes in the market or the product without replacing some or all of the infrastructure. For example, the shift from analog to digital television mandates the replacement of transmission and reception equipment.

There are two *basic types of telecommunications systems*, wired and wireless. *Wired systems* distribute signals through physical networks. They require the construction of a physical network (infrastructure), which can be very costly. While wired networks generally exhibit high fixed costs, operating and other variable costs tend to be low. In fact, average costs tend to decline over the range of the network, at least until congestion sets in. The high sunk costs also act as a significant barrier to entry. Between high economies of scale and barriers to entry, wired networks were often perceived of as natural monopolies. Natural monopolies occur when the scope of scale economies is such that a single firm can satisfy market demand more cheaply than multiple suppliers. Natural or not, monopolies were still viewed negatively, and as a result, wired telecommunications systems were generally regulated, or owned and operated by the state.

*Wireless networks* utilize broadcast spectrum to distribute signals. This still requires the development and deployment of an infrastructure, but infrastructure costs tend to be significantly less than those of wired networks. Partly this results from the shifting of some infrastructure costs (receiving equipment) to potential consumers. While spectrum is theoretically infinite, the usable spectrum is limited and systems must compete for space. Spectrum use is therefore regulated, and policy, along with spectrum limits and characteristics, tends to define distribution reach (→ Telecommunications: Law and Policy; Media Policy).

If the spectrum is used only for distribution, wireless networks epitomize the public good properties of nonexcludability and nonrivalrous consumption. As such, operating costs are constant, regardless of how many in the market acquire the signal, making marginal costs zero. A classic example of “market failure,” wireless broadcast systems often need to develop funding sources not based on consumer sales. On the other hand, interactive wireless systems are rivalrous, and subject to congestion. While it remains difficult to prevent signal reception, interactive network operators do control one side of the system, and can exclude on that basis.

### **EMERGING ISSUES LINKED TO DISTRIBUTION**

There are several emerging issues related to distribution systems. The most dramatic is the emergence of the → *Internet as a digital global distribution system*. This network is flexible and expandable by design, accommodating both wired and wireless networks and any form of information good or service that can be digitized; it threatens to radically transform distribution (→ Internet, Technology of; E-Commerce). It exhibits fairly low barriers to entry (sunk costs), nearly costless distribution costs, and permits users to contribute to both supply and demand. It is a system that is potentially global in scope, although there is still limited diffusion in some areas and among some groups. Its cost structures

are at least competitive with most other distribution systems, and significantly lower than others. Further, the history of the digital computing and telecommunications markets on which it is based is one of constantly declining costs. The global digital network has the potential to disrupt and possibly usurp other distribution systems (→ Digitization and Media Convergence). On the bright side, the emerging global digital network also has the potential to open up new markets and content creation strategies, even challenging the basis of traditional economic approaches, i.e., the idea of scarcity (see Benkler 2006, among others).

The emergence of the network has also made copying and distribution of content cheap and easy, contributing to the rise of content → piracy. This has contributed to a scramble to develop mechanisms to restrict the ability of users to copy and use content in ways not explicitly authorized by the distributor (→ Copyright). Imposing such mechanisms is inherently costly, creating some broader social concerns. In addition, many of the proposed mechanisms would appear to threaten existing rights of use and, to the extent that they involve tracking mechanisms, this also raises privacy issues.

## **Diversification of Media Markets**

*William M. Kunz*

*University of Washington Tacoma*

Diversification is a defining characteristic of media firms and products in the new millennium. There was a time when media companies concentrated on their core business,

whether through management decision-making or government mandate, and when there were fewer distribution channels available to media producers. Time and innovation altered both of these to dramatic degrees. The parent corporations of the major motion picture production and distribution companies in → Hollywood, for example, are now part of diversified conglomerates with holding in broadcast, cable and → satellite television, and → newspaper, → magazine, and → book publishing, and other media industries, as well as many others unrelated to their core businesses (→ Media Conglomerates; Film Production; Cable Television). These same corporations, moreover, distribute their products through countless channels, as the films that once headlined theaters around the world are also now viewed via satellite and cable television, home video, video-on-demand, iPods, and other new technologies.

## CONCEPTUALIZATION AND MEASUREMENT

The conceptualization of diversification varies in different contexts and across disciplines, so definitions are important. Diversification relates to the range of elements in a given population, whether stock in an investment portfolio or businesses in a conglomerate. Much of the literature on diversification can be divided into two broad groups: *product diversification*, which involves the expansion of firms into different lines of business or industries, and *market diversification*, which entails the adaptation of a given product to reach additional customers or users. The most common use relates to product diversification, which can be further classified as either unrelated diversification, also known as corporate or conglomerate diversification, or related diversification, also known as concentric diversification.

Diversification has been *measured* through various methods, and these techniques mirror the more nuanced understanding that has emerged since the 1960s. When Gort (1962) first measured the degree of diversification, his focus was on expansion across broad industrial sectors. Rumelt (1974) refined such measurements, making a distinction between industries and businesses. The importance of this distinction is clear in the two-digit and four-digit standard industrial classification (SIC) codes used in the US that Gort and Rumelt employed. For example, the two-digit code placed printing, publishing, and allied industries under a single title, while the four-digit codes made distinctions between newspapers, periodicals, and books. The four-digit codes under communications, meanwhile, differentiated between broadcast television, cable television, broadcast → radio, telephones, and telegraph (→ Telegraph, History of). In the Rumelt scheme, related product diversification was measured at the four-digit level within a broad industrial sector.

## PRODUCT DIVERSIFICATION

### Motivations

There are various motivations for product diversification. At a basic level, expansion into new businesses creates opportunities to *increase growth and reduce overall risk*. There are more sophisticated theories that explain such behavior. The resource view holds that

diversification results when firms accumulate excess capital, both financial assets for investment and human assets for management (Penrose 1995; Markides & Williamson 1996; Piscitello 2004). These perspectives argue that firms that are successful in diversification exploit their existing strengths, which include their given technical competencies and managerial resources, and create new synergies.

The agency view, on the other hand, holds that in the absence of significant ownership stakes, managers pursue diversification to advance their own interests at the expense of the firm's owners. This includes directing diversification down a path that increases the firm's demands for the managers' particular skills, which results in managerial entrenchment (Shleifer & Vishny 1989).

### Concentric Diversifications

There was a time when diversified conglomerates were in vogue, most evident in the 1960s and 1970s, but *related or concentric diversification* has been far more common since then. That pattern holds true in media industries, most evident with the major motion picture production and distribution companies. The Gulf & Western Industries acquisition of Paramount Pictures in the US in 1966, for instance, was the first in a series of mergers that integrated the studios into diversified conglomerates. Gulf & Western was the quintessential conglomerate of the mid-1960s, as Charles Bluhdorn spearheaded the acquisition of over 90 smaller companies between 1958 and 1969. Most of those properties were in manufacturing sectors, which is where Gulf & Western traced its roots. The Transamerica Corporation acquisition of United Artists in 1967 and Kinney National Services' purchase of Warner Bros in 1969 followed this same pattern (→ Concentration in Media Systems).

The News Corp acquisition of Twentieth Century-Fox in 1985 can be used as a line of demarcation (→ News Corporation). While the Coca-Cola Company purchase of Columbia Pictures in 1982 and the General Electric merger with RCA in 1986 sandwiched that merger, the Fox deal represents the related diversification that has been dominant since the mid-1980s. News Corp's roots were in publishing, but when Rupert Murdoch acquired Twentieth Century-Fox he also controlled Network Ten, a broadcast television network in Australia, and Sky Channel, a satellite service in Europe. In 1986, Murdoch purchased seven broadcast television stations from Metromedia and launched the Fox Television Network. In short order, Twentieth Century-Fox became the content producer for a chain of television outlets around the world.

The conceptualization of related or concentric diversification is critical to this discussion. The literature is replete with studies that conclude that related diversification leads to better performance than unrelated diversification since the former allows firms to build on their strengths (Penrose 1995; Chandler 1962; Rumelt 1974) The reasons for this are quite important. The characteristics of successful concentric diversification include, "existence of a strong core business, diversification into adjacencies that are close to the core business, and leveraging of skills from the core business" (Rijamampianina et al. 2003). Concentric diversification involves the acquisition of firms that are related to the core business in critical areas. This allows firms to improve their strengths and reduce their weaknesses through the investment in logical adjacencies.

### **Examples of Product Diversification**

The impact of such diversification is most evident in the case of the Walt Disney Company. In the early 1980s, → Disney was a corporation that focused on “family entertainment” and derived the bulk of its revenue from its theme parks and merchandise. The domestic and foreign box office from its motion pictures contributed just 15.5 percent of total revenue in 1980. The acquisitions that followed, with the purchase of Capital Cities/ABC Inc. the most significant, transformed Disney into a diversified media conglomerate. In 2005, it derived just under 35 percent of total revenue from its Parks and Resorts and Consumer Products divisions combined, just under 24 percent from Studio Entertainment and just over 41 percent from Media Networks. What was not part of the equation was a collection of newspapers and other publishing assets that Capital Cities/ABC held prior to the merger that Disney sold after it took control. The broadcast and cable outlets that Capital Cities/ABC controlled allowed expansion into logical adjacencies and created synergies for Disney, while the publishing companies did not.

Prominent media holdings have been part of diversified conglomerates since the mid-1980s. The General Electric ownership of NBC is the clearest case in the US. In the 1999 fiscal year, for example, NBC accounted for just 5.2 percent of General Electric consolidated revenues of \$111.6 billion. At the same time, Universal Pictures was part of Seagram Company Ltd., a conglomerate best known for its spirits and wine business. The latter business sector accounted for over 39 percent of Seagram revenues in the 1999 fiscal year, compared to just under 24 percent for the filmed entertainment business, which also included its investment in USA Networks. In 2000, Universal Pictures became part of Vivendi SA, a French conglomerate that traced its roots to water treatment and waste management. That relationship was short-lived, and the creation of NBC Universal in 2004 is more indicative of the diversified media conglomerates that are now dominant.

Media conglomerates around the world followed similar patterns. *Bertelsmann AG* traces its roots to the publishing company that Carl Bertelsmann founded in Germany in 1835 to print hymnals and religious material (→ Bertelsmann Corporation). Bertelsmann expanded its publishing interests in the pre- and postwar periods, but it was in the 1970s and 1980s that its diversification reached new levels when it took control of prominent US publishers Bantam Books and Doubleday and moved into the music business with the acquisition of Arista Records in 1979 and RCA Records in 1987. The impact of such growth was evident in 2004, when just under 25 percent of Bertelsmann revenue came from its book and magazine publishing divisions. This compared to over 42 percent from its television (RTL Group) and music (BMG Entertainment) interests and 21 percent from its media services division, Arvato.

### **MARKET DIVERSIFICATION**

The second dimension of diversification is also quite significant in the examination of media firms and markets. Product diversification remains prominent, but it is also important to consider various forms of market diversification. The most basic of these is geographic or international diversification, and the nature of most media products makes them conducive to such expansion into new markets. One of the defining characteristics of most media products is that almost the entire cost of production is incurred in the

creation of the master unit, known as the “first print” cost in films, with duplicates produced at little additional cost. That is the reason why most media products are said to be infinitely reproducible and infinitely exportable.

The *motion picture business* provides a prime example of the benefits of such diversification. The rise of the studio system in the US in the 1920s created a structure that resembled typical American industries, with production, distribution, and exhibition corresponding to the manufacturing, wholesaling, and retailing in other firms. And similar to other industries, the motion picture business pursued overseas markets. The total feet of motion pictures exported from the US increased from 32 million in 1913 to 235 million in 1925. In the latter period, American films accounted for 95 percent of the market in the UK and 77 percent in France. From that point forward, Hollywood worked hand in hand with the US government to ensure that it maintained unfettered access to foreign markets, with the Motion Picture Export Association of America, formed in 1945, becoming known as the “little State Department.”

The *importance of foreign markets* remains indisputable. The literature is rich with studies on the impact of Hollywood products across oceans and borders. The raw numbers can be rather staggering. *Titanic* shattered the worldwide box-office record with a total gross of over \$1.8 billion. While it established records for the US box office of over \$600 million, more than two-thirds of its total came in foreign markets. In 2004, the Motion Picture Association of America reported worldwide box-office revenues of \$25.2 billion, with \$9.5 billion of that generated in the US, and the major Hollywood studios accounted for a significant percentage of both these figures.

There is another dimension of market diversification that is relevant to media industries. While geographic diversification represents one attempt to access new customers and users, the *adaptation of products* represents another. The evolution of new digital technologies has created additional distribution channels for media products. Motion pictures were once shown in theaters, with broadcast television networks becoming a second alternative in the 1950s. The evolution of cable television set the stage for the creation of premium movie channels such as Home Box Office and Showtime in the US in the 1970s. While those all remain outlets for motion pictures, new technologies allow for distribution via direct-broadcast satellite and video-on-demand, DVD, and iPods. And the development of communication satellites has allowed such patterns to cross the globe, evident in the success of Star TV and other services across Asia.

## Diversity in the Workplace

*Brenda J. Allen*

*University of Colorado at Denver*

Diversity has become an important topic in workplaces around the world, as nations experience changes in demographics. Many countries are adjusting to increases in numbers of nontraditional workers, especially women, older persons, and people with disabilities. Meanwhile, due to global economics, industrialized areas are witnessing influxes of skilled and unskilled migrants seeking employment (→ Migration and Immigration) (Cheney & Barnett 2005). Also, multinational corporations are setting up subsidiaries in foreign locations, where local workers interact with co-workers and executives from the companies' headquarters (→ Communication Networks; Meeting Technologies; Network Organizations through Communication Technology; Technology and Globalization). Thus, people from diverse places with diverse expertise, experience, and expectations are encountering one another at work, where they confront differences in value systems, language skills, and communication styles. As organizations accommodate these workers, they also must serve diverse clientele/consumers in various cultural and geographic contexts.

When organizations first recognized that diversity mattered, they concentrated on compliance issues such as civil rights, affirmative action, and equal employment opportunity. Currently, many companies are striving to leverage cultural differences among employees because they realize that diversity can positively impact their bottom line. Known as the “business case” perspective, this approach sees diversity as a resource rather than a problem (Mor Barak 2005). This viewpoint emphasizes valuing differences, and it encourages members from different groups to contribute their cultural insights to workplace endeavors (Thomas & Ely 2001).

Workplaces that value employee diversity can gain positive outcomes, including increased creativity and learning, better decision-making, and improved performance. However, a

diverse workforce also can generate conflict and tension among employees, which can lead to turnover, charges of discrimination and harassment, and backlash against attempts to integrate workplaces at all levels.

Communication plays a crucial role in developments and outcomes related to workplace diversity because differences among employees, clients, and other organizational stakeholders affect all communication processes in organizations. Therefore, communication scholarship can inform efforts to maximize benefits and minimize detriments of workplace diversity.

## DEFINING WORKPLACE DIVERSITY

*Diversity* is an ambiguous, sometimes contested word whose meaning varies according to context (Konrad et al. 2006). In 1987, the landmark *Workforce 2000* (Johnston & Packer 1987) report indicated that increasing numbers of white women and women and men of color (mainly African-Americans) were entering the United States' workforce. Gender and race became significant as members of these groups and their advocates sought equal access and rights in the workplace, and sometimes faced conflict with members of majority groups. Recent definitions of diversity encompass population trends in the United States of an aging workforce, greater ethnic diversity, rising numbers of immigrants (especially Latino/as), and effects of globalization.

Although the United States pioneered the diversity movement, notions of diversity in the United States do not always correspond with those around the world (Mor Barak 2005). Although many nations have begun to refer to diversity as a human resource issue, their meanings vary. In Europe, "diversity" implies national cultures and languages. In the Netherlands, diversity means "ethnic difference" and "immigrant." In Brazil, persons who appear to be "black" according to US standards may be considered "white." These types of differences make it difficult to define diversity from a global standpoint.

Most contemporary views of diversity center on the idea that members of historically disadvantaged, *nondominant groups* (e.g., women and people of color) are more likely to experience discrimination than members of dominant groups (e.g., men and white people) (Konrad et al. 2006). Mor Barak (2005, 132) incorporates this stance along with the notion of variance across geographic and socio-historical contexts to define global workforce diversity as:

the division of the workforce into distinction categories that (a) have a perceived commonality within a given cultural or national context, and that (b) impact potentially harmful or beneficial employment outcomes such as job opportunities, treatment in the workplace, and promotion prospects, irrespective of job-related skills and qualifications.

This perspective aligns with emerging approaches to research on workplace diversity and communication.

## RESEARCH ON WORKPLACE DIVERSITY AND COMMUNICATION

Early research on workplace diversity concentrated on national cultures, based on initial conceptions of intercultural communication (which centered on national identities) (→ Cultural Patterns and Communication), and due to concerns about globalization and

its potential impacts on the US economy (→ Globalization of Organizations). Projects on nationality and organizational communication often studied organizations in specific countries, or investigated communicative behaviors of members of particular cultural groups, such as decision-making in Japanese organizations and managerial communication in Chinese factories.

Many studies about workplace diversity and nationality refer to Dutch researcher Geert Hofstede's (1984) pioneering project about international differences in employees' work-related values. This large-scale survey assessed *value orientations of workers* from over 50 countries in local subsidiaries of the multinational corporation IBM. Hofstede concluded that national culture explained differences in employees' work-related values and attitudes toward expected, acceptable behaviors in the workplace. For instance, he found relationships between participants' nationality and their tendency to be loyal to their ingroups versus feeling responsible primarily for their own personal needs. Hofstede used this finding to label countries and their citizens as either *collectivist* or *individualist*. This distinction is the most widely studied and cited dimension of Hofstede's model (Triandis 2004).

Studies that employ Hofstede's framework tend to focus on culture and cultural differences by emphasizing communication between individuals. Although these projects offer insight, they usually do not consider organizational issues that can affect interaction, such as formal and informal policies, practices, and norms. Also, they rarely delve into power dynamics inherent in all organizations (→ Power in Intergroup Settings), and especially significant in diverse workplaces. Furthermore, these endeavors are apt to apply an assimilationist model which assumes that all employees will want to adopt the cultural values of organizations in which they work (→ Organizational Assimilation). Finally, they neglect to consider macro-level issues, such as social, cultural, economic, and historical factors that can affect communication processes, especially in newer contexts like multinational corporations (Tanaka 2006).

These criticisms offer useful direction for research based on the global definition of workforce diversity. Related to this, critics also have called for more studies about experiences of nondominant groups (Oetzel et al. 2001). Some scholars promote theoretical frameworks that seem especially suitable for learning about nondominant groups, and for studying power relations. These include critical approaches, which delve into power dynamics that pervade all interactions, but are especially likely when members of diverse groups interact (→ Organizational Communication: Critical Approaches). A related theoretical perspective is co-cultural theory, which describes how nondominant members of dominant organizations strategically use communication to negotiate power relations (Orbe 1998). For example, they may employ various forms of assimilation, accommodation, or separation.

Some scholars recommend using qualitative *methods* such as in-depth interviewing, observation, and narrative analysis because they are more likely than quantitative methods to provide insight into experiences of nondominant group members. Some authors recommend matching researchers and participants according to cultural background to facilitate research interactions (Orbe 1998). They also advocate investigating intersections of identities, such as gender, race, and class, rather than focusing only on one (Allen 2004; → Research Methods).

While scholars offer numerous ideas for studying workplace diversity, they also acknowledge *potential obstacles*. For example, organizations may not allow researchers to study diversity because they fear repercussions from investigating such a potentially controversial topic. Even when researchers gain access to companies, potential participants may be reticent to talk about diversity issues, or they may not be truthful. Due to concerns about social desirability, participants may say what they think researchers want to hear. Also, members of dominant groups may be concerned about being perceived as prejudiced, and members of nondominant groups may fear that researchers will judge them as hypersensitive (Allen 2004). In addition, language and communication style differences can impede effective communication between researchers and participants.

### RESEARCH EVIDENCE

Despite these challenges, a slowly growing body of research employs many of the approaches that critics of previous scholarship have endorsed. Among these projects, gender is arguably the most widely studied topic (→ Feminist and Gender Studies). This type of research adheres to the ideas that consequences of diversity can vary according to membership in dominant and nondominant groups, and that power matters.

A team of researchers conducted case studies of three professional services firms to identify conditions under which cultural diversity enhanced or deterred workgroup productivity (Thomas & Ely 2001). Data collection teams consisted of members of various cultural groups, most of whom were matched with interviewees according to sex and race. Among three perspectives on diversity that emerged, the most effective was the integration-and-learning perspective, which advocates soliciting and using cultural insights and experiences of group members as valuable resources for accomplishing group tasks.

Another study applied qualitative methods to study power dynamics related to employee mistreatment in a culturally diverse workplace (Meares et al. 2004). A team of researchers employed muted group theory, which attends to ways that members of groups in society feel empowered or not to voice their experiences or worldviews. Based on narrative analysis of interview transcripts, the researchers concluded that intersecting identities (race, gender, and organizational role) made a difference in narratives about mistreatment: voices of people with more access to power (i.e., European-American male scientists) were less likely to be muted than those with less access to power (women, persons of color, and employees other than scientists).

As a final example, Tanaka (2006) conducted a longitudinal, ethnographic study of a Japan-based subsidiary of an American chemical plant to explore effects of identity, language, and behavior on intercultural business communication. The researcher interviewed participants in their native language of Japanese or English in order to acquire accurate information and to capture nuances. Analyses indicated that the use of English empowered native speakers, who had to negotiate different discourse systems as they interacted with American bosses and Japanese co-workers and clientele. The researcher shared insights with the company to help them develop strategies for dealing with linguistic and cultural challenges.

The need persists for studies about communication and diversity that delve into complexities of cultural differences and power dynamics in various workplace contexts.

Several scholars have provided blueprints, and some have begun to conduct work which incorporates their ideas. If more communication scholars heed their advice and follow their lead, the discipline can provide invaluable insight and information to help organizations worldwide to address the enduring, important issue of diversity in the workplace.

## **Doctor–Patient Talk**

*Jeffrey D. Robinson*

*Rutgers University*

The world's leading medical schools and journals officially recognize that what doctors and patients say to each other, and *how they say it*, dramatically affect the welfare of both

patients and health-care organizations. Within the discipline of communication (→ Health Communication) generally, and specifically within the sub-field of → language and social interaction (LSI), the study of doctor–patient “talk” involves the study of all conduct-in-interaction between doctors and their patients. “Doctors” include all forms of formally institutionalized practitioners (e.g., medical doctor, acupuncturist), all specialties, and all levels of experience (e.g., residents). “Interaction” typically includes real-time, voice-to-voice or face-to-face encounters, including some mediated ones (e.g., telemedicine). Encounters in which participants are not immediately co-present (e.g., Internet-based forms of textual communication) are studied less frequently because participants do not labor under the standard affordances and norms of interaction. “Conduct” includes all forms of verbal and nonverbal (e.g., artifactual) communication.

### FEATURES OF AN LSI APPROACH

Doctor–patient talk is studied from a variety of LSI perspectives, including → conversation analysis, discourse analysis, (socio)linguistics, and some types of ethnography. Although different perspectives are guided by different theories, methods, and proof-procedures, they are all primarily committed to describing and explaining the content, organization, and meaning of conduct-in-interaction. A second-order concern is with the effects of interactional variables on post-encounter outcomes, such as patients’ well-being and adherence to doctors’ medical recommendations.

The focus on conduct-in-interaction entails a commitment to the repeated analysis of (relatively) detailed transcripts of conduct (→ Transcribing and Transcription). Patients’ self-reports of communicative events (e.g., from post-encounter surveys) do not correspond highly with their actuality. Although audio and video records can be repeatedly analyzed and coded without transcribing them, the process of transcription helps to ensure that consequential details are recorded that might otherwise not be given attention (e.g., silences, self-corrections, intonation). Furthermore, from an LSI perspective, interaction is the primary data, and transcription allows it to be presented in scholarly publications. Because LSI perspectives treat verbal and nonverbal communication as inseparable, there is a commitment to video-taping when relevant. Universities’ institutional review boards permit video-taping, and participation rates tend to be high even in “sensitive” medical contexts.

LSI research on doctor–patient talk does not focus on any conduct; rather, it focuses on conduct that is organized by participants’ orientations to *aspects of the institution* being examined, such as its norms, rules, functions, inferential frameworks, goals, tasks, roles, identities, etc. These “institutional” aspects include both professional and “lay” or vernacular conceptions, and thus can be different, and differentially relevant and consequential, for doctors and patients. Research attempts to discover what these aspects are for participants, how they come to be realized and managed in and through interaction, and what their interactional consequences are.

The abovementioned reference to “participants’ orientations” alludes to LSI’s commitment to inductive methods and grounded theorizing. Early research showed that social-structural predictions (e.g., roles) made from pre-existing theory and/or official medical ideology are not always valid during all types of doctor–patient talk (Emerson 1970). Furthermore, even when social-structural arrangements can be shown to be valid,

they are not always simply *reinforced* by interaction; rather, they are frequently negotiated, contested, or otherwise *modified* in interaction according to the actions and activities that participants are pursuing at the moment. Thus, while recognizing that doctors and patients interact with reference to social structures that are exogenous to interaction (i.e., while recognizing the macro–micro link), LSI studies privilege meanings that are oriented to by participants during actual interaction. Of course, extant theories arising from wide-ranging disciplines, such as those dealing with information seeking and uncertainty reduction, have proven useful in explaining doctor–patient talk.

LSI scholars are similarly wary about (but not completely averse to) understanding doctor–patient talk through the lens of pre-formulated coding schemas. Code categories of the earliest schemas were established deductively from theories that were insensitive to the nuances of human communication (e.g., theories that conceptualized the function of communication as information transmission vs social action), and were originally designed for non-doctor–patient contexts (e.g., studies of small-group decision-making). Even as sensitivity increased, code categories continued to be operationalized in ways that conflated grammatical form with social action (e.g., coding for *statements* vs *medical advice giving*), and in ways that were insensitive to both the organization of interaction itself (e.g., unitizing in terms of the social-psychological notion of *thought units* vs the conversation-analytic notion of *turn-constructive units*) and sequential context (e.g., not differentiating between doctor-initiated and patient-sought advice). Additionally, code categories are frequently transformed into variables that are not relevant to participants (e.g., measuring category-frequency per encounter). Finally, statistical requirements that categories represent single meanings produced by single speakers can run at odds with the fact that even the most basic units of interaction can be polysemic and interactively co-produced.

At least partially due to technological limitations, research in the 1960s was ethnographic. The primary focus was not interaction, per se, but rather how doctors' behavior toward patients, as well as doctors' understandings of patients' behavior, were shaped by professional socialization, including both its official forms (e.g., medical school) and its unofficial forms acquired as doctors labor under a variety of implicit and explicit organizational pressures (Becker et al. 1961). Within the discipline of communication, there has been a dearth of ethnographic research that intersects with doctor–patient talk, and a lamentable disconnect between health-care ethnography and interaction analysis.

### ASYMMETRIES IN DOCTOR–PATIENT INTERACTION

In the late 1970s through the 1980s, research was dominated by three interrelated themes dealing with asymmetries between doctors and patients. First, research examined the asymmetry of (largely medical) knowledge and understanding. Research focused on the interactional causes and manifestations of “miscommunication” (e.g., medical jargon), its resolutions (if any), and its consequences (for review, see West & Frankel 1991).

Second, research examined the structure of medical interaction itself and its underlying norms and rules (which, overlapping the first theme, included those pertaining to repairing problems of speaking, hearing, and understanding). Here, researchers were concerned with the asymmetry between doctors' and patients' levels of participation. Interaction was found to be restricted with respect to speaker identity and sequence structure, such that doctors predominantly initiated topics and sequences (e.g., doctors asked questions),

and patients predominantly responded. Research examined the interactional mechanisms of this asymmetry, such as how doctors design turns in ways that normatively restrict patients' answers (e.g., yes/no questions that are linguistically designed to prefer no-answers), and how patients (fail to) resist such pressures (for review, see Robinson 2001).

Third, overlapping with the second theme, research focused on the types of contributions doctors and patients made. Here, researchers were concerned with the asymmetry of, and conflict between, a variety of different types of doctors' and patients' interactional frames. For example, Mishler (1984) argued that doctors' *voice of medicine* dominated patients' *voice of the life-world*. Along these lines, a variety of researchers demonstrated that doctors, who largely controlled the flow of interaction, systematically restricted their contributions to biomedical topics, avoided psychosocial topics, interrupted or ignored patients' psychosocial contributions, and omitted such contributions from medical records. Additionally, it was argued that doctors' "voices" or frames are biased according to their (Caucasian, male, upper-middle-class) ideologies. Again, researchers examined the interactional mechanisms of frame asymmetry, its negotiation, and its consequences.

### THE STRUCTURE OF MEDICAL ENCOUNTERS

Although most of the abovementioned research was conducted from the perspective that communication is fundamentally produced and understood to accomplish social action(s), it primarily focuses on interactional structure (e.g., lexical choice, turn design, and sequence organization) and relatively broad characterizations of content (e.g., biomedical vs psychosocial). Based on this necessary groundwork, research in the 1990s focused more intently on medical actions and activities per se. It became increasingly clear that doctor–patient encounters have *overall structural organizations*, or normatively ordered and organized sets of medical activities. For example, in primary acute care, these activities are *opening*, *problem presentation*, *information gathering* (i.e., history taking and physical examination), *diagnosis*, *treatment*, and *closing* (Robinson 2003). Because medical activities are themselves distinct contexts that shape participants' understandings, the nature and level of asymmetries of knowledge, participation, and frame differ, and are differentially consequential, in each activity. For over 15 years, research has been explicating the social organization of individual medical activities and their constitutive actions. For example, in a volume by Heritage and Maynard (2006), Anssi Perakyla addresses the activity of diagnosis, including different diagnostic formats (e.g., "You have bronchitis" vs "It seems like bronchitis"), how they embody aspects of doctors' expertise and authority, how they attribute agency to patients, how their meanings are altered according to their sequential positioning, and how they shape patients' responses. Complementing this, Douglas Maynard focuses on how diagnosis delivery is shaped according to the valence of the news for patients (i.e., good vs bad).

LSI research on doctor–patient talk is not, in principle, opposed to coding interaction into statistically manipulable variables and testing their association with each other or with post-encounter health outcomes. However, these moves proceed from basic, inductive research establishing that (at least interactional) variables are relevant to, and procedurally consequential for, participants. For example, Heritage and Robinson (2006) found that certain types of doctors' opening questions are associated with patients responding with

an increased number of discrete symptoms, and Robinson and Heritage (2006) found that these same questions are associated with patients' post-visit satisfaction.

LSI research on doctor–patient talk opens and illuminates the communicative black box of pure survey research. One major consequence is that LSI research promotes efficacious behavioral interventions. For example, survey research indicates that pediatricians' perceptions that parents desire antibiotics (for their sick children) is a primary predictor of doctors' inappropriate prescription of antibiotics (e.g., for viral conditions). Until recently, it was unknown exactly how such perceptions were formed during encounters. Stivers (2006) has since discovered a variety of parents' communication strategies that promote such perceptions, as well as doctors' strategies for combating parents' pressure to prescribe.

## **Document Analysis**

*Michael Meyen*

*Ludwig Maximilian University of Munich*

By no means all method textbooks discuss document analysis because there is disaccord as to whether this is an independent technique or whether it merely aims to apply

different methods to a particular investigation material (→ Research Methods). There is also controversy as to what has to be understood by “document.” Used in a wider sense as a synonym for the word “source” in historical research (→ Historiography), this concept encompasses all objects manufactured by man. However, as a rule, only written sources are considered to be documents. Examples are: reports, the wordings of laws, the minutes of proceedings, records, letters, diaries, leaflets, press articles, books, organization charts, or work instructions. Since these documents have their origin in everyday contexts and there is no contact between the researcher and the production of the investigation material, document analysis is a non-reactive method. Consequently, neither the researcher nor the aim of the investigation has any influence on the material itself. In addition, the costs of document analysis are lower than those of any primary → survey. Against this, the method has two major disadvantages: usually, documents only account for parts of the questions asked by the researcher, and they leave room for interpretations (→ Qualitative Methodology; Objectivity in Science).

Document analysis is the obvious choice whenever the objects of study (persons, groups, or organizations) are not available – either because they no longer exist (historical aspects) or because they refuse to be questioned or observed (like fringe groups and elites). In addition to that, document analysis can prepare for the use of other methods or be complementary to them. In the case of written material, document analysis allows for the use of all the methods that social science and the humanities have developed for the study of texts. However, one must always bear in mind that documents are never made without a definite intention. Consequently, the context of their production must not be disregarded. Methodological literature names numerous rules for dealing with documents that are evocative of the criticism of sources in historiography. The trustworthiness of documents has always to be questioned, and the relationship between the wording and the facts that are being described should be regarded carefully, by examining information about the document’s origin and its purpose, as well as the organization that produced the document and the intentions of the author. Quality criteria applied in document analysis are: transparency, diversity, and comparability. As far as comparison is concerned, data obtained with the help of other methods can be used in addition to other documents.

This approach will be illustrated by way of opinion polls carried out in the pre-computer age (→ Public Opinion Polling). Usually, the results of such surveys are available in written form. Unlike records, diaries, and other documents, opinion polls provide information about behavioral patterns, opinions, and values across the entire population, as well as about the differences between existing social groups and milieus. When interpreting such findings in the context of a document analysis, one has to ask who commissioned the polling, what was the position taken by the opinion research institute, what was the aim of the survey, who were the recipients of the reports, and whether parallel and preceding studies exist. Additionally, it is essential to submit the polling methods used in that time to a critical review. The → validity of the data depends on the instruments being used, as well as on the quality of the random sample, on the way the survey is conducted, on the indicators being implemented, and on the quality of the data analysis. Further methodological aspects to be considered are the questionnaire design and the way the questions are formulated, as well as the interviewers’ motivation and the behavior of the respondents. In order to permit classification of the information

contained in the historical report, one has to consider other data – for instance, the results of opinion polls held in other fields of inquiry and over other periods of time – or documents that might provide further indications for answering the research question (such as official statistics, diaries, or reports on → public opinion).

## **Documentary Film**

*Bill Nichols*

*San Francisco State University*

Among the qualities that distinguish films considered documentary are: (1) explicit reference to the historical world that surrounds the film, (2) a persuasive effort that encourages viewers to see or understand some aspect of the actual world in a particular way, and (3) an indexical relationship between the image and the reality it refers to. Indexical images match in their particulars the physical appearance of what they represent (→ Documentary Film, History of; Film Genres). They do not possess a general likeness to a model or referent, as a → painting would; they are closer to an exact replica of what came before the camera. The cinematic image can capture the look of a person, place, or event precisely. The optical properties of cameras, lenses, and recording media – from film to memory cards – capture aspects of the world with great precision. This allows the indexical image to serve as documentary evidence, as footage from surveillance cameras demonstrates.

The offsetting fact that images can be creatively altered or politically manipulated, be they celluloid or digital, allows for expressive or persuasive intent to complicate the relation of the documentary image to reality. Documentaries are not raw documents or evidence in the way a medical X-ray is. They are *complex forms of communication* and, like any other form of communication, they convey something of their creator's goals or intentions. Caution must be exercised in assessing how images serve as evidence.

Take, for example, Leni Riefenstahl's notorious film of the Nazi party's annual rally in 1935, *Triumph of the Will*. The film, then as now, relies heavily on its indexical relation to

what happened before the camera. The historical actors are authentic and the event actually took place. But Riefenstahl worked closely with Nazi party officials to plan and stage the rally in order to film it more effectively. In other words, she did not just catch reality as it unfolded around her but *staged that reality* for maximum cinematic impact. Like modern-day political conventions, the entire rally is orchestrated as a media event for the camera rather than as a historical event the camera manages to record (→ Media Events and Pseudo-Events). Some historical events, such as the press conference, photo opportunities, political rallies, demonstrations, and conventions, only exist in the form they have in order to be filmed or televised. Documentaries inevitably shape as well as capture the reality they represent.

Filmmakers use their works to convey their own point of view, sensibility, or perspective even though other interpretations are always possible. Michael Moore's *Fahrenheit 9/11* (2004), for example, presents evidence that supports his contention that the American occupation of Iraq was totally unjustified. All the evidence he assembles serves to advance a specific argument. Among the most persuasive forms of evidence used are those images and scenes that carry a strong emotional impact, such as a mother who became a vocal critic of the war after her son died fighting in Iraq. In many documentaries the *emotional impact of images* outweighs their strictly evidentiary value (→ Emotions, Media Effects on). The realism of the documentary image makes viewers feel as if they are witnessing an actual event, or receiving evidence of what really happened in an almost unmediated form. Indexical images are a potent source of documentary evidence, but the interpretation of these images introduces subjective and persuasive factors that allow the same evidence to serve more than one purpose (→ Realism in Film and Photography).

As a rhetorical form of communication, documentary film seeks to move or persuade its audience (→ Rhetoric and Media Studies; Rhetorical Studies). Persuasiveness is achieved by adhering to the “three Cs” of rhetoric. These are what were called “proofs” by Aristotle because they provided proof of the validity of the case being made. The three Cs require that a documentary be (1) credible – the filmmaker or any commentator who appears on his or her behalf must appear trustworthy; (2) compelling – the evidence provided should carry an emotional charge that will move the audience, and (3) convincing – the claims and statements made, either explicitly by a speaker or implicitly by editing, music, composition, and so on, must appear truthful.

What is crucial, rhetorically, is the *impression of truthfulness*. Rhetoric comes to the aid of those who favor a particular course of action when scientific or purely logical analysis cannot decide the issue conclusively. What is known as fact and is now part of the historical record or what is known as true and not open to dispute must be respected, but this is not as great a safeguard as some might think. That global warming has come to be accepted as scientific fact, for example, does not determine what policies governments should adopt, nor does it determine what actions businesses should take. Specific choices become defended by rhetorical means.

The assembly of raw footage, with its powerful indexical relation to the historical world, into more elaborate, rhetorical statements about the world became a common practice in the 1920s. The documentary film provided a potent way for the state to advance its own agenda and for other organizations and individuals to present their own values and views, even if they challenged official state policies.

Decades later, numerous documentaries take up issues and topics that do not involve the state directly at all, from questions of gender and ethnicity to concerns about the environment. In fact, some films, such as Davis Guggenheim's *An Inconvenient Truth* (2006), make clear that the state has become a problem rather than the means to a solution. *An Inconvenient Truth* does not criticize specific state policies directly but makes clear that global warming has become an increasingly serious issue despite the various measures different states have adopted (→ Activist Media). The implication is clear that the measures taken so far are inadequate. The history of documentary film stands, on one level, as a record of the failure of western democracies to address successfully issues such as poverty, disease, environmental degradation, social justice, and war. It was, ironically, the need of the state to promote its particular approach to such issues that led to the rise of the documentary film in the first place.

## **Documentary Film, History of**

*Michael Chanan*

*Roehampton University*

While scholars of early film have been much preoccupied with the emergence of storytelling and narrative (→ Storytelling and Narration), the dominant mode of early → cinema, beginning with the first films of the Lumière in 1895, was the actuality, or what might be called “documentary before documentary” (→ Cinematography; Cinematography, History of). An instinct for what Siegfried Kracauer (1960) called “the seizure of physical reality” produced a huge variety of images that, despite their brief and fragmentary character, were not without ideological implications, since they generally reproduced social → stereotypes unthinkingly and frequently projected and enhanced the iconic imagery of state power and authority. Cinema was born in the “civilized” countries of Europe and North America, and these early films also traded on exotic imagery from every corner of the world, which not surprisingly reflected the colonial ideology of the day. The French at this time used the term *documentaire* for what in English was called the

“travelogue,” which emerged before World War I as one of the most popular proto-documentary genres, along with the wonders of science and expedition films (→ Film Genres). However, the recent rediscovery in Britain of the Mitchell & Kenyon films reminds us that turning the camera on your own community was also a fundamental propensity.

### EARLY TRENDS

The rise of documentary as an art form after the war comprised several trends, which separated the form from both commercial interest films, and association with → propaganda and → public relations (the largest producer of short factual films in the USA in the early 1920s was the Ford Motor Company). One current, favored by European filmmakers influenced by the modernist avant-garde, turned toward the quintessential site of → modernity – *the city*. The “city symphonies” of the 1920s, by directors like Walter Ruttmann (*Berlin, Symphony of a City*), Dziga Vertov (*Man with a Movie Camera*) and Jean Vigo (*A propos de Nice*), have long been celebrated for creating a new perception of the city for the twentieth century; in the process they discovered a visual language for the representation of space and place quite different from that of the enclosed fiction studio: instead of narrative continuity, these films explored and expanded the principles of montage first theorized in the context of the Russian revolution by Eisenstein and others, which still remain an essential resource of documentary film language.

A very different tendency gave the travelogue an *ethnographic twist*, turning the camera on the distant wilderness of “primitive” societies in what the filmmaking metropolis saw as the periphery. When John Grierson (1946) applied the word “documentary” to Robert Flaherty’s film of South Sea islanders, *Moana*, in 1926, he used it as an adjective, speaking of the film’s “documentary value” as “a visual account of events in the daily life of a Polynesian youth and his family.” Within a few years, however, it turned into a noun and a subtle shift of meaning took place. What emerged in the 1920s was thus a range of films distinguished from fiction by their imagery of veridical reality, looking for a term to describe them in all their diversity.

For pioneering documentarists like Vertov, Joris Ivens, and Grierson himself, documentary represented a necessary alternative to the escapism and meretricious spectacle of commercial cinema. Ivens (1969), whose career spanned something like 70 films over 60 years, called documentary “a creative no-man’s-land, an interloper in the genre system.” For this very reason, however, it was largely marginalized from cinema as a site of mass entertainment and reduced to secondary status. One of the consequences is that the history of documentary would be quickly forgotten as the films disappeared into the archives (whence our new digital culture is now beginning to retrieve them rather randomly).

### COMING OF SOUND

The coming of sound was no help, because sound was introduced to serve the purposes of shooting fiction in the studio, and for many years remained deficient for location filming. Despite a few experiments in the creation of soundtracks by filmmakers like Vertov, Ivens, and the famous GPO film unit under Grierson’s leadership (*Enthusiasm*, *Philips Radio*, and titles like *Night Mail* respectively), documentary settled into a conventional

format, using music, commentary and sound effects to impose a preferred meaning on the images. The pretence of omniscience found in the impersonal commentary led to Paul Rotha dubbing it the “voice of God.” Exceptions point in a different direction, like Humphrey Jennings’s wartime *Listen to Britain*, an essay on the collective experience of the nation carrying a soundtrack composed entirely of noises, sounds, snatches of speech and music, matching the visual collage of the image. If the authoritative commentary has remained a feature of television documentary, it is nowadays much less favored in independent films with any pretension to stylistic currency; here, if commentary is employed, it tends to use the personal tones of the filmmaker’s own voice.

Grierson argued for the production of *documentaries in the* → *public interest*, as a form with “sociological rather than aesthetic aims,” although he also famously defined documentary as “the creative treatment of actuality.” When he wrote his “First principles of documentary” in the 1930s, he sought to distinguish “higher” and “lower” forms, to downgrade forms like the newsreel, the travelogue, and the educational “lecture” film, and to reserve the proper use of the term for films that aspired to the virtues of art. This turns out to be a difficult distinction to maintain, since the same skills are involved whatever the mode of the film, and most documentaries comprise an eclectic mix of different styles. Politically speaking, Grierson’s position was reformist (he once said he was always a little bit to the left of whatever government was in power), and the 1930s also saw the emergence on the Marxist left of documentary as a form of political agitation, not only on the part of filmmakers like Ivens, but also aficionados in the workers’ film associations that appeared in places like Japan, Europe, and the USA. This kind of filmmaking did not survive the cauldron of World War II, and would have to be reinvented in another form in the politicization that traversed the world in the 1960s.

Meanwhile, in the post-bellum, a still fairly small tribe of documentarists cultivated an essayistic approach to the form, like the Free Cinema group in Britain. This trend was particularly strong in France, where in 1955 Alain Resnais made the first documentary devoted to the Nazi concentration camps, *Night and Fog*, thus initiating one of the most crucial currents within documentary in the second half of the century: the reconstruction through archive footage of the history of the first half.

## RENOVATION

The 1960s brought technical and political factors into a new alignment. Television, after initial hesitancy, had adopted documentary eagerly but imposed its own codes of compliance, especially in the matter of political “balance,” a code word for not upsetting the conventional wisdom (→ Television: Social History). But this was accompanied by a technical breakthrough which completely changed the ground rules: new lightweight 16 mm cameras capable of hand-held operation and synchronous location sound with portable tape recorders. The result, in the felicitous phrase of Mario Ruspoli (1964), one of a new breed of filmmakers who first filmed this way, was that for the first time “sound and picture stroll along arm-in-arm with the characters in motion.” This innovation produced an effect of remediation in which the quality of filmic representation shifted gear and a new paradigm of observed reality was installed, to be known by epithets like *cinéma vérité*, direct cinema, or fly-on-the-wall.

The result was the paradox, as Brian Winston (1995) put it, that “because the new equipment made filming so much less intrusive than it had been, the finished films were far more so.” The camera is now able to follow its subjects across social boundaries and borders which previously served to keep it from intruding, to enter the semi-private places and even intimate spaces of everyday social life whose portrayal was previously the privileged province of fiction. And since this is a camera with ears, Edgar Morin (2003), co-director with Rouch of the key film *Chronique d'un Été*, spoke of “an authentic talking cinema,” where “there are no fistfights, revolver shots, or even kisses,” in which “the action is the word,” conveyed by “dialogues, disputes, conversations.” But documentary entered the private domain only in order to reflect it back into the → public sphere, and thus also contributed to a breakdown of the separation between public and private that is one of the markers of postmodern culture.

Different tendencies quickly emerged. In France, *cinéma vérité* was self-reflexive and dialectical, while direct cinema in the USA, in the style of Richard Leacock, D. A. Pennebaker, and above all Frederick Wiseman, aspired to unalloyed observation. In Canada, Michel Brault and Pierre Perrault pioneered a new current of French-Canadian documentary which offered a paradigm for the self-representation of cultural minorities until then poorly represented in the media. In Latin America, a radical movement emerged, stretching from Mexico to Chile, which valued documentary as an instrument of social analysis and political activism in opposition to the hegemony of the North. In Cuba, this included the films of Santiago Alvarez, who reinvented the newsreel, the compilation film, the travelogue, and every other documentary genre he laid hands upon in an irrepressible frenzy of filmic bricolage licensed by that supreme act of bricolage, the Cuban revolution.

Films of the *two avant-gardes*, political and artistic, circulated through alternative distribution in 16 mm throughout the 1960s and 1970s, finding audiences of trades unionists, solidarity groups, aficionados, and students wherever there was half a chance. By the 1980s, a new wave of independent documentary emerged aligned with new social sensibilities, from second wave feminism to the multiple strands of identity politics. Here an important tendency was a new mode of first-person address and the self-inscription of the filmmaker, which often translated into the autobiographical, replacing orthodox objectivity with new richer forms of social subjectivity. This is also true of the apogee of documentary as poetic essay in the work of Chris Marker, especially *Sans Soleil*.

Only after television had spawned consumer video would 16 mm decline, to be replaced by the camcorder and the video cassette, transforming the means of both production and distribution, which now began to reach new users and enter new spaces (→ Television Technology). On the one hand, documentary video art would become a regular feature of the art gallery. On the other, the camcorder was employed in countries like Brazil to create an indigenous video movement, dedicated to strengthening community politics, to be shown in the villages where the equipment would be powered by car batteries. But perhaps the most unexpected turn was the *return of documentary to the big screen* in the 1990s. Here the obligatory reference is Michael Moore, but as evidenced by the growing number of locally oriented documentary film festivals, the phenomenon is worldwide, with major documentary movements appearing in countries as diverse as Spain, Argentina, and China, testifying to a hunger for the renewed interpretation of social reality all too

often absent from both fiction cinema and television. However, few of these films are able to reach foreign audiences as long as international distribution is dominated by the same monopolistic distributors who control both entertainment and art cinema (and excluded documentary from the cinemas in the first place).

