A moral dilemma, Foot (2002, 14) said, is “a special case of the dilemma that exists wherever there is evidence for and evidence against a certain conclusion. What is special is that the conclusion is about what an agent ought to do.” As a sub-field of moral philosophy, the discipline of ethics shares an epistemic form; i.e., just as moral philosophy is concerned with the essence that constitutes the “goodness” of something, ethics is concerned with what exactly constitutes the “rightness” of a decision when an individual is presented with a range of plausible (and often equally unsatisfying) options. At bottom, ethical reasoning legitimizes the moral claims we make. Walker (2000, 89) defined ethics as “pursuing an understanding of morality, which provides understandings of ourselves as bearers of responsibilities in the service of values.” The central concern of ethics is the justificatory power of our rational deliberation, rather than the nature of a particular moral stance. While morality and ethics are clearly related, they are not synonymous. Morality refers to a system of beliefs on which we rely to make judgments about right and wrong; ethics is a process to articulate rational justifications for our actions when the values that we hold come into conflict. “Ethics begins when elements of a moral system conflict,” the media ethics scholar Deni Elliott said (Patterson & Wilkins 2005, 3). While the two terms are often used interchangeably in general public discourse, the philosophical distinction is subtle yet significant.

Moral philosophers have sought ways to justify claims for the use of “ought” statements since the *Nichomachean ethics* of Aristotle and the dialogues of Socrates as recounted in the works of Plato. Hegel insisted that moral freedom be grounded in reason as well as in an acknowledgment of man as a vehicle for a larger “spirit.” Kant (1991, 2002) outlined a system of moral law based on our “absolute” duties to honor humanity’s free will and capacity for rational thought. In his landmark *Principia ethica*, Moore (1903) argued that “goodness” was a simple, non-natural property on which our moral judgments were based. Since then, moral philosophers have argued over what constitutes an ethical judgment and whether our conception of morality has any basis in reason.

In our efforts to articulate rational justifications for our actions, ethicists urge us to draw on common, longstanding principles such as respecting human dignity, truth-telling, and transparency, and carrying out our obligations as members of a community or public. These and other key principles comprise the heart of most professional codes of ethics. Ethicists direct us to draw on many different philosophers and theorists depending on the nature of the ethical dilemma we face. Our duties as social creatures with moral obligations are emphasized both in Aristotle’s call to pursue “virtue” through moderation and in Kant’s system requiring us to honor the human capacity for reason above all. The utilitarian approach of J. S. Mill can be useful in assessing the needs and welfare of a majority. The distributive-justice approach of John Rawls challenges us to envision a model of fairness that places a premium on the welfare of society’s most disadvantaged.

## ETHICS APPLIED TO MEDIA

While the broader principles mentioned above play a central role in media ethics theorizing and research, they often manifest themselves in more specific values that are enshrined across media sectors. Media professionals must be committed to a spirit of public service. They must be above-board, or transparent, in their work. They must take reasonable steps to minimize harming others in the course of carrying out their duties. They must allow their audiences to hold them accountable for their performance. Most cases in media ethics involve events or decisions in which two or more of these values come into conflict, and media practitioners must decide which will be given priority in a particular decision and why. Such real-life dilemmas are referred to as applied ethics. For example, there are many instances in which the journalistic mission to serve the public with aggressive pursuit of facts may create some degree of individual harm or discomfort. Most or all of the values mentioned above are explicitly promoted in codes of ethics adopted by professional associations such as the Society of Professional Journalists in the US, the Public Relations Society of America, or even the American Marketing Association. Media ethicists also are concerned with more specific questions such as perceived invasions of privacy, conflict of interest among journalists and people on whom they report, how public relations agents can successfully serve both private clients and the general public through their use of the media, and depictions of minorities and other vulnerable or disadvantaged groups in advertising.

Since media ethics is concerned with such fundamentals of behavior, the field incorporates several other dimensions of media. For example, media ethics research addresses the evolution of ethical standards and norms (→ Media History), questions of how ethical orientations influence professional behavior (→ Journalists' Role Perception), and assumptions and implications of legal and policy decisions (→ Media Management; Media Policy). Much of the media ethics literature that deals with these and other areas generally falls into one of two categories: philosophical explications for normative theorizing and empirical research on issues of media sociology.

### Normative Theory

A large body of media ethics literature attempts to develop theoretical frameworks to guide media behavior and apply elements of moral philosophy to media practice. Much of this work focuses on the organizational and social levels by suggesting how media organizations and professionals *ought to perform* to properly fulfill their ethical duties. This work also explores ethical implications of current practice. It includes arguments about threats posed by the propagandistic tendencies of message campaigns (Cunningham 2002) and the ethical problems regarding trust and truth-telling posed by online communication (Tompkins 2003).

Media ethicists have put forth various, often competing normative theories – calls for what the media ought to do as ethical agents – that advocate different philosophical approaches. These theories draw from the work of Dewey (1985), Lippmann (1922), and others who, while not explicitly concerned with ethical issues, have argued that media systems should serve specific roles in society. Merrill (2006), drawing from John Locke

and other Enlightenment thinkers, has emphasized a media ethics framework predicated on First Amendment, libertarian ideals of freedom and journalistic autonomy. In contrast, Christians and colleagues (Christians et al. 1993) have argued for a communitarian model of media ethics, which emphasizes the obligation of media systems to cultivate community and encourage civic engagement. A considerable amount of the media ethics literature reflecting the communitarian approach draws from philosophers such as Taylor (1990) and Sandel (1982), and from the social theorizing of Habermas (1989) and his notion of the need for the existence of a “public sphere” to promote social harmony and ethical discourse. Regardless of the philosophical approach used, most theorists in the field of media ethics strive to distinguish their work from moralizing punditry.

### **Media Sociology**

Since ethics by definition primarily addresses the efforts of individuals to resolve dilemmas, empirical research in the field of media ethics generally focuses on the individual level of analysis and thus is considered a division of media sociology. Research in this area seeks to explore attitudes of media practitioners toward professionalism, their perceptions of responsibilities, and their decision-making processes and influences. It seeks to find explanations for how practitioners approach particular issues and the key influences in their decision to handle or resolve a conflict or dilemma in a particular way. Researchers have sought to assess the value systems and moral outlooks of journalists and PR officials; the moral development of journalists as compared with other professions also has been studied (Wilkins & Coleman 2005).

Most of the empirical research in this area has been based on surveys and structured interviews. Because of the interpersonal, largely subjective nature of the work in news media, theorists have suggested that the manifestation of personal and professional values and norms can be easily observed in workers’ output, which continues to fuel public debates about degrees of bias in content (→ Bias in the News). Research on ethical decision-making in the media, as a result, often is more directly focused, at least among journalists, on professional norms and on the concept of news as a social construction of reality. Yet even so, many of these studies, which are ethnographic in nature, have directly addressed moral or ethical dimensions of professional media work. Gans (1980), for instance, was focused on how journalists “decide what’s news,” but his topic inevitably required an examination of personal and cultural values that he believed could be regularly found embedded in news content – what some social psychologists would say indicate journalists’ “ethical ideologies.” Shoemaker and Reese (1996) cautioned that routines and organizational constraints are likely to minimize or negate the influence of personal attitudes, values, and beliefs on media content. Conversely, McQuail (1994, 204) warned against ruling out any legitimate degree of autonomy in the newsroom and overestimating the power of workplace socialization. Much ethics-related empirical research, consequently, has focused on manifestations of values in content in efforts to contribute to this debate.

## **Ethnic Journalism**

*Anahí Lazarte-Morales*

*University of Illinois at Chicago*

Ethnic journalism is the practice of journalism by, for, and about ethnic groups. Because ethnicity is a historical and relational construction (Jackson & Garner 1998), the interplay of power and difference is central to the ways scholarly research defines ethnic media. Ethnic journalism relates to how difference is recreated and connected to the social, political, and economic participation of ethnic groups. Ethnicity is a membership formulated around a shared history, religion, cultural ancestry, geographical region, race, or language, which generates a sense of belonging among particular groups. By this definition, all news media are ethnic. What sets ethnic journalism apart as a distinct

category is the involvement of ethnically differentiated groups living within a dominant culture. The literature on ethnic media and journalism maintains conceptualizations of ethnicity marked by contexts of disenfranchisement and limited access to media production (→ Access to the Media).

Ethnic journalism embodies *sociopolitical projects of groups* that remain unaddressed in the news industry. Members of ethnic minorities seldom hold decision-making positions in the media, and content for and about ethnic minorities is marginal. News stories tend to emphasize the cultural and social traits that distinguish minority groups from mainstream culture (→ Minority Journalism), reinforcing constructions of these groups as different, exotic, and a problem (Wilson & Gutiérrez 1995). Ethnic journalism formulates representations of the group in ways that conform to how they see themselves, as a strategy for *political advocacy* and *cultural preservation* (→ Advocacy Journalism). Historical analyses have found that ethnic media and journalism crystallize during times of political and economic stress, to denounce discrimination and energize mobilization (Miller 1987). In some cases, ethnic media link to movements for political autonomy. Catalan and Basque news media in Spain, for instance, point to efforts for cultural reaffirmation and language preservation, but are also implicated in historical struggles for self-determination and the advance of a nationalist identity in seeking political independence (Hourigan 2003).

Ethnic news media do not always deviate from predominant journalistic values (→ Ethics in Journalism). Although in some cases they develop journalistic practices attuned to the group's communicative traditions, ethnic media are more likely to tailor mainstream news content to their audiences. To gain credibility and legitimacy, ethnic journalists often adhere to prevailing *professional standards*. For example, producers and reporters for a nightly newscast serving Latino audiences in the USA reproduce standard practices and the ideology of US journalism (Rodríguez 1996; → News Routines; Journalists' Role Perception). Nevertheless, they push forward a Latino-centered news agenda and configure a map of American society based on the Latino ethnic experience.

*Economic support* is another factor shaping ethnic journalism. Noncommercial ethnic media struggle to maintain operations with limited and intermittent resources. Scant funds translate into small editorial staffs and a dependency on external material, such as press releases and news feeds. Commercial news outlets operate through a profit-driven logic that may suppress diversity within the ethnic group to reach the largest portion of the audience (→ Media Economics). Because ethnic minorities are not unitary groups, the character of the ethnic experience to be communicated becomes a subject for negotiation. Ethnic media place the boundaries of ethnic membership under examination: who gets represented and who addressed?

Research on ethnic journalism emerged with the growth of the foreign-language press during times of increased immigration in the first half of the twentieth century (Park 1922). Given the continuous worldwide migration, the role of the diasporic press in the integration and identity formation of new migrants remains under investigation (Sampedro 1998; → Migrant Community Media). In a context of cultural globalization, ethnic journalism provides an opening to explore the particularistic markers that have resurfaced as a source of cultural identity and a resource for political mobilization (→ Globalization Theories).

Studies of linguistic communities, racialized groups, and indigenous populations historically at the political and economic margins have examined the relationship

between ethnic media production and public discourse (Riggins 1992). For example, indigenous media in Australia and Canada constitute an Aboriginal space, which enables conversation on common issues and experiences that do not find their way into mainstream discourse (Avison & Meadows 2000; → Public Sphere).

Aside from measuring patterns of ethnic news-media use, the social and cultural dimensions of consumption have had little study. But the institutional histories of ethnic media, which often apply political pressure to make communication policies more inclusive and to provide better access to media technologies, receive considerable attention. Researchers are shifting their focus to the levels of production and content, to understand the dynamics that shape ethnic news media and the maps they formulate of the world.

## **Ethnic Media and their Influence**

*Osei Appiah*

*Ohio State University*

Ethnic media are media vehicles (e.g., specific programs, publications, promotional pieces) that carry culturally relevant messages designed for and targeted to a particular ethnic group. Studies have demonstrated the rapid growth and success of ethnic media in North America and throughout the world (Deuze 2006; Gross 2006; Ojo 2006). In the past, media planners were guided by the assumption that they could capture ethnic

minority audiences using the same general messages and mainstream media that appealed to majority audiences (Askey 1995). However, given the current extent, growth rates, and buying power of ethnic minority members' media use patterns, and better understanding of this, there has been a greater effort to target ethnic minorities with culturally relevant media and messages (→ Ethnicity and Exposure to Communication). In fact, research suggests that ethnic media rather than mainstream media may be the most effective way to reach and persuade minority groups (La Ferle & Lee 2005).

Recently, the New America Media Foundation (Chan 2002) found that culturally relevant media reach on average 84 percent of ethnic minorities like Blacks, Hispanics, and Asian-Americans. Also, over 80 percent of minorities reported that they get information through ethnic television, radio, and publications, and over two-thirds reported they preferred ethnic media to mainstream media, particularly for news information (Conner 2004). Studies also suggest that culturally relevant media deliver greater returns on investment for advertisers than white general-market advertising (Cunningham 1999). For example, in a study on Asian audiences, Forehand & Deshpande (2001) found that Asian participants exposed to ethnic-specific media responded more favorably to same-ethnicity spokespeople and advertising than they did to mainstream advertising and spokespeople (→ Advertising).

This is also true for Hispanics, who not only prefer Spanish-language to English-language media but also respond more favorably to Spanish-language ads than English-language ads, regardless of the medium (Chan 2002). Numerous studies have concluded that Spanish-language media validate Hispanic consumers' cultural heritage and, therefore, are attributed with greater source credibility (Lee et al. 2004). Similarly, blacks are more likely to trust ads and editorial content in black media than they are to trust mainstream media, leading them to be more attracted to and positively affected by black media than mainstream media (Appiah 2002).

## **THEORETICAL FRAMEWORK GUIDING RESPONSES TO ETHNIC MEDIA**

The communication literature related to culturally relevant media has inadequately addressed the psychological mechanisms at work when ethnic minorities encounter media and messages targeted to them. In other words, why do ethnic media do a better job persuading ethnic minorities? Identification theory and distinctiveness theory are particularly relevant in addressing this question.

The persuasion literature has indicated that source–recipient similarity has shown that audiences are more likely to be influenced by a message if they perceive it as coming from a source similar, rather than dissimilar, to themselves (Brock 1965). Individuals are more influenced by media content when they identify with media characters, symbols, and values and perceive themselves to be similar to those characters, symbols, and values.

Identification theory (Kelman 1961) states that individuals automatically assess their level of similarity with a source during an interaction and make similarity judgments. This process drives individuals to choose a source based on perceived similarities between themselves and the source (Kelman 1961). It follows that culturally similar source cues that are inherently embedded in ethnic media would be particularly salient cues that lead ethnic minority audiences to not only identify with targeted media and their

content but also favorably respond to targeted media and their content (→ Audience Segmentation).

This notion is supported by distinctiveness theory, which states that a person's own distinctive traits (e.g., black, red-headed) will be more salient to him or her than more prevalent traits (e.g., white, brunette) possessed by other people in his or her environment (McGuire et al. 1978). The theory predicts that ethnicity will be more salient for people whose ethnic group is part of a numeric minority in a social environment than it will be for members of an ethnic majority in a particular social environment. Grier & Brumbaugh (1999) argue that, unlike whites, ethnic minorities appreciate the acknowledgment associated with being the target of media. They also state that ethnic minorities are more likely to use targeting cues based on their ethnically distinctive trait in attending and evaluating media than white majority members are to use targeting cues based on their non-distinctive trait.

Although the source's ethnicity does not seem to matter to ethnic majority members, racially concerned persons like ethnic minorities may react adversely to media sources that feature ethnic group members unlike their own. Although ethnic minorities do attend to some general market media, they often ignore mainstream media messages that are perceived to be targeted to primarily white audiences (Rossman 1994). Appiah (2002) concluded that because ethnic minority members do not identify with many white sources they often find mainstream media personally irrelevant, displaying a conscious form of *dis-identification* that causes them to tune out to white media and characters.

### **ETHNIC AND MAINSTREAM MEDIA SELECTION AS A FUNCTION OF ETHNIC IDENTITY**

While a low proportion of ethnic minorities attend to mainstream media compared to ethnic media (Fannin 1989), mainstream media should not be ignored as a potential method for reaching and persuading ethnic minorities. In fact, an integrated approach that combines both general market and culturally relevant media may be the best strategy. For example, blacks often choose between general media networks or those tailored more narrowly to black audiences (La Ferle & Lee 2005). Like blacks, Hispanics also enjoy both Spanish-language media and mainstream media (→ International Communication), but their preferences vary based on length of time in the US, language ability (La Ferle & Lee 2005), and in particular ethnic identity (Donthu & Cherian 1992).

Although a person's ethnicity is a significant predictor of their response to targeted media and characters, ethnic identity seems to be a more effective variable in explaining minority members' responses to media (Appiah 2004a). That is, individuals' feelings toward culturally relevant media and characters depend largely on their degree of identification with their own ethnic group. Studies demonstrate that minorities with strong ethnic identification perceive themselves as more similar to, and identify more strongly with, ethnic media and characters, and express greater liking for ethnic media and characters than do those minorities with weak ethnic identities (Appiah 2004a, 2004b). For example, strong Hispanic identifiers show more ethnic pride, greater use of Spanish-language media, and greater preference for ethnically advertised products than weak Hispanic identifiers (Donthu & Cherian 1992). Research also shows that minorities with weak

ethnic identities typically respond either indifferently or more favorably to white media and models vis-à-vis targeted media and models (Appiah 2004a; Green 1999).

### **WHITE AUDIENCES' RESPONSES TO ETHNIC MEDIA**

The positive effects of culturally relevant media are not limited to minorities. There is a growing body of work that has investigated how white audiences respond to ethnic-specific media and characters (e.g., Grier et al. 2006). Studies clearly show that these media and characters have succeeded in attracting and persuading mainstream audiences. In fact, in some cases ethnic media have been more effective than mainstream media in connecting to and persuading white audiences. For example, Appiah (2004b) found that white respondents were more likely to believe they were the target audience of black character ads than white character ads, and rated black character ads more favorably than white character ads. White respondents' more favorable responses to culturally relevant media and characters have been explained, in part, by the term *cultural voyeurism* (Appiah 2004b).

Cultural voyeurism is conceptualized as the process by which a viewer seeks knowledge about and gratification from ethnic minority characters by viewing them using a specific medium (Appiah 2004b). This notion implies that white audiences may seek, observe, and emulate ethnic minority characters in ads, in music, and on television to gain general information about their dress, music, and vernacular primarily because these characters are perceived to possess certain socially desirable traits (→ Stereotyping and the Media). For example, because black people often set the trends in many areas like clothing, language, music, and dance, which not only dominate "U.S. youth culture but the entire global youth market" (Rossman 1994, 140), white audiences may find black media and characters particularly appealing. As a result of cultural voyeurism, some white audiences, particularly white youth, may "identify more with Black characters than White characters on dimensions such as product use, social activities, sports, fashion, and music. For White adolescents, the desire to be cool and hip may override the importance of cultural and racial similarity" (Appiah 2004b).

Today, campaign and media planners should be more familiar with cultural values and lifestyles of ethnic minorities, and should have greater access to a wealth of research on these audiences that will enable them to more effectively target minority groups using culturally relevant media and messages (Rossman 1994). By not using ethnic media, campaign and media planners forgo valuable opportunities to effectively communicate with and persuade ethnic minorities, thereby losing out on a huge market and market opportunity (→ Strategic Communication).

## Ethnicity and Exposure to Communication

Holley A. Wilkin

Georgia State University

We live in an increasingly diverse world, not only in terms of ethnic heritage, but also in the forms of communication available. With so many information resources to choose

from, how do we make sure that communication campaigns reach target audiences? Ethnicity is often implicated in the formation of knowledge gaps, in which certain portions of the population receive and gain knowledge through the media at a faster rate than others, creating a difference between information “haves” and “have-nots” (→ Knowledge Gap Effects). As a result, the issue of ethnicity and exposure to communication becomes particularly important when trying to ensure equal access to → information pertinent to life in the twenty-first century.

Ethnic groups are distinguished by common culture, language, religion, and/or ancestral origins. There are no internationally agreed upon ethnic categorizations because history often plays a role in what aspects are considered most important for ethnic identity. For example, the historical conflict between Protestants and Catholics in Northern Ireland makes religious affiliation imperative to ethnic categorization, whereas the history of immigration in the US leads to a greater focus on ancestral origins (→ Migration and Immigration). Most research tends to use broader racial categories to define ethnic groups. In the US, for example, census categorizations of “White/Caucasian,” “Black/African-American,” “Hispanic/Latino,” “Asian,” and “Native American” are used most often in research, with most concentrating in the three largest ethnic categories – Whites, Blacks, and Hispanics. Occasionally case studies focus on a specific ethnic group as defined by religion or country of origin.

Ethnicity is viewed mainly as a potential co-variate in message exposure studies and appears in the literature when ethnicity is a significant predictor of exposure and/or effects (→ Exposure to Communication Content; Audience Research). Ethnic differences in use and/or communication connections could account for some of the significant findings attributed to ethnicity and are therefore the focus for this entry. The two goals of this entry are: first, to review some of the findings of studies comparing ethnic groups in media use and connections (→ Uses and Gratifications; Media System Dependency Theory); and second, to encourage a shift in the way that we study ethnicity and communication connections in the future.

### **ETHNIC COMPARISONS IN MEDIA USE AND CONNECTIONS**

Early media use research in the US concentrated on *television viewing* (→ Exposure to Television). The general consensus of these studies was that African-Americans and Latinos watch more and report greater satisfaction with → television than Whites. Blacks use television for entertainment and as a diversion, and Latinos more for entertainment and information. Both Blacks and Latinos prefer watching programs featuring characters or topics representative of their ethnic groups (Greenberg et al. 2002). This preference for ethnic → identification with television personalities likely spreads beyond these two ethnic groups. In recent years, reality television producers (→ Reality TV) have successfully appealed to a more diverse audience by seeking ethnic diversity while casting the programs.

Recent studies of ethnic groups in the UK found a slightly different relationship with television than found in the US. Ethnic minorities in the UK – including Mixed, Indian, Pakistani, Bangladeshi, Black Caribbean, Black African, and Chinese ethnic categories – watch less television than the general population. These ethnic groups are more likely to

have cable television and Asians, Chinese, and Middle Eastern groups, in particular, report preferring ethnic channels (OfCom 2007).

Ethnicity is also a common feature in → *digital divide research*. While most studies in Europe show that income, not ethnicity, is a key element in the digital divide, in North America studies indicate that lower-income Blacks and Latinos have less access to the → Internet and other new communication technologies, while Asian-Americans lead other ethnic groups in Internet access (→ Exposure to the Internet). In the UK, Black Africans are least likely of all ethnic groups to have Internet access (OfCom 2007). Programs around the globe are attempting to increase Internet access for all ethnic groups and income levels. However, even amongst those with access, ethnic differences still exist. African-Americans are more likely than Whites to search for information on new jobs, places to live, religion, and to download music, video, and audio clips online (Spooner & Rainie 2004). African-Americans indicate more appreciation for the ability to learn new things on the Internet, while Whites are more likely to report the importance of the Internet for staying in touch with family and friends (Spooner & Rainie 2004). Whites are also more likely than Hispanics to indicate interpersonal benefits from the Internet (Hacker & Steiner 2002).

Marketing research tells us the most about ethnicity and use of other media. African-Americans and Latinos are said to listen to more → radio than other ethnic groups. Whites/Caucasians are most likely to read → newspapers daily, followed by African-Americans, Asian-Americans, and Latinos/Hispanics. However, while circulation numbers are down for the traditional newspapers (readership has shifted to online formats), ethnic newspapers have shown some growth in recent years (Project for Excellence in Journalism 2007). Magazine readership studies (e.g., PReSS 2006) indicate that African-Americans prefer → magazines targeted to their ethnic groups (e.g., *Ebony*, *Jet*, and *Essence*) over general interest magazines, while Asian-American adults prefer news publications not found in the top ten magazines for general audiences and other ethnic groups (e.g., *Time*, *Newsweek*, and the *Wall Street Journal*; → Readership Research).

## **MOVING BEYOND “USE” OF SPECIFIC FORMS OF COMMUNICATION**

In today’s media-saturated environment, it no longer makes sense to study single forms of communication. A person can “use” multiple forms of communication simultaneously. For example, a person can watch television, check email, play computer games, and talk to someone on the phone at the same time if they desire (→ Multitasking). Media use studies do not capture this intricacy. Several researchers have stressed the value-added of examining media in context so as to be able to assess their relative importance (→ Media Ecology). The importance of any particular communication connection is relative to the importance of all other available and appropriate options. People usually connect to more than one communication option to achieve any particular goal; that is, they operate in context of the best choices available.

It has been shown that people construct different communication ecologies in order to achieve their everyday goals (→ Communication Infrastructure). For example, while you might find that local newspapers are the best way to find out what is happening in your community (→ Local News), talking to other parents or reading parenting magazines

may be more important when determining how to discipline your child for misbehaving in public. Therefore, while an ethnic group might spend more time using particular media, recall measures may find they were less exposed to particular messages because they were not connecting to the medium for that type of information. Exposure rates may be higher when the messages appear in media that the group spends less time using but considers more important for specific goals. So instead of studying ethnic differences in the use of television, the Internet, or other form of media, the goal should be to identify the communication ecology – the web of interpersonal and media (new and old or mainstream, and local and/or ethnic) connections that ethnic groups construct in the course of everyday life to reach specific goals.

### MOVING BEYOND BROAD ETHNIC COMPARISONS

There are some indications that there may be as many differences within broad ethnic categories as there are between ethnic groups (Resnicow et al. 2002). There are variations within Latino-Hispanic, Asian, and African-American groups based upon socio-economic status, ethnic backgrounds, identification with countries of origins and/or specific regions of a country, language use and accent, and city versus rural distinctions. Acculturation plays a role in whether immigrants of various ethnic backgrounds prefer media in their native language to that of their host country (→ Acculturation Processes and Communication). Sharing a native language does not always lead to common media exposure since the meanings of words and cultural symbols can vary greatly between countries of origin that share a common language. In addition, even people within one country (e.g., China, Brazil, South Africa, etc.) can connect to different media based upon the use of different dialects.

While most research has concentrated on the dominant racial and ethnic categories (e.g., Blacks, Hispanics, Whites, and Asians), a couple of studies have broken *new immigrant groups* down further. For example, one study found that more affluent Caucasian and Chinese-origin groups had the highest quality of Internet connectedness, while Korean-origin, Mexican-origin, and Central American-origin groups had lower-quality connections (Jung et al. 2001). Other studies have shown differences between Chinese and Vietnamese immigrants with regard to newspaper reading, suggesting a potential knowledge gap within the “Asian” ethnic categorization (Mansfield-Richardson 2000).

Not only will we get a more accurate picture of communication exposure when exploring intra-ethnic differences, there is reason to believe that geo-ethnic differences are just as important. The term “*geo-ethnicity*” refers to the interaction of ethnicity and geographical space. Studies have indicated significant communication differences between people of similar ethnic backgrounds who live in different communities – with different communication infrastructures – even when controlling for socio-economic status, immigration history, residential tenure, and home ownership.

These geo-ethnic differences can influence media connections. For example, Latinos in different communities in Los Angeles vary in their preference for mainstream English-language media rather than Spanish-language resources (Wilkin et al. 2007). There are also differences in the relative importance of television versus newspapers in these communities. While three Latino communities had extremely low Internet connections

(less than a quarter of the community surveyed had Internet access), one of the communities studied had almost three-quarters of the sample connecting to the Internet. These geo-ethnic variances were not unique to Latinos. The study also demonstrated that Whites in two Los Angeles communities differed in their connection to interpersonal, television, and local versus mainstream newspapers (→ Migrant Community Media).

There is no question that ethnic differences exist in exposure to communication and these differences can have implications for disparities between groups. With increasing diversity of communication resource options, ethnic and intra-ethnic exposure studies need to take place within an ecological framework.

# Ethnographic Film

Jay Ruby

Center for Visual Communication

It is commonly assumed that an ethnographic film is any documentary about nonwestern cultures. There is scholarly debate about its parameters. Some suggest all film is ethnographic (Heider 1976), while others restrict the term to films produced by anthropologists (Ruby 2000). There are no up-to-date histories of ethnographic film. The scholarly literature in the field is concerned with assumed dilemmas between science and art; questions of → accuracy, fairness, and objectivity (→ Objectivity in Reporting); the relationship between written and visual anthropology; and collaborations between filmmakers and anthropologists (see Banks & Morphy 1997; Crawford & Turton 1992; De Heusch 1962/1988; MacDougall 1998; and the journals *Visual Anthropology* and *Visual Anthropology Review*). The common definition will guide the discussion that follows.

## HISTORY

The earliest ethnographic films were the Lumière Brothers' "actualities," one-reel, single-take episodes of human behavior, such as "Leaving the Lumière Factory" (1895). Among the first anthropologists to produce researchable footage was Felix-Louis Regnault, who proposed, in 1900, that all museums should collect "moving artifacts" for study and exhibit. Scholars, explorers, missionaries, and colonial administrators often made footage for research and public display. However, the crude technology, lack of familiarity with the equipment, and vagueness of the maker's intention greatly limited their value.

In the 1930s Margaret Mead and Gregory Bateson extended Regnault's ideas and "published" fieldwork films like *Bathing Babies in Three Cultures* (1941). This approach continued with: Alan Lomax's Choreometrics study of dance as cultural behavior; Ray Birdwhistell and Edward Hall's cinematic studies of body movement and the use of space as culturally conditioned communications; and the use of cameras by dance ethnologists. In the 1950s the Institut für den Wissenschaftlichen Film in Göttingen launched its Encyclopedia Cinematographica Project, an archive and center for the study of filmed behavior. A similar organization exists at the Smithsonian Institution in Washington, DC. However, such films are seldom seen by nonresearchers.

Ethnographic film designed for the public began with a general educational film movement in the 1920s. Films of "exotic" peoples were produced commercially, sometimes with the assistance of anthropologists and screened as "Selected Short Subjects." For example, Pathé employed members of Harvard's Department of Anthropology when producing "People and Customs of the World" in 1928.

There were a number of early attempts to represent native life in feature-length theatrical film. Edward Curtis's *In the Land of the Head Hunters* (1914), a romantic epic of the Kwakiutl of British Columbia, was a box-office failure but established a precedent for Robert Flaherty's *Nanook of the North* (1922), a film frequently described as the first documentary and ethnographic film (→ Documentary Film). Nanook's international

success prompted Paramount to finance Flaherty's Samoan film, *Moana* (1926) and to distribute Meriam Cooper and Ernest Schoedsack's *Grass* (1926), a study of the annual migration of the Iranian Bakhtari. These films had more impact on Hollywood than on subsequent ethnographic films. When Cooper and Schoedsack again departed to make *Chang* (1927) in Siam, they carried a fully approved dialogue script, ensuring fidelity to executive preconceptions. Hollywood developed its own traditions of Native American, Asian, African, and South Sea Island adventure drama. In *The Silent Enemy: An Epic of the American Indian* (1930), director H. P. Carver employed an all-Native cast to tell the tale of an Ojibway warrior. The advent of sound caused the film industry to move onto the studio stage and abandon location productions until the 1970s. For 40 years, movie audiences learned about the "exotic other" from back-lot Tarzan films and cowboy and Indian movies. Because of the popularity of such films, ethnographic filmmakers are still forced to disabuse audiences of their expectations of seeing cannibals, headhunters, and other clichés. The rapid disappearance of native peoples, as well as western culture's folk customs, caused salvage ethnographic film projects to be undertaken, particularly among the "folk" cultures of Europe. The Heye Foundation supported a series of films on Native Americans from 1912 to 1927 produced by Owen Cattell and Frederick Hodge. However, it was not until after World War II that substantial activity is noted in the US.

### NATIONAL TRADITIONS

In France, film and ethnography were paired together by such pioneers as Marcel Griaule. One of his students, anthropologist/filmmaker Jean Rouch, gained the attention of both academics and filmmakers. In the early 1960s technical advances made it possible for small crews to produce synchronous sound films on location. *Chronique d'un été* (Chronicle of a Summer, 1961) was produced with sociologist Edgar Morin as the first *cinéma vérité* film. It combined the ideas of Soviet avant garde filmmaker Dziga Vertov and those of Robert Flaherty. Rouch took cameras into the Paris streets for impromptu encounters in which the filmmaking process was often a part of the film. Those filmed became collaborators, even to the extent of participating in discussions of the footage, which was in turn incorporated into the final version of the film.

Rouch continued his collaborative approach in a number of films made with West Africans such as *Les Maîtres Fous* (The Mad Masters, 1955), which was criticized for an assumed emphasis on the bizarre. Rouch sought a "shared anthropology" with his "ethnographic science fiction" films, such as *Jaguar* (1965) and *Petit à Petit* (Little by Little, 1968). The impact of Rouch's work was immediately evident in the films of French New Wave directors such as Chris Marker and Jean-Luc Godard. During his long career Rouch produced over 150 films (Feld 2003); he died in Africa in 2004 on his way to a film festival.

Rouch's attempt to present the world through the eyes of natives was taken a step further in the Navaho Film Project of Sol Worth and John Adair (1973), a project designed to teach Native Americans the technology of filmmaking without the western ideology usually attached to it. Similarly, Sarah Elder and Leonard Kamerling launched the Native Alaskan Heritage Film Project, producing more than 20 community films, such as *Drums of Winter* (1988), in which the people filmed play an active role in the film's conception and realization. Given the shift in power and awareness in a postcolonial and

postmodern world, some argue that the only ethnographic films that should now be produced are those that result from an active collaboration and sharing of power between ethnofilmakers and their subjects (→ Image Ethics). Through the efforts of such people as Vincente Carelli in Brazil (1980s), Eric Michaels in Australia (1987), and Terence Turner in Brazil (1992), many indigenous people have produced their own videotapes (→ Community Media; Community Video).

*The Hunters* (1958) is the first North American ethnographic film to gain worldwide attention. It is part of John Marshall's 30-year-long film study of the San (Bushman) of Southern Africa. Marshall subsequently produced dozens of African and North American films including *N'ai* (1980), a life history of a San woman, broadcast on American public television. His final film, *A Kalahari Family* (2004), was completed shortly before his death in 2005.

Robert Gardner, a former associate of Marshall's, released *Dead Birds*, a study of symbolic warfare among the Dani of New Guinea in 1964. The film grew out of a project in which ethnographers, a novelist, and a filmmaker all described the same culture. Gardner later produced several films in East Africa and India.

Timothy Asch worked collaboratively with anthropologist Napoleon Chagnon, creating a series of films on the Yanomamo of Venezuela. Among them are *The Feast* (1968) and *Ax Fight* (1971). These films, along with written ethnographies and study guides, were designed to teach college undergraduates cultural anthropology. In addition, Asch worked collaboratively with anthropologists in Bali and Indochina until his death in 1994.

The educational value of ethnofilm is exemplified by the curriculum developed by Educational Development Corporation in "Man: A Course of Study," produced by Canadian anthropologist Asen Balikci and filmmakers such as Robert Young. Films on Netisilik Eskimo life originally designed for use in a grammar-school course have also been repackaged for college-level courses, a commercial television special, *The Eskimo Fight for Life*, and a Canadian preschool children's series (→ Educational Media). The series became a political hot potato when some US congressmen found the films offensive because they assumed a culturally relative position and were thought to be anti-American (Dow 1991). *Through These Eyes* (2004) is a recent filmic attempt to review this project and the controversy that followed it.

While most European and North American ethnographic filmmakers travel to distant places to film exotic peoples, Australians have been filming their own native people since the turn of the century. The Torres Straits Expedition (1898) is reputed to be the first ethnographic expedition in which a motion picture camera was used. The Australian government provided a consistent source of funding. The Australian Commonwealth Film Unit (Film Australia) made it possible for Ian Dunlap to undertake long-term filming projects such as the "Peoples of the Western Australian Desert" series. The Australian Institute of Aboriginal Studies employed a staff ethnographic filmmaker. In that capacity, Roger Sandall produced films on the ceremonial life of Australian Aboriginal peoples, including *The Mulga Seed Ceremony* (1969). Public showings of these films have been restricted owing to the secret nature of some of the ceremonial acts portrayed. David and Judith Macdougall followed Sandall as the Institute's resident filmmakers. They are most noted for their African films, such as *Lorang's Way* (1979) and *The Wedding Camels* (1981), shot in a distinctive observational style that caught the attention of cineastes as well as anthropologists.

The Institute for Papuan New Guinea Studies has carried on the tradition begun by their Australian colleagues and sponsored a number of films on native life. Of special interest is *First Contact* (1983) by Bob Connolly and Robin Anderson. It employs 1930 footage of the forays of three Australian miners into remote sections of the New Guinea highlands and contemporary interviews with the surviving miners and Papuan natives as they recall their first encounters.

### RECENT DEVELOPMENT AND FUTURE

Television networks have become a significant source of support. In Britain, Granada's long-running series "Disappearing World" established a fruitful collaboration between field ethnographers and producers, resulting in films like Brian Moser's *Last of the Cuiva* (1971). BBC Television ethnographic projects have included the series "Face Values," produced in cooperation with the Royal Anthropological Institute, and "Worlds Apart," in which series producers Chris Curling and Melissa Llewelyn-Davies explored the impact of Leni Riefenstahl's photography in *The Southeast Nuba* (1983). In the United States, the Public Broadcasting Services aired "Odyssey" a series that covered all aspects of anthropology. A similar series was supported by Japan's Nippon TV under the title "Man," produced by Junichi Ushiyama.

Since the mid-1990s ethnographic filmmakers have become increasingly interested in the potential of new digital technologies and multimedia productions, in which video is combined with still photographs and text, resulting in an interactive experience for the viewer that is more often viewed on a computer screen than projected. In addition, the Internet and the world wide web are being explored as new outlets. Among the first to produce such works was Peter Biella with his *Yanomamo Interactive* (1997). More recently there has been Sarah Pink's CD-ROM on bullfighting and Jay Ruby's CD-ROM *Oak Park Stories* (2004–6).

The western world's fascination with people unlike themselves is centuries old and shows no sign of diminishing. It seems certain there will always be an audience for ethnographic film and, as more and more "natives" make their own work, opportunities to see the world through their eyes will increase (→ Visual Representation).

# Ethnography of Communication

*Donal Carbaugh*

*University of Massachusetts Amherst*

What are the means of communication used by people when they conduct their everyday lives; and what meanings does this communication have for them? These are central questions guiding the ethnography of communication. The ethnography of communication is an approach, a perspective, and a method to and in the study of culturally distinctive means and meanings of communication. The approach has been used to produce hundreds of research reports about locally patterned practices of communication, and has focused attention primarily on the situated uses of language. It has also been productively applied to various other means and media of communication including oral and printed literature, broadcast media, writing systems, various gestural dynamics, silence, visual signs, the Internet, and so on.

## NATURE OF THE APPROACH

The approach is concerned with (1) the linguistic resources people use in context, not just grammar in the traditional sense, but the socially situated uses and meanings of words, their relations, and sequential forms of expression; (2) the various media used when communicating, and their comparative analysis, such as online “messaging” and how it compares to face-to-face messaging; (3) the way verbal and nonverbal signs create and reveal social codes of identity, relationships, emotions, place, and communication itself. Reports about these and other dynamics focus on particular ways a medium of communication is used (e.g., how Saudis use online communication, or how the Amish use computers), on particular ways of speaking (e.g., arranged by national, ethnic, and/or gendered styles), on the analysis of particular communicative events (e.g., political elections, oratory, deliberations), on specific acts of communication (e.g., apologizing, campaigning), and on the role of communication in specific institutions of social life (e.g., medicine, politics, law, education, religion).

In addition to its focus on locally distinctive practices of communication, the ethnography of communication is also guided by a *particular methodology* and general concerns in theory development. As a theoretical perspective, it offers a range of concepts for understanding communication in any possible scene and/or community; as a methodology it offers procedures for analyzing communication practices as formative of social life. The methodology typically involves various procedures for empirical analysis including participant observation in the contexts of everyday, social life, as well as interviewing participants about communication in those contexts (→ Research Methods).

## ORIGINS

The ethnography of communication was founded by Dell Hymes. In 1962, he published a paper that called for a new area of study, a kind of linguistics that explored language not just as a formal system of grammar, but as something culturally shaped in the contexts of social life. At the same time, he called for a kind of anthropology that took speaking, and communication broadly, as its focal subject matter. The two interests, together, helped establish an innovative enterprise, a kind of linguistic study that was grounded in the social life of language; and in turn, a kind of cultural study focused on speaking and communication generally. In 1964, Hymes and his colleague John Gumperz published a special section of the journal *American Anthropologist* on the subject, which formed, in 1972, the basis of a highly influential reader, pioneering a general path for ethnographic studies of communication (see Gumperz and Hymes 1972).

Collections of research reports were published in the 1970s that helped move such study from the periphery of some disciplinary concerns in linguistics, anthropology, sociology, and rhetoric to more central concerns in the study of communication and culture. These studies explored aspects of communication that were often overlooked, such as gender role enactment, the social processes of litigation, marginalized styles, social uses of verbal play, and culturally distinctive styles of speaking (e.g., Bauman and Sherzer 1974). By the late 1980s and 1990s, a bibliography of over 250 research papers in the ethnography of communication was published, with another reader and several books appearing (e.g., Katriel 1986; Philipsen and Carbaugh 1986; Carbaugh 1990). These demonstrated how communication was a culturally distinctive activity while examining issues such as the ways communication varied by social agent and class, communication on and about popular movies, talk as done on television, relationships between speaking and silence, and intercultural interactions, as well as Native American poetics, political speech, verbal dueling, and verbal arts generally.

## CONCEPTUALIZING BASIC UNITS OF COMMUNICATION

The ethnography of communication offers a system of concepts that can be used to conceptualize the basic phenomena of study, and a set of components for detailed analyses of those phenomena. The phenomena of study are understood to be, fundamentally, communication phenomena, and thus the ethnographic design focuses investigators on communication as both the data of concern and the primary theoretical concern. Hymes introduced several concepts as basic units for the ethnographic study of communication. Chief among these are communication event, communication act, communication situation, and speech community.

Ethnographers of communication start their analyses by focusing on uses of the means and meanings of communication in particular socio-cultural lives. As a result, the locus of the study is on the practice of communication in contexts. The concept of *communication event* has become a prominent starting point for these analyses, for it draws attention to communicative action as formative of social processes and sequences. A communication event is understood to be, from the point of view of participants, an integral, patterned part of social life. Like gossip sessions, talk shows, and political

meetings, communication events typically involve a sequential structuring of acts, can be understood by formulating norms or rules about them, and involve culturally bounded aspects of social life which have a beginning and ending.

Communication events involve actions of many kinds. As such, events can be understood as the conduct of social actions, with *communication act* being the concept that brings together the performance of that action and its interpretation. One might say, e.g., “I enjoy hiking.” This saying might perform many actions: it might be used to explain one’s office decorations, to account for one’s attire, to counter others with anti-hiking interests, and so on. The concept of communication act, then, ties ethnographic analyses to specific social interactions in order to understand the range of conduct and actions that is getting done within them. Communication acts are most typically parts of larger sequences of social actions and in this sense are often usefully conceptualized as integral aspects of communication events.

In any human community, there are many places where communication is expected (or prohibited). These enter into ethnographies of communication as aspects of a setting in which communication itself takes shape. The concept of *communication situation* is used to identify specific settings and scenes for communication. For example, in some communities, communication situations involve the front porch, the television lounge, the bar, or a medical office (→ Communities of Practice). Unlike communication events, such as a church service, which are typically governed by a set of special rules and sequences, communication situations may involve activities with some particular boundaries or shapes, but without a strict sequencing of acts or activities.

A *speech community* is a group of people who share rules for using and interpreting at least one communication practice. A communication practice might involve specific events, acts, or situations, with the use and interpretation of at least one essential for membership in a speech community. The term “speech” is used here to stand in for various means of communication, verbal and nonverbal, written and oral; the term “community,” while minimally involving one practice, in actuality typically involves many, and is thus used to embrace the diversity in the means and meanings available for communication.

As communities of people gather in communication, so do they conduct themselves in particular ways. It is these patterned *ways of speaking* – e.g., about politics, in worship, or in education – that identify in which community one is, indeed who and where one is. In this sense, ethnographers of communication explore various ways of communicating, the situated variety in the events, acts, and situations of communicative life. Of special interest are specific situations and events in which different cultural styles of communication are simultaneously active (→ Interactional Sociolinguistics; Intercultural and Intergroup Communication; Intercultural Norms; Intergroup Contact and Communication).

## COMPONENTS FOR THE ANALYSIS OF COMMUNICATION

Once ethnographers of communication have identified a specific event, act, situation, or community for study, a subsequent move is the analysis of that selected practice as a multi-faceted phenomenon. This involves a particular methodology: the systematic analysis of the selected practice as it has been observed in its normal social contexts, and as it is discussed by participants. These analyses are conducted systematically

through a range of components. These components were originally formulated by Hymes, and involve explorations of the variety of dimensions of each such communication practice.

The components were summarized by Hymes using the mnemonic device *SPEAKING*, which will be used here for their brief discussion. As Hymes discussed, each component invites us to ask certain questions about the communication practice of concern. Questions such as these provide abstract theoretical bases for analyses that accomplish many objectives, including an understanding of the special qualities of specific communication practices (e.g., how Nigerian social interaction appropriates texts from popular culture), and what is common across a variety of practices. In other words, the components structure both descriptive and comparative analyses.

S: What are the *setting* and *scene* of the communication practice? This component explores two aspects of context: the physical setting in which it takes place, and the scene, i.e., the participants' sense of what is going on when this practice is active. Analyzing the setting and scenic qualities of the practice helps ground the analyses in the specific contexts of social life.

P: Who are the *participants* in this practice? A significant shift is marked here in conceptualizing communication as an event in which people participate, and thus the key concept is "participant" (in the event). This moves away from typical encoding and decoding models, or others which focus initially on senders and receivers of messages. What if a practice such as "reading the paper" is considered an event? Who are the participants in that practice?

E: What are the *ends* of this practice? This asks about two ends: the goals participants may have in doing the practice, and the outcomes actually achieved. In the event of joke-telling, many of us are familiar with an off-color joke, the goal of which was to entertain, with the outcome offending. Communication practice, generally, may target some goals, yet attain other outcomes (intended and not).

A: What *act sequence* is involved in and for this practice? The practice is part of social interaction. When does it arise and as part of what sequence? And further, what are the content of the practice and its form? This component invites a careful look at the sequential organization of the practice, its message content, and form.

K: How is the practice being *keyed*? What is the emotional pitch, feeling, or spirit of the communication practice? Regarding funerals, most are keyed as reverent and serious. Other events, such as some talk shows, can be keyed as more light-hearted. The ways practices are keyed, and the ways the key can shift from moment to moment, are questions raised and analyzed with this component.

I: What is the *instrument* or channel being used in this communication practice? The oral mode may be necessary, or it could be prohibited in favor of a specific gesture or bodily movement. Is a technological channel preferred, or prohibited? Should the practice be conducted in print or via a face-to-face channel, through song or chanting? The range of instruments being used to design a practice, and the ways each is interpreted, are entered into the analysis here.

N: What *norms* are active when communication is practiced in this way and in this community? This component distinguishes the two senses of norms that may be relevant to a communication practice: what is done normally as a matter of habit (e.g., few vote),

and what is the appropriate thing to do (e.g., one should vote in every election). Standards of normalcy can be productively distinguished from the morally infused, normative dimensions of communication practices.

There is a second distinction that guides this component: norms for interaction can be distinguished from norms of interpretation. The norm for interaction can be formulated as a rule for how one should properly interact when conducting the practice of concern: e.g., one should respect one's elders. The norm for interpretation can be formulated as a rule for what a practice means: e.g., sitting in silence with an elder counts as respecting that elder (→ Discourse Comprehension). Both norms are analyzed through this component.

G: Is there a *genre* of communication of which this practice is an instance? This might involve identifying the practice as a type of a formal genre such as verbal dueling, or a riddle, or a narrative. As a result, the properties of those formal genres become relevant to its analysis. Alternately, the practice might be understood as part and parcel of a folk genre, and be analyzed accordingly.

The investigative methodology summarized here involves identifying a unit of communication practice for purposes of analysis, generating data about that practice through procedures of participant observation and interviewing, then analyzing instances of the practice through the components. For any one practice, some components may prove more fruitful for analysis than others, and thus the use of the theoretical framework itself becomes an object of reflection during the ethnographic study.

## RECENT DEVELOPMENTS

Recent ethnographies of communication have examined mass media texts in various societies, political processes at the grassroot and national levels, interpersonal communication in many cultural settings, organizational communication in various contexts from medicine to education, intercultural communication around the globe, processes of power, advantaged and disadvantaged practices, and so on. And further, these studies have been conducted in and about several languages, including Chinese, Danish, English (of several varieties), Finnish, German, Hungarian, Japanese, Russian, and Spanish (in several locations), among many others. The growing number of native ethnographers conducting ethnographies of communication in their own speech communities is important to note, for this helps generate a fund of such studies, from a variety of authors, which is ripe and rich for future comparative work.

Several trajectories of work have evolved over the years that derive from or are indebted to the ethnography of communication. Some ethnographers have recently explicated a model of communication that is a discourse-centered approach both to culture (Sherzer 1987), with developments of it through explorations of indigenous practices (Urban 1991), and to the problem of intertextuality (Bauman 2004). Other trajectories involve a newly formulated theory of cultural communication and codes (Philipsen 1997, 2002), with developments of it through applications to work organizations (Covarrubias 2002), interpersonal life (Fitch 1998), and intercultural interactions (Carbaugh 2005). There is much recent work that is comparative and focuses on aspects of conversation and media, with special attention to the ways people conceive of and evaluate television texts, various uses of the computer, and how these relate to face-to-face channels of communication

(Katriel 2004). In any event, all illustrate what is culturally distinctive about communication, yet also suggest some general properties in communication, additional units for study, and so on.

And thus we have come full circle. For ethnographers of communication, communication is explored as something locally patterned and practiced as a part of social life, and as something crucially important, being formative of all societal and cultural communities. Discovering the locally distinctive means of all communicative media is crucial to our understanding. Interpreting what meanings are associated with these various means of expression is also essential. Knowledge of what is common across our various communities of communication is being served as well. In the process, ethnographers of communication demonstrate how communication is formative of social and cultural lives, comparatively analyzing both the cultural features and the cross-cultural properties of communication.

## Ethnolinguistic Vitality and Communication

*Richard Y. Bourhis*

*University of Quebec at Montreal*

The vitality of language communities can affect the quality of intergroup communication between speakers of contrasting language groups. This is the case where accent, dialect, and language not only provide important cues for the categorization of speakers, but also serve as salient dimensions of ethnic identity. Vitality is defined as “that which makes a group likely to behave as a distinctive and collective entity within the intergroup setting” (Giles et al. 1977, 308; → Collective Action and Communication). The more vitality an ethnolinguistic group enjoys, the more it will be able to use its own language so as to survive and thrive as a collective entity.

Three dimensions of socio-structural variables influence the vitality of ethnolinguistic groups: demographic, institutional support, and status. *Demographic* variables are those related to the absolute number of speakers and their distribution throughout the national, regional, or urban territory (e.g., birth and mortality rates, mixed marriages, and immigration/emigration patterns in and out of an ancestral territory). Demographic factors constitute a fundamental asset for ethnolinguistic groups as “strength in numbers” and they can be used as a legitimizing tool to grant language communities the institutional support they need to foster their development within multilingual settings.

*Institutional control* is defined as the degree of control one group has over its own fate and that of outgroups and can be seen as the degree of social power enjoyed by one language group relative to competing linguistic communities (Sachdev & Bourhis 2005; → Power in Intergroup Settings). The extent to which a language group has gained formal and informal representation in the institutions of a region, state, or nation constitutes its institutional support. Informal support refers to the degree to which a linguistic community is organized as a pressure group to represent and safeguard its own language interests in key state and private domains. Formal support refers to the degree to which members of a language group have gained positions of control at decision-making levels of private institutions and the local/national government. Such control improves the likelihood that the first language will be taught and used in education, provided as a language of health-care in hospitals, used as the language of work in business and government services, and included as the language of broadcasting. The presence and quality of leaders

within formal and informal institutions representing language groups also contributes to the institutional support of language communities. Gains in institutional support often depend on the emergence of activists and charismatic leaders who succeed in mobilizing groups to struggle for greater institutional control of and support for their ingroup language use.

Language groups that have made gains on institutional support factors are also likely to benefit from considerable social status relative to less dominant groups. The *status variables* are those related to a language community's social prestige, its socio-historical status within the state, and the prestige of its language and culture locally, nationally, and internationally. Social psychological evidence shows that speakers from high-status groups enjoy a more positive social identity and are likely to use their own language in a greater range of private and public situations. Conversely, being a member of a disparaged, low-status linguistic group can sap the collective will of minorities to maintain themselves as distinctive language communities, leading to linguistic assimilation. The experience of belonging to a high- vs low-status language community is reinforced through language stereotypes and enshrined through the adoption of language laws that legislate the relative status of language communities within multilingual states (Bourhis & Maass 2005).

The above three dimensions combine to affect in one direction or the other the overall strength or vitality of ethnolinguistic groups. A language community may be weak on demographic variables but strong on institutional support and status factors, resulting in a medium vitality position relative to a language minority weak on all three vitality dimensions.

The *subjective vitality questionnaire* (SVQ) was designed to measure group members' assessments of in/outgroup vitalities on each item constituting the objective vitality framework (Bourhis et al. 1981). Vitality research using the SVQ showed that, overall, group members are realistic in perceiving their vitality position along the lines suggested by "objective" assessments of ethnolinguistic vitality (Harwood et al. 1994). However, studies have also shown that group members can be biased in their assessments of own-group/outgroup vitalities. For example, perceptual distortions in favor of ingroup vitality occur when language groups exaggerate the strength of their own-group vitality while underestimating the vitality of the outgroup. Perceptual distortions in favor of outgroup vitality involve language groups who underestimate the vitality of their own-group while exaggerating the vitality of the outgroup.

Studies have shown that ethnolinguistic vitality can mediate a broad range of language attitudes and communicative behaviors. Combined objective/subjective vitality assessments allow language groups to strategically plan and mobilize not only to limit linguistic/cultural assimilation, but also to act more efficiently to improve their own-group vitality relative to coexisting groups in multilingual settings.

# Ethnomethodology

*Geoffrey Raymond*

*University of California, Santa Barbara*

Harold Garfinkel introduced the term “ethnomethodology” (by analogy to “ethnoscience”) in the 1950s and 1960s and gave the approach its fullest explication in his widely influential *Studies in ethnomethodology* (1967). Ethnomethodology consists of the effort to discover and analyze generic practices – *methods* – found across different occasions by which people in concert with one another deal with the concrete particularities of their circumstances and actions. Though initially misrepresented and trivialized in some corners (owing to a range of factors, including the chaotic state of social theory in the 1960s and, to a lesser extent, Garfinkel’s complex writing style), ethnomethodology is now widely recognized as having provided a radically transformed basis for a science of social life. Garfinkel’s theoretical writings furnished social scientists a powerful alternative approach to a core set of issues that underpin any social theory: the organization of social action; the social constitution of knowledge; and how two or more people develop and sustain a shared – or intersubjective – grasp of the world and each other’s actions (Heritage 1984). Garfinkel laid out his profoundly novel approach to social life in series of papers that involved studies of mundane settings (such as record keeping, jurors’ methods for making decisions, and the like) and reports on the results of his now famous breaching experiments.

## NATURE OF THE APPROACH

Ethnomethodology entails a fundamentally different approach to understanding the orderly character of social life. Beginning with Durkheim, Weber, Marx, and others, and with few exceptions since then, the sine qua non of a scientific approach to social life has entailed the development of (a) deterministic model(s) of actor and society. In this view, the difficulty of grasping the complex particularity and apparently chaotic messiness of actual conduct in concrete situations of action can be overcome by attending to patterns of social life that emerge in aggregated populations, aggregated interactions, or historical periods that have been (in different ways) abstracted from the particulars of singular

episodes of interaction. Once aggregated (or viewed through the lens of theoretical constructs), such patterns can then be explained by reference to whatever variables have been formulated explicitly in the social scientists' model.

As Garfinkel argued, however, such deterministic accounts are pursued at the cost of treating social actors' concrete experience, knowledge, and capacity for choice and reason as irrelevant, except insofar as they correlate with what has been formulated explicitly in the model. In Garfinkel's terms, deterministic accounts of social actions render actors as "judgmental dopes," since how actors recognize, interpret, and reason about their situations, the basis on which they select and design courses of action, and their justifications for acting, are (at best) only marginally relevant to such explanations. Indeed, the tenability of such deterministic theories of social action depends on forms of reductionism that render them inherently problematic (Wilson 1971). Instead of focusing on actors' motivations for acting, Garfinkel argued that social scientists should investigate the procedures by which members of society produce and recognize actions, and by virtue of this, explicate the "knowledgeable ways in which, whether consciously or not, social actors recognize, produce, and reproduce social actions and social structures" (Heritage 1987, 245).

Ethnomethodology simultaneously introduced a novel approach to understanding *the role of social knowledge in social life*. Although ethnographers and interviewers routinely exploit the fact that actors can explain their own actions, social scientists had long struggled over the status this ordinary rationality should be accorded. As had emerged in the "debates on rationality," mainstream social science approaches argued that insofar as the explanations that actors provide for their actions differ from those developed by social scientists, such "lay theories" and the commonsense knowledge they embody could be ignored as a flawed or distorted form of (proto)scientific knowledge. Garfinkel rejected this view, arguing instead that such commonsense knowledge was the stuff of social reality itself – not because the social world is as actors describe it, but because such commonsense understandings are the fundamental bases for their actions. Garfinkel summarized these views in his recommendation that "the activities whereby members produce and manage settings of organized affairs are identical with members' procedures for making those settings 'accountable'" (Garfinkel 1967, 1). Thus, in one elegant theoretical maneuver Garfinkel "integrated the analyses of action and knowledge" (Heritage 1987, 229). Instead of either accepting actors' accounts, *tout court*, or rejecting them as flawed, such formulations could be analyzed as one more form of action, especially insofar as they tend to be preoccupied with moral matters such as justifying, blaming, and the like.