These trends have been extended and diversified by digital video and the Internet, encouraging a variety of new forms and practices to develop on the margins of the commercial industry. Many commentators speak of these developments as a decentering of the public sphere, where the idea of documentary originally took root as a discourse of the factual and the real, and which indeed it helped to reconfigure, with the effect that the modern public sphere is in part defined by its practice. Indeed, it can be said that without the documentary, the public sphere is not functioning properly.

## **Domain Names**

*Wolfgang Kleinwächter*

*University of Aarhus*

The domain name system (DNS) was developed mainly by Paul Mockapetris and John Postel in the early 1980s. The main specifications are laid down in RFCs, or requests for comment, managed by the Internet Engineering Task Force (IETF). These are the accepted technical standards for the Internet; key ones are RFC 1034, RFC 1035, and RFC 1591 of March 1994, which defined the DNS structure and delegation.

### **FROM NUMBERS TO NAMES**

Until 1983 the communication among computers within and via networks was organized by numbers, so-called IP addresses. The IPv4 address had two blocks of numbers, each

divided into two strings of numbers. The first block identified the network, the second one the computer. Such a system was user-unfriendly as IP addresses had more numbers than telephone or fax numbers, and users had to remember 15 or more figures. Mockapetris and Postel wanted to give Internet communication via computers a human face. The idea was to link the numeric IP address to a real name so that end-users could have an identity via a domain name. The system, which became the DNS, follows the three-layer system of names where people have first, second, and family names. The DNS is organized on the basis of a hierarchy with a top level domain (TLD, the family name) at the top.

### **gTLDs and ccTLDs**

Postel introduced six generic TLDs (gTLD) with three characters each: .edu (educational institutions), .gov (governmental entities), and .mil (military) for use in the US only; and .com (commercial institutions), .net (network), and .org (organization) for the rest of the world. .arpa was reserved for the management of the zone files and later .int was added for intergovernmental organizations. The three global gTLDs were managed by Network Solutions Inc. (NSI), which also managed .edu. The US government took over the management of .gov, and the US Department of Defense the management of .mil (→ Communication Technology Standards).

As people asked for TLDs for other countries, Postel introduced a second category, the country code TLDs (ccTLDs). The problem was to specify what counts as a country, and in RFC 1591, Postel argued that “IANA is not in the business of deciding what is and what is not a country” (Postel 1994). Postel used a list of countries and territories managed by the International Organization for Standardization. The list included two-letter codes for 243 countries and territories.

The data zone files for the TLDs were hosted by a system with 13 root servers. For TLD management, Postel – working at this time for the Information Science Institute (ISI) at the University of Southern California – created the Internet Assigned Numbers Authority (IANA) following a recommendation by the US Department of Commerce, which had oversight of the financing of Internet research via the National Science Foundation. ISI and the Department of Commerce entered into a contract whereby IANA was given responsibility for the management of the DNS and the IP address space. The Department of Commerce reserved the right to authorize the publication of TLD root zone files in the A root server, managed by the National Science Foundation via the Department of Commerce.

Postel used personal contacts and recommendations from friends to identify TLD managers with the capacity to manage a name server and with a sense of responsibility towards the global Internet community (→ Internet, Technology of). In the early days, delegation was mainly by a handshake between Postel, who maintained this until his death in 1998, and the designated manager, and neither government legislation nor political or legal processes were involved. Following his death, the Internet Corporation for Assigned Names and Numbers (ICANN) was established. ICANN coordinates the DNS, including the delegation and re-delegation of TLDs, under oversight by the Department of Commerce.

Each manager of a TLD has full responsibility for the second level domains (SLDs). Registries can independently register SLDs, keeping all registered SLDs in their own

databases. Registered SLDs can register more names at the third level, which leads to multilayered domain names. This decentralized and distributed system makes the DNS very robust and efficient.

### **The Commercial Value of Domain Names**

The system has worked efficiently since its introduction. Postel had estimated that the 250+ TLDs offered enough space for global communication, but after the invention of the world wide web and the dot-com boom of the late 1990s, domain names not only created a personal identity in cyberspace, they also acquired a commercial value and came to be treated as commodities or assets and as part of a proprietary system linked to trademark names (→ Information Society). Companies like Amazon, Yahoo! and Google built their empire on domain names.

Domain names were easy to understand, find, and remember, and they became the subject of a growing domain name marketplace. In 1999 domain names like *business.com* or *flowers.com* were being sold for US\$1 million or more, and by 2006 the secondary DNS market was worth approximately US\$1 billion. Highly valued names, such as those in the .com domain, have become a scarce resource and there has been pressure to introduce more TLDs, especially generic names. Theoretically, there is no technical reason to limit the number of TLDs to 250+. Given that a name server under the .com domain managed by VeriSign (until 2000 by NSI) can handle more than 60 million SLD data files, there is no reason why root servers could not manage thousands of TLD data files.

### **The Search for a Global DNS Management System**

By the mid-1990s Postel wanted to introduce 150 new gTLDs and sought to use the newly established Internet Society (ISOC) as an institutional home for the DNS management. NSI opposed this, fearing the loss of its monopoly in the emerging domain name market. Later Postel began talks with the International Telecommunication Union (ITU) and in 1996 he initiated the Interim Ad Hoc Committee (IAHC), with IANA, IAB (Internet Architecture Board), ISOC, INTA (International Trademark Association), WIPO, and ITU as members. The six organizations negotiated a memorandum of understanding (gTLD-MoU), signed in Geneva in May 1997. The plan was to establish a policy oversight committee (POC) as a public–private partnership. The POC was to oversee the DNS and, as a first step, to introduce seven new gTLDs. To demonopolize the registration of domain names in the gTLDs space, a group of some 35 registrars was to be licensed and to join a council of registrars (CORE). Another proposal was to move the A root server from the US to Geneva, giving the ITU a role as the repository of the MoU.

The plan was heavily criticized by the US government and by NSI. In a letter to the ITU the US Secretary of State, Madeleine Albright, rejected the MoU. She argued that the ITU Secretary General had not consulted with member states before signing the MoU and that ITU was therefore not authorized to join the gTLD-MoU. Recognizing that the contracts between the Department of Commerce with IANA and NSI were terminating in October 1998, the US government proposed an alternative strategy for the privatization of the DNS.

### **Towards the Establishment of ICANN**

In January 1998 the Department of Commerce published a Green Paper proposing the creation of a new corporation for Internet names and numbers. This paper became the subject of controversial international discussion. The European Commission and the governments of Canada and Australia rejected the proposal as being unbalanced, arguing that the Internet was a public resource for global communication and needed international oversight. In June 1998 a White Paper proposed the establishment of NewCo, intended to uphold the principles of security, competition, and bottom-up policy development, and global representation. This paved the way for the establishment of ICANN in October 1998. A week before the launch of ICANN, the ITU Plenipotentiary Conference in Minneapolis recognized the principle of private sector leadership for Internet governance and for the management of the DNS.

ICANN entered into a MoU with the Department of Commerce and received the mandate to coordinate the root server system, the IP address system, and the DNS. The plan was that ICANN would become independent of the US government in 2001, but this did not happen. Instead, the MoU was extended and then transformed in 2006 into a joint project agreement (JPA), due to terminate in October 2009.

After its creation, ICANN faced the dual challenge of establishing a policy for handling domain name conflicts over trademark protection with respect to the gTLD domain names space, and of introducing new gTLDs. In 2000 ICANN adopted a universal dispute resolution policy (UDRP) that established a global system for dispute resolution for domain name conflicts in the gTLD domain name space. The UDRP recognizes the role of trademark-protected names in the DNS, defines registration of such domain names in bad faith, and offers a privately organized global online dispute resolution system.

In early 2000 ICANN started a process for the introduction of new gTLDs and in a pilot phase licensed seven new TLDs (.info, .biz, .name, .coop, .aero, .museum, .pro). In 2005 it licensed sponsored TLDs (sTLDs) .asia, .mobi, .cat, .jobs, .tel, and .travel, but rejected other proposals, including one for .xxx. Its generic supporting organization (GNSO) is developing a more stable gTLD policy. The plan is to create a clear legal procedure that would define political, economic and technical criteria for new gTLDs that have to be met by applicants, and it is expected that the ICANN board will adopt the new policy in early 2008, thereby making it possible for a substantial number of new gTLDs to be introduced.

### **DNS and the World Summit on the Information Society (WSIS)**

During the WSIS that started in 2002, the DNS emerged as part of the controversial debate on Internet governance. A number of UN member states, notably China, India, Brazil, South Africa, Saudi Arabia and others, called for a new governmental body to oversee the Internet core resources, including the DNS. The continuing role of the US government in authorization and publication of TLD zone files in the Internet root (not the so-called “hidden server” operated by VeriSign) was criticized. The issue was discussed in the UN Working Group of Internet Governance (WGIG), which was established by UN Secretary General Kofi Annan after the first phase of the WSIS in 2003. During the second WSIS phase in 2005, governments recognized the role of ICANN but agreed on a number

of general political principles. The Tunis Summit created a new Internet Governance Forum (IGF) for discussion of Internet-related issues and a process of enhanced cooperation involving a consultation process was launched to clarify the future oversight of the Internet's core resources, including the DNS. It is expected that in 2010, when the JPA between ICANN and the Department of Commerce will have terminated and the mandate of the IGF is also due to end, the issue will come back onto the agenda of global Internet policy debate.

### ACADEMIC ANALYSIS

The development of the DNS has been analyzed by a number of researchers both from the technical and the social science points of view. A key analysis was published by Lessig (1999) on the theme of *Code and other laws of cyberspace*, (→ Code as Law), arguing that great care should be taken to develop an understanding of the interaction between the code embedded through software development and its effect – and potential constraints – on the way the Internet is used. Mueller's (2002) *Ruling the root* presented a detailed analysis of the politics and institutional processes influencing the decisions of ICANN. Various authors have provided further reflections on the tensions inherent in the need to address technical and policy issues on a global scale, including Drake's (2005) *Reforming Internet governance*, which offered a critical analysis of the work of the WGIG.

There have been studies over the past decade highlighting the complex environment in which Internet governance encompassing issues raised by domain names must operate. Cairncross (1997) highlighted the "death of distance," while others such as Castells (2001) have investigated the network environment from sociological perspectives. Legal issues have been critically reviewed by Drucker and Gumpert (1999) and, with respect to intellectual property considerations, by Lessig (2001). Others, including Loader (1997), have tackled governance issues from different disciplinary perspectives. There is a continuing need for interdisciplinary studies, especially to understand how the technical dynamics of domain names and root servers are played out on the global stage.

## Domestication of Technology

Maren Hartmann

Berlin University of the Arts

The *domestication of technology* is an approach within the area of media appropriation studies. It describes the process of media (technology) adoption in everyday life, and especially within households. It outlines several dimensions of this dynamic adoption process in the context of the household as a *moral economy* and through the concept of the *double articulation* of media as technology. Two major strands of the domestication approach have been developed, only one of which is clearly within the field of media and communication studies. The other is located in the field of social studies of technology (e.g., Lie & Sorensen 1997).

The domestication idea was first developed at the beginning of the 1990s, primarily in the UK. It has its roots, however, in an article by the German ethnologist Hermann Bausinger, published in *Media, Culture and Society* in 1984, where he described a weekend in the life of a “typical” German family and reflected on the communicative role of the media. He stressed the uses of different media, everydayness, and the *collective* use and discussion of media. Building on Bausinger, the main researchers contributing to the early formulation of this approach were Roger Silverstone, David Morley, and Eric Hirsch (and later Leslie Haddon) (e.g., Silverstone & Hirsch 1992). The approach is now used widely in Europe, and also in North America, Asia, and other parts of the world. *Two research projects* shaped the early history: HICT (The Household Uses of Information and Communication Technologies) and PICT (Programme on Information and Communication Technologies). From 1995 to 1998 the EMTEL (European Media, Technology, and Everyday Life) network was crucial in further developing the concept of domestication. This was followed by EMTEL II from 2000 to 2003.

The emphasis of the concept on the media’s materiality represented a move away from a concentration on the media text to the media itself. The emphasis on the context of media use underlines the close relation to → cultural studies as well as to feminist engagements with media use. The technology emphasis was in part inspired by developments in the field of technology studies (→ Technology, Social Construction of). Everett Rogers’s approach to the diffusion of innovations (→ Diffusion of Information and Innovation) shared a concern with the routinization and “making common” of

technologies, but the emphasis in domestication research is less on use itself than on meaning-making via media use, and it also engages critically with any assumption of linearity.

An interesting feature of the domestication approach is the *dimensions of media appropriation*, which include commodification, imagination, appropriation, objectification, incorporation, and conversion. These dimensions suggest that media are first made (invented, marketed, etc.), then adopted and integrated as objects that find a place in daily routines. They are also used to communicate to the outside world that certain media are used in particular ways. This applies to the media as technological and consumption objects as well as to their content, which is also reflected in the idea of *double articulation*. Media are both material objects and content providers. The concept of the *moral economy* draws attention to the idea that people need to be secure in their everyday lives, that is, they strive to achieve ontological security. The household economy is embedded in the wider economy, and media consumption is treated as a transaction process where media enter the home and values and experiences are “traded.”

The moral economy concept within the domestication approach has been *criticized*, by Andrew Feenberg, for example, who described it as “too cozy” (1999, 107), claiming that it is not a general media adoption model. He argued that agency needs to be emphasized and that the possibility for resistance needs to be kept open. The ultimately conservative character of the approach was acknowledged by Silverstone himself, who stated that there would always only be an *attempt* at appropriation and that only that which is *not* domesticated is interesting because this is the site of change (Silverstone, in Berker et al. 2006). This insight also addressed criticisms that the domestication model is too linear. The earlier approach to re- and de-domestication, however, was articulated as a dynamic nonlinear model, although it did not allow for a radical break in the domestication process.

Initially, it was assumed that the domestication approach would be developed only through the use of ethnographic methods to achieve the necessary detail through observations of households over a period of two weeks. This method was soon replaced by qualitative interviews, and this is still the primary research method in this field (→ Qualitative Methodology; Ethnography of Communication). Additionally, time-use diaries, photos, drawings, lists, mental maps, etc., are used to achieve triangulation. Some researchers continue to engage directly with households over the long term and to achieve greater depth of analysis (cf. Berker et al. 2006).

The challenge for the *further development of the domestication concept* is the changing media environments in which the media are consumed, which mean that the study of home as a site for media adoption research (Morley 2003) is limited. There is also debate about whether the domestication concept should be restricted to its core focus on media appropriation. Nevertheless, the domestication approach remains a useful tool for examining the complexity of everyday life and media use and provides entry points for a better understanding of media production and consumption.

## Drama in Media Content

Christine Scodari

Florida Atlantic University

On the terrain of popular communication are cultural artifacts with a potential to entertain, inform, or persuade. Accordingly, dramatic media content has been investigated by way of five interdependent perspectives: (1) genre (→ Film Genres), (2) medium, (3) narrative, (4) ideology, and (5) → meaning. Especially with regard to film and → television, this generic designation has been fluid, with shifting parameters and a tendency toward what Altman (1999) and others have called “genre mixing.” Television awards and DVD sellers may broadly distinguish drama from comedy, but scholars often treat what might otherwise be considered sub-genres of drama as genres in their own right. So, any scripted, narrative program or film that is not comedy, and which cannot be neatly classified under another, more specific brand such as Western, soap opera, film noir, melodrama, science fiction, action, or suspense/thriller, is designated simply as a drama. For instance, television features medical, legal, crime/espionage, political, and teen dramas, among others.

Under the broader view, however, dramatic sub-genres have proliferated due to social and economic imperatives, often rooted in the institutional arrangements of a medium within national and/or international systems (→ Political Economy of the Media). In turn, these sub-genres, their constituent texts, and audience negotiations are further assessed by cultural, media, television, and film critics of popular media according to narrative and other interpretive dimensions as well as particular ideological subjectivities, including class, gender, sexuality, and race.

The crime drama illustrates the influence of the social and economic. It includes film noir, police, and detective/spy dramas on the big screen and police, espionage, and forensic series on the small screen. Recent attention has been given to the re-emergence of the episodic procedural in American television and its most popular manifestation – the forensic drama. The *CSI (Crime Scene Investigation)* franchise, including three series at this writing, has attained international renown. Its success, along with that of similar

procedurals such as the *Law and Order* franchise, is related to the recent reluctance of US networks to invest predominantly in series such as the medical drama *ER*, a type of ensemble, character-driven, serialized, *cinéma vérité*-style program that did not become fashionable until the 1980s and which, it turns out, does not play as well in five-day-a-week syndication as plot-driven, episodic shows that achieve closure at the end of each installment. Serialized dramas thereby curtail long-term profitability. Procedurals have also been said to respond to anxieties generated by the terror attacks of September 11, in that they present public servants working competently, swiftly, and almost always successfully to apprehend and convict the “bad guys.”

Soap opera provides a case by which to better appreciate interrelationships among genre, medium, narrative, ideology, and meaning (→ Soap Operas). In its American, commercial network incarnation, the soap opera’s invention was economically driven by the desire to target female homemakers, aged 18–49, with the power to purchase household products. Like other forms of women’s melodrama, soaps center on the private sphere of interpersonal relations, but feature an array of female characters central to multiple storylines.

Their kinship to tragedy and romance in classical theater, the romance novel, and the “woman’s film” notwithstanding, soaps are often distinguished in terms of one of their myriad “feminine” qualities – the delay or avoidance of narrative closure. While Chatman’s (1978) narrative constituents of story (characters, settings, plot elements) and discourse (story structure) were originally applied to novels and films, Fiske (1987) reconfigured such attributes in order to differentiate between masculine and feminine television, with soap opera exemplifying the latter (→ Gender: Representation in the Media; Masculinity and the Media).

It is not surprising, then, that soap opera studies take on ideological significance. For example, the openness of the soap opera narrative has been said by some to encourage potentially empowering interpretations from female viewers (→ Audiences, Female), although Mumford (1995), among others, has countered that when the individual storylines in soap operas do achieve closure, they often reproduce patriarchal meanings.

While the narratives of many of the soap opera’s international derivations, such as Latin American *telenovelas* and Hindi television serials, eventually resolve, they still refuse tidy, episodic endings and adhere to other feminine traits. They, along with British and Australian soaps, have not typically been conceived as daytime fare. Moreover, they are often produced by public television and, consequently, are not motivated by commercial exigencies to “narrowcast” to women in their childbearing years in order to maximize profit. Such distinctions allow them to display greater diversity in terms of such subjectivities as age and class. With respect to the visual aspect of medium and meaning, it has been noted that the dearth of camera flourishes in British soaps serves to accent their social realism. *Dallas*, the most-analyzed American prime-time soap, clearly eschewed such realism. However, Ang (1985) revealed the resistive power of this series’ “melodramatic heroine” in her study of Dutch viewers.

These lines of inquiry make apparent how genre, medium, narrative, ideology, and meaning generate issues and modes by which to investigate drama. Regardless of the fluidity of its demarcations, popular communication scholars continue to adopt and enmesh these perspectives in determining drama’s evolution and significance.

## **Dual Coding Theory**

*Prabu David*

*Ohio State University*

In the typical demonstration of dual coding, a list consisting of an equal number of pictures and words is presented to study participants. On encountering an item in the list, the study participant is asked to read the word or name the picture. Later, when the items are recalled, twice as many pictures than words are recalled. This picture-superiority effect, or the better recall of pictures over words, can be attributed to dual coding, which is the activation of traces in visual and verbal memory systems. While the verbal system is dedicated to processing of linguistic information, such as words and sentences, which are represented as discrete units or “logogens” and processed sequentially, the visual or imagistic system is dedicated to the processing of images, which are processed more holistically and represented through units referred to as “imagens” (Paivio 2006). The complementary role of two distinct, but interconnected, visual and verbal systems is at the heart of dual coding theory (DCT).

According to DCT, pictures benefit from dual activation. First, the visual system has to interpret or decode the picture. Second, the verbal system has to generate a verbal label for the picture that has been activated in the visual system. Because the systems are interconnected, the activations are pooled, thus enhancing memory for the pictures. The pooling of activations from the visual and verbal systems is referred to as the additivity hypothesis of DCT, which explains the picture-superiority effect.

Unlike the naming of pictures, the reading of a word activates mainly the verbal system. However, because of the interconnection between the two systems, some leakage or incidental activation of the visual system may occur automatically. For example, when reading the word “fire,” a mental image of fire may be triggered. However, because such activations are only incidental, they are weak in comparison to the direct activation created by a picture.

The automatic or incidental activation of the visual system from verbal inputs is the basis for another robust experimental finding in DCT, which is the better recall of concrete items over abstract items. When study participants are presented with a list of concrete and abstract nouns, concrete nouns enjoy a decisive advantage, though their performance is slightly below the recall of pictures. The better performance of the concrete items can be attributed to their imagery evoking properties. A concrete noun, such as “lobster,” has greater imagery evoking potential than, say, an abstract noun, such as “truth.” In other words, just the thought of a lobster automatically conjures up visual images in memory, whereas an abstract construct, such as truth, does not have the same imagery evoking potential. This effect of concreteness has been demonstrated for a range of verbal stimuli, including concrete phrases, sentences, and even passages.

Logogens and imagens, which are the foundational elements of DCT, are not limited only to visual inputs, but can be extended to other senses. For instance, when we hear the word lobster, as opposed to seeing the word, the auditory input can be combined with the visual input. This is an important extension because communication researchers have applied DCT mainly to → television news, in which the verbal information is streamed through the audio channel.

Finally, it is important to note that DCT is not without its detractors. Those opposed to DCT contend that a single code system is more parsimonious than a dual code system. They argue that the better performance for pictures and concrete items could be attributed to the vividness of the picture or richer encoding of concrete items. Such explanations discount the need for two specialized systems that deal separately with pictures and words. However, evidence from recent research, including brain imaging studies, supports the existence of multiple specialized systems that work in concert to decode and integrate sensory information, thus providing support for DCT.

Both effects of the DCT – the additivity hypothesis and the concreteness effect – have *implications for news design and consumption* (→ Exposure to News; News; News Audience). Researchers from a number of areas, including marketing, education, and communication, have focused on the additivity hypothesis. The emphasis of these efforts has been to examine how the dual coding through the audio and the video channels can be maximized to improve learning (→ Educational Media; News Processing and Retention). On the surface, it would appear that inputs from the two channels should be better than separate inputs from either the audio or video channel. But a key limiting factor is human processing capacity (→ Limited Capacity Model). Streaming television video can easily overwhelm human processing capacity if the audio and video are not strategically edited to reinforce one another (Lang 1995). Communication researchers have examined this topic under the rubric of audio-video (AV) redundancy.

The concreteness effect, too, has implications for news practice. An important characterization of news is as episodic and thematic frames (→ Framing of the News). While episodic

news focuses on the concrete details of the four Ws – who, what, when, and where – thematic news focuses on the “why” aspects of a story and tends to emphasize analysis. Thematic stories tend to be abstract, lack compelling visuals, and have low imagery evoking potential. Because of these differences between the two types of stories, episodic news items are better recalled than thematic news items (David 1998). However, thematic news can be concretized through various techniques such as through a metaphor, a conceptual peg, or multimedia elements. Such solutions would require a concerted effort by news producers, but may be well worth the efforts in the interests of maintaining an informed citizenry.

## E-Commerce

*Charles Steinfield*

*Michigan State University*

Throughout history, innovations in communication technology have been associated with important developments in the manner in which people and organizations engage in economic exchanges of goods and services (Beniger 1986; → Information Society). In the past several decades, communication technology researchers have examined the social and economic implications of the use of computer networks as a medium for supporting commercial exchange, an activity that is broadly termed *electronic or e-commerce*.

Research on e-commerce has linked its growth to a wide range of social and economic issues including but not limited to the following: *economic* considerations of its effect on markets (Malone et al. 1987; Wigand & Benjamin 1995) and the pricing strategies of sellers (Shapiro & Varian 1999; Smith et al. 2000); *marketing and strategic behavior of firms* including the viability of e-commerce business models (Weill & Vitale 2001), multichannel e-commerce (Steinfield et al. 2002), and competitive strategy (Porter 2001); *consumer behavior* issues such as privacy and trust (Chadwick 2001; Palmer et al. 2000); *site design and navigation logics* to enhance usability and help buyers find products among the vast numbers of vendors and products (Dieberger et al. 2000; Lohse & Spiller 1998); *organizational and sociological aspects* of exchange such as the influence of e-commerce on the relationships between buyers and sellers (Kraut et al. 1999); *geographical and social* aspects such as the role of e-commerce in developing countries (Mansell 2001; → Digital Divide), its use as a tool for promoting local business and regional clusters (Steinfield 2004), and its role in national and global commerce (Bouwman 1999).

### DEFINITIONS AND DIMENSIONS OF E-COMMERCE

Most commonly, e-commerce is considered to refer to the buying and selling of goods and services over a computer network, and mainly over the Internet. One concern is whether e-commerce includes any exchange of information that facilitates transactions, or must include either an actual order or online payment. In general, communications researchers examining this issue lean toward more inclusive definitions that recognize the role of information and communication technologies (ICTs) in commerce, including support for *production* of goods and services, the *preparation of transactions*, and the *completion*

of transactions (Hawkins et al. 1999; → Technology and Communication; Information and Communication Technology, Economics of; Internet, Technology of).

Other relevant dimensions of e-commerce that concern researchers are the role of the parties involved and the platform over which transactions occur. Related to roles of the participants, business-to-business (B2B) transactions are investigated differently than business-to-consumer (B2C) transactions. The former are more likely to be *upstream* (i.e., acquisition of inputs by producers) transactions involving producers and suppliers, but can also involve *downstream* transactions between the producers of goods or services and distribution channel partners (→ Network Organizations through Communication Technology). In either case, B2B relationships are typically longer in duration, involve higher volumes and value amounts, and are normally structured by contracts (Kaplan & Sawhney 2000). B2C transactions, however, are those that take place directly at the retail level, and typically do not imply the same degree of relational stability between buyers and sellers. The way in which e-commerce is structured, and its influences on buyer–seller relations, are therefore quite different in these contexts. Another role pattern that has stimulated research is represented by services like eBay that support consumer-to-consumer (C2C) selling, and thus expose many issues surrounding how to build trust among strangers so that transactions may occur (Resnick & Zeckhauser 2002).

Platform issues refer to the nature of the ICT infrastructure through which transactions are mediated (→ Communication Infrastructure; Information and Communication Technology, Development of). In earlier times, communication researchers looked at other types of electronic information service delivery platforms, such as *videotex* for consumers and *electronic data interchange* (EDI) for business-to-business transactions. One primary concern in these prior studies was the importance of the openness of the platform – EDI-based networks, for example, were typically constructed around a closed set of invited trading partners, and often were dominated by one powerful player (Hawkins & Verhoest 2002).

The main focus in recent e-commerce work is on the Internet, which differs in terms of the greater ease with which new trading partners can be accessed, and the lower costs that participants incur. In addition, a limited amount of research has also focused on wireless infrastructures connecting to mobile devices to support mobile or *m-commerce* (Balasubramanian et al. 2002; → Mobility, Technology for). As mobile devices and networks become more capable, their use will likely increase the overall commercial impact of electronic commerce by: (1) increasing network access given that more people use mobile devices than computers; (2) creating new opportunities for spontaneous commerce because it frees consumers from their desktops and allows anytime/anyplace interactions; and (3) promoting *location-based* and *context-relevant* commercial opportunities.

### **EFFECTS OF E-COMMERCE ON MARKETS, MARKET STRUCTURES, AND PRICES**

One of the earliest questions raised by researchers was whether the use of e-commerce would enable the rise of electronic markets characterized by lower *transaction costs* particularly in the business-to-business realm (Malone et al. 1987). Transaction costs include such factors as the search for trading partners, negotiation, settlement, and

monitoring. By reducing these costs, and hence the *costs of coordination* with the market, markets would be used for *governance* (i.e., as a means to control the behavior of the participants) in situations that heretofore were governed by *hierarchy* (i.e., a company would purchase needed inputs from external suppliers in a market rather than produce them in-house). E-commerce permits companies to find suppliers regardless of location, freeing them up from the constraints of geography, and thereby reduces vulnerability caused by a need for *specific assets* that potentially could make them victims of *opportunistic* behavior. Although there has certainly been growth in outsourcing on a global scale, the role of e-commerce per se in this is not well understood. Indeed, studies that have explicitly looked at the extent to which the use of network-based transactions has encouraged a “move to the market” have not found this effect. Kraut et al. (1999) found instead that companies were more likely to use computer networks to enhance their ability to work with established trading partners, resulting in what Malone et al. (1987) called *electronic hierarchies*.

A related debate is rooted in the belief that e-commerce enables a buyer or seller to *bypass intermediary actors* in order to engage in a direct transaction and eliminate the excess costs of intermediation. In this view, producers can use the Internet to sell directly to end consumers rather than selling through retailers, for example. Likewise, home sellers might sell directly to homebuyers rather than paying a commission to an agent. Such “dis-intermediation” can profoundly reshape the structure of industries and the roles of actors within an exchange network. Although examples of dis-intermediation are readily observable, the literature encourages a more nuanced view. Just as the Internet can lower transaction costs for producers interested in bypassing intermediaries, it can also enhance the efficiency of existing and new intermediaries. Many of the most well-known Internet commerce companies, in fact, are new intermediaries such as Amazon, eBay, and Craigslist. Additionally, many traditional offline intermediaries – often large retailers who leverage complementary assets such as their brand, their supplier relations, and existing infrastructure – have established online channels as well in a process termed “re-intermediation” (Chircu & Kauffman 2000; Sarkar et al. 1995).

For a variety of reasons, e-commerce is also linked with *expectations of lower prices* of goods and services. Reduced transaction costs, lower costs due to the ability to sell without maintaining physical presence in a market, and the fact that buyers can easily search and compare prices across many vendors all contribute to the hypothesis that one e-commerce impact will be pressure on sellers to reduce prices (Bakos 1997). Yet, again, research shows that the situation is more complex. By 2007, the evidence for lower prices was rather mixed, especially when the added costs for shipping are taken into account. In addition, there is evidence of price dispersion rather than homogeneous prices, contrary to the expectations of economists (Smith et al. 2000). It appears that because it is so easy to change prices (referred to as menu costs), Internet companies make more changes in smaller increments in order to respond to the market. E-commerce also makes it easier to engage in *price discrimination*, whereby vendors sell the same product to different customers at different prices (Shapiro & Varian 1999).

Also, e-commerce can be used in ways that lock in buyers rather than reducing the so-called *market frictions* that make it difficult to switch vendors. For example, companies can gather information from customers, and then use this to help offer highly personalized

services, or provide incentives to keep customers returning to their website, in order to create what has been called “sticky” e-commerce (Shapiro & Varian 1999). In this way, e-commerce raises customers’ *switching costs* (the costs to move to a different supplier of a good or service). *Network effects*, which create positive feedback loops so that the larger the service, the more attractive it is to users, also work to make it difficult for customers to switch. Hence, these techniques allow an e-commerce vendor to maintain higher prices and discourage new entrants who might compete on price.

## **BUSINESS MODELS IN E-COMMERCE**

Much was written in the early stages of e-commerce about Internet business models (Weill & Vitale 2001). Mainly, these authors provided typologies of alternative models, based upon the sources of value for buyers and sellers and the specific mechanisms (e.g., advertising, subscription, margin on sales, etc.) by which revenue was derived. After the dot-com crash, attempts to list the many observed Internet business models gave way to analyses focusing on what was wrong with the models. Critics of the early business-model literature point out that the dominant focus on revenue streams encouraged firms to ignore other benefits that e-commerce offers, such as cost reductions, improved customer relations, or enhanced performance of traditional channels (Steinfeld et al. 2002). For example, a traditional retailer might develop an online storefront, but can use its website to generate more traffic in its physical stores by offering coupons or searches of in-store inventory, rather than evaluating the online site purely on the basis of the exclusive sales it generates on its own. Business models were also easy to imitate, and therefore did not necessarily convey a sustained competitive advantage.

Despite the critiques, the development of e-commerce has enabled the application of many *innovative online selling strategies*. The dot-com crash can be viewed as an inevitable shake-out that follows from the rapid entry of firms into a new area of business. In this perspective, the models that survived represent the winning approaches, promising significant opportunity for the firms that have successfully adopted them.

One issue related to both market structure and the business model of an e-commerce company derives from the statistical patterns of e-commerce site visits. Adamic & Huberman (2001) demonstrated that e-commerce site usage follows a power-law distribution, with a small number of sites accounting for the vast majority of traffic volume. This leads to an expectation of a *winner-take-all* market. However, more recently, the “long tail” distribution is proposed to explain the dominance of niche products and markets on the Internet (Anderson 2006). The reach of the Internet, enhanced by recommender systems and other methods of connecting people to content, products, and services, enables items that are not “hits” to find enough of a market to be profitable. E-commerce vendors are encouraged by this to carry a wide selection of products rather than focusing only on the popular ones.

## **TRUST IN E-COMMERCE**

How to establish trust in online commerce is one of the most heavily researched e-commerce areas, becoming an issue when thousands of new and unfamiliar dot-com companies flooded the Internet (Jarvenpaa & Tractinsky 1999). Factors that are linked to the formation of trust

include website quality, presence of web assurance seals from trusted third parties, use of secure servers for transactions, and specification of privacy policies (Palmer et al. 2000).

One approach to the trust issue, pioneered by eBay, but now widely used in many e-commerce contexts in one form or another, is the use of reputation systems to build trust. Feedback systems whereby buyers and sellers rate each other have been shown to be remarkably effective in overcoming trust problems despite the potential that exists to “game” the systems to build better reputations (Resnick & Zeckhauser 2002). Collectively, the use of other peoples’ behaviors and opinions – either through explicit communication or derived through implicit data-mining techniques – to serve as a guide to making choices in online contexts has come to be called *social navigation* (Dieberger et al. 2000).

## Economies of Scale in Media Markets

Marc Bourreau

Telecom Paris

Since Samuelson (1958), the economic literature has considered that production in the media industries (films, TV programs, music, etc.) is characterized by high fixed costs and economies of scale. For instance, the costs of creating a TV program are high, but the incremental cost of physical distribution to an additional consumer is very low or even nil. Broadcast television should therefore exhibit large economies of scale.

### ECONOMIES OF SCALE IN MEDIA MARKETS

We say that a firm enjoys economies of scale when a proportionate increase in every input by a given percentage yields an increase in output by a higher percentage. A looser (and weaker) definition states that there are economies of scale when a firm's average cost of producing output decreases as the output increases (the former definition implies the

latter, but not the reverse). Finally, the degree of scale economies at given level of output is defined as the ratio of average cost to marginal cost (which also represents the elasticity of output with respect to the cost of production). With this last definition, there are increasing returns to scale if the degree of scale economies is strictly greater than 1.

Media industries are characterized by large fixed costs and small marginal costs (→ Cost and Revenue Structures in the Media; Public Goods); therefore, the degree of scale economies is much greater than 1. A fixed cost is a cost that does not vary with the level of output, and which can be avoided by cessation of production. In the media industries, the fixed costs accrue mainly due to the creation of content (articles for → newspapers; films in the movie industry; recordings in the → music industry; programs in the → television industry; etc.), which yields a first-copy fixed cost (i.e., the cost of the first copy). Promotion costs are also sometimes considered as fixed, that is, independent of the number of units actually sold or of the size of → audience. For instance, in the music industry, it is sometimes argued, producers make some initial promotion, which leads to first sales and triggers word-of-mouth between music fans. To be more precise, the cost of content and the promotion costs are not exactly fixed, but rather *sunk*; the difference between a sunk cost and a fixed cost being that the former cannot be avoided by cessation of production.

Variable costs in media industries accrue due to the copies of the content that are produced and distributed to end consumers. However, the marginal costs of copies are in general very low, in particular compared to the initial fixed costs. Moreover, with the ongoing digitization of content (e.g., the digitization of music), marginal costs of copies are almost zero. Actually, most of the costs of distribution of content could be considered as fixed; for instance, broadcast networks for free-to-air TV involve mainly fixed costs.

As an illustration of this cost structure – high fixed costs, and low variable costs – consider the music industry. According to Vogel (2001), production costs for popular albums are greater than \$125,000 and marketing costs can reach \$100,000. The total sunk cost for those albums (around \$200,000) has to be compared with the marginal cost of a copy, which is around \$2 to \$3. In the movie industry, in 2005, the Motion Picture Association of America (MPAA) member company average theatrical costs were \$60 million for negative costs (the sunk cost of the first copy), \$32.4 million for → advertising and \$3.8 million for copies (movie prints); hence, variable costs of copies represented only 4 percent of total costs.

### **THE RELATION BETWEEN PROGRAMMING COSTS AND EXPECTED AUDIENCE**

Empirical studies have shown that, very often, the more successful a TV program or a movie, the more it has cost (see, in particular, Litman 1983 and Ravid 1999 for → cinema). The existence of a relation between production costs and audiences is also recognized in the economic literature (→ Media Economics). For television, Spence & Owen (1977) think that it may be necessary to increase production budgets to draw larger audiences. Owen & Wildman (1992) consider that a program's production costs can influence its potential audience: "The cost of producing a television program is independent of the number of people who will eventually see it. (The production cost, however, may very well influence how many people will want to see it.)" More generally, there is anecdotal evidence that, in many media industries, operating at small scale is not impossible.

How can the idea of economies of scale be reconciled with empirical evidence that larger budgets for content lead to larger audiences? The idea is that, while there are economies of scale with regard to the actual audience or number of copies sold, the fixed cost of a film or a music recording can be higher when a larger demand is targeted by the producer. Otherwise stated, once the content has been produced, its cost cannot depend on the number of consumers, but *ex ante* the fixed cost of production can increase with the targeted demand. Thus, for instance, we might observe that films with large budgets draw more audience than films with small budgets.

A higher fixed cost of production can increase the expected audience through two different channels. First, the quality attributes of the content can influence demand; higher investments in quality would then lead to a higher demand. For instance, a higher number of journalists ( $\rightarrow$  Journalism) can improve the quality of the information proposed by a newspaper; or a higher number of cameras can improve the image quality of a movie. Second, some inputs can have the ability to attract a large audience.

In particular, “talent” inputs might be a source of the relation between production costs and targeted audience. For instance, in the movie industry, talent inputs (such as producers, actors, or scriptwriters) are used along with inputs of production work (lighting engineers, cameramen, etc.) and capital inputs (scenery, special effects, etc.) to produce movies (e.g., see Crandall 1972). These “talents” are responsible for a large part of the quality of content. But they also have an impact on the information processes that guide demand. Indeed, most media goods are experience goods; that is, their quality can be assessed only after consumption. Because they can be recognized by consumers after the production phase, “talents” are able to attract demand.

Thus, the notion of talent is not only related to the “artistic” character of inputs. There are also artistic inputs that play a part no different from that of ordinary work inputs, because they are not directly known to consumers. For example, designers in the luxury industry, because they are unknown to the general public, are remunerated independently of the success of the products they define. Likewise, most actors are not  $\rightarrow$  “stars,” insofar as their participation in a film has no statistically identifiable impact on audiences. For instance, De Vany & Walls (1999) identified only 19 stars in all North American actors and film producers during the period 1984–1996 (i.e., talents that had a statistically significant impact on success).

Insofar as they contribute directly to the production of demand, stars can, after achieving a degree of autonomy, impose modes of remuneration that reflect a sharing of created value rather than payment for a job done. This trend, now distinct in the television industry, has been clearly observed in the case of the film industry.

In the case of cinema, it seems that stars have progressively managed to capture most of the surplus they generate. In a study on a random sample of 180 films released between 1991 and 1993, Ravid (1999) found that while stars increase the box-office takings of films, they capture the income thus created and finally play no part in its financial success. In the case of US broadcast television, Woodbury et al. (1983) analyzed a sample of 99 series programmed in the US in 1977 and 1978 on the three national broadcast networks, *ABC*, *CBS*, and *NBC* ( $\rightarrow$  Television Networks). These authors showed that the producers of these series were remunerated in accordance with the “popularity” of the programs they had made (i.e., the *ex post* actual audience). For example, if a program drew a larger

audience than expected, the network distributed part of the surplus to the producer. For Woodbury et al. (1983), the network tried to maintain good relations with these producers in order to obtain new programs, and relinquished part of the surplus in order to ensure good performance from them.

## **ECONOMIC IMPLICATIONS OF ECONOMIES OF SCALE**

The presence of strong economies of scale has strong implications with regard to market competition and pricing strategies.

In a market characterized by large economies of scale, competition is unlikely to emerge. Indeed, competition forces would drive prices to marginal costs, and firms would not recover their fixed costs and would make large losses. Therefore, in the medium or long run, only two types of market structures can emerge: either the market is dominated (or monopolized) by one firm, or firms differentiate and target different market segments (again, some firms are likely to be dominant in each segment). This latter pattern corresponds well to media industries, where consumers value variety.

The presence of economies of scale also has implications in terms of pricing. Since media services or products are characterized by high fixed costs and low marginal costs, with cost-based pricing firms would make losses. If a firm has market power, which is what we can expect, different pricing or commercialization strategies are possible (see Shapiro & Varian 1998 for more details).

First, the firm can price-discriminate, that is, it can sell the same good (or similar goods) at different prices, according to the quantity sold, the consumer's characteristics, or various sale clauses. A common example of price discrimination in media industries is the sale of → books in different formats (hardcover vs paperback). Versioning is a form of price discrimination that consists in creating different versions of a good, and inducing each group of consumers through the appropriate pricing scheme to choose the version that was intended for them. For instance, for a DVD, a collector's edition can be commercialized along with a standard edition to target the consumers who have a high willingness for the DVD.

Second, because marginal costs are very low (or even nil), the firm can sell its goods as a bundle. When consumers have very heterogeneous preferences for the different goods, bundling can increase profit.

Finally, the cost structure in the media industries facilitates → piracy. Indeed, the cost of a copy is very low or even nil, not only for the producer, but also for the end-consumer.

## **E-Democracy**

*Thomas Zittel*

*University of Mannheim*

The concept of electronic democracy has intellectual as well as technological roots. Its intellectual roots are anchored in normative democratic theory and in the idea of participatory democracy (→ Participatory Communication). Technologically, it is rooted in dramatic changes in media technology that amount to a revolution in the field of communication (→ Communication Technology and Democracy).

The communications revolution is a process that spans a long period of time, encompassing a multitude of technological developments from the first telegraph wire connecting both sides of the Atlantic Ocean since 1862 through to the diffusion of the → Internet in the 1990s. This chain of technological breakthroughs amounts today to a media infrastructure that provides mind-boggling new opportunities in the field of communication (→ Information and Communication Technology, Development of; Communication Infrastructure). It opens up mass communication to every individual who cares to go public, it dramatically increases the volume of public communication, and it provides for a global presence of any piece of information as well as of any individual. As Nicholas Negroponte (1995) put it: On the net, every piece of information and every individual is just a mouse click away, independent of location.

### **INTELLECTUAL AND SOCIAL CONTEXT**

The communications revolution played to a longstanding debate in normative democratic theory on the role of participation. Theorists of democracy from Montesquieu to Schumpeter

have argued that modern democracy can only be structured as a contest between elites that ought to be held accountable through democratic elections. Most proponents of a more participatory type of democracy grudgingly accepted electoral democracy as a sorry substitute for the real thing. However, with the coming of the communications revolution, proponents of participatory democracy such as Benjamin Barber (1984) saw new prospects for democratic reform. They proclaimed new digital media to be the means to overcome technical impediments to political participation and to move closer to the ideal of comprehensive mass participation in the context of collective decision-making.

Social changes in established democracies such as the “cognitive revolution” of the 1960s and 1970s gave additional mileage to the debate on electronic democracy. It spurred new “postmaterialistic” policy concerns and triggered participatory needs that are no longer met by the established institutions of democracy. As a result, traditional forms of political participation have diminished since the 1980s, leaving political elites with a sense of crisis. The launch of an *e-participation* initiative by the European Commission in 2005 that “aims at harnessing the benefits of the use of ICTs for better legislation at all levels of governmental decision-making and at enhancing public participation in such processes” suggests that e-democracy is perceived as a means to overcome this very crisis (European Commission 2006).

### THEORETICAL CONCEPTS

The notion of electronic democracy includes three different prescriptive models of *how* new media should be used to increase opportunities to participate. Each one of these models is related to distinct concepts that structure distinct and independent debates in the larger context of electronic democracy.

Authors such as Ian Budge (1996) perceive new digital media as the perfect *means to direct decision-making* via electronic voting. Each citizen could be provided with the necessary information on the issue at stake via the world wide web. Their decision could then be taken via a simple mouse click in the private home, could be transferred via the Internet and aggregated in a central computer controlled by voting authorities. According to proponents of electronic democracy, voting via the Internet provides a cost-effective, easy and reliable instrument for direct citizen participation in large-scale democracies. It is seen as a means to reduce the risk of misrepresentation, meaning elected representatives taking decisions that are not in line with the interests of their constituents. With a significant shift to direct modes of decision-making, modern democratic systems would move from representative systems to systems of direct democracy.

Authors such as Amitai Etzioni et al. (1975) perceive new digital media primarily as a means to *strengthen public dialogue*. In their model of a communication tree, digital phone networks are the means to organize mediated dialogues on specific issues among “millions of participants.” In this model, the aggregate is divided into a number of smaller groups deliberating via digital phone networks. The different group positions are aggregated through delegates who again deliberate with each other via electronic media in a smaller number of groups. This process continues until a final decision for the whole community is reached. Etzioni and his collaborators believe that this process will educate participants, that it will foster trust, the quest for the common good, and the cognitive capacities of

those involved, and that the functioning of the formal decision-making structure of democracy – be it representative or direct – is dependent upon informed and educated citizens and their opinions.

Authors such as Iain McLean (1989) see the Internet primarily as a *means to increase the responsiveness of representative democracy* to the demands of citizens. In McLean's view, modern democracy cannot function without representative institutions. But according to this perspective, the medium increases the responsiveness of modern democracy in the sense that constituency interests are aggregated in a more effective manner and that political decision-making is more in line with the demands of citizens. Through the Internet, citizens are able to inform themselves in better ways about the parliamentary agenda, to communicate their opinion on policy issues more effectively to their representatives and to deliberate with representatives. According to McLean, new media technology is also a most cost-effective means to register the preferences of citizens in the context of elections in more differentiated ways.

Some authors suggest also including in this third model of e-democracy the use of new media to make bureaucracies more responsive to demands of citizens and to provide better administrative services to citizens. Given the fact that these forms of digitalized communications do not concern collective decision-making and are not related to civil society either, they should rather be discussed in relation to the concept of → *e-government*. They concern the output-side of politics rather than the input-side. For the sake of analytical clarity, models of electronic democracy should also be kept distinct from the notion of *electronic participation*. While electronic democracy focuses on the macro-level of politics, electronic participation focuses on the micro-level. Both levels are related to each other though, because electronic participation is to some extent dependent on opportunities to participate as provided by models of electronic democracy.

### THE DYNAMICS OF THE DEBATE ON E-DEMOCRACY

The debate on electronic democracy took off in the late 1960s and early 1970s with first glimpses of local computer networks, cable television and digitalized phone networks. Since then, it experienced a multitude of changes at several levels of analysis.

The dynamics of the debate are first and foremost defined by changes in its key concept. In the late 1960s and early 1970s it sailed under the flag of *teledemocracy*. Electronic democracy as a term became more fashionable in a middle phase of the debate during the 1980s and 1990s. The term *cyberdemocracy* is a more recent addition to the language of electronic democracy (see, e.g., Bellamy 2000).

The different concepts signify changes in perspectives, theoretical frames as well as in subject matters. In its first stage, the debate was primarily driven by normative theorists of democracy. Their emphasis was on the potential of new media to implement a more participatory type of democracy in large-scale modern democracies plagued by large distances and great numbers. The debate on teledemocracy was then primarily based on normative reasoning and pilot projects to demonstrate the participatory potential of new media technology (Arterton 1987). With the further development of the technology and the social diffusion of the Internet, the debate became more empirical and more focused on the micro-phenomena of media usage, political communication, and e-participation.

In this phase, the debate closely aligned itself with the term electronic democracy, meaning all forms of communication and participation aided by new digital media (e.g., Browning 1996). It emphasizes *inter alia* spontaneous forms of public dialogue such as newsgroups on the Internet, discussion fora or blogs as a means to increase the quality and quantity of public debate.

Students of political communication such as Blumler and Gurevitch (1995) see increasing public dialogue on the Internet as a viable alternative to biased and irrational forms of public debate through the mass media. Students of democracy such as Robert Putnam (2001) consider public debate on the net as a factor that might strengthen the group basis of modern societies and counteract general trends such as individualization and social fragmentation. The term “cyberdemocracy” signifies a concern for the psychological and social ramifications of the new digital media. It emphasizes that the Internet opens up a new behavioral context that cannot be equated all too easily with mediated communication and that lays the cornerstone for a new cultural sphere (e.g., Shields 1996).

One important change over time in the debate on electronic democracy concerns its basic assumption regarding media impact (→ Media Effects). It started off with an all-embracing cyber-optimism, assuming that the Internet would right all wrongs in modern democracy regarding the concept of participation. In recent years, this tone has given way to a more cyber-skeptic perspective, concluding that “politics on the Internet is politics as usual” (Margolis & Resnick 2000). The truth of the matter, gradually emerging as a third stage in this debate, lies somewhere between these two hyperbolic hypotheses.

A more balanced view on the prospects of electronic democracy is based on two other developments that further define the dynamics of the debate. First, research on electronic democracy is moving from a “mostly American” case-specific type of research toward a more comparative research endeavor (Norris 2001; Zittel 2004). Second and more important, it advances in theoretical terms the construction of cumulative research frameworks and research questions that increasingly focus on testable theories (Jensen 2003; Zittel 2003).

## CURRENT ISSUES IN RESEARCH AND THEORY AND FUTURE DIRECTIONS

The development of coherent theoretical frameworks in electronic democracy research is in a very early phase. The cumulative quality of the debate is increasingly evident in the research questions that transform the many individual research efforts and observations into collective research activities. Four questions recur frequently and need to be highlighted here.

First, how *reliable and safe* are the new media in technical terms as a means for political participation. This question is of particular importance regarding the issue of electronic voting – certainly one of the most specific and thus most visible elements of the e-democracy agenda. The Internet is an open medium which is hard to shield from external intrusion. This makes it difficult to prevent the manipulation of voting results. Technical malfunctions might contribute to further safety hazards in the process of electronic voting. These questions are being tackled in corporations between computer scientists, the private sector, and public authorities in a number of pilot projects across Europe (see, e.g., Cybervote 2003).

A second issue touches upon the question of the *compatibility* between *normative schemes of electronic democracy* on the one hand and *basic principles and structures of*

*democracy* on the other. This question was raised first and foremost in the debate on electronic voting. Democratic principles such as the secrecy of voting and the freedom of voting are hard to implement in the context of electronic remote voting schemes. It remains an open question whether this can be solved through technological means or through institutional design, or whether we should simply accept changes at the level of political principles because of new technological opportunities (Loncke & Dumortier 2004). The question of the compatibility of models of electronic democracy and existing institutional structures has recently moved beyond the issue of electronic voting. The above-mentioned e-participation initiative of the European Commission can be perceived as one attempt to direct research efforts in this very direction. The many initiatives of the Hansard Society (2006) in the British context are another example of current efforts to implement e-democracy within the real-world structures of democracy.

A third crucial research question concerns the *character and the quality of communication emerging on the net*. Social scientists as well as students of political communication invest an increasing amount of energy and time to investigate the quality of communication on the net. They ask whether the Internet is suited as a platform for rational public discourse that could foster trust and create social capital. Theoretically, there are real doubts because of the lack of physical contact and the anonymity of the medium. Empirically, the evidence is mixed at best. While some researchers see the Internet as a “cyberwasteland” full of flaming and monologuing individuals (Wilhelm 2000), others either suggest that this can be augmented by design (Jensen 2003) or that debates on the net could work not in isolation but rather as a complement to physical contacts and thus strengthen social capital and trust (Putnam 2001).

A fourth issue concerns the questions, *who is interested in electronic democracy*, and why? One of the standard findings of empirical research, closely related to the cyber-skeptic perspective in the debate, stresses the fact that political elites take up new media in ways compatible with established structures and interests. According to this research, political elites tend to use the Internet for campaigning and public relations purposes but rarely for interactive communication or in ways that would threaten their political autonomy (Margolis & Resnik 2000). This finding is empirically well-established but tells far from the whole story regarding the politics of electronic democracy. Comparative evidence suggests first and foremost that usage of the Internet differs across systems and that there is no such thing as a given interest for or against electronic democracy (Zittel 2003; → Exposure to the Internet; Digital Divide).

Available impressionistic evidence in the politics of electronic democracy also suggests the existence of three developments that enhance the *prospects of electronic democracy in the long run*. First, political elites are not a monolithic group. Elite pluralism and the competition among elites serve as a mechanism of innovation, with elites trying to use strategies of electronic democracy as a competitive advantage. Second, elites are not wholly independent of changing social contexts and resulting problems. They do develop genuine concerns regarding decreasing rates of participation, especially among the younger generation. Some perceive electronic democracy as a magic bullet to solve this problem. Third, elites could become subject to external pressures from advocacy coalitions that grow stronger with the development of the information society and turn electronic democracy into a powerful political movement (→ Information Society).

## METHODOLOGICAL ISSUES AND PROBLEMS ASSOCIATED WITH THE TOPIC

The diffusion of the Internet is a most recent phenomenon. Any statement on the impact of the medium has to work with projections. There is hardly any reliable or readily available empirical evidence that can serve as a basis to build up or to verify general hypotheses and conclusions. This raises one core problem for any kind of research on electronic democracy. The problem arises from the fact that the social sciences have a poor track record in projections because of the complexity of the human environment and the spontaneous character of human behavior. How do we solve this problem, how do we move beyond mere guesswork, speculation, and wishful thinking in the debate on electronic democracy?

The philosophical tradition of strong technological determinism has never been a serious position in electronic democracy research (Street 1992). Few participants in the debate suggested a direct causal connection between particular media properties and specific social and political changes. Futurologists such as Toffler (1981) come closest to this position; theorists of the information society such as Manuel Castells (2000) are also within close reach of this category. However, most students of electronic democracy are aware of the fact that the impact of new media will be dependent upon a complex interplay between interests, ideas, institutions, and media capacities. The open question is, rather, whether this process can be modeled in order to develop testable hypotheses and to project outcomes.

Students of media and political communication such as William Dutton (1999; Dutton et al. 1987) have tended to answer this question in the negative. They argue in favor of focusing on the diffusion of the Internet and its politics rather than aiming to project the impact of new media. In contrast to this, political scientists have tended to adopt a more positive attitude toward the task of modeling electronic democracy. They point to established theories of politics such as theories of legislative behavior or theories of institutional change as a basis for this very endeavor (Zittel 2003). Such a strategy can only generate short-term projections that will not explain or forecast the impact of new media on democracy in its entirety or in the long term. But it can be used to formulate plausible expectations for the near future with regard to a specific aspect of democracy that can be tested empirically in the course of comparative research.

# Editorial

Barbara Pfetsch

University of Hohenheim

The term “editorial” in the mass media refers to a format designed to express the outlet’s or a particular author’s commentary or political position most openly and legitimately. In editorials the different media outlets establish a particular ideological profile that distinguishes them from their competitors and binds to them certain segments of the audience. Editorials must be seen in contrast to news reporting, which insists on being factual, objective, and impartial, thereby reflecting the world by describing it (→ News; Objectivity in Reporting). The purpose of editorials is related to the more persuasive and evaluative functions of media performance. The newspaper, radio, or television program here seeks to express its distinctive view on issues of public concern, aiming to advise, evaluate, commend, rebuke, and imagine the world as it wishes it to be.

The *significance of editorials* is twofold. First, editorials serve as a figurehead that defines the political identity and values of the outlet, thereby signaling whether it would support either liberal or conservative positions. Through editorials, the media publicly express opinions and make use of their right to present themselves as autonomous actors in public and political debate (Page 1996; → Media as Political Actors). Second, editorials, and particularly the editorials of a nation’s agenda-setting media, are paid close attention by politicians, activist and interest groups, opinion makers, and other media. By speaking up openly in editorials, the outlet may exert influence on decision-makers and their decisions (→ Agenda-Setting Effects; Public Opinion, Media Effects on). There is also empirical evidence that news commentators do have a significant impact on → public opinion and its changes over time (Page et al. 1987).

Editorials are often given a distinct space, which is labeled as *editorial page or story*, to distinguish it from the news coverage. Many publications have an editorial board or a group of opinion editors or commentators who decide on the tone and direction that the publications’ editorials will take. In Anglo-American journalism, editorials must not be written by the regular reporters or editors of news departments. Instead, they are authored by a separate group of individuals, who are not constrained by the rule of impartiality that governs news writing. In some European countries, however, staff policies regarding the separation of roles between newsmakers and opinion writers do not exist.

In contrast to news reporting, which is constrained by the professional rules, the logistics, and the time pressures of newsmaking, editorials are free from these external pressures (→ News Production and Technology). They can be taken as the result of some considered reasoning and opinion formation within the editorial staff (Eilders et al. 2004). Editorials are published without bylines, which means that they represent the newspapers’ or media outlets’ “official” position on issues. Editorials usually tackle current events of public concern or political controversies and intend to take a stance on them.

In order to broaden the spectrum of opinions offered in the newspaper, many outlets carry a so-called *op-ed page*, which is usually opposite the editorial page. These commentaries carry bylines and feature regular opinion columnists who present their own points of

view. Most newspapers feature freelance writers, guest opinion writers, and nationally syndicated columnists to supplement the content of their editorial pages.

In communication research, editorials are primarily discussed as a special form of opinion journalism, which is distinct from news reporting. At the same time, the boundaries between news and opinion and the effect of media commentary on politics and public opinion have always been debated. In addition to ethical questions regarding the use of media power and the right of journalists to impose their opinion on the audience, questions of the instrumentalization of media commentary for political purposes emerge. It is safe to say, however, that the format of editorials is only meaningful in countries that guarantee the right of free speech and free media (→ Freedom of Communication). Thus, editorials by their very nature are sensible expressions of media opinion only under the conditions of democracy and media pluralism.

Looking at editorials with respect to their political functions, it is important to differentiate between the tradition of Anglo-American journalism as compared to that of northern and continental European countries. This distinction is important as regards the partisanship of the press and the norm of objectivity in journalism. In the *United States*, the decline of the party press in the early twentieth century is seen as a consequence of the advent of a neutral commercial press that draws on a broad social consensus shared by the major parties in an otherwise pluralistic society (Schudson 2003). Journalism in this context turned to the norm of objective and factual reporting intended to bring about news that would serve the information needs of a most inclusive audience. Opinion was strictly limited to the editorials. In the *European tradition*, the press has always been granted to be partisan and divided across political party lines. Even if the party press has come to decline in most western European countries, the news media are politicized, which means that they not only represent the political cleavages in society but also feature the ideological spectrum of the political parties (Eilders 2002). Editorials clearly represent this traditional → party–press parallelism (→ Journalism, History of; Journalists' Role Perception).

The principal distinction between news reporting and expression of opinion has set the research agenda on editorials. Even though the norms of journalism prescribe strict separation between news coverage and editorials, it is an empirical question, after all, to what extent this principle is put in practice. This question is particularly pertinent in media systems in which news and editorials are written by the same editors. For instance, media research in Germany has demonstrated that news selection, news writing, and editorial opinion are synchronized to a greater or lesser degree (Schönbach 1977; → Synchronization of the News).

Finally, an essential question is when media opinion expressed in editorials turns into illegitimate political power over public opinion that constrains democratic principles. This question is all the more pressing since there is fairly solid evidence that news commentary does in fact have an impact upon how citizens and policymakers think and what candidates and policy preferences they support (Kahn & Kenney 2002; → Election Campaign Communication). It remains open to further research to clarify the conditions under which these influences operate and to what end.

## **Educational Communication**

*Rebecca B. Rubin*

*Kent State University*

Educational communication is an umbrella term that encompasses all speaking, listening, and relational constructs and concepts that relate to learning. In the past, researchers have been interested in characteristics of teachers that enhance or hinder learning; student characteristics that increase or inhibit learning; teaching strategies that augment learning; how best to give criticism of student writing and speeches; how best to evaluate student work; how public speaking is best taught; and what should be taught in speech communication and media curricula (Staton-Spicer & Wulff 1984). More recent work has expanded to the effects of media on children, child development processes, and the use of pedagogical methods and newer technologies to facilitate classroom or distance education (Waldeck et al. 2001). This essay includes discussion of some of the major and fairly consistent lines of research and findings that have emerged over the years.

### **HISTORICAL DEVELOPMENT**

The speech communication discipline began as a group of teachers interested in how best to instruct students in the basics of public speaking (Wallace 1954; → Speech Communication, History of). Interest in how to teach new and different facets of the field emerged on a regular basis in the academic journals as interest grew in public speaking, rhetoric, persuasion, and debate, and later in group, interpersonal, nonverbal, intercultural,

health, organizational, and family communication. As early as the first issues of the *Quarterly Journal of Public Speaking* (now the *Quarterly Journal of Speech*), first published in 1915, scholars were interested in how best to teach or coach debate, parliamentary procedure, oral interpretation/drama/theatre, and high school and college speech classes, as well as how best to organize departments and regional associations. Scholarly concern about K-12, undergraduate, and graduate curricula, as well as the effectiveness of the basic college communication course and speech across the curriculum, also abounded (→ Curriculum Studies). With the addition of the journal *Speech Teacher* in 1952 (the title was changed to *Communication Education* in 1976), a forum for educational issues gained prominence in the National Communication Association (then called the Speech Association of America) and the profession at large.

Likewise, early interest in journalism education (O'Dell 1935) later extended to radio, television, electronic media, advertising, public relations, and new technologies. Organizations such as the Broadcast Education Association (BEA) and the Association for Education in Journalism and Mass Communication (AEJMC) typify scholarly interests in how best to teach broadcasting, journalism, and other media-oriented classes. This latter area expanded over the past few decades into using television as an instructional device, with or without an instructor present, and the effects of media content on children (→ Educational Media; Educational Media Content; Instructional Television). More recent interest has been in the use of new technology in the classroom or in place of a classroom (→ Classroom Instructional Technology; Computers and Display Programs in Education; Course Organization Programs in Education; Distance Education).

Paralleling these interests were studies focused on how teachers can communicate better in the classroom and contribute scholarship in the education area (→ Pedagogy, Communication in; Scholarship of Teaching). But the traditional lines of research in communication education seemed to be confined to more classroom-oriented teaching/learning effects, ones that help enhance individual communication competence, enable advanced learning, allow civic, economic, and social participation in society, and empower people to become more self-reflexive and responsible for their actions and choices when interacting with others of the same or different cultural heritages (→ Communication Education, Goals of).

## **CURRENT RESEARCH INTERESTS**

Over the years, various literature reviews and review articles in the educational communication area have identified some of the major dimensions of the field. Rubin and Feezel (1986) reported priority and sufficiency ratings for various research topics in the field, which were grouped into three main dimensions: speech education (now communication education), instructional communication, and communication development. Although several other models have been proposed (see Staton-Spicer & Wulff 1984; Waldeck et al. 2001), the dimensions are compatible with the three described below.

### **Communication Education**

Communication education focuses on what is taught in communication classes (and programs), how the topics are chosen, methods of transferring knowledge to students,

and how best to evaluate student learning either in the classroom or through out-of-class assignments. From the early days of criticism research (Is feedback best given right after the speech? Is it more effective when given orally or in writing? How can teachers best grade and critique journalistic writing?) to current assessment concerns about K-12 or college program effectiveness and student public speaking competence, attention has focused on communication classroom content, evaluation, and teaching methods (Rubin & Daly 1999).

Teaching communication classes is one important focus of communication education. Probably because the discipline realizes how important communication in the classroom is, most undergraduate and graduate programs offer classes in how best to teach various communication classes (often in addition to those offered in education programs that cover basic teaching principles) in K-12, college undergraduate, graduate, speaking across the curriculum, and basic course settings. Topics such as the role of student talk, classroom strategies, lecturing, discussions, small group projects, and assessment are often covered. Such training helps new teachers enter the profession with a greater understanding of what and how to teach (→ Teacher Socialization; Teacher Training in Communication).

Vangelisti et al. (1999) have compiled a manual for teachers that summarizes research and best practices for teachers, as well as providing hints for newcomers to the communication profession and teaching in general. Guidelines for preparing specific communication classes, as well as suggestions for organizing content and selecting instructional strategies, are also provided. In addition, chapters deal with unique teaching assignments such as a multiple-section basic course, directing debate, two-year institutions, distance education, and extended learning. This volume is often used when training new college-level communication teachers. A similar volume is available for communication administrators (Christ 1999), and a variety of textbooks and handbooks exist for high school teachers, as well.

Recent advances in technology have seen past interest in the use of television in instruction move to interests in distance learning and computer-assisted instructional technology in the classroom. For instance, teachers are increasingly being drawn to whiteboards, LCD projectors, and presentation software (e.g., PowerPoint) to communicate in the classroom, as well as to course organization programs (e.g., Blackboard, WebCT) to manage the many aspects of teaching, learning, and assessment. Although lectures enhanced by visual technology have consistently produced greater learning, results are mixed for the superiority of traditional vs web-based vs web-assisted instruction.

### **Instructional Communication**

Whereas communication education focused on how to teach speech and related communication classes (e.g., broadcasting, interpersonal, group, journalism, public relations), instructional communication, a broader term, concentrated on how teachers can better communicate with students in the classroom, no matter what the subject (McCroskey & McCroskey 2006). McCroskey et al. (2004) have identified two general approaches to instructional communication, rhetorical and relational.

The *rhetorical* approach portrays teachers as influence agents of students, people who engage in a form of one-way persuasion in the classroom. Teachers select what will be

read, plan the assignments to be completed, and give information in the classroom. This traditional model of instruction views the teacher as demonstrating a particular communication style, one that should demonstrate elements of good Aristotelian rhetoric: delivery, memory, invention, style, and disposition.

The *relational* approach comes mainly from interpersonal communication and examines how teachers interact, share understanding, and develop relationships. Elements of teacher and student personality characteristics, concern for students, socialization into the profession, classroom questioning and interaction patterns, and interaction motives are examined. Also examined are barriers to effective instruction, such as teacher misbehaviors and aggression, student incivility and resistance, and other nonfunctional interaction behaviors.

### *Rhetorical Issues*

Teachers who are clear and make their content relevant structure their messages to achieve greater understanding. Research on teacher clarity shows that care in explaining concepts and use of lecture cues leads to reduced receiver apprehension, improved student affect for teachers and course material, greater motivation to learn, and greater perceptions of learning, whereas dysfluencies, tangents, and vagueness decrease student satisfaction and learning (→ Teacher Clarity).

In the classroom, teachers use questions to lead discussions and assess whether or not learning is taking place (→ Classroom Questioning). Several different types of questions lead to different types of assessments. For instance, recall questions assess memory, whereas summary questions assess ability to synthesize. Researchers have provided teachers advice on how best to include questions in the classroom, how questions can increase student achievement, how student answers correspond in level to the types of questions teachers ask, how much wait time is appropriate between asking the question and receiving an answer, and the effective use of rhetorical questions.

Along the same lines, teacher influence has been examined in literature focused on classroom power, mentoring, teacher credibility, and classroom management techniques (→ Teacher Influence and Persuasion). Teachers exert power in the classroom in several ways. Teachers can punish students (i.e., use coercive strategies) for misbehaving, reward them for behaving in acceptable ways, enact legitimate power in classroom management, use referent power to enhance student identification with them, and increase expert power through increased credibility and authority (→ Classroom Power). Teachers use various → classroom management techniques to take charge of the learning environment, and reward-based techniques tend to work far better than punishment-based ones.

This rhetorical interest in teaching style and classroom management converges with communication education for those involved in teacher training (in communication), mentoring, and classroom management. Teachers provide protégés with academic, career, and social support → mentoring.

### *Relational Issues*

Researchers have studied other communication behaviors used by teachers in the classroom and their effect on student affective, behavioral, and cognitive learning. Teachers who are assertive and responsive are seen as more effective, credible, and competent

(→ Teacher Socio-Communicative Style). Assertive teachers are confident in the classroom; they ably facilitate class discussions, manage the classroom environment, and clearly are in charge (→ Teacher Assertiveness). Responsive teachers show concern for students' well-being and learning (→ Teacher Communication Concern) and provide support and comfort when needed (→ Teacher Comforting and Social Support).

Teacher verbal (e.g., use of "we," more self-disclosure, informal names, etc.) and nonverbal (e.g., use of smiling, head nods, eye contact, touch, etc.) immediacy tends to result in greater student motivation and liking for the teacher and subject taught (→ Teacher Immediacy). Teachers use other affinity-seeking strategies in the classroom, as well (→ Teacher Affinity Seeking). For instance, researchers have found that those who display physical attractiveness, trustworthiness, dynamism, and sensitivity, elicit disclosure, and listen tend to be seen as more credible, and students are more motivated to learn. Teacher self-disclosure also can increase immediacy and affinity, and affect teacher clarity, especially when humor is incorporated. However, the disclosures must be related to the subject matter and not be seen as inappropriate for the classroom (→ Teacher Self-Disclosure). Teacher humor must also be seen as appropriate in order to be effective at motivating students to learn; offensive humor, disparaging humor targeting students, disparaging humor targeting others, and self-disparaging humor are seen as disruptive and demeaning (→ Teacher Use of Humor).

These and other teacher behaviors can lead to feelings of significance, value, and confirmation in students, by which students feel empowered to learn just through teacher–student interaction (→ Teacher Confirmation). Additional forms of teacher–student interaction include teacher-provided emotional, informational, instrumental, appraisal, and instructional support inside and outside the classroom; moreover, teachers confirm students through their responses to students' questions, interest shown in students, and teaching style. Students need to feel as though teachers are concerned about their learning and well-being, and this is done through effective teacher–student interaction.

Furthermore, researchers have examined classroom student–teacher interaction when they have looked at motives for communicating with teachers (both inside and outside the classroom), clarifying techniques used when students do not understand what is communicated, and classroom questioning patterns and interaction. Students often seek direct communication with teachers to gain additional information or have material explained more fully (functional reasons), but they also interact to provide excuses for inadequate work, to make a favorable impression on the teacher, to get to know the teacher on an interpersonal level, or to show their level of involvement in the class. Teachers provide feedback on the level of student achievement through oral or written criticism of speeches, papers, debates, group projects, and the like, in the classroom and privately to individual students (→ Teacher Feedback). Thus, interaction is seen as a direct influence on student learning and skill development.

All in all, the student–teacher relationship can be seen as a professional working interaction in which teachers hone their interpersonal communication skills in hopes of developing relationships that enhance student learning. In the classroom, teachers lecture, lead discussions, assess student progress, and give feedback and instructional support. Outside the classroom, they motivate, mentor, advise, tutor, and provide emotional and instructional support.

## **Communication Development**

Although speech/language pathologists are more concerned with the development of speech and language in children, communication researchers have also been interested in language and skill development and environmental factors that might impact students' growth. Three main areas of development research are communication apprehension, skill development and communication competence, and the impact of the media on skill development.

### *Communication Apprehension*

Communication apprehension (CA) is one area that combines the rhetorical interests from the instructional communication area with development. CA is the fear, anxiety, worry, nervousness, or lack of confidence that people have when speaking with others, either one-on-one, in a small group, or in a public setting. Much of the research in this area has asked people to report on the level of anxiety they experience in various communication environments.

Some studies have considered the trait–state nature of CA. A trait orientation presumes a stable personality trait, one that endures across all sorts of situations, whereas a state orientation presumes a less permanent, but trainable condition. Because measures of the two orientations are highly correlated, discussion continues as to its etiology. Treatments for state apprehension include systematic desensitization, skills training, and cognitive modification; all have been found effective (→ *Communication Apprehension: Intervention Techniques*).

A variety of specialized forms of CA exist in the communication literature. Early interest in the public nature of oral discourse was linked to the concept of → stage fright from theatre. Performance in front of an audience – especially a large audience where one is very conspicuous – can increase the anxiety of the situation for many speakers. This evolved into interest specifically in public speaking anxiety in both small and large settings (→ *Speech Anxiety*), which again is more situational. Reticence, on the other hand, is seen as a condition of skills deficit, which can be decreased through careful analysis of goals and planning of actions (→ *Reticence*). Concentrated effort to improve communication skills is seen as the best way to reduce communication incompetence.

### *Communication Competence*

As mentioned earlier, one of the main goals of communication education has been to increase communication skills. Although this interest stems from the time of Aristotle and Plato, concern in the past century has focused on, first, public speaking, and then communication in both interpersonal and mediated environments. Most definitions of communication competence acknowledge the necessity of communication to be both effective in accomplishing its goal and appropriate for the situation, audience, place, and time. In addition, motivation, knowledge, and skill are three basic elements (Spitzberg & Cupach 1984). Educators have attempted to identify important skills – message construction, persuading, informing, relating – that can be enhanced through instruction and that can be reliably assessed (→ *Student Communication Competence*). Through this feedback, students can later reflect upon and critique their own communication outside the classroom.

Research studies incorporating student traits such as motivational orientations toward communication – reticence, shyness, stage fright, willingness to communicate, public speaking anxiety, compulsive communication, receiver apprehension – and communication competence demonstrate the importance of self-concept and self-efficacy in skill development. Students who think that they are capable of improvement tend to be more open to instruction and growth.

Teachers who focus on improving students' speaking and listening skills, perceptive-taking abilities, and social interaction skills need to understand developmental levels, learning styles, and how to deal with nontraditional and at-risk students. They also need to study the impact of environmental factors – television viewing, video games, and social networks – at various age and developmental levels.

### *Impact of Educational Media*

Two major lines of research have examined the impact of educational media on learning. First, interest in all forms of educational media has led to examination of the programs shown and how learning occurs from this content. In particular, children's programming has been scrutinized to determine how much learning takes place when children watch programs designed to teach them basic skills. Children's Television Workshop (and its production of *Sesame Street*) epitomizes the concern existing in both academia and the television industry about how children learn and factors that enhance this at home or in class (→ *Sesame Street*). In addition, media literacy programs have been created in school systems to teach children (K-12) and college students how best to critique media messages and understand the commercial nature of the media (→ *Media Literacy*).

The second line of research has examined the use of media in education. From the early days of instructional radio and television, when programs were produced to replace, supplement, or complement in-class instruction, educators have been interested in how prepared media can enhance learning. Today, PowerPoint, whiteboards, LCD projectors, and other software and hardware technologies are commonplace in instruction, and concern focuses on whether the technology enhances or diverts learning efforts. Computer technology, course organization programs such as Blackboard, and digital video have allowed educational institutions to offer classes to students at home.

## **RECENT DEVELOPMENTS IN METHODOLOGY**

Despite the large array of research designs effective for educational subjects (Campbell & Stanley 1963), most research in communication education has relied on correlational designs. Examinations of relationships between teacher qualities (or perceived qualities) and student learning outcomes or feelings are prevalent in the discipline's journals (Kearney & Beatty 1994). Student learning is often measured as level of agreement with statements such as "I feel like I've learned a lot from this instructor" or other perceptions of gains in cognitive learning, but most often as affective learning (how much the students like the teacher, subject, or class).

For example, some recent areas of interest are teacher qualities that are related to student learning. Assertiveness and responsiveness, i.e., socio-communicative style, concern, affinity-seeking behaviors, immediacy, and the use of humor in the classroom are

strongly related to self-reports of learning, whereas teacher misbehaviors and teacher anger are not. Students who feel that their teachers confirm them and care about them enough to encourage out-of-class communication report that they are more satisfied, motivated, and knowledgeable.

Another area of current interest in instructional communication focuses on student qualities. For instance, reasons why students communicate with their professors inside and outside the classroom (e.g., by email) have been linked to student liking of the teacher and perceived learning. Sometimes additional factors might influence conclusions that can be drawn about such a direct effect of one variable on another. Accordingly, motivation to achieve/learn, learning style, sensitivity to feedback and punishment, and learner empowerment are seen as important moderating variables in classroom instruction. Research designs that include such variables give a better picture of the complicated influence of teachers on students.

All in all, learning has been one of the most significant dependent variables. Allen et al. (2004) reported that most indicators of learning (in which distance is compared to classroom) have used exams scores and course grades. However, some studies have dealt with satisfaction, finding lower satisfaction in distance format than in the traditional classroom format (Allen et al. 2002). However, in communication literature, we see many measures of affective and cognitive learning that are based on student perceptions and feelings rather than objective measures.

Another dependent variable has been skill enhancement. Speaking ability and communication competence have received a great deal of attention, especially the measurement of these. Also, decreases in apprehension have focused on how intervention can make a difference in reducing anxiety and communication apprehension of students, thereby leading to greater skill and competence. Several measurement techniques, developed from the variety of perspectives that surround this literature, provide an indication of student anxiety levels.

Meta-analysis has allowed researchers to combine datasets into more meaningful summaries of study results (Gayle et al. 2006). By clustering results from several studies, power to draw valid conclusions is increased. This is especially important in educational communication, where researchers necessarily employ pre-experimental designs in classroom settings to investigate predictors of learning outcomes.

## **FUTURE RESEARCH**

Over the years, many suggestions have been made for future research directions for communication education researchers. Some of these have been thoroughly examined, and others are more contemporary concerns. For example, educators have been concerned with teacher education for many years, but with the increase of technology use in the classroom, we cannot expect such concern to wane. As Shelton et al. (1999) noted, computer technology at all levels of education has changed the nature of the communication classroom. Journalism students no longer pound out news stories on manual typewriters, and speech students are expected to enhance their presentations with electronic media products. Furthermore, when teachers move from the role of information presenter to that of guide, coach, motivator, or facilitator, the nature of communication will change, especially when highly evolved interactive multimedia technology is involved.

Effectiveness of distance education most likely will emerge as a related topic, again as the variety of interactive channels increases for interaction with students.

Other trends have been to examine the interactive teaching/learning environment and the use of teams in the classroom (Shelton et al. 1999). Much of the research in the past 20 years has actually examined the teacher–student communication environment, identifying communication behaviors that can enhance learning. This interaction has become more mediated through use of email, bulletin boards, chatrooms, blogs, and other out-of-class opportunities for interaction.

Another upcoming interest will be about culturally centered environments comprised of a multicultural student body. Knowledge of second-language learning, intercultural relationships, and cultural indicators will be important for teachers of all subjects, including communication.

## Educational Media

*Shalom M. Fisch*

*MediaKidz Research & Consulting*

The idea of using mass media for educational purposes is by no means a new one. Books, songs, games: all of these are forms of media that have served as effective educational tools for centuries. In the case of electronic media, however, many discussions of the media's impact on children focus only on negative effects, such as the influences of violent media (→ Violence as Media Content, Effects of). However, such discussions do not, by any means, comprise the entire range of media effects. Just as negative media content can give rise to negative effects, positive media content can – and does – give rise to positive effects as well.

Educational media have been employed and studied in the context of many different settings and purposes. For example, the term → *infotainment* typically is used to refer to “lite” educational content embedded in media that are intended primarily to entertain, whereas *instructional television* often refers to material produced for classroom use and

*entertainment-education* often refers to global, media-based health initiatives (→ Entertainment Education; Instructional Television).

This entry reviews the topic of educational television and interactive media as tools for *informal education* (i.e., substantive educational content delivered primarily outside the classroom). It examines the topic from several perspectives: processes through which educational media are produced, empirical research on the impact of such media, theories to explain children's comprehension and learning, and production features that contribute to the effectiveness of educational television programs and computer games.

## PRODUCTION OF EDUCATIONAL MEDIA

Beyond the aspects of production that are common to all media (→ Media Production and Content), there is a tremendous range of processes through which educational media are produced. On one end of the spectrum, some producers create media based entirely on their own creative instincts, with little or no support from educational content experts or empirical research.

At the other end of the spectrum lies the model used by production companies such as Sesame Workshop (formerly Children's Television Workshop, producers of *Sesame Street*) – a model that has come to be known as the *CTW Model* or *Sesame Workshop Model* (→ Sesame Street). Under this model, production staff, educational content experts, and researchers collaborate closely at all stages of production. Content experts define the educational curricula that guide the project, and subsequently provide input (e.g., via review of scripts and storyboards) to ensure that the content is executed in ways that are educationally valid (→ Educational Media Content). Researchers inform production through an ongoing program of *formative research* throughout the course of development and production. For example, needs assessment research might evaluate children's prior knowledge of and misconceptions about a topic so that the material can address these misconceptions directly. Potential character designs might be tested for appeal. Television scripts or rough cuts might be tested for comprehensibility and appeal, so that improvements can be made before the final product reaches the air. Prototypes of interactive games might be subjected to *usability testing*, to ensure that the interface will be easily usable by its target audience. And so on. By impacting directly on the development of material, formative research makes the voice of the target audience an integral part of the production process.

Most educational media are produced via processes that fall somewhere between these two extremes. The choice of a production model typically is determined not only by the nature of the project and educational content, but also by the corporate culture of the production company, the size of the production budget (i.e., the scope of resources that are available to support content and research), and any requirements set by broadcasters or funding agencies.

## CHILDREN'S LEARNING FROM EDUCATIONAL TELEVISION

Decades of research have demonstrated clearly that both preschool and school-age children learn from educational television series (→ Educational Television, Children's

Responses to). In contrast to the formative research mentioned earlier, these types of studies typically fall within the realm of *summative research* – that is, in-depth research that assesses the impact of these series on their viewers over time (often by comparing the performance of children before and after viewing, or by comparing viewers of the series to nonviewers).

Perhaps the most prominent – and certainly the most extensively researched – example of an educationally effective television series is *Sesame Street*. A number of major summative research studies have examined both immediate and long-term effects of *Sesame Street* on its viewers. Together, these studies demonstrate that extended viewing of *Sesame Street* produces significant immediate effects on a wide range of academic skills among preschool children (e.g., knowledge of the alphabet, vocabulary size, letter–word knowledge, math skills, sorting and classification, knowledge of shapes and body parts, relational terms, time spent reading and in educational activities, telling connected stories when pretending to read). Outside the US, comparable effects have been found for international co-productions of *Sesame Street* in countries such as Mexico, Turkey, Portugal, and Russia.

In addition, several longitudinal studies have found long-term effects of the US series as well; for example, preschool viewers of *Sesame Street* were found to be more likely to read storybooks on their own and less likely to require remedial reading instruction three years later, when they subsequently entered first or second grade. Moreover, in the longest-term study to date, even high school students who had watched more educational television – and *Sesame Street* in particular – as preschoolers had significantly higher grades in English, mathematics, and science in junior high or high school. They also used books more often, showed higher academic self-esteem, and placed a higher value on academic performance (see Fisch & Truglio 2001 for a review of these and other studies).

Beyond this powerful evidence for the educational effectiveness of *Sesame Street*, numerous other studies show that *Sesame Street* is not alone in helping children learn. Summative studies on other educational series for preschool and school-age children have shown that educational television can enhance children’s knowledge, skills, and attitudes in a wide variety of subject areas. These include effects of US series such as *Between the Lions* and *The Electric Company* on children’s language and literacy skills; *Square One TV* and *Cyberchase* on children’s use of mathematics and problem-solving; *3–2–1 Contact* and *Bill Nye the Science Guy* on children’s understanding of science and technology; children’s news programs on knowledge of current events; and preschool series such as *Blue’s Clues* and *Barney & Friends* on more general school readiness. Consistent effects of educational television have been found in other parts of the world, too, as seen in effects of *Al Manaahil* (Jordan, Morocco, and Tunisia) on children’s literacy; *Owl TV* (UK) or *Australia Naturally* (Australia) on knowledge of science; or *Jeugdjournaal* (Netherlands) on knowledge of current events. Many other examples exist (see Fisch 2004 for a review).

## CHILDREN’S LEARNING FROM INTERACTIVE MEDIA

Because interactive media are newer media than educational television, less research is currently available to evaluate their impact on children’s learning (→ Computer Games

and Child Development). However, some research does exist to gauge the reach of such media and their impact on users' knowledge. Specifically, consider two aspects of interactive media: children's use of the Internet as an informational resource, and their learning from educational computer games.

Thanks in part to nationwide efforts to wire US schools with computers, by the year 2000, nearly 90 percent of 6- to 17-year-olds had physical access to computers at either home, school, or both (Newburger 2001). In the United States, national surveys have shown that as many as 94 percent of American adolescents now use the Internet to do research for school, and 71 percent report that they rely on the Internet even more than on traditional sources such as books (Pew Internet & American Life Project 2001). Similarly, an Australian survey found that the most common use of the Internet among 6- to 17-year-olds (reported by 88 percent of children) was for homework or study (NetRatings Australia Pty 2005), although only 41 percent of a Swedish sample of 9- to 16-year-olds said they usually use the Internet for homework (Medierådet 2005).

Students' use of the Internet as an informational resource opens the opportunity for unprecedented access to material on a tremendous range of topics. Yet, students' reliance on online information is also a matter of some concern, because much of the information posted on the Internet is not subject to the same sort of review or validation as material published in a book or newspaper. As a result, information found online may be subject to blatant inaccuracy or bias that children fail to recognize. For this reason, agencies and organizations such as the US Department of Education and the American Library Association have stressed the critical need to train children in *information literacy* – that is, the ability to recognize when information is needed, to find it (either online or offline), evaluate its relevance and credibility, and use it effectively. Children need to learn how to think critically about online information, weighing criteria such as its objectivity and the qualifications of its author (e.g., Alexander & Tate 1998). To date, however, no empirical research has been conducted to assess the degree to which children do so.

Educational applications of interactive technology reach beyond homework support as well. Leading scholars such as Seymour Papert (1998), Henry Jenkins (2002), and James Gee (2003) have argued that computer games provide a compelling context for children's learning. Indeed, several empirical studies have shown that children can acquire knowledge in areas as diverse as prehistory and asthma education from playing relevant computer games (Lieberman 1999; Paquin 2002). Analyses of existing games and case studies of individual users have lent additional (albeit anecdotal) support to the view that educational games can not only motivate children but also provide a framework for exploring, and engaging with, serious academic content (e.g., Gee 2003; Squire 2004). Thus, it seems that well-designed computer games can serve as useful tools for both formal (i.e., classroom) and informal (i.e., outside the classroom) education.

## THEORETICAL APPROACHES

In contrast to the extensive empirical research literature, there have been far fewer attempts to construct theoretical models of the cognitive processing responsible for such effects. Fisch's *capacity model* has its roots in information processing theory and cognitive psychology. From this perspective, all television programs can be seen as complex

audiovisual stimuli that require viewers to integrate a range of visual and auditory information in real time as they watch. Educational television programs pose even greater processing demands, because these programs typically present narrative (i.e., story) content and educational content simultaneously, so that the two must compete for the limited resources available in working memory (→ Information Processing; Limited Capacity Model). Thus, the model predicts that comprehension of educational content will be stronger, not only when the resource demands for processing the educational content are low, but when the resource demands for processing the narrative content are low as well.

In addition, the model argues that comprehension is affected by *distance*, the degree to which the educational content is tangential to the narrative (in which case the two must compete for working memory resources) or integral to it (in which case the two complement each other, so competition is reduced). Thus, comprehension of educational content typically would be stronger when the educational content is integral to the narrative than when it is tangential to it.

Like the capacity model in the context of television, Mayer & Moreno's (2003) *cognitive theory of learning from media* (CTLM) approach to high-tech multimedia is also grounded in the integration of information and the limitations of working memory. In this case, however, the challenge for learners stems, not from the integration of different types of content, but from the integration of multiple streams of information. According to this model, users learning from multimedia must attend to and acquire information from multiple sensory modalities (visual, auditory, tactile, etc.), and their ability to do so is constrained by the limitations of working memory. Thus, users can select only a few bits of information to process at any given time. Moreover, working memory limitations also affect the ways in which bits of information are connected, organized, and integrated, guided by information retrieved from long-term memory. Once the learned information is integrated in the learner's long-term memory, it can be retrieved subsequently as a schema to facilitate further learning. The use of such schemas becomes increasingly automatic with practice, thus reducing the demands of processing new information as the learner's knowledge base expands.

Both of the above models are concerned primarily with cognitive processing that occurs immediately while children interact with media, to explain their initial comprehension of the material. However, they are not sufficient to explain longer-term effects, particularly if the eventual outcomes bear little resemblance to the educational content that was presented on television (as in, e.g., effects of preschool viewing of *Sesame Street* on high school performance). Huston et al.'s (2001) *early learning model* focuses on the long-term effects of educational media, and how such media might interact with all of the other influences in children's lives. Under this model, three facets of early development are proposed as pathways by which long-term effects can result: (a) learning preacademic skills, particularly those related to language and literacy, (b) developing motivation and interest, and (c) acquiring behavioral patterns of attentiveness, concentration, nonaggressiveness, and absence of restlessness or distractibility. These factors contribute to early success in school, which then plays a significant role in determining children's long-term academic trajectories (e.g., placement in higher ability groups, more attention from teachers, greater motivation to do well). In addition, these early successes may also affect the types of activities in which children choose to engage; for example, good readers may choose to

read more on their own. Each of these outcomes can then result in further success over time. In this way, the model posits a cascading effect in which early exposure to educational television leads to early academic success, which in turn contributes to a long-term trajectory of success that can endure for years.

### **CHARACTERISTICS OF EFFECTIVE PROGRAMS**

As noted earlier, all of the above theory and research supports the fact that children learn from educational television. Yet, that is not to say that all educational television programs are equally effective, or have an equally strong impact on their audience. What causes some educational programs to be more powerful than others? Looking across research on a wide variety of educational television series, we can identify a number of features that have contributed to the effectiveness of existing series – and that producers can build into new productions to make them as educationally powerful as possible. These features include:

- engaging children via the use of appealing elements such as humor (with the caveat that children find different kinds of humor funny at different ages), mysteries, and games, among others;
- choosing age-appropriate topics (for both stories and educational content) that are inherently interesting to children and relevant to their lives;
- presenting content via age-appropriate language and at levels of difficulty that are tailored to children’s knowledge and developmental level;
- handling educational content in ways that are clear, direct, and explicit; keeping the educational content “on the plotline” – that is, making the educational content central, rather than tangential, to the narrative plotline (e.g., using a scientific principle to uncover the crucial clue that solves a mystery);
- focusing an individual episode or segment tightly on conveying a small number of ideas;
- reinforcing concepts by repeating them over the course of an episode or segment;
- drawing explicit connections among conceptually related segments, to encourage children to see how similar concepts can be applied to different problems or situations;
- using engaging or action-filled visuals, rather than static visuals or “talking heads”;
- including characters whom viewers see as competent and intelligent, and with whom they can identify;
- encouraging children to actively engage in the educational content themselves through viewer participation (e.g., during a game show, or by attempting to solve a problem before the on-screen characters solve it);
- motivating children to carry their learning forward via activities that extend the experience after viewing (e.g., by trying out hands-on experiments or activities they’ve seen on-screen, or through online games or resources that provide further opportunities for learning).

Naturally, this list is by no means exhaustive. It illustrates just a few of the many ways in which research has contributed to both researchers’ and producers’ understanding of what “works” in creating educational television programs.

## CONCLUSION

Despite critics who claim (without any substantive evidence) that television destroys children's attention spans or turns them into "zombie viewers," research has shown that television is inherently neither good nor bad for children. Rather, the effects of a television program depend on its content. As the late researcher John Wright was fond of saying, "Marshall McLuhan appears to have been wrong. The *medium* is not the message. The *message* is the message!" (Anderson et al. 2001, 134).

Research on educational television has been invaluable in demonstrating that such programming can hold significant benefits for its viewers. On one level, of course, data on the impact of any particular series are of great interest to its production team, who want to gauge the degree to which their efforts have been successful. At the same time, evidence of children's learning from educational television has also been critical for funding agencies interested in accountability and in the evolution of public policy regarding children's television.

Yet, perhaps the most important impact of such research lies in its ability to inform the production of new programming. By identifying what "works" – the approaches and production techniques that contribute to the effectiveness of existing programming – research can help producers build on the most effective techniques as they create new material. When used well, research brings the voice of children into the production process, so that material can be tailored directly to the needs, interests, and abilities of the target audience. In this way, research can help to ensure that future educational television series will continue to be as appealing, age-appropriate, and educationally powerful as possible.

## Educational Media Content

*Jennings Bryant*

*University of Alabama*

Educational media content refers to mediated messages designed to teach or provide opportunities for learning. The nature of mediated education varies greatly, ranging from formal curriculum-based message systems designed for classroom consumption to informal or pro-social media messages with the potential for producing incidental learning or pro-social change.

### BRIEF HISTORY OF EDUCATIONAL MEDIA CONTENT

Education has been an important goal and function of *print media* from their earliest formulations. Whether the words and other significant instructional symbols were carved into clay or writ onto papyrus or vellum, many of the earliest extant media message systems were educational in nature, with contents ranging from an ancient Egyptian Pharaoh's instructional manual on effective communication (McCroskey & Richmond

1996) to canons of early religious communities (e.g., Bible, Torah, Koran), which were employed both to help convert unbelievers and to instruct the converted.

Even today, print media in the form of textbooks, reference books, scholarly monographs, scholarly and professional journals, educational magazines, newsletters, and other educational media are an invaluable portion of the lesson plans for teachers from primary school through postgraduate education, and they are a major source of revenue for publishing conglomerates worldwide.

The story is similar for the place of education and instruction in the history of *film*, although the transition from the celluloid medium to diverse forms of electronic educational media is more complete than for its print cousins. The initial function of early films was largely entertainment, as is the case for current manifestations of this emotionally powerful medium. However, educational and instructional films were a vital part of the midlife of this medium, and 16-mm film projectors are gathering dust in the media centers of schoolhouses around the globe.

Educational → *radio* began when, in 1922, the British Broadcasting Company (later the British Broadcasting Corporation; i.e., the → *BBC*) was formed under the leadership of John Reith to enable independent British broadcasters to utilize wireless communication to *educate*, inform, and entertain all British citizens, free from political interference and commercial pressure. In part, the educational philosophy of the BBC was a reaction to the frontier mentality of America's unregulated commercial radio, which dominated to Britain's west, and the Soviet Union's state-controlled authoritarian system, which held sway to their east (History of the BBC 2006). With this development, electronic education via media began. In 1924, the BBC initiated its first national educational broadcasts to schools, supplementing home educational services via wireless. By the late 1930s, the BBC's educational broadcasts were regularly heard in more than 8,000 schools (History of the BBC 2006). This established a legacy of the centrality of education in public-service broadcasting, a model that would be emulated and extended in countries around the world (Public Broadcasting 2006). Even into the twenty-first century, educational radio is an important part of the media landscape in many locales, although the delivery of educational radio today is as likely to be via the Internet or satellite as from traditional broadcasts.

Unlike educational radio, many of the historically significant developments in educational → *television* were initiated in the US. The development of educational television was greatly facilitated by a television station license "freeze" in the US between 1948 and 1952, during which time the US → Federal Communications Commission (FCC) paused from a period of frenzied development in television's early history to engage in a number of important deliberations that would ultimately shape the future of educational television in the US and, to a lesser extent, worldwide. The concept of educational television programming was extremely controversial at this time. Commercial broadcasters claimed that the reservation of noncommercial channels was not necessary, because their programs already served the educational needs of the audience. Such an industry view had prevailed during the discussion of public radio leading up to the US Communications Act of 1934.

An important voice crying in this electronic wilderness played a pivotal role in shifting the ground rules for television away from radio's prevailing model of pure commercialism.