Garfinkel's concern with the actors' point of view extended to his conception of *intersubjectivity*. In the prevailing approach in the 1950s, Parsons argued that the values internalized by actors would lead them to interpret the world in roughly similar ways. In such situations, actors also sharing a common system of symbols (i.e., a language) could communicate with each other. This approach treats intersubjectivity as a relatively uninteresting problem by handling it as an all-or-nothing affair that is guaranteed, in principle, by shared values and overlapping symbols systems (→ Objectivity in Science). Garfinkel argued that, in fact, shared understanding is a thoroughly contingent accomplishment that is sustained only through actors' persistent efforts in actual situations (→ Phenomenology) – thus, two or more actors' struggle to establish for all practical purposes an intersubjective grasp of a situation (including each other's thoughts, feelings,

and intentions) step by step, through their use of a common set of procedures for building and interpreting action. Garfinkel's concern with the "problem of intersubjectivity" led him to consider the ways in which ordinary understandings are contextual (Heritage 1987) and the complex and detailed ways in which the contexts of events furnish resources for their interpretation. Two concepts, in particular, proved especially important: the Documentary Method of Interpretation and the Indexical Property of Social Action.

### **THE DOCUMENTARY METHOD OF INTERPRETATION**

To describe how social actors recognize their situations and bring to bear relevant background knowledge in making sense of them, Garfinkel borrowed a key concept from the Sociology of Knowledge, the *Documentary Method of Interpretation* (DMOI). According to Mannheim, the DMOI involved the search for "an identical, homologous pattern underlying a vast variety of totally different realizations of meaning" (Garfinkel 1967, 78). Thus, actual appearances are treated as the document of, or as pointing to, a presupposed underlying pattern. Rather than relying on the DMOI as a research methodology, however, Garfinkel appropriated the formulation to describe the fact that humans unavoidably interpret individual appearances in light of an underlying pattern that is imputed to them. Moreover, Garfinkel added that "not only is the underlying pattern derived from its individual documentary evidences, but the individual documentary evidences are in their turn interpreted on the basis of 'what is known' about the underlying pattern" (Garfinkel 1967, 78). Thus, according to Garfinkel, the underlying pattern, and the documentary evidences through which it is grasped, are co-constitutive; each is used to elaborate the other. As Garfinkel argued, the use of this circular process of reasoning is unavoidable – there is no privileged position from which the underlying pattern can be understood apart from the individual particulars, and vice versa. In fact, the DMOI is the only way meaningful phenomena can be understood.

### **THE INDEXICAL PROPERTIES OF LANGUAGE AND SOCIAL ACTION**

To describe how actors make concrete sense of the contextual specificity of concrete situations while using a set of generic resources to construct them, Garfinkel appropriated and radically extended the concept of "indexical expressions," which had emerged in the Philosophy of Language. Language philosophers had long recognized that in order to make sense of sentences containing so-called indexical expressions such as pronouns (I, she, he, etc.) and other pro-terms (it, this, that, etc.), one must inspect the context of their production. Garfinkel borrowed this expression (and the contextual character of meaning it highlighted), arguing that, in fact, all language use, and indeed all action, has indexical properties. As Garfinkel and Sacks (1970, 341) observe, "the understandability of any utterance rather than being fixed by some abstract definition, depends on the circumstances in which it appears . . . [and] because any linguistic usage is indexical, the effort to remedy the circumstantiality of one statement by producing a more exact rendition will preserve that very feature in the attempt" (→ Conversation Analysis; Linguistic Pragmatics). While language philosophers treated indexical expressions as a barrier to analysis, Garfinkel suggested that attending to how actors make definite sense

with such indefinite resources would offer critical insight into the ways that social structures and collective forms are reproduced in concrete situations. Instead of providing a basis on which mutual understanding can be guaranteed, such forms and structures – and the order they afford – could be approached as “an ongoing, practical accomplishment of every actual occasion of commonplace speech and conduct” (Garfinkel & Sacks 1970, 341).

### BREACHING EXPERIMENTS

Garfinkel’s insights into the cognitive underpinnings of social order (→ Cognitive Science) have been massively influential: he articulated a radically novel approach to social action, the nature of shared understanding, the bases of social organization, and the relation between individual action and collective forms. The persuasiveness of his arguments rested in no small part on his ingenious demonstrations of their empirical reality through a series of “breaching experiments” (→ Experimental Design, for a different use of the term). Describing the genesis of these experiments, Garfinkel noted that instead of asking what variables contribute to the stability of persistent patterns of action, “an alternative procedure would appear to be more economical: to start with a system with stable features and ask what can be done to make trouble. The operations that one would have to perform . . . should tell us something about how social structures are ordinarily and routinely being maintained” (Garfinkel 1963, 187). In considering how to make “trouble,” Garfinkel had observed that in coordinating actions with one another, each actor “trusts” that the other will use the same set of procedures and commonsense knowledge as a basis for inference and action. In “perceivedly normal environments,” that trust is validated. The aim of the breaching experiments was to violate this trust by creating specifically senseless situations, for example, by refusing to fill in “what anyone knows” (by having experimenters repeatedly ask “what do you mean”), or by designing senseless actions (such as inviting subjects to play tic-tac-toe, erasing their first move and placing it in a different place on the grid).

According to Heritage (1984, 78–84), the *cumulative results of the breaching experiments* demonstrated three highly significant and previously unknown aspects of how order is maintained. First, the studies demonstrate that there is a staggering range of assumptions and contextual features that people draw on to sustain a particular documentary version of a sequence of events. Second, maintaining a continuing sense of the situation was not done through a set of rule-governed procedures; instead, subjects assumed an underlying pattern from the beginning and used it as the basis on which the appearances should be interpreted – giving that underlying pattern the benefit of the doubt at every possible point. Finally, people treat the use of interpretive resources for “filling in” what anyone can see, as well as the suspension of doubt concerning “what the appearances” amount to, as deeply moral matters.

Ethnomethodology opens up a vast domain of ever-present, but systematically overlooked, human activity for investigation: the generic methods by which people in concert with one another deal with the concrete particularities of their circumstances. While the import of this perspective can be described as “post-structuralist” insofar as it casts social structure as a *product* of social actors’ concerted efforts rather than as the basis for them, it does not entail a rejection of social structure, per se. From an ethnomethodological perspective, social scientists remain committed to understanding

objective social facts; however, instead of privileging their own understanding of such facts, analysts attempt to “rigorously explicate the phenomenon as an accomplishment of actors’ concerted work in making social facts observable, and accountable to one another in their everyday lives” (Maynard & Clayman 1991, 387).

Since its inception ethnomethodology has contributed to a range of fields, including the study of gender, studies of work, studies of science, ethnographies of “normal environments” (→ Microethnography), and studies of cognition, epistemics, and discourse. This entry has focused on Garfinkel’s classic statement of ethnomethodology, which has had the widest impact on the conduct of social science research (Wilson 2003). Garfinkel and his colleagues have continued to develop his transformative vision of social science, advancing a “radical ethnomethodology.” The influence of this later work will await a further assessment as it becomes more widely known and applied.

## **Ethos and Rhetoric**

*Michael J. Hyde*

*Wake Forest University*

Ethos, commonly translated as “ethics” and “moral character,” is a fundamental term in the history of the western rhetorical tradition. For “who does not know,” writes the

ancient Greek philosopher and rhetorician Isocrates, “that words carry greater conviction when spoken by men of good repute than when spoken by men who live under a cloud, and that the argument which is made by a man’s life has more weight than that which is furnished by words?” (Isocrates 1982, 278; → Rhetoric, Greek). Ethos is both a legitimating source for and a praiseworthy effect of the ethical practice of the orator’s art. Heeding the call of public service as a person of “good repute,” the orator’s presence and rhetorical competence are a “showing-forth” (*epideixis*) of a “principled self” that instructs the moral consciousness and actions of others and thereby serves as a possible catalyst for them to do the same for the good of their community.

Isocrates anticipates the doctrine of ethos developed in Aristotle’s *Rhetoric*, but with this doctrine comes a significant change in the technical use of the term. For Isocrates, rhetorical *paideia*, education and socialization, serves the process of character development, but it is a person’s character itself, his or her stellar reputation, that anchors the persuasive capacity of rhetoric. Aristotle, on the other hand, associates ethos not primarily with the orator’s reputation for being such a soul, but rather with the actual rhetorical competence displayed in the orator’s discourse. The practice of rhetoric constitutes an active construction of character; ethos takes form as a result of the orator’s abilities to argue and to deliberate, and thereby to inspire trust in an audience. Aristotle thus directs our attention away from an understanding of ethos as a person’s well-lived existence and toward an understanding of ethos as an artistic accomplishment.

Although the notions of ethos defined by Isocrates and Aristotle are certainly different, there nevertheless exists an “existential” connection between the two (Hyde 2004). Aristotle’s understanding of artful ethos presupposes that the character that takes place in the orator’s specific text is itself contextualized and thereby made possible by past social, political, and rhetorical transactions that inform the orator’s and his audience’s ongoing, communal existence: the “places,” “habitats,” and “haunts” (*ethea*) wherein people dwell and bond together. This earliest use of ethos as “dwelling place” dates back to Homer and Hesiod. Aristotle develops this particular usage of ethos when, in the *Nicomachean ethics*, he discusses how, beginning in childhood, “ethical” virtues can be trained and made habitual (1103a17–30). He also emphasizes this habituating process in the *Eudemian ethics*, when he identifies ethos with the “irrational part of the soul” that is still capable of following the orders of reason (1220b2–6).

The rhetorical tradition owes its technical use of ethos (associated primarily with oratorical skill) to Aristotle’s appreciation of the term as set forth in the *Rhetoric*. Martin Heidegger’s hermeneutical and ontological discussion of this text (“Grundbegriffe der aristotelischen Philosophie,” an unpublished transcript of Heidegger’s 1924 Summer Semester lecture course at Marburg, in the Marcuse Archiv in the Stadtsbibliothek in Frankfurt am Main) has been described as providing “arguably, the best twentieth-century reading” of its teachings (Struever 2005, 127). This reading, however, emphasizes a more robust appreciation of ethos than what is typically found in traditional discussions of the term throughout the literature of the rhetorical tradition. In the most original sense of the term, writes Heidegger, “Ethos means abode, dwelling place. The word names the open region in which man dwells” (1977, 233). This open region shows itself in the ongoing and future-oriented process of human being; the way the objective uncertainty of our spatial and temporal existence is forever challenging us to assume the

ethical responsibility of affirming the burden of our freedom of choice whereby, through thought and action, we bring a sense of order and meaning to our lives. This primordial challenge of human existence defines what Heidegger terms the original “call of conscience.”

Like Aristotle, Heidegger understands the art of rhetoric as a practice that employs logos (logic) and pathos (emotion) to transform the spatial and temporal orientation of an audience, its way of being situated or placed in relationship to things and to others. The genuine enhancement of public opinion requires, among other things, that the orator “modify” the lived and attuned space of others by “making present” to them what the orator has reason to believe is true, just, and virtuous. In so doing, the orator not only places his own character on the line and in the text but also clears a place in time and space for people to acknowledge and “know-together” (*consientia*) what is arguably the truth of some matter of importance (Hyde 2001). The ethical practice of rhetoric entails the construction of a speaker’s ethos as well as the construction of a “dwelling place” for collaborative and moral deliberation.

With all of this in mind, it may thus be said that the “ethos of rhetoric” directs one’s attention to the “architectural” function of the art: how, for example, its practice grants such *living room* to our lives that we might feel more *at home* with others and our surroundings. The ethos of rhetoric would have one appreciate how the *premises* and other materials of arguments are not only tools of logic but also mark out the *boundaries* and *domains* of thought that, depending on how their specific discourses are *designed* and *arranged*, may be particularly inviting and moving for some audiences. The ethos of rhetoric makes use of our inventive and symbolic capacity to construct dwelling places that are stimulating and aesthetically, psychologically, socially, and morally instructive (Hyde 2004; 2006).

# European Court of Human Rights

*Dan V. Kozlowski*

*Saint Louis University*

The European Court of Human Rights, established by and solely responsible for interpreting the Convention for the Protection of Human Rights and Fundamental Freedoms (the Convention), is arguably the most developed and respected international court. Its caseload has swelled in the past two decades thanks in part to its growing legitimacy and to the Council of Europe's expansion since the fall of the Soviet Union. The Court delivered 36 judgments in the 1960s and 1970s. By comparison, it issued 1,560 judgments in 2006. The Court is increasingly seen as a legitimate influence with a vital role to play in protecting individual freedom throughout Europe (→ Communication Law and Policy: Europe).

Until 1999, the Court existed alongside the European Commission on Human Rights. The Commission reviewed cases and attempted to get the parties to the dispute to reach a friendly settlement before it referred deserving cases to the Court. A modification to the Convention – Protocol No. 11 – merged the Commission into the Court. Now the Court directly receives petitions from states and individuals who claim the Convention has been violated.

Membership in the Council of Europe requires acceptance of the jurisdiction of the Court. The number of judges on the Court is set at the number of contracting states to the Convention, currently 47. Judges are elected by the Council of Europe's Parliamentary Assembly. When hearing and deciding cases, the ordinary judicial panel is a seven-judge chamber. Judgments of chambers of the Court are final, unless a case has been referred and accepted by the Grand Chamber. Containing 17 judges, the Grand Chamber has jurisdiction to review decisions if a case raises a serious question affecting the interpretation of the Convention. Parties to a case have three months from a chamber's decision to petition that the case be heard by the Grand Chamber. The Grand Chamber accepts relatively few cases for review.

Final judgments of the Court are binding on the states that are parties to the cases. If the Court rules that a state has violated the Convention, it can award compensation and/or costs and expenses to the injured party. The Court transmits its final judgment to the Committee of Ministers of the Council of Europe, which is responsible for supervising its execution. Although in practice the Court's judgments appear to be followed more dutifully in some states than others, on balance a substantial majority of states respect and follow the Court's judgments, and the Convention itself has been incorporated as domestic law in most of the Council of Europe's states.

One basic human right recognized by the Convention is freedom of expression. Article 10 provides that "everyone has the right to freedom of expression. This right shall include freedom to hold opinions and to receive and impart information and ideas without interference by public authority and regardless of frontiers." That right is not absolute, however. A second section of Article 10 – Article 10(2) – enumerates justifiable limitations on expression. Among other things, Article 10(2) states that restrictions on expression may be "necessary in a democratic society" in the interests of national security, for the protection of health or morals, and for the protection of the reputation or rights of others. The Court's Article 10 case law has thus required it to delicately balance the

right to freedom of expression with the “necessary” restrictions delineated in Article 10(2) (→ Freedom of Communication; Freedom of Information; Right to Communicate).

In a sizable body of case law – several hundred cases to date – the Court has articulated strong protection for free expression. In 2006, for instance, the Court issued 19 Article 10 judgments, finding violations in 17. The Court has said exceptions to the right must be interpreted narrowly and justified convincingly. In its case law, the Court has shown appreciation for instrumental and intrinsic values of expression (Janis et al. 2000). In one of its first Article 10 cases, the Court said freedom of expression “constitutes one of the essential foundations of [a democratic society], one of the basic conditions for its progress and for the development of every man.” The Court in that case held the right to free expression applies to ideas that “offend, shock or disturb.”

The Court has especially championed the value of political debate. In a seminal 1986 case, *Lingens v. Austria*, the Court ruled the criminal defamation conviction of a journalist for criticizing a politician violated Article 10. The Court said freedom of political debate was “at the very core of the concept of a democratic society.” A politician, the Court said, “lays himself open to close scrutiny of his every word and deed.” The Court’s constant approach, it said in a 2006 case, is to require “very strong reasons” for justifying restrictions on speech involving political issues and political figures. In the wake of *Lingens*, the Court expanded protection for allegedly defamatory statements beyond political issues to include discussion of other matters of public concern, even when the plaintiff is a private person (→ Libel and Slander).

The Court has also stressed the importance of protecting the press from regulation and → censorship. The Court has said the press fulfills an essential function in a democratic society and has a “duty to impart information and ideas on all matters of public interest.” On rare occasions, the Court has upheld injunctions against the press, but it has said such restrictions have inherent dangers and “call for the most careful scrutiny.”

In a 1996 judgment, the Court upheld a journalist’s right to refuse an order to reveal a source for his story (→ Source Protection). Because of the potential chilling effect an order of source disclosure has on press freedom, the Court said such a measure is not compatible with Article 10 “unless it is justified by an overriding requirement of public interest” (→ Freedom of the Press, Concept of). And in an important 1994 case, *Jersild v. Denmark*, the Court ruled that a journalist’s hate speech conviction for aiding and abetting the dissemination of racist statements violated Article 10. News reporting based on interviews, the Court said, “constitutes one of the most important means whereby the press is able to play its vital role of ‘public watchdog.’”

The Court’s free expression decisions have not escaped criticism. Scholars have charged, among other things, that the Court has permitted states too much deference in cases involving expression that offends morals or religion and in defamation cases concerning judges and prosecutors. In *Otto-Preminger-Institut v. Austria*, for instance, the Court ruled the seizure of a film that Austria claimed was an “abusive attack” on Catholicism did not violate Article 10. The Court said it was best left for Austria to determine what was required to “ensure religious peace.”

# **European Union: Communication Law**

*Amit M. Schejter*

*Pennsylvania State University*

The European Union (EU) is a unique supranational entity that has adopted an innovative approach to the challenges posed by its distinctive structure, by the convergence of communications technologies, and by the introduction of free market economics. In the process of transforming into a powerful union that preserves the sovereignty of its members, the EU has embraced the free flow of cross-border communications, market-oriented policies, each member state’s unique cultural identity, and the need to create a European cultural identity.

## **EUROPEAN UNION – HISTORY AND POLITICAL STRUCTURE**

The Rome Treaty of 1958, signed by France, Germany, Italy, Belgium, the Netherlands, and Luxembourg, created the European Economic Community (EEC). This treaty set the stage for the political unification of Europe into a single entity. During the 1970s and 1980s, Denmark, Ireland, the UK, Greece, Spain, and Portugal joined the EEC, increasing its membership to 12 nations. The Single European Act of 1987 streamlined the EEC’s decision-making processes with the goal of creating a political union, not an economic one, and it introduced majority voting on a limited number of issues.

After the Soviet collapse in the early 1990s, the Maastricht Treaty of 1993 created the European Union. The EU’s jurisdiction over economic assets was extended to a common foreign and defense policy and to cooperation in law enforcement, thereby trying to balance a central European power with individual national regimes. With Austria, Finland, and Sweden as its new member states in 1995, the “EU 15” adopted two key treaties: the

Amsterdam Treaty (1999) and the Treaty of Nice (2001). Consequently, the EU was restructured in such a way as to further expand to the former Eastern bloc nations. By 2005, the EU had 25 members, as the EU 15 nations were joined by Cyprus, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia, and Slovenia. Two years later, its membership increased to 27 with the addition of Bulgaria and Romania.

The EU resembles a conventional federal state (Tsebelis & Garrett 2001), although it allows each of its member states to maintain its national sovereignty. The Council of Ministers, which directly represents the member states, and the European Parliament, which is elected directly by the citizens of these states, both resemble a traditional bi-cameral legislature. The Commission of the European Communities, the EU's administrative branch, is in charge of drafting bills and enforcing legislation. The European Court of Justice (ECJ) functions as the judicial branch of the EU, charged with interpreting the emerging European law.

Among the binding legal instruments of the Union are: (1) regulations, which take immediate effect and apply to all EU citizens; (2) directives, which apply to the member states and aim to harmonize the goals of national laws across the Union, while leaving individual member states with the means of achieving these goals at the national level; and (3) decisions, which apply to specific situations. In addition, the bodies of the EU may reach nonbinding resolutions and form common positions on different matters.

### **A COMMON REGULATORY HERITAGE**

The basic assumptions underlying each European nation's communications law and policy were quite similar. With the exception of Luxembourg, all EU 15 members originally subjected their media and telecommunication industries to state control, believing that broadcasting was too important to be left to the whims of the free market (Levy 1999), and created national public service broadcasters (PSBs; → Public Service Broadcasting: Law and Policy). Because they considered telecommunications a natural monopoly and a public utility as well, they maintained control over telecommunications through state-owned post, telegraph, and telephone monopolies (PTTs; Sandholz 1993; → Postal Service, History of; Telegraph, History of; Telecommunications: Law and Policy).

All these PTT entities were governed by the public service principles, which derived from the absolute powers of monarchy, while recognizing no particular right for citizens (Garnham 2001). This shared ideology allowed the EU to emerge as a unifying force and for these highly politicized and central public institutions in the member states (see Blumler 1992) to play a critical role in determining future policy for the Union. The majority of the 12 countries that joined the Union in the 2000s, with the exception of Cyprus and Malta, were former authoritarian Soviet bloc regimes, in which the media and the telecommunication infrastructure were government-owned and -operated.

The EU's growing political clout in the 1990s brought about a *change in its public service-oriented policies* concomitant with the ideological revolution that saw most European nations, especially the EU member states, embrace more neo-liberal market-oriented policies, and with the technological revolution that saw the rapid introduction of new media technologies – cable and satellite transmission, digitization, and the Internet – completely transforming the industry. The rise of neo-liberalism notwithstanding, the

Union also committed itself to create and maintain a common European culture, while respecting the cultural uniqueness of each individual member state, under Article 151 of the consolidated European Union Treaty.

## TELEVISION WITHOUT FRONTIERS DIRECTIVE

The first and most significant initiative of the EU in its audiovisual policy was the 1989 *Television Without Frontiers directive* (TVWF) (Hirsch & Petersen 1998), which was substantially revised in 1997 and in 2007, in response to the changing political, ideological, and technological realities of Europe. As its name suggests, the TVWF aimed not only to harmonize legislation across member states, but, more importantly, to unify the rules for → television broadcasts across national borders as “without frontiers” was seen as a basic element of European unity (Wheeler 2004; → Television Broadcasting, Regulation of).

With regard to the flow of content across European borders, the directive advocated openness and minimal cross-border constraints, prohibiting member states from restricting retransmission of television signals from other member states (Article 2 in the original version of the directive; Article 2a in the amended version), with the exception of forbidden broadcasts that harm minors (Article 22) or incite hatred (Article 22a).

The concept of television without frontiers, however, was not always embraced by the EU member states, and the European Court of Justice intervened in several cases. In *TV10 SA v. Commissariaat voor de Media* – a case involving a ban on a channel aimed at the Netherlands – the court ruled that a member state could not be denied the right to ban broadcasting from a foreign territory when the sole purpose of this broadcasting was to bypass rules that would have applied had the broadcaster been operating within that state (Staetmans & Goemans 1995).

The court drew the opposite conclusion, however, in the case of VT4, a Flemish-language channel owned by Scandinavian shareholders and incorporated and licensed in the UK. The court found that the broadcaster was a British entity, and that there was no justification under Article 2 of the TVWF to block VT4’s signal from being retransmitted on Belgian soil. The motivation for the ban on retransmission may explain the contradiction between the two rulings. While the ECJ ruled in favor of the ban in the Dutch case because of TV10’s threat to the pluralism of Dutch broadcasting, the initial ruling against VT4 in Belgium was made in order to safeguard the monopoly of a single Flemish-language commercial broadcaster in Belgium (→ Plurality; Concentration in Media Systems; Competition in Media Systems). Indeed, in a third case – the criminal case of Paul Denuit, who was accused of violating Belgian legislation by retransmitting transborder commercial television stations whose distribution was prohibited by the state – the ECJ held that only under limited circumstances could a ban on the receiving market be justified. Even tax evasion was rendered a legitimate justification for “circumvention” in light of the goals of a common European community in later rulings (*Centros Ltd. v. Erhvervs-og Selskabsstyrelsen*). The 1997 amendment to the TVWF all but incorporated these rulings and further limited the ability of member states to block transfrontier broadcasts.

The TVWF, however, is more often cited for its role in safeguarding Europe against American cultural imperialism (Middleton 2003; → Americanization of the Media;

Cultural Imperialism Theories). Responding to the fear of American media influence, the directive created a quota system that ensures a minimum level of original European content on European channels (Article 4). The minimum quota is at least half the programming, with 10 percent of it produced by people other than the broadcasters (Article 5). These quota provisions, however, have been a source of tension in negotiations surrounding the GATT (the General Agreement on Tariffs and Trade), which would ensure the free flow of “services” but did not include cultural products within its jurisdiction (Barendt 1996).

### **THE CHALLENGE OF COMMERCIAL BROADCASTING**

The fear of Americanization of audiovisual content stemmed from the introduction of commercial broadcasting into Europe, which also threatened the dominant position of the PSBs, the perceived guardians of culture that were closely aligned with their national governments. Consequently, the Fourth European Ministerial Conference on Mass Media Policy decided in 1994 to ensure public service broadcasting’s independence and to secure its appropriate funding framework, which enables it to fulfill its mission. A protocol appended to the Amsterdam treaty defined the mission of public broadcasting as “directly related to the democratic, social, and cultural needs of each society and to the need to preserve media pluralism.”

The legal dispute between commercial and public broadcasters centered on the articles of the treaty that called for fair competition in the Common Market and the meaning of “state aid,” under Article 87 of the Treaty, which prohibits it if competition is undermined or is likely to be so. The commercial television companies argued that the license fees collected by the states to support PSBs constituted such aid.

Under the Amsterdam protocol, the Commission and the ECJ adopted a balanced approach to this issue, limiting the allocation of “state aid” to television programming that fulfilled the public service remit of the PSBs and served the “democratic, social, and cultural needs of each society.” Public service programming decisions were left to the discretion of the member states, which were allowed to include among them entertainment and sports programs. Still, the organization of European public broadcasters, the European Broadcasting Union (EBU), had to change its membership criteria so that commercial broadcasters could join it and enjoy its collective purchasing power, which was seen as a threat to fair competition, in particular with regard to sports programming.

The principles that guide the Commission in addressing the grievances of commercial broadcasters about unlawful “state aid” are proportionality and transparency. Proportionality limits public funding to the fulfillment of the public service mission and considers whether any distortion of competition arising from the aid can be justified by the need to perform the public service. Transparency requires separation of public service from nonpublic service activities of the public broadcaster.

The ECJ held in the *Altmark* ruling that state funding of public service broadcasters, including through license fees, is not “state aid” if it meets four conditions: (1) the recipient has actually and clearly defined public service obligations to fulfill; (2) the compensation is calculated based on parameters that have been established in advance in an objective and transparent manner; (3) the compensation does not exceed the necessary

costs incurred while carrying out the public service obligations; and (4) the level of compensation is based on a cost analysis conducted by a well-run organization or by tendering out the responsibility for the particular public service obligation.

The challenge from commercial television in the EU is also addressed by the TVWF in regulating advertising. The TVWF stipulates that in “fully and properly” protecting the interests of consumers as television viewers, television advertising must comply with minimum rules and standards. Article 10 of the directive states that television advertising must be distinguished from programming by visual and acoustic means, and it prohibits any form of subliminal or surreptitious advertising. Further, Article 20 limits advertising on television to 20 percent of transmission time per day. Advertising of tobacco products and prescription drugs is not allowed, while advertising of alcoholic products and advertising directed at children are limited (→ Advertising Law and Regulation).

### INTRODUCING COMPETITION IN TELECOMMUNICATIONS

Fear of external influences as a motivator for EU communication law was not limited to the fear of American content. Increasingly concerned about possible economic colonization by the US and Japan, which had been far more successful in employing information society technologies (Schneider 2001), the European Commission took control of telecommunications policymaking in the 1990s, and revolutionized the European political structure and regulatory landscape (Sandholz 1998). The first cross-European liberalization policy was not introduced until 1988. By 1990, however, the EU discerned a nexus between growth in the information sector and global economic competitiveness, and it linked this to its liberalization policies. In 1993, it set 1998 as the deadline for its full liberalization of voice telephony, allowing member states and incumbent PTTs a lengthy period of adjustment (Waverman & Sirel 1997).

The concept of an → “*information society*,” introduced by the Clinton–Gore administration of the US, was quickly integrated into the European discourse (Servaes & Burgelman 2000), and its principles, namely the predominance of market forces, became the central focus of a major EU-commissioned policy report, known as the Bangemann report (Anttiroiko 2001). The report’s publication coincided with the debate over telecommunications liberalization in Europe, in which the European Commission asserted itself as a supranational governing body (Sandholz 1998).

The initial European regulatory framework of 1997 was supplanted in 2003 by a new regulatory framework consisting of five directives. One issue that the Commission deemed a top priority, however, was resolved by 2000, when it adopted the regulation on unbundled access to the local loop to enhance Internet access.

The 2003 regulatory framework had two unique features: technological neutrality and preference to competition law over telecommunications law. The technology-neutral approach of the EU allows rejection of the legacy regulation that created different legal arrangements for different technologies, in favor of a new framework that first identifies what services are provided by the technologies and then harmonizes the rules regarding those services, regardless of the technologies involved. The EU’s option for competition law limits specific communications law provisions only to those product markets that are deemed uncompetitive.

## THE NEW AUDIOVISUAL FRAMEWORK

In 2005, the Commission proposed a directive on audiovisual media services that would significantly revise the TVWF. While motivated by technological changes impacted by wider access to Internet broadband, the new directive aimed yet again to promote a neo-liberal market-oriented agenda. Thus, it drew considerable opposition across the Union. The eventual political agreement among the different organs of the Union in May 2007 significantly modified the original proposal. It is expected to take effect in late 2007.

The amended TVWF directive retains the basic principles of the free flow of audiovisual products across Europe and limits the circumstances for creating exceptions to such flow. Based on the principle of technological neutrality, the new directive, popularly known as the *Audiovisual Without Frontiers* directive, distinguishes “linear audiovisual media services” (analog and digital television, live streaming, webcasting, and near-video-on-demand), from “nonlinear audiovisual media services,” (on-demand services). Because “nonlinear services” are distinct from “linear services” in the user’s choice and control, and in their impact on society, the directive imposes lighter restrictions on them. Newspapers and magazines do not fall into the jurisdiction of the directive.

Because of the cultural importance of audiovisual products, however, “nonlinear services” were also obligated to promote European works and “actively contribute to the promotion of cultural diversity” by supporting European works through financial contributions, a minimum share of European works in video-on-demand catalogues, or the attractive presentation of European works in electronic program guides. The new directive also delineates the circumstances in which the practice of “product placement” can be deemed legitimate.

## Evolutionary Theory

Frank Schwab

Saarland University

While social sciences of the twentieth century could be characterized by endeavors to “debiologize” human nature, evolutionary thinking has become increasingly presentable in scientific rationale. The most influential approach utilizing evolutionary theory to answer questions in respect of communication is evolutionary psychology (EP). EP (or Darwinian psychology) is focused on how evolution has shaped human mental architecture. EP is a theoretical approach to psychology that attempts to explain mental traits (cognitive

architecture) as adaptations, i.e., as functional products of natural or sexual selection. This approach introduces the functional way of thinking about biological mechanisms to the field of psychology.

Darwin and Wallace proposed that natural and sexual selection explain why organisms comprise a number of functional mechanisms that often exhibit a surprisingly complex evidence of design. This theory has important implications: (1) all evolved mechanisms must serve some function that ultimately increases the reproduction of the organism, and (2) the design of each mechanism will be best understood in relation to the environment it evolved in.

EP has roots in cognitive psychology and evolutionary biology. It also draws heavily on behavioral ecology, artificial intelligence, genetics, (human) ethology, anthropology, archaeology, biology, and zoology. EP is closely linked to sociobiology, but there are key differences between them, including the emphasis on domain-specific rather than domain-general mechanisms, the importance of mismatch theory (see below), and psychology rather than behavior. Even though EP bears a strong resemblance to human ethology, it was developed to a large extent without taking account of this forerunner.

EP argues against a widespread metaphor used in social sciences to describe the structure of the human mind as a blank slate or general-purpose computer. This metaphor has become the predominant orthodoxy in mainstream anthropology, sociology, communication sciences, and psychology. According to this orthodoxy, all of the specific content of the human mind originally derives from the environment and the social world. The mind's architecture consists of only a small number of content-independent general-purpose mechanisms like "learning," "imitation," "rationality," or "the capacity for culture." Contrary to this, EP assumes that the mind is a set of information-processing machines that were designed by selection to solve adaptive problems faced by our prehistoric ancestors. Adaptive problems are problems that occur very often and with stable characteristics in the evolutionary history of a species.

## PRINCIPLES

EP can be described using five principles:

- 1 The human brain is a physical system. The neural circuits are designed to create behavior apt to the environmental conditions.
- 2 These circuits or psychological mechanisms were designed by selection to solve problems that our hunter-gatherer ancestors faced during our species' phylogeny (evolved psychological mechanisms; EPMs).
- 3 Most of what goes on in our mind is hidden (instinct blindness); consciousness is just the tip of the iceberg of mental processing. Most problems that are experienced as easy to solve are in fact highly difficult to solve.
- 4 Different EPMs are specialized for resolution of specific adaptive problems.
- 5 Our modern skulls house a Stone Age mind.

The mismatch theory is an indication of the fact that not all behavior individuals engage in these days is adaptive (see principle 5). A taste for the sweet may have been adaptive

in an environment of evolutionary adaptedness (EEA) where vitamin-rich sugared fruit was scarce. In a modern environment, with confectioneries at every street corner, it can generate maladaptive behavior. Once an evolved → information processing mechanism exists, it can be deployed in activities that are unrelated to its original function: because we have evolved learning mechanisms that cause language acquisition (= adaptation), we can acquire writing as well (= by-product). But these learning mechanisms were not selected because they created writing capabilities.

## EVOLUTIONARY ANALYSIS

In evolutionary thinking, there are different levels of complementary and mutually compatible explanations. Thus, explanations at adaptive level do not necessarily preclude or invalidate explanations at cognitive, social, cultural, or economic level. Theories of adaptive function serve as guidelines to the investigations of phenotypic structures and mechanisms.

The logic of evolutionary analysis considers a hierarchy of levels, starting with the general evolutionary theory (natural selection, inclusive fitness). It subsequently takes into account middle-level evolutionary theories (parental investment, reciprocal altruism), assumes specific evolutionary hypotheses, and finally formulates specific predictions about empirical phenomena. On the one hand, there is this top-down strategy of formation of predictions and hypotheses, but one can also start with a phenomenon and then generate hypotheses of possible evolved function and design (bottom-up strategy). Both strategies attempt to discover the adaptive problems a given species encountered during its evolutionary history, to then develop a mechanism capable of adequately solving these problems under ancestral conditions. From an adaptationist perspective, one should adopt the stance of an engineer, or rather a reverse engineer. Theories of adaptive problems guide the search for the cognitive programs that solve them; knowing which cognitive programs exist can, in turn, guide the search for their neural basis.

The testing methods evolutionary psychologists (EPs) are actually using include comparison of different species, comparison of males and females, comparison of individuals within a species, and comparison of these same individuals in different contexts and cultures. Their sources of data to test evolutionary hypotheses include archaeological records, data from hunter-gatherer societies and different cultures, observations, self-reports, life-history data, and public records, as well as human products (cultural artifacts).

## EVOLUTIONARY THINKING IN COMMUNICATIONS RESEARCH

In communications research, media psychology, and media theory, the reference to evolutionary arguments is becoming increasingly popular (Schwab 2006; Schwender 2006; Vorderer et al. 2006; → Enjoyment/Entertainment Seeking). Does our preference to be entertained reside in an adaptive function of *Homo sapiens sapiens* or is it only an evolutionary by-product of other adaptations (Ohler & Nieding 2006)? Furthermore, which selection constraints may have produced this adaptation (natural or sexual selection)? Some approaches suggest that entertainment is an evolutionary by-product (e.g., Zillmann, leisure-time approaches; → Mood Management). Pinker's non-adaptive "cheesecake

metaphor” emphasizes that art and entertainment are utilizing evolved cognitive and emotional mechanisms to produce something like “cheesecake for our brains.” Entertainment and art provide useless techniques to trigger our pleasure buttons (Pinker 1997, 2002). Successful TV series or movies like *Titanic* or *Gone with the Wind* contain patterns of intra-sexual competition, mate choice, romance, and life-threatening hostile forces of nature and social environment (e.g., conflict and war). We are allowed to see breathtaking landscapes, be intimate with important people, fall in love with adorable men and women (→ Parasocial Interactions and Relationships), protect loved ones, attain impossible goals, and defeat spiteful enemies. People invent and consume media according to this hypothesis, not because these activities are themselves adaptations, but rather because their content and form artificially activate adaptations that have evolved for different reasons.

Other approaches assume an adaptive function: one of them uses the explanation pattern of sexual selection (the ornamental mind theory; Miller 2000), while others start with natural selection of a play module and attempt to reconstruct the destiny of this module in later stages of phylogeny. The ornamental mind theory accentuates the role of sexual selection in the evolution of skills and preferences for entertaining and aesthetic exhibits. Sexual selection is seen as the driving force behind the development of the human mind and complex human behavior: intelligence, inventiveness, art, humor, and kindness. Miller claims that human minds are entertaining, intelligent, creative, and articulate far beyond the demands of surviving in the environment of evolutionary adaptedness, and that psychology has been wrong to view them exclusively as problem-solving computers; that they are rather entertainment systems that evolved to attract sexual partners (Miller 2000).

Tooby and Cosmides (2001) propose that cognitive adaptations can operate in two ways: in ordinary functional modes and in organizational modes such as play, learning, and perhaps dreaming, to help construction of the mind. They elect art – especially in the form of narrative fictional entertainment – as a fourth organizational mode. Those adaptations, they argue, should be scheduled for off-peak demands: when we are safe and fed, without obvious reproductive opportunities (Schwab 2006).

Tooby and Cosmides (2001) place emphasis on the role of imaginative skills to augment our individual mental faculties to think, feel, and fantasize. They offer concrete grounds for the supposition that → fiction is adaptive. Across cultures, humans engage with pleasure in fictional worlds and there is strong evidence of specialized cognitive design in coping with fiction:

- 1 Fiction engages emotion systems while disengaging action systems.
- 2 We are able to disconnect fictional information from factual – so that it cannot corrupt our knowledge stores – with the efficiency and effortlessness that mark all evolved mental mechanisms (→ Fantasy–Reality Distinction; Media and Perceptions of Reality).
- 3 In communication meant to be accepted as credible, we pay keen attention to accuracy (→ Credibility Effects).
- 4 The malfunction of a specialized cognitive system can indicate specialized cognitive design. The competency to engage in pretend play, a forerunner of fiction, fails in autism, but not in other kinds of mild mental dysfunction.

5 An unexpected feature offers better evidence of functional design than an expected one. That minds should seek out accurate information seems equally predictable, yet this appetite for the truth spectacularly fails to match the frequent human preference for fiction over fact.

In a comparable rationale, Vorderer et al. (2006) propose an evolutionary theory of play by drawing on a cognitive model of entertainment as simulation. They suggest that the biological function of entertainment is learning, that this learning is accomplished by means of cognitive adaptations for mental simulations. This natural pedagogical system comes along with feelings of pleasure and enjoyment in fiction-based forms of entertainment as a necessary design feature. Due to mismatch theory, an evolutionary theory of entertainment does not amount to a claim that modern forms of entertainment deliver genuine benefits. Thus, an evolved function may regulate entertainment preferences, even in a world that has long since outrun the environment in which *Homo sapiens sapiens* evolved.

With the mismatch argument, one can even hypothesize that the ability to disconnect fictional from factual may not always prove satisfactory and thus remain without effect. Modern media worlds may (ab)use outmoded ontologies of human mental architecture and evolved mechanisms, like scarecrows that outsmart crows (Schwender 2006). Some particular emotional modules may react to media content in the same way as to real environmental cues. Pornography is affecting sexual arousal and even – as predicted by evolutionary means (sperm competition theory) – sperm configuration (→ Excitation and Arousal; Sex and Pornography as Media Content, Effects of). On the mental level it seems to affect partnership satisfaction and intentions to break up.

Until now, the proposed evolutionary explanations are highly speculative, albeit with some supporting empirical data (Buss 1999). From an evolutionary perspective, many traditional disciplinary boundaries are not merely arbitrary, but are misleading and detrimental to scientific progress. Studying scientific problems via adaptive problems and their solutions – the organizing principle of EP – provides a natural way of crossing disciplinary boundaries. EP has barely scratched the surface by identifying some of the most obvious problems linked to survival and reproduction. But EP also provides helpful tools to linking communication sciences with the rest of the life sciences to facilitate scientific integration.

## Excellence Theory in Public Relations

*James E. Grunig*

*University of Maryland*

The excellence theory is a general theory of public relations that resulted from a 15-year study of best practices in communication management funded by the International Association of Business Communicators (IABC) Research Foundation. Three books were published from the research (J. E. Grunig 1992; Dozier et al. 1995; L. A. Grunig et al. 2002). This general theory incorporates a number of middle-range theories of → public relations, including theories of publics, public relations and strategic management, models of public relations, evaluation of public relations, employee communication, public relations roles, gender, diversity, power, activism, ethics and social responsibility, and global public relations (→ Public Relations Evaluation). The theory was tested through survey research of heads of public relations, CEOs, and employees in 327 organizations (corporations, nonprofit organizations, government agencies, and associations) in the United States, Canada, and the United Kingdom (→ Survey; Interview). The survey research was followed by qualitative interviews with heads of public relations, other public relations practitioners, and CEOs in 25 organizations with the highest and lowest scores on a scale of excellence produced by statistical analysis of the survey data (→ Interview, Qualitative).

The excellence theory first explained the value of public relations to organizations and society based on the social responsibility of managerial decisions and the quality of

relationships with stakeholder publics. For an organization to be effective, according to the theory, it must behave in ways that solve the problems and satisfy the goals of stakeholders as well as of management (→ Stakeholder Theory). If it does not, stakeholders will either pressure the organization to change or oppose it in ways that add cost and risk to organizational policies and decisions. To behave in socially acceptable ways, organizations must scan their environment to identify publics who are affected by potential organizational decisions or who want organizations to make decisions to solve problems that are important to them. Then, organizations must communicate symmetrically with publics (taking the interests of both the organization and publics into account) to cultivate high-quality, long-term relationships with them. The interviews with CEOs and senior public relations officers revealed that good relationships were of value to organizations because they reduced the *costs* of litigation, regulation, legislation, and negative publicity caused by poor relationships; reduced the *risk* of making decisions that affect different stakeholders; or increased *revenue* by providing products and services needed by stakeholders.

Based on this theoretical premise about the value of public relations, the excellence theory derived principles of how the function should be organized to maximize this value. First, the research showed that involvement in strategic management was the critical characteristic of excellent public relations. Public relations executives played a strategic managerial role as well as administrative manager role. Public relations also was empowered by having access to key organizational decision-makers (the dominant coalition).

Second, the study showed that public relations loses its unique role in strategic management if it is *sublimated* to marketing or other management functions. Sublimation to another function resulted in attention only to the stakeholder category of interest to that function, such as consumers for marketing. Sublimation to marketing also usually resulted in asymmetrical communication. An excellent public relations function was *integrated*, however. Programs for different stakeholders were gathered into a single department or coordinated through a senior vice president of corporate communication. An excellent public relations function did work with other management functions to help them build relationships with relevant stakeholders.

Third, the excellence study showed that a symmetrical system of internal communication increased employees' satisfaction with their jobs and with the organization. However, internal communication generally was not practiced unless organizations had a participative rather than authoritarian culture and a decentralized, less stratified (organic) structure rather than a centralized, stratified (mechanical) structure.

Fourth, the excellence study examined the effect of the growing number of women in public relations and evidence that women had difficulty entering managerial roles. The research showed that organizations with excellent public relations valued women as much as men for the strategic role and developed programs to empower women throughout the organization. The emphasis on gender also led to inclusion of diversity of race and ethnicity as a fifth part of the excellence theory. This focus, along with the international nature of the project, expanded the theory to make it appropriate for use outside the United States – in diverse cultural, political, and economic contexts. Replication of the study in Slovenia (L. A. Grunig et al. 1998) showed that the excellence theory is generic to many contexts, as long as the theory is applied differently when contextual variables are

different. The research in Slovenia also resulted in the addition of ethics to the excellence theory – a sixth component (→ Public Relations Ethics).

Since the completion of the excellence study, scholars in this research tradition have continued to improve and enlarge the theory by conducting research to help public relations professionals participate in strategic decision processes. This research has been on environmental scanning and publics, scenario building, empowerment of public relations, ethics, relationships, the return-on-investment of public relations, evaluation, relationship cultivation strategies, conflict resolution, complexity theory, specialized areas of public relations, and global strategy (J. E. Grunig 2006; Toth 2007).

## **Excitation and Arousal**

*Gary Bente*

*University of Cologne*

*Felix Eschenburg*

*University of Cologne*

Common sense holds that exposure to media content can be associated with different levels of excitement and arousal (→ Exposure to Communication Content). The specific case of a thrilling movie well describes the type of stimuli that come to our mind when using the terms arousal and excitation in everyday language. From a psychological point

of view, arousal is conceptualized in more general terms, as a state of alertness and physical excitation elicited by external or internal stimuli, which challenge an adaptive response of the organism. The modern world is complex and rich in stimuli. It is in many respects different from the environment of our early ancestors, which required the organism to be physically prepared for immediate action, e.g., when possible threats entered the field of perception.

Although vigorous actions like “fight” or “flight” might be dysfunctional or inappropriate in the daily life of civilized humans, evolution has preserved those basic physiological alarm mechanisms, leaving the organism with a new type of adaptive task: to cope with arousal and excitation without launching atavistic behavioral programs (→ Communibiology). The narrow view of arousal as suggested by the fight–flight theory (Cannon 1914) only describes an extreme form of bodily excitation, nowadays subsumed under the term “acute stress response.” Arousal has, however, been recognized as a more universal physiological phenomenon, which is scalable along different intensity levels and which accompanies and/or influences various psychological processes relevant to the reception of communication and media content, such as → attention, → cognition, and → emotion.

## CONCEPTS AND BIOLOGICAL FOUNDATIONS

Several terms have been used synonymously with arousal. These are activation and intensity (Duffy 1972), as well as excitation (Zillmann 1983), the latter being most often used in the sense of sexual arousal. A broadly accepted conceptualization of arousal was introduced by Lacey (1967), considering it a multidimensional phenomenon, which can be differentiated in cortical, autonomous, and behavioral arousal.

*Cortical arousal* is associated with the ascending reticular activating system (ARAS) located in the brainstem. It receives input from the sensory receptors and projects nonspecifically into the cerebral cortex, producing a general cortical activation. The ARAS is responsible for tonic activation (i.e., being awake, drowsy, or sleepy) as well as for phasic activation (momentary alertness). Measures of cortical arousal can be derived from frequency analysis of the human electroencephalogram (EEG). *Autonomous arousal* is associated with the activity of the vegetative or autonomous nervous system (ANS). The ANS consists of two antagonistic parts: the sympathetic and the parasympathetic parts. Arousal is associated with the activation of the sympathetic sub-system, while the parasympathetic part serves mainly inhibitory functions. Indicators of autonomous arousal therefore are mostly derived from peripheral measures of sympathetic activity, as, for example, from the galvanic skin response (GSR). *Behavioral arousal* describes the activation of the motor system, which can be observed as agitation or measured as muscular innervation using electromyography (EMG). As most research on arousal is based on animal studies, we have to be careful with the meaning of the terms. Behavioral activation is not the same as a playful action to cope with an arousing event.

## AROUSAL AND EMOTIONS

There is consensus that emotions consist of *two major components*: an intensity component, i.e., the autonomous arousal (high or low arousal), and a directional component,

i.e., the hedonic valence (positive or negative feelings). Schachter and Singer (1962) formulated the two-factor theory of emotion, in which arousal (or excitation) is considered the unspecific component of emotional experience, identical for all kinds of feelings and blind to their hedonic valence (pleasurable or not). Via bodily sensations, arousal is perceived by the individual and interpreted as intensity of the actual emotional state. The quality of the emotional state, however, is dependent on the cognitive analysis and the labeling of the situation. Based on this assumption, Zillmann (1983) designed his → *excitation transfer theory*, which has broad explanatory value for various media effects (→ Emotions, Media Effects on). Excitation transfer theory holds that due to slower biochemical processes, the unspecific arousal part of emotions has a longer decay time than the cognitive appraisal of the situation. Thus, arousal stemming from a thrilling part of a movie can pertain and affect the intensity of joy during the happy ending. The model has also been applied to aggression as a media effect, suggesting that it is not necessarily the violent content, but the excitation effects of media stimuli, which can create the preconditions for post-receptive aggressive behavior.

Arousal and emotional valence can also be moderated by cognitive processes. By exposing participants to stressful images (e.g., a film of brutal genital surgery), Lazarus and Alfert (1964) could show that intellectualizing information can significantly reduce the level of autonomous arousal (sympathetic activation). Based on such observations, appraisal theories of emotion do not conceptualize arousal as a prerequisite for emotional experience at all and stress the regulatory functions of primary and secondary appraisal processes. These include the detection of the hedonic value of a situation as well as the judgment of the individual coping possibilities. Arousal might occur as a consequence of these cognitive processes but it is not crucial for the genesis of the emotional experience itself (→ Affects and Media Exposure; Emotional Arousal Theory).

## **AROUSAL AND INFORMATION PROCESSING**

In many cases communication content aims at providing information and thus primarily addresses the cognitive system of the recipient. As has been demonstrated, arousal can be an important determinant of → information processing, including attention, comprehension, learning, and → memory (Revelle & Loftus 1992).

A basic automatism preparing the organism for information intake and focusing the attention is the so-called *orienting response*, which occurs whenever the organism is confronted with a new, unexpected, or salient stimulus. The orientation response is closely associated with the activation of the sympathetic nervous system, and is characterized by a general decrease in muscle activity, an orientation of sensory receptors toward the stimulus, phasic heart rate deceleration, and an increase in electrodermal activity (Ravaja 2004). According to Öhman (1979), any stimulus is compared by preconscious mechanisms to the short-term memory. When the stimulus is classified as new, it is processed consciously. This switch from automatic to controlled processing mode is elicited by an *orientation response* and accompanied by an allocation of processing resources to the main channel of information processing. Stimuli that elicited an orientation response are more likely to be memorized later, which is most important for media content with persuasive intention, e.g., advertisement.

Depending on the quality of environmental stimuli, the organism has to decide whether to accept or to reject the input. The *two attentional modes*, environmental intake vs rejection, are reflected in specific arousal patterns (Lacey 1967). Both modes show sympathetic activation, as indicated by increased skin conductance and vasoconstriction. Heart rate, however, decreases during environmental intake and increases during rejection.

A phenomenon of particular relevance to media research is *suspense*, which shows the close connection between arousal and cognition (Vorderer 1996). Contrary to the orienting reaction, the arousal patterns associated with suspense are obviously derived from higher cortical areas, which are necessary for the involvement in a narrative. Suspense has been described as a state between fear and pleasure, based on expectations of bad outcome for the favored protagonist. Arousal goes along with the anticipation of a decisive point in time in the near future, where any uncertainty is reduced abruptly. The clarifying event, be it a positive or a negative outcome, leads to spontaneous relief, and a measurable drop in physiological arousal: “the *gestalt* is closed.”

Tonic aspects of arousal are also related to *cognitive processes*. Since the early work of Yerkes and Dodson (1908), there has been replicated evidence that a medium level of arousal is optimal for cognitive performance. It has to be mentioned that the delay period for recall plays an important role when judging the relation of arousal and memory (Revelle & Loftus 1992). High arousal seems to impede short-term recall and to foster longer-term recall, which is an important finding for advertisement and market research. Newer data also suggest that there is a similar “excitation transfer effect” concerning arousal and memory as for arousal and emotions, showing that memory-enhancing effects are semantically independent of the arousal source (Nielson et al. 2005). Such findings are most relevant for the future design of mediated learning environments and the conceptualization of edutainment software or game-based learning applications (→ Educational Media Content; Learning and Communication).

## AROUSAL AND PERSONALITY

Observations of our social environment as well as the variety of TV programs and movie genres indicate that people differ in their preferences for certain media and media content (→ Film Genres). Some people prefer horror movies; others like comedies or dramas. An important reason for these individual media preferences is personality differences. Two prominent personality constructs formulated on a psychophysiological basis and closely related to the arousal concept are extraversion and introversion, as introduced by Eysenck and Zuckerman’s concept of sensation seeking (→ Sensation Seeking).

*Extraverts* are hypothesized to have a lower habitual arousal level than introverts and thus require stronger external stimulation to achieve or maintain a comfortable activation status. However, the empirical findings to support the psychophysiological basis for the concept are at least controversial and not abundant at all (e.g., Matthews & Gilliland 1999). The concept of *sensation seeking* is germane to the concept of extraversion, although it has a stronger emphasis on stimulus choice than on social aspects. High sensation seekers generally have a lower level of internal arousal and do therefore need novel, complex, varying, and intense stimuli to maintain a comfortable arousal state. They have

been shown to exhibit a stronger orienting response toward novel stimuli. Although the empirical studies with regard to psychophysiological correlates of sensation seeking are also controversial, Zuckerman (2006) could summarize an impressive amount of studies using psychophysiological measures, which support the assumed biological foundation of the concept (→ Physiological Measurement). With respect to media choice, high sensation seekers have been reported to show a higher preference for sexually explicit material, action adventures, and violent action films, and have also been observed to switch channels more often than low sensation seekers (Zuckerman 2006).

It has to be mentioned that the interrelations between arousal measures and psychological constructs are in most cases complex, and interpretations are rarely straightforward. As different sources of arousal may produce similar outputs in a single measurement, the features of the stimulus material have to be regarded thoroughly at the time the reaction occurs (Ravaja 2004). In addition, most authors stress the importance of monitoring more than one physiological end point, as single physiological measures can indicate a different psychological process. The selection of appropriate arousal measures (i.e., a particular psychophysiological end point) very much depends on the research question (i.e., what kind of arousal has to be measured), but also on economic considerations, its invasiveness (i.e., less invasive measurement techniques are generally preferable), and its validity (i.e., whether the measurement technique is a widely accepted indicator for the variable targeted).

## Excitation Transfer Theory

*Dolf Zillmann*

*University of Alabama*

The theory of excitation transfer addresses sequential dependencies in emotional reactivity. Specifically, it predicts an enhancement of emotional reactions to immediately present emotion-arousing situations by portions of excitation that are left over from preceding related or unrelated emotion-arousing situations ( $\rightarrow$  Emotion; Excitation and Arousal). The theory operationalizes excitation primarily as dominance of sympathetic activity in the autonomic nervous system and treats this activity as the main determinant of the intensity of emotional behavior and experience (Zillmann 1983, 1996). Excitation transfer theory was initially advanced and tested to explain emotional reactivity in immediate social interactions. It equally applies, however, to emotional reactivity evoked by exposure to communication. Excitation transfer may be created by emotions from message exposure and affect emotions in social interactions, be created by emotions from social interactions and affect emotions from message exposure, and be both created by and affect emotions from message exposure (Zillmann 2006).

### **ASYNCHRONY IN COGNITIVE AND EXCITATORY REACTIVITY IN EMOTION**

Excitation transfer theory is based on marked differences in the time course of cognitive and excitatory adaptation to changes in conditions that arouse emotions. Cognitive adjustment to situational changes is quasi-instantaneous because of the exceedingly fast neural mediation of cognition. In contrast, the hormonal mediation of sympathetic excitation via the cardiovascular system is lethargic, and excitatory adjustment to situational changes occurs only after considerable passage of time. For most practical purposes, the latency of excitatory reactivity is negligible, but the so-called regulation of excitation – i.e., the homeostatically controlled return of excitation to normal levels – is

not. Elevated sympathetic excitation, once produced, dissipates slowly, usually over the course of several minutes. In the case of extreme excitatory reactivity, recovery may take an hour or more, and a variety of related or unrelated emotional reactions that occur prior to complete recovery may be affected by the persisting residues of excitation (→ Information Processing).

### **EMOTION INTENSIFICATION BY EXCITATION TRANSFER AS A CONSEQUENCE OF ASYNCHRONY**

The consequence of this time discrepancy in cognitive and excitatory adjustment is that residues of sympathetic excitation linger and intensify emotional behavior and experience for some time after cognitive adjustment to a novel situation has occurred. It is therefore expected that, whenever particular circumstances instigate an emotional reaction at a time when portions of excitation are left over from preceding emotions, the composite of newly instigated and residual excitation will foster emotional reactivity whose intensity is greater than that specific to the new instigation alone. *Residual excitation* may thus be considered to have “artificially” intensified the newly triggered emotion. In terms of emotional intensity, the strengthened reaction amounts to an over-reaction.

Excitation transfer theory treats sympathetic excitation as *hedonically neutral*. The function of this excitation is to energize the organism to act on vital conditions. Pleasure or displeasure associated with such actions is determined by cognitive processes and their hormonal concomitants in the central nervous system. As a result, residual sympathetic excitation from pleasurable emotions can intensify noxious emotions and residual sympathetic excitation from noxious emotions can intensify pleasurable emotions. Emotion intensification by residual sympathetic excitation can also occur, however, within sequences of either pleasurable or noxious reactions. For the projection of transfer effects, then, the hedonic valence of preceding and subsequent emotions is immaterial.

### **THE ROOTS OF EXCITATION TRANSFER IN EMOTION**

The expectation that residual excitation from preceding emotions readily combines with excitation to later instigated emotions entails the assumption that heightened sympathetic activity is common to all essential emotions. This assumption derives from *evolutionary theories* that construe emotions as reactions designed to resolve behavioral emergencies (→ Communibiology). Emotions that serve the indicated function require bursts of energy for immediate vigorous action, and it is such energy that heightened sympathetic activity provides. In situations of acute danger, for example, early humans needed to be able to alternate quickly between fight and flight reactions, both of which demanded high energy levels. Similarly high levels were also needed during sexual pursuits and in other vital quests.