Frieda B. Hennock, the first woman FCC Commissioner, argued eloquently and forcefully that 10 percent of television channels should be reserved for educational television. Thanks to an effective public-communication campaign initiated by Commissioner Hennock, when the FCC issued its Sixth Report and Order in April 1952, the license allocation plan included 242 specific channel reservations for nonprofit educational licenses.

The evolution of educational and informational programming – defined by the FCC in 1996 as “any television programming that furthers the educational and informational needs of children 16 years of age and under in any respect, including children’s intellectual/cognitive or social/emotional needs” – has evolved rather dramatically from the 1950s to the present, and the models developed in the US greatly influenced educational programming around the globe.

The 1950s saw major developments in both computing and telecommunications, which fused to inaugurate the information age by *digital media* that was to truly revolutionize the role and form of educational media (→ Digital Media, History of). The introduction of educational videos and DVDs, the maturing of distance education, and the explosion of video and computer games, as well as the remarkable diffusion and adoption of the Internet as a vehicle for teaching/learning, have created an educational media landscape that is undergoing remarkably rapid evolution and reformulation.

## EDUCATIONAL TELEVISION CONTENT

### Trend-Setting Educational Programming in the US

In considering educational media content, our emphasis will be on electronic media. During the 1950s and early 1960s, as educational television stations struggled through a formative period in the US, most of the educational programs introduced for children featured adult “talking heads,” adult characters interacting with child audiences in a television studio, assorted puppet shows, make-believe vignettes, and other relatively primitive means of instruction and edification. Targeted narrative children’s programming, such as *Friendly Giant* and *Tales of Poindexter*, did not occupy a large percentage of programming time on these educational stations, and the programs of this type that were presented were typically low-budget productions. Moreover, new forms and formats for educational television were not given much consideration on the emerging state- and national educational-programming networks.

Because many leading educators, as well as parent opinion leaders, were not very satisfied with these early programming developments for children, the Ford Foundation and other philanthropic organizations not only supported capital facility grants to community and educational organizations, which helped dramatically expand the number of educational stations, they joined with federal education agencies to support a number of remarkable programming initiatives during the late 1960s and throughout the 1970s. As a result, a number of innovative and popular programs were developed and broadcast domestically and internationally, including the perennially popular and educationally effective → *Sesame Street*, developed by the Children’s Television Workshop (CTW, now Sesame Workshop).

CTW programming revolutionized children's educational television, in part because CTW President Joan Ganz Cooney developed an innovative program-development model that brought together producers, educational advisors, and researchers to create innovative and effective educational programming. Not only did the CTW team fuse previously independent forces, they programmed for the developmental level of their programs' targeted audiences, and they harnessed the formal features of the television medium to meet specific instructional goals, while also addressing critical societal needs, such as getting young children reading for school (e.g., *Sesame Street*), improving the reading skills of school-aged children (e.g., *The Electric Company*), and guiding girls toward career interests in science (e.g., *3-2-1 Contact*).

Other programming and production companies successfully imitated the program development and production model of CTW and launched other noteworthy programs like *Freestyle* and *Vegetable Soup*, essentially turning the late 1960s and the 1970s into the first golden age of children's educational television. This period also featured the evolution of programming from "educational" to "public" (or "public service") television, which culminated in the US Public Broadcasting Act of 1967.

The 1980s were to witness a setback in educational programming in the US, because of President Ronald Reagan's "marketplace approach" to broadcast regulation. Specifically, the FCC no longer required stations or networks to broadcast children's programming. Only financially secure and extremely popular children's programs, such as *Sesame Street* and *Mister Rogers' Neighborhood*, were to survive in the era of Reaganomics.

Three developments revived children's educational programming efforts in the US during the 1990s and through the portals of the twenty-first century. The first was the Children's Television Act of 1990, through which Congress took a stand to advocate children's rights to receive educational and instructional programming. The second was the Telecommunications Act of 1996, which reinforced and strengthened the tenets that children's educational programming was a "public good" and specified particular guidelines for broadcasters to follow regarding educational television. The third was the increased advocacy of parents, caregivers, and child advocates, which led cable and satellite programming channels like Nickelodeon and the Disney Channel to effectively create and market curriculum-based programming that could and would be educationally valid and commercially successful domestically and worldwide in the new era of narrowcasting and highly targeted programming.

### **Educational Television Outside of the US**

It is difficult to examine educational television, especially children's educational programming, without focusing on the US. Not only have most of the dominant educational programming developments worldwide been derived from US formats and models, many of the most popular children's educational programs in other countries are co-productions with US agencies and corporations like PBS Kids, Sesame Workshop, Nickelodeon, and Disney. Moreover, other successful educational television-program production and distribution houses with a worldwide reach, such as the Discovery Channel and National Geographic Television, are based in the US. Finally, many television programming organizations and networks located outside of the US that have a stated focus on

children's and educational programming, such as TV Ontario, still telecast more educational programs from US providers than they produce and distribute themselves.

Given these caveats, most countries with any sort of public-service broadcasting initiative have created their own educational and children's programs, and many are successful educationally, financially, and in terms of quality. Perhaps the best way to highlight this claim is to profile the programs that won the Prix Jeunesse International awards in 2006. *Prix Jeunesse* is a foundation that was established in 1964, whose primary aim is to improve television for children and adolescents worldwide, and it has proven to be a major force for cultural diversity internationally (Kleeman 2001). The winners of the 2006 Prix Jeunesse competition included *A Slippery Tale* (Germany), "a heartbreaking story about a frog who falls in love with a slipper"; *Eva's Winterplaster* (Sweden), "which tells the story of the journey of the poo"; *The Scepter* (Poland), "a wonderful story about a magic branch and the ups and downs of friendship"; *Amigo* (Denmark), "an extraordinary, fine-produced game-show for children in which the studio audience can't stop laughing"; and *Stark! Kevin – Hear Me Out* (Germany), "a very moving and touching story about a boy who wants to overcome his stuttering." Runner-up awards went to programs produced in the US, UK, Japan, Estonia, Canada, India, South Korea, Venezuela, Belgium, the Netherlands, Denmark, Norway, and Jerusalem (Prix Jeunesse International 2006). The diversity of topics and countries of origin provides evidence that quality educational and children's programming is being produced around the world.

More general examples of advancements in children's educational television abound worldwide. For example, in 1997 the German public broadcasting stations founded the KinderKanal (or "KiKa" – the "children's channel"), a channel devoted exclusively to programs for children, including educational programs. The founding of this channel was an explicit reaction to the introduction of commercial television in Germany.

### Research Evidence on the Content of Educational Television

Very few studies have systematically examined the content of educational television. In examining the three most popular children's educational television programs of the 1970s – *Sesame Street*, *Mr. Roger's Neighborhood*, and *The Electric Company* – and comparing them with the perennially popular commercial children's program *Captain Kangaroo*, Bryant et al. (1979) determined that the quantity of *formal education* content in the programs varied widely.

Because little or no molar evidence is available to complement such molecular examinations of the content of educational television, a systematic examination of one composite week's programming was developed by compiling the program schedules of six PBS affiliates in the US, thereby creating a normative public television program schedule. When this composite week's programming was categorized by target audience (children, general audience), it was found that an average of 11.5 hours of programming per day was devoted to *children* or adolescents, and an average of 12.5 hours was dedicated to *general audience* programming. Using a very general content-categorization scheme, it was found that approximately 2 hours per day were devoted to *formal education* (e.g., GED preparation), 11.5 hours to *children's education/information* (Educational/Informational,

or E/I, e.g., *Arthur*), 3 hours to *general audience news and public affairs* (e.g., *The Newshour*), 3.5 hours to *general audience E/I programming* (e.g., *This Old House*), and the remaining 4 hours to *general audience entertainment* (e.g., *Mystery*) and/or *special programming* associated with fundraising (e.g., *Celtic Women*), or to on-air fundraising per se.

With the passage of the US Children's Television Act of 1990 and the US Telecommunications Act of 1996, Congress strongly encouraged commercial broadcasters to join public broadcasters in increasing the quantity and quality of educational children's television programs. Specifically, the FCC indicated that commercial broadcasters who wanted to have their license renewal applications expedited must air three hours of core educational programming each week; this is therefore commonly known as the "Three-Hour Rule."

The Annenberg Public Policy Center of the University of Pennsylvania conducted a series of investigations into the impact of this legislation on the quantity and quality of television programming specifically designed for children. Among their abundant research findings were: educational programming appearing on commercial stations that was designed for preschoolers was sparse, but typically not very enriching, and programming for teens had increased in quantity but decreased in quality since the three-hour rule had taken effect; taken as a whole, 77 percent of the E/I episodes were judged to be educationally sound, but 23 percent were judged to be "minimally educational"; and many parents remained unaware of the existence or educational intent of E/I programs (Jordan 2000).

### **EDUCATIONAL VIDEOS AND DVDS, COMPUTER SOFTWARE, AND VIDEO GAMES**

The twenty-first century has witnessed an explosion in electronic educational media, including media with quality production values that target preschoolers and are designed for home use. With names like "Baby Einstein" (video/DVD series), "JumpStart Baby" (computer programs), "V.Smile" (toddler-friendly video game console), "InteracTV" (interactive DVD series), and "Leapster" (hand-held video game systems), these new media products and platforms are specifically designed for very young children and targeted to their "upwardly educational" parents. Moreover, their promotion is typically accompanied by claims that the usage of these products will improve or accelerate children's cognitive development. For example, 16 computer software titles for children between one and two years were listed on Amazon.com in June 2005; all 16 made educational claims, as did all of the top 20 best-selling products for two-year olds (Garrison & Christakis 2005; → Video Games).

The use of such products by young children typically countervails the American Academy of Pediatrics' recommendations that babies under age two have no screen time whatsoever, and that other preschoolers have no more than two hours per day of screen time (→ Media Use by Children).

Because of this potential developmental problem, and because of rather hyperbolic claims made in the advertising and promotion of some of these products, the Kaiser Family Foundation commissioned a report to investigate these so-called educational media. Garrison and Christakis's (2005) research found that educational claims for these

juvenile media products were exceedingly common. However, *no published studies* on any of the products examined were found, nor could the authors find any more general peer-reviewed studies on the cognitive benefits of using any educational videos, computer software programs, or video games for children under six years. In other words, the results of the study were *caveat emptor*.

## THE REALITY OF CONVERGENCE IN EDUCATIONAL MEDIA CONTENT

In reality, as the twenty-first century unfolds, rarely is it valid to consider one educational medium in isolation, because convergence has produced an amalgamation of educational media message systems of all types, typically anchored on the backbone of the Internet. As one example, consider the BBC Learning homepage ([bbc.co.uk/learning/](http://bbc.co.uk/learning/)). Obviously the BBC has long presented educational radio and television programs. Today, those are merely the most public face of what the BBC Learning homepage provides access to. A click on “Course Searches” grants users access to almost any conceivable course for adult learning, delivered in almost any way imaginable; moreover, a related link labeled “Course Materials” lets those who do sign up for a course order instructional supplies, including textbooks, with a very few clicks of the mouse. Learning-success case studies are available for users to model under “Ready to Learn,” and “Learning Zone” grants access to BBC 2’s record and play services. “Spherox” provides access to an engaging educational game; “Ma France” enables you to brush up on French; “RaW Quick Reads” gives you access to the first chapter of a book; “Computer Tutor” is self-explanatory and excellent; “Hotcourses” lets you find courses anywhere within the UK, from beginners to postgraduate; and “BBC Training” links to free TV and radio courses for those who want a career in broadcasting. Seemingly appealing to the rebels among users, “State of Debate” provides a game that lets you use your English skills to get around immigration laws.

The “Children’s Learning” page offers abundant stimulation and education for children of all ages. “BBC Jam” is an interactive learning service for 5- to 16-year-olds; 5- to 7-year-olds are encouraged to tour the world with “Barnaby Bear”; 6- to 12-year-olds interested in art activities (with downloads galore) are invited to visit “CBBC – Art”; if 5- to 11-year-olds want interactive science experiments, they are invited to click on “Science Clips.” On the same page, “Curriculum Online” helps teachers find multimedia resources, and “National Geographic for Kids” offers pictures, maps, and articles to help with geography homework. These examples account for fewer than half of the resources available on this one web page to help children learn and give them an opportunity to love learning.

Convergence has enabled educational media to provide worlds previously unavailable and even unknown to those who would learn. We can only hope that the world’s young citizens are open to these educational possibilities.

## **Educational Television, Children's Responses to**

*Jennings Bryant*

*University of Alabama*

*Wes Fondren*

*University of Alabama*

If commercial success and global presence are valid indicators of acceptance, then it can be said that children around the world have embraced educational television programming. In 2006, the educational program → *Sesame Street* was broadcast in 120 countries. This included 20 international co-productions to utilize local expertise and accommodate for varying educational and cultural goals. Viacom's educational and entertainment network for children, Nickelodeon, continued to experience subscriber increases between 2005 and 2006 in Africa, the Asian Pacific rim, Europe, Latin America, the Middle East, North America, and Russia.

Although variations exist between the different international versions of educational programming, observable similarities in children's responses to educational television exist. Researchers have found common patterns of cognitive behavior when children view educational programming in areas such as attention, comprehension, interactive learning, and altered attitudes. The focus of a large portion of the research has been limited by the means of measurement available to examine children's responses, although researchers have examined many other areas also (→ Educational Media).

## ATTENTION

One of the most immediate ways children can respond to educational programming is simply by choosing to watch a particular program rather than all others available, a process typically referred to as → selective exposure. A question that has arisen is to what degree children are deliberately selecting what they are attending to when watching television.

Other popular measures of attention involve assessing “eyes off” or “eyes on” the television screen, or visual → attention. Researchers have long debated whether this aspect of television viewing by children is primarily active or passive in nature. Not surprisingly, the levels of activity and passivity appear to be dependent on the age of the child and developmental status.

Young children, such as preschoolers, tend to focus their attention on shows that contain frequent changes in visual and auditory stimuli in brief segments presented at a rapid pace. Programs that rely on sequences of relatively independent short segments, often called “magazine format” programs, were pioneered by *Sesame Street*, which later came under attack for allegedly making educational television too passive and/or too frenetic. Critics charged that the format was overly stimulus driven and that children were only responding with reflexive attention, rather than mental engagement. Although still somewhat debated, the majority of studies support the notion that young children are cognitively active while watching magazine-format shows (Anderson 1998).

As children age, they attend to slower-paced programming that is more plot driven than stimulus driven. This shift is believed to reflect the increasing cognitive sophistication of older children, which allows for more goal-oriented viewing. Although younger and older children alike are passively affected by television stimuli, both appear to be cognitively engaged, only in different ways.

A commonality in how older and younger children respond to educational television relates to how comprehensible they subsequently find the programming. If a child determines that the content is beyond what they can comprehend, he or she may well divert attention away from the program. This comprehensibility assessment is typically made at first exposure to content and can be repeated frequently, depending on the level of exposure. A child may make repeated attempts to reassess whether the content is at a level he or she can understand and then adjust attention accordingly.

## COMPREHENSION

As with attention, developmental factors play a crucial role in the comprehension process. A key factor in comprehension is the level of prior salient knowledge the child brings to the content. Increased knowledge of language, social norms, and information about the physical world allows the child to make more sense of the programming. This suggests that comprehension is not solely a function of age, but also of environmental factors that impact development (e.g., educational emphasis in the home, school curricula, level of interaction with the environment). Therefore, by providing novel information that can be assimilated as new knowledge, educational programming can increase comprehension for future educational program viewing.

Similarly, as children develop cognitively and expand the pool of experiences and memories they can draw upon, there is an *increased ability to make inferences*. The ability to make inferences can help children make sense of situations where necessary information may not be explicit. For example, if one character refuses to help another character who is in need, more cognitively sophisticated children should be able to infer that this is undesired behavior that may be the reason for subsequent actions by the characters. Likewise, children's comprehension also increases as they develop the cognitive ability to understand antecedents. With little understanding of cause and effect, younger children may view acts as random and confusing, leading to the assessment that the content is not comprehensible, which in turn further diverts attention. This provides another illustration of how attention and comprehension play a dynamic and interrelated role in children's response to educational programming.

Another aspect of comprehension is  $\rightarrow$  *automaticity*. Over time, learned behavior becomes automatic, requiring less conscious effort, and allowing more mental energy and attention to be spent on  $\rightarrow$  information processing and assimilation. For very young children, understanding language may not yet be automated and may require significant effort. In addition, the formal features of a program may require significant concentration on the part of younger children, making it difficult to comprehend the content. For example, when a character's mouth is not moving, but words are heard in the character's voice, older children will have automated the process of determining that thoughts are being expressed, whereas younger children may be working to understand the convention and miss the content. As children develop, more complicated features and story structures can be employed, allowing for the aforementioned shift from stimulus-driven to plot-driven content.

### ACTIVE LEARNING

If the primary goal of educational television is to educate, then a reasonable question is: how do children respond to programs that attempt to teach? More directly, do children engage in the learning process? For learning to take place, many programs require active participation on the part of the viewer. This cognitive engagement is built upon attention and comprehension, but extends beyond them. The decision must be made on the part of the viewer to accept the challenge of active learning. Some shows ask viewers to read text (which may be laborious for younger children), answer riddles, engage in solving complicated social dilemmas, perform mathematical equations, seek hidden objects, and make comparisons.

An excellent example of this type of programming is a show called *Blue's Clues*. Developed by Nickelodeon, one of the many goals of the program was to teach preschoolers *flexible learning skills* that were adaptive and helpful in problem solving. Some of the formal features used to facilitate participation by the viewers were: a pause typically followed questions directed at the audience as if the characters were waiting for a response; then viewers were asked to find, point to, and call out objects found on the screen; and, finally, clues were accumulated throughout each show that were required to solve a problem. Episodes were repeated five days in a row, allowing younger children to become familiar with the formal features of the show, to utilize prior knowledge, and feel a sense of mastery over the problems.

Early *Blue's Clues* research is unique in that it specifically measured viewer interaction in a natural environment (Anderson et al. 2000). Over two years of collecting data,

researchers found that children did actively participate in the show and that the majority of children reported having helped the main character solve problems. Results showed that children were more likely to interact with the program the more they watched a particular episode. Cognitive participation was also evidenced by improved scores on problem-solving and creative-thinking tests compared to nonviewers. For older children, the show *Ghostwriter* asked viewers to read on-screen text during the show, which 83 percent of children reported doing. In an effort to improve literary skills, the program also asked viewers to compete in mail-in contests that involved elaborate writing tasks, such as creating songs and writing stories. Some 450,000 children sent in letters during the first two seasons.

Numerous other studies of children who view educational television have revealed that they show increased abilities in reading, writing, mathematics, science, and knowing current events (Fisch 2002). One recurring theme throughout the research is that children can learn from age-appropriate educational television. Once children advance beyond the target age audience for most programs, the benefits of viewing quickly diminish.

### ALTERED ATTITUDES

Frequent goals of educational programs have been to present positive social lessons and *promote pro-social attitudes and behavior* in children. Internationally popular shows like *Barney and Friends* and *Mister Roger's Neighborhood* aimed to teach children the value of behaviors like sharing, kindness, and friendship. Research has shown that many of these programs were successful in cultivating an appreciation for these positive characteristics. The pro-social benefits for children often increased when educational messages were accompanied by similar activities separate from television viewing.

A related goal often is to *reduce antisocial attitudes and behaviors*. Research has shown that children classified as having behavior disorders with tendencies toward violence actually increased in their concern for others after having watched pro-social programming. In contrast, many critics have argued that children reinforce gender and racial stereotypes in response to viewing non-educational television (→ Stereotypes). A recurring focus of research has been how to prevent, limit, or diminish many negative effects media can have on children. Areas such as stereotyping, fright responses, the impact of exposure to violence, and advertising to children have received a great deal of research attention. Some of the means of mediating children's response to media, both positive and negative, are limiting exposure, providing supplemental content apart from television, and reinforcing positive messages with dialogue after viewing. One of the most effective means of mediating effects is interactive co-viewing, in which an adult watches the content with the child and asks critical and observational questions (→ Parental Mediation Strategies). Research has shown that adult co-viewing is capable of assisting children to learn facts, acquire positive attitudes, and integrate social norms into behavior. Significant evidence supports the active involvement of adults in enhancing a child's response to educational television.

One shortcoming in the body of research available is that it is often difficult to compare findings due to a *lack of standardization in measurements*. Fields like developmental psychology, educational psychology, and child development typically rely on refined scales and

standard batteries of tests. Many of the scales and tests used have been repeatedly verified in the crucible of research and can provide quantifiable values for concepts such as self-esteem, language development, and cognitive skill. A uniformity in agreed-upon measures would allow for direct comparisons between study results and pave the way for future → meta-analyses (→ Research Methods; Scales; Scales and Indices; Test Theory).

## **E-Government**

*Helen Margetts*

*University of Oxford*

E-government may be defined as the use by government of information and communication technologies, internally and to interact with citizens, firms, nongovernmental organizations, and other governments (→ Information and Communication Technology, Development of). E-government in practice, therefore, consists of both complex networks of information systems within government organizations and a huge range of websites with which citizens can communicate, interact, and transact.

### **OVERVIEW**

In some sense e-government has been around for over half a century in larger developed states; for example, governmental organizations in the US and the UK used computers for

internal operations from the 1950s onwards. But the term e-government only came into common usage in the 1990s as societal use of the → Internet became widespread. While earlier technologies were largely internally facing, the Internet for the first time provided government with the possibility to interact electronically with individuals and organizations outside government. Thus the Internet brought far greater possibility for the “transformation” of government through the use of electronic tools than earlier technologies, and the topic became interesting to a far wider range of researchers, practitioners, and policy-makers than hitherto. By the 2000s, almost all governments had some kind of electronic element, even if only a website describing the main institutions and political leadership (→ E-Democracy).

Information and communication technologies provide both potential advantages and new challenges to government. Such technologies have long provided the potential for government to be more efficient and effective, as the early automation of bureaucratic operations offered potential for reductions in staff (although early investments in such technologies were often hard to cost-justify in practice). With the Internet, the possibilities for cost reduction increased still further, as the marginal cost of Internet-based interactions is generally less than interactions taking place by letter, telephone, or face-to-face. But the implications of e-government are far wider than increased efficiency. Large-scale computer systems have long shown themselves in the public sector to be policy-critical. Most government departments in developed countries that process large volumes of transactions quite simply cannot operate without them, bringing widespread chaos when they fail to work. They also create new possibilities for new policy “windows” in terms of innovation. Margetts (1999) and Hood and Margetts (2007) have shown how digital technologies open up potential for innovation in the use of all four of the “tools” of government policy: nodality (the capacity to collect and disseminate information), authority, treasure (money, or other exchangeable benefits), and organizational capacity.

As use of the Internet became widespread from the early 2000s (→ Exposure to the Internet; Information Society), most developed governments introduced e-government initiatives, accompanied by “targets” for electronic service delivery. Certainly, governments have dedicated increasingly significant resources to the pursuit of electronic government, with most industrialized nations spending over 1 percent of GDP on the government’s own information and communication technologies. The UK, for example, spends around £15 billion annually on its own e-government effort, including a massive £6 billion dedicated to modernization of the information systems of the National Health Service.

In general, however, governments have struggled to develop the skills and expertise to develop their electronic channels. By 2006 most were reliant on a market of private sector computer services providers, who develop and maintain their information systems. In most industrialized states, distinct markets of global and domestic companies have grown up to service the public sector, with wide variations across governments in terms of the shape of the market and the extent to which domestic companies play a role (Dunleavy et al. 2006). These companies have shown themselves to be important players in contemporary government. More recently, the larger Internet corporations have come to play a role in the delivery and holding of information about citizens, in a way that can be difficult for governments to challenge. In 2005, for example, when the Federal Bureau of Intelligence in the US asked Google (→ Search Engines) for a million anonymized

records of the users of pornographic websites, in order to understand patterns of usage of such sites, their request was refused.

### VISIONS OF E-GOVERNMENT

Until the 2000s, academic visions of e-government tended to range from the highly utopian to the severely dystopian, with a lack of sustained empirical research filling the middle of the spectrum. Most of these visions revolved around the modernist notion that technology will somehow lead government to become more rational and efficient, with strong parallels to Weber's predictions for bureaucracy and his analogy of bureaucratic organization as a "machine" (→ Bureaucracy and Communication).

What have been termed "hyper-modernists" (Margetts 1999) have argued that as the Internet and associated technologies become ubiquitous, government will become more and more efficient and therefore smaller, until eventually governmental organizations themselves will become increasingly irrelevant. The most populist writer in this vein was probably Alvin Toffler, who in a trilogy of books running over 20 years from 1970 argued that the decentralization afforded by information technology would inevitably lead to political decentralization as well, so that eventually bureaucracy itself would become irrelevant: "exactly like businesses, governments are also beginning to bypass their hierarchies – further subverting bureaucratic power" (Toffler 1990, 255).

While also believing in transformation for government through technology, "anti-modernists" concentrated on the negative effects, believing that e-government would be more powerful, and more intrusive in the lives of citizens, than traditional bureaucracy. Writers such as David Burnham (1983) argued that the increased possibility for surveillance and control offered by information and communication technologies would lead electronic governments to the "Computer State" or the "Control State," whereby governments use CCTV cameras, "smart" identity cards, satellite navigation systems, electronic tracking devices, and centralized databases with sophisticated search capabilities to maintain an ever-closer eye on the activities of their citizens. These dystopian views are reminiscent of the more literary scenarios portrayed in Orwell's *1984* or Huxley's *Brave New World*. With technological development, surveillance technologies have become increasingly sophisticated and electronic identities more complex, while after the terrorist attacks on the US of September 11, 2001, and in other countries thereafter, many populations appear to have become more accepting of such technologies, believing them to be effective in counteracting terrorist activity. As governments appear to have had a freer rein in introducing surveillance technologies, a new generation of anti-modernists began to define the "Surveillance Society" (Lyon 2003).

Only in the 2000s did a sustained body of *research* into the development, functioning, and implications of e-government really begin to develop, and even by 2007 this research is still rather ghettoized within other academic disciplines. Writers in the field of communications do not tend to focus on government, perhaps because governments' use of communications technologies is less innovative and transformational than that of media organizations. For the same reason, management research tends to focus on the private sector, regarded as more innovative and cutting-edge in the delivery of online services and e-commerce applications. Political scientists tend to minimize or leave aside

entirely the implications of technology in government, regarding it as a straightforward administrative tool with no policy implications. Even by 2005, many standard texts on public administration and public policy barely mention computers or the Internet.

Meanwhile, the study of e-government has become heavily populated by management consultancies, IT corporations, and international organizations, which have produced a number of *reports and rankings of countries* in terms of their e-government development. Most prominently, Accenture produced a series of reports, each covering around 30 countries, from 2002 to 2006, Cap Gemini for the European Union produced a raft of reports on e-government development across European countries, and the United Nations continues to maintain an “e-government readiness” index and annual report for all the countries in the world (for example, UNPAN 2005). The OECD has produced a number of reports and single-country studies. Many of these studies are also based on a modernist notion of development, the so-called “*stages model*” of e-government, whereby governmental organizations (or in many cases, whole governments) are assumed to go through a number of “stages” (first a kind of web publishing model, followed by interaction and transactions, followed by the facilitation of “seamless” government, and ultimately “transformation”).

While most of these international reports tend to emphasize differences between governments, detailed research at the country level suggests considerable variation across governmental organizations. Although most countries with e-government initiatives have some central mechanisms and agencies for control and coordination, such agencies tend to have limited remit over the largest of government departments. So, for example, in many countries such as Australia and Canada, tax agencies lead the field, with some countries attaining very high levels of take-up of online services; 98 percent in Chile, for example. Social welfare agencies tend to have lower levels of online service provision, due in many cases to a (sometimes mistaken) perception of low levels of Internet penetration among their users.

## THE REALITY OF E-GOVERNMENT

In practice, the *transformation of government* through electronic tools, both for good and for bad, still seems elusive. Neither the wildest dreams of the hyper-modernists, nor the worst nightmares of the anti-modernists appear to have materialized. The use of the Internet varies widely across societies and also across governments, but use of information and communication technologies has not in any deterministic way caused liberal democratic governments to become less liberal or less democratic. Neither have authoritarian governments necessarily become more authoritarian, although the nature of their authoritarian techniques has changed. Certainly many countries, particularly China and several Arab states, practice sophisticated Internet filtering techniques (see Deibert et al. 2007; → Censorship). But in all these countries the new capacity for their subjects to develop social networks outside their country and to be aware of developments in the rest of the world can outweigh the increased control that technologies internal to government permit (→ China: Media System; Iran: Media System).

As for the “hyper-modernists,” their visions are challenged by the trend for governments in most countries to lag behind commercial organizations, and indeed society in general,

in capitalizing on the potential benefits of Internet technologies. In the UK, for example, the 2005 Oxford Internet Survey found that only 39 percent of UK Internet users had interacted with government electronically in the last year, while over 85 percent of Internet users had used the Internet to look for or buy goods or services (Di Gennaro and Dutton 2005). Others have identified a number of cultural barriers to e-government development, both from the supply side (in terms of civil servants being resistant to new electronic channels) and the demand side (in terms of citizens being willing to interact with government in new ways). Certainly the economists' dictum that the Internet has transformed the ability of firms to know their customers and treat them differently has not applied to government to anything like the same extent.

However, the *potential for e-government* to look different from traditional notions of government remains, with the opening up of a wide range of new options for policy-makers. Electronic road pricing for example, provides new possibilities for incentivizing drivers to use certain routes at certain times or even to stop using their car in favor of public transport systems. Ticketing systems present new policy options in terms of encouraging the use of public transport and, when combined with congestion charging, encouraging the use of public transport in favor of roads with potential environmental benefits. In law and order, electronic tagging systems allow a new intermediate option between incarceration and freedom for convicted individuals. Most of these potential applications of e-government have a key distinguishing feature: they allow the segmentation of citizens. Governments can identify and treat groups of citizens differently according to their circumstances and need. Such treatments can range across the four "tools" of government policy. For nodality, information can be targeted at specific groups, through websites used by specific age groups or group-targeted emails. Treasure, in terms of social welfare benefits or tax credits, for example, can be easily means-tested according to other financial information held by government. Authority can also be targeted, through "fast-track" border control systems, for example. Even physical organization can be group-targeted, for example through barriers that respond to transponders fitted to police and emergency vehicles but not to normal cars, as used in city centers in several parts of the world.

As noted above, in the early days of e-government the type of systems that governments were using were internal to government. In general they were not used by citizens; even when home use of personal computers became widespread, they were stand-alone machines unlikely to be connected to a wider network. In contrast, the Internet is a societal phenomenon which is making a huge difference to the lives of many citizens. Thus technological development in general, and technology-mediated relationships in particular, have an independent effect on e-government, by placing a continual pressure on governments to innovate. Governments have to respond to technological innovations used, for example, within the criminal world, as many traditional forms of crime and fraud become electronic and cyber-crime itself becomes a rising phenomenon. Many social problems have moved online, as Internet gambling has proved itself more addictive than its offline equivalent, cyber-bullying more psychologically damaging than in the playground, and Internet addiction itself has become recognized as a rising social phenomenon (Hood and Margetts 2007).

Another implication of the changing nature of technology is that government is under increasing *competition for public attention and visibility* in the online world. Governments

have been traditionally deemed to possess “nodality” (Hood 1983, as noted above) – the capacity of being at the center of social and informational networks and in a privileged position with respect to the collection and dissemination of information. In the online world, governments find themselves under increasing competition for that nodality. By 2006, most people used search engines to find information they needed, and few look further than beyond the first 10–20 results. So whether information about an organization is easily found within those results is vital to its visibility. In an online world where at the time of writing the auction site eBay had 168 million users, the social networking site myspace.com had 100 million users, the online bookshop amazon.com had 35 million customers in over 250 countries, and the community site craigslist.org, linking urban communities all over the world, had four billion page views a month, governments may find themselves struggling for online nodality (→ Social Networks; E-Commerce).

Furthermore, as Internet-based technologies themselves developed toward Web 2.0 applications, where users generate content through recommender and reputational systems, blogs (→ Blogger), wikipedias, social networking sites, and user feedback systems, governments too have to innovate if they want to take advantage of applications like these. In 2007 such applications were almost absent from governmental organizations, whereas in other areas they had become ubiquitous. So, for example, in the area of job search where private sector sites were offering job applicants the chance to post video clips and photographs and even teleconferencing interviews, government applications such as the UK Jobcentre plus were offering only text-based systems where employers could paste CVs and jobseekers could look for jobs, but there were few other facilities available. Here competition is also evident, with Jobcentre plus holding only 13 percent of the job application market in the UK, with consequent implications for the capacity of government organizations to tackle unemployment and job mobility issues.

Where governments do innovate in this area, the potential is great. By the mid-2000s, some authors were beginning to suggest that “digital-era” governance was a new potential paradigm for public administration, replacing the dominant trends in public management of the previous 20 years, a cohort of changes termed “*new public management*” (NPM; see Dunleavy et al. 2006). NPM was characterized by disaggregation of public organizations (into agencies, for example), competition (through outsourcing) and incentivization (through performance pay and performance management). In the countries where NPM was implemented in its most extreme form, it led to increased fragmentation and complexity of government, with a concurrent reduction in transparency. In contrast, digital era governance seems to offer new possibilities for increased transparency, with the web offering a “window” into governmental organizations and reduced complexity as Internet-based technologies facilitate a “joining-up” of previously fragmented governmental organizations.

There is nothing inevitable about digital era governance, as the discussion of the reality of e-government over time has suggested, and indeed a number of possible scenarios may emerge. But at its best, digital era governance, where innovations such as Web 2.0 applications are employed, could facilitate new potential for citizens to play a role in solving social problems. In health and social care, for example, where in some countries citizens can already view their own electronic health records online, where electronic booking systems for GPs and hospitals could be readily available, where user-generated

information might enhance the possibility of choice in health-care, and a huge range of health information is available freely online for those skilled enough in Internet use to look for it, there seems potential for citizens to play a greater role in tackling their own health-care than has ever been possible before, just as Internet banking involves users taking a more proactive stance in the management of their bank accounts.

## **Egypt: Media System**

*Carola Richter*

*University of Erfurt*

Egypt occupies a leading political and cultural role in the Arab world as the region's most populous state, with 72.6 million inhabitants. Until 1914, Egypt officially belonged to the Ottoman Empire. However, British economic and geopolitical interests in the region turned Egypt into a semi-colony from 1882 to 1952. The ongoing struggle for independence culminated in the Free Officers Revolution in 1952, which established a nationalist regime. Islam plays a minor but visible role in official politics and legislation. Despite Egypt formally being a parliamentary democracy, the authoritarian president pulls the political strings.

Since 1954, only three presidents have ruled Egypt, each of them shaping the media system differently. Gamal Abdel Nasser (1954–1970) used the media as an instrument of political mobilization within the strategy of promoting Arab nationalism (→ Development Communication: Middle East). Anwar al-Sadat's (1970–1981) politics of liberalization opened up space for party papers. Hosni Mubarak (since 1981) still expects media to support the regime's politics but came to meet the Egyptian business elites' interests to invest in new media and information technologies. Therefore, Egypt's media system is in a transitional stage. Strong media competition in the Arab world during the 1990s led to a cautious liberalization aiming at securing markets without losing political control over the media.

Official legislation does not yet meet the liberalization process. The revised constitution of 1980 grants freedom of expression (→ Freedom of the Press, Concept of). Nevertheless, the press can be censored or suspended by presidential order due to the state of emergency law, which has been in force since 1981 (→ Censorship). Press law no. 96 of 1996 regulates the role of journalists. Journalists can be sentenced for libeling public officials or offending the president. Only corporate entities, not individuals, are allowed to obtain licenses to publish a paper.

The first *newspaper* was launched by the French during Napoleon's invasion in 1798. During British colonial rule, the Egyptians' struggle for independence served as the cradle for a strong nationalist party press. In 1960 Nasser nationalized the press. Today, the government still controls the three leading dailies, *al-Ahram*, *al-Akhbar*, and *al-Gumhuriya*, a number of weekly papers, and the Egyptian *Middle East News Agency* (MENA); 86.8 percent of journalists in the print sector work for the state-controlled media (Korff 2003).

Sadat's reintroduction of the multiparty system in 1976 was meant to establish "straw dollies" to support government politics. However, parties were allowed to publish their own press (→ Partisan Press; Party–Press Parallelism). During Hosni Mubarak's era, the party press developed into a vivid but always controlled mouthpiece of oppositional ideas. The most important of the 14 party newspapers are the liberal *al-Wafd* and the (now banned) Islamist *al-Shaab* (El Gody 2004). Since 2000, a number of independent dailies and weeklies, such as *al-Dustur* and *al-Masry al-Yawm*, successfully obtained licenses. Their existence is often short-lived due to financial problems or political pressure. Nevertheless, the independent press has become a strong and critical watchdog. To avoid licensing, a number of papers are registered abroad. Like all foreign press, these papers are subject to censorship (→ Communication Law and Policy: Middle East).

The British Marconi Company established a radio system in 1934, and TV broadcasting started in 1960 with American help (El Gody 2004). Nasser soon used the radio as an effective propaganda tool to reach the largely illiterate masses. *Voice of the Arabs* became the most important radio channel in the Arab world during the 1950s and 1960s. Until 2001, national *television and radio* broadcasting was run solely by the state-owned *Egyptian Radio and Television Union* (ERTU). Eight different radio networks have been established, including local, national, and overseas programs. Two national TV channels were complemented with six regional TV channels from 1985 to 1990. Egyptian film and TV production dominated the Arab market at that time. In 1990, Egypt became the first Arab country to launch a TV satellite channel, *ESC 1* (→ Satellite Communication, Global). In 1993 the launch of Nile TV followed, carrying news in English and French to improve Egypt's image in the western world.

Egypt's great leap forward into the era of limited pluralism in the broadcasting sector started in 1998 with the launch of the national satellite *NileSat 101*, followed by *NileSat 102* in 2000 (→ Plurality). In 2001, nine private Egyptian channels were introduced, including the successful *Dream* channels. These channels are characterized by rather apolitical programs due to self-censorship to obtain their licenses. Similarly, two private radio channels started broadcasting in 2003. In 1995, the *Egyptian Media Production City* (EMPC) was inaugurated, including film shooting areas and fully equipped studio complexes (→ Film Production). Part of it was declared a Media Free Zone in 2000, offering tax benefits and exemptions from national censorship for foreign investments. The policy behind this deregulation is "the ruling elite's determination to present an image of Egypt as a 'cohesive community' to viewers at home and abroad" (Sakr 2001, 34).

Economic development through deregulation has also been the motive for supporting new information technologies like mobile phones and the → *Internet*. First introduced at universities in 1986, the Internet became available to the public in 1993. Since 1996 Internet service providing has been privatized. User rates have grown over 100 percent per year ever since, reaching 4 million users in 2005. Illiteracy and limited financial resources hamper wider acceptance. A Ministry for Information and Telecommunication technology was founded in 1999, and the government initiated a "one computer for each household" campaign.

Access to and content of Internet sites are officially not restricted in Egypt. Consequently, Islamist and other opposition groups, as well as a vivid weblog scene, adopted the Internet more professionally than official news media did. Nevertheless, websites of unwanted political organizations like the Muslim Brotherhood are shut down occasionally and → bloggers have been imprisoned. A comprehensive Internet law is still lacking (→ Internet Law and Regulation).

# Elaboration Likelihood Model

Daniel J. O'Keefe

Northwestern University

The elaboration likelihood model (ELM) of → persuasion, developed by Richard Petty, John Cacioppo, and their collaborators, is an example of a “dual process” approach to persuasion (another example is Chaiken’s heuristic-systematic model, HSM). The ELM suggests that important variations in the nature of persuasion are a function of the likelihood that receivers will engage in elaboration of (that is, thinking about) information relevant to the persuasive issue. Depending on the degree of elaboration, two different kinds of persuasion process can be engaged – one involving systematic thinking and the other involving cognitive shortcuts. Different factors influence persuasive outcomes depending on which process is activated.

These two persuasion processes are called the “central route” and the “peripheral route” to persuasion. The *central route* represents the persuasion processes involved when elaboration is relatively high. Where persuasion is achieved through the central route, it commonly comes about through extensive issue-relevant thinking: careful examination of the information contained in the message, close scrutiny of the message’s arguments, consideration of other issue-relevant material, and so on. In short, persuasion through the central route is achieved through the receiver’s thoughtful examination of issue-relevant considerations.

The *peripheral route* represents the persuasion processes involved when elaboration is relatively low. Where persuasion is achieved through peripheral routes, it commonly comes about because the receiver employs some simple decision rule (some heuristic principle) to evaluate the advocated position. For example, receivers might be guided by whether they like the communicator or by whether they find the communicator credible. That is, receivers may rely upon various peripheral cues (such as communicator credibility) as guides to attitude and belief, rather than engaging in extensive issue-relevant thinking (→ Information Processing).

## INFLUENCES ON THE DEGREE OF ELABORATION

A number of factors have been found to influence the amount of elaboration (and hence to influence which route to persuasion is activated). These factors can be classified broadly as influencing either elaboration motivation or elaboration ability.

A receiver’s motivation for engaging in elaboration can be influenced by the relevance of the topic; as the personal relevance of the topic (the receiver’s degree of “involvement” in the topic) increases, the motivation to engage in elaboration also increases (→ Involvement with Media Content). Elaboration motivation can also be influenced by the receiver’s level of “need for cognition,” a personality characteristic reflecting the tendency to enjoy and engage in thinking; people higher in need for cognition generally have greater elaboration motivation (→ Personality and Exposure to Communication). The receiver’s ability to engage in elaboration can be influenced by factors such as the presence of distraction in the persuasive setting or the amount of relevant background knowledge; a

person who lacks prior knowledge of the subject matter or is distracted may be unable to engage in issue-relevant thinking.

So, for example, when a topic is personally relevant to a receiver, the receiver is generally predisposed to engage in careful thinking, the receiver has extensive relevant background knowledge, and the receiver is undistracted, elaboration will presumably be high – and the central route to persuasion will be engaged. By contrast, on a topic that is not especially relevant, with a receiver who does not enjoy thinking hard and has little information about the topic, and in a context where there is considerable distraction, elaboration will presumably be low – and peripheral persuasion processes will be activated.

## **INFLUENCES ON PERSUASIVE OUTCOMES**

Because central-route persuasion and peripheral-route persuasion have different underlying processes, the factors determining persuasive success correspondingly differ.

### **Influences on Persuasive Outcomes in Central-Route Persuasion**

Under conditions of relatively high elaboration, the outcomes of persuasive efforts will largely depend on the outcomes of the receiver's thoughtful consideration of issue-relevant arguments (as opposed to depending primarily on the operation of simple decision principles). Broadly put, when elaboration is high, persuasive effects will depend upon the predominant valence (positive or negative) of the receiver's issue-relevant thoughts. To the extent that the receiver is led to have predominantly favorable thoughts about the advocated position, the message will presumably be relatively successful in eliciting attitude change in the desired direction; if the receiver has predominantly unfavorable thoughts, then the message will presumably be relatively unsuccessful.

Two primary factors influence the predominant valence (the overall evaluative direction) of elaboration. One is whether the message's advocated position is *proattitudinal* or *counterattitudinal* for the receiver. Everything else being equal, one expects proattitudinal messages (ones advocating views toward which the receiver initially feels at least somewhat favorably inclined) to evoke predominantly favorable thoughts, and counterattitudinal messages to evoke predominantly unfavorable thoughts.

The second factor is the *strength (quality) of the message's arguments*. Under conditions of high elaboration, receivers are willing and able to engage in extensive issue-relevant thinking, including careful examination of the message's arguments. If such scrutiny reveals weak evidence, slipshod reasoning, and the like, predominantly negative reactions are to be expected. But if the message is seen to contain powerful arguments, good evidence, sound reasoning, and so forth, then more positive thoughts are likely to result. That is, under conditions of high elaboration, the quality (strength) of the message's arguments influence the predominant valence of elaboration and hence affect persuasive success.

### **Influences on Persuasive Outcomes in Peripheral-Route Persuasion**

Under conditions of relatively low elaboration, receivers are not engaged in thoughtful consideration of the message's arguments and evidence. Rather, receivers use heuristic

principles (“heuristics”), simple decision procedures that require little information processing; heuristics are activated by “peripheral cues,” extrinsic features of the communication situation such as the characteristics of the communicator. A number of such heuristics have been identified.

One is the *credibility heuristic*, in which receivers are guided by the apparent expertise of the communicator. Rather than carefully considering the message’s arguments, receivers can simply rely on the communicator’s credibility as a guide to what to believe: where the communicator is judged to be an expert, receivers will be persuaded by the communicator’s view (and where judged inexpert, the communicator will be relatively unpersuasive). A second heuristic is based on the receiver’s *liking for the communicator*; when this liking heuristic is employed, liked communicators will be more persuasive than disliked communicators. A third processing shortcut is the *consensus heuristic*, in which the receiver’s views are influenced by the reactions of others to the message; when this heuristic is activated, seeing approving reactions of others enhances the message’s persuasiveness (and disapproving reactions impair effectiveness).

As elaboration increases, the influence of such heuristics diminishes. When receivers are engaging in close scrutiny of and thinking about the message, peripheral cues such as the communicator’s likeability, the communicator’s credibility, and the reactions of other people play smaller roles as influences on persuasive outcomes. But where receivers are unable or unmotivated to engage in message scrutiny, these cognitive shortcuts are relied upon.

## COMPLEXITIES AND CONSEQUENCES IN PERSUASION PROCESSES

### Tradeoffs between Central and Peripheral Persuasion Processes

Although the distinction between central- and peripheral-route persuasion is convenient, one should remember that in fact there is an underlying continuum of elaboration. The central route and the peripheral route represent idealized extremes of this continuum, but at intermediate levels of elaboration, complex combinations of central-route and peripheral-route processes can be expected.

Thus, broadly speaking, there is a tradeoff between elaboration valence and peripheral cues as influences on persuasion. As elaboration increases, the impact of peripheral cues declines, and the impact of the valence of the receiver’s issue-relevant thinking increases. For example, as variations in argument strength make more difference in outcomes, variations in communicator expertise play smaller roles as peripheral cues. This tradeoff creates the possibility that, at intermediate levels of elaboration, both central and peripheral processes might operate.

### Multiple Roles for Variables in Persuasion

The ELM emphasizes that any given variable might play multiple roles in persuasion. Specifically, a variable might influence persuasion in three ways. First, it might affect the degree of elaboration (and thus influence the degree to which central-route or peripheral-route processes are engaged). Second, it might serve as a peripheral cue (and so influence

persuasive outcomes when peripheral-route persuasion is occurring). Third, it might influence the valence of elaboration (and so influence persuasive outcomes when central-route persuasion is occurring).

The ELM recognizes that a given variable need not play only one of these roles. In different circumstances, a variable might influence persuasion through different mechanisms. For example, communicator credibility might serve as a peripheral cue (activating the credibility heuristic) or it might influence the amount of elaboration (as when receivers decide that the communicator's expertise makes the message worth attending to closely).

The possibility of different persuasion roles for a single variable points to considerable complexity in persuasion. Consider, for instance, the effects (on persuasive outcomes) of varying the communicator's attractiveness. The ELM suggests that the effects will depend on the role played by attractiveness in the particular persuasion circumstance. Increasing the communicator's attractiveness might enhance persuasion (e.g., if attractiveness operates as a peripheral cue that activates the liking heuristic, or if attractiveness enhances message scrutiny and the message contains strong arguments, or if attractiveness reduces message scrutiny and the message contains weak arguments, or if greater attractiveness encourages positive elaboration by serving as an argument – as might be the case in advertisements for beauty products), or might inhibit persuasion (e.g., if attractiveness enhances message scrutiny and the message contains weak arguments, or if attractiveness reduces message scrutiny and the message contains strong arguments), or might have relatively little influence on persuasion (if other factors play larger roles).

### **Consequences of Differing Persuasion Routes**

Although persuasion can be accomplished at any point along the elaboration continuum, differing degrees of elaboration will make for corresponding differences in the nature of the persuasive outcomes obtained. Where people's attitudes are shaped through central-route processes, those attitudes are likely to be more persistent over time, more directive of behavior, and more resistant to counterpersuasion (compared to attitudes influenced through peripheral-route processes). That is to say, central-route processes create persuasion that is more enduring and more integrated with a person's belief system – as might be expected, given the greater amount of issue-relevant thinking involved in central-route persuasion. Persuasion accomplished through peripheral-route processes is likely to be more evanescent.

### **FUTURE DIRECTIONS AND CONTRIBUTIONS**

At least four lines of future development of ELM ideas can be identified. One is continuing articulation of the *nature of involvement* (personal relevance). Several commentators have suggested that different varieties of involvement can be usefully distinguished as having differing effects on persuasion processes. No consensus has yet emerged about exactly how to more carefully specify involvement variations, but this will plainly be a subject of continuing attention.

A second is clarification of the *nature of argument quality*. Although the ELM emphasizes the role of variations in argument quality as an influence on persuasive outcomes under

conditions of high elaboration, the model has not given much attention to unpacking exactly what makes for stronger and weaker arguments. At least some research suggests that the key ingredient of high-quality arguments may be the relative desirability of the properties attributed to the advocated view (e.g., the desirability of the consequences claimed for a social policy, or the desirability of the characteristics of a consumer product); that is, “strong” arguments are ones that mention properties especially valued by the audience.

A third issue is clarification of the *conditions under which a given variable plays one role or another in persuasion*. The ELM has usefully drawn attention to the possibility that a given variable might, in different circumstances, play different roles in persuasion processes. But it is not yet clear how one might predict when a given factor will serve in one role or another. Fashioning such an account is obviously of some importance.

Finally, the relationship of central-route and peripheral-route processes needs some attention. One prominent alternative to the ELM has been Kruglanski and Thompson’s “*unimodel*,” which proposes that the ELM’s two persuasion routes are similar in a fundamental way: in each route, receivers try to reach conclusions about what views to hold, using whatever evidence is available to them. Different kinds of evidence are employed in the two routes (peripheral cues in the peripheral route, the carefully scrutinized message arguments in the central route), but – the unimodel argues – there actually are not two fundamentally different processes here. Rather, there is just the one process of reasoning to conclusions based on evidence – and thus a “unimodel” of persuasion will suffice.

The unimodel stresses that both peripheral cues and message arguments can vary in their complexity, ease of processing, brevity, and so forth. But, it argues, in ELM research, peripheral cues have typically been quite simple and arguments have typically been quite complex – thus giving rise to apparent differences in how cues and arguments are processed. But, the unimodel argues, if cues and arguments are equalized with respect to complexity, then cues and arguments will be seen to be processed in identical ways, thus removing any need to posit two persuasion processes.

The unimodel raises many complicated issues and the empirical evidence bearing on the model is not uncontroversial. For instance, ELM defenders and unimodel advocates each point to research findings they believe only their favored model can explain – and each believes its model can accommodate the other’s findings. It will be some time before these questions can be sorted out, in part because the issues are both empirical (identifying differing predictions of the two models) and conceptual (for instance, whether it is true by definition that peripheral cues are easy to process).

The ELM has *contributed two key insights* about persuasion. One is the recognition of the variable character of topic-related thinking (elaboration) engaged in by message recipients. Because the extensiveness of topic-relevant thinking varies (from person to person, from situation to situation, etc.), the underlying persuasion processes vary and hence the factors influencing persuasive success vary. The second is the recognition that a given variable may play different roles in persuasion – it might in one circumstance influence the degree of elaboration, in another influence the valence of elaboration, and in a third serve as a peripheral cue. Naturally, then, a variable might have very different effects on persuasion from one situation to the next – which can give rise to seeming inconsistencies in research findings concerning the role played by a given factor. Taken

together, these two insights offer the prospect of reconciling apparently conflicting findings and mark the ELM as an especially significant contribution to our understanding of persuasion.

# Election Campaign Communication

*Holli A. Semetko*

*Emory University*

Election campaigns are among the most important events in the lives of democracies and societies in transition. Campaigns often constitute the high points in public debate about political issues (→ Political Discourse). Election campaign communication takes different forms in different national and regional contexts. It is shaped by both party and media systems and by the regulatory environment governing the campaign process (→ Political Communication Systems). Election communication is also influenced by the balance of party and media forces in shaping the news agenda, and that balance has been tipped by the increasing role played by citizens and interest groups in generating messages and news about parties, leaders, and issues.

## THE CAMPAIGN IN THE NEWS

Television continues to be the main source of information for most people at election time (→ Political Media Use). Television news is the most common vehicle through which particularly the undecided voters and people who are politically uninterested get information about campaign events (→ Television News). That said, market pressures have come to affect the availability of main evening television news in many countries. One glaring consequence in the UK, for example, has been the complete evacuation of news from prime time on what were traditionally the flagship television news channels, BBC1 and ITV1 (→ United Kingdom: Media System; BBC). While prime-time television on the European continent by comparison continues to offer a great deal in the way of news and current affairs programming, the wealth of nonpolitical entertainment offerings provide new ways to opt out. Yet, as program formats change and the lines between hard and → soft news as well as between politics and entertainment blur, there are growing chances that election campaign-related information reaches even the politically inattentive citizens (Baum 2002; → Politainment).

The politically interested have a vast array of places to find campaign news, particularly in media systems with a diverse supply of daily newspapers and a well-established public broadcasting system. But even there, the mission of public service television to “inform, educate, and entertain” was probably never before so focused on the need to maintain status and ratings (→ Public Service Broadcasting: Law and Policy). News programs have become increasingly tailored to the demographics and assumed interests of their target audience. Moving from analogue to digital has fragmented audiences further. The 2005 British general election was described by those in the news business as the last election in the pre-digital age in which the general public was able to view the campaign as a common civic experience.

## CHANGING CAMPAIGN COMMUNICATION

Media system changes are a major factor driving the modernization and “Americanization” of election campaigns. The term “Americanization” has been criticized for being

applied by some scholars as a shorthand reference to the range of new techniques and opportunities being used to influence voters at election time in countries around the world (→ Americanization of the Media). The transformation of campaign communication is described as a greater tendency toward personalized reporting on the top party leaders or candidates, greater emphasis on campaign rhetoric as opposed to information about party policies, and increasingly negative as opposed to neutral or favorable reporting on the candidates in the campaign (→ Negative Campaigning; Personalization of Campaigning). Published election polls and forecasts, often commissioned by the media themselves, have given high prominence to the question of who is ahead and who is trailing behind (→ Bandwagon Effect; Election Polls and Forecasts; Underdog Effect).

Yet as far back as the early 1980s, when election campaign communication in general elections in the *US and UK* was compared systematically, it was clear that election communication on television in the US stood quite apart from the UK (Semetko et al. 1991). American election television was found to be more condensed, more focused on the electoral chances of the candidates, and more evaluative and negative in tone. American election news on television was also more inclined to diminish the prominence of the campaign in the news because story selection was primarily guided by conventional → news values rather than by the educational and informational ethos of British public service broadcasting.

In *Germany*, major changes have been observed by long-term studies showing that strategy or horse race frames have become increasingly salient in election coverage over the years (Esser & Hemmer, in press). In the main evening flagship news programs on television, the top candidates are nowadays more often seen with exciting and colorful pictures, which was uncommon in television news campaign reporting in the past (Schulz & Zeh 2005). This is partly due to the news discussions of televised debates that have been launched in recent election campaigns. In many countries → televised debates, as an adaptation of the American television format, became key events of election campaigns, often reaching a larger audience, generating more media coverage, and impacting more on voters' opinion formation than any other single campaign event.

Patterson's (1993) study of US presidential election campaign news over time (comparing news at each election over three decades from 1960 to 1992), found that it had become less descriptive, less issue-oriented, and less favorable over time. It had also become more analytical, more horse race-oriented, and more negative over time, with less time for candidates to speak in their own words (→ Horse Race Coverage). Patterson's (2002) study of the "vanishing voter" in the 2000 presidential election shows how this negative news may be discouraging citizens from taking part in the election campaign and may ultimately have negative consequences for electoral turn-out (→ Political Cynicism; Political Efficacy).

## CAMPAIGN EFFECTS

A central question of election research is whether and to what degree different modes and media of campaign communication have an influence on voters' opinion formation and on the election outcome – or, as some authors put it plainly: Does the campaign matter? The answer varies to some degree, depending on the national context, the political situation, the type of election, the media under study, and other factors (see, e.g., Farrell & Schmitt-Beck

2002; Norris 2006; Gunther et al. 2007). A review of the empirical evidence by Iyengar & Simon (2000) concludes that “campaigns do matter and can be pivotal.”

Election campaigns quite often serve as a kind of “laboratory” for developing and testing media effect models (→ Media Effects; Media Effects, History of; Political Communication). The seminal *Erie County study* by → Lazarsfeld et al. (1944) is an early and highly influential example. Several key concepts of media effects research, such as the selectivity principle and the opinion leader concept, originate from this study (→ Selective Exposure; Selective Perception and Selective Retention; Opinion Leader; Two-Step Flow of Communication).

Likewise, the agenda-setting concept, which is one of the most widely used models in contemporary communication research, has been advanced in election campaign studies (→ *Agenda-Setting Effects*). Over the past few decades, hundreds of studies have found support for the hypothesis of media agenda-setting effects, with evidence that the media play an important role in shaping the issue priorities of citizens in the context of election campaigns by giving priority in the news to some issues over others (for review, see McCombs 2004). But searching for agenda-setting effects does not always lead to finding them. Research on general elections in the UK in the 1980s and 1990s, and on Germany’s historically important “*unity election*” in 1990, for example, has shown that media agendas do not always coincide with or influence audience agendas during campaigns (Norris et al. 1999; Semetko & Schönbach 1994). The type of issue may also condition media’s power to influence public agendas. “Unobtrusive” issues – such as foreign affairs issues with which people have little or no direct experience – may be more susceptible to agenda setting than “obtrusive” issues relating to problems people may have direct personal experience of, such as inflation and unemployment.

Evidence of *media priming* – the media’s role in providing the standards by which citizens evaluate political leaders and candidates – was found in a number of election studies. Through focusing on certain events or issues more than others during the campaign, the media can influence perceptions of candidates (→ Candidate Image). Iyengar & Kinder (1987) defined priming more specifically as changes in the standards used by the public to evaluate political leaders, and found support for the priming hypothesis in their experiments (→ Priming Theory). The cognitive processes at work are the focus of much of the priming research (→ Political Cognitions; Political Persuasion).

*Framing* goes beyond the concept of agenda-setting research to study *how* people think and talk about campaign issues (Reese et al. 2001). Entman (1993) has described the process of framing as selecting certain aspects of a perceived reality, which then promotes a certain definition of a problem, a certain interpretation of its cause, a certain moral evaluation of the situation, and a certain recommendation for solving or treating the problem (→ Framing of the News). Framing effects have been described as evident when the important attributes of a message (the way in which it is organized, or the content, for example) lead us to draw on particular thoughts in making evaluations or judgments about a problem or issue (→ Framing Effects). This is particularly relevant during election campaigns when parties and candidates are trying to communicate their ability to handle some issues more competently than their competitors (→ Issue Management in Politics). Much of the research on issue perception is based on the assumption that the salience and framing of issues have an influence on electoral choices (→ Issue Voting).

Research on → *political advertising* in election campaigns examines the negative character of news and advertising and its potential effects, and negative campaigning and the consequences for voter mobilization. With new technology available in the US to capture targeted advertising and to identify its audience, a new dimension has been added to the investigation of the effects of television → advertising in election campaigns (Goldstein & Freedman 2002). Cable and satellite technology in the US make it possible to identify the (political) advertising broadcast at the (constituency) target level, and researchers have begun to investigate the links between the two. These developments are boosting the professionalization and marketing-orientation of campaigning (→ Marketing; Political Consultant).

Our understanding of campaign effects has been advanced considerably by research that has focused primarily on the US context. Over the past few decades research has also advanced theoretically and methodologically with a number of international comparative studies (see, e.g., Swanson & Mancini 1996; Farrell & Schmitt-Beck 2002; de Vreese & Semetko 2004; Gunther et al. 2007).

### **THE NEW MEDIA CAMPAIGN ENVIRONMENT**

The new media have altered the battle over the campaign agenda that was once waged primarily between journalists on the one hand and politicians/strategists/interest groups on the other. Traditionally, politicians and their political parties sought to control the message through staged appearances on the campaign trail, in preplanned press conferences and media interviews, and via political advertising. In the 1960s, in the UK and the US for example, the most important journalists reporting on the campaign were “on the bus” with the candidate traveling from one campaign venue to another. Common perspectives on a candidate’s or party leader’s abilities and accomplishments often emerged; the term “pack journalism” was used to describe how those collective judgments emerged among journalists who traveled together, like wolves, in a pack.

Apart from the increasing reliance on air transport to get candidates and party leaders from one campaign event to another, a bigger change was felt with the arrival of the → *Internet* as a widely available source of campaign information used by citizens, journalists, and strategists. Candidates have more to gain and more to lose in this new media environment. The technology-driven reality check provided by the occasional transmission of citizens’ candid videos of political gatherings can potentially dramatically alter the campaign or the chances of a candidate if a gaffe or inappropriate remark ends up posted online. Citizens can also become actively involved in interacting with the candidates’ campaigns while never leaving their computer. In many countries nowadays politically interested citizens can have a potentially greater voice and impact on the day-to-day campaign agenda simply by consistently offering their opinions and developing a reputation online (→ E-Democracy).

Success is measured by the volume of hits at a website or the times that new news spills over from the website into the mainstream campaign media agenda and causes others to recognize it and respond. Blogs have become very popular and have created new ways of campaigning and even more opportunities for grassroots organizing and fundraising (→ Blogger). Mobile telephones and text messaging (SMS) as well as direct marketing

mailings and email spamming are also used for mobilizing and influencing voters. For example, during the 2007 French presidential campaign, the winning candidate Sarkozy sent unsolicited emails to more than a million voters (→ Political Marketing).

A key characteristic of media convergence is an *emphasis on visuals* (→ Digitization and Media Convergence). We may expect more visuals, in relation to text, in the future. Visuals play a vital role in political learning, as Doris Graber's (2001) research demonstrates, and in the retention and understanding of political information. As television and the Internet become more graphic and visual and less text-driven, there will be new forms of political learning (→ Political Knowledge). Unsophisticated viewers differ from sophisticated viewers in handling messages that contain complex and possibly contradictory verbal and visual cues. The new media environment for election campaign communication will have implications for both groups (→ Visual Communication; Television, Visual Characteristics of).

With the arrival of *virtual worlds* in 2003, such as [www.secondlife.com](http://www.secondlife.com), candidates, protestors, campaigns, and corporations have opportunities to reinvent themselves online in a virtual space that leading business publications are now claiming is the edge marketing of the future (→ Avatars and Agents). Virtual worlds face many of the same problems of governance and empowerment as can be found in the real world. Recent election campaigns in a number of countries around the world, such as France, Japan, and the US, have been the subject of activity in the virtual world. There has also been discussion of challenges posed to those activities by regulations in the real world. In Japan, for example, the strict regulations guiding the forms of campaigning in the real world meant that one politician had to shut down his virtual world office during the official campaign period.

As the early onset of the 2008 US presidential elections has demonstrated, with numerous internal party debates among the candidates, television news is moving to accommodate and feature the new media. One of the new developments in summer 2007 in one nationally televised debate among the many contenders in the field of Democratic Party candidates was → CNN's decision to cooperate with YouTube to feature questions to the candidates from viewers via YouTube. Some viewers whose questions were aired were also brought into the studio to comment on the debate's content and new format. Overall, the post-debate coverage evaluated this new format quite positively, suggesting that the combination of old and new media brings excitement into the debate because of the direct involvement of citizens in the campaign process. We can therefore expect more efforts to create new formats with old and new media, and not only in the US.

Election campaign communication is a vitally important part of the electoral process. It has become increasingly important to electoral outcomes over the decades in advanced democracies, as voters have shown themselves to be more volatile and willing to switch parties or candidates between and during election campaigns (Dalton 2000). Given the new media landscape, we may anticipate more voter involvement in creating election campaign communication in the future.

## Election Polls and Forecasts

Thomas Petersen

Allensbach Institute

The history of survey research is inseparably entwined with the development of election polling. As early as 1904, social scientists completed the first quantitative study focusing on the constituency of the Social Democratic Party in Germany. The breakthrough of the representative survey method in the year 1936 was brought about by the spectacularly successful election forecasts published by researchers George Gallup, Elmo Roper, and Archibald Crossley prior to the US presidential elections of that same year (→ Election Surveys). From the start, election forecasts contributed significantly to both public acceptance of modern survey research and new methodological advances, since they offered researchers the rare opportunity to prove the efficacy of the representative survey method (→ Survey).

Over the course of the past few decades, the methodological approaches employed in election polling have diverged strongly (→ Public Opinion Polling). Today, election forecasts are based on face-to-face surveys, or on telephone surveys or, most recently, on online surveys. In this regard, we must fundamentally distinguish between exit polls – in other words, post-election surveys conducted among voters immediately upon leaving the polling station – and election surveys that are completed prior to an election and that, as a rule, employ the same interviewing methods as are used in representative surveys on other issues.

Almost right from the start, it was suspected that election forecasts might have an influence on voting behavior – a suspicion that often went hand in hand with the concern that election polls actually represented an illegitimate way of manipulating the electoral decision-making process. In the US, this seems likely because voting is time-lagged from region to region. When polling stations on the East Coast close and the initial results are announced, the polling stations on the West Coast are still open so that it is possible that the publication of early results or exit polls has an effect on voters who are still going to cast their vote.

Published election polls and forecasts are supposed to shape voters' preferences and prompt tactical voting. A → *bandwagon effect* might occur when published poll results are demonstrating that a particular party or candidate is clearly leading in the race. In that case, voters might change their vote intentions in favor of the leader. However, there is also the possibility that the polls are stimulating an → *underdog effect*, i.e., changing

voting intentions in favor of the parties or candidates that are trailing behind. Published poll results are also supposed to affect voter *turnout* and thus increase mobilization or abstention, depending on the political circumstances of the election.

A number of studies have examined whether publishing election surveys affect voter behavior. Based on a thorough → meta-analysis of relevant empirical research, Hardmeier (in press) concludes that the impact of polls on voter turnout is rather marginal and that there is also no strong effect on voting intentions. The empirical evidence speaks for a weak bandwagon effect rather than for an underdog effect. If poll effects occur, they are more likely on undecided voters and on people with weak or no predispositions. In the light of these results, fears expressed in public debate about the manipulation potential of polls are exaggerated in most cases.

The reason why election polls have less impact on voter behavior than is often assumed is illustrated by experiments examining the persuasive influence of survey statistics as compared to illustrative single cases. As the findings show, exemplifying illustrations – e.g., remarks of passers-by interviewed on the street – have much stronger effects on people's opinion formation than statements based on representative statistics (Brosius & Bathelt 1994; Daschmann 2000). Many people appear to have great difficulties in grasping the significance of statistical data in day-to-day life. Concrete single cases seem considerably more accessible and thus more convincing than abstract numbers (→ Exemplification and Exemplars, Effects of).

Nonetheless, parties and candidates are frequently suspected of launching polls in order to improve their chances in the election campaign race. Similarly, mass media are sometimes falsely accused of publishing poll results that could be instrumental in furthering the political interests of their sponsors. In any event, election polls and forecasts, because of their high → news value, are a preferred topic of campaign coverage and serve media interest insofar as they attract audience attention (→ Elections and Media, History of; Polls and the Media).

Although most voters are unimpressed by election polls, this does not mean that their influence on the course of an election campaign is generally negligible. Even if survey results have only weak *direct* effects on voters, there are still indications – albeit no certain proof – that election polls could, under certain circumstances, have a considerable *indirect* impact. In contrast to the majority of the population, journalists are used to dealing with survey data. Poll results may thus prompt journalists to change their definition of the political situation and ultimately alter the basic tenor of their reporting. Hence, the population's voting behavior could be influenced by the overall tenor of media campaign reporting – i.e., not just reporting on survey findings, but on the political situation as a whole (→ Election Campaign Communication; Political Persuasion).

In most democratic countries, therefore, the question of whether it ought to be forbidden to publish the results of election polls in the final weeks prior to an election has occasionally been the subject of heated public debate. Almost half of the 78 countries covered by a worldwide survey have embargoes on the publication of poll results on or prior to election day (Spangenberg 2003). In many countries, however, calling for such bans is legally problematic – and also seems dubious from a democratic viewpoint. On the one hand, it does not contradict the principle of democracy when tactically minded voters obtain information on the strength of the parties or candidates and then make

their decision in light of this information. On the other hand, survey findings represent only one of many different kinds of public statements made on the presumable outcome of an election. Forbidding their publication would mean suppressing the only scientifically based information and allowing less reliable statements, speculations, and contentions based on personal opinion and hearsay to go uncontradicted.

# **Election Surveys**

*Thomas Petersen*

*Allensbach Institute*

Election research has played a decisive part in the development of the methods of → survey research from the beginning. More than market and media research, election research has awoken, in a special way, the curiosity and the ambition of researchers, and thus strongly affected empirical social research. It is significant that the breakthroughs of both the modern method of the representative survey and of empirical methods in communication research are connected with studies in electoral choice (→ Research Methods).

## **HISTORY**

The first attempts at analyzing elections using statistical methods can be traced back to the early twentieth century. In 1905, the German researcher R. Blank published a detailed social science analysis of the social democratic party's electorate (Blank 1905). A decade later, attempts began to predict future electoral behavior on the basis of pre-election polls. In 1916, an American magazine, *Literary Digest*, began to conduct write-in mass surveys

before presidential elections, so-called “straw polls.” This endeavor became rather gigantic over the years, with 20 million ballot forms being sent to addresses taken from telephone registers and automobile licensing offices in the election year of 1932.

At the same time, another approach to studying consumer behavior had established itself in business life since the 1920s: interviewing a few hundred people, but taking care that the interviewed people exactly reproduced, in reduced size, the socio-demographic structure of the population at large (→ Sampling, Nonrandom; Sampling, Random). There was also at this time a shift from sending out questionnaires by mail to interviewing face-to-face (→ Interview, Standardized).

The researchers George Gallup, Elmo Roper, and Archibald Crossley first applied this method to the prediction of election results in the US presidential election in 1936. They predicted Franklin D. Roosevelt’s victory, while *Literary Digest* had anticipated Republican candidate Alf Landon would win. Roosevelt made it with a clear margin. Gallup, Roper, and Crossley had demonstrated that it was not crucial to interview as many individuals as possible to reproduce the people’s opinion correctly, but that, given an appropriate representative selection of respondents, a few thousand interviews would suffice to know, with computable confidence, what a population of millions thought – Gallup had interviewed 6,000.

The three avoided two crucial methodological mistakes that caused the failure of the *Literary Digest’s* forecast:

- 1 Respondent selection relied on telephone registers and the files of car licensing authorities. The share of well-to-do people was above average among the respondents chosen in this manner, and the well-to-do voted Republican to a larger degree than the average population.
- 2 The method of the write-in questionnaire further created problems: only a minority of the people contacted did indeed fill in and send back the postcards, and those who sent them back were not representative of the total sample. The problem of self-selection is considered an especially serious disadvantage of write-in and most online surveys to this day. The principles applied by Gallup reduced the detrimental effect of self-selection considerably and are regarded to this day as the methodological bases of representative surveys (→ Public Opinion Polling).

The 1944 election study *The people’s choice* by → Paul F. Lazarsfeld is of crucial significance for the development of communication research. Lazarsfeld studied voters’ decision-making and the effects of media coverage on voting behavior in a broadly designed six-wave panel survey (a panel survey is one that allows for the repeated interviewing of the same respondents over a period of time; Lazarsfeld et al. 1944). Several influential communication theories grew out of the results of this study, among them the hypothesis of a → two-step flow of communication (→ Communication and Media Studies, History to 1968; Media Effects, History of).

Very soon after George Gallup’s success in 1936, election surveys became a fixed quantity in the media’s election coverage, at first in the USA and after World War II in western Europe also. Today, election surveys are conducted in almost all democratic states. From the start, the institutes conducting election surveys were confronted with the

allegation that the publication of their results affected the democratic process and thus interfered with the voters' free decision. Studies, however, have clearly shown that the effect of published election survey results is in fact weak (→ Election Polls and Forecasts). For this reason, and because of fundamental judicial considerations, repeated attempts to ban the publication of election survey results before elections have failed in several countries. Nevertheless, such attempts are still made time and again, and some democratic countries sustain such bans (Donsbach 2001).

## EXIT POLLS AND PRE-ELECTION SURVEYS

Today, there are two basically different types of election surveys: exit polls and pre-election surveys, with the former usually dominating media coverage on election day, while the latter are more important for in-depth analyses of the background of elections. The method of the *exit polls* was essentially developed in the 1960s by the American researcher Warren Mitofsky, who was responsible for the election coverage of the US television network CBS. In exit polls a representative sample of voters is interviewed immediately upon leaving the polling station. Results are published before the first returns come in on election night. They mostly allow a very precise estimate of the election result. In countries where it is doubtful whether the vote count is conducted correctly, exit polls are also a good control on the official electoral process, provided they can be conducted independently.

In contrast, *pre-election surveys* use the same methods as surveys on other subjects. They are one of the few situations that allow survey research firms to test the validity of their methods using verifiable external criteria. Pre-election surveys today are conducted in many countries with the traditional method of the face-to-face interview. In the USA and many other western countries, however, telephone interviewing has come to dominate. For some years, there has been an increasing number of experiments with online surveys, but in spite of some spectacular success (Martin et al. 2005, 359), telephone and face-to-face surveys appear to be more reliable at this stage. Pre-election polls offer a much more detailed analytical potential than exit polls, especially when conducted as panel studies, which can be considered the only truly reliable basis for the analysis of changing electoral preferences.

## METHODOLOGICAL REQUIREMENTS FOR PRE-ELECTION POLLS

The public's expectations for the precision of pre-election surveys are especially high. This increases the risk for the research institutes active in this field to be publicly accused of failure. To meet the high expectations, the institutes conduct election surveys with a considerable methodological expenditure. The following are among the methods applied in these surveys.

In some countries, the shares of parties or candidates cannot simply be determined by the question, "If the election were held tomorrow, which party would you vote for?" Depending on the electoral system, whole series of questions may be necessary. In Germany, for instance, every voter has two votes, one to choose a local candidate for parliament, and the other to determine a party's number of seats. Questions to model the outcome of

an election not only have to consider both votes, but also have to account for the fact that a large share of the population is unaware of the functions of the two votes.

One of the biggest problems in predicting election outcomes is created by the fact that even shortly before election day, a considerable share of respondents is still undecided about whether they will vote, and if so, which party or candidate they will vote for. There is widespread disagreement in election research on the right procedure to deal with these *undecideds*. In many cases, they are just left out of the computation of party shares or allotted proportionally on the candidates standing for election (Mitofsky 1998), a risky procedure when an overproportionally large share of potential adherents to one of the political camps is among the undecideds. The problem seems to be somewhat smaller in countries with a two-party system than in countries with a multiparty system and proportional representation. In these systems, a method of distributing undecideds with the help of  $\rightarrow$  cluster analyses (“statistical twins”) has proven its worth.

A special problem for predicting election outcomes appears in situations in which one political camp comes under the *pressure of public opinion*, which causes its adherents to no longer (or only hesitatingly) admit to belonging to this camp in survey interviews (Noelle-Neumann 1993). In these cases, *weighting* the data according to the so-called recall question (Which party/candidate did you vote for last time?) can become necessary. The difference between the marginal results of the recall question and the actual outcome of the last election serves as the basis for the computation of the weighting factors (Noelle-Neumann & Petersen 2005).

Time and again, attempts are made to compute *long-term election forecasts* on the basis of figures acquired through experience over a long period of time. In spite of some remarkable successes of this approach (e.g., Norpoth 1995), it cannot replace traditional pre-election polls, no matter how instructive and analytically useful such procedures may otherwise be. Pre-election polls may help to control these forecast models. Attempts at combining the figures gained from long-term experience with new surveys are to be considered somewhat problematic. They may improve the precision of a pre-election poll in some cases, but they are always misleading when voting behavior, for whatever reason, does not follow the patterns observed earlier.

### PRECISION OF ELECTION POLLS

The reputation of election surveys among the public in many countries is strongly affected by a few erroneous prognoses, while the large number of correct prognoses is noticed less attentively by the media and the public. *Spectacular errors* in election forecasts, such as in the US presidential elections in 1948, 1980, and 1996, the British general election in 1992, the French presidential election in 2002, and the German parliamentary election in 2005, have always produced, aside from intensive scientific research of the causes of the failure, a public discussion of the uses of survey research as a political information medium and its quality.

Partly, these discussions are based on a misunderstanding of the *possibilities and limits of survey research*, for instance when the surveys were correct within the margins of standard error, but picked the wrong winner in a close race, as was the case with some exit polls in Germany in 2002, or when the survey results correctly showed the overall percentage shares of the vote but failed to reliably predict the resulting distribution of seats in parliament

because of a first-past-the-post electoral system, as was the case in the Indian parliamentary election in 2004.

A scientific analysis of the quality of election surveys faces the question of how their precision can be measured objectively. As early as 1949, Mosteller et al. listed eight different ways to measure the deviation of election forecasts from election outcomes in their study of the causes of Gallup's failure in predicting the result of the 1948 US presidential election. Most of these use either the difference between survey and vote shares of individual parties or candidates in percentage points or the gap between the two leading candidates as the basis of their computation.

Especially the latter are suited to the US political system, in which elections are almost always dominated by two parties or candidates. More complex modern computation models, which try to connect the various advantages of traditional methods, also assume an electoral or party system that is at least similar to the US system (e.g., Martin et al. 2005). In countries with a more complex party system, the average deviation of prognosis from actual outcome across all parties, multiplied by the largest deviation for any single party, usually provides a practical basis for analysis.

# Elections and Media, History of

Karin Wahl-Jorgensen

Cardiff University

In mass democracies, where it is impossible for candidates to meet most voters in person, political campaigning has always relied centrally on mass media. Since the beginnings of democracy, vast resources have been committed to campaign communications, motivated by the “widespread belief that media coverage matters to the outcome of elections” (Franklin 2004, 8). Friedenberg (1997), in his history of political consultants in the US, traced mediated campaigns back to colonial elections of the mid-1700s. He suggested that the first “media blitz” in a political campaign took place during the failed presidential bid of Thomas Jefferson in 1796, in which the campaign manager flooded the targeted state of Pennsylvania “with thousands of political handbills and over 30,000 sample ballots” in an election where only 12,000 Pennsylvanians voted (Friedenberg 1997, 4).

The 1828 presidential campaign of Andrew Jackson has been widely recognized as the first orchestrated media campaign in the US. The most prominent medium of Jackson’s day was the → newspaper, and his campaign team took ample advantage of its potential. Campaign activists lobbied sympathetic editors and publishers for positive coverage, and produced an unprecedented quantity of campaign literature in the form of pamphlets, handbills, and broadsides. This literature pioneered negative advertising in its attacks on other candidates in the election, especially the incumbent, John Quincy Adams (Friedenberg 1997, 9; → Negative Campaigning). In response, his opponents issued handbills which “charged Jackson with ordering . . . executions, massacring Indians, stabbing a Samuel Jackson in the back, murdering one soldier . . . and hanging three Indians” (Jamieson 1996, 7; → Advertisement Campaign Management; Election Campaign Communication).

## RESEARCH ON US ELECTIONS

From the beginning, the mediatised campaign exerted its own logic on political life by encouraging a conflict-driven, personalized, and image-centered focus. Correspondingly, debates about whether campaigns should be image- or issue-driven began as early as the 1920s (Franklin 2004, 5). The need for careful management of media campaigns eventually gave rise to a new class of professionals: political consultants. The first *professional* → *political consultants* were Clem Whitaker and Leonora Baxter, who made their names as the advisers for the 1934 re-election campaign of California governor Frank Merriam. To undermine the image of his Democratic opponent, the writer Upton Sinclair, Whitaker, and Baxter “produced phony newsreels of staged events. In one, dozens of bedraggled hoboes [sic] leap off a freight train, presumably having arrived in the Promised Land of California. Explains one bum [sic]: ‘Sinclair says he’ll take the property of the working people and give it to us’” (Diamond & Bates 1992, 36–37).

With the rise of → television, the micro-management of candidates’ media images became increasingly important (→ Candidate Image). The need for campaigns to be image-savvy was most famously illustrated in the first *Nixon–Kennedy debate* of 1960, in which radio listeners believed that Nixon had won the debate, while TV viewers had little

doubt that Kennedy had emerged victorious (→ Televised Debates). As Jamieson (1996, 158) puts it, “Nixon’s pale complexion, the byproduct of a recent illness and inadequate make-up and lighting, his dark beard and the sweat that trickled over his upper lip and down his chin suggested a desperate person crumbling under the stress of the encounter with Kennedy.” To observers, the outcome of the Nixon–Kennedy contest highlighted the triumph of style over substance, image over issues, personality over politics, and emotional connection over rational deliberation.

Following the assassination of Kennedy and the ascent of Lyndon B. Johnson to the presidency, the power of images to pull on the heartstrings of the electorate was driven home in Johnson’s 1964 re-election campaign. He ran against the conservative Republican candidate Barry Goldwater, and his campaign produced the *most famous political ad* in the history of political broadcasting. Capitalizing on voters’ fear that Barry Goldwater might employ nuclear weapons in Vietnam, the spot juxtaposed the image of a young girl standing in a field, plucking petals from a daisy as she counts: “1, 2, 3, 4, 5, 6, 7, 8, 9. . . . When she reaches ‘9,’ a Cape Canaveral voice begins a countdown of its own . . . At zero the camera, which throughout this second countdown has been closing on the child’s face, dissolves from her eye to a mushroom cloud that expands until it envelops the screen” (Jamieson 1996, 198). The ad, which never mentioned Barry Goldwater’s name, was aired only once, creating so much controversy that it was immediately pulled. Subsequently, however, it was shown innumerable times in news stories about the controversy. The “daisy ad” quickly became a symbol of the power of sophisticated campaign communications.

## PROFESSIONALIZATION OF CAMPAIGNS

Though much scholarly attention has been focused on the US case, the techniques developed there have slowly percolated through to media campaigning elsewhere. In most western European democracies, where paid political advertising on television is not allowed, and where public service broadcasting providers instead give the parties equal time to put across their message, the professionalization of politics and the image-consciousness that goes with it have been somewhat slower to emerge (→ Public Service Broadcasting: Law and Policy).

Most scholars tend to agree that the first media-driven election in *the UK* took place in 1957, when the Conservative party spent a then staggering sum of £468,000 on a poster campaign which insisted that, “Life is better with the Conservatives: Don’t let Labour ruin it” (Kavanagh 1995, 49). After they won the election by a landslide, media strategy took center stage in future elections. For the 1978 general election, the Conservative party, led by Margaret Thatcher, hired the advertising agency Saatchi and Saatchi, whose glossy campaign on the theme of “Labour isn’t working” ushered in the era of professionalized media electioneering in the UK (Kavanagh 1995).

Since the 1980s, the practices of campaign media management that started their life in the US have been globalized. In a process referred to as the “Americanization” or “modernization” of politics (e.g., Mancini & Swanson 1996, p. 4; → Americanization of the Media), campaigns around the world have become increasingly professionalized and personalized (→ Personalization of Campaigning). Political marketing is now a fact of life

in western industrialized democracies, in Sweden, Argentina, Israel, Japan, and beyond (→ Political Marketing). Such campaigns have often drawn on ideas and, in some cases, personnel from the United States, but have been shaped by the unique political, economic, and social circumstances of each national context. For example, in the 2005 *Palestinian authority elections*, Hamas paid a media consultant, Nashat Aqtash, \$180,000, to help them with strategy. Aqtash advised the party to change their image by “explaining that they do not hate Israelis because they are Jews. And he [attempted] to persuade influential foreigners that Hamas is essentially a peaceful organisation that was forced to fight, but is now committed to pressing its cause through politics, not violence” (McGreal 2006). Hamas also sought to soften its image at home with the launch of a television station in Gaza that includes a children’s show presented by “Uncle Hazim” and men in furry animal suits (McGreal 2006).

### FUTURE TRENDS

The strategies of campaign media management have had an influence that extends beyond the electoral context. In 1980, the author and political consultant Sidney Blumenthal coined the term, “the permanent campaign,” to describe how the emphasis on image making and strategy has colonized politics, remaking “government into an instrument designed to sustain an election official’s popularity” (Blumenthal 1980, 7). In the UK context, the New Labour government has gained a reputation for its obsession with image management and message control, earning prime minister Tony Blair the labels of “King of Spin” and “Phony Tony.” As Franklin (2004, 73) noted, in the months before the 2001 general election, Blair’s government “spent £3 million on a single advertising campaign about benefit fraud: the same as McDonald’s budget for promoting ‘Big Macs.’”

The increasing resources spent on persuading the public in elections and beyond have not, however, translated into more widespread public participation. If anything, observers lament the “crisis in public communications” (Blumler & Gurevitch 1995), reflected in a decline in conventional forms of political participation, including voting and newspaper readership. Some have linked this public apathy to an increase in negative and often deceptive campaigning. As early as 1981, Jay Blumler voiced his concern that “more and more people seem to be getting into a frame of mind where campaign propaganda is almost automatically expected to be off-putting” (1981, 59). While some scholarly evidence suggests that negative campaigning turns off voters to “shrink and polarize” the electorate (e.g., Ansolabehere & Iyengar 1996), other work suggests it may have a positive effect on voter turnout (Wattenberg & Briens 1999). Nevertheless, the emphasis on style over substance in election coverage remains a concern for observers, who worry that democracy is in danger when politicians and their policies are “branded and marketed like cornflakes or Big Macs” (Franklin 2004, 14).

In recent years, political campaigns have pinned their hopes for the revival of participation on new technologies. While the → Internet has been hailed as a revolutionary technology of emancipation, the scholarly evidence is ambiguous. Philip Howard (2005) has documented how the rise of the “hypermedia campaign,” drawing on new media technologies, including direct marketing, has led to the “managed citizen.” Howard suggests that new technologies, despite their promises of empowering the citizenry, also enable

increasingly sophisticated forms of surveillance, employed to cunning effect by hypermedia campaigners. And while citizens appear to appreciate the interactive opportunities inherent in new media campaigning, there is also evidence to suggest that such opportunities are severely circumscribed. As James Janack (2006) found, in his study of discussion on Howard Dean's campaign blog, supporters of Dean policed debate to focus it on issues of strategy and style over substance (→ Blogger). Contributors who wanted to actually discuss politics were silenced by other posters, who felt that such discussion was inappropriate. As such, the media through which electoral campaigns are channeled may change, but the debates surrounding their role in shaping political campaigns are as old as democracy itself (→ E-Democracy).

# Electronic Mail

*Robert Hassan*

*University of Melbourne*

Since the 1970s, electronic mail (email) has changed from being a rudimentary method of text-based communication between a very few computer users in military research establishments, universities, and commercial telecommunications labs, to become a highly sophisticated and widespread media form. The growth of email has helped underpin not only the rise of the → Internet as a primary communicative technology of the early twenty-first century, but has also been an important contributor to the ongoing expansion of the “network society” more generally (Castells 1996). Today, email has become a basic means of communication in the everyday life of hundreds of millions of people in the developed and developing economies of the world, linking and expanding their social, cultural, political, and economic realms in ways that continue to be unforeseen and innovative; bringing new issues, problems, and opportunities to the processes of institutions and to individual lives, which are increasingly shaped by digital technologies.

Email continues to be a media that primarily uses text-based forms, but it now increasingly incorporates digital video, → photography, and sound files (→ Digital Imagery). Moreover, in the body of the text an email addressee can click on a hyperlink that will automatically direct the user to a website, or email attachments can be opened to reveal files in, for example, portable document format (PDF), which can contain large documents such as → newspapers, reports, → magazines, and → books – indeed, any media form of almost any size that is able to be digitized (→ Digital Media, History of).

It has been estimated that 60 billion emails are generated each day, and this figure grows exponentially. They are used to convey almost every conceivable message between humans (and between human and computer), and this phenomenon has been claimed to help reflect the constitutive forms of human experience (economic, cultural, and social) within the networked society (Castells 1996).

## GENESIS AND EVOLUTION OF EMAIL

As a form of communication via computers, email began in the USA in the 1960s as a method through which multiple users of large time-sharing mainframe systems could share information to enable them to work jointly on projects in a more efficient manner. The *original email users* were also its developers, working as scientists and engineers in the US Department of Defense, in the computer research institutes in the major universities, and in the research laboratories of the large telecommunications corporations. The practical utility of email allowed it to develop rapidly into networked email, where users from different computer systems were able to communicate. In 1969 the US military computer network ARPANET, which was a precursor to the Internet, further helped to drive email use and contribute to its continuing technological and practical sophistication. In 1971, Ray Tomlinson, an engineer working within the ARPANET network, began the use of the @ symbol as a means of separating the name of the user and their host machine.

The effectiveness of email as a way of interconnecting users created demand for its use on non-ARPANET systems, such as in business and in universities. This, in turn, called for more innovative computing hardware and software solutions that would allow *email communication between different network systems*. Enhanced email allowed the creation of new forms of networking between users clustered around shared interests. For example, the usenet system was developed in 1980, which allowed the categorization of emails into topics of interest. These categories formed newsgroups that enabled users to email each other on the topics that interested them. It was in these early newsgroups that acronyms such as FAQ (“frequently asked questions”) and terms such as “spam” (unsolicited email) were coined. These newsgroups, in fact, acted as “public discussion groups” – a spilling out into the public domain that further enhanced the popularity of email and fed directly into a greater use of what was, by the early 1990s, a growing Internet system.

It was around this time that the Internet and email began to shape each other’s developmental trajectory in an increasingly close nexus. Increased use of Internet-based email systems led to demand for more email accounts, which in turn spurred the growth of *Internet service providers* (ISPs). The perceived negative “control” by ISPs over the free flow of email traffic led in 1996 to the introduction of an email service called Hotmail. Developed by Sabeer Bhatia and Jack Smith, Hotmail was a free email service that could be accessed at any time or place through the open Internet. The service was bought by Microsoft in 1997 and now has over 230 million users and processes 100 million emails a day (Microsoft 2006). The success of Hotmail motivated many competitors, such as Yahoo! Mail and Google’s Gmail. In these and other systems, emails can be received and generated through mobile phones or PDAs. Internet- and networked-based systems such as short message service (SMS), instant messaging (IM), and ICQ (“I seek you”) allow users to communicate on an almost real-time basis.

## SOCIAL AND ECONOMIC CONTEXT

### The Optimistic View

From its earliest days as a growing media form, email has been argued to be either a positive or negative social phenomena, but there exists no real preponderance of opinion either way (→ Information Society). On the positive side, the popularity of email as part of the general networking process has been hailed by observers such as Howard Rheingold (2001) as contributing to the *creation of a “virtual community”* where the obstacles of time and space are substantially overcome by communication through computers. Email has also been argued to be a creative medium where *self-expression* took new and unexpected forms, such as through the use of “emoticons,” where “emotions” may be expressed in text by arranging printable characters into “icons,” such as :- ) to symbolize happiness. Some theorists, such as Pierre Lévy, argue that email, as part of larger computerized systems, is generating “*qualitative change in the learning process*”, whereby in “the new virtual campus, professors and students will share . . . material and informational resources. Teachers will learn along with their students and continuously update their knowledge along with their teaching skills” (2001, 151). And across the world, *network support groups* made possible through the use of email are transforming the way many

people approach issues such as illness, bereavement, trauma, or facing challenges such as giving birth, raising children with special needs, and so on (→ Network Organizations through Communication Technology). The Internet hosts thousands of such networks, and creates what are argued to be constructive “communities of interest” for millions of people (→ E-Democracy).

From the point of view of business, many have grown through creative use of email as a *link to their customers* through → advertising. The trading website eBay, for example, would be a much less attractive alternative to interested parties if they were not able to get together through email to discuss the particularities of the goods or services being bought or sold. Again, from the *perspective of some businesses, email serves as a powerful strategic means* for “old” media such as television, newspapers, and radio to become “relevant” in the information age. To keep their businesses within the increasingly important digital technology connection, these media forms increasingly use email to link “old” media with the “new” by obtaining the involvement of the user or customer. Viewers, readers, and listeners of traditional media are encouraged to use email to “stay in touch” by, for example, voting on the popularity of a television program, writing letters or opinion pieces for newspapers to print, or commenting on the content of radio across the whole spectrum of its activities.

### **The Pessimistic View**

From the opposite perspective, the proliferation and increasing sophistication of email use has brought with it what many observers see to be a significant downside in a number of social, economic, and cultural realms. Prominent in this regard is the growing volume of spam, which takes up memory on individual computers, slows down overall network traffic, and “degrades” the Internet experience (Pew Internet Research 2003). It has been estimated that 75 percent of the total volume of daily email traffic is taken up by *spam* (Ferris Research 2007). Concern has also been raised over the prevalence of *phishing* through email, a practice where individuals posing as representatives of legitimate businesses, such as banks, make fraudulent attempts to gain sensitive information such as credit card details.

Email use has been blamed by some for contributing to a *decline in writing standards*, with poor grammar (and ultimately poor communication) being the result of the brevity and speed of writing that email supposedly produces (Dillon 2004). Others see it as degrading the “art of conversation,” where, again, the speed and ubiquity of email, mobile phones, instant messaging, and so on have had the effect of being face-to-face “conversation avoidance devices” (Miller 2004). Alternatively, however, it can be argued that email and other modes of electronic communication have ensured that there has never been a time when people have conversed more. This is an ongoing argument that relates quality to quantity.

This very argument feeds into another concern regarding the proliferation of email – *information overload*, where too much information creates the basis for miscommunication or noncommunication because there is simply too much data to be digested. A major issue of concern for both network architects and the wider user public is the use of email to disseminate *computer viruses*, which are created to do damage to personal computer

files as well as the large databases of commercial entities (Thompson 2004). Another growing problem, especially for those involved with the protection of civil liberties, is that of privacy. With the appropriate technology, governments are able to intercept private communication, corporations are able to read their employees' emails, ISPs can in theory capture the email traffic of those customers who use its servers, and anonymous "hacktivists" can intercept email as it journeys through possibly several routers on the way to its destination (Lyon 2001; → Hacktivism).

## FUTURE TRENDS

Most commentators see the growth of email continuing as a central feature of networked communications. However, some also identify a bifurcation in email that divides along generational and task-oriented lines. For example, surveys in advanced network economies such as South Korea and the USA show that younger people use email less and SMS, IM, and ICQ more (Lee 2005). They view email as an "older" and more "formal" mode that a previous generation grew used to. The younger demographic increasingly view it as a way to communicate with "adults" such as teachers or institutions like schools, and to convey longer and more detailed information to large groups (Pew Internet Research 2005).

Social communication with friends and peers, alternatively, is conducted through more mobile technologies (→ Mobility, Technology for). Nonetheless, much evidence suggests that diverse modes of electronic communication (including email) will become increasingly sophisticated, leading to yet more complex and complementary (or divergent) forms within the overarching dynamics of the information society. But this brings with it the caveat that forecasting in this particular instance is only ever able to be provisional, and that new forms of communication and new uses of email will present ongoing analytical and interpretive challenges.

## Embedded Journalists

*Nick Mosdell*

*Cardiff University*

The concept of journalists accompanying troops into combat is not new, but the scale and manner of media operations on the battlefield transformed in the 2003 Iraq war. The change in terminology from → “war correspondent” to “embedded journalist” gave rise to debates among media, military, and other commentators about the implications for the coverage of current and future conflicts (→ Conflict as Media Content).

The origin of the term “embedded” is unclear but not specific to the Iraq war. Some Pentagon officials suggest the term originated with units having a distinct mission placed within a larger force, but others (ominously) suggest it involves fixing or placement so deep that the element is hard to get out.