As neither the emotion-controlling limbic brain structures nor the autonomic nervous system have undergone appreciable changes during recent millennia, the evolutionary consideration of human emotions leads to the conclusion that, in our times, excited emotions are still being triggered by circumstances of consequence. The energizing reactions occur despite the fact that nowadays adaptive actions do usually not require

bursts of energy and that such energization may often prove counter-productive in fostering unreasonable, nonadaptive actions. Considering the transfer of excitation from emotion to emotion specifically, the evolutionary rationale projects that the combination of emotion-intensifying excitation is primarily one of compatible elements of sympathetic excitation. It further suggests that, as awareness of combining energetic resources could only distract from urgent behavioral objectives, the specifics of excitatory integration generally elude cognizance.

### **A CASE ILLUSTRATION OF EXCITATION TRANSFER**

Imagine a woman who steps on a snake in the grass of her backyard. Deep-rooted survival mechanisms, organized in the brain's limbic system, will be activated and make her jump back and scream. A rush of adrenaline will have been released alongside to elevate sympathetic excitation. Following these initial reactions, the woman is bound to construe her emotional behavior as fear and panic. She might also notice herself shaking and thus realize that she is greatly excited. Upon looking once more at the object of her terror, she recognizes, however, that the snake is a rubber dummy, planted by her mischievous son, who enters the scene laughing his head off.

This recognition, a result of instant cognitive adjustment to changing circumstances, proves her initial emotion of fear groundless and calls for a new interpretation of her experiential state. Still shaking from the scare, she is likely to feel acute anger toward her son. In her infuriation she might even lash out at him. But after fully comprehending the prank, she might consider anger to be inappropriate, and cognitively adjust once more, this time joining in his laughter and appraising her experience as amusement. Throughout this cognitive switching from experiential state to state, the excitatory reaction to the detected danger in the grass persisted to varying degrees. It initially determined the intensity of the fear reaction. The *left-over excitation* from this reaction then intensified the emotion of volatile anger and, thereafter, the experience of amusement in fits of hysterical laughter. In short, residual excitation fostered over-reactions in a string of different emotions.

### **EXCITATION TRANSFER IN SITUATIONALLY EVOKED EMOTIONS**

The facilitation of primary emotions by residual sympathetic excitation from prior emotional reactions has been demonstrated in numerous experiments. In these investigations, an initial emotion is elicited to provide excitation for transfer, and an immediately following one is evoked to receive the excitation transfer and be intensified by it. In both emotions, excitatory reactivity is ascertained, usually in peripheral manifestations such as blood pressure and heart rate. This assessment focuses on the magnitude of transferred residual excitation. Cognitive reactivity is ascertained alongside to ensure the experiential quality of the emotions. Finally, the intensity of the subsequent, focal emotion is recorded in expressive and behavioral manifestations.

Using this research paradigm, it has been demonstrated, for instance, that excitatory residues from acute sexual excitedness can intensify such diverse emotions as anxious apprehensions, anger, aggressive behavior, altruistic inclination, and help rendering.

Conversely, residues from noxious emotions such as fear have been found to intensify sexual attraction to viable partners. But residual excitation may also come from emotionally neutral sources. Residues from strenuous physical exercise were found to facilitate anger and aggressiveness, this in accordance with the prevailing magnitude of the slowly dissipating residual excitation. Excitatory residues from neutral sources were also found capable of enhancing sexual excitement and amorous inclinations (cf. Zillmann 1996).

Research on the relationship between fear and joy similarly shows that excitatory residues from acute fear intensify the experience of pleasure upon the cessation of fear. Newcomers to parachuting, for example, showed considerable apprehension before jumping, but also the greatest joy upon landing. As jumping became routine and fear diminished, the experience of joy, no longer invigorated by appreciable amounts of measured sympathetic excitation, faded away along with the fear (Klausner 1967).

Investigations addressing yet other constellations of emotions give further evidence of the excitation-transfer intensification of primary emotions that are evoked in social situations or by environmental challenge (Zillmann 1996).

### **EXCITATION TRANSFER IN COMMUNICATION-MEDIATED EMOTIONS**

The transfer facilitation of feelings and emotions evoked by exposure to media presentations has been examined within the same research paradigm. It has been shown, for instance, that residual sympathetic excitation from pleasant emotions, such as sexual excitedness, or unpleasant emotions, such as disgust and dejection, can enhance the subsequent enjoyment of music (Cantor & Zillmann 1973), the appreciation of humorous presentations (Cantor et al. 1974), and feelings of sadness in response to happenings featured in motion pictures (Zillmann et al. 1974). Hedonically neutral residues from physical exercise, moreover, were found capable of enhancing favorable affective reactions to televised commercials (Mattes & Cantor 1982).

The application of excitation transfer theory to communication-mediated emotions is not limited to presentations that are composed of independent reports or programs. The → news, for instance, commonly presents an admixture of unrelated, differently arousing reports. For such aggregations it must be expected that arousing reports leave much undecayed sympathetic excitation behind for the immediately following, potentially entirely unrelated reports. Affective reactions to these subsequent reports thus should be enhanced by the excitatory residues from the preceding reports. A highly exciting documentary may analogously enhance reactions to material presented in its aftermath (→ Fear Induction through Media Content; News Processing and Retention).

For example, an emotionally upsetting report about a tribal massacre in a developing country, being followed without delay by a report about an expanding avian flu epidemic, is likely to enhance felt concerns about the flu and foster increased assessments of the risk of contracting it. In the reverse direction, a preceding fear-arousing report about a flu epidemic should intensify feelings of terror and revulsion in response to a subsequent report about a massacre. Facilitatory effects may also cross the hedonic divide, however. After learning of a glorious victory by a supported sports team and basking in reflected glory, the report of a stock-market debacle may strike one as being especially severe and

damaging to economic interests; and after learning of such a debacle and feeling miserable accordingly, the report of a glorious win by the supported team may prove extraordinarily exhilarating.

Excitation transfer theory applies analogously to the *aggregation of singular events* within a report or story. Successions of differently arousing events regularly occur in news programs, but are most characteristic of entertaining storytelling. The undisrupted presentational compression of scenes of limited duration defines, in fact, a unique forum for excitation transfer because excitatory reactions are, as a rule, not allowed to decay. Unlike in situations that permit interruptions, information intake in audiovisual presentations is continuous. New scenes are presented and cognitively assimilated before appreciable excitatory decay can manifest itself. Under these conditions, residual excitation is bound to enter into and enhance reactions to scenes that immediately follow arousing ones (→ Information Processing).

An excitation transfer variant of interest is the simultaneous presentation of *differently arousing events in a message*. The transfer expectation is that the more arousing part of the message will intensify emotional reactivity to the less arousing part and, to a lesser degree, vice versa. This expectation was confirmed, for example, in an investigation of the enjoyment of music presented in music videos (Zillmann & Mundorf 1987). The music-accompanying imagery was manipulated, featuring either highly arousing violent scenes, highly arousing erotic scenes, or unarousing innocuous scenes. The music was additionally presented without the accompaniment of imagery. In accordance with excitation transfer expectations, the identical music was experienced as more enjoyable when accompanied by arousing imagery than when accompanied by either unarousing imagery or no imagery at all.

Research on the phenomenon of *suspense in fiction* confirms the transfer facilitation of satisfactory resolutions to arousing tensions. It has been demonstrated that witnessing a liked character in acute danger generates empathic distress, that this distress is accompanied by elevated sympathetic excitation, and that residues thereof enhance joyous reactions to the display of the character's triumph over the endangering circumstances (Zillmann 2006). This enhancement of enjoyment has been observed for miniature plots (i.e., a scene of endangerment followed by a scene of overcoming) as well as for plots spanning an entire dramatic presentation (e.g., a motion picture). Numerous other dramatic transitions can be similarly explained. In "comic relief," for example, an acutely distressing event is immediately followed by an amusing one, which regularly triggers intense laughter in a transfer-intensified over-reaction (→ Entertainment, Effects of).

Dramatic entertainment does not necessarily serve the maximization of pleasure, however. It may focus on the creation of reflexive, contemplative states or on the evocation of somber and even grievous emotions. In case reflective states are targeted, arousing events should obviously be avoided. If such events are dramatically essential and must be featured, ample time must be allowed for the dissipation of the arousal produced by these events. In case grievous emotions are the object of drama, such as in tragedy, these emotions are again subject to excitation transfer. It has been shown, in fact, that grievous emotions can be intensified by residual excitation from preceding distressing experiences. This intensification functions analogously to that of suspense resolutions, except that the resolution of tragedy is, in terms of pleasure, very unsatisfactory.

## **Exemplification and Exemplars, Effects of**

*Gregor Daschmann*

*Johannes Gutenberg University of Mainz*

The term “exemplification effect” describes the influence of illustrating and aggregating case descriptions in media presentations on the recipients’ perceptions of issues. Aggregating case descriptions emerges whenever media coverage presents any kind of generalizing claim about natural or social phenomena and an arbitrarily selected sample of single cases to illustrate the issue at hand. General claims (e.g., “growing poverty in society”) often are supported by presenting quantitative information (so-called “base-rate information”) about a large number of cases (e.g., statistics about poverty; → Statistics, Descriptive).

Single case information often describes events, episodes, individual experiences, or testimonials (e.g., the fate of an individual homeless person, testimonials of homeless, etc.). This suggests that the general claim can and should be applied to events or subjects beyond the displayed cases. Therefore, single cases serve as examples (also called “exemplars”) that illustrate (i.e., exemplify) the general claim about the total population of phenomena (the exemplified) from which these cases are drawn. However, as a rule, the recipients’ conceptions of frequency, urgency, or potential risk of the events covered are strongly influenced by the number and type of the exemplars, whereas the general information often is ignored.

### **SINGLE CASES, EXAMPLES, AND COMMUNICATION**

From an epistemological perspective, all events and objects have distinctive features: no two cases are truly alike. Nevertheless, we can combine individual cases into classes of cases with similar or equal characteristics. This grouping strategy is a basic tool in human → cognition (categorization; → Information Processing; Schemas). If we select a case out of such a class of cases and regard it as representative for all other cases of the class, we use it as an example, assuming that it is typical or representative for other unobserved cases (Zillmann 1999). Thus, an individual case becomes an example whenever an observer generalizes from an individual observed case to other unobserved cases, or if a communicator uses the individual case as an illustration of a general statement (Daschmann 2001; Zillmann 2002).

The use of examples is frequently based on a *persuasive intention* – the aim is to present the general claim particularly convincingly and impressively – and obviously, episodic information has this quality (→ Persuasion). In the mass media, the use of examples is even on the increase: journalists have to make their contributions vivid, comprehensive, and interesting. Therefore, they prefer episodic information and illustrating single cases: this type of information is easy to understand and obviously more vivid and more dramatic than pallid and abstract general information. Iyengar (1991) showed the frequent use of episodic information in television. Zillmann et al. (1992) pointed out that the combination of abstract general information and exemplifying single cases is a prototypical format of media contributions. Content analyses document that examples frequently present a biased selection of cases, consistent with the news report’s focal contention and often selected due to their dramatic and emotional potential (Daschmann & Brosius 1999; Zillmann & Brosius 2000; → Instrumental Actualization). Biased selection of examples in the media is a particular problem, since there are no professional rules for exemplification in journalism – besides the self-evident requirement that the examples have to be true.

### **RESEARCH DESIGNS AND FINDINGS**

Most experiments in the effects of exemplars use the following design: subjects read, hear, or watch news coverage containing statistical information (base-rate) about the focused issue (in most studies, information about the climate of opinion provided by survey results) and a sample of five to nine examples illustrating the focused issue (in most studies,

**Figure 1** Estimates of climate of opinion as a function of exemplification

*Note:* The base-rate indicated the majority would not like card phones, was not content with the quality of the food or the wine, and liked the idea of computer lessons (Brosius & Bathelt 1994).

testimonials by a few individuals that articulate their personal opinion). While the base-rate information is kept constant over all experimental versions, the number and content of the exemplars is varied: in one version, the pro–contra distribution of the exemplars is in line with the general claim of the base-rate data, in the other version it contradicts the base-rate. After the presentation, subjects are asked to estimate the frequency and urgency of the issue (in most studies, the → climate of opinion), as well as to indicate their own opinion about the topic (→ Experimental Design).

For example, Brosius & Bathelt (1994) presented radio reports about four different issues. Each of the reports contained five testimonials (examples). The pro–contra distribution of the examples was varied in two versions. Subjects' estimates of the climate of opinion were in line with the number of exemplars while ignoring the base-rate data (Fig. 1).

## EXEMPLIFICATION EFFECTS – A RESEARCH OVERVIEW

In the 1990s, findings in social psychology led to exemplification research as a new branch in communication science. The impact of exemplification has been investigated in nearly 40 studies (for an overview, see Zillmann & Brosius 2000; Daschmann 2001), mainly in the US and Germany. Only one of these studies did not confirm exemplification effects as described above. All other investigations found an impact of the distribution of exemplars on perceived climate of opinion, on estimates of frequency of occurrence, on urgency of the issue (→ Agenda-Setting Effects), or on perceived risk ratio (→ Risk Perceptions). In addition, several studies found an influence of exemplification on the personal opinion of the recipients.

The more examples are presented, the more one-sided their distribution is. The more dramatic, extreme, and emotional the displayed cases are, the stronger are the effects. Presentation features such as personalization, vividness, or direct speech increase these

effects, too. Exemplification effects are reproduced in different kinds of media (radio, television, and print). Most studies focus on exemplification in nonfictional media coverage, mainly in the news, but confirm the effect for very different issues, e.g., the introduction of new technologies, the threat of crime (→ Fear Induction through Media Content), the safety of means of transport, including social topics such as the poverty of farmers as well as current political topics and questions of fashion or taste (Gibson & Zillmann 1998). For all issues, exemplification effects are confirmed, some studies document effects even two weeks after exposure. As yet, there are no systematic hints concerning interactions of the effect with socio-demographics like age, gender, or education. Different psychological traits or states, e.g., empathy, involvement, knowledge, preconceptions, or former experiences also do not interact with exemplification effects. In addition, exemplification effects seem to occur unconsciously: even when subjects regard the presented examples as a nonrepresentative sample, their judgments are influenced by the examples.

### CAUSES OF EXEMPLIFICATION EFFECTS

Findings in social psychology indicate that most people ignore available statistical information when forming judgments about frequencies, probabilities, or risk (*base-rate fallacy*) but rely for their judgments on information about a few nonrepresentative cases. Obviously, the relevance of information for human cognition is in contrast to its diagnostic value as seen from an epistemological point of view. Social psychologists assumed that due to their vividness examples are more available in memory and therefore have a stronger impact on *memory-based judgments* (→ Availability, Cognitive). Empirical studies did not support this hypothesis. Instead, it was found that many other presentation features, such as direct speech or personalization, or characteristics of the examples such as credibility or perceived representativeness, as well as characteristics of the recipients such as preconceptions or involvement also did not satisfactorily explain the findings (→ Involvement with Media Content).

More recent theories (Brosius 1995; Zillmann & Brosius 2000; Zillmann 2002) assume that the exemplification effect is rooted in a basic *cognitive mechanism of inductive learning* (“episodic affinity”) from episodic case information (Daschmann 2001). The mechanism is a cognitive tool, increasing the ability to draw general conclusions based on everyday experiences. The “heuristic” may be seen as a product of evolutionary development because it is helpful and reasonably correct when general conclusions are drawn from typical cases (→ Observational Learning; Elaboration Likelihood Model). However, if applied to untypical cases, misperceptions and wrong conclusions are the rule. In the process of reception of media coverage, the heuristic may thus lead to inadequate judgments due to the special type of examples used in the media.

This hypothesis implies *consequences for journalism*: since journalists cannot do without examples due to their advantages for presentation, they should use them in a more responsible and representative way (Meyer 2002; → Precision Journalism). They should present less extreme examples and include counterexamples in their contributions. On the other hand, recipients should be aware of the biased exemplification presented in the media and try to validate their judgments and conceptions by including further information sources.

While the existence of exemplification effects is well-confirmed, there are still *questions open* concerning the connections to other approaches in media effects research (e.g., → cultivation effects). These concepts describe different effects but can be based on the same cognitive mechanism. With respect to the methods and issues used, further research is necessary. Because nearly all studies tested students only, there is a lack of field research that could improve the external validity of the findings. There should be a greater focus on investigations of exemplification within domains of communication other than news coverage (commercials, entertainment, etc.). In addition, surveys of journalists about the selection and use of examples are necessary.

# Expectancy Value Model

*Jörg Doll*

*University of Bamberg*

*Icek Ajzen*

*University of Massachusetts Amherst*

Human beings have a natural tendency to react with some degree of positive or negative affect to any object or concept of psychological significance (Fishbein & Ajzen 1975; Eagly & Chaiken 1993). We like or dislike certain people, support or oppose various policies, regard some activities as pleasant and others as unpleasant, have favorable views of certain television programs but unfavorable views of others, and so forth. The expectancy value (EV) model is concerned with the origins and structure of these “social attitudes” (Feather 1982; → Attitudes).

According to the EV model, the overall evaluation of or attitude toward an object is a function of the information or “beliefs” we have about the object in question (→ Information Seeking). In the domain of communication research, the EV model has been applied to predict viewer attitudes and viewer exposure to various types of television programs and shows: news in general (Palmgreen & Rayburn 1982; Babrow & Swanson 1988) and health-related news reports in particular (Cooper et al. 2001), → soap operas (Babrow 1989), and prime-time entertainment programming (Galloway & Meek 1981). In recent years, it also has been applied to predict computer technology use of Canadian elementary and secondary teachers from schools in Quebec (Wozney et al. 2006; → Enjoyment/Entertainment Seeking; Exposure to Communication Content; Exposure to the Internet).

## ASSUMPTIONS

The EV model assumes that in the course of our daily lives our experiences lead us to acquire different beliefs about various objects, actions, and events. These beliefs may be formed as a result of direct experience with the object (e.g., watching a new Steven Spielberg film); they may be acquired indirectly by accepting information from other people or from printed and electronic media about the new Spielberg film; or they may be self-generated through inference processes based on knowledge stored in → memory about Steven Spielberg films in general.

Each belief associates the attitude object with an attribute. For example, we may come to believe that a → newspaper (the object) is created by a team of competent journalists and covers new and relevant information that is presented in an unbiased way (the attributes; → Journalists, Credibility of; Neutrality; Objectivity in Reporting). Because the attributes that come to be associated with the object are already valued positively or negatively, we simultaneously and automatically acquire an attitude toward the object. Specifically, the subjective value of each attribute contributes to the attitude in direct proportion to the strength of the belief, i.e., to the subjective probability that the object has the attribute in question. The way in which beliefs about an object (*o*) combine to produce an overall attitude is shown in the following equation:

$$A_o = f\left(\sum_{i=1}^n b_{io} \cdot e_i\right)$$

It can be seen that the strength of each belief ( $b_{io}$ ), i.e., the subjective probability that object  $o$  is characterized by attribute  $i$ , is multiplied by the evaluation of the associated attribute ( $e_i$ ), and the resulting products are summed over the  $n$  beliefs about the object. According to the EV model, a person's attitude toward an object ( $A_o$ ) is a *function of this summative belief index*. In this fashion, we learn to like objects we associate with largely desirable characteristics, to hold unfavorable attitudes toward objects we associate with mainly undesirable characteristics, and to form ambivalent attitudes toward objects we associate with both desirable and undesirable characteristics.

Of course, individuals are not expected actually to perform the mental calculations specified in the equation. The EV model is taken not as an accurate description of the way in which attitudes are formed but rather it is assumed that the attitude formation process can be modeled as if individuals were performing the stipulated calculations. It is also important to realize that people can form many beliefs about any psychological object, but that only a relatively small number is readily available in memory at any given moment. It is these readily *accessible beliefs* that are assumed to be the prevailing determinants of a person's attitude ( $\rightarrow$  Attitude Accessibility).

### IDENTIFYING ACCESSIBLE BELIEFS

Different approaches exist to identify accessible beliefs about an attitude object. *Two popular approaches* are the thought listing technique and the use of focus groups. For the thought listing technique, individuals are asked to list in a free response format any positive and any negative aspects of the object that come readily to mind. In focus groups, potential users of, say, a mass medium (e.g., television program, newspaper,  $\rightarrow$  Internet) are brought together in small groups and, in a permissive atmosphere under the guidance of a moderator, discuss various aspects of the media offering in question.

Based on one of these techniques in most applications of the EV model, the most frequently listed responses (thought listing technique) or most frequently mentioned beliefs from group discussions (protocol from focus groups) are selected to construct a *list of modal accessible beliefs*, i.e., beliefs that are common in the population of interest. Once a list of accessible attributes has been constructed, a new sample of participants is asked to rate the likelihood and the valence associated with each attribute. That is, they are asked to rate how likely it is that the object has the attribute (belief strength) and to rate the attribute on an evaluative scale (attribute evaluation;  $\rightarrow$  Rating Methods; Scales and Indices). These two ratings are multiplied, and the products are summed in accordance with the above equation. In addition, as a direct measure of attitude, participants are also asked to rate the attitude object itself on an evaluative scale. In accordance with the EV model, empirical research has demonstrated strong correlations between this direct attitude measure and the summed belief  $\times$  evaluation index.

In short, in the EV model it is assumed that our beliefs form the informational foundation for our attitudes. Although often quite accurate, beliefs can be biased by a

variety of cognitive and motivational processes (→ Consistency Theories). They may be irrational, based on invalid or selective information (→ Cognitive Dissonance Theory), be self-serving, or otherwise fail to correspond to reality. However, no matter how they were formed or how accurate they are, beliefs represent the information we have about the world in which we live, and they form the cognitive foundation for our attitudes toward aspects of that world.

### APPLICATION OF THE MODEL

The EV model can be used not only to account for the formation and structure of attitudes but also to help explain behavioral decisions (→ Attitude–Behavior Consistency). People form attitudes not only toward physical objects, institutions, social groups, events, and mass media offerings, but also toward behaviors. Thus, we may hold favorable or unfavorable attitudes toward watching a television program, reading a newspaper, playing a computer game, using a certain computer technology for teaching purposes, and so forth.

When the object of the attitude is a behavior, the relevant beliefs that determine the attitude are readily accessible *beliefs about the consequences of the behavior*. For these behavioral beliefs, again, a list of modal accessible behavioral outcomes must be constructed, and participants are asked to rate the likelihood that the behavior will produce each outcome and to rate the valence of each outcome on an evaluative scale. Belief strength and outcome evaluation ratings are multiplied and the products are summed to produce the EV composite, which is again found to correlate well with a direct measure of attitude toward the behavior. Some research has focused on the question of whether the EV composite can be decomposed by factor-analytic methods into belief sub-groups representing different functions that a certain behavior serves (→ Factor Analysis; Uses and Gratifications). In a study on watching soap operas among college students, Babrow (1989) identified four positively correlated EV subscales: perceived opportunities for social interaction, anticipated learning, anticipated general amusement and entertainment, and expected opportunity for romantic fantasy.

The EV model also has a number of *implications for attitude change* (Ajzen & Fishbein 1980; Fishbein & Ajzen 1981). Change in an attitude can be produced by changing the beliefs that are already accessible for the recipients or by making new beliefs accessible. According to the EV model, to change an attitude in a favorable direction, the summed EV products of the beliefs that underlie the attitude must become more positive than prior to the influence attempt, whereas a change in an unfavorable direction is produced by a negative change in the summed products.

To illustrate, if a person seeks information about basketball and believes that a certain television sports channel would supply a great deal of relevant information, the individual may seek such information from that sports channel. If the individual receives basketball information at a lower level than expected, it should reduce belief strength with regard to this attribute and as a consequence change the attitude in a negative direction. If, however, the same sports channel offers information about football at a higher level than expected (and this information is also positively valued by the individual), the resulting increase in belief strength can compensate for the decrease in the former belief strength,

leading in sum to an increase in the product sum and to a more positive attitude toward watching that sports channel. According to the EV model, changes in beliefs can occur either via changes in the belief strengths of the attributes or via changes in the evaluations of the attributes, or in both terms. Empirically, persuasive attempts trying to change belief strengths tend to be more effective than attempts trying to change belief evaluations, probably because evaluations of attributes are well anchored in prior learning.

## METHODOLOGICAL ISSUES

A methodological issue of the EV model concerns the scaling of belief strengths and outcome evaluations that are multiplied in EV products ( $\rightarrow$  Scales). Usually, respondents make their ratings on 7-point scales for both belief strengths (e.g., likely vs unlikely) and outcome evaluations (e.g., good vs bad). Derived from the conventional assumption that evaluations have a bipolar quality ranging from negative to positive with a neutral midpoint, bipolar scaling of outcome evaluations is used (from  $-3$  to  $+3$ ). Controversial, however, is the most adequate scaling for the belief strength ratings. Either bipolar scaling (from  $-3$ , very improbable to,  $+3$ , very probable) or unipolar scaling (from 0, very improbable, to  $+6$ , very probable) has been used. The bipolar scaling method allows respondents to express the falsity of modal accessible beliefs (Eagly & Chaiken 1993) and enables strong disbelief in very negative attributes to make a large positive contribution to the product-sum ( $-3 \times -3$ ).

To illustrate, perceiving it as very unlikely ( $-3$ ) that a television program will show pornographic material ( $-3$ ) can contribute positively to the composite score. However, unipolar scaling may appear more reasonable given the interpretation of the belief strength as a subjective probability. Unipolar scaling requires disbelief in negative attributes to make either no contribution (0 expectancy:  $0 \times -3$ ) or a small negative contribution (1 expectancy:  $1 \times -3$ ) to the composite. Most studies explaining media-related attitudes by the EV model have employed the combination of bipolar scaling for outcome evaluations and unipolar scaling for belief strength ratings.

## Expectancy Violation

Laura K. Guerrero

Arizona State University

People have expectations about how others should and will act in a given situation. Some expectations are based on personal knowledge about an individual, relationship, or situation. Other expectations are based on rules of social and cultural appropriateness. When a communicator's behavior deviates from these expectations, an *expectancy violation* has occurred.

Expectancy violations theory (EVT) explains how people respond to unexpected communication. EVT, which was developed by Judee Burgoon, initially focused on violations of personal space (→ Proxemics). The theory was later expanded to apply to other nonverbal behaviors and more general interpersonal events, including unexpected moves to escalate or de-escalate a relationship, transgressions such as deception and infidelity, and dating behavior (Burgoon & Hale 1988; Burgoon et al. 1995).

According to EVT, expectations come from three sources: communicator characteristics (such as personality), relationship characteristics (such as being friends vs being romantic partners), and context characteristics (such as culture and the situation). Behavior that confirms people's expectations generally goes unnoticed. Unexpected behavior, on the other hand, captures people's attention and leads to heightened arousal. Sometimes arousal change is aversive, leading to a fight-or-flight response. At other times arousal takes the form of an orientation response that leads people to scan the environment for information to help them interpret and evaluate the unexpected behavior. Evaluations are largely made on the basis of the perceived valence of the behavior and the reward value of the partner.

*Valence* refers to how positive or negative an expectancy violation is compared to the expected behavior. *Positive expectancy violations* occur when the unexpected behavior is better than the expected behavior, whereas *negative expectancy violations* occur when the

unexpected behavior is worse than the expected behavior. Some expectancy violations are unambiguous. For example, receiving an especially nice gift from a relational partner is almost always a positive expectancy violation; infidelity is almost always a negative expectancy violation.

*Reward value* refers to the level of regard a person has for someone. Reward value is associated with characteristics such as physical attractiveness, social attractiveness, and status (→ Interpersonal Attraction). When the meaning of an expectancy violation is fairly ambiguous, reward value is often the key determinant of whether the behavior is evaluated positively or negatively. For instance, a hug by an acquaintance is likely to be valenced negatively or positively depending on whether the acquaintance is perceived as unrewarding or rewarding, respectively.

According to EVT, valence and reward value work together to predict behavioral and emotional responses to expectancy violations, including patterns of reciprocity and compensation (→ Reciprocity and Compensation in Interaction). *Reciprocity* occurs when a person responds to an unexpected behavior with a similar behavior (e.g., one person is flirtatious, the other person responds with a coy smile). *Compensation* occurs when a person responds to an unexpected behavior with a dissimilar or opposite behavior (e.g., one person is flirtatious, the other person pulls away). People often engage in compensation when a change in the intimacy level of an interaction makes them uncomfortable. Expectancy violations can also produce uncertainty (→ Uncertainty Reduction Theory).

Burgoon and her colleagues have conducted numerous experimental studies applying EVT to the exchange of nonverbal behavior. In particular, EVT has been used to explain reactions to changes in nonverbal involvement. *Nonverbal involvement cues*, such as eye contact, touch, and vocal expressiveness, signal interest in an interaction. Other scholars have applied EVT to relationship transgressions (infidelity, deception) and dating behavior. Two consistent findings have emerged: when rewarding communicators engage in positive expectancy violations, people respond with positive affect and reciprocity; when unrewarding communicators engage in negative expectancy violations, people respond with negative affect and reciprocity.

Findings for *rewarding communicators* who engage in negative expectancy violations are less consistent. Studies looking at patterns of nonverbal communication have shown that when a rewarding communicator engages in a negative expectancy violation, the partner often compensates, at least initially. However, if the rewarding communicator continues acting negatively, the partner eventually reciprocates. Research on relational transgressions suggests that people are more likely to grant forgiveness and engage in constructive communication if the partner and the relationship were previously regarded as highly rewarding and the transgression only constituted a mildly negative expectancy violation. Highly negative expectancy violations often lead to destructive communication, even within the context of previously satisfying relationships.

Findings for *unrewarding communicators* who engage in positive expectancy violations have also been mixed. Sometimes people are suspicious of positive behavior by unrewarding partners; other times they evaluate the partner as more rewarding in light of the positive expectancy violation. Burgoon's research suggests that unrewarding communicators fare best when they confirm expectations and act in socially normative ways. In contrast, rewarding communicators have more leeway to violate expectations – either positively or negatively.

EVT provides a good example of how the scope of a theory can broaden over time. The theory has been successfully applied to the study of nonverbal behavior for decades. Recent work on EVT expanded the theory's scope by examining relational transgressions, dating behavior, expectations about sex, and sexual resistance, suggesting that the concept of expectancy violations explains a variety of human behaviors (Afifi & Metts 1998; Bachman & Guerrero 2006; Bevan 2003; Morr & Mongeau 2004).

## **Experiment, Field**

*James B. Weaver, III*

*Emory University*

Research utilizing experimentation is increasingly being conducted in venues outside the research laboratory (→ Experiment, Laboratory; Experimental Design). Such projects, when they involve the manipulation of an independent variable in realistic circumstances, are called “field experiments.” Natural experiments, involving research conducted in realistic circumstances where the researcher *does not* manipulate the independent variable, are discussed elsewhere (→ Experiment, Natural).

### **DISTINCTION FROM LABORATORY EXPERIMENTS**

Field experiments provide an excellent approach for studying both theoretically derived → hypotheses and problems of practical application. Conceptually, the differences between the laboratory experiment and the field experiment are slight; ideally, both are structured on one of the true experimental designs and consequently incorporate

randomization and manipulable experimental treatments or interventions (i.e., independent variables) as fundamental components (→ Sampling, Random).

Similarities in the two experimental contexts diverge considerably, however, in terms of *experimental control*, with the researcher's ability to guard against circumstances that might provide alternative or rival explanations, threatening the → validity of causal explanations, frequently challenged in field experiments. Yet, field experiments, because they are undertaken in circumstance not radically different from everyday life, can afford the researcher greater external validity. Following the initial experimental treatment, for example, research participants in field experiments typically continue functioning in their everyday social settings with little investigator interaction until outcomes assessment (i.e., dependent measures). This can significantly reduce the reactive or interactive influence on subsequent outcomes resulting from participants' awareness of the research procedure and enhance external validity.

At the same time, however, undertaking experimentation in the field can involve *complications* rarely seen in laboratory experiments. Field experiments, for instance, typically entail a significantly longer time frame (e.g., weeks and months rather than hours and days) and often engage a substantially larger number of research participants. They frequently require a variety of exigencies and preliminaries, such as establishing contacts, gaining cooperation, and securing permissions, which can strain research resources and researcher patience. The process of identifying eligible research participants in field experiments, for example, can be difficult, and the failure to retain research participants for follow-up (i.e., outcomes assessment) can be a serious threat to the → generalizability of research results. Additionally, field experimentation commonly occurs in settings permeated with systematic and random noise where achieving an adequate degree of measurement precision or accuracy can be difficult (→ Measurement Theory). Some threats to internal validity (e.g., compensatory rivalry and the Hawthorne effect) can be particularly problematic in field experiments.

### EXAMPLES OF FIELD EXPERIMENTS

Field experiments, although not prominent in the communication research literature, have appreciably informed our understanding of important phenomena across diverse areas, including → interpersonal communication (Fennis et al. 2006), language and communication disorders (Cohen et al. 2006; → Language and Social Interaction), → political communication (Gerber & Green 2001), and → media effects (Robinson & Borzekowski 2006). Generally, field experiments appear most commonly in → health communication research, with such projects typically operationalized as randomized controlled trials. Guidelines and practices incorporated in the randomized controlled trial, which is a refinement of the basic pre-test/post-test control group design, assist the researcher in overcoming many of the common limitations encountered in field experiments (Moher et al. 2001). Consequently, the randomized controlled trial, if effectively implemented, can yield the strongest evidence of causality of all research undertaken in realistic environmental and situational circumstances.

An *informative example* of the application of key communication concepts in a field experiment is provided by a study of an HIV sexual risk-reduction intervention by

DiClemente and Wingood (1995). This single-blind, randomized controlled trial employed a communication and social skills enrichment program in an intervention (i.e., experimental treatment) to enhance the consistency of condom use for HIV prevention (→ Communication Skills across the Life-span; Interpersonal Communication Competence and Social Skills). A sample of 128 sexually active, heterosexual, African-American women aged 18 through 29 years were recruited using street outreach techniques in an economically disadvantaged neighborhood of San Francisco, CA. The women were randomly assigned to one of three groups: (1) a communication and social skills intervention, conducted over five sessions, which emphasized communication skills, ethnic and gender pride, proper condom use skills, and development of partner norms supportive of consistent condom use; (2) an HIV risk-reduction education program administered in a single session; or (3) a control condition in which administration of the HIV risk-reduction education program was delayed three months until after outcomes assessment (i.e., dependent variables).

The findings revealed that, compared with the delayed HIV education control condition, women in the communication and social skills intervention demonstrated increased consistent condom use, greater sexual communication, assertiveness, and self-control, and increased partners' adoption of norms supporting consistent condom use. No significant differences in the outcome variables were observed between the HIV risk-reduction education condition and the control condition. Overall, this field experiment demonstrates that community-based HIV risk-reduction programs that provide communication and social skills training within a gender- and culture-sensitive framework can effectively enhance consistent condom use and promote HIV prevention.

Another instructive example of a field experiment is provided by the work of Vaughan and his colleagues (2000; Rogers et al. 1999), who explored the impact of an entertainment education radio program on HIV/AIDS prevention in Tanzania (→ Entertainment Education). The project employed a radio → soap opera, *Twende na Wakati* ("Let's Go with the Times"), as the communication intervention. The program used negative, transitional, and positive behavioral role modeling to promote HIV prevention, family planning, gender equity, and other health themes, and was broadcast in Swahili, the national language of Tanzania, twice per week for 30 minutes from July 1993 through the end of 1999.

The field experiment was structured on a variant of the pre-test/post-test non-equivalent control group design, with restricted access to the program within a large geographic region of Tanzania during the first 2 years of the project providing the control group. Outcome measures were assessed through five personal interview surveys conducted annually. Each survey, the first of which was initiated just prior to the first program broadcast, involved a unique randomly selected sample. The survey instrument tapped personal characteristics, exposure to and perceptions of *Twende na Wakati*, knowledge and attitudes about HIV/AIDS, and HIV/AIDS preventive behaviors practice.

The findings revealed that *Twende na Wakati* positively influenced behaviors facilitating HIV/AIDS prevention, significantly reducing the number of sexual partners reported by both men and women and significantly increasing condom adoption. The radio soap opera influenced these behavioral changes through several intervening variables, including increased self-perception of HIV/AIDS contraction risk, enhanced self-efficacy for HIV/AIDS prevention, and more extensive interpersonal communication about HIV/AIDS.

## **Experiment, Laboratory**

*James B. Weaver, III*

*Emory University*

Research utilizing experimentation (→ Experimental Design) is undertaken in a variety of contexts and settings. Decisions concerning the circumstances under which to conduct an experiment typically reflect a combination of considerations including the nature of the research question (→ Hypothesis), the availability of research resources, and the researcher's

interest in balancing concerns about the → validity and the → generalizability of subsequent findings. Overwhelmingly, the most common setting for experimentation in communication is the *laboratory*.

### ADVANTAGES OF LABORATORY EXPERIMENTS

Laboratory experiments, when effectively operationalized (→ Operationalization) and carried out, afford strict experimental control by allowing for isolation of the research situation from the variety of extraneous influences that can impact both experimental treatment or intervention (i.e., independent variable) and the subsequent outcome (i.e., dependent variable). Accordingly, laboratory experiments are typically structured on the more rigorous “true experimental designs” and, consequently, yield the strongest evidence of causality (Wimmer & Dominick 2003).

An array of *locales* can be utilized in staging laboratory experiments ranging from general purpose accommodations such as conference rooms, classrooms, lecture halls, and theatres to facilities specifically designed for experimentation. It is the researcher’s ability to structure and manipulate the experimental environment (e.g., lighting, temperature, soundproofing, seating arrangement of research participants), not the specific locale, that is the defining characteristic of experiments in the laboratory setting.

Beyond situational and environment control, the laboratory setting allows *substantial control* over all aspects of the research process. Working in a laboratory setting, for example, significantly enhances the researcher’s ability to accurately identify eligible research participants, insure their random assignment to treatment conditions, and extensively observe their progression through the research activity. The level of specificity achievable in the operationalization of independent variables – or, in other words, the extent and certainty with which treatment manipulations can be accomplished – and the consistency of their re-enactment are both extremely high in laboratory experiments. Equally important, the degree of precision possible in outcomes (i.e., dependent variables) assessment, which promotes measurement reliability, is a key aspect of experimentation in laboratory settings (Kerlinger 1986).

### DISADVANTAGES OF LABORATORY EXPERIMENTS

While many aspects of laboratory experiments offer crucial advantages in research endeavors testing causal relationships, experiments in laboratory settings can also involve potential disadvantages. Perhaps the most obvious shortcoming is *operational and environmental artificiality*. Laboratory experiments facilitate the precise and systematic observation of human reactions under controlled conditions; but sometimes the experimental situation and/or experimental procedure is rather sterile and unnatural. Some behavioral and perceptual outcomes observed under such circumstances can have little direct application to those occurring in natural surroundings. In extreme cases, laboratory experiments can involve such artificiality that little or no confidence in the external validity and generalizability of resulting observations is warranted. Consequently, several research questions simply do not lend themselves to examination through laboratory experiments (Miller & Salkind 2002).

Because laboratory experiments typically involve extensive interaction between the researcher and research participants, the potential is great that *researcher biases* can emerge as threats to internal and external validity. Two forms of subjective bias, that unconsciously and unintentionally affect laboratory experiment results, are experimenter bias and observer bias. Experimenter bias is introduced into the experimental process when the researcher subtly communicates expectations about outcomes to the research participants. Observer bias occurs during outcome measurement when the researcher overemphasizes expected behaviors and ignores unanticipated ones. Blinding methods are frequently incorporated into experimental procedures to avoid such distorting influences. The double-blind method, in which neither the researcher nor the research participants know who belongs to the control or experimental groups, is most common (Myers & Hansen 2005).

### AN EXAMPLE OF A LABORATORY EXPERIMENT

Laboratory experiments have proven instrumental in communication research enlightening both our understanding of basic communication phenomena and informing theory construction. The scholarship of Judee Burgoon (→ Deceptive Message Production; Interaction Adaptation Theory), James Dillard (→ Goals, Cognitive Aspects of), Robin Nabi (→ Selective Attention), and David Roskos-Ewoldsen (→ Attitudes; Attitude Accessibility) summarized in this encyclopedia provides numerous examples. Perhaps the most sophisticated and diverse utilization of laboratory experiments in communication research emerges from the work of Dolf Zillmann (→ Empathy Theory; Excitation Transfer Theory; Educational Television, Children's Responses to; Entertainment, Effects of; Selective Exposure).

One study in particular, entitled *Effects of an opposite-gender companion's affect to horror on distress, delight, and attraction* (Zillmann et al. 1986), provides an informative illustration. The study was built on the observation that teenagers love to be terrorized – at least at the movies. Most of the audience for slasher or slice-and-dice horror films are adolescents and young adults. Further, the horror film audience is typically evenly split between male and female viewers. This is not coincidental, argued Zillmann and his colleagues, noting that horror films seems to serve an important function as “date movies” for young audiences. As one teenager, quoted in *Seventeen*, put it: “Sometimes you feel weird and self-conscious holding onto a guy's hand on the first date but this way you can just grab him.” Another teenage girl observed, “Guys like to take you to horror movies, hoping you'll be real afraid and need them to comfort you.” A third said, “You can get all rowdy with boys and jump into their lap.”

Casting these observations within the framework of a gender role socialization of affect model (Zillmann & Weaver 1996; → Emotional Arousal Theory), Zillmann and his colleagues designed a post-test-only control group design experiment. Specifically, they implemented a  $2 \times 3$  factorial design with research participant gender (male, female) and the affective reactions to a horror film that were enacted by an opposite-gender companion (mastery, indifference, distress) as independent variables. Male and female college students watched, with an opposite-gender companion, several of the final scenes from the horror film *Friday the 13th, Part 3*. The four companions (one with lower and one with higher

physical appeal within each gender) participating in the study were actually research confederates; students who were trained by the experimenters to enact mastery, indifference, or distress at critical moments throughout the film segment. This behavioral enactment by the research confederates provided the crucial independent variable manipulation (i.e., experimental treatments) across which the research participants were randomly assigned.

Several outcomes were measured following the experimental treatments. These dependent variables included the research participants' affective reactions to the movie; their perceptions of the companion's physical appeal, personality traits, and desirability as a working partner; and the research participants' tendency to acquiesce to apparently erroneous contentions on the part of the companion.

The findings from this laboratory experiment revealed that men enjoyed the film most when their female companion acted distressed and least when she displayed mastery. Women, in contrast, enjoyed the film most when viewed with a mastering male and least in the company of a distressed male companion. The intensity of distress experienced by research participants in response to the film followed the same pattern.

The enactment of mastery while co-viewing the horror film did not enhance the physical appeal of female companions. Perceptions reported by female research participants of the lower-appeal male companion were enhanced significantly, however. The lower-appeal companion also benefited from the display of mastery in that pronounced positive traits were ascribed to him by co-viewing female research participants. Male research participants co-viewing with female companions did not yield a significant pattern of perceptual shifts.

And, finally, the display of distress in response to the horror film segment reduced the desirability of both male and female companions as working partners. Furthermore, female research participants showed a clear tendency to acquiesce to assertions made by male companions who had shown mastery while viewing horror. Taken together, the results of this laboratory experiment support both the conventional-wisdom observations of teenage movie-goers and predictions derived from theory. They highlight a complex interaction between the mass media and their audiences and show that the social context in which mass media content is consumed can have a significant influence on perceptions of and reactions to both the media message and media users.

## Experiment, Natural

*James B. Weaver, III*

*Emory University*

Our understanding of several communication phenomena has benefited extensively from informative reports of “natural” experiments. Natural experiments are infrequently detailed in the social and behavioral sciences, however, because they result only when naturally arising circumstances make it possible to separate and examine typically confounded phenomena. Like field experiments (→ Experiment, Field), natural experiments occur in venues where the researcher has limited control over environmental or situational conditions. Distinctive in the natural experiment, moreover, randomization is impossible and the researcher exercises no influence over the independent variable (→ Experiment, Laboratory). That is, the independent variable is not manipulated but rather varies (often presence vs absence) due to a naturally occurring event or situation.

Natural experiments, consequently, are not actually experiments; but, instead, are observational studies (→ Observation). In a natural experiment, the researcher identifies and anticipates the progression of an evolving phenomenon (→ Hypothesis), isolates and defines unique characteristics of the incident or event to articulate different levels of the independent variable (→ Operationalization), and develops systematic techniques to observe outcomes (i.e., dependent variables; → Measurement Theory). Quasi-experimental designs typically provide the logical structure for natural experiments. The strongest evidence emerges from variants of the pre-test/post-test nonequivalent control group design (→ Experimental Design), with systematic observations recorded both before and after the onset of the naturally occurring phenomenon (i.e., independent variable). It is important to recognize that causation can never be unequivocally determined through natural experiments. Nevertheless, this alternative research method can inform theory development by providing data unattained through other means.

A classic example of a natural experiment is a study initiated in 1973 by Williams (1986) and her colleagues. They conducted an elaborate investigation of the impact of → television – or more precisely, the absence of television – on a non-isolated working-class community in Canada. “Notel,” the name given the town, received no television programming. Two other communities that were demographically and socio-economically matched with Notel, but which received either only a single Canadian Broadcasting Corporation

(Unitel) television channel or television content from four channels (Multitel; → Canada: Media System), were identified. The three communities were operationalized as three levels of a TV-content independent variable.

Using the *pre-test/post-test nonequivalent control group design*, Williams and her associates first surveyed (pre-test or  $O_1$ ) the residents of the three communities about one year prior to the introduction of television in Notel and then surveyed (post-test or  $O_2$ ) the communities two years later. In each community adults and children were assessed on a number of dependent variables including aggressive behavior, personality characteristics, sex-role perceptions, cognitive and creative task performance (e.g., intelligence, reading ability, and vocabulary), and leisure-time activities. Television programming was also content analyzed for aggressive behavior and sex-role portrayals (→ Content Analysis, Quantitative).

Williams and her associates found that television viewing significantly affected other everyday activities concluding that “television affects viewers negatively in a variety of areas via displacement” (p. 395) since each day viewers spent several hours of their limited discretionary time watching TV (→ Exposure to Television; Media Effects). They observed that activities that could not be multitasked with TV use (e.g., reading and creative activities), especially those conducted outside the home (e.g., participation in community activities), were most adversely displaced. Williams and her colleagues also found, consistent with prior laboratory experiments, that television was a prominent source of social learning (→ Social Cognitive Theory; Observational Learning), particularly for children, with significant content effects observed in both aggressive behaviors and sex-role perceptions. Finally, they found that the presence of television, not the number of channels available, was the origin of television effects. The effect of television on residents of Notel appeared significantly different from that observed in Unitel and Multitel; but residents in Unitel and Multitel, despite variations in the source and number of television channels available, tended to be similar.

More recently, Weimann (1996) conducted a natural experiment exploring how the rapid diffusion of → cable television access affected television viewers in Israel (→ Diffusion of Information and Innovation). Specifically, he employed the pre-test/post-test nonequivalent control group design to compare a sample of residents with newly established cable access (cabled residents) with a matched sample unreachable by cable television (uncabled residents). Weimann found significant behavioral, cognitive, and affective differences. Residents with cable reported substantial increases in television viewing, and more positive feelings toward television, despite the fact that increased TV viewing displaced time spent with other activities. Cabled residents also reported considerable uneasiness, discomfort, and shock as “family feuds,” conflicts, and disagreements emerged following adoption of cable television in their homes.

Finally, Snedeker et al. (2007) provide an excellent example of a natural experiment structured on the time series design (→ Time-Series Analysis) in their work examining language development among children of international adoption (→ Language Acquisition in Childhood). Parental reports and speech samples were collected from 27 preschool children repeatedly for 3 to 18 months after US parents adopted them from China. These children, the authors observed, showed the same developmental patterns in language production as much younger monolingual infants (matched for vocabulary size). Initially, their vocabularies were dominated by nouns and their utterances were short. The children,

at later stages, displayed vocabularies that were more diverse and produced longer utterances with more grammatical morphemes.

*Emory University*

Experimental design provides the logical architecture for scientific research examining causal relationships. Most people intuitively recognize causal relationships. It is not uncommon to hear, for instance, that increased time studying caused an improved test grade, that a “sweet tooth” enabled a friend’s weight gain, or that traffic congestion instigated a “road rage” incident. The tendency to attribute causality, often spontaneously, in commonsense explanations of everyday behaviors punctuates both private and public discourse and appears a distinctively human characteristic (Frey et al. 2000).

In scientific endeavors, we are typically much more deliberate when making causality inferences (Hill 1965) and often rely on experimentation to inform judgments about causal relationships. Experimentation is a process used to determine the extent, if any, of causal connections between two or more variables. Through experimentation, we test predictions about causal relationships by manipulating aspects of a particular context or activity and then observing the resulting perceptual and behavioral outcomes.

### **BASIC CHARACTERISTICS OF EXPERIMENTAL DESIGN**

Effective experimentation is guided by a testable descriptive causal → hypothesis asserting the conditions under which a manipulable independent variable, commonly called an

“experimental treatment” or “intervention,” involving at least two levels, influences measurable outcomes or dependent variables (→ Operationalization; Measurement Theory). Experimentation typically incorporates *systematic procedures* maximizing, to the extent possible, the researcher’s ability to guard against or control circumstances that might provide alternative or rival explanations threatening the → validity of causal explanations. Unfortunately, when working with human research participants, an inverse relationship often emerges between the extent of control exercised in experimentation and the → generalizability of subsequent research findings. Equally important, sometimes, even when experimentation is possible, ethical considerations preclude its use (→ Research Ethics).

Experimental design is the logical system providing the foundational framework for experimentation utilizing well-developed principles of scientific inquiry. Contemporary understanding of experimental design has emerged from the incremental accumulation of new concepts and practices proposed by a range of scholars working in diverse disciplines (e.g., agriculture, education, health/medicine, psychology, and statistics) over the last hundred years (Cochran & Cox 1957; Fisher 1971; Kirk 1995; Winer 1971).

Two concepts, randomization and control, are the cornerstones of experimental design. Randomization, first popularized by McCall (1923) and Fisher (1925), refers to the assignment of research participants to treatment groups or conditions (i.e., levels of an independent variable) based on mere chance. *Random assignment* can be accomplished using any procedure (e.g., tossing a fair coin) in which each participant has a nonzero probability of being assigned to each treatment group. For instance, in an experiment with two conditions (control vs treatment), on a “coin toss” yielding heads, a research participant would be assigned to the control condition; but if tails comes up, the research participant goes into the treatment condition (→ Sampling, Random).

*Control*, in experimental design, involves holding constant or systematically varying extraneous variables (e.g., mediators, confounders, and suppressors) to minimize their effect on the focal causal relationship. Campbell and Stanley (1963; also see Shadish et al. 2002) were instrumental in articulating the critical importance of control in experimental design. In their seminal work, *Experimental and quasi-experimental designs for research*, they identified 12 factors jeopardizing the internal and external validity of various experimental design configurations. They outlined eight different classes of extraneous variables that, “if not controlled in the experimental design” (p. 5), might threaten the study’s internal validity and obscure otherwise meaningful findings. These factors – including history, maturation, testing, instrumentation, statistical regression, selection bias, and experimental mortality – are detailed elsewhere in this encyclopedia. Factors jeopardizing external validity or generalizability included reactive or interactive effects resulting from participant selection, experimental arrangements, and outcome assessment.

## TYPES OF EXPERIMENTAL DESIGNS

Incorporating these threats to research validity, Campbell and Stanley also advanced a comprehensive *typology of experimental design configurations*. Specifically, they divided designs for experimental into four general types: (1) pre-experimental designs, (2) true experimental designs, (3) quasi-experimental designs, and (4) ex post facto designs. To facilitate description of experimental designs a standardized notation has been developed.

When research participants are exposed to an experimental treatment (i.e., independent variable) the letter  $X$  is used. The letter  $O$  indicates an outcome or dependent variable measurement. The absence of a manipulative treatment ( $X$ ) is indicated by the symbol “ $\_$ ” and the letter  $R$  denotes random assignment to experimental treatments. Directionality, which refers to the temporal order in which a treatment ( $X$ ) and outcome ( $O$ ) occur, is symbolized as “ $\rightarrow$ ” when forward and “ $\leftarrow$ ” when backward. Treatments ( $X$ ) and outcomes ( $O$ ) presented vertically take place simultaneously.

### Pre-Experimental Designs

Three configurations are categorized as pre-experimental designs including the “one-shot case study” ( $X \rightarrow O$ ), the “one-group pre-test/post-test design” ( $O_1 \rightarrow X \rightarrow O_2$ ), and the “static-group comparison” (Fig. 1). Although these configurations have been frequently employed in endeavors testing causal relationships, they lack many of the basic characteristics crucial for effective experimentation (e.g., random assignment, control of validity threats, equitably treated comparison groups) and afford little or no utility for testing causal inferences. The horizontal line separating the treatment groups in Figure 1, for instance, highlights the absence of random assignment in the static-group comparison pre-experimental design.

**Figure 1** Static-group comparison pre-experimental design

### True Experimental Designs

Randomization and the inclusion of controls against threats to internal validity are fundamental to the three configurations within the true experimental designs category. For instance, the *pre-test/post-test control group design* (Fig. 2), considered by many to be the “old work-horse” of traditional experimentation, controls for eight threats to internal validity if effectively implemented. Randomly assigned from the same sample to both the treatment ( $X$ ) and control ( $\_$ ) groups, research participants are first observed prior to treatment via a pre-test ( $O_1$ ). The first group then receives the experimental treatment ( $X$ ) while the second group, called the control group, engages a comparable, but unrelated, task ( $\_$ ) and both groups complete a post-test assessment. The differences between the pre-test and the post-test ( $O_2 - O_1$ ) are compared between the treatment and control group. If this comparison yields a significant difference then we assume that the experimental treatment was the primary cause. The *randomized controlled trial*, a mainstay in health communication and health-related disciplines, is a refinement of the basic pre-test/

**Figure 2** Pre-test/post-test control group design

**Figure 3** Solomon four-group design

post-test control group design that incorporates several contemporary methodological guidelines intended to enhance both validity and generalizability.

The *Solomon four-group design* (Fig. 3) is an extension of the previous configuration and perhaps is the most precise and powerful experimental approach. In order to minimize any potential negative consequences resulting from testing, the design incorporates each pre-test and treatment alternative. Systematic comparisons across the six pre- and post-test assessments allow the researcher to check both the efficacy of randomization and for any interaction between the pre-test ( $O_1$ ) and the treatment ( $X$ ). Practical considerations, in particular the required additional resources (i.e., research participant, time, and money), appear to have limited the popularity of this experimental design.

Recognizing that the pre-test, while a deeply embedded practice in social/behavioral sciences, is not an essential component of a true experimental design, Campbell and Stanley detailed the *post-test-only control group design* (Fig. 4). This design is particularly effective in circumstances where a pre-test is ill-advised because it could sensitize research participants or where limited resources require an efficient research implementation. The crucial role of random assignment distinguishes this design from the “static-group comparison” pre-experimental design outlined above.

**Figure 4** Post-test-only control group design

While these simple, single independent variable or one-factor experimental designs promote conceptual clarity, their application in contemporary research activities is relatively rare. Instead, researchers often elaborate on the conceptual basis of the pre-test/post-test control group and the post-test-only control group designs to produce *factorial designs*. A factorial design involves the simultaneous analysis of two (two-factor design), three (three-factor design), or more independent variables within the same experimental design. Factorial designs, unlike the one-factor designs detailed above, permit examination of the interaction or interdependence between two or more factors or independent variables in the effects they produce on the outcome or dependent variable.

The *repeated-measures design* is another variant commonly employed in social and behavioral science research. The previously detailed experimental designs all involve a *between-group* structure in that research participants are assigned to a particular treatment group (a level of the manipulated independent variable), their outcome measures are combined as group outcomes, and then differences between group outcomes are analyzed. The between-group structure, for example, guides the analytical process outlined for the pre-test/post-test control group design above. The repeated-measures design, on

$$\begin{array}{c} O_1 \rightarrow X \rightarrow O_2 \\ \hline O_1 \rightarrow \_ \rightarrow O_2 \end{array}$$

**Figure 5** Pre-test/post-test nonequivalent control group design

the other hand, involves multiple assessments of a single outcome or set of outcomes within each research participant. In repeated-measures designs, research participants encounter and respond to every level of an experimental treatment so that the effects of such manipulations materialize as variations within each individual's pattern of outcomes rather than as differences between groups of people.

### Quasi-Experimental Designs

Research situations can arise in which the random selection and assignment of research participants is not possible. Experimentation undertaken under such conditions can utilize quasi-experimental designs. These nonrandomized designs, while providing valuable information, must be recognized as involving basic faults that can influence data interpretation. The strongest and most widely used quasi-experimental design is the *pre-test/post-test nonequivalent control group design* (Fig. 5). This design differs from the true experimental designs because the test and control group are not randomly assigned (emphasized by the horizontal line) and, consequently, are not equivalent. Deliberate comparison of the pre-test results reveals the degree of equivalency between the treatment (X) and control (\_\_\_) groups.

Other quasi-experimental designs advanced by Campbell and Stanley are all built on the notion of serialized assessment of the dependent measure both before and after the introduction of an experimental treatment ( $O_1 O_2 \rightarrow X \rightarrow O_3 O_4$ ). If substantial change follows introduction of the treatment then there is reason to suspect that the treatment caused the observed change. Referred to as "time series designs," these configurations can be expanded to incorporate multiple treatment levels (i.e., a control group in the simplest form) and other variants intended to bolster validity.

### Ex Post Facto Designs

Often characterized as "experimentation in reverse," the ex post facto design has emerged as an important investigative tool for researchers in behavioral and social sciences. Commonly referred to as a *case-control study* (Fig. 6; Gordis 2004), the general concept underlying this design is to identify individuals with an outcome or consequence of interest (case group) and, following backward directionality, compare their experiences

$$\begin{array}{c} \text{Case group} \quad X \leftarrow O \\ \hline \text{Control group} \quad X \leftarrow \_ \end{array}$$

**Figure 6** Case-control study

(i.e., antecedent variables) to a similar group without the outcome of interest (control group). Research participant matching is used in the strongest form of this design to minimize potential threats to validity. The case-control study design, it must be recognized, employs observational data. Consequently, interpretation of findings requires careful consideration of several criteria, such as biological, environmental, and temporal plausibility, before causation can be projected (Hill 1965).

## EMERGING TRENDS

The simple designs for experimentation summarized here continue to provide the essential logical building blocks for much contemporary research. At the same time, however, it is important to recognize that these designs are, at least to some extent, bounded by the era in which they were articulated. We often forget that the work of most researchers was aided by slide-rules and mechanical calculators when these designs were proposed. Contemporary advances in both computer technologies and statistical software have, of course, substantially expanded our analytical prowess and, as a result, the sophistication of experimental designs.

Factorial designs involving several independent variables, mixed-measures models combining factorial and repeated-measures designs, and multivariate designs that simultaneously include multiple dependent measures – all of which were emerging trends just three decades ago – are now commonplace (Smith et al. 2002). And new developments, such as multilevel modeling (Luke 2004), which promotes experimentation in diverse cultural, social, and behavioral contexts, are rapidly evolving. Nevertheless, the basic tenets of experimental design outlined here remain as the benchmarks for scientific inquiry, attempting to satisfy our distinctively human desire to understand causality and causal relationship (→ Statistics, Explanatory).

# Exposure to Communication Content

*Peter Vorderer*

*Free University Amsterdam*

“Exposure to communication content” describes one of the most recent areas of specialization within the communication discipline. It is located at the intersection of → media effects research and audience research, two academic traditions that have remained relatively separate. Over the past half a century, the well-established tradition of media effects research has revealed a rather complex and increasingly differentiated view of the individual and social processes that underlie and accompany notable changes in people’s thinking, feeling, and behavior, caused by exposure to media content. The more recent work in this area has considered not only psychological mechanisms that manifest themselves in people’s minds or behaviors some time *after* they have been exposed to communication content, but has also studied what happens *while* those individuals or groups are responding to media content or immediately after doing so. Book titles like *Selective exposure to communication* (Zillmann & Bryant 1985) or *Responding to the screen* (Bryant & Zillmann 1991) seem to indicate this trend and demonstrate that media effects research has become more involved with psychological *processes* rather than only with the end result. Conceptual and theoretical differentiations have also evolved, e.g., various attempts to distinguish between short- and long-term effects, or between their cognitive, affective, and behavioral manifestations (→ Affects and Media Exposure; Media Effects Duration). But, despite multiple conceptual differentiations in this area of research, which also include distinctions between observations and explanations of effects at psychological (micro) versus sociological (macro) levels of analysis, media effects research maintains its focus on the consequences of exposure to media rather than on exposure itself. Meanwhile, the work focusing on “exposure” itself and on the individual and social processes that accompany exposure has outgrown the more traditional lines of research on media effects by simultaneously expanding its scope and differentiating its levels of analysis.

## DEVELOPMENT AND MAPPING OF THE RESEARCH FIELD

Audience research, the second tradition in this new study of “exposure to communication content,” originated in scientific disciplines other than communication, specifically psychology, but also in the humanities (→ Audience). In an attempt to not only describe

and explain the final effects of communication but also to include the processes involved during and even before exposure, scholars have defined new concepts, models, and even theories from these different disciplines and academic backgrounds to better understand how all of these processes eventually may contribute to media effects. Scholars in psychology primarily have formed a more differentiated understanding of how and why different (groups of) individuals approach specific media contents, whereas those with a humanistic background primarily have examined the media content (the “text”; → Text and Intertextuality) itself and its (often social, socio-economic) context and potential to attract a “reader” (or in more general terms, a “user”). In doing so, humanist scholars complicated what social scientists have often oversimplified. Thus, the overall picture of what is believed to happen during exposure to media content has become rather complex.

Due to this complexity, many humanistic communication scholars have developed their own approach: the so-called “critical” or → “cultural studies” approach, in which the criteria for scientific work are more similar to those in the humanities (→ Critical Theory). At the same time, the more social scientifically oriented scholars have tried to incorporate theories from the other disciplines to explain the phenomena of interest according to their psychological and social scientific point of view. What scholars have called “audience research” sometimes has, at other times, been labeled “reception research” or even “media psychology.” This psychological and social scientific manifestation of audience research appears remarkably strong in communication departments in Europe (e.g., the success of establishing the term “media psychology” in Germany, the Netherlands, and Switzerland) compared to the “critical approach” still dominantly located in the humanities. In the US, however, both traditions focusing on “exposure” often coexist in one school or department (→ Communication as a Field and Discipline).

Jensen and Rosengren (1990) called for an *integration of these various traditions*, which are all “in search of the audience.” But although some have supported this proposition and have tried to substantiate it (e.g., Vorderer & Groeben 1992), few have attempted this conceptual advancement. Nevertheless, in this new research area, “exposure to communication content,” we find research that follows Jensen and Rosengren’s initial request, probably without even being aware of it. This new perspective is primarily, but not exclusively, “psychological” in its theorizing; it focuses on micro-level analyses but also describes macro-structures in explaining what happens during exposure. It certainly looks at new technology as much as it looks at more “traditional” media, but most importantly, it studies what happens before people become exposed to media content, what happens while they are exposed, and finally what happens right after exposure, i.e., as immediate consequence of it, thereby reaching into the realm of media effects research.

To organize the more than 60 different entries on “exposure to communication content” for this international encyclopedia, one can envisage them in a two-dimensional field (Fig. 1). The horizontal line indicates whether the respective entry focuses on processes that primarily occur *before*, *during*, or *after exposure*, whereas the vertical line distinguishes between (1) the *theoretical constructs/processes* studied (again, from more complex objects/processes at the top to more specific ones at the bottom within that category); (2) the *theories and models* that have been developed to describe and explain these objects and constructs; (3) the *areas of content* that have been investigated; and

	Before exposure	During exposure	After exposure
Constructs/processes			
Theories/models			
Media/communication content			
User/audience			

**Figure 1** Two-dimensional categorization of the “exposure to communication content” entries

(4) the major constructs that have been specified with respect to the media *user/audience*. The following explication of the various elements (“entries”) within this area follows the structure given in Figure 1, from the left (“Before exposure”) to the right (“After exposure”) and within the columns from the top (“Constructs/processes”) to the bottom (“User/audience”).

## CONSTRUCTS AND PROCESSES

### Pre-Exposure

Most of the theoretical constructs that researchers have developed to describe the specific processes that precede and impact exposure to communication content have examined topics at the psychological level of analysis. Although → media use by social variable has also been included and social variables like → ethnicity and exposure to communication have been considered as well, the bulk of theoretical developments concern *individual processes* that lead to exposure. On a rather abstract level, attempts to explain individuals’ exposure to media content by referring to their → personality and exposure to communication or to their → intrinsic and extrinsic motivation and volition exist. But so do claims that attribute such exposure to very specific individual motives and interests, such as → enjoyment/entertainment seeking, → escapism, → information seeking, → sensation seeking, or → mood management.

The main differences between these concepts lie in their theoretical complexity, their empirical usability, and also in their specificity. For example, the concept of *escapism* has a long history not only within the discipline of communication but also in related areas, such as the empirical study of literature, and it seems to have some prominence in lay persons’ explanations of their own media-related behavior as well. But it is not based on any well-defined theoretical assumptions, nor does the concept have any remarkable empirical support.

At the same time, constructs like *mood management* seem to reduce the complexity of a media user’s decision process to a single dimension (i.e., to decide on such a media

product, which promises to enhance somebody's mood), but its empirical support is overwhelming. The more inclusive concept "behind" mood management, → selective exposure, claims that the selection of specific media content follows some psychological regularity, mood management being the most important one. To date, the selective exposure research seems to be the most differentiated, best specified, and most empirically supported in the entire field of exposure to communication content, and it developed from a truly interdisciplinary perspective (with communication and psychology as the host disciplines).

The research on → automaticity is dominantly psychological in nature, and remarkably successful, particularly in social psychology, which has not yet been leveraged fully by scholars in communication. In contrast to these more psychological constructs, → suspension of disbelief is one that clearly stems from the humanities and has only been incorporated, discussed, and questioned by communication scholars very recently (Zillmann 2006). Finally, within this intersection of constructs/products studied as antecedents to exposure, → channel/program loyalty is a very applied concept that comes from neither a social scientific nor a humanistic background but from the applied research area, where knowing (i.e., being able to predict) what makes the audience stick to a program or channel is crucial (→ Applied Communication Research).

### During Exposure

Examining what has been thought to occur *during* exposure, again, ethnicity and media use by social variables are considered to affect how the audience deals with content. In addition to this, an international perspective on comparison of media use has also been applied, so that findings about exposure in one country can be related to those in other countries (→ Media Use, International Comparison of). We find, in fact, the highest level of differentiation and specification among the psychological processes studied here. Researchers in this area have been studying → habituation as a form of media use that does not require the audience's full attention when selecting or using a program. They have been looking at what is different when these users engage in → co-viewing as opposed to an individual exposure situation. More specifically, they have been studying how individuals relate cognitively and – even more importantly – affectively to characters on the screen by engaging in so-called → parasocial interactions and relationships with them, or by coming to terms with → interactivity in reception.

Because much of the work in this context relates to new and rapidly evolving media and technology, it is no surprise that these various interactions with media content have been described and explained differently, not only over time but also depending on the specific theoretical background of the respective researchers. Within communication, → involvement with media content has long been used to specify such a relation, whereas some researchers have incorporated a construct used more often outside of the social sciences, i.e., → identification. Due to many new technologies emerging recently and a variety of possible applications of these new media, researchers have imported and applied additional constructs from technical disciplines, which is why → presence is now often considered the best way to describe this relation in the context of new media.

This also holds true for studying → computer–user interaction, and includes more cognitive processes such as → fantasy/imagination, → playing, or → simulation, but to

some extent also physiological processes like → excitation and arousal. Some of these constructs are defined on the basis of what we know from psychology and from cognitive science about → perception and, even more specifically, about → selective perception and selective retention. Other entries refer to the affective quality of such experiences; the investigation of affects and media exposure has become very relevant to the study of exposure. More specifically, researchers have scrutinized and explicated → suspense because it seems crucial in exposure to entertainment products. On a more behavioral level, → navigation through the wide array of what is offered and available today, → zapping and switching between different channels or products, and → multitasking, reflecting the fact that some media products are used simultaneously, have moved to center stage.

### **After Exposure**

Of course, we regard most of these processes as lasting throughout exposure, and hence can still identify and often measure them even after exposure. In fact, constructs like “habituation” describe the course or the process of exposure, i.e., the time period from before the actual exposure to some communication content through the moment that exposure is terminated. We consider other constructs, e.g., personality and exposure to communication, to impact each step in the process differentially, and to selectivity play out differently in terms of perception.

Nevertheless, it is interesting to note that compared to the many processes and constructs studied during and before exposure, only a few were considered to “belong” to this sub-category, probably because they have most often been linked to the area of media effects. In fact, only two will be outlined within this area of exposure, because they are so closely related to what happens while being exposed to communication content. One is → entertainment education, which we can think of as a media effect but can only understand if we take into account the development of the effect during exposure. The other is → addiction and exposure, which does not limit itself to any step in the process, from before to after exposure, but refers to an effect of exposure that leads someone to constantly reinitiate the process again and again and without much awareness of its coercive nature.

### **THEORIES AND MODELS**

Most attempts to describe and explain the aforementioned processes have been quite similar. The majority of available theories and approaches have tried to analyze exposure by referring to what precedes it, i.e., by linking exposure to the reasons media users may have for acting in a particular way. Those theories focus on either cognitive or affective processes. Most prominent among those examining cognitive processes are → *consistency theories*. Such theories, which developed out of social psychology, use the social situation in which individuals live, interact, and think to derive specific hypotheses about the factors that contribute to or detract from cognitive coherence.

Among those theories, → cognitive dissonance theory has been very specific and extremely successful. According to the theory, exposure to communication content is a function of whether a specific action, e.g., the selection of a newspaper article, agrees (is consistent) with a reader’s thinking (here: the political opinion). Thus, media users

expose themselves to communication content that will not produce cognitive dissonance. Attempts to explain exposure by → social comparison theory are somewhat similar. From this perspective, the presence or cognitive representation of others also impacts a media user's decision in a specific act of exposure. In → social identity theory as well, others and our group membership with others determine our behaviors regarding exposure to communication content. Finally, various → expectancy value models focus on cognitive factors but differ from consistency theories. According to expectancy value theories, people (hence: media users) act (here: in their decisions for exposure) in a manner consistent with their values and beliefs.

Two families of theories that focus on the *affective dimensions of exposure* are → affective disposition theories and → empathy theory. The latter describes how media users feel about and toward protagonists in the media. However, affective disposition theories suggest that media users are primarily interested in witnessing protagonists succeed and antagonists fail, having developed affective dispositions toward them – which explains exposure to entertainment content. More generally, the → uses and gratifications perspective asserts that media users choose content that promises to gratify their interests and needs. Thereby, it provides a theoretical framework for some theories that examine people's interest in using the media, as well as the historical starting point for comparable research. Within communication, it certainly has been the most important paradigm that first explored media users' interests and preferences, when much of the research was still focusing on the media's potential and actual effects.

Two more recent theoretical developments also need to be considered: the recently developed → media equation theory examines new technologies and acknowledges that people deal with and understand new technology differently compared to more traditional media. Therefore, new media require new theoretical approaches. In contrast, → evolutionary theory is all but new, but has only very recently been applied to people's exposure to media content, i.e., to the reasons users might want to be exposed to a specific content. It does not seek its explanation in the situation nor in the personality of the media user, but rather in the audience's evolutionary history, which – according to this reasoning – makes individuals interested in specific types of content.

Whereas all of the aforementioned theories focus more or less explicitly on processes preceding the act of exposure, → transactional models focus on *what happens during exposure* instead. They indicate most obviously how far the underlying theories of communication have moved away from traditional behaviorist approaches, which assume a rather passive media user. The same applies to → transportation theory, which contemplates the media user moving away from the “here and now” and toward the place and time depicted by narrative. Since new media seem particularly able to “move” users to other places cognitively and emotionally, it is not surprising that several other and quite related constructs describe this phenomenon (e.g., “presence”). But only transportation theory seems to have adequately systematized some key constructs and propositions to justify calling it a theory.

Looking at the *immediate consequences of exposure* to communication content, two theories come to mind. Most importantly, → social cognitive theory is arguably the most influential attempt to describe and explain why exposure to a specific content may lead to certain consequences. The theory has also triggered and directed a huge array of empirical

studies in this domain. In contrast, the → stages of change model is a rather recent and more specific model that nevertheless has impacted theorizing and research, particularly in health-related domains.

### **MEDIA/COMMUNICATION CONTENT**

Another way of looking at what the discipline has achieved in terms of understanding and explaining exposure to communication content is to distinguish between various types of media and communication content. Note that some of the theoretical and empirical work done in this area is quite diverse, depending on which medium or what kind of content it considers. In that respect, research on → exposure to news or → exposure to print media, for example, follows a theoretical tradition that is well embedded in the discipline of communication.

In contrast, more recent lines of research, such as those that study → exposure to the Internet, are more interdisciplinary in nature. This has not only to do with the fact that different media and different content provide different opportunities for users but also with the fact that users and audiences approach various media and content forms with different expectations. Although → exposure to television and → exposure to radio are most often daily activities and experiences for many users around the globe, what TV and radio have to offer is often hard to compare and so are the ways in which people use them. Hence, the users' expectations, experiences, and gratifications with respect to these media are rather diverse and so is their scientific description and explanation by communication.

### **USER/AUDIENCES**

The final perspective that is taken here to systematize the various contributions to the field of exposure to communication content is one that distinguishes between the different agents who approach such content. Traditionally, the most important stakeholder for the field of communication has been the → *public*, and some scholars still argue that it is this public that constitutes the discipline's core. Much of the work in this domain has been advanced by theoretical conceptualization from sociology and political science.

Yet, psychological theories have had a greater impact on research about the audience (though clearly this topic has also been studied from a more applied and therefore less theoretical point of view). In fact, empirical research on the audience has not only grown in size but also diversified itself, so that today we can also identify more specific perspectives, like the one that focuses on the → news audience.

While being studied, the *audience itself has changed*, and the constitution of the audience is highly relevant to those who try to provide the best, i.e., the most profitable, content. Thus, → audience segmentation has attracted a lot of interest within the discipline as well.

Finally, and again this is due to the most recent developments in new media and technologies, we must consider not only the user or the audience, but also those *entities created by the user*, i.e., → avatars and agents. They certainly represent content or forms of content, but the media no longer provide them (as, e.g., a TV show) but (at least in their specific appearance and constitution) the users themselves do. Some may argue that

interacting with avatars and agents does not constitute exposure to media content because “exposure” implies user passivity (“reception” in some European countries), meaning that users of new technologies interact with but no longer are exposed to communication content. But this is a dispute that touches upon the self-understanding of the discipline and therefore will not be pursued here.

## OUTLOOK

### New Theoretical Developments

This leaves us with a comparatively new but already rather voluminous, almost exuberantly *expanding field of research*. Where will this development lead, and what may we expect? In a situation like this, scholars often suggest or even ask for the integration of loose ends, i.e., a synergistic approach to integrate various perspectives, if not paradigms. However, this expectation is probably unrealistic, at least for the next five to ten years. One can be skeptical because the various advancements we have seen lately in this area are moving in opposite directions. An example of this is the diverging yet simultaneous development of *two movements* within the area: the application of cognitive science or social cognition models to the study of exposure to communication content and the exertion of evolutionary theory in communication. Both have been successful within the field, yet they work on opposite ends.

As some psychologists and psychologically oriented communication scholars became more involved with various *cognitive processes* underlying or antecedent acts of media exposure and effects, they started to differentiate them more and more specifically and precisely, sometimes even using a language that modeled these processes after functions and algorithms of a computer. By doing so, they have been able to explain various phenomena that were widely accepted but not sufficiently understood in communication. One example of this is the process of “cultivation” through exposure to media messages, which has been prominently investigated by → Gerbner and his collaborators (Gerbner et al. 1994) but never really well explained. The social cognition approach, mainly coming from social psychology, helped explain cultivation by addressing the question of *why* a specific content may demonstrate the cultivation effects in the minds of the viewers that were predicted in the first place (Shrum 2007; → Cultivation Effects; Cultivation Theory). The important point here is that such an explanation was possible by referring to certain cognitive constructs and processes that were thought to be responsible for the overall effect. In this respect, the scientific inquiry went from using rather broad constructs (such as “cultivation”) to considering, including, and referring to much more specific and detailed micro-constructs (like “accessibility of cognitions”).

At the same time, attempts to explain, e.g., the motivation of media users to expose themselves to content went in the opposite direction. Whereas interest in such forms of content has primarily been explained by psychological constructs (e.g., moods) on a micro-level (e.g., affective disposition theories), most recently this problem has also been approached by *evolutionary theory* (Ohler & Nieding 2006) or by those concepts that have tried to combine evolutionary and psychological approaches (Vorderer et al. 2006b). Here, the idea is to explain a current interest someone has in media content and various

motivations to expose themselves to this content by taking into account the evolutionary history, not of the individual, of course, but of the species (→ Communibiology). This development certainly indicates a tendency to produce rather abstract macro-phenomena, i.e., it utilizes such macro-phenomena as “explanans” in order to explain the “explanandum” and thereby proceeds in a direction opposite to the one mentioned before. It can be suggested that the area of exposure to communication content is developing rapidly, and it is doing so by expanding in different directions. A consequence of this observation may very well be that increased theoretical coherence and integration in the area is a rather long way off.

### Changing Object of Investigation

A more immediate question for the area of exposure to communication content might therefore rather have to do with another fact, i.e., that the very object under investigation is about to change dramatically. Researchers used to study exposure to a given content, which newspapers, television, or any other media provided. In addition, this content was both stable for the exposure’s duration and independent of what the user preferred and anticipated. Although research established that users do not simply “receive” messages – they select, process, and elaborate on them in a way that is specific to the person and the situation in which exposure takes place (thereby going beyond the initial information offered) – the message itself always remained the same.

In a media environment that includes online communication, playing video games, and human–computer interaction, however, this has become different. If somebody plays a → video game, e.g., the narrative to which he or she is exposed to changes according to the player’s actions. In more general terms: the content changes. Strictly speaking, those users are no longer exposed to a given content. Rather, *users create, modify, and manipulate content* – one of the main reasons why they like to play such games so much (Vorderer et al. 2006a). Thus, it is likely that the way the user creates this content determines its impact on the user as well. Naturally, this change of perspective has several consequences for the study of exposure.

Again, an example might help to illustrate this point: affective disposition theories assert that a central requirement for a media user to experience entertainment is a strong (either positive or negative) affective disposition toward the narrative’s protagonists and/or antagonists. With interactive media, however, these protagonists are often not only chosen but also manipulated by media users (cf., avatars and agents). We do not yet know what this may mean for the affective disposition. Not only is it unclear what kind of protagonists players will create (e.g., a representation of themselves, a character opposite to themselves, somebody unrelated to themselves, etc.), but most importantly, we do not know how such an affective disposition is impacted by the fact that someone is responsible for the target of this disposition. After all, it is “his or her” character that acts in a specific way and toward whom the user feels an affective disposition.

In other words, many of the problems that scholars have investigated in the context of this rather new research area will appear (or have appeared already) in a new light. Most of the questions will have to be addressed again and answered in a new way. It is not a given that the communication discipline will be able to answer all related questions by

means of its established theoretical and methodological techniques (→ Research Methods). But if we consider the great number of challenges this relatively new area of research on exposure to communication content has identified and successfully dealt with already in a comparatively short time, one can only be optimistic for the problems that lie ahead.

## Exposure to Film

*Holger Schramm*

*University of Zurich*

One of the most challenging tasks in research on media exposure is quantifying the amount of film viewing. Currently, people watch films via a variety of media, such as → television, VCR (→ Video), DVD player, computer and → Internet, and → cinema. For some of these media, it is difficult, if not impossible, to track the number of viewings. Especially when it comes to international comparisons, reliable numbers are often rare due to heterogeneous measurement systems. Nevertheless, we can obtain some valuable information from nonacademic sources about disparities in film exposure between different countries.

### THE AUDIENCE FOR FILM IN INTERNATIONAL COMPARISON

According to these data, even people from western industrialized countries vary in their amount of contact with films, as they differ in access to *audiovisual equipment* (Table 1) as well as in frequency of use of this equipment. Between 30 and 40 percent of TV viewing is dedicated to films, series, and other fictional narratives (→ Exposure to Television).

Table 1 Audiovisual equipment in selected countries

Country	TV households (%)	VCR (in % of TV households)	DVD (in % of TV households)
USA	98.2	88.7	76.2
Japan	99.4	82.6	32.5
Germany	95.8	68.2	43.1
France	95.4	72.0	68.6
UK	97.6	77.6	78.6
Russia	99.5	58.1	22.2
Spain	99.5	60.5	63.1
Italy	98.9	58.8	44.0
Iceland	98.7	94.0	84.8
Romania	94.8	5.4	3.1

Source: IP Network (2006)

Table 2 Admissions to cinemas in selected countries (in millions)

Country	2000	2001	2002	2003	2004	2005	2006	Population (millions)	Average admission per capita
USA	1421	1487	1639	1574	1536	1403	1449	298	4.80
Japan	135	163	161	162	170	161	164	128	1.29
Germany	153	178	164	149	157	127	137	82	1.66
France	166	188	184	174	195	175	189	62	3.07
UK	143	156	176	167	171	165	157	60	2.60
Russia	30	36	41	68	77	83	90	143	0.63
Spain	135	147	141	138	144	128	122	45	2.72
Italy	104	113	116	111	116	106	107	59	1.83
Iceland	1.6	1.5	1.6	1.5	1.5	1.4	–	0.3	4.80
China	115	120	110	117	138	157	–	1314	0.14

Source: European Audiovisual Observatory (2007)

Thus, the average time of exposure to film via TV in western industrialized countries can be estimated at between 60 and 100 minutes per day.

Particularly with regard to *cinema access and cinema visits*, there is an enormous discrepancy between western industrialized countries (including Japan) and, for example, Russia or China. Every year, US citizens go to the movies almost as often as the rest of the world combined. On average, US citizens go to the movie theater 4.8 times per year, whereas Russians (0.63) and, even more notably, Chinese (0.14) go less than once a year (Table 2).

## PSYCHOLOGICAL REACTIONS TO THE EXPOSURE TO FILM

### Overview

Films and movies belong to those prototypical media programs that can elicit emotional effects during exposure (→ Affects and Media Exposure), which is explicitly reflected in the categorizing of many → film genres, such as romance, erotica, thriller, horror, tear-jerker, tragedy, drama, and comedy. Other sub-genres, like adventure, war film, science fiction, fantasy, pornography, mystery, and action film, evoke strong emotions during reception, too, because the stories generally are conceptualized with respect to the assumed psychological affect structures of the viewers (Bordwell 1985).

Although music is only an accessory to films, it can effectively influence the meaning of single frames, scenes, and the whole narration (Cohen 2001). Not only are specific sequences of the film interpreted differently depending on the music in the background, but the subsequent plot of a film can also be anticipated differently. Thus, music serves the film and fulfills dramatic, epic, structural, and persuasive functions.

The psychological processes that occur during film exposure encompass a wide range of different categories (Tan 1996; Plantinga & Smith 1999). Sympathy and empathy, → excitation and arousal, suspense, fear, cognitive, and affective involvement, as well as joy and entertainment are key elements of most film genres (→ Empathy Theory;

Enjoyment/Entertainment Seeking; Involvement with Media Content). Tan (1995) proposed that interest is the central reception category in film viewing: “interest is the urge to watch and actively anticipate further developments in the expectation of a reward. The film’s control of the viewers’ perceptions of events imposes on them special attitudes towards those events and characters. The events themselves together with the attitudes coloring them determine the viewers’ emotions” (Tan 1995, 7). Additionally, Tan (1996) distinguishes → emotions that arise from concerns related to the film as *artifact* (A emotions) from those emotions rooted in the *fictional* world and the concerns addressed by that world (F emotions). Moreover, some communication scholars discuss whether the viewers are only witnesses of the events in the film or whether they can partly or completely identify with the heroes of the film (→ Identification). The extent to which one’s own identity is given up during film exposure has a significant influence on the spectrum of cognitions and affects being experienced (→ Emotions, Media Effects on).

### Suspense

One of the most central categories in film exposure (very often the reason/motive for film consumption) is → suspense. Suspense has primarily been investigated in the context of semiotics-oriented film studies, → cultural studies, and → popular culture research. Across all disciplines, one can distinguish between psychological and text-oriented approaches (Vorderer et al. 1996; Plantinga & Smith 1999). While psychological approaches (e.g., → Affective Disposition Theories) concentrate on the interplay of various cognitive and affective constructs within an individual, the text-oriented approaches (e.g., structural affect theory; Brewer 1996) have their starting point in the narrative structure of texts and stories (→ Storytelling and Narration). Integrative works on film exposure try to combine both, as it has become apparent that the relation between the film text and psychological effects is more complex than assumed so far (Tan 1996; Plantinga & Smith 1999).

All of these approaches primarily explain the formation of suspense, but do not really explain why viewers consciously expose themselves to suspenseful and even frightening films that involve strong negative arousal and inner conflicts. Based on the background of excitation transfer theory, it is plausible that the relief and euphoria of a happy ending are more positive the more suspenseful and “stressful” the film was (→ Emotional Arousal Theory). But how can the fascination with suspenseful and frightening plots be explained when they are not resolved by a happy ending (Weaver & Tamborini 1996)? For an explanation of this phenomenon, communication scholars have developed and adapted a number of reasonable approaches, such as → sensation seeking, → playing, meta-emotions, catharsis theory, or emotion regulation.

### Fear

Especially for children, suspenseful and frightening films could have long-term effects (Weaver & Tamborini 1996; Cantor 2002; → Media Effects Duration). Researchers found that long-lasting states of anxiety after film exposure are not rare even among juveniles (→ Fear Induction through Media Content; Fear Induction through Media Content in

Children). And even college students report being nervous after viewing scary films, experiencing sleep trouble, avoiding exposure to other scary films, and being afraid to go into certain rooms of their own house (Cantor 2002). “The extent to which adults experience these lingering fears after media exposure suggests that something other than the willing suspension of disbelief occurs when audiences view horror films” (Sparks & Sparks 2000, 85; → Suspension of Disbelief).

With this background, it is remarkable that most parents are not aware of these effects on their children and underestimate how much time their children spend watching frightening films. However, children gradually develop a set of regulation strategies to deal with such films. Children at the age of 7 years or younger use *behavioral strategies* in almost every situation (87.5 percent) when they are confronted with scary media content, whereas children between 8 and 12 years of age choose such strategies in 66.7 percent of such cases, and children at the age of 13 and older choose behavioral strategies in only 42.3 percent of all scary media situations (Cantor 2002). As they grow older, children learn that cognitive strategies are often more effective in regulating negative affect in a sensitive and constructive way (→ Cognition; Mood Management).

## Exposure to the Internet

*Robert J. Lunn*

*University of Southern California*

*Michael W. Suman*

*University of Southern California*

How has the spread of the → Internet been studied and explained? Numerous studies have established that the spread of Internet access follows an S-shaped curve. What is not well understood is the factors responsible for different levels of Internet access among different countries (→ Digital Divide; Media Use, International Comparison of). Many theories of the diffusion of innovations, such as the Bass model, are oriented toward individual factors, such as perceived need (Bass 1969; → Diffusion of Information and Innovation; Media Use by Social Variable). The inadequacy of this theoretical stance becomes readily apparent when we consider that cultures exhibiting low levels of gender empowerment deny Internet access to half of their populations. Thus, adoption of the Internet is affected by factors beyond simple exposure to the technology. What are the theoretical and methodological problems with the current approach to cross-country studies of the Internet diffusion process?

### CROSS-COUNTRY RESEARCH DESIGN ISSUES

A common misconception, termed the *pro-innovation bias*, occurs when researchers assume that innovations, such as the Internet, will eventually be adopted by all members of a social system (Rogers & Shoemaker 1971). Related aspects of a pro-innovation bias concern attitudes that rapid diffusion is superior to slower diffusion and that innovations are not typically rejected. In reality, the degree to which innovations diffuse through a population is a complex function of many different factors, some of which act to impede the diffusion process. Part of the reason for the prevalence of the pro-innovation bias occurs because much of the diffusion literature exhibits a US and western European research focus. Data collection is expensive, and consequently data availability is higher in richer countries, which also happen to exhibit higher levels of adoption of new technology.

Pro-innovation biases are inadvertently created when researchers plot percent adoption of an innovation at a single time point, across multiple countries. The resultant curve is indeed often S-shaped (see, for example, Figure 1[a]), but it carries with it the implicit assumption that all of the plotted countries will follow a universal diffusion trajectory, and that, in time, countries at the lower left of the curve will eventually “catch up” with the countries on the top right of the curve.

**Figure 1** (a) Six different countries' percentage Internet access adoption, 1999 (b) Three different countries' percentage Internet access: S-shaped diffusion curves

Figure 1(a) plots percent Internet access adoption for six countries for the year 1999; Figure 1(b) plots the full Internet access diffusion curves for three countries from 1986 through 2006. Clearly, these three countries are following very different Internet diffusion trajectories, a finding that is not apparent in Figure 1(a).

Another cross-country research design issue concerns the *homogeneity assumption* (Fforde 2005). Many studies use country summary data in multiple  $\rightarrow$  regression analyses. One of the primary underlying assumptions of multiple regression analyses is that the underlying population is homogeneous with respect to the pattern of associations (Cohen & Cohen 1983;  $\rightarrow$  Statistics, Descriptive; Statistics, Explanatory). In reference to Figure 1(b), are the factors responsible for Internet adoption the same for those three countries? The development of multiple regression models across non-homogeneous countries leads to misconceptions with respect to causal outcomes and applies a form of epistemological and ontological universalism that assumes people can be understood the same way, and are everywhere the same (Fforde 2005).

Cross-country *sample selection issues* abound in the literature. There are numerous examples of studies using "samples of convenience," consisting of a relatively small number of countries. The problem here is that the results from these studies only generalize to that particular mix of countries. While these studies state generalization limitations in their discussion sections, the knowledge value of so many publications with limited generalization potential is questionable ( $\rightarrow$  Sampling, Random).

*Country grouping effects* are another area of concern. Clearly, different people find it convenient to divide the world in different ways. Grouping countries on the basis of their being on the same continent, a common practice, ignores the fact that there is a considerable degree of between-country variability within these global groupings.

## FAILURE OF THEORY

The Bass model (1969), developed in the marketing domain, provides an efficient mathematical description of the S-shaped diffusion pattern over time ( $\rightarrow$  Longitudinal Studies; Time-Series Analysis). The Bass model resembles epidemic models that describe the spread of a disease in a population through contact with infected individuals (Bailey

1957). In the Bass model, the concept of disease contagion has been replaced by the concept of a social communicative “contagion,” which is postulated to be chiefly responsible for the resultant S-shaped form of the diffusion process. *Social contagion* is defined as a spread of behavior from one individual to another, where one person serves as the stimulus for the imitative actions of another. The definition of the Bass model coefficients reflects the model’s connection with a social contagion explanation. The  $m$  parameter describes the market potential (the projected asymptotic level). The  $p$  parameter is interpreted as the coefficient of innovation because it presumably reflects the spontaneous individual rate of adoption in the population. The  $q$  parameter is interpreted as the coefficient of imitation because it presumably reflects the effects of prior cumulative adopters on subsequent adoption (Rogers 1995).

Defining a model’s fit parameters in terms of the influence of mass media and interpersonal communications from prior adopters presumes that communication processes in conjunction with individual decisions are chiefly responsible for the diffusion of innovations (→ Interpersonal Communication; Two-Step Flow of Communication). But defining a model’s fit parameters in terms of speculative causal mechanisms is problematic. This raises the generalization issue known as construct validity. In this situation, do the Bass model’s  $p$  and  $q$  coefficients actually reflect the influence of mass media or interpersonal communication?

### **NON-INDIVIDUAL FACTORS RELATED TO INTERNET DIFFUSION**

Several researchers have suggested that the primary reason for cross-national inequalities in Internet access resides in *differential economic development* (Hargittai 1999; Rodriguez & Wilson 2000; Norris 2001; Chen & Wellman 2003). Findings that implicate public investment in human capital and infrastructure are important because they associate aspects of economic influence beyond the concept of GDP per capita with a country’s degree of Internet access. Increases in life expectancy and literacy require long-term investments in large-scale public services and facilities, such as public health, power, water, public transportation, telecommunications, roads, and schools. Aspects of wealth such as education and infrastructure take a considerable amount of time to develop and consequently policies designed to enhance Internet access through the insertion of short-term economic aid are questionable.

Norris (2001) considers individuals who prescribe to an economic interventionist policy as “cyber optimists.” In conjunction with short-term economic aid, a cyber optimist would expect Internet access to eventually defuse throughout a country’s population. This diffusion pattern (the “normalization” pattern) might be expected to occur in wealthy countries with cultures that value and reward innovative behavior. Alternatively, cyber pessimists would expect that, irrespective of economic aid, digital technology will more likely amplify existing inequalities of power, wealth, and education, creating deeper divisions between the advantaged and disadvantaged (→ Technology and Communication). This “stratification” pattern of Internet diffusion suggests that individuals who do adopt mostly consist of a country’s advantaged. Basically, Internet diffusion patterns that resemble the stratification pattern suggest that the individual’s ability to adopt is substantially moderated by country-specific cultural and economic considerations rather

than the fulfillment of individual needs. Both adoption patterns yield S-shaped curves that can be fitted by mathematical formulations such as the Bass model. However, results similar to the stratification pattern are difficult to explain in terms of social contagion theory.

Given the normalization and stratification diffusion patterns, it is natural to question if the factors responsible for the diffusion of Internet access are amenable to “quick fix” treatments, such as the insertion of technology or short-term economic aid, or whether the degree of Internet access is shaped by more *deep-seated forces, such as culture* (→ Culture: Definitions and Concepts). Norris reports that affluent Middle Eastern countries have relatively low Internet access levels, a finding that raises concerns with the notion that, in all situations, economic factors are solely responsible for the degree of Internet access. Several Middle Eastern countries are wealthy and have been wealthy for some time, but aspects of their culture act to inhibit Internet access for half of their population, i.e., females (→ Feminist and Gender Studies). This is decidedly not a small effect and points to the danger of making generalizations when predictive factors are causally entangled. In that circumstance, a single correlation may yield a high degree of association, but the ability to predict something is not necessarily synonymous with understanding how something works.

A second point of consideration here is that explanations based on social contagion theory should work best in countries that support a normalization pattern of Internet adoption (i.e., the US and western European countries). In these countries, we would expect the adoption decision to be largely under an individual’s control. However, social contagion models should fail when attempting to predict Internet diffusion in countries that follow the stratification pattern of diffusion. When examined from this perspective, social contagion explanations for the diffusion of innovations appear to be an artifact of early diffusion research that predominantly focused on US and western European countries. These are the countries where the individual-oriented normalization diffusion pattern is found. These are the countries where the inhibiting effects of fear, diminished gender empowerment, and low levels of long-term economic development are minimized.

Clearly, social contagion theory provides an incomplete picture of the innovation diffusion process, and this theoretical deficiency naturally extends to explanations of that process based on definitions of the ubiquitous Bass model’s  $p$  and  $q$  coefficients. The implication is that models that seek to enhance understanding of the cross-country diffusion process need to utilize a mixed-level hierarchical modeling approach, where one level defines the moderating influence of country-specific factors and another level deals with individual decision factors.

## **Exposure to News**

*Dagmar C. Unz*

*Saarland University*

In democratic societies “being informed” is regarded as part of the citizen’s duty in order to form a political opinion and to participate in political life. The media, on the one hand, play a major role in the transmission of information about current events, and they are thought to be very influential. To fulfill its democratic responsibilities, the audience, on the other hand, is expected to consume news with a high level of attention in order to get detailed information, to learn as much as possible. Corresponding to these expectations, television is the principal source of information about current events for most people, and getting the news belongs to their daily routines. Research indicates that the acceptance of the civic duty to be informed is correlated with the frequency of news consumption (Poindexter & McCombs 2001).

### **NEWS CONSUMPTION IN THE MID-2000S**

Television is the most popular source of news, but half of the public uses multiple news sources (→ Television News). On a typical day the average US American spends 66 minutes consuming news: 30 minutes watching television, 15 minutes listening to radio, another 15 minutes reading newspapers, and 6 minutes using the Internet for getting news

(Pew Research Center 2006). However, in the mid-2000s the percentage of US Americans who get news from any medium is lower than it was a decade ago (about 80 percent in 2004 and 90 percent in 1994; Pew Research Center 2006).

This is the case for *young people*, in particular. Whereas among older adults (31 years and older), 60 percent watch TV news, 40 percent listen to radio news, and 35 percent read newspapers every day, only 30 percent of young adults (18–30 years) watch TV news daily, 25 percent listen to radio news, and 16 percent read newspapers on a daily basis (Joan Shorenstein Center 2007). For some scholars, these figures are alarming, since research indicates that news habits develop early in life and remain rather stable. The Internet alone is a medium with rather low age differences in news consumption: about a fifth of the older and younger adults get news from the Internet every day (Joan Shorenstein Center 2007).

### NEWS PROCESSING AND RECALL

In contrast to the expectations that the audience should learn as much as possible in order to fulfill its democratic responsibilities, a lot of studies show that people remember only a relatively small amount of the information presented in the news. *Audience → memory and comprehension of news* is often very poor (Schaap et al. 2001; → News Processing and Retention). Furthermore, findings from exemplification theory indicate that news consumers rely on single cases rather than on more accurate, base-rate information when making judgments about the social phenomena described in news stories (Zillmann & Brosius 2000; → Exemplification and Exemplars, Effects of). It seems that consuming the news cannot be equated with rational, highly involved information processing. Some scholars suggest that consuming television news is associated with a rather *heuristic mode of information processing* (→ Elaboration Likelihood Model). Because people want to assure themselves that nothing important has happened, that the world keeps on going as usual, they watch the news without great attention and interest, and without the objective to learn any details. Nonetheless, in contrast to these findings, the audience feels well informed (Robinson & Levy 1986).

In order to understand these discrepancies, it may be helpful to consider → information processing theories. Top-down processes largely account for the *selectivity of information processing*: people selectively expose themselves to messages; pay attention only to those aspects of the content interesting to them; interpret information according to their needs, interests, and prior knowledge; and remember information within their individualized mental schemas (→ Selective Exposure; Selective Perception and Selective Retention). This may explain, for example, research findings that people tend to remember stories about more familiar topics better than stories about unfamiliar topics.

Individual variables, such as prior knowledge, cognitive abilities, and interests or attitudes toward the media (such as credibility or perceptions about how difficult it is to learn from different media) influence selective exposure, perception, attention, information processing, and recall. *Knowledge gap research* shows that socio-economic status is an important variable in understanding knowledge gain from news (→ Knowledge Gap Effects). People with higher socio-economic status are more likely to selectively expose themselves to news; they typically gain more knowledge and gain knowledge more quickly than people

with low socio-economic status. Socio-economic status is of such high importance because it combines many other variables, like political interest, prior knowledge, access to information sources, communication skills, etc.

Moreover, motivations for watching the news play a major role in understanding knowledge gain from the news media. *Uses and gratifications research* has identified a series of motivations drawing people to news media (→ Uses and Gratifications). The motivations influence information processing and acquisition. Watching the news for information is linked to deeper, more elaborative information processing, and therefore to greater knowledge gain (Eveland 2002). However, the news serves needs beyond orientation; it also fulfils affective and social needs, and this is especially the case for television news. For most persons, watching the news is not a matter of being well informed; rather, it is a kind of social activity and entertainment. Television news connects the individual to society and provides topics to talk about (McQuail 2001).

Despite the rather disappointing results on news retention, there are also some clear and consistent research findings about news consumption and retention. First of all, people who regularly consume news are generally better informed; news attention and news reliance are effective predictors of political knowledge. Second, there are certain *presentation features* that can influence understanding and remembering (Perse 2001). For example, visuals or the personalization of stories can increase news retention: story placement, the frequency or length of a message, as well as visual/verbal redundancy affects recall. As part of bottom-up processes, such formal elements can attract attention and lead to orientation reactions, which might lead to mental engagement if the message is interesting or important.

*Framing research* suggests that the way the news is presented affects what people think about issues and events (→ Framing Effects; Framing of the News). Moreover, each news source exhibits characteristics that make its content easier or more difficult for the individual to process cognitively; thus, individuals may learn more effectively from some news sources than from others. For example, people remember more from print news than from a comparable television news presentation (DeFleur et al. 1992). Some researchers assume that whereas certain characteristics of television news (such as its fast pace and emphasis on pictures rather than text) inhibit viewers' information processes, print news may be easier to process cognitively, since a reader can read at his or her own pace and can reread portions of the text that are difficult.

### **NEWS CONSUMPTION IN TIMES OF CRISIS**

Much of the work in news research, carried out since the 1950s, has focused on the informational impact on the audience. However, the field of news effects research covers a much broader range of topics. Other prominent topics are the study of news diffusion (the question of how rapidly and by what means information about an event is spread throughout a system; → Diffusion of Information and Innovation) or the agenda-setting hypothesis (→ Agenda-Setting Effects). Another interesting topic is the study of news consumption in times of crisis.

Times of crisis are particular situations that are reflected in changed conditions of news consumption (Perse 2001). Due to heightened uncertainty and fear, television as an

immediate source of the most current news is of great importance for receiving confirmation and details. The diffusion of news is rapid and complete. People rely on mass media for information, explanation, and solidarity. Even if media are unable to fulfill surveillance and correlation needs, because of constraints on news gathering, the function to offer assurance and tension reduction is very important for the audience. The solidarity-building effect is associated with a heightened willingness to accept censorship and limits on press freedom, as well as with a strong increase in patriotism (the so-called rally effect – a sort of “rallying around the flag”). Many of these effects are uniform and universal; the role of audience variables is quite small.

### NEWS CONSUMPTION IN TIMES OF GROWING INTERNET USE

Looking at news consumption, we are currently at a turning point. There are more news sources than ever before: newspapers, network and cable TV, radio, the WWW, news headlines sent directly to mobile phones and PDAs, etc. (→ Internet News; Online Media). The Internet allows people immediate access to news and the efficient selection of the news of interest to them. Some media analysts see the Internet as a threat to the traditional news media. On the other hand, there is evidence that people tend to remain relatively faithful to news sources that they have habitually used in the past, and that they often visit websites of the traditional media but the news they select on those sites differs from what they may have received via the traditional media. People seem to use online news to supplement, not to replace, their core news consumption (Ahlers 2006). The reliance on traditional news media and the adoption of online news seem to be influenced by lifestyle variables (Chang & Leung 2005). However, the exposure patterns on Internet news are not yet well understood; new technologies may change the nature of news consumption.

## Exposure to Print Media

*Wiebke Möhring*

*Hanover University of Music and Drama*

*Beate Schneider*

*Hanover University of Music and Drama*

The term “print media” can be defined in different ways. In its broadest sense the term is used for a whole range of publications that can be subdivided into two main categories in terms of their format and content: media published at regular intervals such as → newspapers and → magazines, and media for one-time publication such as → books in their different genres (→ fiction, nonfiction, and textbooks). For the purpose of this entry, we will narrow down the definition of print media and concentrate on the periodically published mass media newspaper and magazine and their use, with a focus on dailies.

The print media are significant players in the development of a society. They are, at the same time, reflections of that society as well as social artifacts and, as such, are subject to societal change. They are seen as agents of social change or agents of social control (Demers & Viswanath 1999). Generally speaking, people use print media in many different ways. Print media are used as sources of → information, they provide models of behavior and serve as a frame of reference for possible dissociation and → identification, differentiation, and participation in everyday life. Additionally, they provide content for personal communication (→ Interpersonal Communication; Media Content in Interpersonal Communication), relaxation, and emotional relief.

International comparative research on the use of print media has to take into consideration that motivation for using print media, as well as their circulation and availability, is embedded in the cultural, political, and societal structures of the national systems in question, and that it is also dependent on economic conditions (→ Media Use,

International Comparison of). In the case of (national) dailies, the format (daily publication) and the strong dependence on national language and local events contribute to a marked restriction of the print media to national concerns.

### THE BASIC PRINCIPLES OF PRINT MEDIA USE

Use of the print media assumes certain skills on the part of readers. Level of education and literacy are therefore significant socio-cultural indicators for media use in a given country (→ Media Use by Social Variable). Countries with a high rate of illiteracy lack this basic prerequisite. In contrast to audio or audiovisual media, print media require a minimum ability to read. Reading skills and motivation, both essential conditions for reading, are complexly interrelated. The general historical and social as well as the specific situational context influences the reading process.

Reading is a *cognitive process* (→ Cognition). The reader actively and constructively incorporates the content of the text into pre-existing knowledge structures, based on the reader's familiarity with the language and knowledge of the world (→ Information Processing). The process of reading begins with the perception and processing of visual information (→ Visuals, Cognitive Processing of). Following the identification of individual words, the reader moves on to sentence level, interrelating and structuring word sequences according to their semantic and syntactic correspondences. On text level, the → meanings of the individual sentences are put into context to form individually varying meaningful structures. Conclusions that the individual reader draws from the text, and that transcend the tangible information it contains, play a significant role in this construction of meaning. Its quality is largely determined by the reader's working → memory, previous knowledge of the subject, how the reader relates this previous knowledge to the content of the text, and also the reader's familiarity with the genre. Mastery of these sub-processes identifies competent reading as a key qualification for the use of print media (Christmann 2004, 435–436). Moreover a developed linguistic sensitivity is required to be able to grasp the connotative potential of the text, such as ambiguities, allusions, irony, etc.

In addition to reading competence, the reader's *motivation and interests* play a pivotal role. Generally speaking, we can identify three subject areas that provide an incentive for readers to use print media. These are "hard news," (e.g., politics and business; → News), → "soft news," (e.g., people or society), and sports (→ Sports and the Media, History of), while local interest topics (→ Local News) cut across these three subject areas and can be found in each of them. This system has proved helpful in explaining preference for different types of media content. Deliberate use of the media as motivated by a desire for information or distraction, entertainment or instruction, varies considerably with media genre.

The reading of print media, unlike that of electronic media, requires complete → *attention and focus*, excluding all other activities. At the same time, the mode of exposure allows the reader to use print media irrespective of place and time and thus offers higher accessibility and flexible use at all times, to be interrupted and resumed at the user's discretion. The print media and their content are less ephemeral and can easily be transported, filed, and passed on. The reader determines the length and speed of use in accordance with his abilities and needs. Also, it is primarily the reader who selects the information and the order in which it is read.

## EXPOSURE TO NEWSPAPERS

Newspapers can be published daily (daily press), weekly (non-daily press) or on specific days (especially the Sunday press). Their geographic orientation can focus on a specific area of distribution. In this case they are referred to as local or regional newspapers, as opposed to national newspapers, which are distributed nationally. All newspapers have in common that they offer different sections, i.e., recurring thematic units. Beside a variety of subject areas, the main sections are national and international politics, business, sports, culture, and local or regional news. In addition, there are newspapers that are solely concerned with one subject area, as for example sports or business papers. Newspapers are either distributed through subscriptions, i.e., the newspaper is delivered directly to the subscribers' homes, or through sales outlets.

Dailies play a significant role in shaping the day-to-day local and political orientation of their readership. They strengthen political interest and knowledge (→ Political Knowledge), increase participation, and improve understanding of political events. Moreover, in many countries the need for local information is one of the most important reasons for reading daily newspapers. Hence, in many societies newspapers play an important role, which is also constitutionally granted in many democracies.

Newspapers cannot fulfill these functions if they are not used. Notwithstanding the continuing strength of the newspaper market in many countries a *downward trend in newspaper reading* can be observed worldwide. Their share of → advertising is declining. Selling price can only partly make up for loss of revenues and is strongly limited by what customers are willing to pay (→ Advertising, Economics of; Media Economics). Additionally, → circulation and coverage of dailies have been decreasing for years.

A number of *factors influence newspaper use*. These are: income, age, sex, level of education, race, length of residence in a particular region or community, mobility, number of children in a household, marital status, housing condition, and interest in politics. In addition to these socio-demographic factors, respondents name lack of time, lack of interest, preference for a different medium, and cost as reasons for not reading newspapers. Content and general reading interest are the least significant factors. Moreover, in recent years other media have been taking over as information and entertainment providers and dailies are having a harder time holding their ground in the media competition.

In particular the *share of younger readers* has seen a noticeable decline for years. Many studies in the US and also in Europe have shown that age is the first and foremost predictor of shrinking coverage. This changes only to a limited extent with increasing age, as it is unlikely that those who did not read newspapers when they were younger will become newspaper readers later in life (cohort effects). They will be reached less and less by the political information in dailies. If they do read newspapers they tend to be interested in other subject matters (Lauf 2001). Apart from age, income has played and continues to play a significant role. In some countries it has been shown that readership increases with household income (Schönbach et al. 1999).

The number of available daily newspapers and their use varies widely from country to country (Table 1). The table compares a selection of countries in terms of three parameters: (1) circulation per 1,000 population, (2) average daily coverage, and (3) number of newspaper titles per 1 million adult population. The values provide a clear picture of the

**Table 1** An international comparison of newspaper circulation and use: average circulation size and daily coverage of daily newspapers and number of newspaper titles in the year 2002

widely varying significance of daily newspapers in individual countries. The Scandinavian countries, Japan, and Switzerland have the highest circulation of newspapers, followed by Great Britain, Austria, and Canada. The Scandinavian countries also show a clearly higher level of coverage of daily newspapers than, for instance, the southern European countries. The case of Japan in particular is remarkable, with only a few mass circulation newspaper titles (per 1 million population) published. The average number of copies distributed per

title is 674,400 in Japan, 69,500 in the EU and 37,600 in the US. This is another example of the diverse supply structures in different countries.

## EXPOSURE TO MAGAZINES

The term “magazine” encompasses a wide variety of differing subject matters and forms. Especially as regards the different national markets, a systematic approach or rather categorization proves difficult. Generally speaking, we can distinguish television magazines, news magazines, general interest magazines, special interest magazines, as well as the large sector of customer magazines and professional journals.

Magazines are especially sensitive to trends and fashions, both national and global, and therefore require constant reorientation of content and form to current conditions. Traditional economic and social structures are evidently undergoing a process of change in many countries. The worlds of work and leisure are changing. An increasing individualization and differentiation of consumer and living habits can be observed not only in western countries. Among the print media, magazines are the ones that adapt most quickly and strongly to the changed needs. Consequently, fluctuation in the magazine market is high. This trend is reinforced by readers’ behavior. Nowadays readers use a broader range of different titles, they experiment more, and traditional target groups and definitions of readers are losing validity (→ Audience Segmentation).

Reader motivation and the functions of magazines vary widely and cover the whole spectrum, from specific information about different topics to distraction or entertainment. At the same time, magazines represent certain images and thus can also take over functions of social identification for the user.

It is difficult to find comparable magazine coverage and circulation figures on a national level. On an international level it is almost impossible, due to the enormous heterogeneity of titles. Use is too dependent on magazine content and reader motivation and interests. However, it can be said that the pronounced independence of magazine readership from specific reading times is a main characteristic of magazine use, not least because magazines do not as a rule offer up-to-the-day information.

## METHODS AND DIFFICULTIES OF PRINT MEDIA RESEARCH

Measuring print media use and impact presents a methodological challenge. There is a long tradition of → readership research arising from this challenge. Readers often use different sources of information, talk about content, and understand reports differently. The general problem in readership research is the respondents’ recall of sources. The subjective importance attached to a piece of information and thus also its storage in long-term memory results primarily from its content, i.e., the sender (communicator) and the information carrier (medium) of a piece of information are of secondary importance to the recipient (the reader) of the information. As a result, sources of information are usually more easily forgotten than the information itself.

The following models (often labeled differently) can be regarded as the best established *models of readership research* (Wiegand 1996). *Through-the-Book* (TTB) is the oldest method of readership → survey. It was introduced in the US in the 1930s. Respondents

are shown a specific edition or several editions of a newspaper title. The interviewer goes through the edition(s) page by page with them, asking whether they have read specific “key articles.” The growing number of titles has made this method almost impracticable for national surveys, but it is still useful for targeted surveys.

*Recent Reading* (RR) was first introduced in Great Britain in the 1950s. RR records whether the respondent has read a given title within the previous publication period. The flaws in this method lie in the difficult time identification and in the problem of cumulative and extended reading. However, RR is considered a standard model.

The *First Read Yesterday* (FRY) approach was developed in the 1980s. While respondents have to remember their reading over quite a long period of time (when questioned about weekly titles) under RR, FRY asks about what they read on the previous day. Here a large sample is indispensable in order to get sufficient data on titles with a longer publication period.

In addition, surveys are conducted with the help of panel data or also with diaries (→ Longitudinal Analysis; Research Methods).

## NEW TECHNOLOGIES AND THEIR IMPACT

Print media use is going through a phase of profound change. Traditional use patterns are increasingly difficult to identify. The processing of written texts remains one of the main reception strategies, but technological developments have changed the manner of distribution. The computer screen has now ousted paper as the center of attention.

Today, most publishing houses at least in western countries offer online information in addition to their traditional printed papers. Their strategies range from complete transcription of contents and form (digital editions) to online newspapers and online information platforms (van der Wurff & Lauf 2005; → Online Media; Internet News). The goal of this commitment is to reach new markets by using new technology and to strengthen traditional products as an information brand. Furthermore, in many countries there are online newspapers that are not published as printed papers as well. The typical online newspaper reader is mainly younger, highly educated, and male. In general, studies on the use of online newspapers show that online newspapers seem to be used in a complementary manner, i.e., they do not replace printed newspapers. However, in particular younger online newspaper readers do not read the printed edition (de Waal et al. 2005). This might be one reason for the decline of the traditional papers in this target group.

Multimedia offerings have led to new forms of media use that continue to be based on traditional reading. At the same time, the hitherto existing print media remain complementary sources of information alongside the Internet for a large part of the population. For others, they still are – for the time being – the most important source of information, particularly with respect to political and local information.

## **Exposure to Radio**

*Holger Schramm*

*University of Zurich*

Radio is the medium with the highest relevance for media users in daily life – at least with respect to the amount of exposure time (→ Radio; Radio: Social History). In western industrialized countries, people listen to radio for about three hours each day, with about 80 percent of daily reach (Table 1).

Radio consumption has decreased massively since the beginning of the twenty-first century, especially among people under the age of 40, due to the increasing use of mobile music media like MP3 players (Schramm 2006). About 90 percent of the radio consumption occurs while people pursue other activities at the same time, such as eating, working at home (e.g., cleaning, cooking, ironing), working outside home (e.g., gardening, office work), or car driving. For instance, 85 percent of US Americans listen to the radio during

Table 1 Exposure to radio in selected countries

morning drive time (6 a.m. to 10 a.m. weekdays), and 80 percent listen during afternoon drive time (3 p.m. to 7 p.m.; MacFarland 1997). Studies have shown that radio music listening can positively affect reaction time during simple routine driving (for example, monotonous driving on a highway) and negatively during difficult, demanding driving (for example, in heavy city traffic). In addition, loud music can lead to driving faster, while slower music can lead to improving reaction time in dangerous situations. If a driver experiences music as pleasant, the number of driving mistakes is often reduced.

Besides the central function of accompanying other activities in order to ease workload, to abridge time, and to compensate monotony, primarily emotional motives can be identified in radio use (MacFarland 1997; Rubin & Step 2000; Schramm 2006; → Affects and Media Exposure). To these belong mood regulation (→ Mood Management), stimulation of excitation, activation versus damping/catalyzing of excitation, abreaction, relaxation (→ Excitation and Arousal), wallowing in memories, distraction, day dreaming (→ Escapism), social belonging, affiliation (→ Social Identity Theory), distinction, social comparison (→ Social Comparison Theory), → parasocial interactions and relationships, social alternative, and → information seeking and life assistance (→ Audience; Audience Research).