Within the *Iraq context*, “embedded” combined with “journalist” to denote a correspondent traveling with and reporting on the activities of a military unit, especially one engaged in direct conflict, for the duration of the operation. Journalists not embedded with the troops (*unilateral correspondents*) were free to investigate and file reports from anywhere in the region, without military reporting restrictions but, importantly, without agreed military protection. They were like any other civilian on a battlefield the military aims to control.

Military organizations have grown aware that global, 24-hour news can be a weapon as well as a way to avoid conflict. US and UK forces pursue what they call *information operations*, with the media playing an integral part. Coverage of professional, effective combat operations not only deters adversaries but also bolsters domestic opinion (→ Public Opinion), an important factor given worldwide opposition to the 2003 war. The scale of the media operations in Iraq represented a shift away from overt → censorship toward a more subtle technique of media management (→ Communication Management). Such concerted effort may be → propaganda by another name (Miller 2004; → War Propaganda), but may reflect an increasing sophistication and media awareness among military elites (Lewis et al. 2006).

Among the thousands representing world media organizations in the Iraq region during the 2003 invasion (→ CNN; BBC), between 600 and 700 were embedded with Coalition forces. Some 80 percent of those the American organizers placed were US nationals, and British officials required that all embedded journalists they placed hold a

British passport. The one embedded reporter from the Arabic network Al Jazeera said he met with such suspicion that his reports were no more informative than others from the Coalition press centre (→ Arab Satellite TV News).

Embedded reporters gained unprecedented access to personnel and their strategic plans and received logistical assistance from the military. The American media abandoned the pooling system, and British networks, after initially agreeing to pool material, eventually followed suit. Military officials rarely subjected material to security review, and embedded journalists recalled an unprecedented degree of cooperation and openness from the military. Officials required every embedded journalist, however, to sign a document outlining restrictions on the content of reports, principally for reasons of operational security. Reporters relied on their units for transport and safety and therefore could rarely conduct independent investigations (for example, to interview Iraqi civilians).

News organizations feared that “embed” could become “in bed,” sacrificing journalistic perspective by becoming so close to and reliant on their units. There is little evidence to support the concern. On occasion an embedded story originating from military sources was incorrect. Reports of a popular uprising in Basra implied initially that the war was a liberation rather than an invasion, but Al Jazeera reporters inside the city quickly discredited the story. Embedded journalists were, however, free to clarify official briefings.

Embedded reporters brought viewers closer to combat than ever before, but the absence of images depicting casualties and death was still notable (Aday 2005; Lewis et al. 2006), partly because of military restrictions to maintain secure operations and to protect combatants’ next of kin. Even so, the news culture of western media organizations arguably shies away from portraying the brutalities of war.

Embedded journalists on the whole gave a dramatic but narrow view from the front lines, focusing on individual engagements with greater freedom, but supplying only part of a larger picture (→ Objectivity in Reporting). Intrinsicly, embedding results in personalized stories and reports of individual skirmishes at the episodic and tactical levels (Aday et al. 2005; Tumber & Palmer 2004). The strategic picture required independent reports from unilateral correspondents. The three weeks of official combat operations saw a startling casualty rate among independent reporters (→ Violence against Journalists), with at least 14 killed and many more injured, the majority as a result of so-called blue-on-blue (or friendly fire) incidents. The American administration had warned media organizations that the military would not take responsibility for, and actively discouraged the presence of, non-embedded journalists.

The risk for journalism is that embedded reporting may become the only option in conflict coverage. News organizations find embedding attractive because it can supply compelling footage, but unilateral reporters who supply a broader view of events face greater danger. During asymmetric warfare, regular troops cannot clearly identify their adversaries in civilian dress and civilian vehicles, and the casualties may include not only unilateral reporters but also the larger picture of the military conflict.

## **Emic vs Etic Research**

*Thomas R. Lindlof*

*University of Kentucky*

Derived from anthropological research, *emic* and *etic* describe two broad approaches to analyzing language and culture. The emic–etic duality has influenced the ways in which fields as diverse as personality psychology, consumer behavior, organizational science, and intercultural communication study cultural systems. The terms also refer to distinctive research strategies, particularly in the context of ethnographic fieldwork (→ Field Research).

*Emic* and *etic* were coined by the linguistic anthropologist Kenneth L. Pike (1954). Pike’s intent was to apply the principles of structural → linguistics to the problem of how and why language usage varies within and across cultures. The term *emics* – adapted from *phonemics* – conveys the idea that only members of a culture possess valid knowledge of their own language usage. As Pike defined it, an emic unit is any physical or mental item regarded as meaningful, real, accurate, appropriate, coherent, or relevant by the culture members themselves. Thus, the emic approach to research always starts from the “inside” of a culture. By studying the accounts, explanations, and social action that are meaningful to a group of people, researchers can better understand how symbolic communication varies from one situation to the next. A valid emic account is one that matches the consensus view of native informants. Emic accounts often require the stance of *verstehen* (→ Verstehen vs Erklären), and are typically idiographic in scope (→ Idiographic vs Nomothetic Science).

In contrast, the term *etics* – adapted from *phonetics* – refers to concepts and descriptive systems that belong to a community of analysts. Etic units express the scientific observer’s perspective on a phenomenon, and are often thought to be valid in any culture where they

are applied. Following from this logic, etic concepts, such as “uncertainty avoidance” or the value orientation of “individualism–collectivism,” can be used to compare, classify, and explain behavior or attitudes across many different groups. The members of a culture need not agree with, nor even understand, an etic concept. Rather, a valid etic explanation is one that satisfies certain scientific criteria, such as falsifiability, replicability, and logical consistency.

In communication studies, emic and etic are referenced most often in sub-fields that focus on language use and cross-cultural communication (Sigman 1987; → Intercultural and Intergroup Communication). Due in part to its affiliation with sociolinguistics, the ethnography of speech has a long tradition of applying the concepts (→ Ethnography of Communication). For example, Philipsen (1975) used an emic approach to study what it means to “speak like a man” in one urban neighborhood. Scholars of ethnic and cross-cultural communication also employ emic- and etic-related concepts to theorize about cultural codes (Gudykunst 1997). For example, Edward Hall’s (1976) low-context/high-context message scheme is often used in etic fashion to compare communication styles across cultures.

The concepts also appear frequently in discussions of the appropriate methods to use for studying culture (→ Research Methods). According to Pike (quoted in Kaye 1994, 296), the emic/etic distinction “insists on the relationship of the observer to the data, as against an abstract science in which the observer is somehow eliminated in principle even when this would be impossible in fact” (→ Qualitative Methodology). Emic research tends to focus on a single case (or single culture), in which investigator and subjects engage interactively. Participant observation and semi-structured interviews are two of the most popular fieldwork techniques used to study emic constructs. Some ethnographic practices, such as member validation (or member check), rely heavily on the elicitation of emic accounts. Etic research, on the other hand, stresses data gathering across multiple cases or social systems. Etic data are often collected by means of tests, measures, scales, and other instruments that can be standardized and easily replicated. However, even in qualitative field research, etic concepts can be used strategically for formulating hypotheses or propositions.

Among the problems cited for the exclusive use of emic data is that they can leave the researcher immersed in the native language, unable to move up to the analytical plane. In addition, people are not always fully aware of the emic codes of their own culture. Therefore, any explanations they give of these items might be erroneous. Etic data have been criticized for being little more than the emics of observers. That is, an etic construct could simply describe the “insider” perspective of a scientific culture. In a related critique, the points of comparison gained from etic analysis may come at the cost of severe understatements of cultural difference.

Most contemporary researchers no longer view the terms as opposed or incompatible. In fact, it is now typical for the concepts to be discussed as symbiotic (Berry 1999; Headland et al. 1990; Helfrich 1999). The emic perspective alerts researchers to the “first-order” (indigenous) constructs of a culture or group, which can then be used in deriving the “second-order” constructs of a scientific community. Deployed together in research, each concept has the potential to compensate for the shortcomings of the other.

## **Emotion**

*Brant R. Burlison*

*Purdue University*

*Jessica J. Rack*

*Purdue University*

Emotion is a core part of human experience and, as such, plays a central role in numerous aspects of human communication. Contemporary communication research examines how emotion influences various communication processes and outcomes, how different aspects of communication influence diverse emotional states, and the multiple ways in which emotional states are expressed during the course of interactions.

### **CONCEPTUALIZATIONS OF EMOTION**

Definitions of emotion vary widely (Solomon 2000), but there is broad agreement that emotion is a subset of the broader construct “affect,” and should be distinguished from the related construct “mood.” As forms of affect, both emotion and mood are feelings that have some valence (typically on a positive–negative continuum), some level of intensity (mild to strong), and some duration (brief to enduring). Emotions are typically episodic (provoked

by a particular circumstance), exhibit a relatively brief duration, and are comparatively intense. Alternatively, moods are typically tonic (more global and diffuse in character), are not usually tied to any particular provoking incident (and thus typically have no obvious cause), often endure for considerable periods of time, and are milder than emotions.

Moods are typically background states of which people may be only vaguely aware; moods generally have few direct motivational consequences. When moods influence behavior, they typically do so through subtle effects on perception, memory, information integration, and other forms of information processing (Forgas 2001). Emotions, however, have comparatively *strong and direct motivational implications*, arousing the distinct motivational and behavioral orientations termed “action tendencies,” biologically based behavioral responses that help organisms cope adaptively with emotion-eliciting environmental demands (e.g., the action tendency for fear is flight; the action tendency for anger is attack). Action tendencies provide orientations to action, not automatically executed behavioral programs; an aroused action tendency may be suppressed, ignored, or transformed rather than acted upon.

Although virtually all conceptualizations of emotion include the elements of feeling (especially valence) and action tendency, theorists diverge with regard to the essential nature of the emotions (for review, see Guerrero et al. 1998). Some maintain that emotions are categorically *distinct states*; proponents of this view hold that there is a small number of “basic emotions” (e.g., happiness, anger, fear, sadness, surprise, disgust), each of which consists of distinct (and discrete) patterns of feeling, arousal, and expression that are culturally universal. Others conceptualize *emotions as fluid, fuzzy conditions* best characterized as intersections of several different dimensions, such as valence (positive–negative), activation (active–passive), and intensity (mild–strong). A third perspective, the *prototype approach*, incorporates elements of both these approaches by maintaining that there is a small number of prototypical emotions, each of which consists of several distinguishing features (e.g., distinct feelings, → cognitions, physiological reactions, expressive behaviors); in turn, each core emotion encompasses a family of related emotions that differ from one another on one or more dimensions (e.g., the “joy” family encompasses amusement, enthusiasm, contentment, pride, etc.).

Contemporary theories often treat *emotion as a syndrome* that is constituted from several components (Parkinson 1995). There is general agreement that the most complete emotional experience is characterized by a distinctive (1) feeling state (a sensed subjective experience that is relatively brief and intense), (2) action tendency (motivational orientation), (3) set of cognitions (appraisals of the environment), (4) collection of expressive behaviors (including nonverbal, paraverbal, and/or verbal signals and symbols), and (5) physiological state (including patterns of neuroendocrine, cardiovascular, and respiratory responses). Theorists vary on which (if any) of these components are necessary (or sufficient) for emotional experience, and different theories give distinctive weights to each component in their depictions of emotional phenomena.

## THEORIES OF EMOTION

Four broad perspectives inform most current theories of and research on emotion: the Darwinian perspective, the Jamesian perspective, the cognitive perspective, and the social

constructionist perspective (Cornelius 1996). Each of these has had a significant influence in areas of communication research.

### **The Darwinian Perspective**

Grounded in Darwin's *Expression of the emotions in man and animals* (1872/1965), the Darwinian perspective maintains that emotions are universal (species-wide) response patterns that developed over the course of evolution. These response patterns function to help the organism cope with (and survive) persistent environmental challenges. Viewing emotions as adjustment mechanisms leads to a focus on the action tendencies and expressive behaviors (i.e., facial displays, gestures, vocalizations) associated with particular emotions since these are the vehicles through which coping occurs; the physiological response patterns associated with emotions also receive attention by some Darwinians. Because they are products of evolution, all humans should share the same emotions (especially the same set of basic emotions) and should experience and express these in similar ways. Further, because the genetically based patterns of expression for particular emotions are universal, these expressions serve an informative function (communicating the organism's internal experience), as well as an adaptive function.

Some research in this tradition focuses on identifying and assessing the universality of facial expressions for a variety of basic emotions, and considerable evidence indicates there are notable cross-cultural similarities in the facial displays associated with several distinct emotions (→ Facial Expressions). Other research suggests substantial cross-cultural universals in the meanings (i.e., experience) of different emotions, a finding consistent with the notion that basic emotions represent species-wide semantic primitives. Darwinians recognize, of course, that people do not always fully express every emotion they experience, nor does every emotional expression correspond to an experienced emotion. These facts are reconciled with the claim of universals in emotional experience and expression through the notion of "display rules," "socially learned, often culturally different, rules about the management of expression, about who can show which emotion to whom and when they can do so" (Ekman 2003, 4). The Darwinian perspective is evident in communication research examining social implications of spontaneous, socialized (rule-governed), and strategic (planned) expression of emotion, especially in deception contexts (Buck & VanLear 2002; → Deceptive Message Production).

### **The Jamesian Perspective**

The Jamesian perspective, inspired by the speculations of William James (1884), is also informed by evolutionary theory and assumes that emotions evolved as adaptive mechanisms that facilitate *copied with environmental demands*; however, it assumes that emotional experiences arise as a consequence of bodily reactions. Accordingly, bodily responses – including facial expressions, postural changes, neurological activity, and visceral reactions (e.g., changes in heart rate, blood pressure, respiration, and other autonomic activity) – follow directly from the perception of an "exciting fact" (i.e., an external stimulus), and the organism's sensing of these bodily responses *is* the emotion.

On this view, “we do not smile because we are happy. Instead, we are happy because we smile, and also angry because we frown, sad because we sit slumped and listless, and so forth, for all emotions” (Laird & Bresler 1992, 213).

One point of division within this perspective concerns the physiological (especially autonomic) specificity of different emotions. Some Jamesians hold that each emotion encompasses a distinct pattern of physiological arousal, it is the unique physiological pattern associated with a particular emotion that people experience as a discrete emotional state. Consistent with this view, some tests of the *facial feedback hypothesis* have found reliable changes in subjective feelings and autonomic activity when people pose certain facial and postural expressions of emotion; emotional experiences appear to follow these expressions. Communication scholars have observed that because people engaged in face-to-face interaction tend to mimic one another’s expressions, one implication of the facial feedback hypothesis is the social contagion of emotion; that is, an emotional state may be passed from one person to another through the unconscious mimicry of the other’s facial expressions and body positions (Cappella 1993).

*Empirical evidence* regarding the autonomic specificity of different emotions is mixed; although autonomic activity reliably differentiates negative from positive emotional experiences, specific emotions have not been reliably differentiated by distinct patterns of autonomic arousal. Thus, a second group of Jamesian theorists suggests that although physiological arousal is a necessary condition for emotional experience, and may precede that experience, the arousal associated with most emotions is undifferentiated and must be interpreted or labeled to acquire significance. For example, Schachter’s (1964) two-factor theory of emotion maintains that undifferentiated arousal gives rise to searches for the cause of the arousal, with individuals examining features of the setting, the status of goal-directed behavior, and other contextual cues in the effort to label the arousal. In communication scholarship, this multifactor Jamesian view of emotional experience is best represented in Zillman’s → excitation transfer theory and three-factor theory of emotion; these frameworks provide explanations for the emotional effects of media exposure, among other emotion-related communicative phenomena.

### **Cognitive or Appraisal Theories**

A third perspective on emotion, cognitive or appraisal theories, maintains that bodily reactions are generated as consequences of the individual’s cognitive interpretation (appraisal) of the situation (→ Appraisal Theory). These theories view emotions as arising from an individual’s *cognitive evaluation of a situation* and its appraised implications for personal well-being. Because appraisal theories view emotion as generated by cognitive evaluations of specific person–environment relationships, different patterns of appraisal about how the environment affects well-being lead to the experience of distinct emotions. Associated with the cognitive appraisals, subjective feelings, and consequent physiological activity that constitute the emotional experience are action tendencies that function to help the person cope adaptively with the emotion-arousing event.

Research within the cognitive perspective addresses a variety of issues, including the general dimensions along which events are appraised, the specific appraisal patterns associated with particular emotions, how emotional reactions are altered through modifying

appraisals, and the consequences for action that follow from particular appraisals and emotions (see review by Smith & Kirby 2001). Communication scholars have utilized the cognitive perspective to explore how appraisals and their attendant emotions influence – and are influenced by – interaction goals, message processing, and message use in a variety of social settings (MacGeorge 2001).

### **The Social Constructionist Perspective**

A fourth approach to emotion, the social constructionist perspective, conceptualizes emotions as *transitory social roles* enacted by people in particular, socially defined settings (Averill 1980). Action tendencies and patterns of expressive behavior receive focused attention within this viewpoint, but social constructionists see emotions originating in cultural conventions about the feelings and actions that are appropriate in particular social situations. Thus, the social constructionist perspective denies (or de-emphasizes) universals in emotional experience and expression, instead suggesting that the character of emotional experiences and modes of expression for these experiences are developed within particular communities. Emotions – particular patterns of thought, action, and feeling – are socially recognized and constituted roles within a community. Thus, “being angry,” for example, means taking on the role of an “angry person” – a role that includes particular actions (e.g., threatening others), expressions (e.g., a contorted face), and cognitions (e.g., seeing oneself as demeaned by an unwarranted insult) that are conventionally associated with anger within a given community. As such, emotions are social institutions for accomplishing social functions (→ Emotion and Discourse).

Research within this perspective focuses on identifying the emotions common within particular communities, detailing the social circumstances associated with the experience and expression of those emotions, and documenting the community’s rules governing legitimate occasions for, and expressions of, particular emotions. In communication research, the social constructionist perspective on emotion is most visible in research examining aspects of “emotion labor,” the notion that the emotional experiences and expressions of individuals in organizational contexts are heavily regulated by organizational norms and rules (→ Emotion and Communication in Organizations).

## **EMOTION IN COMMUNICATION RESEARCH**

In most communication research, emotion is treated in one of three manners: (1) as a dependent variable influenced by some aspect of the communication content or process (e.g., effects of media content on fear reactions; effects of interactional synchrony on feelings experienced by interaction participants), (2) as an independent variable that influences some aspect of the communication process (e.g., effects of anxiety on verbal performances; effects of anger on verbal aggression), or (3) as the focal or background content of communicative behavior (e.g., expressions of happiness during greetings; behavioral leakages that signal anxiety during an interview) that conveys information about internal states of actors.

The contributions of different theories of emotion to communication research are most evident when emotion is considered a *dependent variable* impacted by communica-

tion processes and contents. Creating, changing, moderating, and intensifying others' emotions is a common objective for communication. For example, → advertising research regularly examines how the form and content of ads can generate moods or emotions so that these feelings can (1) become associated with a particular product, person, or image, or (2) influence the processing and outcomes of particular persuasive messages that are presented in conjunction with or subsequent to the affect-arousing stimulus (→ Advertising, Emotions in). An important thread of → persuasion research examines the aspects of messages and situations that reliably create perceptions (appraisals) of threat and feelings of fear, anxiety, and concern (Witte & Allen 2000), as well as effects of these emotions on the processing and outcomes of associated persuasive appeals. Other research examines the properties of fear-arousing media entertainment and its effects on various audiences; there is also research examining how media entertainment produces humor, mirth, and other positive emotions in audiences and the diverse effects of these emotions (→ Emotions, Media Effects on). Still other research examines message strategies intended to help those who are sad, anxious, fearful, or otherwise distressed (→ Comforting Communication).

Communication research examining emotion as an *independent variable* seeks to understand how emotional (or affective) states influence communication processes and outcomes. For example, considerable attention has been given to how various emotions and moods influence message production (Burlison & Planalp 2000) and message processing (Dillard & Nabi 2006). Other research examines how specific emotions impact particular communicative behaviors (e.g., the effects of anxiety on speech preparation, presentation, and outcomes; → Communication Apprehension and Social Anxiety). Emotion can play a varied role with respect to communication, acting as a motivator (focusing and directing communicative activities), an energizer (enhancing the speed, fluency, or accuracy of communicative activities), or a disruptor (interfering with the conduct of communicative activities).

Finally, a substantial body of communication research treats emotion as the *content or substance of communicative encounters*; emotion is what people convey (both intentionally and unintentionally) during interactions. This research tradition addresses numerous issues, including how and why emotion is communicated, the nature of the verbal and nonverbal vehicles through which emotion is conveyed, the occasions for the expression of various emotions, the spontaneous vs strategic expression of emotion, the function of emotional expressions in the regulation of interactions, and the constitution of emotional meanings within interactions (for review of these and related issues, see Planalp 1999).

Emotion is inseparable from communication, just as it is from human life. The fundamental questions confronting scholars thus concern how the relationships between communication and emotion should be conceptualized and studied. Our understanding of how communication influences emotion will be deepened by improved theories of emotion; these will help us better appreciate the nature of emotional experiences and expressions, the sources and consequences of these, and how varied aspects of communication influence these. Our understanding of how emotion influences communication will be deepened by improved theories of core communication processes; these will help us better appreciate the mechanisms through which emotional arousal motivates, energizes, and disrupts particular communicative activities. And our understanding of how communication conveys emotion will be deepened by improved theories of both

emotion and communication; these will help us better appreciate how, when, and why emotions are experienced and expressed by people as they interact.

# Emotion and Communication in Organizations

Sarah J. Tracy

Arizona State University

Emotional communication is central to many jobs (→ Emotion). Stockbrokers express aggression, nurses communicate care, and emotions such as shame, pride, and fear are central in organizational evaluation. Nonetheless, organization studies have traditionally written out emotion, treating it as a private issue, a barrier to effectiveness, or something that should be controlled (→ Organizational Communication). Early research suggested that organizations were and should be rational, scientific entities (→ Bureaucracy and Communication). In this paradigm, if emotions were examined, they were measured as variables of job satisfaction, morale, or commitment. Furthermore, emotions have traditionally been subjugated to the private, personal, feminine sphere (→ Feminist and Gender Studies).

Despite this early resistance, in the past 15 years, increasing numbers of scholars from communication, management, sociology, and psychology have examined emotion formation, expression, and control in the workplace. Researchers have explored how emergent work feelings are an integral part of organizational life (Mumby & Putnam 1992) and how emotional display and “emotional intelligence” (Goleman 1995) are co-opted by organizations to achieve an economic mission. As such, researchers have recognized that emotions are a core part of organizing and that emotionality is not the opposite of rationality or cognition (Planalp 1999), but, rather, is part of organizational processes.

## KEY TERMS AND DEFINITIONS

A communicative approach to emotion and organizations emphasizes several key issues (Waldron 1994). First, emotion is not just a reaction, but functions as both a performance and a rhetorical act that achieves specific objectives. Second, emotion is an interactive, negotiated process that is continuously experienced across work groups and relationships. Third, communication not only serves as emotional packaging, but fundamentally constructs feelings. Through interaction and storytelling, employees negotiate cultural expectations of emotion, interpret the emotional displays of others, recreate and make sense of past emotional events, and elicit emotion in others.

Emotions have *several components*, which include (1) a cognitive appraisal of a situation, event, or object (→ Cognition; Appraisal Theory), (2) a feeling of action-readiness, (3) internal feelings, and (4) external physical characteristics. “Feelings” are generally considered subjective experiences that reside in individuals. “Emotions,” in contrast, generally refer to the external display of the affected state, the meaning of which is negotiated and constructed through organizational norms. Emotions are connected to direct objects or causes, while “moods” refer to enduring pleasant or unpleasant feelings with no direct object. The term “affect,” often connected to concepts such as job satisfaction and morale, is usually considered to be a valence that is determined by the appraisal of good or bad.

## **RESEARCH AREAS**

### **Stress and Burnout**

Burnout is generally considered to be a three-dimensional concept characterized by (1) emotional exhaustion (or a “wearing out” from a job), (2) depersonalization or a negative shift in responses to others, particularly clients, and (3) a decreased sense of personal accomplishment (Maslach 1982). Burnout is especially linked to professions that require high levels of client contact, such as teaching, social work, and human service work. Additionally, burnout has been associated with role conflict, close contact with emotional clients, work overload, cognitive dissonance, and lack of organizational identification. Communicative factors that mitigate burnout include social support, strong superior–subordinate relationships, participation in decision-making, and high levels of organizational identification.

Kathy Miller and her colleagues conducted several foundational organizational communication studies of burnout, and operationalized empathy as a two-pronged concept consisting of (1) emotional contagion, in which the caregiver experiences emotional responses parallel to the client’s emotion, and (2) empathic concern, which is a concern about the welfare of the other without feeling parallel emotions of the other. While empathic concern leads to increased satisfaction and decreased burnout, emotional contagion is counterproductive, as it leads to the depersonalization of clients and burnout for the worker (Miller et al. 1988).

### **Emotional Labor**

Sociologist Arlie Hochschild is recognized as being the founder of the emotion labor literature. In her study of the emotional display rules of Delta flight attendants, Hochschild (1983) distinguishes between emotion management and emotion labor. “Emotion management” is the effort that individuals put into making their private feelings align with socially accepted norms, such as looking sad at a funeral or jovial at a party. “Emotion labor” is the commercial exploitation of this process, as when employees are paid to smile, laugh, be polite, or be caring. The bulk of the emotion labor literature focuses upon professions in which employees put on a happy face, such as Disney employees, cruise staff, and waiters. Other research has examined professionals who feign negative or disinterested emotions, such as bill collectors or police officers, as well as health-care workers, who control emotions of disgust and express care.

Communication researchers have examined emotion labor among a variety of professions, including emergency communication call-takers (Shuler & Sypher 2000), teachers (Miller 2002), firefighters (Scott & Myers 2005), and correctional officers (Tracy 2005), among others. This research highlights the importance of everyday activities and organizational structures for socially constructing emotion norms, the purposeful selection and socialization of workers to exhibit certain emotions, the importance of social support in times of organizational tragedy, and the ways employees communicatively deal with emotion labor through storytelling, joking, and venting.

### **Emotional Intelligence**

A concept closely connected to emotion management is emotional intelligence (sometimes called EQ). EQ is a big business, producing consultants, scholarly research, and popular press books. The concept is based upon the idea that individuals have “multiple” intelligences and that rationality and emotionality are complementary rather than contradictory.

In the popular press book *Emotional intelligence*, science journalist Daniel Goleman (1995) summarizes the research, claiming that emotionally intelligent people: (1) know their emotions; (2) manage their emotions; (3) motivate themselves; (4) recognize emotions in others; and (5) can handle relationships. While the empirical research backing some of these claims is tenuous (see Dougherty & Krone 2002), research does suggest that emotionally intelligent people can identify and perceive emotion in self and others (e.g., have empathy), and understand, shape, and channel emotions successfully (Fineman 2006).

### **Bounded Emotionality and Compassion**

“Bounded emotionality” is likely the most referenced emotion and organizing concept emanating from the communication field. In contrast to prevailing views of emotion as either a pathology (e.g., burnout) or something to be rationally managed, bounded emotionality provides an “alternative mode of organizing in which nurturance, caring, community, supportiveness, and interrelatedness are fused with individual responsibility to shape organizational experiences” (Mumby & Putnam 1992, 474). The concept frames emotion in organizations not as a commodity to be controlled but as “work feelings” that are integral to the workplace.

Likewise, research has focused on how emotion, in the form of compassion, can constitute an ameliorative to organizational and employee pain. Compassion includes noticing another’s suffering, imagining the feeling of that person, and easing that pain through verbal and nonverbal communicative responses. Significant compassionate encounters rely on the degree to which individuals are attuned to provide compassion and the amount of organizational support of this behavior. Dutton et al. (2006) have developed a theory of compassion organizing which suggests that organizational structural features can be redirected toward responding to members’ pain. Their research, along with recent work by Miller (2007), has found that caring interactions at work dramatically influence people’s experience of organizations.

### **Affective Events and Mood Theory**

Affective events theory (AET), developed by Weiss and Cropanzano (1996), has been proposed as an overarching model of emotions in organizations (Fineman 2006). The theory suggests that organizational policies, roles, and events initiate emotional responses in organizational members, which, in turn, affect members’ behaviors and performance. The empirical work associated with AET has found that performance at work is not defined by long-term attitudes about satisfaction, but by the frequency and accumulation of everyday organizational emotional highs (“uplifts”) and lows (“hassles”).

Consistent with AET, research suggests that positive and negative mood states can determine employees' attitudes and actions. Employees in negative moods are less satisfied, more burned out, and more likely to leave their job. However, those in negative moods are also likely to better process cognitive information and make finer judgments. Positive moods help facilitate creativity and boost optimism (→ Mood Management).

### **Humor and Organizing**

The connection of positive moods and organizational effectiveness has spurred research on humor, laughter, and joking in the workplace. Research has found that employees are individually motivated to engage in joking and/or find certain messages to be funny because of superiority, tension relief, or incongruity (Lynch 2002).

Humorous communication in the workplace has been found to enhance job satisfaction, provide ingroup solidarity, manage the emotions of others, help employees to cope with low-level or dangerous work, construct organizational culture, provide an opportunity to strategically avoid certain topics, issues, or people, reduce burnout and job stress, reveal organizational values and beliefs, help employees adjust to change, and provide an avenue for organizational sense-making (Tracy et al. 2006b).

### **Workplace Bullying**

While sustained attention has been paid to workplace conflict and sexual harassment, generalized emotional abuse is a recently emerging line of research (→ Organizational Conflict). Bullying is negative, persistent, and long-term hostility in the workplace that may or may not be racially or sexually motivated. Bullying is an uneven onslaught of negative behavior in which targets often find themselves unable to escape.

Bullying is largely communicative, coming in the form of insults, nonverbal contempt (e.g., eye rolling), isolation, and discounting the target's voice. Most of the workplace bullying scholarship has been pioneered by Scandinavian and British organizational psychology researchers. American communication scholars have examined the prevalence, harm, and cycle of workplace bullying, the emotional pain of abuse, resistance to bullying, and the difficulty of telling stories about abuse at work (Tracy et al. 2006a).

## **THEORETICAL CONCERNS AND CONTROVERSIES**

Researchers continually grapple with how best to conceptualize emotion. Scientific approaches link emotions to physiological, biological, and psychological impulses, suggesting that emotions derive from genetically based programs of response, instinctual bodily perturbations, facial expressions, and urges to act. The *cognitive approach* urges scholars to explore environmental variables that affect cognitive processes, which in turn affect emotions. If an encounter is congruent or incongruent with the actor's goal, the actor will feel positively or negatively, respectively.

The most prevalent approach among communication scholars is conceptualizing emotions as *socially constructed*. This standpoint suggests that emotion develops in light of linguistic labels and a repertoire of social practices that are operative within the local

moral order. Similarly, a poststructuralist standpoint highlights emotion as a subjective and interactional process, constructed through multiple contradictory and overlapping discourses (→ Constructivism; Organizational Communication: Postmodern Approaches).

Capturing and making sense of emotion requires *methodological ingenuity*. Organizational burnout, stress, satisfaction, and morale have primarily been measured with self-report surveys. However, most emotion and organizing research has been interpretively analyzed using qualitative data such as organizational stories, dialogue, interactions, nonverbal cues, and pictures drawn by employees (→ Qualitative Methodology). Employee stories allow emotion to be known through embedded lived experience. Ethnographers argue that to write emotionally, scholars must experiment with the format of their representations through creative writing and scholarly performances. Ellis (1991) has developed an “emotional sociology,” which aims to purposely and reflexively portray emotion and evoke those feelings in readers/audience members.

In addition to these epistemological and methodological issues, two emotion and organizing topics are marked with *controversy*. First, researchers continue to grapple with why and to what extent emotion labor is difficult and/or psychologically painful. Some research suggests that emotion labor can be enjoyable, emotionally healthy, and even fun (Shuler & Sypher 2000). People who maintain a positive outlook on life have greater immune functioning and less disease. Furthermore, because individuals often infer their attitudes and beliefs from their behaviors or actions, employees who feign pleasant emotions may be more likely to believe they are happy.

Despite this evidence, the bulk of research has associated emotion labor with *negative psychosocial effects* such as alienation, stress, burnout, depression, cynicism, role alienation, and emotional numbness (Wharton 1999). Discomfort of emotion labor has been linked to “emotive dissonance” or a clash between inner feelings and outward expression (Hochschild 1983). The acting method used also affects the pain of emotion work. “Deep acting,” wherein members internalize the prescribed emotions, is connected to alienation and burnout. Surface acting – in which members do not change their inner feelings, but put effort into changing their outward emotional expression – may not cause estrangement, but may result in an unconvincing performance. Finally, Tracy (2005) suggests that power is a key factor in understanding whether or not employees feel discomfort with emotion labor (→ Organizational Communication: Critical Approaches). Faking low-status emotions that do not align with a preferred identity is much more difficult than feigning those that paint an employee in ways that align with dominant organizational discourses. Furthermore, members can more easily feign low-status emotions when they can also interact with one another “backstage” and resist through using “hidden transcripts.”

Last, the *emotional intelligence concept is controversial* (Fineman 2006). Questions remain over how it is best measured and whether it is distinct from other constructs. EQ has been critiqued for overstating the extent to which individuals can control and channel their own emotions and understating the extent to which EQ can be used not only for good (e.g., charismatic leadership) but also for evil (e.g., manipulative bullying). Because EQ is associated with productivity, it is the most “marketable” of all emotion and organization concepts, and has been criticized for being inappropriately commodified.

## TRENDS AND FUTURE DIRECTIONS

With a dramatic increase in the use of new communication technologies and alternative organizational structures (→ Telework), questions emerge about whether employees can feel emotionally connected when they are physically in *different spaces* (Fineman 2006). Future research may fruitfully examine how employees develop trust and warmth and avoid loneliness when they work in virtual organizations, telecommute, or work at home.

A second trend is the *positive psychology movement*, and its offshoot, positive organizational scholarship. This research argues that scholars have spent too much time studying what is wrong with organizations, (e.g., bullying, emotive dissonance, burnout) and that attention should be turned to positive organizational emotions (such as well-being, happiness, compassion, love, and pleasure). As such, researchers have been increasingly motivated to study the factors that contribute to optimal and positive functioning of employees and institutions, the goal of which is to enhance the quality of life for workers.

A third trend is examining *emotion and work–family interference/spillover*. Recently, individuals have been exploring how organizational emotional display expectations, as well as issues of stress, burnout, and bullying, are carried with employees when they go home at night. Likewise, women who are expected to do caring and nurturing emotion management both at home and at work have higher levels of stress and depression.

Last, while organizational research has examined the gendered nature of emotion expectations, as it stands, there is little research on emotion and organizing beyond white, professional employees. A fruitful area of future research includes examining the raced and classed nature of emotional labor expectations and characteristics of EQ (→ Organizations, Cultural Diversity in).

## Emotion and Discourse

Charlotte Bloch

University of Copenhagen

Human emotionality is an ongoing stream that pervades every aspect of social life, talk, conversation, and discourse. Emotions are appraisals of situations; they have somatic bodily characteristics and their expressions can take nonverbal forms (facial, vocal, posture; → Emotion). Theoretical approaches to the emotional dimensions of discourse are found within three traditions of research: psychology of emotions, sociology of emotions, and psycho- and socio-linguistics. Although Charles Darwin's pioneering work in this field emphasized that different emotions are expressed in particular ways on a vocal level as well as a facial level, the vocal level has been rather ignored, both in classical

psychological works (Tomkins 1963) and in the later development of this field. The same tendency has characterized the development of psycholinguistic research.

A number of laboratory studies of *vocal expressions of emotions* have, however, been undertaken in recent years; some are designed to measure acoustic characteristics with the aid of technological instruments; others are based on observers' coding of vocal behaviors (Pittam 1994). These studies demonstrate a relationship between emotions and their vocal expressions; between, e.g., joy, anger, fear, and different patterns of pitch, loudness, and speed.

Conversational and discourse analytical studies of vocal behavior should also be mentioned (→ Conversation Analysis). These studies focus on different displays of emotive communication, i.e., intentional expressions of feelings, rather than on emotional communication, i.e., the spontaneous, unplanned externalization of internal affects (Arndt & Janney 1991). Emotive communication is an important dimension in discourse. Most of our emotions, however, occur rapidly and below our immediate consciousness, and therefore outside the scope of our intentional planning.

The sociologists Thomas J. Scheff (1990) and Susanne Retzinger (1991) have developed a *theory of emotions in discourse* taking spontaneous vocal expressions into account. Their analysis has its starting point in a theory of interaction. Social interaction involves the building, repair, or damaging of social bonds. Self-feelings in relation to the other or others are, in other words, always involved in a process of interaction, while the emotional dimension of this process includes feelings of shame, on the one hand, and those of pride and confidence, on the other. Shame and pride are inner emotional states, which seem to be an almost continuous part of human existence.

Inspired by the psychoanalyst Helen B. Lewis, Scheff and Retzinger distinguish between *acknowledged and unacknowledged feelings of shame*. The latter refer to episodes involving feelings of shame that, while remaining unacknowledged by either party in the interaction process, nevertheless affect the course of its development in systematic ways. Feelings of shame find expression in specific paralinguistic *markers* such as stammering, repetition, extended narrative pauses, speaking in a low tone of voice, rapid speech, etc. Inspired by the work of Lewis, as well as a number of other contributions to micro-linguistics, Retzinger has assembled a list of the paralinguistic markers of shame and anger, whereas Bloch (1996) has identified paralinguistic markers of pride and joy. Markers of anger include staccato speech, loudness, and heavy stress on certain words; markers of pride include rapid, flowing speech, melodious speech, and mid-stream inhalation.

Scheff and Retzinger have developed a theory about the subtle *dynamic of shame* in discourse. Other sociologists have developed theories concerning the generation of solidarity among conversationalists through turn-taking processes and synchronization of various vocal features: pitch register and range, loudness, tempo, accent, and duration of syllables (Collins 2004).

Psycholinguistic and sociological studies of vocal expressions of emotions focus on variables such as: loudness; speed, as in rapid speech, stammering, stuttering, pauses; pitch level and range; changes in quality of voice, as in harsh voice vs soft voice; vocalizations that do not have the character of speech, e.g., sighing, coughing, laughing, in- and ex-halations; and specific linguistic patterns such as filler words, incoherent speech, and mitigations. The available, if limited, literature points up relationships

between these vocal markers and different affective states. However, these individual markers must not be confused with the emotion itself. Rather, they are to be understood as signs that, in particular contexts and given combinations, can indicate specific inner emotional states. Markers, therefore, are signs that can be ascribed meaning in the course of a contextual process of interpretation.

Many contemporary researchers show an increased awareness of emotions as active forces in social interaction, talk, and discourse. Micro-sociologists have developed theories concerning the dynamic and expression of shame, pride, and solidarity in discourse. Nevertheless, a comprehensive and systematic theory regarding the subtle structure of emotional meaning in discourse and the relationships between open and covert emotional meaning, including processes of encoding and decoding, is still not available. The growing research on emotions in interaction is a promising step toward a comprehensive theory; however, we also need to develop methodological tools to facilitate access to the different facets of emotions. The nonverbal level is an important emotional channel. This level includes not only facial and postural cues, but vocal cues as well.

## **Emotional Arousal Theory**

*Dolf Zillmann*

*University of Alabama*

Arousal is commonly construed as the experience of restlessness, excitation, and agitation. It manifests itself in heightened overt and covert bodily activities that create a readiness

for action (→ Physical Effects of Media Content). Acute states of such arousal characterize all vital emotions, and the subjective experience of these acute states is part and parcel of all strong feelings. Emotional arousal is consequently seen as an essential component of such experiences as pleasure and displeasure, sadness and happiness, love and hate, despair and elation, gaiety and dejection, rage and exultation, exhilaration and grief, frustration and triumph, merriment and fear, anger and joy, and so on (→ Emotion).

Features common to all acute emotions are that their high arousal intensity is comparatively short-lived and that they show a strong focus on both causal circumstances and motivational implications. Moods are also considered affective or emotional states that are associated with elevated arousal states. In contrast to emotions, however, moods are typified by lower arousal intensities and longer periods of persistence. Additionally, whereas emotions are instigated by apparent causes and, in turn, instigate cause-determined actions, moods lack such focus and are marked by motivational diffuseness instead.

As both the evocation of emotions and the modification of moods are essential factors in the appeal and effects of media presentations, and as the intensity of both emotions and moods is largely determined by excitatory reactivity, it is imperative to consider arousal in the context of media influence (→ Sensation Seeking; Mood Management).

### **THEORIES OF AROUSAL AND ITS FUNCTION IN EMOTION AND MOOD**

In early theories of motivation and emotion, arousal has been treated as a unitary force, energizing behavior that receives direction by independent means. In *behavior theory*, arousal was likened to an engine that drives but does not guide overt actions. The necessary guidance was considered to result from impulses that are at any given time prepotent in the habit structure, this structure being partly determined by instinct but mostly established through learning.

*Activation theory* similarly construed arousal as the behavior energizer and considered some form of cognition accountable for behavior guidance. The theory focused on activities in the brainstem reticular formation. Measured in wave patterns and rhythms of the encephalogram, states ranging from coma through sleep, drowsiness, relaxed wakefulness, and alert attentiveness to strong, excited emotions were distinguished and used to map emotion intensity.

In a *two-factor theory of emotion*, Schachter (1964) adopted the emerging dichotomy of energization by arousal and guidance by cognition. As some of the research conducted in connection with the theory involved the injection of epinephrine, an adrenal hormone that activates sympathetic excitation, arousal was implicitly operationalized as heightened sympathetic-nervous-system activity. Schachter focused on both the intero- and exteroception of arousal as emotion determinants (e.g., heart pounding, palm sweating) and suggested that this feedback indicates the intensity of feelings. He further argued that the feedback-mediated awareness of a state of arousal instigates an epistemic search for the causes of the reactions, and that the resultant cognitive appraisal of the causal circumstances allows individuals to comprehend the particular feelings or emotions they are experiencing (→ Appraisal Theory).

Zillmann (1996) proposed a *three-factor theory of emotion* that retains the distinction between energization by arousal and guidance by cognition. However, in order to explain

the origin of arousal reactions, this being left unaddressed in Schachter's theory, the guidance function is divided into a dispositional and an experiential component. The dispositional factor integrates ontogenetically fixed and acquired dispositions in accounting for the autonomic mediation of excitatory reactivity and the guidance of immediate, deliberate, overt behaviors. The experiential factor entails the cognitive evaluation of prevailing circumstances, including the appraisal of bodily feedback. In case these appraisals indicate inappropriate reactivity, this factor functions as a corrective by redirecting overt behavior and also, as far as possible, by initiating the regulation of autonomic activity.

Three-factor theory incorporates the conception of emergency emotions that implicates sympathetic dominance in the autonomic nervous system with the function of providing energy for an episode of vigorous action as needed for fight or flight. Although the conditions of modern life render most fight/flight reactions inappropriate, information about non-immediate threats to personal welfare, or about non-immediate opportunities for its enhancement, still generates strong arousal reactions that are meant to energize immediate emergency-resolving action. These strong arousal reactions become linked to all basic emotions and determine their behavioral intensity and the intensity of associated experiences.

Sympathetic arousal of both emotions and moods is controlled by brain structures integrated in the limbic system (LeDoux 1996). The episodic versus tonic arousal supply of emotions and moods is more directly mediated by different endocrine mechanisms. The high excitatory intensity of emotions is primarily a function of activity in the sympathetic adrenomedullary system with its release of catecholamines. In contrast, the low excitatory intensity of moods is primarily mediated by activity in the pituitary adrenocortical system with its release of cortical steroids. Activity in the pituitary gonadal axis with its release of gonadal steroids is likely to assist the excitatory function of both these systems (Henry 1986).

### **SENSATION SEEKING AND CONSEQUENCES OF EMOTIONS IN MEDIA COMMUNICATION**

The state of acute bodily arousal that accompanies intensely felt emotions is hedonically ambiguous and therefore liberally interpretable. When connected with fear, for instance, experienced sympathetic arousal is bound to be construed as unpleasant. When the same kind of arousal is linked to triumph, however, it will intensify the experience of genuine pleasure. Despite this hedonic plasticity of arousal, or perhaps because of it, its accumulation to extreme levels is often sought and the experience valued in its own right.

Intense excitement is sought via *exposure to the communication media* as much as through overt individual or social actions. The fact that the evocation of diverse emotions can be compacted in media presentations or in interactive media formats, such as games, actually provides optimal conditions for the creation of arousal escalations and, ultimately, for intense experiences of joyous excitement (Zillmann 2006).

Tannenbaum (1980), in pondering the tendency to maximize arousal for pleasure, placed the experience of intense arousal in juxtaposition to boredom, a state characterized by minimal arousal levels, and then proposed that essentially any jolt of arousal would be appreciated and hence sought out by persons living in the comparatively secure and often hapless environments of modern times.

Zuckerman (1979) elaborated this consideration, arguing that humans, like other primates, are genetically prepared to cope with aversive conditions on a regular basis, but that modern life deprives them of opportunities. He focused on a *need for stimulation*, essentially an inclination to seek out challenges, as an individual difference variable in order to explain why some persons are more driven than others to jump from airplanes, climb cliffs, do drugs, listen to deafening music, or watch horror movies. In Zuckerman's conceptual framework, stimulation is sought for its excitatory quality. Although such stimulation may be noxious on occasion or even most of the time, the dominant sensation of attained excitement is deemed to be one of pleasure. It seems more likely that, as arousing challenges are overcome, their termination will give impetus to pleasurable reactivity, and that the intensity of this reactivity increases with the severity of overcome challenges.

In contrast to Tannenbaum's and Zuckerman's contentions, the theory of excitation transfer does not stipulate the seeking of arousal for its own sake but explains any build-up of arousal as the unavoidable accumulation of remaining portions from preceding arousal reactions (Zillmann 1996; → Excitation Transfer Theory). Independent of the hedonic valence that may be linked to particular arousal reactions, residual sympathetic excitation from earlier reactions combines and ultimately intensifies later experiences in the progression of emotional response. If a later reaction is appraised as pleasant, an intensified euphoric reaction will be experienced. If the later reaction is deemed unpleasant, an experience of displeasure will be intensified, instead.

In this conceptual framework, noxious arousal is not sought for its immediate experiential quality. Rather, such arousal is accepted as a necessary prelude to intense joyous reactions that are evoked by the resolution of distressing events, and it is the stimulation package featuring both challenge and its triumphant management that is sought out. The phenomenon of suspense in drama, sports, reality programs, and the news, as well as in the drama of daily life, generalizes this particular "dramatic" conversion. The appeal of media violence has been similarly explained as due to terror arousal that intensifies the satisfaction experienced in the justice-restoring heroics of concluding events (Sparks & Sparks 2000).

Arousal influences permeate numerous other effects of media exposure too. It has been shown, for instance, that exposure to highly arousing pleasant erotica can facilitate social aggression more than can somewhat less arousing exposure to violence. Such findings have called into question the sole focus on media content in the creation of behavioral effects and fostered a reorientation that demands the consideration of excitatory circumstances (→ Violence as Media Content, Effects of; Media Effects).

An illustration of arousal consequences other than emotion enhancement is, for example, the *arousal-induced attention deficit* concerning events unrelated to the specific arousal instigation. It has been observed that, within a newscast, reports that follow emotionally disturbing reports receive little attention and are poorly processed as a result. During states of acute arousal, the limited capacity for information processing is apparently preoccupied with the witnessed events that caused that state (→ News Processing and Retention).

As the hedonic quality of mood also depends on the cognitive appraisal of the prevailing circumstances, mood changes are analogously subject to transfer enhancement. Although

residual amounts of arousal from earlier moods may be comparatively small, they should nonetheless elevate the experience of different, newly materializing moods. During low arousal states of boredom, for instance, exposure to arousing dramatic programs as well as to arousing musical selections is generally preferred to exposure to less arousing stimulation. Immediate arousal supplementation is apparently an effective way to normalize and improve mood.