## FORMATS AND MUSIC CONFIGURATIONS

The main motive for turning to radio and the primary content of most radio programs is music (aside from news and talk radio) with a music portion, on average, of about 70 percent. According to MacFarland (1997), the most popular music format is *adult contemporary* (AC) with a target group aged between 25 and 49 years. Its features are hits from the 1980s and 1990s and current hits, primary melodic pop and rock songs, an extensive playlist, and a moderate/reserved young presentation/moderation. Its variations are “hot AC,” “soft AC,” and “oldie base AC.” The format *contemporary hit radio* (CHR)

targets teenagers and young adults between 14 and 29 years. It plays current top-40 hits, has a very small playlist, variance in music genres only according to the formation of the charts, and a young, fresh presentation/moderation. Its variations are, among others, “mainstream CHR,” “dance-oriented CHR,” and “rock-oriented CHR.” The format *rock/album oriented rock* (AOR) was created as a backlash against the CHR formats. Its target group consists of higher educated people aged 18 and older. It plays progressive rock music, mainly album songs that have never been in the charts. The presentation/moderation style is unobtrusive and factual. The *oldies/gold* format is mostly concentrated on songs from one specific decade, e.g., songs from the 1940s and 1950s (rock ‘n’ roll), the 1960s (beat), or the 1970s (disco). The target group is at least 30 years old, depending on the music genre/decade. Further common formats include “country,” “urban contemporary,” “Hispanic,” “Classic,” and jazz (→ Audience Segmentation).

In order to create music programs compatible with large groups of people, the degree of complexity of radio music must remain rather low (Barnes 1989; Ahlkvist & Fisher 2000); consequently, music research conducted by radio stations remains rather simple (Schramm et al. 2002). One can assume that most radio stations would rather offer music programs at the lowest common complexity level and risk boring the audience than overtax and possibly lose them (Schramm 2006). Because of the fact that “activation” diminishes when people listen to a series of titles with a similar complexity level, radio programmers take certain tonal-structural contrasts between the titles into account when putting together radio programs, specifically changes between fast, more activating, and slow, more calming titles (MacFarland 1997). A radio program can be diversified by changes between music genres, as far as the format allows (for example, switching between pop, rock, soul, rhythm and blues, hip hop, etc.), female and male singers, pure instrumental and vocal, fast/activating and slow/calming songs, old and new songs, text languages, well-known and unknown songs, and changes in the song’s mood, for example changes between happy and sad songs.

## LISTENING MODES

Music listening is composed of cognitive, affective, and behavioral elements; in other words, it is determined by mental/intellectual elements (music structure, composition idea, and construction), psychological-emotional elements (sound, sensual stimulation), and physical elements (rhythmic components). Roughly, we differentiate between intentional/concentrated and unintentional/distracted listening, whereas most radio listening can be assigned to the latter. Moreover, music research has identified quite a number of different listening modes (Schramm 2006).

“Motor or kinetic listening” is associated with bodily movements while “compensatory listening” leads to repression of unpleasant moods. “Physiological listening” comes along with physical reactions such as goose bumps. Listening is called “diffuse or vague listening” when the audience member performs other activities parallel to listening to the radio. Other forms include “emotional listening” (associated with emotional abandonment to music), “sentimental listening” (associated with memories of past experiences), “associative listening” (associated with visual concepts or images), and “distanced listening” (associated with analytical, evaluating attitudes). The mode of radio use can be composed

of different listening modes at the same time, e.g., analytical listening can positively influence the intensity of emotional listening and vice versa.

### AUDIENCE TESTS

Because of individual differences in abilities and capacities in the perception of music, it is very difficult to develop radio programs which will be favorably evaluated and used regularly by a large group of people (→ Information Processing). Nevertheless, radio stations try to reach this ambitious goal by relying on standardized music research (Fletcher 1987; Balon 1990; → Test Theory). This research is primarily assigned to check the acceptance of each song and to avoid audience switching to competitor stations. Within the music research of commercial stations, two kinds of music tests stand out: telephone surveys/“call-outs” and audience/auditorium tests.

Telephone → surveys are faster and more favorable, and are preferred by most radio stations. Every week or at least every two weeks, 30–50 music titles in the form of *hooks* (salient excerpts from a title with a length of approximately 8–12 seconds and with the highest presumed recognition value, most often from the refrain) are played over the phone to approximately 100–200 people randomly selected from the target group (→ Sampling, Random). The sample judges every title along several *evaluative criteria*. As a rule, these criteria involve three aspects: familiarity (“Have you heard this title before?”), pleasure (“How do you like this title?”), and saturation (“Would you like to hear this music title on your favorite radio program more often?”).

In the case of *saturation* (or “burnout”), listeners are asked whether they hear these titles too often. In telephone surveys in particular, the test titles are those that receive very frequent airplay, and therefore have a high rotation rate, where saturation tendencies are more likely to occur. Telephone surveys have the advantages of quickly gauging the mood changes of listeners and of continuously observing music title developments over short intervals. Accordingly, radio programmers can include or exclude titles with certain characteristic values of current interest from their playlists. Off and on, radio researchers ask additional questions that go beyond the three above-mentioned criteria. For example, they inquire about *station affinity* (“To which radio station does the title fit?”), emotional expression of the music, or the desired time of the day during which the music should be played.

In data analysis the researchers compile the results from the three criteria (familiarity, pleasure, and saturation) in a so-called “power score” and, through combination with media use data by socio-demographic variables, create *target-group-specific title indexes* that indicate which title is preferred by which group of listeners. Enriched with additional information about various music parameters, such as music genre, tempo, instrumentation, gender of the performer, lead-in time to the beginning of singing, title length, the way the title ends (“cold” = abrupt end; “cold fade/quick” = quick fade-out; “fade” = slow fade-out), and the desired rotation, the data are fed into the data banks. Based on these data, special computer programs such as “Selector” compute music programming lists that target a specific group of listeners. Subsequently, a music editor has to revise these lists in ways that guarantee a harmonious music program reflecting the philosophy of the radio station.

The second method, *audience or auditorium tests*, costs more and, for this reason, is funded only once or twice a year by radio stations. For audience tests, a group of up to 300 persons is recruited (in most cases reflecting the socio-demographic composition of the target group) and invited to a large auditorium like a movie theater or hotel hall. There they listen to hundreds of music titles in the form of hooks and evaluate them according to the criteria mentioned above. The group listens to the titles either together on a stereo set (here mutual distractions and possible group behavior limit the validity of the data) or they listen to the titles in an individual random sequence through headphones. In the first phase, sequence effects are neutralized by playing the titles in reverse order (the mirror image method) to a second group of the same size. Such audience tests work well in testing large parts of the playlist, as well as those titles that do not appear on the highest rotation. They also have the advantage of generating a great amount of data in a short time and improving the sound quality of the hooks, or, if headphones are used, optimizing that sound quality, as compared to telephone interviews.

# Exposure to Television

Uwe Hasebrink

University of Hamburg

Research on exposure to → television builds a large and heterogeneous field with one common denominator. Studies of television viewing try to provide evidence on the question: What do people do with television? Exposure to television has developed as a major research field since we cannot understand television as a medium of public communication without considering those who actually watch it. In particular, the television industry has an existential interest in finding out how many people watch its programs; it is exactly this kind of audience data that it can sell to the → advertising industry (→ Media Economics). But even beyond this economic interest, information on exposure to television is a necessary condition for any statement on the role of television in people's everyday lives and on potential social and individual consequences of television (→ Exposure to Communication Content; Audience Research).

## MAJOR DIMENSIONS OF THE TOPIC

The field of research on exposure to television can be structured according to several levels of analysis. The main differentiation refers to the *level of aggregation*: at one end of the spectrum, the dominant line of research on exposure to television aims to describe and explain the viewing behavior of "aggregate audiences." If we see television as a mass medium, we can conceptualize exposure as behavior of aggregate audiences (→ Audience). We cannot regard these audiences as a countable group, as for example the audience as present in a theatre or cinema. Instead, we have to construct television audiences by certain operational definitions and methodological procedures. All over the world, the television and advertising industries have developed similar mechanisms to construct the "mass audience" as the dominant model of research on exposure to television (Ang 1991; Webster & Phalen 1997).

At the other end of the spectrum, some lines of research, mainly in the academic area, examine exposure to television as individual behavior or individual social action. This kind of research is more interested in the psychological processes linked to the selection, interpretation, and appropriation of televised content, in interindividual differences between different viewers and viewer groups, and in intraindividual differences between different situations and social constellations.

Another differentiation of the field reflects the fact that the theoretical and empirical core, i.e., contacts between television and viewers, is examined from *different perspectives that complement each other*. Besides the plain audience research, which is satisfied with counting the numbers having contact with a specific channel or program, most studies link the contact to other theoretical concepts that might be called: (1) selection, (2) reception, and (3) consequences. The most important perspective here is research on the selection of television as a medium and of specific channels or programs (→ Selective Exposure). Selection processes mainly refer to the pre-communicative phase of television viewing.

Studies try to understand why people have selected the channel or program they watch, or why certain programs reach bigger audiences than others. In these studies, exposure to television is treated as the dependent variable, which is influenced by individual, situational, and program-related factors.

The second perspective focuses on the processes during the communicative phase of television viewing (→ Selective Perception and Selective Retention). Once a certain program has been selected and viewers watch it, the question is how they perceive, process, and interpret the program. The focus is on the → attention and involvement of the viewers (→ Involvement with Media Content), and on their parasocial interactions with the personae portrayed on television (Klimmt et al. 2006; → Parasocial Interactions and Relationships). In these studies, exposure to television is categorized according to different kinds or qualities of contact – emphasizing the fact that two contacts with the same program can be very different from each other.

Finally, the third perspective examines the consequences for viewers of the programs watched and thus the consequences of exposure to television in the post-communicative phase; the question is how people integrate the televised messages into their knowledge and belief systems, how they deal with them in follow-up communication (→ Media Effects). Within this perspective, two lines of research can be identified: on the one hand, research on media effects treats exposure to television as an independent variable, influencing cognitive, affective, and behavioral processes and structures on the viewers' side. On the other hand, research on media appropriation focuses on how viewers actively integrate the television experience into their everyday lives.

Within the major dimensions of the topic as outlined so far, two areas can be regarded as the most important: the measurement of pure audience behavior, and the determinants of exposure to television. We shall treat these in more detail in the next two sections.

## RESEARCH ON TELEVISION AUDIENCE BEHAVIOR

In dealing with mass audiences, the media industry's research on exposure to television mainly focuses on structural factors, besides the basic question of the size of the audiences reached by certain channels or programs; this research examines how exposure to television is related to time and to channels.

The first indicator for describing audiences is their *size*. The most common indicator is the reach, which is defined as the percentage of the population that had at least one contact with the particular television offer. This measure can be assessed for different levels of the medium, e.g., for television as a whole, for single channels, or for certain programs, and for different periods, e.g., per day, per week, per 14 days, etc. In most developed countries the percentage of people reached by television on an average day has been stable on a high level (between 75 and 85 percent of the population; IP 2006; → Rating Methods; Nielsen Ratings; People-Meter).

As a rule, the information about the size of the audience is complemented by additional information on *how long people have watched*. The “viewing time” indicator reflects the average duration of use for the whole population; it is usually expressed as minutes per day or hours per week. Whereas this indicator is based on the whole population, another indicator, “time spent viewing,” is the average duration of use of

**Table 1** Average individual television viewing time in selected countries (in minutes per day, Monday–Sunday)

Country (age group)	2000	2001	2002	2003	2004	2005
USA (adults 18+)	262	270	277	290	297	299
Japan (adults 20+)	205	201	207	218	223	214
Germany (adults 14+)	203	205	215	217	225	226
France (adults 15+)	204	209	212	212	216	219
United Kingdom (adults 16+)	234	231	228	239	237	235

Source: IP Networks (2002–2006), based on national people-meter systems

those viewers only who have actually used the medium or the specific channel in the period concerned. According to data from people-meter systems, the amount of television viewing has been increasing in many countries over recent years (Table 1; → Media Use, International Comparison of). Thus, according to these criteria, television is still expanding its role in people's everyday lives.

Another time-related aspect of television exposure is the *distribution of viewing sessions over the day*. For all countries, the highest viewing figures are observed in the evening, which is clearly television “prime time.” However, as for the rest of the day, there are important intercultural differences concerning the medium's reach. Countries in southern Europe show high viewing figures at lunchtime, which reflects the cultural habit of having extensive “siestas”; Japanese television morning shows reach fairly high figures at breakfast time, whereas in many other countries, the morning is clearly devoted to listening to radio.

Due to heavy competition between television channels in many countries, particular attention is paid to *channel-related indicators of television exposure*. As a general indicator, the “share” of a channel or program expresses the percentage of viewing time devoted to this channel or program compared to the total viewing time in the period concerned. In recent years, as a consequence of the increasing number of channels available, the average share of channels has been decreasing substantially. We can interpret this process as audience fragmentation or segmentation (Webster 2005, 367; → Audience Segmentation). However, as studies from many countries show, people who have access to multichannel systems do not use the whole spectrum of channels. Instead, viewers develop their personal “channel repertoire,” i.e., the selection of channels they regularly watch. The size of these channel repertoires generally does not exceed 10 to 15 channels. For multichannel systems with more than 150 channels, this means that many channels do not have an opportunity to reach a wider audience.

Besides these limited channel repertoires, research has identified some other patterns of television exposure, which have become extremely important for program planners. This kind of research is called *audience duplication research*, because it is empirically based on the percentage of viewers of a certain program who also watch a certain other program at another time (see Goodhardt et al. 1987; Cooper 1996). The concept of “channel loyalty” refers to the empirical observation that viewers tend to select programs on a particular channel (→ Channel/Program Loyalty). More specifically, the “inheritance effect” means

that viewers of a program are likely to watch the next program on the same channel. "Repeat viewing" is defined as the degree to which viewers are likely to watch two different episodes of the same program. Since these effects are to some extent confounded, it is difficult to identify their exact prognostic value. However, program planners consider these effects.

Another relevant aspect of channel-related behavior is the *frequency and pattern of changing channels*. Since the remote control became part of the usual technical equipment, many studies have dealt with the question of why people change channels (→ Zapping and Switching). Several types of changing channels have been identified, such as avoiding advertising ("zapping"), watching two or more programs at the same time ("parallel viewing"), looking around for interesting programs on offer ("grazing," see Eastman & Newton 1995). There has been particular interest in changing channels as a means of finding out what to watch. In an early study on watching television under the conditions of cable systems, Heeter proposed a choice process model (Heeter 1988), which distinguishes different phases of orientation, such as orienting search and re-evaluation.

## RESEARCH ON INDIVIDUAL VIEWING BEHAVIOR

### A General Model of Program Choice

As a complement to the classical audience research of the media industry, academic research on exposure to television is interested in individual processes, in explaining why viewers select the programs they watch, how these programs are perceived and the consequences they have. As a general model in this area, the theory of television program choice proposed by Webster & Wakshlag (1983) has become very influential. According to this model, exposure to television – in this case defined as the choice of a specific program – is determined by the following factors:

*Availability:* Television exposure depends on whether people have time to watch television, and whether they are at home or at any other place where they have a television set at their disposal. This factor represents the necessary condition for any kind of exposure to television.

*Needs and preferences for program types and specific programs:* The main theoretical line included in the model refers to research on the → uses and gratifications approach. It is assumed that certain social and communicative needs shape people's expectations toward television programs. Based on their individual needs, people develop preferences for program types that fulfill expectations or satisfy gratifications sought (→ Expectancy Value Model). Through preferences for specific programs, the model assumes that program type and program preference strongly influence the individual choice behavior.

*Group:* As an intervening factor, the model considers potential influences of other people being present during television use, who might have different interests and preferences and thus might alter or moderate the decision on what to watch.

*Structure of the television offer:* The choice of a certain program is influenced by the structure of the television channels and, quite importantly, by the extent to which the viewers know about the available channels and programs.

In integrating these factors, the model emphasizes that exposure to television is jointly shaped by individual, social, and structural variables. In the next section, we shall describe some of these variables in more detail.

### Determinants of Exposure to Television

In order to explain individual exposure to television and interindividual differences between (groups of) viewers, several determinants have been investigated. One area of research provides strong empirical evidence on stable *differences between social groups*. A general finding is that elderly people watch substantially more television than younger people; the reason for this is a higher degree of availability and the fact that they have less alternative options for spending their time and television is a cheap and accessible activity (→ Media Use across the Life-Span). Beyond that, there is a tendency that people with less formal education watch more television than better educated people (→ Media Use by Social Variable). Men and women do not show substantial differences regarding viewing time, but men tend to switch channels more often than women do and they devote much more of their viewing time to sports programs, whereas women have stronger preferences for serial fiction programs (→ Audiences, Female).

Another explanation for stable interindividual differences in exposure to television refers to traits. In particular, the trend toward sensation seeking has been investigated as one factor that might explain differences in the extent to which people prefer exciting action and violence-oriented programs (→ Sensation Seeking).

Below the level of broad social categories and traits, *individual preferences for certain kinds of programs* are regarded as the most important determinants of viewing behavior. These preferences are regarded as temporarily stable dispositions, which depend on the viewers' needs and interests; inasmuch as these needs and interests change, e.g., due to major life changes and challenges, individual program preferences might change as well. The broad research on selective exposure to television has provided strong evidence of how viewers selectively compose their personal television repertoire.

On the lowest level of concrete situations of exposure to television, *affects and moods* are treated as important determinants of viewing behavior (→ Affects and Media Exposure; Mood Management).

### METHODOLOGICAL ISSUES AND FUTURE CHALLENGES

Exposure to television and, more generally, television audiences are not natural entities that can be objectively observed by researchers. On the contrary, assessing television exposure and measuring audiences is a constructive process shaped by underlying theoretical conceptualizations and methodological procedures (Kent 1995). Therefore, it is important to reflect on how different methodological approaches define "contact with television" as the core aspect of television exposure.

The dominant approach to measuring television exposure is *people-meter systems*. These systems are run by the television and advertising industry in most countries. Electronic devices are installed in representative samples of households, which continually register the channels watched on any of the households' television sets. While data from people-meter

systems are sometimes re-analyzed by academic researchers (e.g., Krotz & Hasebrink 1998), most studies run outside the television industry rely on less expensive methodologies.

Studies on the links between television exposure and everyday practices often use standardized or nonstandardized *diaries*, in which subjects have to note their activities over a certain period. Partly for pragmatic reasons, the most popular method of investigating television exposure is *questionnaires*, which allow for an easy combination of indicators of exposure with other dependent and independent variables (→ Survey). Other methods, like participating → *observation* or, more generally, *ethnographic methods* have been used more often in recent years; these methods allow for an examination of television exposure as an integrated part of cultural and social practices (e.g., Lull 1990; → Ethnography of Communication).

Due to this diversity of methodological approaches, the comparability of these studies is often limited. Exposure to television as measured in the people-meter-based research might be completely different from exposure to television as measured by questionnaires or participating observation. Consequently, results from the different areas of research are often hard to integrate, and exposure to television, although being a core element of public communication and of any process of media effects, has not yet developed as a coherent field of research with an agreed set of theoretical concepts and empirical methods (→ Qualitative Methodology).

One of the *future methodological challenges of research on television exposure* will be how to identify and classify the increasing number of audiovisual services that are similar to television but not (yet) regarded as television. Watching a television news program or a movie downloaded via the → Internet on a computer screen; following a sitcom on the small screen of a mobile phone; watching vodcasts offered on broadcasters' or other institutions' websites: a decision will be necessary as to whether we should define all these activities as "watching television," or whether there should be conceptual distinctions between different kinds of audiovisual services.

## Extended Parallel Process Model

Kim Witte

Michigan State University

The goal of the extended parallel process model (EPPM) is to provide guidance on how to manage fear generated from communications about a threat. Fear is a powerful motivator, and the key to a successful communication about a threat is to channel this fear into a direction that promotes adaptive, self-protective actions, and prevents maladaptive, inhibiting, or self-defeating actions (→ Information Processing).

According to the EPPM, when people are faced with a threat they either control the danger or control their fear about the threat. The variables that cause individuals to either control the danger or control their fear are defined as follows. *Perceived threat*, or the degree to which we feel susceptible to a serious threat, is composed of two dimensions. The first, severity of threat, refers to the perceived seriousness of a threat or the magnitude of harm we think we might experience if the threat occurred (e.g., injury, loss, death, disgrace, etc.). For example, do you think contracting HIV is serious? Do you believe there would be harm if you did not prepare for a natural disaster? The second dimension, susceptibility to threat, is the perceived likelihood of experiencing a threat. For example, you might ask, am I at-risk for contracting HIV? How likely is it that a natural disaster will occur?

*Perceived efficacy*, or the degree to which we believe we can feasibly carry out a recommended response to avert a threat, is also composed of two dimensions. The first is response efficacy – our beliefs about whether or not a recommended response works in

averting a threat. For example, do you think condoms prevent transmission of HIV? Do you think preparation will mitigate harm from a natural disaster? The second, self-efficacy, is beliefs about our ability to perform the recommended response. For example, do you feel able to use condoms to prevent HIV transmission? Is it feasible for you to prepare for a natural disaster?

### THEORETICAL PREDICTIONS

Research has shown that perceptions of threat and perceptions of efficacy jointly influence behaviors such that one of three responses occur – no response to the message, a fear control response, or a danger control response.

When perceived threat is low, there is no response to the message. If a threat is believed to be trivial or irrelevant to a person, then individuals simply ignore any communication about a threat. For example, if people hear about a polio outbreak in China but live in Ethiopia, then they will perceive the threat to be irrelevant to them and they will not pay any attention to messages about polio (an example of low perceived susceptibility). Similarly, if there is a flu outbreak in Ethiopia, but people do not think of the flu as being serious, then they will not respond to a message about the flu because it is of so little priority in their lives (an example of low perceived severity; → Risk Perception).

In contrast, when people perceive a threat, they are motivated to act. The greater the threat perceived, the more motivated we are to do something (anything!) to get rid of the negative feelings caused by the fear arousal. That is, the more serious we believe a threat to be and the more vulnerable we feel toward that threat, the greater the fear aroused, and the greater the motivation to do something. Thus, when individuals feel susceptible to a serious threat, they are motivated to act.

Perceived efficacy determines what *type of action* is taken. Once motivated to act, perceived efficacy about recommended responses determines whether we will control the danger or control our fear. When perceived efficacy is high, i.e., people believe they are able to do a recommended response that effectively averts the threat, then they are motivated to control the danger and they adopt the recommended action. In contrast, when perceived efficacy is low, i.e., people doubt if they are able to do a recommended response and/or they believe the recommended response to be ineffective against the threat, then they turn instead to controlling their fear and engage in psychological defense mechanisms like denial (e.g., “there’s no such thing as HIV”), defensive avoidance (e.g., “I just don’t want to think about it”), or reactance (e.g., “this is just a government plot”). Thus, when perceptions of threat are strong, high perceptions of efficacy promote danger control actions (self-protective actions) and low perceptions of efficacy promote fear control actions (self-destructive actions).

In short, perceived threat motivates action, perceived efficacy determines the nature of that action. The greater the threat perceived, the greater the behavioral actions, as long as perceptions of efficacy remain stronger than perceptions of threat. However, at some critical point, when people begin to doubt their efficacy in averting the threat, they shift to controlling their fear instead of the danger (Fig. 1).

Overall, the EPPM suggests that when people feel at-risk for a significant threat (high level of perceived susceptibility and severity), they become scared and are motivated to

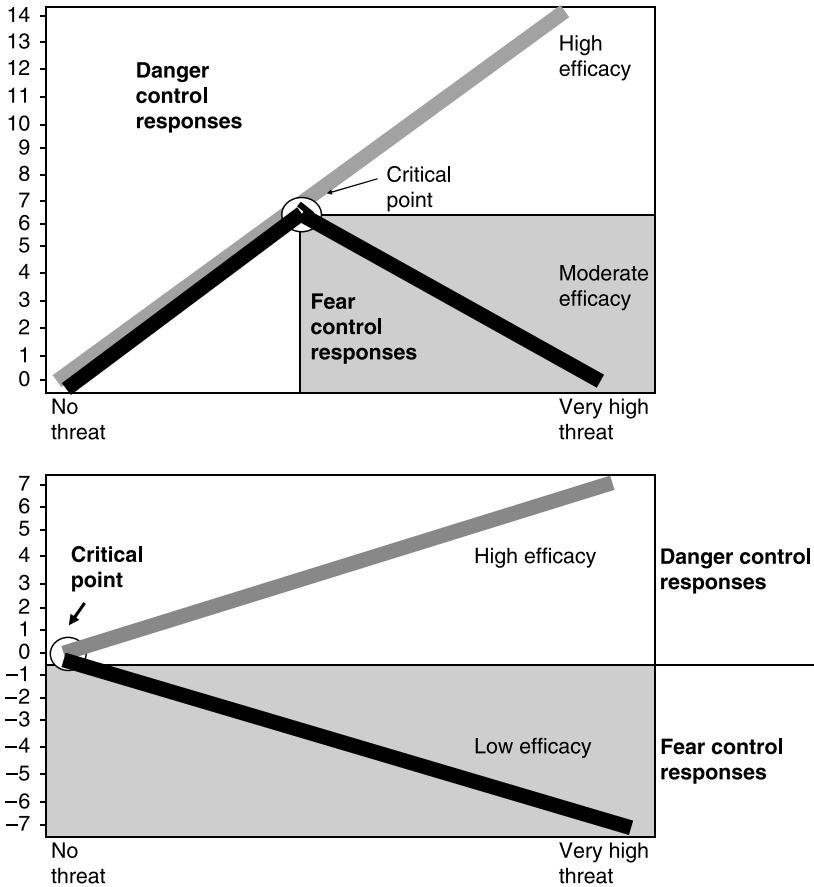

Figure 1 Graphical depictions of the EPPM

act. Perceptions of self-efficacy (i.e., perceived ability to perform a recommended response) and response efficacy (i.e., whether or not the recommended response is seen as effective in averting a health threat) determine whether people are motivated to control the danger or control their fear. When people feel able to perform an action that they think effectively averts a threat (strong perceptions of self-efficacy and response efficacy), then they are motivated to control the danger and engage in self-protective health behaviors such as condom use to prevent HIV infection. In contrast, when people either feel unable to perform a recommended response and/or they believe the response to be ineffective (e.g., they believe condoms have holes), they give up trying to control the danger. Instead they control the fear by denying their risk, defensively avoiding HIV/AIDS issues, adopting a fatalistic attitude, or perceiving manipulation (e.g., “AIDS is a hoax that really is a government plot to repress people”).

### APPLICATION OF THE THEORY IN COMMUNICATION RESEARCH

The EPPM has been applied to a large variety of topics and populations across different channels. It has been used to guide education entertainment radio dramas, worker

notification programs for beryllium exposure, statewide gun safety courses, and is currently used to guide individually tailored counseling in HIV clinics across the nation (→ Entertainment Education).

Empirical investigations consistently show the theory predicts behavioral responses as long as cultural definitions of threat and efficacy are taken into account. For example, western industrialized nations tend to focus (with good success) on threats to physical health, whereas in poorer countries, economic or social threats may be more threatening and relevant than physical threats (→ Communication Modes, Western). Further, it is critical that studies measure intended *and* unintended effects, because in order to distinguish between “no response” to a message versus “fear control response” (which masks as “no response,” because if an individual is in denial they are not adopting a behavioral recommendation), a researcher must measure things like denial, defensive avoidance, and reactance. Specifically, a “fear control response” masks as a “no response” because there is no behavior change, yet in reality, there was a huge defensive response to a message that prevents behavior change.

The EPPM can be used to tailor messages to promote danger control responses via interpersonal channels (as in counselor–client, doctor–patient (→ Doctor–Patient Talk), or peer educator encounters) or mass media channels (as in a public service announcement or entertainment education programs).

# Extra-Media Data

*Wolfgang Donsbach*

*Dresden University of Technology*

The term “extra-media data” describes a methodological approach to assessing the quality of media content. The phrase was coined in the early 1970s by Swedish scholar Karl Erik Rosengren (1970) during a controversy about the criteria needed to assess bias in the news. Scandinavian researchers Galtung and Ruge (1965) had criticized the coverage of foreign countries in the Norwegian press for highlighting certain news factors and thus creating a distorted picture of these countries. The researchers’ conclusion was based exclusively on the occurrence of news factors like personalization and negativism (→ News Values). Rosengren instead suggested that researchers should evaluate the performance of news media by comparing their coverage to external, primarily statistical indicators. In his own study Rosengren investigated how newspapers in three different countries covered parliamentary elections in countries around the world. He then related the coverage to information about the countries and about the respective elections as listed in contemporary archives. By doing this, he was able to compare media coverage of the events with their “objective” news value according to, e.g., country size, GNP, or whether an election brought about a new majority.

In communication research today we can find at least three different approaches to assessing the quality of media content by sources from outside: statistical data (as suggested by Rosengren), participant observation of events, and the use of expert opinions. Funkhouser (1973) compared the number of news articles on several political issues in the sixties in the USA with statistical indicators for their real salience. For instance, in the case of the Vietnam War Funkhouser used the number of US soldiers fighting in Vietnam; in the case of the labor market he used the number of unemployed Americans. He found almost no correlation between the number of news stories about these issues and their salience as indicated by these statistical data. However, he did find a strong correlation between media coverage and public opinion. In a similar manner, Kepplinger (1992) compared the coverage of the ecological condition of air and water in Germany with statistical data on air and water pollution over a period of 20 years. Adams (1986) developed a “news geography” of US media by comparing the death tolls of natural disasters with the emphasis given in the news.

Almost 20 years before Rosengren wrote about extra-media data, Lang and Lang (1953) compared the impressions of an event when seen on television with the impression of the same event when participating in it. The event was General MacArthur’s parade in the streets of Chicago. People who watched the parade on television received the impression that there was much more excitement in the streets than there actually was. The authors attributed this discrepancy to a → reciprocal effect created by the presence of the television camera itself. Many years later Donsbach et al. (1993) applied the same approach in an experimental study on a campaign speech. While one group of subjects attended the event live, another watched several versions of a television broadcast of the event. The impressions received of the event, the speaker, and his speech when watching him live and when seeing a television broadcast differed significantly, with the television versions usually creating much worse ratings.

Finally, experts can be used as an external benchmark for evaluating the quality of media content. Lichter et al. (1986) surveyed experts on nuclear energy about the potential risks of this technology and compared the result to the opinions expressed by experts cited or interviewed in the media. In a similar study, Snyderman and Rothman (1988) surveyed experts on human intelligence and compared this to the coverage of the IQ controversy in the US media. According to both studies, the media misrepresented the distribution of opinions among experts.

These examples show that the use of such reality indicators for an assessment of media coverage by extra-media data is problematic. In most cases the concrete indicators used either represent only a certain aspect of the issue or event they are supposed to indicate (e.g., the number of American GIs in Vietnam), or may be biased themselves (as in the case of the experts). Further, there are many areas of media coverage where no such extra-media data exist to be used to assess media content. Schulz (1976) even went so far as to negate the possibility of any benchmark for media content. He argued that each system had its own criteria for constructing reality (→ Constructivism; Objectivity in Reporting) and each of these would necessarily differ from the dominant criteria used by the news media, i.e., the value of news factors. Nevertheless, if one assumes that some scientific measure of the quality of reality representation in the media is important, the comparison of media content with extra-media data is probably the strongest tool.

# Eye Behavior

Mark L. Knapp

University of Texas at Austin

People use their eyes during social interaction in three primary ways: looking in the direction of the other person's face, often referred to as *gaze*; looking away from their partner's face or *gaze aversion*; and *mutual gaze*, in which both interactants look in the direction of the other's face and eye area at the same time. Human beings engage in relatively little direct eye-to-eye contact. For humans and other animal species, eye behavior plays an important role in survival, reproduction, and building/maintaining social and role relationships. Being watched is as important as watching others. As the target of another's eye gaze, a person's performance is infused with significance – in either positive or negative ways. Because of its importance to human interaction, people are sensitive to the absence of gaze when it is expected and its presence when it is not. We often perceive eye-to-eye contact when the eyes are actually tracking many points around the area of the eyes.

## FUNCTIONS

The direction, frequency, and duration of eye gaze serve several individual and communicative functions in human transactions. Gaze can serve more than one function at a time. One function of gaze is to serve as a mechanism for *regulating the flow of interaction*. To initiate interaction, people often look into the eye and face area of another person to signal an open channel for communicating. When strangers meet, they typically give each other a brief glance of recognition. When a person's gaze is extended too long, it can make a more elaborated response seem almost obligatory. The closing of communication channels, in contrast, is accompanied by a decrease in gaze. Eye gaze also regulates the flow of interaction during conversation. As a listener, it can signal a desire to take a speaking turn; as a speaker, an other-directed glance may signal the end of a thought unit or grammatical break. The amount of eye gaze varies from situation to situation, but listeners typically gaze more than speakers. *Seeking feedback* is another function of eye gaze. Each interactant wants to know whether their partner is paying attention, understanding, accepting, or in some other way registering a response to the dialogue.

Eye behavior also plays a major role in signaling the degree of *interpersonal involvement* as interactants negotiate their relationships. For example, eye gaze, or the lack of it, is a critical element in communicating increasing or decreasing intimacy. We look at things and people that are rewarding or potentially rewarding to us. Our pupils dilate when we are interested, attentive, and aroused. Some evidence suggests that other people notice pupil dilation and respond favorably to it, even though they may not be aware of the reason for their positive attraction. With strangers and acquaintances we tend to reciprocate or match eye gaze when we perceive their behavior to be generally congruent with our expectations and involvement preferences; we tend to compensate or offset another's eye gaze when it is perceived as a major violation of our expectations and preferences.

Eye gaze is used by infants and caregivers to establish an early bonding, but mothers with “difficult” children manifest less intimacy with their children by looking at them less. Gazing at others is also a way for adults to signal a desire for affiliation and affection, and for romantic partners to indicate the depth of their intimate feelings. In western cultures, women often call attention to their eyes by decorating them. One female flirtation ritual involves a pattern of relatively short glances at a person of interest followed by slightly longer ones. Gaze and mutual gaze frequency and duration are key factors in establishing close relationships, but a variety of patterns may develop as a couple sets their own rules for a long-term relationship. Happily married couples may even look at each other less than those who are dissatisfied, particularly when negative messages are being exchanged. If a close relationship continues to deteriorate, the need to threaten and monitor the other’s behavior decreases and eye behavior will decrease correspondingly as the desire for involvement wanes. Thus, the frequency and duration of eye gaze can be a reflection of a negative or confrontational relationship as well as an intimate one, but both show a high degree of involvement by the participants.

Many formal and informal relationships necessitate the negotiation of *dominance*. Human beings, like other animals, tend to exert dominance visually by staring and subordination/submission by avoiding eye gaze. In informal conversations, dominance is exhibited by increasing the amount of gazing typically exhibited while speaking so it approximates the amount of gazing while listening. The pattern for people who perceive themselves to be relatively similar in power and status is to look more while listening than speaking. Reciprocated staring signals a challenge associated with dominance. It is a peaceful way of signaling aggressive intent, but mutual gaze can be highly arousing, which can lead to more physical forms of aggression. Variations in eye gaze patterns may also accompany a person’s ascribed status in an organizational hierarchy. The eye behavior of new and lower-status employees may signal alertness and attentiveness as they try to learn the rules and accommodate to those who have more status and power. For those with status and power, the motivation to monitor the behavior of those around them may not be particularly strong if they feel their status and power are unchallenged. However, when challenges to their status and power are perceived, we would predict an increase in gaze used to monitor feedback as well as an increase in the use of gaze to assert the kind of dominance and power a person feels is befitting his or her status.

The way a person uses his or her eyes may also reflect both *cognitive and emotional activity*. It is not unusual for a person to avert his or her gaze during “difficult” or complex information processing. Silently looking away from high-intensity visual stimuli with a “thinking face” not only creates a cognitive processing environment with less noise, but may simultaneously tell the listener not to assume the speaking turn. Averting gaze to collect one’s thoughts represents a major interruption in the flow of speech, but decreasing eye gaze is also likely to accompany less dramatic breaks and hesitations in speech fluency. Some research makes a connection between the direction of gaze aversion and the type of cognitive activity occurring. For example, glances to the right have been associated with left-hemispheric brain activity and glances to the left have been associated with right-hemispheric brain activity.

Mutual gaze, whether it reflects a positive or negative intent, has an emotional impact and increases a person’s heart rate, galvanic skin response, and other physiological

measures of arousal. The eyes themselves may also reflect a person's emotional state, as in the excess blinking accompanying anxiety. In addition, a person's eyes are a crucial feature in communicating facial expressions of emotion – e.g., anger, surprise, sadness, fear, disgust, happiness. Some emotions can be accurately identified by viewing only the eyes. The tensing or relaxation of the lower eyelid helps to distinguish fear from surprise, for example. The upper eyelid is very different in expressions of sadness and happiness. With the addition of the eyebrows, still more facial expressions of emotion can be accurately identified.

### **INFLUENCES ON PATTERNS OF GAZE**

The meaning of gaze patterns, like other communication behavior, is dependent on the context in which the behavior takes place – i.e., the relationship of the interactants; their gender, age, and status; the situational expectations; the goals and motivations of the participants; accompanying verbal and nonverbal behavior; and the like. For example, eye gaze may decrease when interactants are physically closer than they want to be and increase when the distance between them is perceived as too great. This same eye pattern can be observed with conversational topics perceived as too intimate or not intimate enough for the parties involved.

Certain characteristics of the interactants themselves may also affect eye gaze. Vast differences in height will necessitate increasing conversational distance, which, in turn, will affect the pattern of gaze. When people expect to interact with a disabled person, they tend to gaze in their direction less than when they don't expect to talk to them. The frequency, duration, and reciprocity of gaze by females in informal conversation is greater than for males. The greater a person's racial prejudice, the more likely this person is to gaze less when interacting with members of the racial group in question – provided, of course, it is not clearly a confrontational encounter. The frequency of eye gaze seems to be correlated with certain personality characteristics as well. Socially dominant individuals gaze more in informal conversation, but shy people who want to be sociable tend to look less. Extraversion and openness tend to be associated with a tendency to gaze more while the clinically depressed and autistic people tend to avert their gaze more often. During critical feedback, people with low self-esteem tend to gaze more at the source of the feedback than do people with high self-esteem. The opposite pattern occurs during positive feedback.

Rules about looking and not looking vary from culture to culture, but too much looking and too little looking are commonly not approved. Too much gazing is often associated with anger or disrespect and too little gazing with shyness, inattention, and dishonesty (→ Gaze in Interaction).

### **MEASUREMENT**

The most common measure and the basis of most behavioral research is the frequency of gaze. To a lesser extent, studies draw conclusions from the duration of gaze. Relatively little of what we know is based on the direction of gaze.

Measurements are taken by observers, with or without stopwatches and counters. Some observations are made by coders as they view video-taped interactions. A few studies use eye-tracking devices, but they are too intrusive to be of much use in studies of natural

interaction. Observers may be reliable, but validity is likely to suffer except under pristine conditions. Glances that appear to be in the direction of the other person's face may, in fact, not be. Coders often use head movement as the basis for decisions about gaze. The greater the distance between observer and observed, the greater the chance for error. Animated conversations often involve frequent and erratic head and body movements, some of which may even shield an observer from viewing eye behavior. Some of these problems can be reduced with careful preparation and observer training.

Most of what we know about eye behavior is based on observations of individuals. We need to learn more about how eye gaze is manifested and coordinated over the course of an interaction and how each person's eye behavior affects the behavior of the other. In addition, we have relatively little knowledge of how eye gaze is perceived. A split-second image from one's peripheral vision may be enough to register awareness and trigger reaction to another's eye gaze.

# F

## Facial Expressions

*Valerie Manusov*

*University of Washington*

When people use cues other than words to communicate, they often think first of facial expressions. Facial expressions involve movements of the face that change dynamically in the course of an interaction. People also use more static facial features (e.g., eye color, shape of nose) as part of the communication process. Both facial expressions and static face cues are considered here.

### STATIC CUES

The face has long been a source of curiosity. Early interest in faces focused on “face-reading” or *physiognomy* (Fridlund 1994). Pythagoras, Hippocrates, Galen, Aristotle, Della Porta, and Caspar Lavater were among the many well-known figures to propose methods of assessing static (and sometimes dynamic) features of the face to determine medical conditions, personality, temperament, and divinity (Fridlund & Russell 2006).

Whereas dynamic cues are thought to be more communicative, and the bulk of contemporary scholarship on the face seeks to understand how they function, static cues are still studied for the ways in which they work as identity displays and affect perceptions (often negatively). For example, Heatherton et al. (2000) looked at the ways in which certain craniofacial anomalies, like harelips and scarring, “can lead to aversion reactions and, like all stigma, result in social marginalization” (Fridlund & Russell 2006, 301). Cole (1998) likewise details the identity issues that arise for people with various physical conditions that affect the face and, for instance, make it immobile (→ Marginality, Stigma, and Communication). In his work, he found that people with Mobius syndrome (a condition where people, from birth, have immobile faces) are often assumed to be unintelligent, even though the condition only affects motor movement. Cole also discusses the effects of facial disfigurement and Parkinson’s disease on people’s view of themselves and their experience of emotion.

Other scholars have looked at the more general feature of “facial attractiveness.” In a recent review, Guerrero & Floyd (2006) argued that specific characteristics tend to make up faces that, across cultures, are seen as more attractive (→ Interpersonal Attraction). The static facial features that tend to be judged as more attractive include *facial symmetry*,

*neoteny* (i.e., looking more juvenile; this includes full lips, shorter noses, and eyes that are more widely separated), and *koinophilia* (i.e., faces with “average” rather than extraordinary traits). The authors also make the argument that there are survival-based explanations for our tendency to make attractiveness judgments for these facial features.

### DYNAMIC CUES

As noted, there is a larger set of studies focused on the movements that faces make when people engage in conversation. These dynamic cues are often referenced as *facial expressions*. Perhaps best known of the work in this area is scholarship that has documented the range of movements that the face can make. Ekman’s *Facial Action Coding System* (Ekman & Rosenberg 1998) and the *Maximally Discriminative Facial Movement Coding System* (MAX) developed by Izard (1979) are two of the well-known schemes used to reveal the range of dynamic cues available to most communicators.

The concern with *facial* expressions in modern scholarship often co-varies with an interest in *emotional* expressions (→ Emotion). That is, for many scholars, a, if not *the*, primary function of facial expressions is as a vehicle for the expression of emotion. Stemming from this assumption, much of the scholarship on facial expressions, particularly work by Izard, Ekman, and Matsumoto, has sought to determine the extent to which emotional expressions are innate and universal. Matsumoto (2006, 222) summarized the origins of this research, stating that

[q]uestions concerning the universality of facial expression find their roots in Charles Darwin’s work. Darwin’s thesis, summarized in *The Expression of Emotion in Man and Animals*, suggested that emotions and their expressions had evolved across species, were evolutionarily adaptive, biologically innate, and universal across all human and even non-human primates. According to Darwin . . . , humans, regardless of race or culture, possessed the ability to express emotions in exactly the same ways, primarily through their faces.

The large body of scholarship concerning the universality of emotional expressions has resulted in a range of conclusions, with some scholars arguing for universal recognition of at least some basic emotions. Specifically, although cultures develop *display rules* that affect when, where, how, and with whom we express emotions, people from diverse cultures can recognize photographs where persons are posing or have generated spontaneously particular emotional expressions such as anger, happiness, and sadness (see, e.g., Matsumoto 1990; → Nonverbal Communication and Culture). Moreover, work by scholars looking at congenitally blind infants finds evidence for emotional expressions that must arguably be innate (see, e.g., Charlesworth & Kreutzer 1973).

Others argue that the question is less clear. For instance, some scholars assert that the methodologies employed in many of the “universality studies” were based on a form of facial expression (posed photographs) that does not mirror how people actually use their faces. Motley (1993), for example, had study participants interact while being videotaped. His assessment of those tapes showed that most of the facial movements associated with emotional expressions tended to be relatively brief and ambiguous, understood only in relation to what was being said concurrently in the conversation. There were no instances of the types of expressions used to assess universality in many studies.

Still other scholars have taken issue with the central contention that facial cues are best characterized as emotional expressions. Fridlund and Russell are perhaps best known for their work in this area. Following what Fridlund (1992) labeled the *Behavioral Ecology View* (BEV) of *facial displays*, the authors have explored the idea that *social motives* rather than emotions are the primary internal concepts that drive communicative facial displays (see review in Fridlund & Russell 2006). They argue that it is rare to see a facial expression that extends only or even largely from an emotion; rather, the dynamic features of our faces are more likely to be tied to other meanings or functions.

In support of this, Chovil (1991) worked to identify the primary forms that facial movements take in everyday discourse. A careful analysis of 1,184 facial movements drawn from 12 pairs of people talking to one another led her to assert that there were five primary types of facial displays. Chovil referred to these as *syntactic displays*, which are facial movements connected with either intonation or syntactical features of talk that are redundant with what the speaker is saying. *Speaker illustrators* depict or represent what the speaker is discussing; *speaker comments* show information that is separate from what the speaker is stating verbally; *listener comments* appear to respond to what the speaker is saying; and *non-linguistic adaptors* seem to have no clear relation to ongoing speech, and include such things as biting one's lips. In only some cases were these movements tied to what could be described as an emotion (→ Gestures in Discourse).

Facial cues are an important part of interactions. Static cues provide the source of information people use in their assessments of others. Dynamic cues make up the larger array of potentially meaningful communicative messages. Although the messages people assume are communicated through the face are emotional messages, many scholars argue that the picture of what is expressed through facial expressions is a murkier, if more interesting, set of meanings.

## Factor Analysis

*Andreas Fahr*

*Ludwig Maximilian University of Munich*

Factor analysis is a data analysis procedure that aims at extracting a small number of factors from a large number of items, that is, from variables. The extracted few factors should be able to describe and explain the core characteristics of a phenomenon, without the loss of too much information. Hence, factors show the essence of a large amount of measured items.

### ORIGIN AND APPLICATIONS

Charles Spearman pioneered the use of factor analysis and is credited with the invention of this statistical technique (→ Statistics, Descriptive; Statistics, Explanatory). He found out that children's scores on a wide variety of seemingly unrelated items were somehow correlated (→ Correlation Analysis). He postulated that a general mental ability underlies and shapes cognitive performance. Factor analysis was and is therefore often associated with intelligence research and the development of objective tests for its measurement (→ Measurement Theory). Raymond Cattell expanded on Spearman's idea in using a multifactor theory to explain intelligence. He addressed alternate factors in intellectual development, like motivation and psychology. Still very well-known is Cattell's 16 personality factors (16 PF) theory of personality. However, the technique has also been used to find

factors in a broad range of domains such as psychology (personality, → attitudes, beliefs, motives), → marketing, sociology, etc.

An important and famous *application* of factor analysis in communication research is the derivation of general motives for media use that stem from numerous single reasons for using media (→ Uses and Gratifications). Factor analysis was able to reveal that television is mainly used because of general motives such as → information seeking, entertainment (→ Enjoyment/Entertainment Seeking), (para)social interaction, and orientation (→ Parasocial Interactions and Relationships). Known as the *television viewing motives scale* this measure, developed by Bradley Greenberg and adapted by Alan Rubin, is the most widely used measure of viewing motivation. Other popular communication and/or psychological scales derived from factor analysis are the *need for cognition* scale, *big-five* personality inventories, the *parasocial interaction* scale, the *personal involvement inventory*, the *source credibility* scale, etc. (see Rubin et al. 2004 for detailed references; → Scales; Scales and Indices). Because of their ability to reduce the complexity of extensive phenomena, factor analysis procedures are frequently used in communication research. Out of 550 published articles in *Human Communication Research*, *Communication Research* and *Communication Monographs* between 1990 and 2000, 119 (21.6 percent) used factor analysis procedures (Park et al. 2002).

## FORMS OF FACTOR ANALYSIS

The technique can be differentiated into exploratory factor analysis (EFA), principal component analysis (PCA), and confirmatory factor analysis (CFA). While the general goal of EFA (outlined above) is to find the latent structure of observed variables by uncovering *factors* that influence the measured variables, PCA tries to reduce the measured variables to a smaller set of *components* that finds as much information as possible in the measured variables with as few components as possible. While EFA focuses on the shared variance among the variables by separating common variance from unique variance, PCA does not distinguish between common and shared variance and focuses on the variation among the variables. Therefore PCA is less suitable to reveal latent constructs (i.e., factors), but more appropriate for reducing measured variables into a smaller set of items (i.e., components). In doing this, PCA keeps as much variance as possible out of the total variance (Park et al. 2002). For example, if a researcher wants to reduce measures such as indicators for education, income, occupation, and qualification into a composite component such as socio-economic status, PCA would be more appropriate than EFA. In short, as in EFA the measured variables are a function of factors, in PCA the components are a function of the measured variables. The latter will retain as much information as possible from the original variables (Fabrigar et al. 1999).

This being said, EFA is usually performed in the early stages of research, providing a technique for consolidating variables and for generating hypotheses about the underlying constructs. While in this exploratory stage we may want to determine a structure among many variables, factor analysis can also be used in a *confirmatory fashion* (CFA). In that case, we are either testing a hypothesis, or wanting to find the statistical proof that one specific theoretical construct is responsible for the correlation of several theoretically relevant variables (→ Structural Equation). CFA should therefore be used when constructs are measured with multiple items, when the items have a linear relationship to the scale

average or total, *and* when an a priori idea of which items measure which constructs is present (Levine 2005). The latter procedure therefore aims mainly at construct validation and requires a more thorough and sophisticated approach than does EFA, which is a relatively simple task due to sophisticated and user-friendly data analysis software.

### STATISTICS BEHIND FACTOR ANALYSIS

Technically, factor analysis uses the correlation coefficients between all measured items as a description of the similarity of items. For example, the researcher starts out with a very large number of items reflecting a first guess about the items that may eventually prove useful – different reasons for watching television, for instance. The researcher is now interested in the dimensions that lie “behind” these individual reasons. The statistical procedure tries to maximize correlations within one factor and minimize correlations between the factors. Hence, the factor is the underlying theoretical construct that is able to explain the correlation between the items. The “correlation” between one item and the factor is called “factor loading” and represents the importance of this variable for the factor. The sum of squared factor loadings of one variable is called “communality.” It indicates to what degree the variance of this variable can be explained by all factors. An item with a low communality is therefore deficiently represented in the model.

Mathematically, the technique produces several linear combinations of measured variables, each linear combination a factor. As an example, a high correlation between the items “fun,” “well-being,” “tension,” and “liking” could be subsumed under the factor “entertainment.” While a factor reduces complexity and is able to illustrate phenomena on a higher abstraction level, the interpretation and naming of the factors is derived from the particular combination of the measured variables that correlate highly with it. Thus, the final choice among alternative interpretations and – mathematically identical – solutions depends on the researcher’s assessment of its interpretability and scientific utility.

The → validity of the factors is tested in research where predictions are made regarding differences in the behavior of persons who score high or low on a factor. The researcher tries to prove that scores on the factors (latent variables) co-vary with the scores on other variables. Nevertheless, in PCA and EFA there is no external criterion against which to test the solution – as there is with group membership in → discriminant analysis or logistic regression, for instance (Tabachnik & Fidell 2007).

Factors – and factor scores of every subject – can be used for further analyses. The advantage is that we do not have to deal with long lists of variables anymore. The problem, however, is that part of the variance explained by all items is lost by using factors as variables. Nevertheless, when scores on factors are estimated for each subject, they are in the majority of cases more reliable than scores on individual observed variables.

## **Fair Trial and Freedom of the Press**

*Ahran Park*

*University of Oregon*

Fair trial and freedom of the press concerns how to balance the right of a free press and the defendant's right to a fair trial. News reporting on judicial proceedings helps the public understand the legal procedure better and contributes to the public's right to know about the working of the justice system (→ Right to Know). The media play an important watchdog role in monitoring the administration of justice (→ Freedom of the Press, Concept of). However, the news media sometimes misrepresent court trials and mislead viewers and readers (→ Yellow Journalism). This kind of inaccurate media coverage might affect jurors or judges in such a way as to prejudice their supposedly impartial judgment.

The idea of balancing the right of the news media to cover judicial proceedings with the right of the accused to a fair trial has been incorporated into a number of international conventions and national constitutions. For example, the European Convention on Human Rights, while guaranteeing freedom of speech and of the press, protects the right of the accused to a fair trial. Its Article 6(1) states that the press and public may be excluded from all or part of a trial "where the interests of juveniles or the protection of the private life of the parties so require" or "where publicity would prejudice the interests of justice." The International Covenant on Civil and Political Rights also regulates access of the press to a trial when it is necessary to maintain public order, to protect national security and to prevent the prejudice from publicity. In the US, the First Amendment to the federal constitution on a free press collides with the Sixth Amendment on a fair trial. The UK, which does not have a written constitution, relies on a criminal statute to regulate the media coverage of a trial. The Canadian Charter of Rights and Freedoms places freedom of the press and fair hearing by an independent and impartial tribunal on an equal footing.

### **PREJUDICIAL PUBLICITY AND PRIOR RESTRAINTS**

In jury trials, jurors must consider only the facts relating to the defendant's guilt or innocence in the specific case before the court. But the media sometimes report a

defendant's prior criminal records or his confessions that may not be admitted into evidence during a trial. Although jurors are more likely to be influenced by the prejudicial media coverage than judges are, judges are not entirely free from a possible media impact.

Over the years, the → European Court of Human Rights (ECHR) has ruled on prejudicial publicity as an issue. The ECHR case of *Sunday Times v. United Kingdom* (1979) arose when the House of Lords affirmed an injunction against the *Sunday Times* of London on the grounds that its news reporting concerning children deformed by thalidomide would lead to a "trial by newspaper." The ECHR held that the injunction against the *Sunday Times* was a violation of the European Convention on Human Rights, because the newspaper stories dealt with a matter of public concern, and it would not substantially undermine the authority of judiciary. The ECHR's 1997 decision in *Worm v. Austria* addressed whether a publication during a criminal trial might exert an influence on the members of the trial court. Worm, a journalist, was convicted under the Austrian Media Act for creating a "prohibited influence on criminal proceedings" with his article about the trial of a former finance minister. The ECHR agreed with the Vienna Court of Appeal that Worm's conviction was necessary for maintaining both the authority and the impartiality of the judiciary in Austria (→ Communication Law and Policy: Europe).

In the past, the common law in Canada emphasized the right to a fair trial over freedom of expression. But the Canadian Supreme Court, in *Dagenais v. Canadian Broadcasting Corporation* (1994), held that the common law on the right of the accused to a fair trial was no longer sustainable under Canada's 1982 Charter of Rights and Freedoms. The court ruled that the Charter principles require the rights both to a fair trial and to a free press to be respected, without a hierarchical approach. In considering a publication ban because of the threat to a fair trial, the court suggested that trial judges should ask (1) whether the ban is necessary to prevent a real and substantial risk to the fairness of the trial; and (2) whether the salutary effects of the ban outweigh the deleterious effects to free expression. Further, even if the ban were aimed at preventing a substantial risk to a fair trial, it could not be upheld if alternative measures were available (→ Communication Law and Policy: North America).

In overturning Dr Sheppard's conviction for his wife's murder, the US Supreme Court in *Sheppard v. Maxwell* (1966) criticized the state trial judge for failing to control the courtroom and to take proper measures against the prejudicial publicity. The court suggested several fair-trial remedies, which included: (1) a continuance to postpone the trial (adjournment); (2) change of venue (moving a trial to a new location); (3) change of venire (changing the pool of potential jurors); (4) admonishing the jury; or (5) sequestration of the jury.

Gag orders were widely used against US media in the early 1970s, although the *Sheppard* court did not suggest a gag order. In *Nebraska Press Association v. Stuart* (1976), the US Supreme Court addressed the validity of gag orders. Chief Justice Warren Burger, writing for a unanimous court, stated that before issuing a gag order, the trial judge should consider three factors: (1) the nature and extent of pre-trial news coverage; (2) the availability of other measures to mitigate the prejudicial publicity; (3) the effectiveness of the gag order. Unfortunately, gag orders are occasionally abused to silence the media publication (→ Gag Orders).

When a reporter disobeys a court order or shows disrespect for the judicial process, a judge can use the *contempt of court proceedings*. In England, the Contempt of Court Act allows judges to use contempt of court when news reporting creates a substantial risk that judicial proceedings will be seriously affected. Sometimes criminal contempt might be used by courts to punish criticism or commentary about judges' work. But the US Supreme Court, applying the "clear and present danger" test, ruled in 1941 that judges could punish commentary on pending cases only when such publications presented an imminent and extremely serious threat to justice. In contrast, Bangladeshi journalists got a jail sentence for contempt of court when they published stories about a judge's secret conversation with a party in the lawsuit in 2002 and about a judge's fake qualification in 2005.

### **"OPEN JUSTICE" PRINCIPLE**

Open justice is a basic principle in Anglo American judicial proceedings. In *Scott v. Scott* (1913), Lord Atkinson of Great Britain said that, even if a public hearing would be painful and humiliating, it should be endured. He reasoned that public trial is, on the whole, "the best security for the pure, impartial, and efficient administration of justice, the best means for winning for it public confidence and respect."

But this open justice principle does not mean that every trial should be open to the public or the press. In the US, the Supreme Court held that the public and the press have a constitutional right of access to criminal trials under the First Amendment. Despite the right of access, however, the court said trials could be closed under certain extraordinary circumstances. For example, grand jury proceedings and juvenile proceedings are closed as a rule. Also, civil proceedings can be closed when a compelling interest exists and the closure is narrowly tailored to serve the interest. The German Constitutional Court recognizes a right of reporters to attend criminal trials, but the right to obtain information about the judicial process may be limited under the Basic Law.