Mood manipulation may also serve opposite ends, however. Tranquil environments, real or mediated, are capable of dissolving arousal and thereby relax noxious tensions from preceding emotional experiences. Deliberate exposure to calming media presentations can thus remove the possibility of arousal from undesirable emotions and moods. The indicated ameliorating effect was observed, for instance, in viewers who had watched a distressing newscast. The aroused viewers expressed grievous concerns about the issues addressed in the news. Their concerns greatly diminished, however, by the intervening exposure to an emotionally calming report. The dissipation of arousal is apparently capable of reducing the intensity of apprehensions and fears. This effect seems to be well understood by news programmers, as news programs routinely conclude with light-hearted news items (→ Fear Induction through Media Content).

# Emotions, Media Effects on

*Werner Wirth*

*University of Zurich*

Emotions are commonly understood as a complex of interactive entities encompassing subjective and objective factors and consisting of affective, cognitive, conative, and physiological components. The affective component includes the subjective experience of situations, which is connected to feelings of arousal (→ Excitation and Arousal), pleasure, or dissatisfaction (→ Emotion). The cognitive component refers to how situations relevant to emotions are perceived and evaluated (→ Cognition). The conative component is related to expressive behavior, including facial and vocal expression and gestures (→ Facial Expressions; Gestures and Kinesics; Paralanguage). Also, emotions embed action tendencies such as approach (e.g., anger) or avoidance (e.g., anxiety; → Appraisal Theory). Finally, the physiological component encompasses peripheral reactions of the body that are mediated by the autonomous nervous system (physiological arousal).

Studies on media and emotion usually follow one of two research logics. They focus either on effects on arousal and valence of emotions (dimensional view) or they explore the effects on discrete emotions such as anxiety, fear, anger, or aggressiveness (discrete emotion approach). There is no doubt that media are capable of inducing emotions during the communicative phase – and there is a growing body of research dealing with the conditions and effects of emotional responses (Wirth & Schramm 2005). Here, → television is viewed as more emotionally arousing as compared to print, partly due to technological features and the emotional storytelling of television (→ Storytelling and Narration). In addition, media-induced emotions play a crucial role for → media effects, for example for learning, perceived risk (→ Risk Perceptions), → persuasion, and decision-making (→ Excitation Transfer Theory). It is mainly this intermediary role that makes emotion so essential for media effects research.

## EMOTIONS AS INTERVENING AND DEPENDENT VARIABLES

This entry focuses on short-term and long-term media effects on emotions after the communicative phase. There are at least two major and four minor research areas with a special emphasis on emotional media effects: (1) effects of media violence on hostile feelings and aggressiveness (→ Violence as Media Content, Effects of), (2) effects of media on the cultivation of fear (→ Cultivation Effects; Fear Induction through Media Content), (3) effects of political media content on emotion, (4) fear and frustration as effect of terrorism reports, (5) dissatisfaction with one's body as effect of thin model images, and (6) positive feelings and parasocial relationships as effect of repeatedly viewing favored serials and soaps (→ Parasocial Interactions and Relationships; Soap Operas).

### Effects of Media Violence on Aggressiveness

Within the media and violence research, effects on aggressiveness are discussed as emotional effects. Experimental research finds consistently that youths who heavily watch

violent television scenes or movies subsequently display more aggressive behavior, aggressive thoughts, and aggressive emotions than those who do not (Anderson et al. 2003; → Experimental Design; Violence as Media Content, Effects on Children). In a prolonged exposure experiment, Zillmann and Weaver (1999) demonstrated that after watching violent films on four consecutive days, male and female respondents showed increased hostile feelings and hostile behavior, independently of whether they had been provoked or not. Experimental studies explored as well the impact of violent computer games on state hostility, state anxiety, and arousal. Participants reported significantly higher state hostility, but not higher state anxiety. Playing a violent video game for as little as 10 minutes increases the player's automatic association of "self" with aggressive actions and traits, thus making aggressive thoughts and feelings salient. Past history of exposure to violent video games might fortify this process (Uhlmann & Swanson 2004). Moreover, evidence from correlational studies suggests that exposure to violent video games results in lower empathy (→ Computer Games and Child Development; Correlation Analysis).

The theoretical framework for many of the more recent studies on the effects of violence is the General Affective Aggression Model (GAAM). It suggests that violent media contents may increase aggression by increasing hostile feelings and the accessibility of aggressive thoughts. Furthermore, it provides a link between short-term and long-term effects of media violence. According to this model, viewing violent media content primes related aggressive thoughts in semantic memory (→ Framing Effects; Priming Theory). In turn, priming effects increase the probability of an aggressive response to provocations, real or imaged, by increasing hostile affect, by promoting hostile interpretations of the provocation, by instigating use of aggressive behavioral scripts, or by using learnt role models. Meta-analyses allow the conclusion that high levels of violent TV programs in childhood can promote aggression in later childhood, adolescence, and even young adulthood (Anderson et al. 2003; → Meta-Analysis).

Another emotional effect of exposure to violence is → desensitization. Emotional desensitization occurs when people who heavily watch media violence no longer respond with as much unpleasant physiological arousal or feelings as they did initially. Because unpleasant physiological arousal and empathy normally have an inhibitory influence on thinking about violence or on behaving violently, emotional desensitization can result in a heightened likelihood of violent thoughts and behaviors (Huesmann et al. 2003).

### **Effects of Media on the Cultivation of Fear**

Media programs are able to evoke fear that is comparable with fear experienced in other situations than media use. In their cultivation studies, → George Gerbner and colleagues have shown that the reception of media programs can have the effect of fear and anxiety. Frequent TV viewers have exaggerated ideas about how many persons are involved in cases of violence per week, and correspondingly have inappropriately high levels of fear (→ Media and Perceptions of Reality). In other studies only small cultivation effects or only effects of high exposure to dramatic programming like crime-saturated local television news could be found. Especially for children, anxiety-evoking media programs can have long-term negative effects (Cantor 2002). However, children gradually develop a set of regulation strategies to deal with anxiety-evoking media content. Blunting is applied most

frequently – followed by monitoring, and seeking support. Several researchers found that long-lasting states of anxiety after early childhood media reception are not rare among juveniles or college students.

### **Effects of Political Media Content on Emotion**

Emotional responses to politicians or to political events are often determined by an interaction of predispositions (e.g., conservative versus liberal) with media characteristics. Gross and D'Ambrosio (2004) experimentally explored possible framing effects on emotions, using news reports about the 1992 Los Angeles riots (→ *Framing of the News*). They found interaction effects between different frames (social conditions versus criminality as cause for the riot) and predispositions like ideology and resentment. Similarly, research demonstrated that emotional responses to politicians are generated by an interaction of predispositions and nonverbal displays.

### **Fear and Frustration as Effect of Terrorism Reports**

News of catastrophes or terror attacks can induce lasting emotional effects. In the context of the September 11, 2001 terrorist attacks, a couple of studies explored emotional reactions of the media users. Results from a panel study suggested that heavier television news use sustained a higher level of negative emotional reactions (fear, frustration, anger) to the terrorist attacks than heavier newspaper use (Cho et al. 2003). Simultaneously, it was found that respondents' emotional responses to the attacks had a significant positive effect on the following television news viewing, thus indicating a reciprocal process.

### **Body Dissatisfaction**

The media have been criticized for depicting the thin woman as ideal, because these images could cause body dissatisfaction (→ *Body Images in the Media; Women in the Media, Images of*). These studies are based on → Leon Festinger's social comparison theory, on Gerbner's cultivation theory, or on → Albert Bandura's social cognitive theory. Two recent meta-analyses revealed mixed empirical results, maybe because of inconsistently used concepts, media measures, design types, and comparison stimuli. At least for some groups (participants under 19 years and those who are vulnerable to activation of a thinness schema), effects of thin model images on body dissatisfaction seem to be likely (Holmstrom 2004).

### **Parasocial Interactions and Relationships**

Parasocial interactions and relationships are those between television viewers and the characters they watch, involving mainly positive, warm feelings like intimacy. Contrary to parasocial interactions, parasocial relationships continue beyond the viewing period. Viewers experience characters as close friends or at least as good neighbors. According to Cohen (2003), women develop stronger parasocial relationships than men. In a hypothetical situation, when the favored character would be taken off the air (parasocial breakup),

viewers tend to fear breakup from fictional characters more than from real characters. Furthermore, parasocial interactions and parasocial relationships seem to reinforce reciprocally.

## THE FOCUS OF MEDIA EFFECTS RESEARCH

Taken together, it can be stated that there are considerable short-term and long-term, positive and negative media effects on emotions beyond the reception situation, regarding different media, different programs, and different parts of the audience (age and sex). However, media effects on emotion beyond the reception situation seldom constitute the basic interest of communication researchers. More often, research deals with media-induced emotions during the reception phase or with the intermediary role of emotions for further effects.

# Empathy Theory

*Dolf Zillmann*

*University of Alabama*

Empathy is a social → emotion. It comes in response to bearing witness to the emotions of others, usually persons but also other beings thought capable of experiencing emotions. Prototypically, an empathic reaction is evoked by the immediate observation of others' acute emotions, and it manifests itself in an emotional experience that the witness believes to have some degree of similarity with the witnessed emotions.

The evocation of empathic reactions is not limited, however, to the direct observation of others' emotions in terms of their facial, bodily, and other behavioral expressions. Empathy can be evoked by the presentation of information about the circumstances of others that are presumed to cause acute emotions in these others. Moreover, empathy can be evoked by information about others' situations and actions that are presumed to have been caused by acute emotions these others experienced earlier (Stotland 1969; Hoffman 1978; Zillmann 2006b). The evoked empathic reaction itself constitutes an emotional experience, primarily because it is associated with increased excitement and awareness thereof (→ Excitation and Arousal). This awareness tends to foster a subjective appraisal of the reaction as *feeling with* or *feeling for* the observed party.

## THEORIES OF EMPATHY

The theoretical examination of empathy has pursued two different objectives. First, it has addressed the biological function or purpose of empathic reactivity, essentially the question *why* we empathize. Second, it has focused on the mediation of empathic reactivity in psychological, physiological, and behavioral terms and yielded various mechanisms of *how* we empathize.

### Evolutionary Approaches

The phylogenetic roots of human empathy have been derived from an abundance of empathy-like reactions in numerous animal species (Plutchik 1987; Buck & Ginsburg 1997). The principal observation is that genetically fixed expressions of emotional reactions, when witnessed, trigger genetically fixed like reactions, and that such emotional contagion fosters behavioral coordination that ultimately serves the survival of the species.

The coordination of flight by the empathic spread of fear in groups of endangered animals is a prime illustration of the adaptive value of empathy. The adaptive utility of empathic contagion extends to all behaviors of consequence, including coordinated aggression (→ Communiobiology).

### Empathy as Reflexive Reactivity

Theories that base human empathy on the reflexive contagion of emotions may be considered direct extensions of bio-evolutionary proposals. These theories posit that, as

we observe others' emotions, innate response dispositions initiate parallel emotions that resist inhibitory efforts (McDougall 1922). In a more elaborate form of this rationale, it is posited that observers, in giving way to innate dispositions, involuntarily mimic the observed party's posture and gestures, and that afferent feedback from this mimicry liberates empathic affect because it connects to the observers' affective experiences associated with the mimicked expressions (Lipps 1907; Tomkins 1962; Izard 1977).

The recent discovery of so-called mirror neurons has given support to the involuntary nature of empathic response by showing that the perception of others' actions excites areas in the human motor cortex that correspond with those controlling the observed actions, thus creating a propensity for empathic motor mimicry (Buccino et al. 2001; Fadiga et al. 2005).

### **Empathy as Acquired Reactivity**

Theories that project empathic reactivity as acquired invoke traditional learning paradigms. Socially parallel affective experiences define the forum in which empathic response connections are formed on a trial-by-trial basis. As particular environmental stimuli jointly and concurrently induce specific emotional experiences in both an observed person and an observer, the observed person's expression of emotion becomes associated with the observer's own emotion. With repeated experiences of this kind, the expression of specific emotions observed in other people will gradually assume the power to elicit the same or a similar emotion in observers (Humphrey 1922; Aronfreed 1970).

Such acquisition of empathic reactivity is developmentally relevant and, accordingly, considered essential during childhood and adolescence (Hoffman 1978). Regardless of developmental considerations, however, acquired empathic reactivity is spontaneous, but may be more malleable than reflexively controlled empathy.

### **Empathy as Cognitively Mediated Reactivity**

In contrast to theories that base empathic reactivity on built-in or acquired elicitors, cognitive theories project empathy as a result of deliberate and mostly conscious cognitive efforts, along with deliberately or spontaneously recruited associations in the cognitive network of the person who witnesses or is informed about another's emotions. The deliberateness of empathy is apparent in the formula that characterizes cognitive theory, namely "to put oneself into another's position." Such cognitive assimilation of another's emotional experiences places considerable demands on the imagination and resolve of those who attempt to empathize. The purely cognitive efforts are usually assisted, however, by the encounter of, and connection with, related experiences of the responding person. The result is that memory-based affective reactivity enriches the experience of cognitively relating to others' emotions and, in fact, tends to render it an emotional one (Rogers 1967; Stotland 1969; Smith 1971, 1st pub. 1759).

As empathic reactivity via the cognitive assimilation of others' emotions presupposes comparatively mature mental skills as well as rich emotional experience, it is usually considered a domain of post-adolescents and adults.

### Integration of Theoretical Approaches

The various mechanisms of empathic reactivity that are proposed in these distinctive theories can be considered established by pertinent research findings (Davis 1996; Eisenberg 2000).

It has become clear, however, that the validity of each of the theories is partial to, and ultimately limited by, specific situational and behavioral contexts. Moreover, it is apparent that, in producing empathic reactivity, the operation of several of the specific mechanisms is usually confounded. For instance, the reaction to witnessing others' acute emotions may be reflexive initially but then be supplemented by acquired dispositions, and it may eventually involve reflection of the circumstances that further deepens the empathic experience.

This likely interplay of mechanisms that contribute to empathic reactivity is addressed in integrative theories such as the *three-factor theory of empathy* (Zillmann 2006b). The three-pronged approach entails evolutionary considerations in a "dispositional factor" that combines reflexive and acquired response components in the elicitation of spontaneous and impulsive incipient empathic reactivity. An "excitatory factor" focuses on the emotional intensity of empathic reactivity that is analogously mediated by reflexive and acquired dispositions. The third, "experiential factor," addresses the contemplation of the emotion-evoking circumstances as well as of the evoked reactivity for both the observed party and the empathizer. As this contemplation is likely to activate salient emotional memories in the empathizer, the experience may be greatly enhanced, even in excitatory terms. Contemplation may also function as a corrective, however, and diminish reactivity that is deemed inappropriate under the given circumstances.

### WHEN EMPATHY FAILS

In accordance with evolutionary rationales, empathy may be considered to constitute a default system for affective reactivity in that concordant affective response is generally more adaptive than alternative reactions. However, except for incipient empathic reactivity that is reflexively controlled, empathy is subject to curtailment and even to hedonic reversal (→ Affective Disposition Theories).

The condition that is primarily responsible for the eradication of empathic response inclinations as well as for the hedonic reversal of empathic reactions is the *affective disposition* toward those whose emotions are witnessed or inferred (Zillmann 2006a, 2006b). Put simply, dispositions of indifference do not appreciably engage the affections of witnesses to others' emotions, and those who hold dispositions of disdain and hatred toward witnessed parties are bound to enjoy these parties' misfortunes and suffering as much as they would be distressed by witnessing their good fortunes and happiness.

Dispositions of enmity, then, are not only capable of eliminating all empathic inclinations but will foster *hedonically reversed affective reactions* whose experiential intensity tends to be comparable to that of empathic reactions by people with dispositions of amity. To the extent that dispositions of enmity are stronger than those of amity, which is frequently the case, reversed affect can be more intensely experienced than empathic

affect. The reversal of empathy can be considered accomplished by the same mechanisms that yield empathy. Analogous to the formation of empathic dispositions, the dispositions for hedonically reversed reactivity, also referred to as counterempathy (Stotland 1969) and discordant affective reactivity (Berger 1962), may be acquired via repeated learning trials. Additionally, reflective assessments, culminating in moral judgments, may not only disapprove and censure empathic reactivity, but may endorse and actually demand discordant affective reactions.

## EMPATHY AND ITS REVERSAL IN MEDIA COMMUNICATION

Empathic and counterempathic reactivity is obviously not limited to immediately witnessed social situations but extends to simulated realities, such as in the cinematographic representations of actual events or in linguistic accounts of these events (→ Emotions, Media Effects on).

Research evidence leaves no doubt about the fact that representations of realities are capable of engaging the emotions of respondents as strongly as the direct observation of these realities. Depending on affective dispositions held toward people in reality programs or the → news, empathic and counterempathic reactivity to such programs abounds (Bente & Feist 2000; Zillmann & Knobloch 2001; → Exposure to News).

Surprisingly, empathic and counterempathic reactivity is not necessarily diminished by the unreality of depictions. Such reactivity occurs despite the fact that respondents may recognize and, at least at times, be aware of the fabricated nature of presentations. In fact, fictional narration has been viewed as the ultimate forum for empathy and related affections (Zillmann 2006a; → Fictional Media Content).

The principal reasons for the apparent power of fictional media presentations to evoke empathic and counterempathic reactions are the following: (1) the dispositions toward characters, whether of admiration or contempt and disdain, are readily created by the display of the characters' morally approved versus condemned intentions and actions (Raney 2006); (2) the characters' experience of good or bad fortunes and the respective emotional consequences thereof can be displayed in greater detail than usually can be perceived in the direct observation of events (Zillmann 2006a); and (3) segments of the narrative are compacted and can be arranged such that residual excitation from empathic or counterempathic reactions elicited by some segments will intensify empathic or counterempathic reactions to segments that more or less immediately follow (→ Excitation Transfer Theory).

Given these *manipulatory possibilities*, elements of fictional narratives can be creatively composed so as to maximize empathy in order to make happy occasions wonderfully enjoyable and, analogously, heart-rending outcomes supremely tragic. At the same time, fictional narratives can be arranged so as to maximize counterempathy in order to torment those who deem the good fortunes of resented characters a travesty and to give unmitigated joy to those who consider patently brutal punishment of evil characters their just deserts. The latter consideration points to a potential benefit of fictional portrayals that feature the liberal punishment of wrongdoers. Only the fictional format allows unhampered counterempathic rejoicing upon witnessing the destructive, punitive treatment of those deemed deserving of such fate.

# Endorsement

*Cecilie Gaziano*

*Research Solutions, Inc.*

Newspapers report → political news and may also attempt to influence voting decisions through editorial endorsements, that is, formally stated support of political candidates or parties (→ Election Campaign Communication). In countries following the US and British system of organizing newsrooms, the news media have separate news and editorial staffs and pages, although it is not unusual for a news editor to sit on the editorial board. In other news systems, e.g., in most continental European countries, it is quite common that the same individual journalists who cover the news might also write editorials about the same events (Esser 1998). Nevertheless, in all systems the editorial goal is to give meaning and context to news and complex issues, whereas news reporting seeks to be impartial (→ Balance; Objectivity in Reporting). Many newspapers try to present a range of viewpoints in the editorial pages, such as letters to the editor and opinion columns from various sources, including the → public. The editorial staffers meet to discuss and vote on positions; however, publishers sometimes overrule them. The larger the newspaper, the easier it is to maintain separation of news and opinion. Other media endorse less frequently than newspapers.

Endorsements of political candidates, parties, or issues are only an ethical problem of the press when the endorsed candidate, party, or issue also receives more favorable coverage in the news pages. Whether or not *synchronization of news and editorials* happens unconsciously or by directions given by management or senior editors is a matter for empirical research. Some research has shown that journalists with favorable attitudes towards a subject tend to attribute a higher → news value to news items that speak in favor of this subject and a lower news value to items that speak against it (Kepplinger et al. 1991; → Instrumental Actualization). Although in many democratic political systems newspapers seek to clearly separate editorials and the news, many researchers question whether or not endorsements of candidates or parties influence their campaign coverage, since many studies link endorsements and people's voting choices (→ Separation of News and Comments).

Some researchers have found that newspaper-endorsed candidates in the US received more favorable treatment than non-endorsed candidates, on various election levels – local, state, and national (e.g., Kahn & Kenney 2002). Others reported mixed results (Pritchard 2002) or little influence of endorsement (Dalton et al. 1998). Research on newspapers across several US elections indicated that, for more than 60 years, those newspapers increased frequency of federal and statewide office endorsement, yet their partisanship decreased markedly (Ansolabehere et al. 2004). In addition, the papers increasingly preferred incumbents, reflecting an increasing shift in American politics toward greater voter support of incumbents.

As the group ownership of newspapers increased in the US between the 1960 and 1972 election years, concern about the *influence of economic concentration on editorial policy* intensified (→ Concentration in Media Systems). Wackman et al. (1975) concluded that, compared with non-chain papers, chain papers typically were high endorsers and

substantial numbers of chains were homogeneous in endorsements within elections and across at least three of the four elections. Only multiregional chains demonstrated less homogeneity. In the subsequent four elections, groups still tended to be homogeneous endorsers, but this tendency was much less pronounced (Gaziano 1989). Chains that grew in size and regional breadth tended to be heterogeneous endorsers. Homogeneous chains outnumbered heterogeneous chains, but heterogeneous chains had larger circulations. Busterna & Hansen (1990) analyzed data also from three of these four subsequent years, using somewhat different definitions and methods, concluding that chains and non-chains both tended to endorse Republicans and that results on homogeneity were mixed. One Canadian study found structure of ownership did not influence editorial positions (Wagenberg & Soderlund 1975).

Corporate newspapers, which tend to be in larger, more pluralistic communities, tend to publish more editorials oriented toward local issues and criticism of mainstream organized groups than do entrepreneurial newspapers, which are more often located in smaller, more homogeneous communities (Demers 1996). Newspapers in democratic systems tend to perceive their editorial role as providing leadership and stimulating discussion while preserving neutrality in their news coverage, whereas “endorsement” in authoritarian systems involves little or no separation of news and editorial sides and strives to maintain social control by suppressing debate.

## English-Only Movements

Valerie E. Barker

*San Diego State University*

English-only movements seek to establish English as the official language of a nation, part of a nation, or a colony. As such (as with other dominant languages), English acts as a communicator of social identity (→ Personality Development and Communication) and a vehicle of culture and economic power (→ Power in Intergroup Settings). Although proponents of English-only cite concerns about the erosion of English as a primary language, English is often seen as a language of wider communication, a world language, the language of globalization, and of the Internet. Underlying these descriptors is the notion of English as somehow “neutral” and non-threatening to multilingualism. Historically though, English either spread to or was imposed on minorities, indigenous populations and colonized peoples. This occurred first under English monarchies and the British Empire, exemplified by its imposition upon the Scots, Welsh, and Irish as well as its use almost exclusively in education systems of far-flung colonies like India and Africa. In the USA, Native Americans were systematically punished for non-English use and their children educated in boarding schools in order to diminish indigenous languages. Recently, English has come to be considered a “lingua franca” largely because of the number of English speakers (native and non-native) in the EU and because of USA corporate dominance globally (→ Media Conglomerates). Thus, among those of “Anglo-Saxon” origin especially, English has served as a tool for maintaining the proverbial upper hand and consequently possesses high linguistic vitality (→ Ethnolinguistic Vitality and Communication).

That said, conservative Anglo-American interest groups in the USA (e.g., US English; English First) especially and USA Anglos in general have supported moves to legislate English as the official language. As an intergroup marker, language triggers social comparison (→ Language Attitudes in Intergroup Contexts), becoming a lightning rod whenever dominant groups feel beleaguered by growing minorities (Barker & Giles 2002). *English-only policies*, such as prohibition of other languages in government, education, and the workplace, represent strategies designed to maintain a group’s ascendancy over others (Barker et al. 2001), and are akin to other forms of limitation such as denial of government services, education, and citizenship. So far, 27 USA states have adopted English as

their official language, a largely symbolic act. However, in May 2006, the USA Senate voted English as the “national” language, declaring that federal services should not be in any other language except for those already allowed by law. President George W. Bush stated that immigrants must learn English and that the national anthem should be sung only in English (a reaction to a Spanish-language version of the “Stars and Stripes”).

This underscored the widely held assumption that immigrants do *not* learn English, an assumption which is not supported by research (or by the USA census), since most immigrants are monolingual English speakers by the second or third generation. Regardless, perceptions about the disappearance of English have led to a backlash against bilingual education in the USA and a return to English-only immersion for immigrant children (particularly in California and Arizona, where Spanish speakers are numerous). This in turn has led to negative outcomes for English acquisition and academic achievement among immigrant students. So far USA English-only advocates are most active, although factors associated with support for English-only policies do exist in other core English-language nations.

In *Britain*, immigrants have brought different languages from former colonies and recently from the Middle East and the EU. While immigration is a source of public concern, language conflicts are less salient than issues such as “bogus” applications for political asylum. However, in 2002 the home secretary, David Blunkett, caused controversy by recommending that immigrant parents should not only learn English but also speak English to their children at home. Additionally, since November 1, 2005, naturalization candidates are required to show English, Welsh, or Gaelic proficiency by passing a test or by attending English-language and citizenship classes. In *Australia* and *New Zealand*, national governments have acknowledged the importance of linguistic diversity. Nonetheless, studies investigating perceptions of linguistic vitality among Australian Anglos report that high contact and lower education predict exaggerated perceived vitality of minority languages relative to English. English is the majority language in New Zealand, but Maori is the official language and is widely represented in signage and English-based publications. However, although immigrants to New Zealand complete language shift relatively rapidly, some Anglos are hostile to non-English languages.

Much popular and academic commentary debates English-only issues, but little *communication* research has investigated the impetus for such measures. In the USA, over 82 percent of residents speak *only* English and for most Anglos contact with non-English speakers is still limited. (In Iowa 94 percent of the people are non-Hispanic whites, and yet the state lately adopted English as its official language.) Future research should examine the potential influence of the news media (→ Framing of the News) as a source of information concerning language minorities and language shift in the USA and other core English-language nations. Similarly, the influence of non-English mass media on subjective perceptions of linguistic vitality is still largely unknown and should be assessed (→ Ethnic Media and their Influence).

## **Enjoyment/Entertainment Seeking**

*Christoph Klimmt*

*Johannes Gutenberg University of Mainz*

As early as 1962, → Elihu Katz and David Foulkes wondered why communication researchers had almost exclusively addressed mass media's persuasive capacities (→ Persuasion) and almost completely neglected its role as an agent of entertainment. Their surprise was caused by the simple observation that the bulk of mass media consumption at that time served entertainment needs – an observation that is equally, if not even more, valid today (→ Exposure to Communication Content). Cinema movies, television series, radio music, illustrated magazines, and video games (to name just a few examples) frequently attract mass audiences and serve as reliable “cash cows” of the media industries (Wolf 1999). Interestingly, communication research has begun to reflect the remarkable importance of media entertainment very late in the day. Since then, significant theoretical progress has been made on the description and explanation of entertainment experiences (Bryant & Vorderer 2006).

### **THE DIVERSITY OF MEDIA ENTERTAINMENT**

Entertainment research is confronted with a huge number of different manifestations of its object. For instance, a broad range of television content is categorized as entertainment programming: crime drama, comedy and → situation comedies, reality shows, live shows, call-in shows, melodrama, sports broadcasts, adventure movies, mystery shows, daytime talk shows, late night shows, and many more. Other media offer a similar bandwidth of entertainment, such as dozens of video game genres, countless radio music styles, or highly distinct types of novels (→ Media Production and Content). To say that somebody is seeking media entertainment can therefore mean very different things: highly diverse motives may evoke entertainment seeking; highly diverse reaction processes may trigger

actual entertainment experiences; and specific person–medium interactions may produce numerous kinds of entertainment media effects.

This diversity challenges the perspective of a unified and simple theory of media entertainment that could describe and explain why people attend to *any* enjoyable media messages and how media enjoyment unfolds. Therefore, entertainment theory is trying to find the common base for the diverse manifestations of media enjoyment and, at the same time, to collect the many different psychological mechanisms and pathways through which actual entertainment experiences occur (Vorderer et al. 2004, 2006).

### MOTIVES BEHIND ENTERTAINMENT SEEKING

Klimmt (2006) has proposed two general classes of motives that can manifest in the wish to expose oneself to very different kinds of media entertainment. One class of motives refers to a *short-term action disposition* that is similar to the notion of → escapism. Media entertainment provides possibilities to distance oneself from undesired conditions such as boredom, loneliness, overexcitation, sleepiness, or frustration. Individuals who are seeking experiences that contrast their current, undesired condition have the choice between various entertainment media that provide the matching mode of escape (→ Excitation and Arousal; Fantasy/Imagination). As a consequence, negative moods that accompany the undesired state are improved and repaired (Zillmann 2000). So the experience of media entertainment contrasts the stressful states that arise from day-to-day activities (for instance, professional work, housekeeping, or family conflicts) and contributes to mental relaxation and recovery. The motive to seek media entertainment is thus the desire to overcome aversive and/or undesired short-term (state) conditions through temporal mental distancing (“escape”) from these conditions. What kind of escape is strived for, then, depends on the quality of the undesired state the media user perceives. The short-term compensation motive is thus capable of explaining decisions for very different entertainment media (→ Mood Management).

While the escape motive to seek entertainment is rooted in communication, the other class of motives underlying entertainment seeking is derived from the *psychology of play*. Playing displays several striking conceptual similarities with the use of media entertainment (→ Vorderer 2001; Evolutionary Theory; Intrinsic and Extrinsic Motivation and Volition; Playing), and Klimmt (2006) argues that the desire to cope with life and to resolve developmental challenges drives entertainment seeking. Developmental challenges are typically overcome through learning. Social orientation about what other people do in certain (e.g., emotional or family) situations is helpful to expand one’s repertoire of conceivable actions (Bandura 2001).

Watching *talk shows*, for instance, can help to cope with specific life situations, as they transport information about what other people have done (→ Broadcast Talk). Watching action movies can reassure viewers of the world being a just place in which it is worth working for morally good goals and striving for one’s individual happiness. Another good example has been elaborated by Jansz (2005). He argues that violent video games are enjoyable for male adolescents because these games provide a virtual test laboratory to experiment with properties and emotions associated with the male gender role (e.g., courage, honor, competition, defeat, fright). Violent *video games* are thus a tool to resolve the major

developmental task male adolescents are confronted with; that is, the adoption and definition of a male gender role. Playing such games is experienced as negotiation of masculinity, which in turn is enjoyable. In this sense, violent games help male adolescents to cope with life. That does not, of course, mean that this support will necessarily lead to appropriate and socially acceptable role images (→ Computer Games and Reality Perception; Video Games).

Vorderer et al. (2006) argue in a similar way when they root the wish to be entertained back to evolutionary processes. Playful learning about life is part of humankind's genetic survival program, as it facilitates gain of competence and flexible adaptation to environmental conditions. In the modern world, entertainment seeking is, according to Vorderer et al. (2006), a residual motive of this urge toward playful learning. The evolutionary perspective thus backs up the assumption of coping with life as generalized (class of) motives underlying entertainment seeking.

### **SPECIFIC SELECTION OF MEDIA ENTERTAINMENT**

Entertainment seeking is, of course, more than the enactment of a more or less abstract motive to escape from certain states and/or to cope with certain life conditions. Since there is so much media entertainment out there, specific decisions about which media product is to be used are required. The most effective heuristic to decide for a given entertainment offer is prior experience. Zillmann's (2000) concepts of → selective exposure and mood management assume that media users memorize what a specific product of media entertainment has done to their mood and use this memorized information for subsequent media selection. When people face a situation in which they desire a certain kind of mood repair, they will select an entertainment product that they remember to have facilitated that kind of mood repair in the past (→ Affects and Media Exposure).

Specific selection of media entertainment may be executed on the base of other heuristics as well. In most entertainment media, people play a central role – for instance, sports stars, movie actors, talk show hosts, or famous video game characters such as “Mario.” Several lines of entertainment theory address the quasi-intimate, social-emotional bonds between media users and people in entertainment media, such as → empathy theory, → identification, → parasocial interactions and relationships, and disposition-based theories of enjoyment (→ Suspense). Positive attitudes toward certain media characters (e.g., a favorite actor, a preferred sports team) may thus serve as a heuristic to decide for specific entertainment media (e.g., to decide for *CSI: Miami* and against *CSI: New York*).

### **READINESS TO ENGAGE IN THE EXPERIENCE**

To achieve the desired experience of “being entertained,” media users have to accomplish more than finding and deciding on a suitable entertainment medium. They must also adjust their personal mode of processing to allow the according entertainment experience to occur. Most entertainment media are only enjoyable if their users are deeply absorbed, immersed, and fascinated. Several concepts have been proposed or applied in entertainment research that describe this condition; for instance → involvement with media content, → presence, and → transportation theory, or flow (Sherry 2004).

Such states of “diving into” the media world can be evoked by certain media attributes (e.g., a large screen size or a thrilling story). But media users have to admit this absorption in order to achieve the desired state of intensive entertainment (Wild et al. 1995). For example, movie viewers have to (actively) ignore their knowledge that everything they see is artificial and unreal in order to access a strong experience of the movie world (→ Suspension of Disbelief). Deciding for a specific piece of media entertainment, then, also implies some self-adjustment by the users to “let the desired experience happen to them.” Such self-regulatory processes have not been researched extensively so far (→ Sensation Seeking), but there are theoretical arguments for their importance in the process of media entertainment (Klimmt 2006).

Enjoyment/entertainment seeking is a complex phenomenon that is driven by different motives, can refer to very different media products, and is connected to complex and diverse responses to those media products (e.g., Ritterfeld & Weber 2006). The use of media entertainment is vital for everyday life; it supports coping with aversive states (e.g., stress, loneliness), long-term life situations, and developmental tasks. It can thus impact well-being and life-satisfaction positively. From an evolutionary perspective, seeking entertainment is a “natural” human behavior, and most people benefit from entertainment consumption. However, as with any other activity, an overdose of media entertainment is likely to counteract these benign consequences or even turn them into negative ones. The complexity and the potentially huge implications of entertainment (seeking) for individuals and society therefore justify the increased research efforts in communication and suggest a further expansion of entertainment research in the future.

## Entertainment Content and Reality Perception

Gabriel Weimann

University of Haifa

Our perceptions of reality may often rely on mass mediated images. Walter Lippmann's classical work, *Public Opinion*, first published in 1922, highlighted the possibility that factual features of the world often have little relation to the perception and beliefs that people entertain about the world (→ Lippmann, Walter). Lippmann (1922) argued that the press's depiction of events was often spurious; the images it created were misleading, distorted, and shaped false "pictures in our heads" of the "world outside." Although Lippmann never formulated his ideas in terms of a model or theory of reconstructed realities, his notion of the reliance of the public on the often distorted presentation of reality in the media should be acknowledged as such. Lippmann made the important distinction between the real environment and the pseudo-environment, sketched and delivered by the mass media. However, although Lippmann had vision concerning the differences between reality and perceptions of reality, he could not anticipate the emergence of the electronic media and the ever-growing role of the new media in shaping "the pictures in our heads." As radio, and then television, cable, and satellite technologies,

and then the Internet, appeared, the world shrank to a global village, exposed to the flow of mass-produced news and entertainment, and the notion of a mediated world became more realistic and powerful. Consequently, a common focus of communication research has been the public's perceptions of reality as based on mass mediated contents and images (Eveland 2002) (→ Media and Perceptions of Reality). Social reality perceptions, or the "pictures in our head," are best defined as individuals' conceptions of the world. They include perceptions of others' opinions and behavior, social indicators such as crime, wealth, careers, professions, sex roles and more (→ Reality and Media Reality).

### **INTEGRATING NEWS AND ENTERTAINMENT**

The modern electronic forms of mass communication have only strengthened the power of the media in mediating reconstructed realities. The boundaries between news and entertainment are blurred: journalism is mostly storytelling, thus providing a structured account of the environment, and like all stories, these articles structure events and experiences for us, filtering out many of the complexities of reality (→ Construction of Reality through the News). An important element of the mass-mediated world is the integration of news and entertainment, facts and fiction, events and stories into a symbolic environment in which reality and fiction are almost inseparable. Thus, the news becomes storytelling while soap operas become news. They present to us realities from other cultures, other social strata – and despite their fictional nature – are seen and interpreted as realities: "The dominant stylistic convention of Western narrative art – novels, plays, films, TV dramas – is that of representational realism. However contrived television plots are, viewers assume that they take place against a backdrop of the real world. The basic 'reality' of the world of television drama is highly informative. Television offers to the unsuspecting viewer a continuous stream of 'facts' and impressions about the way of the world, about the constancies and vagaries of human nature, and about the consequences of actions. The premise of realism is a Trojan horse which carries within it a highly selective, synthetic, and purposeful image of the facts of life" (Gerbner & Gross 1976, 178). Moreover, the nature of news "stories" (note the storytelling nature of reporting news) is a reconstructed format of presenting events. The importance of the narrative presentation in the reconstruction of reality was noted by Schudson (1982, 18), who argued that "the power of media lies not only (and not even primarily) in its power to declare things to be true, but in the power to provide the form in which the declaration appears. News in a newspaper or on television has a relationship to the "real world", not only in content but in form; that is, in the way the world is incorporated into unquestionable and unnoticed conventions of narration, and then transfigured, no longer for discussion, but as a premise of any convention at all."

The so-called → "infotainment" narrative of the modern media affects us all. How can one make the distinction between fictional representation and factual "real world" information when both are so well integrated into our mediated environments? Living in a mass-mediated world is the result of several processes: our reliance on media sources to know and interpret the "world out there," the distorting effect of the selection process in the media and the practice of writing news as "storytelling," and the mixture of information and fiction where real and fictional worlds become a homogeneous, synthetic reality.

Many scholars suggested that when we study media impact on perceptions of reality we should step beyond a singular focus on news. Gamson (1999) distinguished between various categories of television content and contended that prime-time entertainment television may be particularly influential in constructing and maintaining political attitudes. The presentation of what Gamson defined as “life-world” content engages the audience on an emotional level, bases truth claims on experiential knowledge, and treats the audience as being physically present within the program. Each of these unique characteristics of prime-time television dramas allows for the creation of a unique set of effects relative to those found in the traditional study of news.

### **CULTIVATING IMAGES OF REALITY**

The most important work on the impact of mass-mediated realities on audiences’ perceptions has been done within the tradition of → cultivation theory. Cultivation theory (sometimes referred to as the cultivation hypothesis or cultivation analysis) was an approach developed by → George Gerbner. Essentially, the theory states that heavy exposure to mass media, namely television, creates and cultivates perceptions of reality more consistent with a media-conjured version of reality than with what actual reality is. It began with the “Cultural Indicators” research project in the mid-1960s, aiming to study whether and how watching television may influence viewers’ ideas of what the everyday world is like. Cultivation theorists argue that television has long-term effects which are small, gradual, indirect, but cumulative and significant. Cultivation analysis generally begins with identifying and assessing the most recurrent and stable patterns in television content, emphasizing the consistent images, portrayals, and values that cut across most program genres. In the next step, cultivation analysis tries to ascertain if those who spend more time watching television are more likely to perceive the real world in ways that reflect the most common and repetitive messages and lessons of the television world, compared with people who watch less television but are otherwise comparable in important demographic characteristics (→ Cultivation Effects).

One of the major constructs of cultivation theory is → *mainstreaming*, the homogenization of people’s divergent perceptions of social reality into a convergent “mainstream”. This apparently happens through a process of construction, whereby viewers learn “facts” about the real world from observing the world of television. Memory traces from watching television are stored “relatively automatically.” We then use these stored images to formulate beliefs about the real world. When this constructed world and the real world have a high degree of consistency, *resonance* occurs, and the effect is even stronger. The notion of cultivation has been applied to various areas, including the amount and forms of violence and crime, depictions of women, elderly people, minorities, professions, sex roles, health and sickness, science, and scientists, to name only a few (Weimann 2000). But despite its popularity, the theory continues to be criticized, debated, and modified.

### **SOME LIMITATIONS AND SOME MODIFICATIONS**

The notion of cultivating images of reality was often criticized for being oversimplified. Critics argue that the theory ignores the complexity of media consumption and its role in

our lives today. Cultivation theorists tend to ignore the importance of numerous intervening factors such as developmental stages, viewing experience, general knowledge, gender, ethnicity, viewing contexts, family attitudes, and socio-economic background, which all contribute to shaping the ways in which television is interpreted by viewers. Moreover, when the viewer has some direct lived experience with the subject matter, this may tend to reduce the cultivation effect. Most criticisms of cultivation theory have focused on the validity of cultivation research, arguing that cultivation effects found in various studies are statistical artifacts of demographic differences in both TV viewing and perceptions. Another perceived shortcoming of the original cultivation research has been the treatment of TV viewing as a uniform activity, ignoring variations in viewers, in content to which viewers are exposed, and in the contexts in which they view (Shanahan & Morgan 1999). Several scholars noted that the cultivation effect may be program-specific rather than the result of total television viewing. Specific programs, such as crime-related shows, would be most influential in affecting perceptions of crime.

The tradition of studying cultivation effects essentially concludes that some contents may have some effects on some people under some circumstances (Cohen & Weimann 2000). Several researchers attempted to refine the notion of cultivation by examining closely the cognitive processes involved. A key distinction suggested by these studies is that there are two stages of the cognitive process: “first order” effects (general beliefs about the everyday world, such as about the prevalence of violence) and “second order” effects (the resulting specific attitudes, such as fear of strangers or of walking alone). Other studies revealed the psychological processes involved in cultivation of reality perceptions. Thus, some argued that “source confusion” (the tendency of individuals to confuse events from news stories with those from fictional contents) is promoting stronger cultivation effects while others explained the cognitive mechanism of cultivation in terms of accessing information in the memory (e.g., Shrum 1996).

## **NEW MEDIA AND VIRTUAL REALITIES**

The concepts of cultivation and mainstreaming emerged with the age of television. Toward the end of the twentieth and the beginning of the twenty-first centuries the age of the new media technologies–based computer-mediated communication (or CMC) began to increase in use and in prominence. The important assets of CMC are its “vividness” and speed, easy access to everywhere in cyberspace with no time or distance limits. What happens when virtual reality becomes more appealing than “real” reality? Will large numbers of us abandon socially relevant pursuits for virtual travel in the media world? As computers’ capabilities to develop increasingly complex and realistic images advance, the illusion of reality will become even more convincing. Shapiro and McDonald (1995) expressed concern about people being unable to distinguish virtual experiences from reality (→ Virtual Reality). Based on a survey of communication literature, they argue (1995, 331) that “mass media with elements of virtual reality are at least as likely to shape our attitudes, beliefs, and behaviors as other forms of mass media. Those judgments are likely to be continuous, not dichotomous and, with experience, relatively sophisticated”. Moreover, Shapiro and McDonald argue that just as with other mass media, there is likely to be a media dependency effect (→ Media Systems Dependency Theory). People are most

likely to be influenced by media information when they have little other experience that enables them to evaluate the new information. When virtual realities in computer-mediated entertainment are the only source of information people can use to experience places, situations, and actions, one can expect a powerful impact. Williams (2006) applied a longitudinal, controlled experiment of a video game to the notion of cultivating perceptions of reality due to the use of the game. He found that participants in an online game changed their perceptions of real-world dangers. However, these dangers only corresponded to events and situations found in the game world, not to real-world crimes. Computer-mediated communication is giving new meaning to the idea of “mediated realities” and should be related to cultivation theory. Although the cultivation paradigm highlighted the role of television, the basic argument seems even more valid in the case of CMC.

It appears that the introduction and spread of modern communication technologies and applications such as computer-mediated communication will only enhance the necessity of studying the role of entertainment media in communicating and cultivating unrealities. Today’s technologies of communication, with their speed, vividness, interactivity, and multi-sensual totality, may provide a more powerful impact on our “virtual realities.”

# Entertainment Education

*Michael J. Cody*

*University of Southern California*

*Miguel Sabido*

*University of Southern California*

Entertainment education is defined as the “process of purposely designing and implementing a media message to both entertain and educate, in order to increase audience members’ knowledge about an educational issue, create favorable attitudes, shift social norms, and change over behavior” (Singhal & Rogers 2004, 5). Parables, fables, and morality plays have been used for centuries not only to entertain but also to transmit knowledge of history, culture, values, and life lessons. Modern entertainment education includes designing a campaign strategy that incorporates radio and television dramas, talk programs, comedies, music, → animation, participatory theatre, interactive websites, and → video games, largely to promote health and social issues (Singhal et al. 2004; → Drama in Media Content; Broadcast Talk; Situation Comedies).

Most scholarly research has focused on *the uses of dramatic serials*. Dramas offer many advantages, including capturing the attention of specific audiences, altering viewers’ → emotions, developing characters, viewing characters’ conversations with others, and decision-making, allowing for multiple examples of social modeling, focusing on issues from multiple perspectives, focusing on issues repeatedly over time, and showing characters overcoming resistance and adversity (Sabido 2004). They also provide a perfect vehicle in which to put communication theory into practice and test theories in both experimental and non-experimental contexts (Green et al. 2002; Slater & Rouner 2002).

Much of the work on entertainment education stems from Miguel Sabido’s *methodology*, which was utilized in Latin American *telenovelas* to promote adult literacy and family planning before being adopted globally (→ Communication Evaluation Research; Communication and Social Change: Research Methods). It is based on four key elements. Utilizing → Albert Bandura’s social learning theory, the methodology relies on multiple examples of *similarity modeling* (→ Observational Learning). Central characters are portrayed “suffering” and unhappy. Viewers watch as the characters discuss their plight with others, decide to take action, overcome difficulties, and eventually succeed in achieving intended goals. “Satellite characters” are minor characters who observe key characters successfully change their lives, and they too decide to take action. Modeling, reinforcements, and self-efficacy are pivotal. The entertainment education program needs to prompt characters to utilize an existing infrastructure, such as family planning or adult literacy offices.

The methodology also relies on Jungian “archetypes,” and characters in dramas represent archetypal characters well recognized in a particular culture. The methodology also relies on key aspects of *drama theory*, including → suspense, cliffhangers, → interpersonal conflict, and a final conflict between protagonist and antagonist. Viewers watch as multiple characters progress through “stages of change” toward fully adopting and maintaining a new behavior. Finally, characters in the particular program have to communicate with an

appropriate “tone,” or physical tension, usually animalistic (terrifying, aggressive), intellectual, or emotional (love, dignified; Sabido 2002).

A number of *theories* are relevant to the effective use of entertainment education, including → parasocial interactions and relationships, → empathy theory, → identification, → transportation theory, suspense, → social cognitive theory, and the → stages of change model.

## **Entertainment, Effects of**

*Jennings Bryant*

*University of Alabama*

One of the dominant functions of modern media is entertainment (Zillmann & Vorderer 2000). Moreover, entertainment offerings presented by virtually all mass media seem designed to provide immediate gratification of the diverse hedonic needs of modern media consumers.

If entertainment is the primary goal of modern media, why are so many critics concerned that those who consume such fare will suffer detrimental social and psychological effects? Indeed, if the real purpose of modern commercial fare were to create high levels of audience enjoyment (→ Enjoyment/Entertainment Seeking), negative effects might not be such a major issue. However, in reality, in the US and other capitalistic media systems, creating a satisfying entertainment experience is barely a secondary goal of the executives

in charge of modern media institutions. The dominant goal is to garner the → attention of as many consumers as possible for those omnipresent advertisements and commercials. In other words, the primary objective of commercial media systems is profitability (→ Media Economics). Entertainment reactions are a functionally necessary *by-product* if one is to gain and retain the eyes and ears of consumers and guarantee ample advertising exposure for profitability. Entertainment really is the means to an end, not the goal.

Although the distinction between entertainment as a means rather than an end may be subtle, it is important. If your primary goal is audience attention to commercial messages, entertainment programs become *vehicles* for → advertising. Moreover, commercial potential is best served through audience maximization; that is, by attracting the largest possible audience of desirable entertainment users. How much those consumers really enjoy the entertainment is of little importance, unless lack of enjoyment motivates audience defection or adversely affects processing of or responses to advertising messages.