### **CAMERAS IN THE COURTROOM**

Another issue relating to access to trials is whether *cameras should be permitted in legal proceedings*. The presence of cameras in trial might disturb the parties, witnesses, and even jurors. On the other hand, the public's attendance at judicial proceeding might be best served by a complete audio and video account, which requires cameras in the courtroom. In *Chandler v. Florida* (1981), the US Supreme Court held that the presence of television cameras does not inherently violate a defendant's constitutional right to a fair trial. In the years following *Chandler*, all states developed rules on allowing television or still photographic coverage of some court proceedings. With regard to US federal courts, only a few circuit courts allow electronic coverage of trials.

Broadcasting of trials in other countries varies. In France, during the preliminary stage of a judicial investigation, information likely to put pressure on witnesses cannot be published. Besides, during court proceedings, French courts prohibit photographing, filming, and recording of trials. In England, the Criminal Justice Act bans the taking of photographs or drawing sketches of any person involved in trial. But Scottish courts have permitted the recording and broadcasting of judicial proceedings under strict conditions

and restrictions. After the → BBC sought permission to film the Lockerbie bomb trial, the Scottish appeal court proceedings in 2002 were broadcast live in English and Arabic by television and on the Internet. The International Criminal Tribunal for the former Yugoslavia (ICTY) also offered real-time video and audio coverage of its proceedings in three courtrooms through its web page.

In South Africa, the South African Broadcasting Corporation (SABC) sought permission to broadcast live (on both television and radio) the entire proceedings involving a corruption. The Supreme Court of Appeal rejected the request because televising the trial would cause undue stress to counsel and judges and might prejudice the defendant. The Constitutional Court ruled in 2006 that the Supreme Court of Appeal was within its discretion in regulating its own process when it refused to allow the broadcasting of the corruption trial. This South African case shows that balancing the media's right to a free press and the defendant's right to a fair trial remains a challenging issue, which reflects each country's social, legal, and cultural backgrounds (→ Communication Law and Policy: Africa).

## **Fairness Doctrine**

*Kyu Ho Youm*  
*University of Oregon*

The Fairness Doctrine, from its inception in the 1940s to its demise in the 1980s, epitomizes American broadcast law in flux. In adopting the broadcast policy, the → Federal Communications Commission (FCC) of the United States intended broadcast licensees to make reasonable effort to discuss controversial issues *and* to do it fairly by

affording equal treatment to conflicting viewpoints. But the doctrine was abolished in 1987 by the Reagan administration, which thought it had outlived its usefulness (→ United States of America: Media System; Radio Broadcasting, Regulation of; Television Broadcasting, Regulation of).

Nearly every democratic media system considers impartiality and balancing the *sine qua non* of its broadcasting law and regulation (→ Balance). Yet few countries impose impartial and balanced programming upon their broadcasters the way the United States did with the Fairness Doctrine. Perhaps Israel is the only nation that has directly borrowed from the US broadcasting rule, but the Israeli Fairness Doctrine is not identical to its American model, and should be instructive to those interested in the international and comparative approaches to the Fairness Doctrine.

The US Fairness Doctrine has evolved through the policy statements and rules of the FCC. In 1949, the FCC officially announced the doctrine:

Broadcast licensees have an affirmative duty generally to encourage and implement the broadcast of all sides of controversial public issues over their facilities, over and beyond their obligation to make available on demand opportunities for the expression of opposing views. It is clear that any approximation of fairness in the presentation of any controversy will be difficult if not impossible of achievement unless the licensee plays a conscious and positive role in bringing about balanced presentation of the opposing viewpoints (Report on Editorializing by Broadcast Licensees, 13 F.C.C. 1246, 1251 [1949]).

When revising the Communications Act's Equal Time Rule for political candidates in 1959, Congress noted the obligation of a broadcaster "to operate in the public interest and to afford reasonable opportunity for the discussion of conflicting views on issues of public importance" (47 U.S.C. § 315(a) [1981]). Courts and the FCC read into this statutory language the Fairness Doctrine as a legal obligation for broadcasters.

When challenged in the late 1960s, the Fairness Doctrine was upheld by the US Supreme Court, along with its corollary rules on personal attacks and political editorials. When the public interest requires, the Court held, the FCC may direct the licensees to "present those views and voices which are representative of the community, and which would otherwise be barred from the airwaves" (*Red Lion Broadcasting Co. v. FCC*, 395 U.S. 367, 389 [1969]). The Court noted spectrum scarcity and the broadcast licensees' fiduciary duty to the public.

In the 1980s, however, the FCC started questioning the Fairness Doctrine. Given cable and other new electronic technologies (→ Cable Television; Satellite Television; Television Technology; Radio Technology), the FCC wondered about the doctrine's scarcity rationale. A federal appeals court in 1986 declared that the doctrine was not a statutory requirement but an administrative policy, and one year later the FCC repealed the doctrine. It argued that broadcasters suffered from the doctrine's "chilling effect" and that the scarcity issue was no longer valid. In 2000, the DC Circuit Court of Appeals ordered the FCC to abolish the Fairness Doctrine's component rules on personal attacks and political editorials. The Court found no justification for retention of the doctrine's corollary rules, for it had already repealed the doctrine.

Congress has tried unsuccessfully to reinstate the Fairness Doctrine since its abolition in 1987. President Ronald Reagan and his successor, George H. W. Bush, vetoed legislation that would codify the doctrine. Most recently, in 2005, two bills – the Fairness

and Accountability in Broadcasting Act and the Media Ownership Reform Act – were introduced to Congress. Neither bill has made progress.

The theoretical and conceptual foundation of the US Fairness Doctrine is recognized in broadcasting law and regulation internationally. This is no surprise. Whether or not free speech jurisprudence is libertarian, the broadcasting media are more tightly regulated than the print media. Fairness in broadcast programming is mandated or recommended by way of → right of reply or impartiality/balance requirement. A case in point is the European Union Directive (→ European Union: Communication Law), which provides for the right of reply for any natural or legal person when television broadcasting damages the person’s reputation. The right of reply under the EU Directive parallels the personal attack rule of the US Fairness Doctrine.

Broadcasters in Europe have a general duty to present news and issues in an impartial, objective, and neutral way (→ Bias in the News; Neutrality; Objectivity in Reporting). The impartiality requirement especially is accepted in most western European countries. The UK Broadcasting Act, for example, states: “(b) that any news given (in whatever form) in its programmes is presented with due accuracy and impartiality; (c) that due impartiality is preserved on the part of persons providing the programmes as respects matters of political or industrial controversy or relating to current public policy” (→ Accuracy; United Kingdom: Media System).

In a number of European nations, the right of reply is also accepted to insure balance and impartiality in broadcasting. If a program questions the reputation of an individual or institution, the BBC Producers’ Guidelines stipulates, it is presumed that those criticized have a fair opportunity to respond. On the other hand, the impartiality doctrine in European countries does not allow broadcasters to editorialize public issues. This stands in sharp contrast with the US Fairness Doctrine. American broadcasters could express their views on public controversies if they provided others with the opportunity to counter their opinions.

The Israeli Fairness Doctrine traces its origin to the US Fairness Doctrine. Nonetheless, its underlying principles relate more to the European concept of impartiality than to the American notion of fairness. The Broadcasting Law and the Second Authority for Radio and Television Law mandate a fair representation of ideas, but proscribe editorializing. Nor do they provide for discussion of controversial issues as part of programming requirements. Rather, broadcasters should present different views that are “prevalent” in Israeli society.

The right of reply is recognized statutorily (i.e., Second Authority for Radio and Television Law) and administratively (i.e., Telecommunications Regulations). It is also included in an internal broadcasting guideline (i.e., Broadcasting Authority Regulations). Besides, Israeli courts accept it in incorporating the personal attack rule of the US Fairness Doctrine into Israeli law. Most significantly, the Israeli Fairness Doctrine is thriving while its US progenitor has died. In tweaking the American doctrine to their legal system, Israelis have turned to the European principle of impartiality and pluralism (→ Israel: Media System; Plurality).

## **False Consensus**

*Ronald E. Ostman*

*Cornell University*

False consensus is the inaccurate perception that our own beliefs are similar to those of others, when in fact they are not similar (Ross et al. 1977), and the tendency to see our behavioral choices and judgments as common and situationally appropriate, while viewing alternative responses as uncommon, deviant, and/or inappropriate (Mullen et al. 1985; Bosveld et al. 1994). Overestimation inaccuracies and deviance perceptions are based on a social judgment projection that opinions, beliefs, values, traits, and behaviors like one's own are more prevalent than they in fact are. This “egocentric self-anchor” or tendency to overestimate inaccuracies apparently exists even when the individual's attribute is in the minority (Sanders & Mullen 1983; → Social Judgment Theory; Social Perception).

Two major predictors have been offered as a partial explanation for false consensus: the notion of self-serving bias and the notion of available heuristic. *Self-serving bias* refers to the human tendency to take personal credit for successes (as the result of our own disposition). It also refers to the individual's tendency to ignore, rationalize, and/or deny responsibility for failures, often viewed as dependent upon situation (Sherman et al. 1984). We tend to overestimate the typicality of our undesirable actions or unsuccessful

efforts. This cognitive bias is generalized to an evaluation of ambiguous information to benefit self-interest (Miller & Ross 1975).

*Available heuristic* connotes a bias toward estimating an outcome's probability based on simplicity. It is easy to imagine. Available heuristics are often emotionally tinged. Imagined consensus lends an implicit aura of support from others for our position and/or behaviors. This sense of certainty reduces the need to alter ourselves or to change the status quo, a basic assumption of → consistency theories. Other explanations for the false consensus phenomenon include selective exposure to and recall of others who agreed with our own choices and judgments. This personal strategy enables us to appear “normal,” provides self-enhancement, and satisfies need for social support.

Further theoretical elaboration of false consensus comes from studies examining concepts such as need for uniqueness, threats to the self, self-schemas, differential construal, embarrassment, overconfidence, attitude importance, social distance, outgroups, monetary incentives, and selectivity processes (Bosveld et al. 1994; Jones 2004; → Selective Exposure; Selective Perception and Selective Retention). Availability of similar others facilitates false consensus. Availability of dissimilar others depresses the effect. False consensus tends to be most prevalent concerning issues on which there is wide diversity and heterogeneity of opinion range (Bosveld et al. 1994). Perceived social distance, or overall level of perceived similarity between self and typical target group member, reflects the extent to which self is perceived as generally representative of the group (→ Group Communication). Perception of social distance is theorized to mediate the false consensus effect, further explaining why ingroup false consensus exceeds outgroup false consensus – more social distance is perceived with the outgroup (Jones 2004; → Third-Person Effects).

Evidence suggests a *cultural influence* on self-serving biases. The phenomenon is routinely found in studies focusing on western individuals, but may not generalize to Asians. Markus & Kitayama (1991) noted that many Asian cultures stress the harmonious and interdependent collective, whereas American culture emphasizes unique individuals who seek independent self-fulfillment (→ Communication Modes, Western; Communication Modes, Asian). Kitayama et al. (1997) studied American and Japanese university students and found American situations tended to be conducive to self-enhancement and that Americans took advantage of those situations. Japanese situations fostered self-criticism and stimulated Japanese engagement in self-criticism. Historical and cultural processes are thought to influence collectively shared ideas of the self as independent or interdependent and ultimately reinforce psychological tendencies and processes, thus extending and sustaining cultural norms and values from generation to generation.

False consensus has been linked with social issues, such as tobacco, alcohol and drug consumption, beliefs concerning welfare reduction, presidential preferences during election campaigns, body shape and weight, risky sexual behavior, and depression (Mäkelä 1997; → Applied Communication Research).

## False Uniqueness

Ronald E. Ostman

Cornell University

A person expresses false uniqueness, an inaccurate social comparison, when that individual perceives that differences between his or her own attitudes, abilities, and behaviors and those of others are larger than they really are (Suls & Wan 1987). This difference is thought especially prevalent when one's own behavior is desirable and the individual estimates the prevalence of others exhibiting, or willing to exhibit, the same or similar behaviors (Monin & Norton 2003) (→ Pluralistic Ignorance; Pluralistic Ignorance and Ideological Biases). The result is an underestimate of how common one's desirable attributes and successful behaviors are in relation to those of others and one essentially casts oneself in the role of "better than thou."

Historical treatises stimulating investigation of false uniqueness can be found in Festinger (1954) (→ Festinger, Leon), Schachter (1959), and Fields and Schuman (1976–1977). Their various approaches to explaining the human mind focused on the social comparisons that an individual makes between self and others. According to Fields &

Schuman, a particular problem humans face during this process is that direct information on others' views may be absent, unavailable, equivocal, or for some reason not sufficiently compelling. Nonetheless, humans do not let informational deficiencies prevent them from estimating what others think or do. Holmes (1978) used the term "attributional projection" to summarize situations when differences are found between perceptions and actuality, but noted that the functionality of the process requires more evidence than projection theories have been able to provide. Campbell (1986) found that individuals overestimated consensus for their opinions and low abilities ( $\rightarrow$  False Consensus), but underestimated consensus for high abilities. In other words, people tend to think their high abilities are shared by a smaller proportion of the population than really exists. Campbell isolated important predictors of over- and underestimation. Higher relevancy on ability was associated with decreased accuracy, greater overestimation on low abilities, and greater underestimation on high abilities. Individuals with higher self-esteem were more likely to overestimate the sharing of opinions by others, but also were more likely to underestimate others' shared high abilities. Psychological fear also has been shown to be an important mediating variable in explaining false uniqueness. Low-fear subjects tended to underestimate the incidence of low-fear among their peers, while high-fear subjects were more inaccurate in their estimates of high fear among peers (Suls and Wan 1987).

Earlier, Fields and Schuman (1976–1977) explored three Detroit sample surveys to examine social comparisons concerning issues of racism. They found great inaccuracies in perceptions of others across a spectrum of racial issues. In particular, they isolated a process demonstrating that respondents felt others' opinions were the same as their own. They also postulated a "conservative bias," the perception that the population is more conservative on racial issues than it actually is (see also Glynn 1989). They explained these phenomena by evoking the widespread understanding that American ideals were at odds with racial prejudice. In this case, racial conservatives thought of themselves as no worse than others (who were perceived as even more conservative), but liberals were prone to think of themselves as closer to the ideal than the average, illustrating the difference between false consensus (conservative perception) and false uniqueness (liberal perception). Fields and Schuman (1976–1977) summarized additional factors affecting or interacting with accuracy of perceptions: communication, coordination, object salience, role relationships, attraction, personality traits, and view of others' social positions.

There may be a cultural bias implicit in the concept of false uniqueness. Heine et al. (1999) found the phenomenon was rare among Japanese, whereas it was common among Americans (Campbell 1986). Vignoles et al. (2000) referred to a "distinctiveness principle," or a motive within identity that pushes toward establishing and maintaining a sense of difference between oneself and others. This motive, apparently typical within western cultures, is not incompatible with non-western cultural systems; however, distinctiveness in non-western cultures more likely will be associated with group distinctiveness rather than individual distinctiveness.

## Family Communication Patterns

*John P. Caughlin*

*University of Illinois at Urbana-Champaign*

*Allison M. Scott*

*University of Illinois at Urbana-Champaign*

Communication patterns in families refer to repeated interaction styles and behaviors. A single family member's communication behaviors over time can be patterned, but family communication scholars tend to focus on patterns among family members. Family relationships are typically involuntary and long-lasting (Vangelisti 1993). One usually cannot choose one's siblings, for instance, and sibling relationships – even strained ones – commonly endure for most of one's lifetime. The involuntary and lengthy nature of family relations provides myriad opportunities for various communication patterns to emerge.

The meaning of any particular interaction between family members is informed by previously established communication patterns, sometimes even patterns involving previous generations (Vangelisti 1993). Such family communication patterns are so central to family life that some scholars state that the very nature of family relationships is constituted by the ongoing pattern of exchanges (Rogers & Escudero 2004).

Although there is widespread agreement that patterns are important in families, the notion of a pattern can have many different meanings. One reason that conceptualizations of patterns vary is that patterns develop over different temporal periods. Messman

and Canary (1998, 122) stated that most of the empirical literature defines patterns as “recurring act-to-act sequences of interaction behaviors.” Yet many meaningful communication patterns take longer to unfold. Crouter and Maguire (1998), for instance, found seasonal patterns in parent–adolescent interaction: parents were more involved with adolescents during the summer than during other seasons. Additionally, there are intergenerational communication patterns; those that develop in one generation appear to influence patterns in the subsequent generation (Koerner & Fitzpatrick 2002). Individuals who are raised in families that discourage open conflict, for example, tend to expect little conflict in their adult relationships and react negatively when conflict does occur (→ Conflict and Cooperation across the Life-Span; Intergenerational Communication).

### PROMINENT RESEARCH FOCI AND FINDINGS

Although patterns of family communication can be conceptualized in various ways, there are two main *clusters of existing research*. The first is a typological approach, which focuses on relatively broad patterns of interaction and the rules and norms associated with those broad patterns (→ Communication: Relationship Rules; Relational Schemas). The second is a behavioral sequence approach, which examines how behaviors are patterned within particular conversations (→ Interpersonal Communication).

#### Typological Perspective

The typological approach has its roots in McLeod and Chaffee’s (1972) research on family types (→ Chaffee, Steven H.). McLeod and Chaffee identified four general family communication patterns, which were based on two communication dimensions: *concept-orientation* (i.e., the degree to which open discussion of ideas is encouraged) and *socio-orientation* (i.e., the degree to which harmonious family relations are fostered and emphasized). Fitzpatrick and her colleagues (Fitzpatrick & Ritchie 1994) adapted McLeod and Chaffee’s framework to create the Revised Family Communication Pattern (RFCP) instrument. The more recent conceptualization retains two dimensions that are similar to the original, but concept-orientation has been renamed “conversation orientation” and socio-orientation has been relabeled “conformity-orientation.”

*Conversation orientation* is the extent to which families foster open interaction among family members about their thoughts and feelings. In families at the high end of this dimension, members interact frequently and for large amounts of time. High conversation orientation is associated with the tendency to engage rather than avoid conflict and the belief that rewarding family life depends on open, frequent, and substantive communication. In families at the low end of conversation orientation, family members interact less frequently and discuss fewer topics openly with one another. Associated with low conversation orientation is the belief that open, frequent, and substantive interaction is unnecessary for family effective functioning (Koerner & Fitzpatrick 2002).

*Conformity orientation* is the extent to which families encourage all members to have similar attitudes, beliefs, and values. Interactions in families at the high end of this dimension typically emphasize obedience to parents and the interdependence of family members (→ Family Decision-Making). Families high in conformity orientation tend to

favor hierarchical family structure and conflict avoidance. Conversely, families at the low end of conformity orientation encourage individuality in family members' thoughts and feelings and tend to be less cohesive. Communication in these families stresses the independence and equality of family members, including children (Koerner & Fitzpatrick 2002).

The impact of each orientation depends on the degree of the other (Koerner & Fitzpatrick 2002). Thus, instead of considering conversation and conformity orientations separately, it is useful to conceptualize the two dimensions as underlying *four patterns of family communication*: laissez-faire, pluralistic, protective, and consensual. "Laissez-faire families" are low in both conversation and conformity orientation. Family members in these families do not communicate often, and when they do, they tend to focus on a few topics without becoming very involved in the conversation (Koerner & Fitzpatrick 2002). Parents in laissez-faire families tend to believe that all members should be able to make their own decisions, and they demonstrate little interest in their children's decisions. Children in these families are relatively likely to be influenced by social ties outside of the family (Fitzpatrick & Ritchie 1994).

"Pluralistic families" are high in conversation orientation and low in conformity orientation. Family members interact openly and supportively while exerting little pressure on one another to conform. Parents in pluralistic families encourage their children to autonomously develop their opinions through active participation in family discussions. Children in pluralistic families learn to think independently and to value rational argumentation (Koerner & Fitzpatrick 2002).

"Protective families" are low in conversation orientation and high in conformity orientation. Family interaction stresses obedience to parents and discounts independent thinking in children (Fitzpatrick & Ritchie 1994). Parents in protective families tend to make family decisions without sensing a need to explain their logic to their children. Children in protective families learn to avoid conflict and not to question authority figures outside the family system (Koerner & Fitzpatrick 2002).

"Consensual families" are high in both conversation and conformity orientation. Communication in these families attempts to maintain the existing family hierarchy while also considering new ways of expressing thoughts and feelings (Fitzpatrick & Ritchie 1994). Parents in these families engage their children in decision-making discussions although they hold the ultimate decision-making power. Children in consensual families tend to evaluate messages according to how consistent they are with their parents' attitudes, beliefs, and values (Koerner & Fitzpatrick 2002).

This typology of families based on family communication patterns is important beyond the theoretical utility of categorization. The predictive power of the typological model is evidenced by a number of studies of children's outcomes. For example, there is evidence that family communication patterns influence children's communication apprehension, conflict behavior, and social restraint and social withdrawal (Koerner & Fitzpatrick 2002).

### **Behavioral Sequences**

Another large group of studies examines family communication patterns by focusing on specific behavioral sequences in interaction. Given the wide variety of research on

interaction patterns in families, it is impossible to note all the specific patterns that have been examined. Three *types of patterns* are particularly prominent.

### *Relational Control*

The relational control perspective holds that relationships are self-regulating systems characterized by three dimensions: trust, intimacy, and control (for a review, see Rogers & Escudero 2004). Control is the primary focus of the → relational control perspective. The perspective recognizes three types of messages, or control maneuvers. *One-up* movements attempt to gain control of the exchange; e.g., ordering or commanding another family member to do something counts as a one-up message. *One-down* movements allow the other person to control the definition of the situation; e.g., indicating support for and acceptance of another's command is a one-down message. Finally, *one-across* maneuvers attempt to neutralize control; e.g., extending another person's assertion by simply continuing with the theme of that statement is considered a one-across message. One-across messages neither assert control nor grant it to the other person.

A series of control maneuvers forms a control configuration, or pattern. In a symmetrical pattern of control, interaction partners respond similarly, using the same type of message. Symmetrical configurations can be competitive (one-up/one-up), submissive (one-down/one-down), or neutral (one-across/one-across). In a complementary pattern, partners respond differently, using opposite (one-up/one-down or one-down/one-up) types of messages. In a transition pattern, one partner uses a one-across message.

The relational control perspective characterizes family relationships on the basis of two continua. The first dimension – i.e., rigid vs flexible – refers to the extent to which the same individual remains in control or different individuals gain control over time. The other continuum – i.e., stable vs unstable – refers to the extent to which control shifts are predictable or unpredictable. Several studies have indicated that relational control patterns are associated with marital satisfaction (for a review, see Rogers & Escudero 2004). For example, rigid dominance by either partner (i.e., when one person consistently responds to their partner's one-up messages with one-down messages) is related to dissatisfaction in marriage (Rogers & Escudero 2004).

### *Negative Reciprocity*

Extensive empirical research based on a variety of definitions and coding schemes suggests that family relationships tend to be dissatisfying when they are characterized by exchanges of negative behaviors (e.g., defensiveness, expressions of negative affect, complaints). The inverse correlation between negative reciprocity and relational satisfaction holds even after controlling for overall negativity rates (Gottman 1979). This connection between negative reciprocity and dissatisfaction has been established with measures focusing on nonverbal behaviors, verbal behaviors, and a combination of both verbal and nonverbal assessments (for a review, see Messman & Canary 1998). Although some studies have suggested that the verbal exchange is less important than the affective aspect of negative reciprocity (Pike & Sillars 1985), the link between negative reciprocity and marital dissatisfaction is one of the most consistent findings in family communication research (Messman & Canary 1998). There is also a link between negative reciprocity in marriage and eventual divorce (Messman & Canary 1998; → Marital Communication).

*Demand/Withdraw*

In the demand/withdraw pattern of communication, one relational partner nags, complains, or criticizes while the other person avoids the demanding partner. No particular order of behavior is implied in the pattern's label. Indeed, sequential analyses indicate that withdrawal can lead to demands just as demands can lead to withdrawal (Klinetob & Smith 1996). Additionally, both men and women sometimes play the role of demander and withdrawer in relationships (Eldridge & Christensen 2002). Although most demand/withdraw research has been conducted in the context of marriage relationships, it also occurs between other family members, including between parents and adolescents (Caughlin & Malis 2004).

Numerous studies have confirmed the importance of this pattern to family well-being. An inverse association between the demand/withdraw pattern and concurrent marital satisfaction has been established through both observations and participant reports of demand/withdraw (Heavey et al. 1993). The prospective outcomes associated with demand/withdraw are somewhat less clear. Demand/withdraw (particularly woman-demand/man-withdraw) often predicts declining relational satisfaction (Heavey et al. 1995) and marital dissolution (Gottman & Levenson 2000). Some studies, however, have failed to replicate such findings (Heavey et al. 1993), and demand/withdraw also can presage increasing relational satisfaction (Heavey et al. 1995). More longitudinal research is needed to clarify the impact of demand/withdraw over time in marital relationships.

In addition to being linked to dissatisfying relationships, demand/withdraw is associated with other important outcomes. A rigid pattern of husband-demand/wife-withdraw, for instance, may be associated with spousal abuse (Eldridge & Christensen 2002). Also, demand/withdraw between parents and adolescents is correlated with low self-esteem and high drug use among the adolescents, even after controlling for overall level of parent-adolescent conflict (Caughlin & Malis 2004). Future investigations should continue to examine the implications of demand/withdraw apart from the well-documented connection with concurrent marital satisfaction.

## **FUTURE DIRECTIONS**

The research on family communication patterns is already quite varied and has produced important advances. Still, future research could yield even greater insights. One possibility involves investigating different combinations of patterns and communication behaviors in families. Research on patterns is often rooted in a systemic perspective (Rogers & Escudero 2004), which implies that the impact of various patterns needs to be understood within the larger communicative context. There is evidence, for example, that the aversive influence of demand/withdraw in marriage is moderated by affectionate communication (Caughlin & Huston 2002). More research ought to examine the interplay among various types of patterns as well as the impact of this interplay.

Another potentially important direction would be to pay more attention to behavioral patterns involving multiple family members. The important literature on alliances and coalitions indicates that alliances, especially intergenerational alliances in which a parent turns to a child rather than a spouse, are associated with poor well-being for the child (Jacobvitz & Bush 1996). Overly strong mother-father coalitions can also be problematic

(Vuchinich & Angelelli 1995). Compared to the voluminous work on dyadic patterns like negative reciprocity, the research on alliances and coalitions has not been a dominant focus, particularly within the communication discipline. However, the research that has been completed demonstrates the potential utility of focusing on patterns in triads and even larger groups of family members.

## Family Decision-Making

Lisa Sparks

Chapman University

The family is a complex unit comprised of individuals with varied cognitive, emotional, and behavioral characteristics and abilities that can greatly affect family decision-making across an individual's life-span. "Decision-making" describes the process by which families make choices, judgments, and ultimately come to conclusions that guide behaviors. Family decision-making implies that more than one member's input and agreement is involved (Scanzoni & Polonko 1980). The decision-making process is centered on core communication processes involved in creating shared meaning. In the decision-making process, families can acknowledge the differences among members and negotiate their needs for closeness and independence (Baxter & Montgomery 1996).

### NATURE OF FAMILY DECISIONS

Aspects of verbal (e.g., words, syntax) and nonverbal communication (e.g., eye contact, tone, vocalics, gestures, expressions, etc.; → Nonverbal Signals, Effects of), listening (e.g., passive or active), and conflict (e.g., collaborative, competitive, or avoidance) negotiation skills play important roles in the myriad of family decision-making across the life-span (→ Conflict and Cooperation across the Life-Span). Such elements range from everyday decisions such as where to live, to rent or buy a home, and which schools or universities to attend, to increasingly life-altering decisions such as whom to marry or whether or not to have children and how many. Difficult family decisions are made when faced with more multifaceted family issues ranging from "should mom move into our household because she can no longer independently take care of herself" to excruciatingly difficult chronic health and end-of-life decisions such as treatments for a cancer diagnosis or a "do not resuscitate" (DNR) decision. Such decisions are made either within the family unit or in consultation with extended family from birth to end-of-life.

Decisions within families can be classified into types such as: instrumental, affective, social, economic, and technical. *Instrumental decisions* are those that focus on issues of money, health, shelter, and food for the family members (Epstein et al. 1982). *Affective decisions* deal with choices related to feelings and → emotions such as deciding about getting married. *Social decisions* typically consist of decisions related to the values, roles,

and goals of the family (see, e.g., Noller & Fitzpatrick 1993). Such decisions may include whether the children will be raised going to one church or another or whether one parent will stay at home while the children are preschool age. *Economic decisions* focus on choices about using and gathering family resources, such as whether an adolescent should get a job and contribute to the family income or buy his or her own car. *Technical decisions* consist of the smaller decisions that must be made to carry out a larger decision. For instance, if a family decides that one member must stop working in order to go back to school for an advanced degree, then a series of technical decisions must be made so the larger decision will materialize (Noller & Fitzpatrick 1993). Families use a variety of decision-making processes ranging from using familiar approaches over and over to more varied methods depending on the type of decision, their emotional state, and most often their stage of development across the life-span, from when the children are babies to when they are in school to midlife and later-life issues.

### **DECISION-MAKING IN EARLIER FAMILY LIFE**

The temperament and disposition of each child can greatly vary within the same family. Consequently, the relationship between parents and different siblings is dynamic and unique, with each individual responding to and modifying the behavior of the other (e.g., Pecchioni et al. 2005). Family decision-making processes are a two-way street with parents influencing communicative patterns of their children and vice versa. Joint decision-making and autonomy are best achieved through collaborative problem-solving, parental modeling, negotiation, and compromise (e.g., allowing the child to decide when to set the table or when to walk the dogs; Crockenberg et al. 1996).

When children are given opportunities for decision-making in areas that matter less, they are more likely to conform to parental expectations that matter more. Conflict resolution in collaborative decision-making between parents and children has been found to play out in later childhood in the resolution of peer-group interpersonal issues (e.g., Kochanska 1992). Developmental stages and child dispositions are important factors to consider in family decision-making in the early years of family life. As children grow older and more mature, they can be granted more autonomy and play a larger role in individual and family decision-making (Baumrind 1996).

### **DECISION-MAKING IN LATER FAMILY LIFE**

Research has consistently shown that serious illness impacts the lives of patients, their families and loved ones, with a number of scholars making the argument that serious illness is indeed a family issue (e.g., Sparks & Pecchioni 2007). Serious illnesses such as a cancer diagnosis add demands, strains, and hardships to families who must deal with numerous changes and decisions that impact the entire family (→ *Bad News in Medicine, Communicating*). Families are often uniquely qualified in terms of understanding patient attitudes and decision-making strategies and can therefore assist as an important resource in helping the patient to make better decisions about their care (Blustein 1998).

In a review of *variables affecting family decision-making* and family dynamics in later life, Rothchild (1994) found that there are a range of factors confronting families as they

decide about terminal care of a family member. Many families react to their sense of guilt and hopelessness by pushing for maximal medical intervention until the end of life. This often results in patient failure to resist such pressure and → persuasion, consequently accepting treatments that they very likely would not have chosen on their own. Rothchild claims that family decision-making is impacted according to the following variables: (1) patient's role in the family (boss, scapegoat, caregiver), (2) ages of patient and family members, (3) family continuity and cohesion, (4) who is considered to be "family," (5) how information and decisions are shared within the family, (6) presence of denial, guilt, and anger, (7) communication of treatment wishes to proxies, (8) comfort with sophisticated technology, (9) ethnicity and religion, and (10) economic pressures.

Family decisions are negotiated every day from family decisions in the childhood and adolescent years to middle- and later-life family decisions, many of which occur in health-care environments. Family decision processes in the health-care environment are particularly difficult and complex because of the uncertainties, emotions, technical language, and subsequent health outcomes (e.g., Sparks 2003). Conflicting information from various sources can be difficult to navigate and process to make the most informed health-care decisions. Families make decisions about health issues using information from a variety of sources, including insurance provider lists, internet research, recommendations from primary care physicians and specialists, interpersonal communication with friends and family members, and mediated messages (see Pecchioni & Sparks 2007).

Individuals and their family members process the uncertainties involved in health-care decision-making in different ways due to individual differences in message processing and the history of family member dynamics. For example, developing the most effective communication to encourage detection and prevention of a health concern assumes that the patient will engage in message-relevant thinking (see, e.g., Sparks & Turner, in press). Early research on persuasive message processing focused on issues such as the time and attention allocated to the message, the comprehension of the message content, and the acceptance of the message conclusions (Todorov et al. 2002; → Aging and Message Production and Processing; Memory, Message). Even though people can carefully process messages they do not always do so. Individuals who process messages systematically will think carefully about the message and engage in thoughts and judgments that are relevant to the message content. Individuals are economical and will only invest in the cognitive effort required to complete the current task. In order to engage in systematic processing people must be suitably motivated, and have adequate cognitive resources.

If messages are perceived to have features that are high in quality or very appealing, the message receiver should generate positive ideas and opinions. If the message is reviewed to have features low in quality the thoughts generated by the message will be negative, leading to less influence or a different outcome. Thus, *systematic processing* is the highest pursuit of cognitive processing (→ Cognition; Information Processing). Systematic processing of messages occurs in various ways. Cognitive processes refer to such information-processing activities such as perceiving, abstracting, judging, elaborating, rehearsing, and recalling from → memory. If one can motivate careful processing, message receivers will engage in message elaboration and engage in the recommended actions, which will result in more effective decision-making and long-term change. For family decision-making related to an emerging or chronic health issue, this could mean the difference between

(1) early detection of alcohol abuse and living, or failing to detect alcohol abuse and dying; (2) early detection of heart disease and living, or failing to detect heart disease and having a heart attack; or (3) early detection of cancer and living, or failing to detect cancer and dying. In addition, the role of the family in the decision-making process in the initial stages that surround the end of life can be particularly important as the care-giving team is often comprised of the patient's family, loved ones, and interdisciplinary health-care teams (Connor et al. 2002).

### **FAMILY DECISION-MAKING SOLUTIONS TO CONSIDER**

Family decision-making has become increasingly complex as family life has dramatically changed over the last several decades. Changing roles of women, increasing integration of women in the labor force, increases in divorce rates, increased mobility, increased longevity, and complex health-care environments are just some of the crucial changes that are impacting families and thus, arguably, impacting family decision-making across the life-span. Where does this leave family decision-making in the twenty-first century?

A few final thoughts that families should consider when implementing decision-making processes: (1) identify the issue, (2) understand all possible alternative strategies and options, (3) achieve satisfaction in choosing the best strategy for the family, (4) enact an action plan for implementing the decision, (5) evaluate the decision and refine as needed. These are a few simple steps to get families started in decision-making processes. However, more evidence from empirically based studies is needed to substantiate ways in which family decision-making processes are impacted by and impact individuals and their family units in our increasingly complex multicultural society.

## Fandom

*Debra Merskin*

*University of Oregon*

A fan is someone who is more than an ordinary, occasional → television viewer, → book reader, → Internet user, music listener, or movie-goer (→ Cinema). The etymology of “fan” is the Latin word *fanaticus*, which is also the source of the word fanatic. Bielby et al. (1999, 35) state, while being a consumer of a medium is one thing, “to be a ‘fan,’ however, is to participate in a range of activities that extend beyond the private act of viewing and reflects an enhanced emotional involvement” with the narrative.

Fandom is a community of fans, a sub-culture of fans, who share common interest, empathy, and enthusiasm for a → popular culture product as well as camaraderie and communication with each other. The origins of the concept are often associated with the 1939 World Science Fiction Convention (aka Worldcon), the longest running science fiction convention, which continues today (→ Fantasy–Reality Distinction). Fandom, however, is a sub-culture that goes well beyond the science fiction/fantasy genre. While Trekkies (fans of the television series and movie versions of *Star Trek*) are perhaps the most often referenced group (as well as parodied on television programs such as *Saturday Night Live*), others include *Harry Potter* devotees, romance novel readers, celebrity fan clubs, → soap opera viewers, and team sports fans. With the arrival of → reality TV series, fans have organized for communal viewing around programs such as *The Bachelor* and *American Idol*.

The totality of fans dedicated to a particular object or subject is referred to as its “fan base.” The concept of this interconnected base started with sports fans but the same phenomenon quickly became apparent in behavior ranging from symbolic appreciation

to extreme parasocial interaction, when a fan's interest extends beyond accepted boundaries of viewing and behavior associated with a particular celebrity, television show, film, → video game, author, or details about them (→ Parasocial Interactions and Relationships; Sports and the Media, History of; Sports as Popular Communication). Responses fall along a continuum, ranging from "normal" adoration to "extreme" obsession, in the form of stalking and harassment. Jenkins (1988, 86) argues, "Fans appear to be frighteningly out of control, undisciplined, and unrepentant, rogue readers." The 1971 film *Play Misty for Me* is a classic example of a female radio listener's obsession with a DJ (played by Clint Eastwood). Examples of other fan fixations include repeated break-ins to late night talk show host David Letterman's home, the tragic 1989 fatal shooting of *My Sister Sam* star Rebecca Schaeffer by an obsessed fan, and the 1995 murder of *Tejano* singer Selena by the president of her fan club.

Participating in the community of fandom involves more than active consumption of media; it also involves "doing" (→ Exposure to Film; Exposure to Television). Some fans are active on related Internet sites, posting opinions on television programs, commentary on characters, or playing games and downloading images (→ Internet and Popular Culture). Others write fan fiction and critiques, produce art, scratch videos, construct websites, and share their enthusiasm with like-minded others (→ Fiction; Fictional Media Content). The activity of fiction fans who rework storylines, find continuity errors, or construct alternative endings is called fanwank. Fanzines are another popular expression, originally in printed form but today increasingly found on the Internet (→ Zines). Fans also hold conventions dedicated to topics, genres, titles, or characters, such as a 2004 academic conference dedicated to what is known as Buffy Studies. Groups also dress in costumes and clothing associated with an event or cast such as fans of the *Rocky Horror Picture Show*.

As a result of the size of groups and purchasing potential, fans constitute an *economic base* of great interest to product marketers and advertisers. Sports fans are an emotionally invested group and buy millions of dollars worth of team-related, logo-laden t-shirts, hats, jackets, mugs, and related paraphernalia. Fans of particular television programs not only buy show-related merchandise, but also other products advertised within the time the program airs. Not all fans organize spontaneously, however. Creating communities around particular media phenomenon is frequently the result of public relations and → advertising campaigns designed to organize consumers.

Advertisers focus on this self-selected audience in hopes of building brand loyalty to the program and to products associated with it, hence creating a brand community (→ Brands). Examples include product placements such as in the HBO hit *Sex in the City* of Absolut Vodka, Barneys Department Store, and Manolo Blahnik shoes, and advertisers "surrounding" programs, such as General Motors' ads during the CBS reality television program *Survivor*. Public relations firms capitalize on the interactivity of the web by inviting visitors to join clubs or fan groups, and take online quizzes. The website for the television program *Desperate Housewives* invites viewers to shop for show-related merchandise, take the "Which housewife are you?" quiz, and watch recent episodes.

Defining who is a fan and the degree of fandom requires engaging with definitions of *audience*. Beyond discussions of active versus passive consumers, level of involvement, degree of enthusiasm, and questions of consistency in relation to media use or symbol consumption are also assessed. Sandvoss (2005) argues for the importance of the polysemic

(multiple meanings) readings of fan texts and the relationship between that and audiences' ability to evade, resist, or participate in acts of social and cultural power (→ Power and Discourse).

## **Fantasy/Imagination**

*Patti M. Valkenburg*

*University of Amsterdam*

The past three decades have witnessed a considerable increase in empirical research into the origins, contents, and effects of people's fantasy and imagination. What exactly is meant by fantasy and imagination, however, often remains unclear. Moreover, the two terms are often used without distinction, suggesting that they capture one and the same

experience. Of course, fantasy and imagination overlap to some extent. Both activities require the generation of thoughts, and in both activities associative thinking plays a role. However, there are also differences between the two activities. First, fantasy usually takes place separately from the context from which the fantasy emerged. Fantasizing is a shift of attention away from an ongoing task or external stimulus toward a response to an internal stimulus. Imagination, by contrast, does not necessarily take place apart from an external context. Imagination is the ability to reproduce images or concepts originally derived from the basic senses but now reflected in one's consciousness (Singer 1966).

A second difference between fantasy and imagination lies in the degree of goal directedness. Fantasizing is typically a free-floating mental activity (Klinger 1990). Imagination, on the other hand, is more goal directed. Typical examples of imagination are efforts to visualize the appearance of a monster described in a book, to "see" a friend's face when she is not around, or to give an accurate account of a movie just seen.

Fantasy and/or imagination can be related to media exposure in three successive phases, namely before, during, and after exposure (→ Exposure to Communication Content). This entry focuses only on the first phase. The role of fantasy and imagination during and after exposure to media content is discussed by Valkenburg and Peter (2006). The role of fantasy and imagination before exposure to entertainment lies in their potential to influence one's → selective exposure to media content. Three hypotheses have been proposed for how certain types of fantasy may cause changes in people's exposure to media entertainment: the → escapism hypothesis, the thematic correspondence hypothesis, and the thematic compensation hypothesis.

According to the *escapism hypothesis*, exposure to media entertainment is stimulated by an overproduction of unpleasant fantasies. There are two versions of the escapism hypothesis. First, the thought-blocking hypothesis argues that individuals suffering from many unpleasant fantasies expose themselves more often to media content in order to drive away these unpleasant thoughts. Second, the boredom-avoidance hypothesis argues that individuals suffering from a fantasy style called "poor attentional control" spend more time with media content. Individuals with poor attentional control are easily bored and distracted, and hence experience a great deal of fantasies, mind-wandering, and drifting thoughts (Henning & Vorderer 2001). Both versions of the escapism hypothesis have been investigated only in correlational research (→ Correlation Analysis). Consistent with the thought-blocking hypothesis, people with an unpleasant fantasy style watched more television (McIlwraith 1998). In line with the boredom-avoidance hypothesis, people suffering from poor attentional control watched more television in general and more entertainment programs in particular (Schallow & McIlwraith 1986). News and informational programs were watched less frequently by these people, probably because news and informational programs are less likely to fulfill an escapist function than entertainment programs (→ Enjoyment/Entertainment Seeking; Exposure to News).

The *thematic correspondence hypothesis* argues that the themes people fantasize about directly influence the types of entertainment they prefer to view. It assumes, for example, that people select more violent or heroic entertainment contents if they have more aggressive or heroic fantasies. This hypothesis received support in a series of studies (Huesmann & Eron 1986). It is, however, an open question whether fantasy is the

causal factor in this relationship because watching violent entertainment may also stimulate people to fantasize more about such themes. The fantasy–media exposure relationship may be bidirectional: certain types of media content could stimulate corresponding fantasy themes, which in turn could stimulate interest in watching these media contents.

The *thematic compensation hypothesis* proposes that people select media contents that reflect those types of fantasies that they cannot produce themselves. For example, individuals who are unable to produce arousing sexual fantasies may turn to erotica or pornography. This hypothesis is consistent with Freud’s (1908/1962) assumption that one’s motivation for fantasies is unsatisfied wishes. The thematic correspondence hypothesis presumes a negative relationship between fantasizing about specific contents and the viewing of corresponding program contents. However, the research to date has only shown null and positive relationships between exposure to specific media contents and corresponding fantasies. As discussed, frequent viewing of aggressive media content goes together with more fantasies about aggressive themes. Frequent watching of erotic content is related to fantasizing about similar themes (Leitenberg & Henning 1995). These findings suggest that the thematic compensation hypothesis may not be tenable.

Two out of three hypotheses forwarded in this entry seem to be valid. Both the escapism hypothesis and the thematic correspondence hypothesis received empirical support. However, the thematic compensation hypothesis, which assumes that people choose entertainment themes that are opposite to their fantasies, appears to be invalid.

# Fantasy–Reality Distinction

*Dafna Lemish*

*Tel Aviv University*

The ability of young children to distinguish between fantasy and reality with regard to television, and the changes that occur in those perceptions have significant implications for their preferences in television content, their comprehension of such content, and their emotional responses (e.g., fear reactions; → Fear Induction through Media Content in Children). By applying developmental psychology theories, researchers primarily in the field of communication studies have found that developing the ability to distinguish fantasy from reality may influence the tendency to imitate dangerous behaviors, to expect unrealistic solutions to problems, and to hold misconceptions about the nature of social life. It may also have an impact on purchasing decisions.

While “television reality” is a complex and multidimensional concept, the literature relates more specifically to the degree of factuality of the mediated reality, for example: (1) the ability to determine when people and events presented on television exist beyond the screen; (2) the understanding that some characters on television are real people representing themselves while others are actors playing a role; (3) the distinction between events depicted on the screen that happen in the outside world and those that are staged and created according to a script.

Research studies have sought to determine at what age and through what processes children learn to understand that television is not a “magic window” (Hawkins 1977) to the real world, but a constructed reality. Studies of social realism focus on children’s answers to questions such as: Are the people, places, and events on television similar to the ones familiar to us in the real world? Are they believable? Is it probable that events depicted in fictional programs will take place? (→ Fiction). Is knowledge acquired through viewing television applicable in real life?

In most cases, children are not systematically instructed in developing such distinctions, but rather they develop them on their own – as they mature, as they gain experience and come to understand the real world, and as their knowledge of the media expands. Until the age of 4, on average, children believe that everything on television is real, that television characters also live outside of the screen, and that action in the real world can affect these characters directly (e.g., they can pet an animal on television; they expect a television character to recognize them and react to their speech; Lemish 1987). As children grow older, their perception of television as a “magic window” is gradually replaced by a growing understanding that television reality is not quite like the everyday reality in which they live (→ Media Use and Child Development; Developmental Communication).

## **EXTERNAL AND INTERNAL DIMENSIONS OF FANTASY–REALITY DISTINCTION**

Studies indicate that *children use two principle types of criteria* to make distinctions between fantasy and reality on television: external versus internal dimensions (Hodge & Tripp

1986). The external dimension refers to the reliance of children on their knowledge of the real world that results from their individual life experiences. The internal dimension refers to cues within the television program itself that direct children's evaluation of its realism.

Dorr (1983) specified three levels of the *external dimension*. The first level refers to the concreteness of the television image – when something on television is exactly as it is without television. This ability to evaluate the reality of television based on the perceptions of people, objects, and events actually existing outside of the television world has also been called “physical actuality” or “factuality.” The other two levels accept the fabricated nature of the television world and judge each specific content item according to the criteria of possibility or probability. For the most part, elementary school children evaluate the reality of television based on their perception of whether events portrayed are possible in the reality familiar to them beyond the screen. As they move into the *formal operations* stage of cognitive development, around the age of 12, they gradually learn to evaluate the reality of television based on their perception of whether it is probable that it represents something that could happen beyond the screen, even if it is possible. Thus, while it is possible that one family will experience all the intensive events happening in the life of one television-family and solve them in similar ways, the child's life experience suggests that it is not very probable that this would be the case. In contrast, adult thinking about reality on television is mostly characterized by an understanding that everything on television is constructed to some degree and therefore cannot be “purely” real, but it is defined as real if it is representative of real life or probable in real life.

The second group of criteria for judging television reality has been defined by researchers as relating to the *internal properties of the program*, namely those related to the formal features of television (i.e., production elements such as camera shots, editing conventions, sound effects, and the like). According to this line of research, formal features also serve as cues through which children learn to perceive the reality of television content and to classify programs as real or fictitious (Fitch et al. 1993). For example, by the age of 4–5 on average, children begin to identify the grouping of television programs that are distinguished by the co-occurring features of form and content, i.e., the concept of program genre. Thus they come to understand that a live, unedited series of pictures of a war scene followed by a medium range camera shot of an adult who seems to be talking seriously and who is seated in a studio behind a desk indicates a “real” news report, while a colorful, animated scene of talking animals in children's voice with background music is “unreal.” Similarly, children learn to identify commercials as a distinct genre (Lemish 1997).

These two interactive dimensions – external and internal – can be framed as “real-world knowledge” versus “television-related knowledge.” Both forms of knowledge are used by children, in varying degrees, to make sense of the reality of television and to classify genres. The demand or urge to organize the world of television according to the integration of both these dimensions and to establish content and form expectations of different programs seems to be a central cognitive task undertaken by young viewers in particular.

### **AGE DIFFERENCES IN FANTASY–REALITY DISTINCTIONS**

It is possible to organize the above criteria in a complementary manner. Generally speaking, researchers have found that younger children are more heavily dependent on

internal criteria (e.g., → animation is “imaginary” because it is drawn and does not use live actors). However, as they mature, children learn to incorporate external criteria as their knowledge of the world expands (e.g., a specific animation series can be much more realistic in content than many programs employing live actors). However, similar to adults, there are many levels at which it is possible to interpret children’s responses in research situations when they are asked to evaluate something as fantasy or real (Messenger-Davies 1997). Children may say “this is not real,” or may remind themselves that “this is just pretend stuff,” but not be able to apply such knowledge to the reduction of anxiety, for example.

Therefore, some researchers disagree about the age at which children can distinguish between fantasy and reality and the various stages in the process. The age of 7–8 (the beginning of the *concrete-operational stage*, according to cognitive development theories) has been pinpointed by researchers as an important turning point in the development of such understanding. As children grow older, however, the task becomes more complicated as it involves answering the question, “real in what sense?” Through their elementary school years, their knowledge of both the world and the making of television expands significantly and they become more critical of the lack of realism they find in much of programming and commercials.

### **FANTASY–REALITY DISTINCTION, FEAR, AND IMAGINATION**

Related to this ability are the age-related differences in *fear reactions* to television content. On the whole, children before the 7–8 turning point are much more fearful of fantastic content on television that looks and sounds scary, while older children gradually become more aware of the implications of real and more abstract dangers (Cantor 2002). Effective parental strategies for coping with such fears were also related to their children’s developmental stage on the fantasy–reality distinction continuum, with physical strategies (e.g., hug, snack, favorite comforting object) found to be most appropriate for children who were scared of fantastic elements, and verbal strategies more effective with older children who already had a clearer ability to detect real dangers.

Also related is the research that investigated children’s *creativity, imagination, and play* as related to the developing ability to distinguish between fantasy and reality, and to the role television fantasy has in children’s make-believe world (Götz et al. 2005). The argument put forward in such work is that children build upon a wealth of fantasy-related information gathered from mediated resources in playing out their wishes to imagine and act. Even when clearly capable of making cognitive distinctions, they purposefully mix and interweave fantasy and reality elements taken from their media experiences to suit their needs and desires.

Similarly, there is evidence that *children’s trust of commercials* and vulnerability to their persuasive messages is related to their difficulty in distinguishing between the *fantastic* elements, including size of product, its performance, and the implied psychological and social gains from purchasing the product. Here, too, the development of associated cognitive skills, as well as children’s real-world experiences with the product or those similar to it, both of which develop over time, facilitate the development of such distinctions. There is no evidence that heavy exposure to television fundamentally transforms such

cognitive processes as the ability to distinguish between reality and fantasy. Media literacy efforts that sought to accelerate and facilitate it at an early age have also had only limited success (→ Fantasy/Imagination).

The task at hand for children – as well as adults – is becoming increasingly complicated with recent trends in the television industry worldwide. One such trend is the development of new television genres that purposefully aim at *blurring the distinction between fiction and real* for the purpose of infusing entertainment content with relevant real-world information, such as those coined “edutainment,” “infotainment,” and “informacials.” A second is the widespread flourish of reality TV genres in prime time around the world. These texts require much more sophisticated, media-literate consumers in order to manage the influence that such content can have on cognitive processes, attitudes, behaviors, emotions, purchasing decisions, etc.

In addition, studies on the fantasy–reality distinction have focused to date almost exclusively on the medium of television. The convergence of various audiovisual media into an *integrated “screen culture”* that also includes computers, Internet, mobile phones, video games, and hand-held consoles, and probably more in the near future, requires the development of a new research agenda that will address the concerns created by such a rich, diverse market.

# Fashion

*Katherine T. Frith*

*Southern Illinois University*

*Debra Merskin*

*University of Oregon*

Fashion, as extension of a human being beyond the corporeal body, is also a method of demarcating sameness and difference. As communicated through advertising, fashion not only reflects an individual's self-image, but also is done in anticipation of how others will regard the dramaturgical display (Goffman 1959). As an expression of popular preferences and culture (→ Popular Culture), fashion is constructed not by an actual garment, but by the desire it creates (Barthes 1983). Theories of communication studies suppose and propose that audience or consumer liking/disliking is often expressed in ways that reflect not only what people value, but also what producers want them to value (Merskin & Tankel, in press; → Communication Theory and Philosophy; Audience; Audience Commodity). As a creative cultural expression and commodity, fashion functions ecologically as a system of → meaning. To survive and thrive, fashion requires the constant cultivation, renewal, commodification, and reproduction of public desire.

Because fashion is “playful,” it is easy to overlook its *role in maintaining social cohesion*, marking social class and rank, and its “disciplinary power” in pressuring people to conform (Noelle-Neumann 1984, 117). School uniforms, dress codes, and sexually alluring garments are all used to make distinctions between youth and age, masculinity and femininity, social class, occupation, attitudes, values, and beliefs. As an effective social control mechanism and means of integration, fashion is a powerful ideological tool to instill fear of ostracism and isolation if an individual is perceived to be “in” or “out” of touch with the fashion scene. As an expression of dominant ideology, fashion is (1) functional, (2) a form of communication, (3) a political statement, (4) a tool of conformity, (5) a mechanism of ideology, and (6) a weapon for resistance.

The tools used to critique fashion and media images are interdisciplinary. Critical methods draw on a variety of theoretical positions, including literary theory, feminist critique, postmodernism, neo-Marxism, semiotic analysis, and Freudian analysis, to name a few (→ Critical Theory; Feminist and Gender Studies; Postmodernism and Communication; Semiotics).

## UNDRESSING THE AD

The conventional way that marketers define → advertising is as messages that impart information about products and services. The limitation of this definition is that it falls far short of giving us the whole picture. Advertising does much more than impart product information; it tells us what products signify and mean and how the use of these products can help us socially. Advertisers do this by marrying aspects of a product with aspects of a society. Embedded in advertising's messages about goods and services are the cultural

roles and cultural values that define our everyday life. Advertising not only tells us about the products we consume, it also informs us of their meaning within our culture (→ Culture: Definitions and Concepts; Advertising as Persuasion).

Analyzing the social and cultural content of an advertisement involves interpreting both the verbal and visual aspects of the advertising text to determine not only the primary sales message but also additional secondary social or cultural messages (Frith 1998; → Visual Communication). Fashion advertisements reflect society in a sometimes slightly distorted way, and by deconstructing ads we can begin to see the social and cultural messages (O’Barr 1994). By critically examining fashion ads that target women in Singapore we can begin to deconstruct some of the social structures related to the role of women in a society that is undergoing a significant paradigm shift in terms of gender roles.

### **WOMEN IN ASIAN FASHION ADVERTISING**

Across Asia, women are shaking off their stereotypical portrayals as submissive, traditionally attired, shy, neglected introverts or hardworking housewives. Singapore is no exception. In women’s magazines throughout Asia, women are being portrayed as trendy, carefree, and even in some countries in sexual roles wearing western clothes – for better or worse, they are invading what was once the reserved territory of western and Caucasian women models.

Models in women’s magazine fashion advertisements throughout Asia closely follow the stereotypical gender portrayals of thinness and flawless skin so popular in women’s magazines in the west (→ Gender: Representation in the Media). Women’s magazine ads are mainly targeted to young, predominantly female, consumers. Despite the liberalizing influences that are sweeping through Asia, in countries such as Korea, Singapore, Taiwan, and China women’s magazines – both the local and the country-specific international editions of magazines like *Vogue* and *Elle* – tend to use Caucasian models more frequently than local models when portraying sensuality in ads for women’s intimate wear and personal care products (Frith et al. 2005). Thus, foreign models are used to express more liberal attitudes and in some ways set beauty standards for thinness and fairness. Some authors, e.g., Kim and Cha (in press), question whether the tendency of women’s magazine advertising in Korea might project western beauty as superior to traditional Korean beauty and might be responsible for insecurity in Korean women. Kim and Cha argue that the imported beauty ideal has become so crucial among young Korean women that they are willing to spend fortunes having plastic surgery on their noses, eyes, and jaws. Growing numbers of young women are having their noses lifted, their jaws shaved, and their eyes widened in a drive to attain the western image of beauty. Most recently, Kim and Cha report, young Korean women are using plastic surgery on their calves in the hope of obtaining the “Barbie” legs sported by the world’s supermodels.

### **LEVELS OF MEANING**

All advertisements rely on the social knowledge and background of the reader. We all “make sense” of advertisements by relating them to our culture and to the shared belief

systems held in common by most people in our society. These beliefs are ideological in nature. They appear to be “commonsense” beliefs because they are widely held in a given culture, at a given moment in history; nonetheless, they are not universal beliefs. In addition to the more obvious social and cultural beliefs, subtle ideological values are expressed in fashion advertisements.

The underlying assumption in Singaporean fashion ads is that being slim and flawless is implicit in being a beautiful woman. For women in most cultures “looking beautiful” is part of being a woman. Advertising can only work if it appeals to an audience and presents the audience with something they want or need. Many fashion ads play on the fact that women who are even mildly overweight often feel guilty and less-than-beautiful. These kinds of advertising messages work because women in Singapore accept that it is part of their cultural role to be slim – at whatever cost (and in this case, \$38.00 per session). Within the culture it is a “commonsense” belief that women must be thin and fair to be attractive. Beauty ideals differ from country to country, and while women in most countries certainly do feel a need to be beautiful, this is not always defined as “being slim.” In the US, for example, big breasts may be an important marker of beauty, while in another culture thick, long hair may be the most defining factor. Based on fashion ads in women’s magazines in Singapore, we could reasonably conclude that slimmness and fairness are (or have become) a major cultural component of female beauty.