The heavy reliance on various media ratings systems (e.g., → Nielsen Ratings) as the primary performance indicators of media messages is strong evidence of the pre-eminence of this drive for potential exposure to advertising. In general, such ratings are measures of *exposure* that are designed to serve the advertising industry; they are not ratings of the entertainment value of media message systems (→ Exposure to Communication Content). The end result of this drive toward numbers is that media producers, distributors, and exhibitors consistently favor content that they believe will attract the largest possible audience. This is the primary reason for media's over-reliance on violence, sexual titillation, voyeurism, and other sensationalistic fare (→ Violence as Media Content; Sexualization in the Media).

This hypercapitalistic, sensationalistic programming provides the financial infrastructure of most modern media and is a primary reason why critics are perennially concerned about harmful side-effects of consuming popular (or "pop") culture, including watching entertainment television, playing → video games, reading romance novels, browsing fashion or fan magazines, surfing the net, and the like.

## TYPOLOGIES OF MEDIA EFFECTS

Many different typologies of media effects (→ Media Effects) have been posited. A popular system of categorization is to divide effects into *cognitive* (e.g., learning) versus *affective* (e.g., emotional displays) versus *behavioral* (e.g., aggression) effects. However, such typologies work best when types of media content other than entertainment are also considered (e.g., education, news and public affairs, commercial messages, political communication). Therefore, we employ a relatively simple system in which four types of *detrimental* effects of entertainment are considered: displacement, stereotyping, sexual attitudes and behaviors, and violence and aggression.

### Displacement Effects

Communication scholars have often discussed media effects as being either content-dependent or content-irrelevant; displacement effects fall into the latter category. Displacement effects occur as a result of devoting time to entertaining media fare instead of engaging in other activities.

When television was a new medium of communication, discussions of displacement effects were commonplace. Classic early large-scale investigations in England, North America, and Japan addressed issues such as whether television viewing was associated with later bedtimes, less time spent on homework, less recreational and educational reading, and a variety of other displacement issues. These early studies presented an array of mixed findings, although a common summary was that watching television typically resulted in less time spent in general play but not in substantial losses in other realms (Furu 1962; Himmelweit et al. 1958; Schramm et al. 1961; → Media Effects, History of).

Canadian Tanis McBeth Williams (1986) designed and conducted a classic longitudinal field investigation to attempt to clarify displacement effects. The findings of this naturalistic investigation were complex. For example, it was reported that television viewing does displace some activities directly, such as playing sports. However, other activities, such as reading, were often time-shared with television viewing and did not appear to be affected markedly by displacement mechanisms.

More recent research has combined investigation of displacements effects with examinations of content-specific programming factors. For example, displacement research conducted in Europe, especially in the Netherlands, found that although viewing highly violent programs reduced imaginative play, viewing so-called neutral programs seemed to have no detrimental effects, and in some cases, viewing entertaining educational television enhanced creative play (Valkenburg 2001).

With citizens of → information societies devoting increasing time to playing video games and using the → Internet in addition to consuming traditional entertainment media, displacement effects have become of increasing concern to many modern social critics, especially in light of highly publicized reports on the poor state of health of citizens of various information societies. For example, Robinson (1999; 2001) has argued that heavy usage of entertainment media causes obesity by one or more of three mechanisms: (1) displacement of physical activity, (2) increased caloric consumption while watching or via direct effects of advertising food products, and/or (3) reduced resting metabolism.

When discussing displacement effects, two *cautionary notes* offered by Perse (2001) appear germane: (1) displacement appears to assume that time is spent on only one activity at a time, whereas research documents that media usage often is a secondary activity to other tasks – it often accompanies rather than displaces activities; (2) some displacement effects of entertainment may include consuming content that is also educational or inspirational, which may be more enriching than the activities the entertainment usage replaced.

### **Stereotyping**

The use of overly simplistic or overly narrow representations of a particular group without consideration of their true diversity occurs in entertainment media for a variety of reasons. Writers, producers, and directors may not have had primary experience with anyone of the ethnicity of the character they are being asked to present in a program, so they rely on prevailing “pop culture” representations without finding out how accurate their images are. An even more common reason for relying on → stereotypes is because they serve as dramatic shortcuts. In short-form fiction, including → magazines, television

programs, and video games, creators rarely have enough time to develop a character in full-blown form. In fact, true character development is extremely rare in popular electronic media fare. Therefore, in order to present a hero, villain, agent of justice, or whomever efficiently and parsimoniously, writers and directors rely on commonly held stereotypes to present easily understood and identified character types. Essentially, stereotyping is a cost-effective way of taking shortcuts in drama, and it is an all-too-common practice (→ Popular Communication; Popular Culture).

Unfortunately, media stereotyping can have very detrimental effects. Much of what people learn about the world outside of their immediate sphere comes from the media. In other words, media are potent agents of socialization that can cause entertainment-message consumers to classify the world around them to some extent in the terms and categories provided by television's reality (→ Socialization by the Media). Portrayals that are biased, overly narrow, or lack diversity in depictions of one or another gender or ethnic group can affect the way in which people create the *scripts* they use to deal with real life. Although research has been conducted on several categories of stereotypes – racial, gender, age, sexuality, disability, occupation, etc. – we will focus primarily on the effects of racial and gender stereotypes in entertainment programming.

Research over the past 30 years consistently has found that minorities are underrepresented and misportrayed in entertainment fare. Another common form of stereotyping in entertainment television is gender stereotyping (→ Sex Role Stereotypes in the Media). Although some improvement has been made during the past three decades in this regard, media messages are still infused with stereotypes of both men and women. In general, women are portrayed less often in entertainment media fare than are men, and women typically are presented in roles of lesser status or importance than their male counterparts (Signorielli 2001).

So what do consumers learn from stereotypes on entertainment fare? Social learning theory, → social cognitive theory, and → cultivation theory suggest that media consumers should learn stereotypical attitudes and may perform associated behaviors from watching, listening to, or reading about a steady stream of stereotyped roles. In most cases, this is what the research has shown. Meta-analyses of research on television stereotyping, for example, conclude that entertainment television has a significant overall effect on holding gender-role stereotypes in all age groups; however, among children younger than 6, the relationship is more pronounced; and for children younger than 3, the relationship is most pronounced (Van der Voort & Valkenburg 1994; → Meta-Analysis). Moreover, the findings on racial/ethnic stereotyping in entertainment programming indicate that media portrayals of racial/ethnic minorities influence majority group members' real-world perceptions about minority groups in addition to minority group members' evaluations of self (Greenberg & Collette 1997; Greenberg et al. 2002; → Cultivation Effects; Stereotyping and the Media).

### **Sexual Attitudes and Behaviors**

According to a 1998 Time/CNN national poll (→ Public Opinion Polling), 29 percent of American teenagers indicated that television was their primary source of information about sex, whereas only 7 percent cited parents and 3 percent cited sex-education classes

as primary sources. Given the way that television presents human sexuality, that finding is very frightening. The nature of sexual content in the media – e.g., sex is presented or alluded to frequently; fictional media characters and live media “personalities” are pre-occupied with sex; media role models often behave irresponsibly about sexual behaviors – adds dramatically to the nature of public concern about vulnerable audience members’, especially young people’s, exposure to sexual content via the media.

What kind of social and psychological effects might exposure to hypersexual entertainment-media content and even explicitly sexual materials have? Here are just a few of the many extant findings (Zillmann & Bryant 1984). Because depictions of sex in the media often take place outside of supposedly durable, legal relationships like marriage, regular exposure to such content may *undermine the values of marriage* and having a stable family. Feminists often claim that depictions of sexual behavior in the mainstream media have tended to *show women as sex objects* and subordinates to men, and repeated exposure to such images may create images of women as promiscuous, hypersexual creatures whose primary function is to serve men (→ Feminist and Gender Studies; Sex and Pornography as Media Content: Feminist Perspectives; Women in the Media, Images of). Rape and rape victims are commonly alluded to if not depicted on television, films, and video games. Some evidence suggests that repeated viewing of such materials leads to more *callous attitudes about rape*, less sympathy for a rape victim, and more sympathy for those accused of rape (→ Sexual Violence in the Media). Whatever else sexually oriented entertainment fare does, it serves as *informal sex education* for millions of readers, listeners, and viewers.

### **Violence and Aggression**

Over the years, far and away the most active area of media-effects inquiry has been that of media violence (→ Violence as Media Content, Effects of; Violence as Media Content, Effects on Children of). Literally scores of books and thousands of scholarly and popular press articles have been devoted to this topic. Obviously doing the topic justice in a short space is impossible, so the key elements of the social issue have to be summarized succinctly. They include recognition of the common assumption of entertainment message designers that media violence attracts numerous readers, listeners, and viewers. Therefore, pop culture fare is replete with violence. Moreover, entertainment consumers around the world consume a great deal of this fictional and real-world violence.

What effects does this steady diet of symbolic violence have? Abundant research has addressed this question from a variety of perspectives, and several theories have been advanced both to generate hypotheses and to clarify findings. In terms of theoretical mechanisms, the most prominent theories of the effects of media violence on human aggression fall into the general categories of: social learning (→ Observational Learning), priming (→ Priming Theory), arousal (→ Emotional Arousal Theory), cultivation, → desensitization, and catharsis (→ Catharsis Theory).

What does the research say? In general, the bulk of the extant empirical evidence – bolstered by findings from several recent meta-analyses of the effects of violence across types of media – concludes that consuming a heavy diet of media violence in entertainment fare results in higher levels of personal and societal violence (Sparks & Sparks 2002).

## FUTURE TENSE

With the advent of newer forms of mediated communication, in which the end-user is both producer and consumer and assumes considerable agency over media content, through interactivity and other means of selectivity and control, the potential for entertainment – and for productive entertainment-effects research – is almost unlimited. Understanding entertainment needs – and creating media content to address these needs beneficially – while at the same time avoiding unwanted detrimental social and psychological effects, is almost certain to be one of the new frontiers in media-effects inquiry.

## Environment and Social Interaction

Miles L. Patterson

University of Missouri-St Louis

Every face-to-face interaction occurs in a specific location. Although it is typically assumed that the course of particular interactions is a product of the individuals involved and their relationships to one another, the surrounding environment has important effects at both the macro- and micro-levels.

Where people live has an important effect on social behavior. For example, urban dwellers are less likely to initiate eye contact with passing strangers than are suburbanites or small-town residents (Newman & McCauley 1977). More importantly, helping behavior also decreases as *population density* increases from small to large cities (Levine et al. 1994). One explanation for the decreased sensitivity to others in large urban areas is *social overload* (→ Proxemics). That is, because urban dwellers are consistently overstimulated by the presence of large numbers of people, they adapt by automatically filtering out less important events (Milgram 1970).

Sensitivity to others is affected by more than just population density. Levine et al. (1994) found that, in the United States, the incidence of helping strangers was greater in the south and mid-west than in the northeast and west. Historical and technological changes have also contributed to decreased sensitivity to strangers, and even neighbors, in both low- and high-density situations. Sixty years ago, prior to the common availability of television and air conditioning, people in small towns and large cities spent more time outside, interacting with their neighbors. In addition, although the current technological environment, with the Internet, mobile phones, and palm pilots, extends our ability for remote communication, the frequency and quality of face-to-face communication may be adversely affected (Bugeja 2005; → Interpersonal Communication).

*Weather* also plays a role in social interactions. In good weather, people are more likely to be outside and engaged in a variety of activities that, in turn, increase the likelihood of contact with one another. In contrast, stormy weather and extreme temperatures reduce the opportunities for outside interactions. Nevertheless, very hot temperatures can increase negative affect and the probability of aggressive encounters (Bell et al. 2001, ch. 8).

The approach of ecological psychology provides a broad perspective on how the immediate environment shapes social behavior (Wicker 1979). The concept of a *behavior setting* is basic to explaining the role of the environment on behavior. A behavior setting refers to a geographically limited location with a specific physical design where goals and norms direct the behavior of individuals over a limited time period. For example, a college class on communication, a church service, or a school board meeting all occur in specific locations with distinct design features, have a particular agenda, and last for a limited length of time. Social behavior is also constrained by self-selection, with more similar people choosing common settings. The result of these coordinated influences is that most people in a given setting tend to behave in a relatively homogeneous fashion.

The initiation and development of social interaction are also affected by *territory* (→ Initial Interaction). When individuals are at home, in their office, or simply claiming a picnic table in the park, they have more discretion in initiating and controlling interactions with others (Altman 1975). Visitors typically recognize their own status and defer to the territory holder (→ Power, Dominance, and Social Interaction). For example, territory holders usually meet visitors at the doorway, invite them inside, and direct them to a particular room or location. As a result, territory facilitates order and predictability in interactions.

A number of *physical characteristics* of settings also affect interactions. In the business world, higher-status individuals have larger, better-furnished offices, with nicer views of the surrounding area. Their larger desks not only signal their importance, but also serve to keep visitors at a greater distance. Thus, the immediate physical environment reinforces the office holder's power in interacting with subordinates. Furniture arrangement also affects the ease of interaction in home settings. For example, the furniture in most living rooms and dens is usually arranged to accommodate the easy viewing of a television. Such an arrangement does not, however, typically facilitate the more comfortable facing positions that most people prefer in interactions. One accommodation might be moving to a kitchen or dining-room table with a closer and more directly facing arrangement.

Finally, the *number of individuals* in a given setting influences affective and behavioral reactions. High-density settings typically increase physiological arousal, precipitate negative attributions (e.g., feeling crowded), and often lead to behavioral withdrawal – but not

always (Bell et al. 2001). Parties and sporting events can also be arousing, but precipitate positive attributions (e.g., interest or excitement) and foster greater engagement with others.

Most people assume that they are active agents operating on their social worlds. Nevertheless, research indicates that the physical and social environments not only constrain our behavioral options, but also prime specific actions, often automatically and outside of awareness (Bargh & Williams 2006). An appreciation of the role of the environment on behavior facilitates a better understanding of social interaction and provides an opportunity for greater control in contacts with others.

# **Environmental Communication**

*Robert J. Griffin*

*Marquette University*

*Sharon Dunwoody*

*University of Wisconsin-Madison*

“Environmental communication” refers to communication about the natural environment and ecosystem, commonly focusing on the relationships that human beings and their institutions have with the nonhuman natural environment. Much of this communication, historically, has been generated by concern about various environmental problems and issues (global warming, energy, smog, extinction of species, land uses, population growth, water quality, to name but a handful). Some messages, such as Rachel Carson’s popular and controversial *Silent spring* in the early 1960s, which revealed the deleterious side-effects of pesticides, have been credited with spurring public concern and major policy changes. However, there has also been a prevalent thread in literature and storytelling in many cultures that urges people, often through descriptive imagery, to appreciate beauty

and harmony in nature (or, in some cases, to fear nature). Sometimes, of course, nature description has also been a vehicle for teaching social and ethical values and ecological principles and for alerting people to environmental issues (e.g., Henry David Thoreau's *Walden* and Aldo Leopold's *A sand county almanac*).

### THE SCOPE OF ENVIRONMENTAL COMMUNICATION

Environmental communication can take many forms and can occur through a diverse set of communication channels. Thus, communication scholars of various stripes might readily find environmental communication applicable to their interests in various media. Overall, "the rate of growth in environmental communication research . . . is phenomenal," observe Pleasant et al. (2002, 200), based on their review of 963 articles about environmental communication published in academic journals from 1945 to 2000.

The meaning of the term "environmental" has evolved over time from earlier, more limited, and more human-centered terms such as "conservation" (Schoenfeld 1983), to a more global perspective, encompassing urban as well as rural locales, tough ecological choices, and grassroots participation in policy formation – in essence, "a recognition of pervasive interdependencies, in which everything is connected to everything else" (1983, 471). In more recent years, increasing attention has been paid to risks to human health stemming from a variety of environmental contaminants. Some in the environmental movement seem to welcome this new nuance as a means of widening the environmental constituency to include those whose main concern is human health and as a way of showing larger segments of the public that various kinds of environmental degradation can ultimately threaten their health. Others in the environmental movement seem to object that emphases on health return environmentalism to an anthropocentric philosophy. Nonetheless, communication about risk – whether to the natural environment or to human health – has emerged as the top environmental communication topic investigated by researchers, according to the review by Pleasant et al. (2002).

### ORIENTATIONS TO THE ENVIRONMENT

Over the years, various researchers have attempted to gain more insight into differences in individuals' environmental orientations, e.g., their beliefs, affects, values, attitudes, and behaviors as related to the environment. Although much of this research has been atheoretical, there have nonetheless been numerous studies that have applied one communication model or another (e.g., framing, agenda-setting, and others) to environmental orientations as objects of study (→ Framing Effects; Agenda-Setting Effects). Rather than reviewing these models here, we will instead concentrate on just a few of the models that have shown considerable promise and usefulness for studies of environmental communication and that, in some cases, may not be well known among communication scholars more generally.

#### **New Environmental Paradigm**

The most widely used model designed to reflect individuals' general beliefs about the environment is the new environmental paradigm (NEP, more recently amended as the

new ecological paradigm) of Dunlap and Van Liere (1978) and various collaborators. NEP is not a process model, but rather a conceptually based measurement scheme designed to “tap ‘primitive beliefs’ about the nature of the earth and humanity’s relationship with it,” state Dunlap et al. (2000, 427; → Measurement Theory; Scales and Indices; Research Methods). “Social psychologists,” they explain, “see these primitive beliefs as influencing a wide range of beliefs and attitudes concerning more specific environmental issues” (2000, 428). Fundamentally, the NEP scale was designed to measure individuals’ beliefs about limits to growth for human societies, humanity’s right to rule over nature, and humanity’s ability to upset the balance of nature – what Stern et al. (1995) have termed a “folk ecological theory of how the world works, the nature of the biosphere, how it functions, and how it is affected by human actions” (1995, 726). NEP scores generally reflect a more ecocentric set of beliefs about humanity and the ecosystem.

In a multinational study of more than 2,000 students in 14 countries, Schultz and Zelezny (1999) found that NEP scores were positively associated with values of universalism and negatively with values of power and tradition. US respondents scored lower than those from most of the other countries. Stern et al. (1995) integrated NEP and another scale of environmental beliefs – an amended awareness of consequences (AC) scale based on Schwartz (1970) – into a framework of social psychological theory. In a telephone sample → survey of 199 adults in Fairfax County, Virginia, in the US, they determined that NEP and AC → scales represented generalized environmental beliefs that could affect beliefs, attitudes, and behavioral intentions in regard to specific environmental problems and, in turn, could be affected by values and social structural variables. Major (1993) combined the NEP scale with Grunig’s (1983, 1989) situational communication theory and found that these basic environmental beliefs helped to explain the ways various publics responded to and communicated about two environmental issues: air pollution and landfill shortages.

Fairly few studies, as Major (1993) notes, have examined the relationship of communication to general environmental dispositions. Nonetheless, Dunlap et al. conclude that NEP measures “should be responsive to personal experiences with environmental problems . . . and to information – diffused by government agencies, scientists, environmentalists, and the media – concerning the growing seriousness of environmental problems” (2000, 429). It is likely that these primitive beliefs might also affect individuals’ information seeking and processing as well (→ Attitudes, Values, and Beliefs, Media Effects on).

### **Environmental Behavior**

Two of the more significant behavior models that offer frameworks for exploring connections between communication and environmental behaviors are Ajzen’s (1988) theory of planned behavior (TPB; → Planned Behavior, Theory of), which is based on the Ajzen & Fishbein (1980) theory of reasoned action (TRA; → Reasoned Action, Theory of), and the theory of environmentally significant behavior (Stern 2000).

TRA and TPB have been widely applied to investigations of a variety of human behaviors, including a number of studies of communication and environmental behavior (see Trumbo & O’Keefe 2004). Trumbo and O’Keefe (2004) employed TRA in a study of factors that affect individuals’ voluntary water conservation behavior in the Truckee River

watershed and augmented the model by incorporating measures of NEP, past behavior, communication exposure (→ Exposure to News), → attention, and → information seeking with regard to water conservation information. They found that communication was at least as strong as the key TRA variables, subjective norms and attitude toward the act, as a predictor of intention to conserve, and appears to mediate an effect of NEP and past behavior on behavioral intention.

Stern (2000) has proposed a compelling theory that synthesizes a variety of factors, including NEP, into a comprehensive values-beliefs-norms model to predict environmentally significant behavior – the extent that a behavior “changes the availability of materials or energy from the environment or alters the structure and dynamics of ecosystems or the biosphere itself” (2000, 408). Although communication itself is not central in this theory, nonetheless there are various components of the model that might be affected by communication, or interact with it, with ultimate impacts on environmental behavior.

## **COMMUNICATION AND ENVIRONMENTAL RISKS**

Ecosystems inhabit a world rife with risks, just as humans do. Assaults on the environment are the stuff of much environmental reporting in the mass media, and while members of the public might learn about risks to the ecosystem in various ways, media depictions are a pre-eminent source and the most studied by scholars.

### **Media Coverage of Risks to the Environment**

One might argue that environmental reporting is all about sending signals regarding real or potential harm to an ecosystem. It is easy to unearth content analyses of media coverage of these risks to the environment. Most examine print – not broadcast or Internet – outlets (the former has historically been more accessible than the latter) and most offer descriptions of patterns of coverage across media or over time. Although there exists no → meta-analysis of these studies, we isolate a few of the more common patterns below.

*Coverage of a single environmental issue* will be erratic, not sustained, over time. Journalism tackles individual topics in relatively brief, discrete bits and does so only when events or processes coincide with news values such as timeliness or magnitude (→ News Routines; News Values). This means that context of all kinds is often missing from individual stories, leaving audiences to build a more comprehensive picture of an issue on their own. For example, Bendix and Liebler (1991) analyzed newspaper coverage of deforestation in the Brazilian Amazon and found it to be intermittent and sensitive to crises.

*Journalistic norms* may be prominent drivers of coverage strategies (→ Journalists' Role Perception; Ethics in Journalism). For example, since journalists cannot be arbiters of scientific truth when that truth is contested (a common situation in science), they instead aim to include in stories a variety of truth claims, often “balancing” these viewpoints in an effort to convey to audiences a sense of the range of views. Boykoff and Boykoff (2004) found that roughly half of the global warming stories they examined from US newspapers hewed to this balancing act, and they concluded that such coverage may lead to misperceptions by audiences.

Stories, by definition, are dominated by *interpretive frameworks*, and scholars argue that these frameworks can be important predictors of the “take-home message” that a reader or viewer will derive from a journalistic piece. Studies of frames employed in stories about risks to the environment suggest that they can stem from a complex welter of factors, including a journalist’s a priori knowledge of an issue, a willingness to buy into the first frame that is offered as an issue comes to light, and even the social structure of the community in which the media organization operates. In a study of media coverage of three Superfund sites in Wisconsin, US, for example, Dunwoody and Griffin (1993) found that coverage of these sites over the course of years adopted community-specific interpretive frameworks.

### Communicating about Risks to the Environment

Human beings engage in a host of risky activities, much to the alarm of policymakers and the health community. Much effort and many dollars are devoted to trying to persuade people to stop smoking, to engage in safe sex, and to employ infant car seats correctly. But how can one persuade individuals to change their behaviors when the risk in question does not affect them directly? When a lake is in trouble, when warming temperatures allow beetles to overwinter and destroy ash trees, how do you jump-start behaviors that would help fix the problems?

*Risk campaign* managers say that it is hard enough to convince individuals to adopt behaviors in service to their own personal needs, much less devise means of convincing people to be responsive to risks to bodies of water or to ecosystems (→ Risk Communication). Complicating this scenario is the fact that truly lessening many, if not most, risks to environmental systems requires concerted efforts by many individuals, agencies, and even nations. It can be difficult for individuals to feel that their personal efforts could make a dent. Models such as Ajzen’s (1988) theory of planned behavior (TPB) can offer guidance regarding the behavioral beliefs, outcome evaluations, attitudes toward the behavior, feelings of efficacy, and felt social pressures (subjective norms) that can contribute to individuals’ behavioral change. As people process information about at least some environmental risks, they might experience a change in a number of these behavioral intention predictors (e.g., felt social pressures, outcome evaluations or beliefs in regard to taking old paint or mercury thermometers to a community recycling center instead of throwing them away in the trash). Of course, individuals would seemingly have to attend to and process this kind of information in the first place.

Kahlor et al. (2006) investigated some of the factors that could increase the likelihood that people would seek and process information about impersonal risks, that is, risks not to oneself but to others or to the environment. Specifically, they used elements of the *risk information seeking and processing (RISP) model* (Griffin et al. 1999) to examine how residents of two cities on the Great Lakes – Milwaukee, Wisconsin and Cleveland, Ohio – dealt with information about risks to the lakes (e.g., to the ecological health of the lakes) rather than the effects the lakes might have on human health. The RISP model combines aspects of other theories, most notably TPB and Eagly and Chaiken’s (1993) heuristic-systematic model of information processing. It proposes that more active seeking and processing of risk information is facilitated, directly or indirectly, by combinations of

some key variables, including (1) information insufficiency (i.e., a person feels the need for more information to confidently form an opinion or otherwise deal with the risk), (2) a person's capacity to seek and process the risk information, (3) a person's beliefs about communication channels that carry the information, (4) informational subjective norms (felt social pressures to be informed about the risk), and (5) affective responses to the risk (→ Affective Disposition Theories). Deeper processing of the risk information is expected to lead to more stable attitude and behavioral changes over time. (Affective response, including attitudinal and behavioral outcomes, was not analyzed in this study.)

The Kahlor et al. analysis found that *informational subjective norms* bore a much stronger relationship with seeking and processing the risk information than any other predictor, a relationship stronger than expected based on some past tests of the model that had examined how individuals seek and process information about risks to themselves. Among possible explanations, they suggested that social normative forces might be more powerful predictors of seeking and processing risk information in the absence of motivations based on perceived risk to the self. Although more research is needed, the results suggest that a variety of cultural and social forces, working through or with communication, might influence the ways people attend and respond to information about risks to the natural environment.

### **SOME DIRECTIONS FOR RESEARCH AND PRACTICE**

In general, environmental communication offers a rich area for studies of individual, cultural, social, and structural forces affecting human behavior. It takes place through various media, old and new. For example, the local → newspaper's series about water quality in nearby rivers, the → television network news broadcast that spotlights an inexplicable reduction in the number of bee colonies, and the pamphlet explaining mercury risks from eating fish caught in a local stream are, arguably, archetypical forms of environmental communication. But environmental communication can also be discovered in the → Internet → blogger's opinions on global warming, the local environmental group's interactive website mapping hazardous chemicals stored in the community, a government agency's public hearings on the siting of wind turbines for renewable electric power, chats people have with friends about recycling, and parents' emails discussing the best sunscreen lotion to limit their kids' exposure to solar ultraviolet rays.

Among the challenges to environmental communicators, and among the key topics of interest to those who study environmental communication, are the communication of risk and uncertainty to lay audiences, the interpretation of the attendant technical and scientific information for non-experts, differences in orientation to the environment based on various cultural, structural, and social factors, and issues related to public concern about the "impersonal" environment. Studies of environmental communication, regardless of whether they are based on quantitative or qualitative methods, would benefit from the continued application and development of theory.

# Escapism

Christoph Klimmt

Johannes Gutenberg University of Mainz

Escapism was introduced as an explanation for people's use of entertainment media in the 1950s. The tremendous popularity of entertainment programming in radio and, especially at the beginning of the 1960s, in television inspired communication researchers to discuss the reasons why mass audiences felt attracted to these programs and what consequences should be expected from this development (→ Audience). Escapism – a Latin-based term that could be translated as “tendency to evade one's current situation or environment” – was elaborated as an important motivation of entertainment consumption (→ Enjoyment/Entertainment Seeking; Selective Exposure). The concept centers on the assumption that diversion and distraction from real-life circumstances are desires felt by many individuals in many situations, and that entertainment media can serve the purpose of diversion very effectively. The most influential reflection on escapism was authored by Katz and Foulkes (1962). Their work exemplifies that escapism theory and research was dedicated both to motivational determinants of entertainment use and implications of escapist media consumption for the individual and society at large.

## DESCRIPTIVE AND NORMATIVE SUBSTANCE

The original understanding of escapism was rooted in the assumption that many working-class people in western mass societies were alienated and suffered from poor life satisfaction (→ Media Use by Social Variable). “Alienation” was assumed to breed the *desire to evade everyday sorrows and troubles* by involving oneself in fantasy worlds that offer relief and distraction (→ Fantasy/Imagination). “Escapist worlds, for most critics, are made of unreal or improbable people who are very good or very bad (or very good–bad) and whose successes and failures conveniently cater to the supposed wishes of the audience” (Katz & Foulkes 1962, 382). As the typical content of 1950s and 1960s entertainment programming indicated a sharp contrast to the stipulated social reality of “the masses” (e.g., radio → soap operas), involvement with such programming was theorized to serve the function of making people forget temporarily about their troublesome life circumstances by “diving” into mediated worlds of (more) happiness and luck (→ Involvement with Media Content). Some empirical evidence was collected that supported the need for diversion and “escape” as the motivational driver of entertainment consumption (Pearlin 1959).

In addition to the motivational dimension of escapism, the notion was also discussed in terms of the *effects* of escapist media use on people's life and performance in social roles

(→ Attitudes, Values, and Beliefs, Media Effects on; Entertainment, Effects of; Social Behavior, Media Effects on). Mostly negative consequences of such media use were stipulated. Katz and Foulkes (1962) list examples of conceivable dysfunctional effects of escapist media use at different levels. One is the level of political affairs (e.g., “a housewife is assured by a soap opera that there is perfect justice in the world, and, as a result, is socially unconcerned and politically apathetic” [Katz & Foulkes 1962, 386]). They refer to interpersonal relations as another dimension of escapism impact (e.g., “an adolescent goes to the movies, whatever is playing, to get away from his parents, and there is a resulting strain in the parent–child relationship” [Katz & Foulkes 1962, 386]).

*Intrapsychic dysfunctions* are suggested as a third dimension of negative consequences of escapism (e.g., “through identification with a drama character, a person’s own impulses are negated or denied, impairing personality integration” [Katz & Foulkes 1962, 386]). While empirical evidence for such negative impact was scarce, it is clear that a normative dimension was loaded onto the concept of escapism from its very beginning. Katz and Foulkes (1962) warned against estimating solely negative consequences from entertainment media content and suggested positive feedback from escapist media use to social role performance as a realistic alternative. However, the term “escapism” was and partly still is today negatively valenced through its connection with normative tenets of mass audiences seduced by the media industry not to cope with, but just to forget, their real-life challenges and problems.

## CONTEMPORARY RESEARCH DEVELOPMENTS

While the notion of escapism has not been addressed by much research since the public debate in the 1950s and 1960s, its motivational component (i.e., a diversion and relief motivation as driver of media use) has been picked up in various lines of research (→ Exposure to the Internet; Exposure to Print Media; Exposure to Radio; Exposure to Television).

For instance, Anderson et al. (1996) found positive relationships between personal stress level and preference for entertainment media. Henning and Vorderer (2001) elaborated a specific escape motivation, namely the desire to avoid thinking about oneself. Based on research on the “need for cognition” trait, they demonstrated that the wish to avoid situations of intense thinking predicted television viewing.

In terms of *communication theory*, elements of escapism are reflected in most approaches to media selection, for instance → mood management theory (Zillmann 1988), and contemporary accounts of → uses and gratifications (LaRose & Eastin 2004). Thus, the tradition of escapism has continued in the history of research on media choice. In contrast, the normatively loaded effects component of the original concept formulation (i.e., the proposition of dysfunctional impact of escapism on people’s life performance) has been criticized, and contemporary research rather argues for the *benign effects of entertainment consumption* for people’s lives. The notion of well-being has been advanced in the social sciences (Kahneman et al. 1999), and some scholars consider the use of media entertainment and the accompanying “escape” from real-life stressors as a benign contribution to well-being (that is, as “vacation” instead of “flight” from real-life circumstances; cf. Klimmt 2006).

Overall, the concept of escapism has been very influential and has founded important elements of today's communication research on media choice. It is a good example, however, of how theory building can mix up conceptual and normative issues and, as a result, justify and promote pessimism and stereotyped attitudes concerning "mass audiences" using "mass media." Nevertheless, a careful consideration and theoretical elaboration of the actual scientific substance of escapism has turned out to be very fruitful (e.g., Henning & Vorderer 2001) and is likely to continue to be so in future (entertainment) research as well.

## **Ethics in Journalism**

*Clifford G. Christians*

*University of Illinois at Urbana-Champaign*

Journalism ethics is a branch of applied philosophy of moral values and rules. Beginning with moral issues in medicine, the field expanded since the mid-twentieth century to

include such professions as law, business, journalism, and engineering. Applied ethics has developed over the decades from merely describing actual moral behavior to establishing principles that guide decision-making. Journalism ethics retains an interest in the concrete, everyday challenges of professional practice, but considers it crucial to integrate those principles as well.

In its ideal forms, → news serves the public interest, that is, the interests not of readers and viewers but of citizens. From this perspective, social responsibility theory has become the most common form of journalism ethics in democratic societies around the world (→ Journalists' Role Perception). With the same core ideas but different nuances in countries across the globe, this ethical framework parallels the socio-political character of news. Through an ethics of social responsibility, the major issues facing journalism are: the market, truth, diversity, privacy, and technology.

### **SOCIAL RESPONSIBILITY WORLDWIDE**

In the US, the Commission on Freedom of the Press published its report, *A free and responsible press*, in 1947. Named for the commission chairman, Robert Hutchins of the University of Chicago, the report insisted that the news media have an obligation to society, instead of promoting the interests of government or pursuing private prerogatives to publish and make a profit. Believing that the press was too committed to its own individual rights, the Commission stood both terms on their heads with the label *social responsibility*. For socially responsible news to fulfill its duties to the community means, among other principles, giving a representative picture of the constituent groups in society and presenting and clarifying society's goals and values.

A similar emphasis on the press serving society has emerged elsewhere since World War II without any reference to Hutchins. In 1980, the MacBride report, *Many voices, one world*, put social responsibility in explicitly international terms. The UN delegate from Ireland, Sean MacBride, spearheaded for → UNESCO this review of international media policies and practices, cultural diversity, human rights, and professional journalism (→ Media Policy). It described a world information and economic order concentrated in media industries that downplayed local cultures and silenced diverse voices in developing countries (→ Development Journalism; Development Communication). MacBride recommended quality → journalism education around the world, so that countries could report effectively on themselves.

Against the backdrop of MacBride, the International Order of Journalists and its counterparts – a total of 400,000 working journalists, the majority of the organized profession in the world – produced a document entitled “International principles of professional ethics in journalism” at meetings in Prague and Paris from 1983 to 1988. While calling for the autonomy of journalists, it asserts that journalism should operate in the public interest without undue government or commercial influence (→ Journalists: Professional Associations).

These examples illustrate social responsibility thinking in academic studies and professional codes. Most of Europe takes social responsibility for granted as the dominant policy in journalism practices and media structures, including public service broadcasting (→ Public Service Broadcasting: Law and Policy). The protocols and regulations for the European Union take as their starting point the need to preserve media pluralism, to ensure

representation of the democratic, social, and cultural needs of each country and language group. Public service broadcasting pursues national priorities, in an exception to the predominantly market-oriented EU philosophy (→ European Union: Communication Law; Plurality).

Since the 1990s, *civic or community journalism* has been restyling the press toward greater citizen involvement and a healthier public life (→ Public Journalism; Community Media; Participatory Communication). Sam Chege Mwangi has researched this movement internationally (Mwangi 2001). In Kerala, India, indigenous knowledge in agriculture, health, and housing is shared in local languages. In New Zealand during general election campaigns, journalists from *The Evening Standard* and *Waikato Times* live among the citizens and give voice to the public. In Latin America, more public journalism projects have been carried out than on any other continent, especially through community radio. In the language of the Brazilian educator Paulo Freire (1970), the aim is a critical consciousness that empowers people. When journalists represent the voice of the people instead of speaking for themselves and for the dominant class, the press becomes an instrument of liberation.

In countries of Africa and elsewhere, communication confirms, solidifies, and promotes the communal whole. The Zulu maxim *umuntu ngumuntu ngabantu* [“a person is a person through other persons” or “I am because of others”] reflects one kind of communalism. Humans are social beings and personhood is a gift from other persons. Ethics is not a question of personal choices but a matter of social and cultural duties. Because communal energy knits together public life, humans by definition have a moral obligation to one another. Societies are moral orders and not merely functional entities; journalism ought to appeal to listeners and readers about human values and conceptions of the good (Blankenberg 1999).

Parallel with these developments in the profession, education, and public policy, the expanding and deepening work in *feminist ethics* has strengthened social responsibility theoretically (→ Feminist and Gender Studies; Feminist Communication Ethics). Feminist ethics calls for a dialogic version more public than the usual private definitions of care and nurturance (Koehn 1998). The axis of feminist ethics around human relations resonates with social responsibility, in contrast to an ethics of individual selves adhering to formal principles. The work of the multinational alliance for a responsible, plural, and united world, in producing the *Charter of human responsibilities*, is testimony in the public arena to the viability of social responsibility guidelines for the media.

## BUSINESS INTERESTS

Media corporations are among the largest businesses in the world at present: → Disney, → Bertelsmann Corporation, General Electric, Microsoft, → News Corporation (Fox), Nokia, Samsung, and Sony operate on a global scale unprecedented in corporate history (→ Media Conglomerates). To cope with institutions of this magnitude, social responsibility ethics insists on social justice (→ Corporate Social Responsibility). A dynamic, multilayered ethics of social justice is at the leading edge of new information technologies.

The just distribution of products and services would allocate media access to everyone according to essential needs, regardless of income or geographical location (→ Access to the Media). In contrast, the standard conception among private media would allocate

according to ability to pay, letting the open marketplace determine who obtains the service (→ Media Economics; Markets of the Media). This standard assumes that decisions about allocating the consumers' money belong to them alone as a logical consequence of their right to exercise their own social values without coercion.

In an ethics of justice where distribution responds to subsistence needs even if circumstances prevent adequate provision, information nonetheless remains one of the necessary goods. Practical wisdom (to form conceptions of the good and engage in critical reflection) and using the mind (for political and artistic speech) are essential to the quality of human life (Nussbaum 2000). As a necessity of life in a global order, the information system ought to reach everyone, regardless of income, race, religion, or merit.

The marketplace is unlikely itself ever to fulfill a need-based distribution. Digital media are disproportionately concentrated in the industrial world, and, under the business principle of supply and demand, no structural reasons exist for changing those proportions (→ Digital Divide). Universal diffusion driven by profits is unlikely. History indicates that communications media follow existing political and economic patterns; inequities in society lead to inequities in technology. A social responsibility ethics requires intervention through legislation, government policy, and public ownership to implement open access. One approach is to model media institutions on schools, which taxpayers accept as a responsibility in common, rather than leaving engineers or profits to decide alone.

## TRUTH

The press obligation to truth is standard in journalism ethics. Truth-telling is the generally accepted norm of the media professions, and credible language is pivotal to the very existence of journalism. But living up to this ideal has been virtually impossible. Budget constraints, deadlines, and self-serving sources complicate the production of truth in news writing. Sophisticated technology accommodates almost unlimited news copy and requires choices without the opportunity to sift through the intricacies of truth-telling (→ Truth and Media Content).

Social responsibility ethics requires not just technical changes and better effort but a *new concept of truth*. The mainstream press has defined itself overall as objectivist, so that the facts seem to mirror reality and genuine knowledge is scientific. The objectivity of physics and mathematics sets the standard for all forms of knowing. In this type of journalism, beginning most prominently with the wire services (→ News Agencies), news corresponds with accurate representation and precise data, and professionalism stands for impartiality. Journalistic morality is equivalent to unbiased reporting of neutral data (→ Accuracy; Balance; Bias in the News; Neutrality; Objectivity in Reporting; Reality and Media Reality). Objective reporting is not merely a technique but the moral imperative to withhold value judgments.

The prevailing view of truth as accurate information is too narrow for today's social and political complexities, though objectivity remains entrenched in ordinary practices of news production and dissemination. With the no-longer-tenable dominant scheme, philosophical work is critical for transforming the concept of truth intellectually.

A more sophisticated concept of truth is *disclosure*, getting to the heart of the matter. Reporters seek what might be called *interpretive sufficiency*. The best journalists understand

from the inside the attitudes, culture, language, and definitions of the persons and events that enter news reporting. In the process of weaving a tapestry of truth, reporters' disclosures will be true on two levels: they will be theoretically credible, and they will be realistic to those being covered. Rather than reducing social issues to the financial and administrative problems politicians define, social responsibility requires that the news media disclose the depth and nuance that enable readers and viewers to identify the fundamental issues themselves.

### **CULTURAL DIVERSITY**

Indigenous languages and ethnicity have come into their own. Religious fundamentalists demand recognition. The cultures of 20,000 ethnic groups have become more salient than nation-states. Rather than melting-pot Americanization, for instance, US immigrants now retain their cultures, religions, and languages (→ Migration and Immigration). Identity politics as a dominant world issue after the Cold War, along with ethnic self-consciousness as a source of social vitality, challenge social institutions, including the media, to develop cultural pluralism.

To respond to the challenge, social responsibility ethics yields an individualistic morality of rights to the common good. Only specific social situations that nurture human identity can determine what is worth preserving. The public sphere becomes a mosaic of distinguishable communities, a pluralism of ethnic worldviews that intersect to form a social bond but remain seriously held and competitive. Active participation articulates and mutually implements the common good.

As the basis for cultural pluralism, social responsibility ethics replaces melting-pot homogeneity with the politics of recognition (Taylor et al. 1994). Democracies may engage in morally troubling discrimination when they fail to recognize their constituent groups. How should specific cultural and social features of Buddhists, Jews, the physically disabled, Native Americans, or Afrikaners matter publicly? Or should public institutions continue treating groups as free and equal without regard to race, gender, or religion, ensuring only that democratic citizens share equally in political liberty and due process? Language is the public medium for realizing individual identity, and its vitality or oppression inevitably conditions individual well-being (→ Language and Social Interaction). Thus journalism ethics requires a commitment to cultural pluralism, encouraging with other public institutions the flourishing of particular cultures, ethnicities, and religions (→ Ethnic Journalism; Minority Journalism).

### **PRIVACY**

Polls about public attitudes toward the press identify invasion of → privacy as a premier issue in media ethics, at least in western cultures. Such intrusions create resentment and damage press credibility. Despite the technical sophistication of case and tort law, definitions of privacy are porous and inadequate. They fail, for instance, to distinguish between newsworthy material and gossip or voyeurism (→ Rumor).

The journalism ethics of privacy builds on such moral principles as the dignity of persons and the redeeming social value of information disclosure. Privacy is a moral good

because controlling intimate information about oneself is an essential component of personhood. However, privacy cannot be absolute because cultural beings also have social and political responsibilities. As individuals, human beings need privacy; as social creatures, human beings need public information about one another. For individuals, eliminating privacy would end existence as humans know it; for social beings, elevating privacy to absolute status would likewise render human existence impossible. Thus emerges the formal criterion forbidding an invasion of the intimate life space of individuals without their permission, unless, and only after exhausting all other means, the revelation would avert public crisis or have overriding public significance.

The social responsibility perspective turns the issue of privacy inside out. Instead of journalists deciding about falsehood, innuendo, or legitimate intrusion, people have power to decide for themselves. A reasonable public determines whether to expose its life space. Whether publicity places individuals in a false light or is warranted belongs first to humans as ends-in-themselves.

From the theoretical debate about what constitutes community, journalism ethical practice applies moral principles to three areas: (1) reporting personalia about social groups that vary from criminals to innocent victims, (2) storing confidential information in computer databases, and (3) allowing ubiquitous advertising to intrude on everyday activities. In all three areas, neither the journalist's prerogatives nor the legal technicalities but the citizens themselves have priority and moral authority.

## **MEDIA TECHNOLOGY**

Harold Innis (1951; 1952) argues that social change accompanies media transformations (→ Innis, Harold). Technologies are not neutral; shifting from one medium to another alters how societies organize and how individuals think. Following Innis, → Marshall McLuhan (1964), and the Toronto School, media ecologists examine all forms of media technology, from cuneiform writing to the Internet, to understand their properties deeply and distinctly. This perspective divides the history of media technologies into oral, print, broadcast, and digital, but nearly all the important ethical issues received their sharpest focus in a print context. The intellectual roots of the democratic press were formed during the reign of print technology, and media ethicists have a predilection for news in literary rather than broadcast form.

In the digital era, journalism ethics must establish an agenda appropriate to the distinctive properties of a system of networking, search engines, and computer databases (→ Technology and Communication). This ethical framework can orient most fruitfully around social structures, recognizing that political and cultural formations offline and online are fundamentally different. Cyberterrorism, cyberwarfare, and other urgent new threats to social order are impossible without a digital infrastructure. The ethics of representation has a new orientation as persons enact and symbolize gender, race, sexuality, and religion in anonymous cyberspace. Some issues are new, and some amplify past ethics to levels of complexity heretofore unknown. Other problems inhere in the accessibility of computer mediated technology itself (→ Blogger; Citizen Journalism; Online Journalism). Digital technology weakens the distinction between home and work, emphasizes the character of interactivity, alters the struggle to engage social issues, and

shifts the means to build human communities. These changes require special emphasis on developing appropriate ethical principles.

The new media must pass the same social responsibility test as the old: to what extent they fulfill their democratic potential. The important question is whether educational and information services will be primary. Interactive technologies give people a voice and connect users directly without professionals or gatekeepers in between. The technologies are democratic tools in principle – hence the concern that the new media serve people’s needs rather than those of special interest groups or the market. Multitudes of online channels are technically feasible. Will they tangibly improve the quality of education, broaden the political horizons, or make public policy alternatives more understandable? Important social issues raise moral conflicts that the public itself must negotiate so that the media provide the soil in which democracy can flourish.

### NEW DIRECTIONS

New technology can be *tools for conviviality* (Illich 1973). *Convivio* means “living together,” and Ivan Illich emphasizes the means for communities to prosper, rather than destroying or homogenizing public life. Convivial tools are dialogical and publicly accessible. They do not require users to submit to expert pedagogy; they encourage experimentation, disassembly, and repair. Because of their simplicity and open design, they do not give rise to professional monopolies of knowledge. Fulfilling the principles of general morality often requires small, distributed technologies rather than massive or centralized ones.

Social responsibility is explicitly cross-cultural in character. The canon of journalism ethics has been largely western, gender-biased, and monocultural. To succeed under current conditions, professional ethics must instead be international, gender-inclusive, and multicultural. The global reach of communication systems and institutions requires an ethics commensurate in scope. Thus the current efforts toward a diversified ethics of social responsibility journalism build on a level playing field that respects all cultures equally. Because every culture has something important to say to all human beings, a journalism ethics in the interactive, transnational mode is the greatest challenge today worldwide.

## Ethics of Media Content

*Patrick Lee Plaisance*

*Colorado State University*

Questions of media ethics address the way media practitioners – journalists, public relations (PR) representatives, bloggers, technical support staff – resolve various types of dilemmas they face, as well as the value judgments that media audiences make regarding media content and performance. What does it mean to be “responsible” as a media professional? How should journalists balance the need for sensitivity with their mission to convey accurate, comprehensive depictions of events? What should a PR practitioner do when the interests of a business client conflict with professional values of public service and transparency? How do newspaper readers and television viewers expect news organizations to minimize potential harm to people without sanitizing the news? These are examples of key questions that concern media ethicists. As such questions make clear, ethics generally is not concerned with defining “right” and “wrong,” which is the subject of the broader

field of moral philosophy. Instead, ethics provides tools to help navigate “gray” areas in which conflicting or competing solutions may be legitimately argued. The purpose of ethics, then, is not to provide clear-cut answers regarding what constitutes good behavior or the “right” thing to do, but to enable people to resolve conflicts and dilemmas by asking the right questions based on the promotion and prioritization of key ethical principles and values.

### THE PHILOSOPHY OF ETHICS