# Fear Induction through Media Content

Glenn G. Sparks

Purdue University

The capacity for media messages to induce fear has been the object of scholarly inquiry since at least the 1930s when the Payne Fund Studies launched the first systematic effort to study the impact of media on children and adolescents. As part of that effort, Herbert Blumer (1933) found that 93 percent of the children who participated in his study reported that they had been scared by something seen in a motion picture. Some scholars maintain that, taken together, the Payne Fund Studies introduced the “legacy of fear,” a phrase used to describe the main attitude that audiences had to media content at that time. Despite the prevalence of fright reactions to media indicated by Blumer’s finding, there was little research on this topic for nearly 50 years. Nevertheless, the phenomenon of media-induced fear certainly manifested itself repeatedly over that 50-year period (→ Media Effects, History of).

## RESEARCH HISTORY

The fact that media presentations induced fear became apparent in sporadic scholarly reports about media impact or in news reports such as those that followed the 1938 broadcast of the radio play by Orson Welles, *The War of the Worlds*. Researchers at Princeton University (Cantril 1940) investigated reactions to this broadcast in order to discover which features of the program contributed most to the widespread panic that seemed to characterize audience response. A few scholarly reports in the 1950s and 1960s devoted attention to the media’s capacity to induce fear in audiences (Himmelweit et al. 1958), but, for the most part, the topic received little attention until the 1980s.

Several factors probably helped to contribute to the scant attention devoted to media-induced fear during the 1960s and 1970s. During this time, research was devoted heavily to the problems associated with violent media content and its possible effect on aggressive behavior (→ Violence as Media Content; Violence as Media Content, Effects of). In addition, the prevailing theoretical emphasis in psychology and communication was upon behavior instead of emotion and cognition. Once the area of emotion became a primary focus of research in the 1980s, the door was open to consider fright responses to media in a more sophisticated fashion. Finally, the level of graphic horror in mainstream entertainment increased in the 1970s and 1980s. Movies such as *The Exorcist* and *Jaws* had such dramatic impact on audiences that scholars were naturally drawn to study the phenomenon of media-induced fear.

In the 1980s, research initiated by Joanne Cantor at the University of Wisconsin-Madison under the funding of the National Institute of Mental Health developed the research on media-induced fear in a theoretical and systematic fashion (Cantor 1994). The first studies in this program of research were designed in order to identify the types of movies and TV programs that were most likely to cause fright reactions in children at different points in their cognitive development. A second emphasis in this research was to

identify the coping behaviors that parents could employ to successfully reduce media-induced fears in their children (→ Emotions, Media Effects on; Emotion).

### **CANTOR'S RESEARCH ON CHILDREN'S FEAR REACTIONS**

Building upon the developmental psychology of Jean Piaget, Cantor attempted to make sense of children's fright reactions to media by emphasizing the level of a child's cognitive functioning at either the pre-operational (2–7 years) or concrete operational (7–11 years) stage of development. This theoretical approach was used to guide numerous investigations conducted by Cantor and her associates and resulted in a number of empirical generalizations that were consistent with theoretical expectations. For example, in the younger age group, children's fright reactions to media are far more likely to be determined by visual appearances – consistent with the emphasis in Piaget's writings on the perceptual dependence of the pre-operational child (Flavell 1963). In simplest terms, if something looks scary, then younger children are likely to be scared. In contrast, children in the older age group are able to integrate various pieces of conceptual information into their perceptions of media content such that they can discount visual appearances in favor of other facts that help to override any fear. For example, a monster like *The Incredible Hulk* might not be so scary to the older child who is able to realize that although the Hulk appears to be threatening, his primary motivation is to help people in trouble and perform charitable acts that serve the common good. Thus, while the Hulk might be extremely frightening to young children, he loses his capacity to induce fear in older children (Sparks & Cantor 1986; → Violence as Media Content, Effects on Children of).

An important corollary to this empirical generalization is that younger children are much more likely to be frightened by content that is appropriately described as fantasy (i.e., containing events and characters that could not possibly occur in the real world). In contrast, older children who are more able to recognize that fantasy is “just pretend,” are more likely to be frightened by the sorts of media content that feature events and characters that could actually occur in the real world (→ Fantasy–Reality Distinction).

An important consequence of these tendencies is that children's susceptibility to the experience of media-induced fear does not necessarily diminish with increasing age. On the contrary, older children are likely to recognize the ubiquity of media content that, while failing to present ugly visual features that younger children find upsetting, presents various natural and technological disasters (e.g., earthquakes, fires, tornados, nuclear accidents, and war). This research suggests that any parental tendency to become more lenient about exposure to media content as children grow older is likely to underestimate media threats to induce fear and emotional upset.

In terms of the coping strategies that parents might effectively employ to reduce media-induced fear in their children, Cantor's research supports the notion that cognitive strategies are more likely to work for older children (e.g., telling a child that a character is not real) while noncognitive strategies are more likely to work for younger children (e.g., distraction from the object of fear; Cantor 1998).

In addition to bringing a new developmental perspective to the study of children's fright reactions, the research by Cantor is noteworthy for some of its methodological innovations. Insofar as fear is an emotional reaction with both subjective and physiological components,

both self-report and physiological reactions are of interest. The use of physiological monitoring in the context of experiments with young children proved influential in the general conduct of research on emotional reactions with older participants as well, which now routinely includes the use of physiological measures (→ Physiological Measurement).

Although conducting research on fright reactions to media (particularly the reactions of children) may raise concerns about the possible risk to the research participants, scholars who conduct these studies have been able to chart a careful methodological course that gains approval from institutional review boards and appears to offer more than adequate protection from unreasonable risk. When working with children, the procedures often involve: (1) the use of media material that would already be common in the participants' media diets, (2) required informed consent on the part of the participants and their parents or legal guardians, (3) the opportunity for parents to screen the media materials prior to providing informed consent, and (4) a debriefing procedure that is designed to leave the participant in a positive emotional state upon leaving the study.

The popularity of frightening entertainment poses an interesting theoretical problem for emotion theorists and media scholars. Fear is a negative emotion that involves perceptions that some aspect of our well-being is threatened. This suggests that the popularity of frightening media is not linked to the experience of fear per se but arises from other sources that occur simultaneously or nearly simultaneously. For example, Dolf Zillmann's theory of "excitation transfer" would suggest that the physiological arousal associated with fear may quickly transfer to positive emotions that viewers may feel at a movie's conclusion (→ Emotional Arousal Theory; Excitation Transfer Theory). This additional arousal can serve to intensify the positive emotion such that attendance at frightening movies is associated with post-viewing euphoria (Zillmann 1980).

Another explanation for the appeal of frightening entertainment involves individual difference variables such as "sensation seeking" (→ Sensation Seeking). Individuals who are high on sensation seeking may seek out frightening media for the extreme adrenalin rush that such entertainment provides. For these individuals, the fear associated with the heightened arousal is still experienced as a negative emotion but does not outweigh the positive sensation of the high arousal itself. Individuals who are low on sensation seeking are more likely to become avoiders of frightening entertainment since there is little reward to counterbalance the negative experience of fear (Zuckerman 1979).

For some individuals, the enjoyment of frightening media is undoubtedly related to the experience of satisfaction that arises with being able to conquer a threatening stimulus. According to this scenario, levels of post-viewing gratification are specifically linked to the level of fright experienced during the media event (Sparks 1991). The more difficult it is to cope effectively with the frightening stimulus that is presented, the greater the level of gratification experienced upon successfully making it through to the end. This process may be more likely to take place among males, who tend to be socialized to express satisfaction in conquering a threat.

## **FUTURE RESEARCH**

One phenomenon studied by Cantor and her associates that is likely to continue to attract the attention of future researchers is the tendency for some individuals to suffer lingering

emotional reactions to frightening media that may endure for days, weeks, months, and even years after initial exposure to the media stimulus. The fact that some people suffer such disturbances is well documented. For example, following the movie *The Exorcist*, reports appeared in the clinical literature that documented numerous patients who had to be hospitalized due to the experience of uncontrollable fear, anxiety, and general emotional upset (Bozzuto 1975).

Presentations most likely to induce fear are those that excel in convincing the audience that the depicted threatening events may actually occur – while simultaneously presenting the impression that there is little hope for the viewer to identify a successful defense against the threat. Thus, *The Exorcist* was often reported to produce lingering emotional upset perhaps because its depiction of demon possession seemed so realistic and viewers left the theater feeling relatively helpless in protecting themselves from demonic attack. In general, paranormal themes that are depicted as if they can actually happen, but that allude to a mysterious world beyond understanding and control, offer considerable potential for the occurrence of lingering fears.

The experience of lingering fears that are only induced by projected images instead of encounters with their real-world counterparts is also a phenomenon of considerable interest. One goal of future research is to increase understanding about the way parts of the brain may influence this experience. Already, in following the work on the brain, Cantor has suggested that the amygdala may play a pivotal role in preserving fright responses that arise from media (Cantor 2006). As understanding of these processes increases, perhaps strategies to reduce lingering fears may be refined and applied successfully.

## Fear Induction through Media Content in Children

Joanne Cantor

University of Wisconsin-Madison

There is a growing body of evidence that the mass media, especially television shows and movies, often induce fear and anxiety in children. Fear is an → emotion characterized by the subjective feeling that one is in danger, and is usually accompanied by physiological reactions, including increased heart rate, blood pressure, muscle tension, and other forms of arousal of the autonomic nervous system (→ Physiological Measurement). Fear is often referred to as an intense response of short duration, whereas anxiety usually refers to lingering feelings of nervousness that endure over longer periods (→ Media Effects Duration). Research shows that feelings of fear or anxiety produced by media exposure often result in sleep problems and can cause children to dread or avoid activities that they once considered non-threatening (→ Affects and Media Exposure).

There are *methodological challenges* inherent in studying media-induced fears because it is unethical to show scary movies to children in order to prove that they cause nightmares and intense anxieties (→ Research Ethics). Research on long-term fears, therefore, uses either → surveys or a more detailed, retrospective approach, in which individuals report on their reactions to television shows and movies they have seen in the past. Research exploring the types of media images and events that scare different sub-groups of children is usually done experimentally, using short excerpts of relatively mild fare, often manipulated into different versions (→ Experiment, Laboratory; Experimental Design). Experiments sometimes supplement self-reports of feelings of fear with physiological measures, the → coding of facial expressions, or behavioral measure of approach or avoidance (→ Observation).

There are important *developmental differences* in what frightens children in the media, and these are based on a child's level of cognitive development. First, the *importance of appearance* decreases as a child's age increases. Both experimental and survey research support the generalization that preschool children (approximately 3–6 years old) are more likely to be frightened by something that looks scary but is actually harmless (such as E.T., the kindly but weird-looking extra-terrestrial) than by something that looks attractive but is actually harmful (e.g., a beautiful villainess); for older elementary school

children (approximately 7–11 years), appearance is much less influential, compared to the behavior or destructive potential of a character, animal, or object.

Second, as children mature, they become *more disturbed by realistic, and less responsive to fantastic dangers* depicted in the media. This change results from developmental trends in children's understanding of the fantasy–reality distinction. Because of this, older elementary school children begin to be especially susceptible to fear produced by the news and other realistic presentations. Younger children are sometimes vulnerable to fear produced by the news as well, however, especially when the threat is explicitly visual, as in natural disasters.

A third developmental change is that as children mature, they become frightened by media *depictions involving increasingly abstract concepts*, such as world problems (e.g., the threat of war or famine) and invisible environmental threats (e.g., AIDS, anthrax). Themes that adolescents and young adults report as extremely disturbing include sexual assault and stalking, and attacks by supernatural and occult forces.

*Retrospective studies* show that fear produced by the mass media can be surprisingly long lasting and may result in seemingly irrational responses. For example, many adults who saw *Jaws* (a movie about a man-eating shark) before the age of 10 report that they are still afraid to swim not only in oceans, but in lakes and pools. Such long-term reactions involve the physiological responses of fear whenever the individual is reminded of an earlier traumatic experience. These reactions are consistent with recent research on the neurophysiology of fear, which suggests that traumatic incidents may leave virtually indelible memory traces.

A large amount of research has been conducted on the impact of the *terrorist attacks* on the US of September 11, 2001. These studies reveal that greater exposure to media coverage of the attacks was associated with more frequent symptoms of post-traumatic stress in both children and adults even a year or more later (→ Mediated Terrorism).

Strategies for *coping with media-induced fears* need to be tailored to the age of the child. Up to the age of approximately 7 years, nonverbal coping strategies work the best. These strategies, which do not depend on words or explanations, include removing children from the media situation, distracting them, giving them warmth and attention, and under some circumstances, desensitization (gradually exposing children to small, less threatening parts of a program). Children aged 8 years or older can benefit from verbal coping strategies, including logical explanations of why they are not in danger. If what they saw is pure fantasy, it helps children in this age group to be reminded that what they have seen could never happen. If the program depicts frightening events that can possibly occur, however, it may help to give older children information about why the specific event they have seen cannot happen to them or to give them empowering instructions on how to prevent it from occurring. Research shows that explanations that minimize the likelihood that a horrible event will occur (e.g., “that sort of thing is extremely rare”) are not effective. Teenagers and adults can also benefit from writing about what has frightened them.

Because it is often difficult to calm children's media-induced fears, parents and caregivers are urged to be vigilant about what children are exposed to in the media, to seek information about a show's contents in advance, and to err on the side of caution when unsure how a child will respond (→ Media Use by Children).

# **Federal Communications Commission (FCC)**

*Chris Paterson*  
*University of Leeds*

The Federal Communications Commission (FCC) is the regulatory agency in the United States charged with oversight of electronic communications (→ Television Broadcasting, Regulation of; United States of America: Media System). Since the 1980s, it has taken much of the blame for the lack of diversity and the concentration of ownership in US broadcasting, and the rise of → media conglomerates. The FCC has a larger range of responsibilities and more autonomy than regulators in other industrialized countries. It was partially the model for the consolidation in 2003 of British regulatory agencies into one communications regulator, OFCOM, which, like the FCC, has a laissez-faire approach.

Since its creation, the commission has been controversial, largely because it was formed through conflicting philosophies. It was meant to uphold the decision of Congress following World War I that broadcasting should be mostly commercial and free of government control; but also to ensure that access to the airwaves was allocated responsibly and that those granted access put the public’s interest before their own.

## **HISTORY AND STRUCTURE**

The agency was created on June 19, 1934, when Congress passed the Communications Act. It was formed from its predecessor the Federal Radio Commission, along with parts of the Interstate Commerce Commission and Postmaster General. It was organized into a

broadcast, telegraph, and telephone division (it has been reorganized since), but the overall entity is directed by five commissioners (it was seven until 1983). They are appointed by each president, but only three can be from the president's party. With the chairman and two members essentially working for the president, broadcast policy has been kept in alignment with ruling party ideology in the US, and less mainstream ideologies are effectively locked out of policymaking. Ironically, the FCC is constituted so as to enable it to act with considerable autonomy from the executive branch (→ Media Policy).

The Communications Act has been amended many times but still dictates most US communications policy and determines most of what the FCC does. Key broadcast laws, including the public service requirement (→ Public Interest), came into effect with the Radio Act of 1927, but these were incorporated in the 1934 law (→ Radio Broadcasting, Regulation of; Public Service Broadcasting: Law and Policy). Importantly, section 326 within Title III of the Act prevents the FCC from censoring broadcasting in the US, although modern debates about media content have suggested that threats of penalties for certain content serve as a form of control tantamount to censorship. This received attention in 2004 when singer Janet Jackson revealed a breast – allegedly accidentally – in the most-watched annual US television event, the “Superbowl.” Under political pressure, the FCC reacted with record fines, and US broadcasters subsequently became extraordinarily cautious, especially when airing live events.

## COMPETENCES

The best-known and perhaps most crucial function of the FCC has been to *license broadcast stations* and ensure that basic regulations are adhered to. It does so through its authority over use of the radio spectrum. In the 1969 Red Lion case the Supreme Court reaffirmed that FCC actions to ensure broadcasters serve the public are not a violation of the First Amendment right to free speech. In practice, broadcasters have wide leeway in what they can and cannot do, and fines for breaching regulations are rare; revocations of licenses or denials of license renewal are rarer. Grassroots organizations such as Rocky Mountain Media Watch have worked to catalog license violations by stations and derail the nearly automatic renewal process, but such efforts have yet to significantly improve standards. In one of few license denials for failure to serve the public interest, in 1969 Mississippi television station WLBT had its license revoked for bias against African-Americans, following years of complaints by citizens' groups; this only happened after the FCC was ordered to do so by a federal appeals court.

In 1962 the FCC was given *authority over satellite communications* in the US (although international satellite communications are governed by treaty; → Satellite Communication, Regulation of). Its influence over the → cable television industry was gradually increased with the Cable Act of 1992 and the Telecommunications Act of 1996. The Media Bureau of the FCC licenses and regulates broadcasters and enforces cable television regulations. Separate bureaus deal with telephone communications, wireless services, and satellite communications (→ Telecommunications: Law and Policy).

Through its history the FCC has sought to increase the diversity of views available in US broadcasting – with the presumption that doing so is in the public interest

(→ Plurality). The cross-ownership, duopoly, prime-time access (PTAR), and syndication and financial interest rules are examples. Rules restricted how many broadcast outlets one company could own, locally and nationally, but these have been relaxed to the point that it is now possible for one corporation to own up to a third of broadcast outlets in the US and reach nearly all the audience. Since the same corporate entities dominate most other information and cultural products used by the US audience, the worst fears of critics of media consolidation, like Bagdikian (2004), seem close to realization (→ Ownership in the Media).

## PHILOSOPHY AND DECISIONS

The philosophy of letting profit, rather than quality, be the determinant of who is permitted to broadcast in the US began under Democrat President Carter prior to 1980, but the approach has been aggressively pursued and expanded under Republican presidents and congresses since. Since the 1980s and the presidency of Ronald Reagan, the FCC has aggressively deregulated. Mark Fowler, an FCC chairman under Reagan, was one of the most influential proponents of this philosophy. He is remembered for his assertions that “the public interest is what interests the public” (as opposed to something governments should determine and protect), and that television is “just another appliance – it’s a toaster with pictures.” By denying television’s social and cultural role in snappy quotes, Fowler empowered himself and the conservative FCC chairs that followed to decimate 50 years of regulation intended to police that role.

The *Telecommunications Act of 1996*, in particular, was promoted by Congress and the FCC as a public benefit because of its potential to increase competition, but it did the opposite – resulting in mergers, increased concentration of control over mass communications, a lack of local radio programming and reduction in local television production, and increased cable television costs with little content diversity. It was also made more difficult for the FCC to deny a license.

The role of the FCC as a catalyst for economic and technological change has been a point of contention. While it was not originally given this mandate, presidents have sought to use it for these purposes; critics charge this happens only in support of their narrow political and economic interests. Robert McChesney (2004) has argued that starting with the 1934 Communications Act, the profit-making potential of companies has been the main criteria used by the FCC in permitting entities to broadcast, rather than ill-defined efforts to serve the public interest. Indeed, there has been little opportunity for public input in policymaking, and when further relaxation of ownership rules was proposed in 2003 the FCC held only one official public hearing. But the public demonstrated a new interest in communications policy when a broad coalition of groups, and nearly one million citizens from across the political spectrum, sent messages to the FCC to demand an end to further deregulation. The changes were still passed, but were rejected in a court challenge.

US communications policy has been as much determined by courts as by the FCC. Courts have sometimes upheld the agency’s broad latitude to make policy, and sometimes castigated it for going beyond its remit or ignoring the consequences of its actions (→ Communication and Law; Communication Law and Policy: North America). The

FCC has taken some steps to ensure minority representation in the broadcast industry and minority ownership of broadcast outlets, although the latter rules were relaxed in recent deregulation (→ Access to the Media). A number of rules have been aimed at protecting children. Limits on the amount of commercials in children's programming were strengthened by the *Children's Television Act of 1990*, but critics charge that much of what passes for children's television in the US is essentially long-form commercials (→ Child Protection, Media Regulations for).

An important aspect of deregulation was the FCC's *rejection of the → Fairness Doctrine*, a rule that stated that broadcasters must give equal time to both sides of a controversial issue. Media corporations argued it had a "chilling effect," causing broadcasters to avoid controversial issues. In 1987 the FCC repealed it, and a new breed of political broadcasting captured much of the radio audience; opening the way to conservative cable television outlets like Fox News. Until the advent of the left-leaning Air America radio network in 2004, all of the new one-sided political broadcasting had a right wing – occasionally reactionary or racist – perspective, and reinforced the platforms of the Republican presidents and members of Congress making policy (Aufderheide 1990; Hilliard & Keith 1999; Barker & Knight 2000; McChensney 2004; groups like fair.org and mediamatters.org have documented these trends). Critics of the FCC have observed that as the White House attempted to convince the public of the need to invade Iraq, media with the most to gain from the further relaxation of ownership rules largely abandoned neutrality and critical news coverage and fueled support for war (for example, Boyd-Barrett 2005).

Broadcasting in the US has historically been dominated by networks, although the power of these has decreased in the last decade due to market fragmentation (→ Television Networks). The FCC does not have authority over networks, so has sought to control them through the regulation of stations. Legal scholars have argued that Congress was "eloquently vague" (Pember & Calvert 2005, 589) in defining what the FCC should do, providing room for interpretation to adapt to a fast-changing communications landscape. But the 1934 mandate that broadcasters serve "the public interest, convenience, or necessity" has never been aggressively interpreted by an agency which that critics argue was co-opted from the outset by the industry it was to regulate. FCC chairman Newton Minow (1961–1963) famously called television broadcasting "a vast wasteland," (Messere 2005) but his challenge to broadcasters to raise their standards has never been taken up.

Low-power radio broadcasting can take place within local communities and there is broad agreement that it usually does not interfere with other broadcasting, but the FCC, under pressure from business, has aggressively banned it and sent armed agents to close amateur radio stations. In 2000, the FCC finally permitted some low-power stations, but continued to ban them from cities. And it is noteworthy that while the FCC is nominally a domestic agency, its officials have worked in other countries to influence broadcast policy to the benefit of US corporations (Paterson 1994).

O'Siochru and Girard (2002) observed that, globally, media regulation has been oriented either toward regulation of media as an economic sector, or toward the enrichment of society through the promotion of diversity and plurality. The US model has always sought to do both, but while the FCC's enabling legislation emphasizes a social and political role, it has played mostly an economic one; shifting to an almost entirely economic role in service to the media industry since the 1980s.

## **Feedback Processes in Organizations**

*Vincent R. Waldron*

*Arizona State University*

Engineers have linked the concepts of feedback and enhanced performance since the time of the industrial revolution, but the term “feedback” was coined only in 1948 by cybernetic theorist Norbert Wiener. In this early work, feedback was a *signal* which indicated a discrepancy between the *goal* of a system and its current state (→ Cybernetics). Based on feedback, systems could recalibrate and improve performance. Research on the concept

expanded rapidly as managers came to believe that effectively communicated feedback could increase the motivation and performance of individual employees. Given this understanding, researchers worked to understand the psychological mechanisms people used to encode performance signals and adjust their work output. However, by the 1980s, it became obvious that the cybernetic model was only modestly successful in accounting for the complexity of human feedback processes. Further progress would come when researchers addressed such neglected factors as the linguistic qualities of feedback messages, relational and cultural context, interactivity, and the construction of meaning (Cusella 1987; Fairhurst 2001).

### TRADITIONAL THEORETICAL CONCEPTS

Discussion of feedback often begins with its context. *Interpersonal contexts* such as performance evaluation interviews have received much of the attention from communication researchers and practitioners. However, *system contexts* are of primary importance, as when corporations receive feedback from the stock market, environmental protesters, and other entities. *Formal feedback contexts* are different from *informal* ones, in that the former may be regulated by law, work procedure, and prescribed roles. A supervisor may share performance feedback informally over a cup of coffee or in the formal context of a required annual review. Finally, feedback is interpreted with reference to the *goals* or *standards* of individuals or systems. The nature of the goal, whether it is chosen or imposed by an outside entity, and the extent to which the goal is realistic, are among the contextual factors that shape employee interpretations of performance feedback (Latham & Locke 1991).

The *form* of feedback is another much-studied factor. Researchers use the term *valence* when describing positive or negative feedback. Positive feedback communicates satisfactory or accelerated progress toward a performance goal. Negative feedback is corrective; it suggests unsatisfactory performance. *Specificity* refers to the amount of detail in the performance message. Specific feedback contains more information that can be used in the modification of performance. Feedback *frequency* refers to rate of communication. More frequent messages create more opportunities for adjustments in performance. *Timeliness* is a measure of the delay between a performance and the feedback that follows.

The *source* of feedback is an important variable. Feedback can be derived from the *task*, as when a surgeon observes improvement in a patient's vital signs during an operation. However, feedback is typically *social* in nature. Andrews and Kacmar (2001) confirmed that employees differentiate among sources including organizational, supervisory, peer, and the self. A key research issue is the priority given to each of these sources by employees. Feedback from a low-priority source may have limited effects on performance. In contrast, feedback from high-*credibility* sources is weighted more heavily.

### CONTEMPORARY ISSUES IN INTERPERSONAL FEEDBACK

Much contemporary communication research considers feedback as an interpersonal phenomenon, typically involving interactions between leaders and members (→ Supervisor–Subordinate Relationships). Whereas cybernetic models tended to view recipients of

feedback as passive, newer interpersonal models acknowledge that partners actively seek feedback (Ashford & Cummings 1983; Larson 1989). *Feedback seeking* can be accomplished through *inquiry*, as when employees seek informal evaluation from a supervisor or co-worker. A more indirect *monitoring* process can also be used. This may involve noting others' reactions to a task performance or comparing one's own behavior to that which is being rewarded.

In contrast to early work that focused primarily on *downward* feedback, more recent research has examined feedback communicated *upward* in organizational hierarchies. Supervisors tend to overestimate the amount of upward feedback they receive. In fact, limited feedback is communicated from low-power to high-power employees. That which is delivered tends to be unrealistically positive. Bad news rarely travels upward, in part because employees fear being blamed. One consequence is that organizational decision-makers fail to adjust course because they remain unaware of unfavorable business circumstances. Leaders who maintain strong communication relationships with employees and reward upward feedback may overcome the tendency to suppress negative information. Upward feedback may be related to the ethical climate of an organization. Organizations that foster the upward expression of constructive *dissent* (→ Dissent in Organizations) are more likely to detect ethical lapses and make needed adjustments (Kassing 2002). In contrast, in organizations that suppress dissent employees may feel compelled to hide their ethical concerns or express them anonymously to outside sources. Some organizations foster this kind of upward feedback by establishing special communication channels for ethical complaints (e.g., telephone "hotlines") and employment protections for "internal whistleblowers."

The relatively recent term *360-degree feedback* describes the practice of seeking performance information from multiple raters rather than a single source (Atwater & Waldman 1998). This approach acknowledges that employees function within a web of work relationships. In a 360-degree feedback process, the typical leader receives performance feedback from lower-level employees, peers, supervisors, customers, suppliers, and other more distant sources. This approach is now widely used to evaluate and develop the communication skills of managers and team leaders.

Feedback *message quality* is an important concern of contemporary communication research. Here the concern is with the message features that promote positive or negative outcomes. For example, the degree to which negatively valenced feedback is delivered with consideration for the recipient's identity may determine the degree to which it is accepted (Larson 1989). At the same time, overly tactful feedback can be misconstrued when the recipient concludes that no substantive change in behavior is necessary. Feedback seekers may frame their messages so as to deflect blame for poor performance or to encourage positive responses.

## CONTEMPORARY ISSUES IN FEEDBACK SYSTEMS

At the systems level, feedback is frequently associated with *organizational learning* (Weick & Westley 1996). Organizations increasingly exist in fragmented, changing, competitive environments. Accordingly, they foster cultural practices which aggressively question traditional ways of doing business and cultivate continuous performance feedback from external sources (→ Learning Organizations). In learning organizations, feedback seeking

is embedded in such functions as new product development and employee evaluation. Similarly, the importance of feedback from external sources is associated with the functioning of decisionmaking groups. Effective groups seek external information as part of a reality checking process that curbs excessive conformity. External feedback supplements a group's internal resources and reduces chances for *group think*. For Weick and his colleagues, feedback from the external environment varies in the extent to which it is subject to multiple interpretations or *equivocality*. Highly equivocal feedback requires more communicative cycles (e.g., staff meetings) as the organizational system processes the meaning of external cues.

Feedback can also be conceptualized as a *control chain* rather than a singular message (Fairhurst 2001). From this point of view, the *patterns* of feedback that define dyadic or group systems are of more concern than individual communicators. Interpretation of feedback messages is influenced by the parties' shared communication history, including past criticisms and adaptive responses. Feedback exchanges not only result in adjustments in task performance, they also define relational control. For example, the act of offering performance feedback is a means by which leaders assert power in relationships with members. By unconditionally accepting feedback, employees affirm the leader's relational position; in contesting feedback members signal an unwillingness to accede relational control. As Fairhurst has noted, in contrast to traditional hierarchical relationships, some leader-member relationships are characterized by patterns of shared control and mutual feedback.

## MEASUREMENT AND FINDINGS

Progress has been made on a variety of feedback measures (Fairhurst 2001). For example, processes for multi-rater evaluation have been refined in recent years. Coding systems have been developed for assessing control chains, valence, sources, style, and other dimensions of the feedback process. Yet relatively few studies have assessed *naturally occurring* feedback interactions, or carefully coded the *qualities* of effective feedback messages. Exceptions include a study by Zorn and Leichty (1991), who found that effective messages were responsive to the identity concerns of the recipient.

Research on the effectiveness of feedback processes is still evolving, and results are subject to numerous qualifications. Effectiveness is typically defined in terms of receiver acceptance and performance enhancement. Research suggests that recipients prefer positive feedback over negative and respond more favorably when messages are adapted to their unique circumstances and identity concerns. Constructive feedback, which includes instructions for improvement, is typically preferred over messages which simply communicate negative evaluations of performance. Receivers may be more satisfied when feedback includes encouragement, particularly for recipients who believe they can exercise control over their work environment. Employees who receive ambiguous feedback are inclined to interpret it positively and often choose not to make behavioral adjustments. Recipients prefer to receive negative feedback in private but may be appreciative when positive feedback is shared in public.

The link to performance improvements may be enhanced when feedback is linked clearly to performance goals. Timely, specific, and concrete feedback processes have been linked to positive performance outcomes in some studies, in contrast to feedback which is

delayed, ambiguous, and abstract. Frequent and informal feedback may result in more rapid performance adjustments than occasional, formal feedback such as that communicated in annual performance reviews. Effectiveness is enhanced when recipients receive feedback about the performance of their peers (normative feedback) in addition to feedback about their personal performance. Some evidence supports the efficacy of feedback systems that include multiple raters, credible feedback sources, developmental information as opposed to merely evaluative information, and clear ties to organizational rewards, such as salary increases and promotions.

## **Feminine Mystique**

*Patricia Bradley*

*Temple University*

The 1963 publication of *The feminine mystique* by Betty Friedan (1921–2006) is certainly linked to, and sometimes considered the starting date of, the second wave of feminism in

the US. Despite a lackluster “launch” by its publisher, the book quickly became a brisk seller in its hardback edition and went on to sell 1.5 million copies when it was issued in paperback a year later. The book remains available after a dozen republications, including one in 2001, more than forty years after it first appeared. Its title, a phrase that Friedan coined, has come to represent the accumulation of expectations attached to women, especially those that are dissonant and conflicting. Friedan called this liminal status, wherein women are dissatisfied but cannot quite identify why, as “the problem that has no name.”

In its time, the success of the book provided a platform for its author to claim for herself the role of the mother of the US women’s movement. For the purposes here, we may consider that the book helped establish the second wave in the US as a social movement that was largely dependent upon mass media attention for the distribution of its messages (→ Women’s Movement and the Media).

On a theoretical level, the subject of a mass-media product calling for social change emphasizes the notion, as explored by Frankfurt School theorists, of the difficulties, and perhaps the impossibility, of a capitalist economy promoting socio-economic change that challenges its own foundations (→ Critical Theory; Political Economy of the Media). That *The feminine mystique* owed much of its style and substance to US mass magazines suggests its popularity was in part because it did not demand such systemic changes, the characteristic that was immediately noted when it was reviewed by a sociology journal. The book can also be explored from the perspective of the interpretation of individual readers, who brought their own backgrounds and experiences to the book. Nonetheless, however readers interpreted the book, its impact in the US was widespread and included a role as a starting place for many feminists of the period, including those who would later consider themselves to be radical feminists.

The intellectual influences on the book included Friedan’s personal background and her interest in Marxism, as well as the direct influences of ideas already articulated in Simone de Beauvoir’s *The second sex* (1972, 1st pub. 1949), but the discussion here emphasizes a political economy approach in examining how the book was influenced by expanding media markets at the time. These influences included a publishing industry seeking to enlarge the market of suburban women readers; the role of executive women in paperback publishing; and an author who understood the demands of the emerging practice of book promotion and consciously emulated the style and substance of US women’s magazines. It should also be noted that republication of the book by the major British publisher Penguin helped distribute the ideas of the book to an international audience.

## POSTWAR FEMINISM AND WOMEN’S MAGAZINES

On an immediate level, *The feminine mystique* represented Friedan’s success in establishing herself as a freelance writer. In the mid- to late 1950s, she achieved moderate success in placing nonfiction articles, from “The coming ice age” for *Harper’s Magazine* (Friedan 1958) to “Women are people too” for *Good Housekeeping* (Friedan 1960), the article that represented many of the ideas developed in her subsequent book. As an experienced freelance, Friedan not only learned how to reach the magazine audience, but she also had learned the limits of mass media, as in a 1955 *Redbook* article on an interracial

housing project, wherein an editorial pen had eliminated a reference to “Negro” families in favor of “people with the widest range of cultural differences” (Bradley 2004).

Still, in the period, the women’s service magazines were turning to concerns beyond domesticity. Although Friedan claimed in her book that women’s magazines unilaterally promoted women’s oppression (→ Sex Role Stereotypes in the Media; Sexism in the Media; Women in the Media, Images of), various communication scholars now suggest that postwar magazines represented to some degree the complex nature of changing ideas around women’s roles. In this respect, *The feminine mystique* was indebted to women’s magazines (→ Women’s Media Genres). Moreover, the book not only expanded upon the themes already present in such publications, but also used a magazine writing style familiar to readers. Friedan’s survey of her college alumnae, for example, likely resonated with readers familiar with magazine surveys. The book, in fact, represented a compilation of magazine strategies – the professional voice of the advice columnist, the anecdotal and other “proofs” of the nonfiction articles, the small but achievable steps presented by the self-help articles, and the epiphanies that routinely climaxed fiction. Moreover, as in the magazine article on the Arctic ice cap, her zeal to tell her story strongly led her to exaggerate or misinterpret social science evidence.

Friedan’s freelance writing career contrasts with her previous experiences as a radical journalist. In the 1940s, she was sufficiently involved in radical politics to draw the attention of the Federal Bureau of Investigation. In 1946, working for the left-oriented Federated Press, she covered the formation of the Congress of American Women, the American branch of a pro-Soviet organization, which, in its US context, took positions against racism and anti-Semitism, for equal pay for equal work, and for childcare facilities, and sought to include working-class women in women’s rights activities. In 1952, as a writer for the United Electrical, Radio and Machine Workers of America, considered the most pro-communist of all American unions of the postwar period, Friedan wrote an unsigned pamphlet, *UE fights for women workers*, calling for an end to gender-based wage discrimination. “It is no accident that big business all over the world opposed the movement for votes and equal rights for women . . . the public acceptance of women’s equality would mean the loss of a huge source of labor they could segregate and exploit for extra profit and as a means to hold down the wages of all workers” (United Electrical, Radio and Machine Workers 1952; → Activist Media; Alternative Journalism; Radical Media).

She closed out her career as a radical journalist after marriage, children, and a shift of interest to paid, freelance writing. Perhaps unwilling to risk blacklisting because of the red-baiting McCarthyism of the period, she eschewed her earlier interest in systemic notions of female oppression when she came to write *The feminine mystique*. The book is significantly silent on societal analysis issues in favor of feminist promptings on an individualistic, woman-by-woman basis. In a book filled with personal anecdotes, none had to do with her own challenges to race and class. Feminism is framed as “the problem that has no name,” a phrase that better represented the general unease in Cold War America than feminist issues in particular. However, Friedan, ambitious for success in the mass marketplace, chose a framing that would comport with the demands of the field in the time it was written. As she would lecture and write in professional contexts, the secret of successful commercial writing was to explore a subject in ways that emphasized personal stories (Friedan 1962b; Bradley 2004).

### MARKETING NONFICTION BOOKS TO SUBURBAN WOMEN

Book publishers in the late 1950s sought to expand sales among the female suburban audience (→ Audiences, Female). Although bookstores in suburban malls offered easy access to book buying, suburban women were not regular book purchasers and were occasionally lumped with other “nonreaders” who needed to be enticed with specialized marketing. Doubleday Company hired the long-time women’s editor Margaret Cousins in the expectation that her knowledge of the women’s magazine market could translate into increased book sales to women. However, her collection of short stories culled from women’s magazine fiction, *Love and marriage*, failed, considered too traditional for the changing times. Following the cue of the women’s magazines, book publishers also considered nonfiction aimed at women’s interests as a possible approach that would appeal to women readers. Friedan’s article on “The coming ice age” (although disavowed by the scientists she interviewed for the piece) caught the eye of the W. W. Norton Company and led to an invitation to write a book prospectus.

*The feminine mystique* was not the only book on the subject of emerging feminism. However, its hardback US sales of 60,000 in its first year quickly overshadowed other entries and it became a national phenomenon when it sold 1.5 million copies in paperback before its second edition. The book quickly went on to be published in paperback not only because of its strong hardback sales, but also because the paperback industry was seeking to enlarge its audiences by widening its lists beyond the romance and detective genres. Moreover, more women existed in the ranks of the less-prestigious paperback houses than in hardback publishing. This fact played an essential role at Dell, where women executives lobbied for publication of Friedan’s book. Under chief executive officer Helen Meyer, Dell paperbacks had already broken new ground in publishing books by women that transgressed traditional female genre boundaries – Francois Sagan’s *A certain smile* and the nine-million sale bestseller, *Peyton Place*. *The feminine mystique* quickly joined the Dell bestseller roster, prompted by its cheap price, the readiness of the audience for its messages, and, not an inconsiderable factor, Friedan’s understanding of book promotion.

At a time when many publishers still relied on the review process for book publicity, newer publishers viewed books as products to be promoted like any other commodity. At one extreme, Bernard Geis Associates only published books by celebrity authors who were likely candidates for the new television talk shows, or, failing that, books about seamy subjects that would elicit media interest. Geis published another major bestseller of the era, Helen Gurley Brown’s *Sex and the single girl*, promoted by Brown, another media professional, in ceaseless interviews (Bradley 2004).

Less attuned to the new trends, Norton provided a publicist for *The feminine mystique* only at Friedan’s angry insistence. On her own, Friedan engaged a booking firm for paid speaking engagements. When the book went into paperback, Friedan also turned to television, as in her two-part article for *TV guide*, “Television and the feminine mystique,” and on one of the new talk shows, *Girl Talk*. This latter appearance was considered strident and controversial, partly because Friedan demonstrated an inability, unlike her writing style, to adapt to the conventions of talk television.

## FEMINISM REDEFINED

Friedan's ongoing efforts to remain a prominent media figure in the second wave of feminism contributed to the US mass media emphasis on defining feminist leaders in terms of stridency, a definition that was only furthered by Friedan's argumentative role in the organized movement. Her ability to harness women's dissatisfaction in an accessible way and to promote the book in popular venues accounted for the growth of the feminist message to women who otherwise may not have come to any sort of feminist understanding. Many anecdotal accounts exist in which women claim that reading *The feminine mystique* changed their lives (Friedan titled her second book *It changed my life*, based on the comment she most frequently heard). Many of these women formed the leadership base of various activist organizations, including the National Organization for Women (NOW), and publications (such as *Ms. magazine*), and influenced legislative and social change.

However, it should also be noted that the popular and individualistic framing of feminism in the book set US feminism along a trajectory that necessarily involved the mass media at every step. At a time when it was believed that the mass media could be agents for powerful change, feminists on both the political left and right tended to take the messages of feminism directly to them for distribution. Once on the news agenda, feminism was subject to its craft traditions that often pitted feminism against anti-feminists and emphasized their differences in negative ways that remain in the US culture today.

*The feminist mystique* had its greatest influence in the US, but its success helped make Friedan an international figure and, to some, the representative of US feminism in her subsequent travels. In the same year as its US debut, the book was published by the British publisher Victor Gollancz and by Penguin Books in 1965. Penguin's worldwide distribution channels helped introduce the book to other English-speaking nations. It was translated into German and French in 1966 and later into Hebrew.

## Femininity and Feminine Values

*Myra Macdonald*

*University of Stirling*

Femininity and feminine values refer to the qualities of appearance, behavior and practices conventionally attributed to women. Feminist thinking strongly endorses the view that these qualities are not innate, but exist as ideological constructs, defined in opposition to masculinity and masculine values (→ Masculinity and the Media; News Ideologies). The superiority ascribed to masculinity in patriarchal thinking devalues the "feminine," despite assigning it some positive characteristics. As ideological constructs, femininity and feminine values are differently inflected in diverse cultures. White Anglo American definitions and perspectives have predominated in western writing but are being increasingly challenged by postcolonial feminist thinking (→ Feminist Media Studies, Transnational).

### HISTORIES OF FEMININITY

Simone de Beauvoir's *The Second Sex*, first published 1949, provided an early critique of the construction of the feminine woman, defining her as "an artificial product" manufactured by society's expectations and norms (1972, 428). This view gained popular dissemination with the 1963 publication of Betty Friedan's *The Feminine Mystique* (1992). Friedan argued that women, denied equal education and social opportunities to men, were stereotyped as passively content to perform housewifely duties. Her attention to the role of media images in seducing women into entrapment within the home marked the beginning of feminist enquiry into the power of media depictions in reproducing ideologies of femininity. Friedan's views were later challenged for perpetuating a myth of femininity that was based on white, middle-class norms.

Recognizing that “being, becoming, practising, and doing femininity are very different things for women of different classes, ‘races,’ ages, and nations,” Beverley Skeggs (2001, 297) has focused on the *intersections* especially *between class and gender* (1997; 2001) (→ Popular Communication and Social Class). She traces the exclusion of working-class women from the development of normative ideas of femininity and feminine qualities, but notes how, for women of this class, performing femininity offered a route to social acceptability. Post-colonial criticism emphasizes how white femininity was constructed in opposition to the colonial derogation of the black female body and its sexualized associations. When bell hooks (1981) re-posed the question attributed to the black nineteenth-century slave, Sojourner Truth – “Ain’t I a woman?” – she was stressing the need to take account of ways of being female that had been edited out of the dominant script of femininity (→ Black Feminist Media Studies). Other ethnic identities are equally excluded. Assumptions about the relationship between Muslim women’s modesty in dress and their sexual reticence are, for example, read through Western discourses in ways that ignore Islamic thinking (→ Communication Modes, Muslim).

The *qualities attributed to women* under the rubric of femininity or feminine values include a mix of positive and negative characteristics. While attributions of passivity, weakness, fickleness, or guile identify traits that have pejorative connotations, and are linked to the inexpressibility by women of overt sexual desire, other attributions ostensibly credit femininity with positive value. Femininity is also associated with nurturing, and demonstrating empathy and sensitivity to others. Yet within the context of male domination, these feminine values perform the dual function of associating femininity primarily with the private rather than the public sphere, and ensuring that responsibility for caring, whether within the family or within work contexts, falls principally on women. In this sense, feminists observe that discourses of femininity have operated to “keep women in their place” while off-loading on to women central responsibility for the social well-being of their communities. As one commentator observes, women consequently “become a kind of dumping ground for all the values society wants off its back but must be perceived to cherish” (Williamson 1986, 106). In Western cities, Victorian statues of female bodies are used to symbolize positive qualities such as “love,” “justice,” and “liberty,” but the women doing this representational work remain anonymous and depersonalized. Male statues, more typically, represent identifiable individuals who have acquired official status and recognition in the public sphere (Warner 1987).

### **POLICING AND CELEBRATING THE FEMININE**

Conventional ideas of femininity and feminine values have been powerful agents in policing female behavior. Forms of conduct or appearance that diverge from feminine norms are judged to be aberrant, deviant or unruly. These judgments apply with especial stringency in relation to the female body and female sexuality. While passivity and reticence have been historically applauded, the open display of sexual or other forms of desire attracts disquiet or censure. Women have, as a consequence, incurred blame for provoking male violence through their own style of dress or non-verbal behavior (→ Sexual Violence in the Media).

In contrast to the containment that typifies femininity, loudness, occupation of space and large female body size are all perceived as *signs of “unruliness”* (Rowe 1995). Continuing

dilemmas confront young women who wish to participate in sporting activities that are still perceived as “masculine”: whether to resist the pressures of gender conformity, or risk the danger of being identified as unfeminine or as “tomboys” (Cockburn & Clarke 2002). Women who achieve prominence in occupations formerly associated primarily with men (such as professional sport, business or the military) frequently have their achievements belittled, either through a process of sexualization or through being labeled as surrogate men (Woodward & Winter 2003). While the advent of “girl power” in the 1990s was ambivalently regarded as self-indulgent youthful exuberance or as an empowering tribute to feminism, the phenomenon of the “ladette,” as a binge-drinking, loud-mouthed young woman, offered a more direct challenge to established conventions of acceptable feminine conduct (→ Sexualization in the Media).

At the same time, the inferior status granted to femininity has led some feminist theorists to argue for an instatement and celebration of feminine values that have been suppressed by hegemonic masculinity. While these critics have been accused of adopting an essentialist approach to femininity, their primary aim is to emphasize the silencing of particular kinds of voice rather than to endorse, even in inverted form, the structure of a binary divide between masculinity and femininity. Within French feminist theory, Hélène Cixous (1981) argues for improved status for *écriture féminine* as a less linear, more exploratory style of writing than that privileged within the rational logicity favoured since the Enlightenment and typified in dominant forms of the written word. Her labeling of the suppressed style as “feminine” (or “female,” as the French “*féminine*” covers both) marks its excluded status without claiming that all originators of this type of writing will be women. Similar arguments have been advanced in relation to masculine/feminine ethics. Carol Gilligan (1982) suggests that morality based on sensitivity to interpersonal relationships is dubbed “feminine” and devalued relative to “masculine” forms of morality based on rule-governed systems.

Feminine values have also acquired positive connotations in contexts where masculine values have been thought to exert undue authority. In the spheres of *sport, business, journalism, and politics*, for example, the historical primacy of masculine values of competitiveness, conflict, and blindness to the interests and achievements of women or other marginalized groups has been increasingly questioned. In journalism, the constructed dichotomy between “hard” (masculine) and “soft” (feminine) news has appeared to evaporate as news selection has become more responsive to the interests of women, and news presentational styles have become increasingly personalized (→ News Values; Soft News).

Critics such as Liesbet van Zoonen (1998) have commented on the double bind of regarding such changes as a “feminization” of news. Applauded, on the one hand, for wider inclusivity, the notion of “feminization” can also devalue and ghettoize the changes that are taking place (→ Feminization of Media Content). In other areas, the incorporation into mainstream areas of the media of material once deemed to be only of feminine interest produces cosmetic, rather than radical, shifts of direction. The re-labeling of “women’s pages” as “lifestyle” or “style” pages or supplements, or the introduction of fashion or grooming features into men’s magazines, masks the extent to which gender binaries are still maintained, with adventurous sporting activities, for example, or the most up-to-date technologies, continuing to be associated with men rather than women.

Within *sociolinguistics*, debate has also revolved around the degree to which feminine and masculine language and interactional styles are either inherently different, or differently valued in terms of a gender hierarchy (→ Interactional Sociolinguistics). Early claims that women's speech was more polite and conservative than men's, less given to interrupting others and more hesitant in articulating strong opinion, have been increasingly reviewed. Critics argue that these expectations of difference ignore the degree to which language use varies with social context and with relative positioning within the social hierarchy. As more women engage in forms of work or leisure pursuits formerly deemed "masculine," styles of speech and communicative interaction display greater diversity and synergy with masculine modes (→ Women's Communication and Language). Through the influence of post-structuralist theory, many linguists reject the notion that we speak *out of* a masculine or feminine subject position, and prefer to argue that language is one of the practices through which we fashion our own identities (Talbot 1998).

### **COMMERCIALIZING FEMININITY**

One of the questions frequently raised about femininity and feminine values is how these concepts can have continuing discursive validity, given the radical changes in women's and men's social roles in the latter part of the twentieth and beginning of the twenty-first centuries. In line with the concept of "hegemony" advanced by the Italian Marxist Antonio Gramsci, consent has to be continually renegotiated and won against other competing versions of what it means to be a woman. The longevity of femininity as a dominant ideology has been achieved through its continuing ability to appeal to female desires, especially in its association with an idealized, if changing, bodily appearance. The long-established synergy between "femininity" and "consumerism" has been especially productive in sustaining women's own complicity in versions of femininity that remain associated with consumption-oriented pleasures and aspirations (→ Consumer Culture).

Femininity invites constant re-performing of its consumer rituals, and consumption forms a significant part of young women's identity-forming practices. Young women are socialized into feminine values through education, the media, family life and peer pressure, and their performance of femininity wins them acceptance in a variety of social contexts. Early constructions of masculinity and femininity through binary characteristics of "male" and "female" toys, and styles of teen and sub-teen dress, lay the foundations that invite adoption of contrasting masculine and feminine identities. Feminine values have no specific age connotations, but femininity, in its bodily inscription, is associated especially with youth. The women's magazine press, in its dependence on advertising, embodies particularly youth-oriented models of femininity, and these are further endorsed within the beauty and fashion industries and within celebrity culture (→ Celebrity Culture; Women's Media Genres).

### **PERFORMING FEMININITY**

Modes of "performing" femininity have undergone change in line with the evolving social roles of women. The notion of femininity as "performance" took particular form in the concept of the "masquerade" advanced by film critics. Appropriated from psychoanalysis,

this concept suggests that performing femininity to excess (as in the screen roles of Marilyn Monroe, for example) draws attention to its fabricated and artificial nature, and invites the viewer to be critical of normative assumptions. In the wake of feminism, femininity is regarded as being performed with knowing irony, leading to an undermining of its power to circumscribe female identities.

*Post-feminism* acknowledges the changing roles of women, and the greater opportunities for equality in education, employment, relationships, and lifestyle experienced by contemporary women (→ Postfeminism). Post-feminists argue that the struggles of feminism have been won, and that acknowledgement of feminism's achievements is inscribed in contemporary representations of femininity. A number of critics writing especially about television programmes such as *Buffy the Vampire Slayer*, *Sex and the City*, or the rise of "chick-lit," claim that central female characters exhibit traditional characteristics of femininity alongside feminist-inspired self-confidence and ambition. This mixing of femininity with feminism has been welcomed by some (Moseley & Read 2002), but it has also sparked less optimistic readings (Tincknell et al. 2003). Angela McRobbie, who had in the 1990s seen the alliance between feminism and femininity as offering space for feminist development, later retreats from this position, arguing that what is being offered to young women is "female individualization and the new meritocracy at the expense of feminist politics" (2004, 258).

Post-structuralist anxieties that the concepts of femininity and feminine values connote essentialist categories inimical to social change co-exist with recognition that they continue to inform thinking about women's identities and social roles. The growing instability within these concepts derives in part from their interaction with feminism and in part from the need to respond to a culturally diverse world.

## Feminist Communication Ethics

Linda Steiner

University of Maryland

Feminist ethics is concerned with how people can live together with others in healthy, productive ways and how we can build social or political structures to support this. As a way of thinking and acting that is fundamentally transformative and concerned with human good, feminism is itself normative. Its resistance to codification and preference for contextualization mean that its applications for communication and media are implied, rather than explicit; feminist philosophers, especially ethicists, rarely focus on media per se. Nonetheless, feminist ethics – derived from feminist insights and theories – is highly relevant to communication and media, as practices and as subjects of research (→ Ethics in Journalism; Ethics of Media Content).

Of central concern for feminists are media representations: news that demonizes subordinated populations or neglects vulnerable communities (→ News; Bias in the News), sexually exploitative advertising, entertainment content that traffics in gross stereotyping, objectification, and symbolic annihilation (→ Sexism in the Media). Besides issues of content, feminist approaches to ethical dilemmas in media may be derived from several strands of feminist work, each elaborated below. First is the issue of feminist ethics itself, a debate over whether women and men behave in fundamentally different ways, including with respect to ethical reasoning. Feminists' concerns with methodology and researcher–subject relationships apply both to media and communication scholarship, and to media practice (→ Journalism: Normative Theories;

Objectivity in Reporting; Research Ethics). Feminist activists' complaints about workplace discrimination and their experimentation with organizational forms also provide accounts of ethics in media workplaces.

### THE EMERGENCE AND DEVELOPMENT OF FEMINIST ETHICS

Gilligan's (1982) *In a different voice: Psychological theory and women's development* was a ground-breaking study of women's ways of analyzing and resolving ethical dilemmas. Gilligan accused then-prevailing notions about moral development – based upon abstract notions of rights, rules, and justice – of ignoring women's distinctive ways of thinking. Interviews with women convinced Gilligan that women's moral development emphasizes care, relationships, and responsibility. “[A] morality of responsibility and care begins with a self who is enmeshed in a network of relations to others, and whose moral deliberation aims to maintain these relations” (Kittay & Meyers 1987, 10).

Gilligan was criticized for essentializing sex and gender, falsely universalizing women, and ignoring the distorting impacts of a history of sex stereotyping and subordination (Steiner 1989). Some feminist ethicists remain unreceptive to ethics based on caring. Still, for the next two decades, feminist scholars openly challenged utilitarian, contract, neo-Kantian or rights-based theories.

While scholars seemed originally to assume that women's ways of thinking were feminist, Gilligan (1995) eventually distinguished between a *feminine* ethic of care, emphasizing special obligations and interpersonal relationships, and a *feminist* ethic of care, which exposed the disconnections of feminine selflessness. Moreover, Gilligan now denies that care and justice are opposites; nor is one a better form than the other. The net effect of the emphasis on face-to-face and personal relationships was to mitigate the impersonality of justice and rights-based models, and challenge abstract, universalized and disembodied conceptions that inherently marginalized women as moral agents and excluded women's experiences as a source of moral reflection.

### ATTEMPTS TO REVISE THE ETHIC OF CARE

Some feminists have tried to extend or amend the ethic of care. Given her concern that an ethic of empathy discourages self-reflection, and that caregivers may indulge in self-righteous anger or manipulation, Koehn (1998) emphasizes *dialogue*. She would carve out a space where receivers of care can contest the expectations of caregivers; her dialogic female ethics thus incorporates, she says, the principles of male ethics into the consultative ethos of female ethics. Others have integrated care and justice approaches, arguing that this integration raises political questions about who needs what kinds of care. Even Gilligan eventually conceded that all relationships, public and private, can be characterized in terms of equality and attachment; both inequality and detachment are morally questionable. Tronto insists that “care is not solely private or parochial; it can concern institutions, societies, even global levels of thinking” (1995, 145).

Conceiving caring in the neighborly sense as well as at the universal level, Denzin (1997) and Christians (2002) advocate “*feminist communitarian ethics*.” This takes the community as ontologically and morally prior to persons and presumes that values,

moral commitments, and existential meanings are negotiated dialogically. Denzin and Christians see this as facilitating civic transformation and promoting universal solidarity. Communitarianism, they say, takes as fundamental the social nature of the self, the connection of personal dignity and communal well-being, as well as the importance of care, justice, and interpersonal respect.

### **APPLYING THE ETHIC OF CARE TO RESEARCH**

Among other implications for communication and media research, caring as an ethical way of knowing requires researchers to be highly self-reflective about their ethical and scientific obligations, especially to subjects, so they do not objectify or “otherize” those being studied. Researchers must be self-conscious in deciding whose problems are important (those of vulnerable communities), what to research (with potential for transformative impact), and how and when to share it (among subjects themselves, as the research proceeds). Feminist ethics insists that researchers be humble, acknowledge their partiality, and not claim to have “the” knowledge; researchers are held accountable for their methods and their effects.

Feminist scholars, especially Sandra Harding (1993; 2004), challenge *andocentric science* not merely as bad but as unethical, given that its ideological practices and procedures conceal how power works, rather than revealing it. Feminist standpoint theory is thus also highly relevant, with its emphasis on consistent attention to how knowledge is always socially situated. Standpoint researchers start with the lives of marginalized peoples. Dominant classes do not need to understand those they dominate, and therefore do not understand them. However, since marginalized people are compelled to understand their oppressors, careful listening to them enables researchers to foreground and then incorporate bias into their method. Such knowledge-seeking concedes that inquiry and representation are inevitably partial and perspectival; reflexivity discloses partiality. Again, standpoint theorists’ claim that strong reflexivity produces “strong objectivity” is not uncontested; it may ignore how women’s lives are themselves socially constructed (→ Objectivity in Science).

Denzin (1997), a prominent scholar of qualitative research methods, especially in communication, says that ethnographically, feminist communitarian ethics requires giving participants a voice in research design (a position long advocated by feminist scholars), and building collaborative, reciprocal, friendly, trusting relations with subjects (→ Qualitative Methodology). Rejecting positivism’s ethical principles (beneficence, anonymity, and justice (→ Quantitative Methodology), its norms are grounded in community: research serves the community and reflects a community’s multiple voices so that participants can act to transform their social world. This also echoes critiques of empiricist epistemology, with its (misguided) view of agents of knowledge as culturally and historically disembodied individuals and of knowledge as homogeneous, unitary, and consistent.

### **FEMINIST ETHICS OF MEDIA PROFESSIONALS**

Foundational literature in feminism describes care almost entirely in the context of private and/or personal relationships. This would seem by definition to exclude application

of a care ethics to professional relationships, or at least the kind of abstract relationships that media professionals have with audiences. Articulating a practicable ethic of care for journalism requires at a minimum extending the world of moral considerability beyond the family to include caring for strangers and communities. Ethical schemas that work only for women, or only in the private or intimate domain, will not suffice.

Nevertheless, caring can be reconstructed. A politicized and “socialized” caring applies to journalism practice, as well as public relations, photojournalism, and other media work. Again, as with epistemology, the ethic of care has implications, including decisions about what to report on (important problems, with potential for having impact) and making journalism accessible to those most disenfranchised; and about the proper relationship of reporter to subjects (not “othering” interviewees). Feminist theorizing also implies something about the need for reporters to be humble, to acknowledge their privilege, and not claim to have complete knowledge about others. Media ought to serve the community, represent many voices (again especially of the marginalized), and critique power. Denzin calls for a (feminist) “communitarian journalism that treats communication and newsmaking as value-laden activities and as forms of social narrative rooted in the community” (1997, 157). He applauds → public journalism and asks ethnographers (→ *Ethnography of Communication*) to function as public journalists.

Given the ongoing concern about objectivity in journalism, the concept of “strong objectivity” has important, albeit subversive, applications. Standpoint epistemology requires journalists to rethink their craft “from the position of marginalized Others, thus uncovering unconscious ethnocentric, sexist, racist, and heterosexist biases that distort news production” (Durham 1998, 132). At the very least, this means journalists using those without power or privilege as sources and acknowledging their own position.

Relevant here is Fraser’s discourse ethics, emphasizing a contextual, collective dimension in order to advocate the standpoint of the collective concrete other. For Fraser, norms of collective solidarities as expressed in shared but non-universal social practices should govern interactions. She insists that people need enough collective control over the means of interpretation sufficient to enable them to participate in moral and political deliberation; “that is, to speak and be heard, to tell one’s own life-story, to press one’s claims and point of view in one’s own voice” (1986, 428). This requires journalists to abandon formalist, rights-based ethics privileging neutrality and to engage in self-reflection, deliberation, and informed debate. Not all intimate relationships and contexts are moral. Not all political “causes” are equally progressive. Thus, journalists must both evaluate and help audiences evaluate claims about suffering and policies to ameliorate suffering.

## FEMINIST ETHICS AND THE WORKPLACE

Feminist scholars are also divided on how best to organize work (→ *Organizational Ethics*). But relevant to workplace structures in media organizations and other communication organizations is feminists’ critique of the distorting and distorted polarity between public arenas as the legitimate site of work (and masculinity) and a private arena devalued for its association with emotional, domestic, and reproductive processes (and women). Feminists have experimented with horizontal and collective forms of organization and organizing

that are flexible and rotating and that grant agency rather than objectifying people. Notably feminist work or organization practices may fail to merge personal and emotional dimensions with rational, political, and professional dimensions. Indeed, the aspirationalist aspect of feminist ethics, and feminism's openness to contradiction, or at least to provisional, experimental processes, explain failures to achieve ethical purity. Ashcraft (2000) studied a feminist organization whose principles of "ethical communication" mandated members to disclose emotions and "name" conflict. However, this produced tensions. For example, in the name of empowerment and ethics, the system subjected interpersonal relationships to scrutiny and, ironically, preserved boundaries.

Nevertheless, presumably feminist ethical principles (caring, protecting those disenfranchised, understanding people as situationally embedded, and resisting sexism) imply active opposition to workplace sexism, including unfair wage scales, sexual harassment, and undermining active parenting. Creating double binds for women (that is, defining professionalism as acting like men but then judging women's behaviors as unsuitable because they seem like men's behaviors) is thus unethical.

Finally, an open question remains as to whether feminist ethics must always rely on ideas about gender or sex differences. Feminism as a political theory takes women seriously. Feminism as a movement hopes to transform social and political relationships to eliminate patriarchal distortion. Nonetheless, as a social construct, albeit a consistently powerful one, gender is assumed to be interstructured with sexual orientation, class, race, ethnicity, and religion. Feminism's ethical and epistemological principles need not always privilege women. Ultimately, a feminist ethic will take seriously values (community) and responsibilities (caring) long associated with women, without insisting that all women are always oppressed and pressed into economically, socially, and culturally dependent roles (→ Community Media; Community Structure Model). The history of male bias in ethics does not require feminist ethics to reify women's experience.

## Feminist and Gender Studies

*Cynthia Carter*

*Cardiff University*

*Kaitlynn Mendes*

*Cardiff University*

Feminist and gender studies represent key fields of research within communication studies today. It is difficult to discuss their emergence and developments as two separate entities, as the two often overlap. However, it can be noted that mainstream forms of gender studies research tend to differ from feminist studies politically, theoretically, and methodologically. As Dow and Condit (2005, 449) argue, “The field of communication has come too far to categorize all research on women, or even gender, as feminist in its orientation. Rather, the moniker of ‘feminist’ is reserved for research that studies communication theories and practices from a perspective that ultimately is oriented toward the achievement of ‘gender justice,’ a goal that takes into account the ways that gender always already intersects with race, ethnicity, sexuality, and class.”

As a political movement for gender justice, feminist communication scholarship always has at its core a goal of examining how gender relations are represented (→ Media and Perceptions of Reality; Gender: Representation in the Media), or the ways in which audiences make sense of them, or how media practitioners contribute to perpetuating gender injustice. At the center of this is the view that hierarchical gender relations (re)produce social inequalities across time and cultures, thereby making it difficult for men and women to be equal partners in democratic society. Feminist communication research is tied to a political movement for structural social change rather than individual change. As such, feminist scholarly research is inseparable from activist forms of feminism. On the other hand, gender studies are not implicitly political in the sense of having an agenda for social change on the basis of gender equality. Instead, the principal aim has been one of raising public awareness about the ways in which gender affects the individual’s life choices and chances, and thus women’s and men’s relative opportunities for personal and career success.

## GENDER STUDIES IN COMMUNICATION

Communication scholarship examining gender issues has a longer history than that of feminist scholarship. “Gender studies” usually refers to the social constructions of masculinity and femininity. However, studies on sex roles – or the false belief that women and men are innately different – are often included in this definition (→ Constructivism). Gender studies, as a recognizably distinctive field of academic scholarship, dates back to at least the 1960s in the disciplines of psychology, sociology, linguistics, and anthropology. Insights from these disciplines provided a formative basis for the establishment of gender studies in communication from the 1970s onward. Until the 1980s, it was generally assumed that communication studies gender research would focus on women. As the twentieth century came to a close, gender and communication scholars became much more interested in also researching some of the ways in which men and masculinity were portrayed (→ Masculinity and the Media), and began to explore how communication systems and processes contributed to the construction of different forms of masculinity. This preoccupation represented a shift from assumptions about masculinity as an unquestioned norm, to one in which masculinity became the focus of scholarly examination.

As noted above, gender and communication studies have largely been grounded in assumptions about the individual’s acquisition of gendered attitudes and behaviors, and the ways in which socially constructed gender roles can negatively impact on the individual’s life chances, especially in terms of sense of self-worth, → social perceptions of women, and their career prospects. Here it is assumed that portrayals of women in the media that depict them as less able, mentally and physically, or where their beauty or domestic service are the aspects most highly valued in them, will hold women back from achieving individual (career, wealth) success (→ Women in the Media, Images of; Body Images in the Media). More recently, a central concern with some of the ways in which masculinity is depicted centers on the extent to which the media contribute to the construction of masculinity as inherently violent and out of touch with everyday (domestic) life.

Aside from mass communication research on gender, two key areas examined by gender researchers in interpersonal and human communication include: (1) the ways in which media *organizations portray gender*, where the relationship between gender and such organizations is said to shape both individual consciousness and a sense of collectivity within the organization (→ Gender and Media Organizations); and (2) women’s and men’s *language styles* and how these might maintain social inequalities in personal and professional life for women (→ Women’s Communication and Language; Gender and Discourse; Interpersonal Communication, Sex and Gender Differences in; Language and Social Interaction).

In the first area, there has been a growing interest in making global comparisons around the extent to which *women appear as news reporters and news subjects* so as to judge the extent to which women’s voices are making a contribution to democratic political systems (Sarikakis & Shade 2007; → Gender and Journalism). Research projects such as the global media monitoring project, conducted in 1995, 2000, and 2005, for instance, show little improvement over a ten-year period in women’s position as media professionals or news actors (Gallagher 2005). Indeed, this project has consistently shown

that female journalists tend to be younger and less authoritative than their male counterparts, and are also visibly less present. Also, women are rarely news subjects. When they do show up in the news, they tend to be in the roles of victim or celebrity (and sometimes both).

In the second area, some researchers have argued that there is in fact little quantitative proof that *women's and men's language differs*. Instead, it is social perception of differences (women are thought to be more talkative, circuitous, and elaborate in their language than men) that in turn holds women back, because such differences are the basis upon which women's speech and communication come to be less valued than men's (Eckert & McConnell-Ginet 2003). On the other hand, other researchers refute this claim, providing what they assert to be evidence to show that there are often real differences in women's and men's language use and that these differences are what continue to hold women back from achieving personal and career success. More recently, some researchers have claimed that both perspectives are right, in that there are instances when men's and women's language is not that different, and others where it is, and it is up to researchers to document when such differences occur and why. Additionally, recent years have also seen an increasing interest in documenting men's and women's speech in different parts of the world, with some of this research echoing findings in countries such as the US and UK, whereas some findings are specific to the culture under scrutiny. For example, research in Japan has noted that women's language more clearly expresses a perception of powerlessness than does women's language in the US (Mulac et al. 2001). Similar findings have recently been published on women's language in Morocco (Sadiqi 2003; → Language Varieties).

### FEMINIST STUDIES IN COMMUNICATION

Feminist communication studies has only been a distinct scholarly field since the 1970s after the "second wave feminist" movement emerged in western countries and in many others including Japan, India, and Egypt. Feminist thought, political activity, and scholarship comes in a myriad of different forms, from western constructions such as liberal, radical, socialist, and postmodern feminism (→ Postmodernism and Communication) as well as the more recent phenomenon of → postfeminism, to the development of postcolonial and transnational feminist theory (→ Postcolonial Theory; Feminist Media Studies, Transnational). Additionally, more specifically focused forms of feminism have emerged recently. For instance, in the US, examples include Latina, Black, and Asian feminist theory (→ Latina Feminist Media Studies; Black Feminist Media Studies). Elsewhere, various forms of Islamic feminism have developed both within and outside the Middle East. Globally, this range of conceptual and methodological approaches within feminism and their differences as well as commonalities have led to different forms and practices of communication research and feminisms that are increasingly sensitive to cultural, social, and economic differences (as well as points of connection locally and internationally).

In considering the *challenges* that second wave feminist communication scholars have faced, it is important to note, as Gill (2007, 9) argues, that "the tide of feminist creativity, thinking, and activism that swept the western world in the late 1960s and 1970s faced a

challenge that earlier women's movements had not known: a world dominated by media." This has necessarily meant, Gill maintains, that since the 1960s, feminists have had to come to terms with the ways in which women are represented in the media. This realization, she suggests, underpins the rapid growth of feminist research and political action over the past 40 years. Typically, early feminist studies emerged from researchers and students in universities, particularly in the fields of communication in the US and cultural studies in the UK, who had become only too aware of the extent to which these disciplines failed to address gender issues (McLaughlin 1993; Carter et al. 1998). As Gill (2007, 9) further states, "Women in universities found that they were up against the 'male as norm' problem, in which women were frequently entirely invisible, and men were taken to stand for the whole human population."

Turning to look specifically at the development of *feminist communication studies in the US*, Dow and Condit (2005, 448) suggest that, historically, we can trace the emergence of feminist communication research to the growing visibility of feminism in society more generally (from the early 1970s). Early research in media studies, especially on → television, showed that women were rarely portrayed and that when they were, such portrayals tended to be heavily stereotyped (Dow & Condit 2005, 448; → Sex Role Stereotypes in the Media; Social Stereotyping and Communication; Stereotypes; Stereotyping and the Media). Other research highlighted the experiences of women working in the media, noting the dearth of opportunities open to women and the difficulties that they faced in seeking promotion.

Many studies during the 1970s, in the US and elsewhere, utilized *content analysis* to provide evidence for the narrow and often negative fictional roles available to women in the entertainment media as well as the absence or marginal status of women working behind and in front of the camera in journalism (→ Content Analysis, Qualitative; Content Analysis, Quantitative). Here, the argument was that all of these things led to an undervaluation of women's contributions to society and how they were regarded. Some researchers, however, came to the view that content analysis was problematic because it was only able to comment on the manifest media content of specific images rather than wider structures of meaning. Out of this developed, particularly in Europe, critical forms of analysis of methodological approaches, such as the semiotic and ideological analysis of British → cultural studies in the late 1970s (→ Semiotics).

From the 1980s onward, *more complex approaches* to the analysis of gender in the media were influenced by studies that sought to examine what had become, in some researchers' view, "a much more plural and fragmented set of signifiers of gender. There was a new playfulness in media representations, a borrowing of codes between different genres, and a growing awareness and interest in processes of image construction" (Gill 2007, 11). At the same time, theoretical advances encouraged a movement away from a transmission model of the media, i.e., the view that somehow its messages were directly conveyed to audiences, carrying with them stereotypical or ideological assumptions about femininity (→ Models of Communication). In its place, new theories put forward by post-structuralist scholars such as Jacques Derrida, Michel Foucault, and Jacques Lacan provided feminist communication scholars with a conceptual framework that would allow them to go beyond calls for the media to reflect more realistic images of women (with all of the attendant problems associated with defining what is real and therefore

what is realistic), and to embrace a position arguing that the media play an important role in constructing reality. In other words, “rather than there being a pre-existing reality to the meaning of the categories masculine and feminine, the media were involved in actively producing gender” (Gill 2007, 12).

This research eventually led the way to an interest in understanding how the media help to *construct gender identity and subjectivity*, which are seen to be partial and fragmented, rather than unified and rational, assumptions underpinning previous notions of gender subjectivity. This development allowed feminist communication scholars to see gender as fluid and open to change, rather than immutable and ahistorical. A related point coming out of this theoretical shift was that → meaning itself is never fixed across time and culture. “In poststructuralist theory meaning is never single, univocal, or total, but rather is fluid, ambiguous, and contradictory: a site of ongoing conflict and contestation” (Gill 2007, 13; → Identities and Discourse).

In opening up gender to this sort of theoretical scrutiny, it also followed that feminism itself was re-examined with a view to exploring the ways in which mainstream forms of feminism could be used to advance the position of certain women (particularly white, middle-class, heterosexual women), while at the same time doing little to raise awareness or improve the position of women of color, working-class women, lesbians, women with disabilities, etc. It was at this point that there began to develop postcolonial and transnational forms of feminism, as well as black feminism, Latina feminism, and third wave feminism, among others, highlighting the extent to which western political thought, including that of some forms of feminism, had tended to silence the voices of those who were not included in the dominant discourses of western feminism.

## **GENDER AND FEMINIST RESEARCH BY SPECIFIC MEDIA FORM**

In the next sections, gender and feminist research is reviewed by specific media form. No distinction is made between studies that are positioned within gender or feminist scholarship as these have already been noted, as has the point that in scholarly practice there is often much overlap between them.

### **Advertising**

Feminist and gender communication scholars have examined advertisements, viewing them as potentially debilitating, demeaning, and inaccurate reflections of “real women” (→ Advertising). Many initial studies examined *women’s sex roles*, and found that common images were of submissive wives and mothers located within domestic settings. Other studies examined gender power imbalances and found that advertisements depicted a parent–child relationship between men and women. Women tended to symbolize the child, had less power, and were shown as smaller to men and submissive to them. When other scholars began examining advertisements’ representations of the female body, they found that advertisements often portrayed fragmented body parts rather than the whole person, which had the effect of de-humanizing the subject. While in the past, this fragmentation was reserved for women, gender communication scholars show that it is now evident with men too.

Men and women are typically portrayed *advertising gender-specific items* – men with alcohol, vehicles, or business products, while women tend to be associated with domestic products. Authority has also traditionally been associated with men, and voice-overs are almost always male. While women have tended to be depicted as passive, sexual objects, more recently there has been an increase in the number of advertisements that show them to be active, sexual subjects. This has coincided with a growing → sexualization in the media, meaning that there has been an increase in sexual representations of both men and women. In western countries, the rise of second wave feminism helped incorporate feminist messages into advertising. This has contributed to several changes, including more images of women in the workplace, in positions of authority, and as independent beings. Older and minority women, however, typically have been marginalized in advertisements, depicted in a limited range of roles, or portrayed as having diminished mental and physical capacities (Lauzen & Dozier 2003). Stereotypically, black women have tended to be often represented as exotic or as a mammy (Cortese 2004), while Latinas are often shown to be passionate and emotional (Fregoso 1993) and Asian women as sexually submissive (Espiritu 1997).

### Magazines

Research on → magazines has variously examined constructions of femininity, masculinity, the rise of the “lad magazines,” discourses surrounding romance, sex, beauty, and consumption. Feminist media critics, such as Betty Friedan in the US who wrote *The feminine mystique* (1962; → Feminine Mystique), were among the first to become interested in women’s magazines in the 1960s, and argued that they reinforced traditional gender differences and inequalities (→ Women’s Media Genres). As such, they were not a site of innocent pleasure, but instead an arena that undermined women’s “real” identities. Not all scholars were as pessimistic about readers’ relationships with magazine texts, and some viewed them as an arena of political contest, not just ideological manipulation. Magazines therefore became a site where women’s oppression was debated and negotiated, not just reinforced. This meant that despite promoting notions of traditional womanhood and femininity, magazines could still be a source of pleasure for women (even feminists), because their meanings are polysemic, unstable, and subject to subversive interpretations. Second wave feminism brought about changes in women’s magazines. In the UK, as the women’s movement grew in the 1960s and 1970s, there was more coverage of political issues, including those that had previously been described as “feminist.”

*Men’s magazines* have been the subject of much discussion worldwide (Benwell 2003), and there has been a change toward including more sexualized images and photos of women. Gill (2007) has argued that these “lad” magazines assert their heterosexuality through a “laddish” tone that fetishizes women’s bodies and represents a defensive assertion of masculinity, male power, and men’s rights against feminist challenges. However, men’s lifestyle magazine content is not the same everywhere. An Italian study found that the recent success and growth of men’s magazines signaled a positive and progressive change of gender roles and identities (Boni 2002). Tanaka’s (2003) study of Japanese men’s magazines focused on the difference between the UK’s “new lad,” and Japan’s “city boy,” who is preoccupied by what his girlfriend thinks of him. Tanaka

describes how gender lines are more easily crossed in Japan, which is evident in magazine discourses.

### Film

For some time, western feminist film studies was shaped by the key theoretical contribution of Laura Mulvey's pioneering article "Visual pleasure and narrative cinema" (1975), where she argued that psychoanalytic theory could be used to understand how visual pleasure in → Hollywood film has been organized around the male gaze or masculine perspective. As such, film audiences experience narrative → cinema through the eyes of men, subjugating and objectifying women and suppressing feminine sexual desire.

In recent years, feminist film scholarship has become much broader in its theoretical and methodological orientations (→ Film Theory). For instance, Shohat's research (1990) has explored Hollywood's fascination with the Orient, and found Arab and black women were shown to be controlled by their libidos, while white women needed to be lured, made captive, and almost raped to awaken their desire. Much feminist film research has been geared toward studying pornography and other forms of sexual violence (→ Pornography, Feminist Debates on; Sex and Pornography as Media Content: Feminist Perspectives; Sexual Violence in the Media). Horror films have been analyzed to see how men, women, and sexuality are portrayed.

While there are many studies devoted to examining women in different → film genres, a growing number of gender researchers are now examining *men in films*, including sexuality and masculinity. De la Mora (2006) has investigated Mexican films from the 1930s and found that at the time masculinity was deployed differently than in western, and particularly Hollywood films. Studies have also examined heroes in film, heterosexual and homosexual masculinity, and working-class men and the relationship of the body to the male gaze.

Feminist research has also begun to look at political economy of films, examining the integration of patriarchy and capitalism (→ Political Economy of the Media). Riordan (2004), for example, has appraised the film *Crouching Tiger, Hidden Dragon* (Lee 2006) to see how the film was marketed, and how it constructed and commoditized culture and feminism.

### Television

As with the other media, television studies have found women to be shown in a narrow range of roles that tend to revolve around domestic settings or portray women as subordinate or as sex objects. Studies have also found this to be true in nonwestern countries, such as Japan (Suzuki 1995), where there are two images of men for every woman. Thus far, no European study has found a television category where women outnumber men. US television programs from the 1970s tended to ignore feminist characters and themes in television programs. However, by the 1980s there was a marked increase in the use of feminist rhetoric with shows such as *Cagney and Lacey* (1982–1988) and *LA Law* (1986–1994) being among the most successful. This continued through the 1990s into the twentieth century in a much wider range of television genres, including drama, situation comedy, and in factual programming.

Media researchers have used ethnography to research television viewing habits and have found that gender affects almost everything about the individual's relationship with television (→ Ethnography of Communication). At the other end, production studies have shown that women tend to hold lower-ranking jobs, take longer to gain promotions, and often face the "glass ceiling" (Joseph 2004). In addition, the percentage of female reporters diminishes with age, whereas this is not the case with men (Gallagher 2005). There have been several studies on specific television genres such as → soap operas, talk shows, and anime. Studies on women from ethnic minority groups in the US have typically revealed the use of traditional racial and gender-based hierarchies. For instance, Gillespie (1999) has established that African-American women have often been depicted as faithful companions to white women and, sometimes, men. In Puerto Rican television, research has found that traditional gender roles are often sustained by showing female characters receiving personal rewards, such as love from a man, for being well-behaved, and, conversely, loneliness for those who behave badly or outside the boundaries of socially constructed gender expectations.

US research examining depictions of men also appears to suggest that men tend to be presented in highly stereotypical ways. "Real men" are inevitably portrayed as dominant, aggressive, rational, and competent, whereas their opposite (desirable, compliant, domesticated women) featured mostly in comedies and soap operas (Craig 1992). Researchers have also examined minority men, male relationships, and the male gaze (see Craig 1992). Findings suggest that men tend to appear more in action/drama programs, and are least likely in sitcoms and soap operas. Men are more likely than women to be depicted as employed in high-status jobs, are less likely to be shown as married, are generally shown as older, and more likely to be involved in violence. The masculinity portrayed on television tends to be white, middle-class, and heterosexual, and more work needs to be done examining black, transsexual, rural, and working-class men (see Craig 1992).

## News

Feminist and gender studies scholars have analyzed the gendered nature of news culture (Carter et al. 1998; → News). More specifically, scholars have researched → journalism production, content, the gendered use of sources (→ News Sources), reporting men's and women's issues, representations of male and female athletes, politicians, → war correspondents, and sexual violence, among other topics.

In the US, Croteau and Hoynes's research (1992) has demonstrated that the *newsroom's gender imbalance* has led to male-centered news practices, such as the demand for objectivity and detachment, the importance of public matters over private ones, and limited definitions of what is "newsworthy" (→ Objectivity in Reporting; News Values). When it comes to stories about women in the US, Rakow and Kranich (1991) have argued that women are rarely, if ever, used as sources, and men speak for them all (see also Chambers et al. 2004).

Gallagher's (2005) international research on gender and news has found that men tend to report more "hard" news with topics such as politics, business, and economics, while women are most likely to report on → "soft" news, or social issues such as health-care and education. Her survey of one day of news (television, radio, and print) in 76 countries

(undertaken by volunteers), revealed that 79 percent of news subjects were men, and that one woman appears for every five men. There is no consensus on why this is. Global research examining *women's representation as news subjects* have found that women are often portrayed as victims (Lemish 2004; Gallagher 2005). A Chinese study has established that women's images were more likely to appear in the news than their voices or opinions (Yuan 1999), and in Japan, women tend to be used to give personal reaction to a given news event, while men show up more often in the role of providing expert comment. In India, the increased presence of women in the newsroom has had a positive effect on the macho culture, but much more could be done to speed up progress (Joseph 2004).

When reporting on women in politics, there tends to be a focus on gender roles and domestic and childcare services. Unlike women, men are rarely described in terms of physical attractiveness in news reports. Women's age and marital status are often discussed, and women are often referred to by their first name, and photographed in domestic settings (Ross 2002). Studies from around the world have found women's appearance is discussed more than their policies or messages (Lind & Salo 2002).

## Radio

Very little feminist or gender research has been undertaken to date. That which has been done tends to reflect upon and assess feminist attempts to create gendered → radio spaces for female audiences. Many women's community stations have been feminist projects, where the top priority has been to increase women's visibility and experience in the public sphere. There is a difference between women's and feminist production, where the former is not necessarily political, but the latter demonstrates resistance to patriarchal oppression. Feminist radio is grounded in the notion that women have a right to broadcast on their own terms, use their own voices, share their concerns, and represent their own lives. Studies have focused on histories of women's community radio, and this is one area in which studies are not predominantly from the US or UK (→ Community Media).

Many African nations have witnessed an increase in *community radio* since the 1990s when political systems opened up. These stations have been used to strengthen democracy and increase representation of people (particularly women) and issues previously ignored (Mitchell 2004). Radio listening in many of Africa's poorer areas has become a communal activity, and "listening clubs" have been developed (→ Radio for Development). Community radio has been around Asia-Pacific, New Zealand, and Australia since the 1980s. Asia has some of the fewest women's community radio stations while Latin America and the Caribbean have many, often in remote or rural areas. One of the most successful stations is the feminist international radio endeavor (FIRE), an online radio station located in Costa Rica, and broadcast in Spanish and English (Mitchell 2004).

Radio studies show that although women are not represented proportionately in production, radio still tends to be defined as a female medium, as women are frequent users because of its low cost, and their ability to do other work while listening (Hobson 1980). Even though radio tends to be perceived as a feminine space, Gill's UK (1993) study confirms that there are few female DJs (at the time of her research, male DJs outnumbered female ones by 10 to 1). To explain this anomaly, she discussed several myths about female DJs, including the idea that women could become DJs but chose not to;

that audiences prefer male DJs; that women lack the necessary technological skills; and that women who are more interested in broadcasting become journalists rather than DJs.

### Internet and New Media

The diversity in research on the → Internet and other forms of new media is difficult to summarize because of its expansive and multilayered theoretical and methodological approaches. Though this entry mainly focuses on Internet, there is an entire research area devoted to other forms of new media such as young people and new media, and gender and gaming. While other media have a strong focus on the western world, Internet studies tend to be more global. Scholars have examined the relationship between gender and technology, gendered consumption and technological production, activism and technology (particularly feminist-oriented), Internet pornography (→ Sex and Pornography Online), technology and gendered identity construction, etc. Much communication technology research recognizes that gender affects how everyday life is organized, and that the home has different meanings for men and women. Taking this into account, some studies have looked at how women use new information technologies at home and found that they consume technologies reluctantly, but feel they need to because of family responsibilities (Sing 2001).

Scholars have identified three distinct *narratives surrounding women in technology*, all related to views or assumptions about the Internet: (1) that it is a tool for feminists' search for social activism, organization, and networking, (2) that it is a misogynist sphere promoting sexual harassment, and (3) that it is a tool for women to combat globalization. Lee (2006) argues that new technologies can be problematic because they create and reinforce power imbalances in women's → communication networks, where technological knowledge is unequally distributed. In addition, women use new technologies differently in different parts of the world, and current technological discourses are seen to have a capitalistic, colonial, and western bias (Kurian & Debashish 2003; → Information and Communication Technology, Economics of). In addition, some feminists, particularly those situated in the global south, point out that a discourse exists saying that if women do not use technologies to increase and improve women's organization, they are not seen as putting the technology to good use. When examining policy in developing countries, Steeves (1996) outlines areas organizations should consider, such as women's employment, access to information, and selection of appropriate technologies (see also McLaughlin, in press).

## Feminist Media

Linda Steiner

University of Maryland

Around the world, → newspapers and → magazines, → cable and → satellite television programs, → radio broadcasts, → documentary film, and more recently → Internet sites

produced by, for, and about women have been crucial to the process of resisting dominant conceptions of women, celebrating oppositional visions of womanhood, and adopting lives as “new women.” Until the 1960s, such journalism outlets rarely used the term “feminist.” Nonetheless, “feminist media” usefully describes media that consistently advocate expansive political, social, and cultural roles for women and expose gender oppression (interstructured with oppression by sexual orientation, class, “race,” ethnicity, and religion). By definition, these largely women-run media enable them to redefine news, exchange information unavailable in mainstream media, and nurture a feminist community. Participants experiment with alternative working styles, organizational systems, and ethical standards, and develop their media skills (→ Femininity and Feminine Values; Feminist Communication Ethics).

### FIRST AND SECOND WAVES

Historically, feminist journalism was an outgrowth of efforts on behalf of other causes, such as the abolition of slavery and moral edification, as well as ones important specifically to women, such as health and dress reform, and especially suffrage or voting rights. Already in the mid-eighteenth century, especially in the US and UK, feminists published papers advocating equal rights for women, universal suffrage, abolition, liberalizing of divorce laws, birth control, and free education. Other feminist journals advocated quite different causes, including free love, anarchy, and socialism.

Notably, not merely mainstream media but also radical countercultural movements of the 1960s, and their periodicals, marginalized – if they did not altogether ignore – feminist issues and the so-called *second wave of feminism* (→ Women’s Movement and the Media). The 1970s, therefore, gave rise to literally hundreds of feminist periodicals. Some lasted only for a year or less, given the economic, physical, and time burdens of production. There were feminist magazines specifically for different races, ethnicities, religions, professions, ages, as well as for “goddess-minded wimmin,” Marxists, prostitutes, and celibates.

In the 1970s, a few leading women’s liberation magazines genuinely aimed at a general readership. *Spare Rib*, in the UK, originally limited the ads to nonsexist messages for crafts, but then was relaunched for the same reasons with a glossy cover and new style. In the US, *Ms.* quickly generated 26,000 subscriptions after its 1972 launch but also faced financial instability. For a time it solved advertiser resistance by rejecting all advertising. Since 2002, the Feminist Majority Foundation has owned *Ms.* as well as operating a quarterly newsletter and *Daily Feminist News*, a news website. Canada’s *Herizons*, which dates back to 1979, claims to be “a unique hybrid” of nonprofit business (with revenue from subscriptions, donations, advertising, and sales of music and clothing), feminist publishing and advocacy journalism, but attempts at this combination are common (→ Activist Media).

Second wave publications innovated along several dimensions. They sought grants from private foundations and government agencies to send issues free to prisons and mental hospitals, and to train women in publishing. Evolving distinctively feminist ways of working often was equally important, although developing collective, noncompetitive modes proved difficult. The Washington DC collective that has published *off our backs*

(oob) since 1970 continues to make decisions by consensus. Exemplifying feminist journalism's explicitness regarding activism and advocacy, and disdain for conventional journalistic principles, oob says: "We intend to be just; but we do not intend to be impartial" (→ Advocacy Journalism).

Most feminists disdained professionalism, which smacked of hierarchy and elitism, and even bylines (→ Professionalization of Journalism). In particular, second wave feminists experimented with alternative formats and innovative organization, often nonhierarchical collectivities or rotating jobs. To avoid editing, several published everything submitted. Some limited the kind of advertising they would carry or declined all advertising. As a matter of political education, some feminist papers charged men more for than women. Likewise, some lesbian periodicals charged extra for brown paper wrapping. Some rejected information from straight people and/or gay men, or declared, "TO BE SOLD TO AND SHARED BY LESBIANS ONLY" (→ Gay, Lesbian, Bisexual, and Transgender Media Studies). Others referred to "wimmin" to avoid the word "men." Still, the major problem, as well as the final straw, is nearly always that costs exceed revenues. Furthermore, most feminist periodicals can only be found at independent or feminist bookstores, a dying breed.

### NONPRINT AND THIRD WAVE JOURNALISM

The US-based Pacifica network is known for its leftist and pacifist perspective; but Pacifica, founded in 1946 by an outspoken pacifist as the first listener-supported radio network, also carries some feminist radio. The women's international news gathering service (WINGS), also based in the US, produces global-minded news programs about women for noncommercial radio stations and the Internet. Feminist television is even more infrequent, since television production is more difficult, complex, and expensive than radio. Even with relatively low production values, public access shows – such as *New Directions for Women*, produced since 1994 by a New Jersey collective for public access channels – require the coordination of many trained people, who end up concentrating on processes (not content).

Arguably, the Internet is a more accommodating space for feminist journalism, especially if the goal is not financial profit (→ Alternative Journalism). The low production and distribution costs and design plasticity allow *cyberfeminists* to experiment in the name of individuality, self-expression, and choice. Nearly all feminist periodicals also maintain an Internet presence, but increasingly feminists abandoned other media forms, given the relative expense and the availability of online feedback and interactivity. Operating on their understanding that "the personal is the political," feminist online media often tie personal experiences to larger structural principles, illustrating how personal problems transcend the individual (→ Cyberfeminism).

Still, it is rarely profitable. Some feminist Internet sites have been co-opted by corporate agendas and a few feminist standalone sites cease altogether each year. Korean feminists have successfully operated *Unninet* (Sisters' Village) since 2000, using metaphors of home-like spaces to welcome young feminists to their critiques of the gender politics of everyday life, but their attempt to establish a profit-generating corporation failed.

Beginning in the late 1980s, a *third wave of feminism and of feminist media* emerged, both as a response to the second wave's tendency to essentialize women and to defend the second wave in the face of a popular backlash. Typical of third wave feminism's concern to avoid defining itself in terms of the experiences of upper-class US white women, *Expository Magazine* bridges the gap among various feminisms by remaining cross-generational, cross-cultural, and cross-theoretical, but it frantically pleads for donations and feminist advertising to help "raise awareness about the plight of women worldwide" (→ Feminist Media Studies, Transnational).

However, this generation of feminists is also concerned with the micro-politics of everyday life, so most of the emerging opportunities for third wave feminist journalism emphasize edginess, or at least funky humor, even when they aim to sustain a visionary global women's network. And for some, sassiness is the point. "Girl power" and "girl culture" are more about fashion and marketing than social change. Unlike many western second wave feminists, who refused to answer to "girls," US-based *Bust* magazine and its online "Girl Wide Web" are "for women with something to get off their chests." *Bust* describes itself as "the voice of the new girl order." Likewise, *Bitch* magazine, publishing from Portland, Oregon, critiques media images of femininity and feminism and highlights "girl-friendly" media. Katha Pollitt, reporter for *The Nation*, has described *Bitch* magazine as "cheerfully attitudinous updated feminism" (→ Postfeminism).

Many US websites provide a platform for young women to speak on their own behalf, such as *Feministing*. Online "zines" or magazines are also available for older women. *Crone Chronicles*, a → zine which began in print, highlights the aging process. Moreover, serious print and online sites are continually emerging. *Trivia*, which appeared in print from 1982 to 1995 before going online, addresses the pattern of relegating women's most important concerns to the margins of patriarchal history. *The Women's Space* provides news and commentary from "radical feminist" and "distinctively and unapologetically woman-centered" perspective. *The F word*, a UK-based site launched in 2001 for young feminists, now emphasizes "contemporary" feminism.

According to *Altar Magazine*, since problems are not monolithic, neither are solutions; it therefore calls for socially progressive women and men fighting on many fronts against racism and heterosexism, and for feminism and economic justice. *Azizah* reflects the experiences and perspectives of North American Muslim women. Among the few journals managing to bridge the gap between activists and scholars is *Manushi*, founded in 1978 by two Delhi scholars to cover South Asian women's issues. Several lesbian magazines are published in Europe, especially in Germany, and in the US; some are highly politically edgy, others much flashier.

Few are genuinely international. Launched in 1975 as a quarterly emphasizing development, human rights, and especially, female genital mutilation, *Women's International Network (WIN) News* is "a world-wide open participatory communication system by, for, and about women of all backgrounds, beliefs, nationalities, and age groups." Since 1999, using freelance writers from around the world who are committed to professional standards but paid in free copies, *Women's eNews* has distributed news about women's issues globally to individual subscribers and commercial media. In 2003 *Women's eNews* launched an Arabic language version. *Scum Grrrls*, "a 100% feminist energy magazine,"

appears in French and English. Nonetheless, most US, European, and Asian outlets, including online, are available in only one language.

## DIRECTIONS FOR RESEARCH

Scholars seldom analyze feminist media. Suffrage papers have drawn historians' attention, but historians often use periodicals as sources of data about the early women's rights movement, rather than subjects deserving analysis themselves. In particular, Internet sites warrant study. They seem to avoid most of the problems that plague feminist periodicals and broadcasting, although feminist sites have died when participants were diverted by other causes, new jobs, or families, or because of personality and political rifts. Whether the content producers and audiences of feminist Internet sites can enjoy the kind of camaraderie that sustained first and second wave feminists is unclear. That is, the extent to which feminist websites will sustain a feminist community remains to be investigated.

# Feminist Media Pedagogy

*Leda Cooks*

*University of Massachusetts Amherst*

Feminist media pedagogy is a critical teaching practice and body of scholarship concerned with the lives and relationships of both women and men as mediated through cultural forms and institutions. Primarily, feminist media pedagogy focuses on the processes of teaching and learning about the politics of teaching and learning, especially as they are related to media production, content, reception, and consumption.

## EMERGENCE OF THE FIELD

This critical teaching practice emerged from feminists' concern both with the portrayals of women in media (→ Women in the Media, Images of) as well as with the uncomplicated critiques of power in critical and radical pedagogy. Feminist media pedagogy is an interdisciplinary body of scholarship, with contributions coming from the fields of film studies, communication, education, English, women's studies, among others. Its theoretical foundations are equally eclectic, with contributions from → cultural studies, neo-Marxist, poststructuralist, postcolonial and psychoanalytic feminist theory, as well as well-known educational theorists and philosophers such as John Dewey, Jean Piaget, Lev Vygotsky, Paulo Freire, Michel Foucault, Pierre Bourdieu, Henry Giroux, Gayatri Spivak, bell hooks, and many others. Feminist educators from around the world, working in a variety of contexts, from international grassroots and NGO efforts at media literacy with adult populations to undergraduate and postgraduate classrooms, focus their pedagogical work on the tenuous and complicated relationships among media critique, consumption, pleasure, and production.

From these theoretical and practical concerns, feminist media pedagogy has developed a strong orientation toward both interaction in the classroom and broader critiques of media and educational institutions. It has also developed some tensions and contradictions in its analyses of power dynamics. Nonetheless, feminist media pedagogy can be distinguished by its willingness to confront the complexities of power in a world where teachers are not always powerful while students remain powerless, and where interactions with the media and their institutions may be occasioned by choice and agency among viewers (→ Classroom Power). Thus, feminist media pedagogy offers an emphasis on classroom dynamics that necessitates a more complex reading of power as shifting and changing, located completely neither in the teacher nor in the student.

## FEMINISM

Feminism is defined by its focus on patriarchy as it shapes all aspects of women's lives. From this assumption, there have developed multiple feminist theories, each of which posits power, identity, and discourse differently. Each of these perspectives positions both the teacher and student as agents, capable of making small or radical changes in their lives

and communities (→ Feminist and Gender Studies). The feminist theories that apply particularly to feminist media pedagogy are, broadly speaking, liberal, socialist, and poststructural, although other strains of feminism critical of these areas are also influential (e.g., black, queer, radical, postcolonial, and transnational feminisms). Liberal feminism is often defined through its vision of equality for men and women in the workplace, home, and politics. Its proponents do not look to make deep structural changes in society, as much as they argue for equal representation within existing institutions. Here, the concern lies with educating students about the disparities in employment and pay between men and women working in media industries, as well as in media ownership. Liberal feminist pedagogy often focuses on the numbers: how many women are portrayed in the media and in what roles? Students are taught to analyze representation within current programming and institutions in the hope of increasing access for women to better roles in front of as well as behind the camera.

Socialist feminism in media pedagogy is closely tied to political economic theory and class analysis in media representation. From this perspective, attention is concentrated on the ownership and hierarchization of media industries, the class implications of media policies, as well as analysis of media representations and the slippage between their use and exchange value (→ Gender: Representation in the Media). Students are encouraged to become active outside the classroom in boycotting certain programs and advertisers and creating opportunities to influence government regulation of the media industry.

Poststructuralist feminism is also influential in teaching about the media. Whereas in other forms of feminism, identity may be viewed as essential – based primarily on a common understanding of what it means to be female, poststructuralist feminists see gender as a performance of femininity or masculinity that is dependent for its meaning on the contexts in which it is enacted. In fact, all aspects of the “self” are constructed in this manner, and so identities can never be stable or unified in their meaning (→ Identity Politics). Indeed, an individual can take on performances of race, gender, class, etc. that may be contradictory from one moment to the next. The media accordingly address viewers in terms of the performances with which they hope they will identify. Post-structuralist feminist teachers, thus, might ask, who do the media think you are? And, in turn, who are you when you interact with particular media?

Feminist teachers concerned with the media focus their efforts in several areas: on the level of institutional power in ownership of multinational media conglomerates that hierarchize production, distribution, and programming power in the hands of a few (western, white males); on the representation of gendered, sexualized, raced, classed, able-bodied, aged images in those programs that reach the widest range of people; and on the ways people make meaning of those mediated images and stories in their everyday lives. The variety of feminist approaches to pedagogy encompasses a wide range of topics and approaches to teaching those topics inside and outside the classroom.

## **ROLE OF THE MEDIA**

Feminist media pedagogy brings to pedagogical theory and practice an emphasis on the intersection between media studies – of production, effects, and content – and the everyday lives of women. Building on Freirean concerns about the relationship between

the word and the world, it asks how both are constituted in the media as cultural common sense. In other words, the media use symbols and language practices (words) to represent the past, present, and future social world. The social world created through the media, much like the everyday world of social life, is created through relations of power that situate women and other groups in the minority in positions of lesser moral, political, cultural, and economic value. Although distinctions are made among for-profit and not-for-profit media ventures, as well as between mass-marketed and private or independent media productions, all media traffic in the symbol systems that tell our most pervasive cultural stories of identity, relationships, justice, and community.

Although most feminist media pedagogues analyze the media as an “object” to be represented and understood, others are interested primarily in the ways people create → meanings for the media and communicate through media in their everyday lives. Where the former are primarily interested in the media as symbolic object and artifact, the latter are primarily concerned with symbolic processes of meaning-making that rely, more or less, on media in constructing modes of being and doing in the world.

Concerned foremost with the media’s power to represent identities and maintain dominant groups’ versions of common sense, those feminist pedagogues who analyze the media as object examine the ways people (primarily oppressed groups) are portrayed in the media. They work with their students to unpack the motivations behind such representations and try to envision and construct (via production of alternative media stories and forms) narratives that reverse or alter the relations of power. Examples of this type of pedagogical work abound, and many are associated with efforts to promote media literacy (→ Media Literacy). For example, studies that examine Disney narratives and the resistance among students to critique and/or construct alternative narratives that empower women exist in both the feminist media pedagogy and the media literacy scholarship.

On the other hand, those teacher-scholars interested in the media as mediator of common sense look at the ways in which discourse in the media becomes part of common sense in the classroom (→ Discourse Analysis). They ask how students come to compare their bodies, relationships, lives with those they see in the media. For example, has reality television increased or lessened the distance between real (immediate) and mediated events? Do images of the ideal mate portrayed in the media make their way into everyday stories about dating and relationships? Moreover, can pedagogy as an intervention into discourse-as-usual change student awareness of the pervasiveness of media? How might female students in particular gain both self-awareness and the motivation to resist unhealthy media images and messages? (→ Classroom Questioning).

Responses to these questions can be found in the attempts by some teachers to incorporate community action projects into their courses, asking students to develop media projects in coordination and consultation with women’s groups. For instance, the grassroots media literacy movement takes feminist pedagogy out of the classroom and into the streets, barrios, and countryside – where the idea of media developed by and for poor and/or rural women is becoming a reality (Riaño 1994). In these examples, there are few differences between media literacy projects and feminist media pedagogy; however, as we discuss in the section to follow, feminist media pedagogy focuses more on the process of teaching and learning while media literacy often focuses on the outcome (→ Grassroots Media).

## PEDAGOGY

In addition to its similarities with media literacy, feminist media pedagogy also shares many of the characteristics of *critical pedagogy*. Critical pedagogy concentrates on what is learned, how it is learned, who defines what is learning, and in whose interest knowledge is defined and achieved. Critical pedagogy is concerned with schooling as an oppressive institution that stifles learning and creativity. As a body of theory it promotes empowerment of students through recognizing and respecting their knowledge and experience. Critical pedagogy deconstructs schooling as a tool of the government and multinational corporations to reproduce a corporate citizenry focused on dreams of individual material wealth at the expense of true democratic community. While not all critical pedagogues espouse these goals, they are all critical of an institutional structure and curriculum that maintains the power of the dominant culture.

Feminist media pedagogy builds on these ideas and also critiques them, mindful of the ways gender, “race,” class, and sexuality position some teachers and students differently from others in the classroom. Where critical pedagogy situates the traditional teacher as powerful and the student as powerless, feminist pedagogy paints a more complex picture. Teachers and students are situated in discourse, in interaction, and through the power relations that construct various episodes in the classroom as teaching and learning, desire and resistance. Authority may be upheld or contested and both teacher and students negotiate status in conversation; such as when an open discussion is cut off or closed down, or when a lecture is interrupted by a student disagreement. Moreover, feminist pedagogy is concerned with the embodiment of teaching and learning in their performance – in the gestures, actions, and bodies that make a “good” teacher or a “difficult” student and in the spaces that contextualize these performances (→ Teacher Communication Style; Classroom Student–Teacher Interaction).

In other words, pedagogy in a feminist frame concentrates on the relationship between the teacher, the student, and the knowledge that they together produce (Lusted 1986). Feminist teachers work to create an atmosphere of safety in the classroom, where women especially can feel encouraged to give voice to previously silenced experiences of oppression or marginalization. Feminist educators are also concerned by the division of mind and body in western philosophy, where mind is equated with rationality and with men and body is equated with emotions and with women. In the classroom this division often plays out in the discounting of emotion and the discipline of the body (→ Femininity and Feminine Values). Critical knowledge encompasses embodied experience – past, present, and future – as well as desire for and resistance to alternative curriculum. In this vein, resistance is not viewed as noncompliance or as the teacher’s lack of control over her class, but as the logical extension of experience. Resistance, thus, is *not* not knowing, but is knowing differently, or knowing “other than” the dominant epistemology.

When the focus of feminist pedagogy is on media, attention turns to the relationship between performances of identity on the screen or in magazines and actual interaction in the classroom and everyday life. Feminist media pedagogy differs from critical pedagogy and from media literacy in its focus on the complications and messiness of bodies in the classroom – bodies disciplined by educational and media institutions and bodies interacting in the process of teaching and learning.

## **Feminist Media Studies, Transnational**

*Radha S. Hegde*

*New York University*

Transnational feminist media studies, an emergent area of scholarship, is both a critical intervention and a response to the challenges posed by globalization (→ Globalization of the Media; Globalization Theories). The transborder movement of capital, commodities, images, and people has set in motion a range of social and political issues, affecting multiple aspects of lived experience. Globalization reproduces gender and sexuality in ways that demand academic attention. Media systems, forms of representation, and communication practices serve as key points from which to unravel the complexity of global configurations. The rubric of the transnational enables feminist scholars to revise and rethink theoretical frames in media studies and produce critical, alternative accounts of globalization. Key aspects of globalization, detailed below, serve as impetus and set the agenda for transnational feminist media scholarship.

### **GENDERED GEOGRAPHIES**

Defying any singular form of definition, globalization is being heralded, celebrated, and deplored simultaneously by different constituencies. The contemporary landscape is characterized by social and political formations that have reconstituted the relationships

between the national, local, and global. Technology and corporate expansion have popularized the global → discourse of connectivity. Reality on the ground, however, speaks to great disparity in terms of media access and distortions (→ Access to the Media). While most mainstream accounts of globalization emphasize the inevitability and speed of transformations, far less attention is paid to the gendered contradictions that are inherent in these processes.

The rapid transformations engendered by the new technologies and the hypermobility of capital create new forms of inequity in the global landscapes and at the same time reinforce existing schisms by spatially extending old logics of domination in global guises. Lines of power are constituted, consolidated, and deployed in highly interconnected circuits that cross borders, resulting in what feminist scholars Grewal and Kaplan (1994) term “*scattered hegemonies*.” New technologies, systems of media representation, and information networks serve as crucial nodes in the transport and circulation of these modalities of power (→ Technology and Globalization). The issues here demand innovative theoretical responses, paying nuanced attention to the inequalities and asymmetries inimical to the global scene.

Enmeshed in these changes are various regulatory regimes that remain deeply classed, raced, and gendered. Transnational critical practice works against models that privilege binary cultural critique based on universalism, essentialization of cultures, and an unquestioned Eurocentrism. In addition, the emphasis on the transnational locates and identifies culture and cultural politics as traversing borders and hence exceeding the boundaries of nation (→ Culture: Definitions and Concepts). As Appadurai (1996) argues, globalization constitutes a “complex overlapping, disjunctive order that cannot any longer be understood in terms of existing center-periphery models.”

The demands of the global economy and colonial legacies have led to vast demographic movements of people. These *new patterns of migration* have stirred debates on borders and national identity in various corners (→ Identity Politics). Inflected by the nuance of local politics, the subject of immigration is inevitably compounded by larger discourses of nationalism, “race,” religion, and community. It is important to note that this economic expansion has set in motion alternate circuits that travel through shadow economies and invisible pathways, constituting counter-geographies of globalization. With the shift of dominant structures of capitalism to flexible modes of production and accumulation, there is a significant feminization and transnationalization of labor. New actors enter the global stage, calling into question conventional assumptions about agency, choice, travel, and mobility. The free flow and mobility of some is predicated on the fixity and status quo of others. For example, women from the global south are increasingly occupying low-paid jobs created by the fast-growing global service economies. This range of new global actors typically falls outside the frame of dominant accounts of globalization that, as Sassen (1998, 82) describes, read like “narratives of eviction.” Hence Sassen argues for a feminist analytic that allows a reconceptualization of globalization capturing “strategic instantiations of gendering.”

## **MODERNITIES AND NEO-LIBERAL TRANSLATIONS**

Along with deregulation and privatization, a pervasive neo-liberal worldview is taking shape, privileging consumerism and individuality. Packaging market-driven interests as

social values, neo-liberalism reshuffles the meaning of public responsibility and citizenship into the language of private choices and entitlements. Spurred by a consumer economy, this ethic is rapidly reshaping social formations and cultural practices in its transnational travels, with gendered consequences.

Discourses of consumption working with global popular culture and new technology script global identities based on strategic models of *cultural homogeneity*. In the deterritorialized world of free-floating commodities, local desires and cosmopolitan desires are connected. However, the networks of global consumer culture, in their commodification of difference, erase the complicity of interconnected historical forces in the production of global hierarchies that are both gendered and racialized (→ Consumer Culture). Simultaneously, the enduring power of western modernity continues to exert its hold globally, reproducing old colonial hierarchies in new sites as exemplified in the hegemony of the Eurocentric gaze in popular media.

At the same time, competing with the dominance of western popular culture, there is an emerging global presence of images and media products from the global south (for e.g., Hong Kong and Indian films), shaping local understandings of gendered categories. Mediated and technological regimes connect the diasporic and national spaces and also form the backdrop for distinctive types of transnational affiliations and gendered identities. There is increasing attention being paid to how issues concerning gender and sexuality are being drafted into the transnational public sphere, and whether new media flows are interrupting or restaging the hegemonic ordering of cultures.

The landscape of global cultural production underscores the need for discursive definitions and material constructions of gender to be situated within the complex intertwining of local and global fields – a rich and important site of investigation for transnational feminist media scholarship.

## MAPPING THE TRANSNATIONAL

These issues require media scholars to engage with globalization in new and revised terms that necessitate going beyond the familiar binaries of local/global, east/west, private/public or civilized/oppresed. The objective is to open up the terms of analysis and expand the ways in which media scholars conceptualize the material and concrete conditions within which cultural practices are constituted. The production, circulation, and consumption of cultural products have to be situated against the flow of migrants, transnational communities, and the neo-liberal worldview that is re-articulating difference and inequality on a larger global stage. Feminist scholars begin with the assumption that to evoke the transnational is not merely to aggregate different cultures. The transnational serves as an analytical frame to interpret the contested relational structures between cultures situated within a complex field of power relations. The transnational framework enables a rethinking of the categories of the nation-state, culture, identity, and modernity (→ Migration and Immigration; Modernity).

The mediascapes of globalization create *transnational public space* and accentuate the deterritorialization of culture and community (→ Public Sphere). These new types of global communities are the focal point of contemporary discussions regarding inclusion, modernity, citizenship, and the policing of borders. Feminist media scholars working on

transnational issues are paying critical attention to the racialized and gendered discourses and routes through which people are drafted into global processes. These varying levels of interconnections require a shift in theoretical approaches that work from the premise of the bounded, homogeneous nation-state. Contemporary global processes cannot be captured by resorting to models employed in communication and media studies that are entrenched in Enlightenment paradigms and the normative privileging of the west (→ Communication Modes, Western). Feminist research in transnational media studies assumes an interdisciplinary stance in order to make visible the interrelated issues of ethnicity, gender, and sexuality, mindful of their historical and political specificity.

In this endeavor, the intellectual contributions of postcolonial theories have been influential, particularly the focus on addressing the problematics of western modernity with reference to race, gender, nation citizenship, and sexuality (→ Postcolonial Theory). Postcolonial critique of universalism and theoretical attention to colonial power and its discursive translations have made a significant impact on feminist critical practices and theorization of global syncretisms, contradictions, and heterogeneities (Hegde 2006). This is the challenge, as Mohanty (2003, 229) poses it: “How we think of the local in/of the global and vice versa without falling into colonizing or cultural relativist platitudes about difference is crucial in this intellectual and political landscape.”

Media practices provide the standpoint from which we can understand globalization, as it is scripted and enacted. It is through communication and media practices that we apprehend the dynamics and everyday translations of globality. We need to think about media culture and practices in more expansive ways and revive an analytical interest in the intersections of media practices and everyday life, and in the connections between representation and experience in various global locales. Herein we see the power of mediated images as they mobilize global versions of modernity. New forms of sociality and cultural practices are currently emerging, constructed through the coming together of media, migration, mobility, and the flow of capital. These formations, exploding traditional categories of space and time, also forge new relationships between the national and the global, crafting new conceptualizations of belonging, national community, and citizenship.

## **FEMINIST TRANSNATIONAL INTERVENTIONS**

Globalization has seized the imagination of scholars from many disciplines. To feminist scholars, however, the goal is to bring into focus the multiple ways in which gender is defined, reworked, and deployed in the global context. Producing a *gendered understanding of globality* is not only about pointing to the absences but also showing through systematic analysis how these invisibilities are produced and sustained through discursive reiterations that resonate across borders and communities. The term “transnational” offers conceptual pliability and enables a theoretical framework that can account for various types of economic, political, and cultural interconnections. The transnational provides an analytical rubric for feminist scholars to move beyond modes of liberal multiculturalism and produce politically and intellectually incisive scholarship.

These theoretical moves also reflect the shifts within feminism and the trajectory of feminist scholarship within the field of communication and media studies. Transnational

scholarship continues to build on the third wave feminist insistence on historical and geographical particularities in the construction of gendered systems of power and social relations. The focus on the transnational forces a rethinking of stable, bounded definitions surrounding categories such as gender, identity, nation, and community (Shome 2006). Transnational feminist scholarship does not claim allegiance to a particular method or approach that privileges political economy over cultural approaches. Instead, the transnational directs our scholarly response to the cross-cutting issues of “race,” class, and gender that intersect and travel across geographic and political landscapes (→ Ethnic Media and their Influence; Gender: Representation in the Media; Popular Communication and Social Class).

Sreberny (2001) asserts that feminist media studies in the twenty-first century should be global in purview and should not become overly media-centric. A transnational focus together with a commitment to feminist politics furthers the contemporary study of media and media forms as it relates to wider social, historical, and cultural practices. Feminist scholars have answered this call by addressing both the need to globalize and pay attention through a gendered lens to emerging issues related to the global public sphere, media systems, emerging technologies, “race,” gender, and modalities of representation (Gajjala 2002; Valdivia 2003; Lemish 2005).

Current geopolitical conditions have created the need to conceptualize issues that often exceed national borders (for e.g., militarization, immigration, and labor flows). The terrain is bristling with questions for scholars, demanding the provision of alternative feminist accounts of global geographies as they intersect with the transnational constitution and complexities of gender and sexuality.

## Feminization of Media Content

Johanna Dorer

University of Vienna

The term “feminization” tends to be used in communication studies in two basic ways. On the one hand, it describes any increases in the proportion of women working in a particular media profession. On the other, it refers to a process in which communication norms, values, and behaviors coded as “masculine” are becoming gradually modified, if not replaced, by others associated with the “feminine.” Some communication researchers use the notion of feminization to refer, for example, not only to increases in the number of women working in particular media but also to what they regard as a trend toward media organizations gradually acquiring a “feminine image,” i.e., undergoing a shift toward norms and values coded as feminine, with their attendant lower professional status (→ Femininity and Feminine Values; Gender and Journalism).

The association of the *two meanings of feminization* can be traced back to the concept of the “feminization of culture” (→ Culture: Definitions and Concepts). Huyssen (1986) gives a striking description of how the increasing presence of women in cultural production starting in the late eighteenth century led to a fear of culture being feminized and losing its character as a male construction. This cultural ideology, in which women are equated with lower-status mass (popular or low) culture, while men are associated with a superior, high culture (fine arts and serious media), today forms the implicit subtext of the concept of feminization (Spigel 1992/1997; → Popular Culture). It is precisely these gender-based dualisms that deconstructionist approaches seek to challenge to prevent their confirmation. In this, the seemingly inevitable, natural connection between gender and gendered attributions is questioned and decontextualized.

There are many dualisms in media studies that are gender based. Well-known *gendered binary hierarchies*, read as chains of equivalents for masculinity versus femininity, include: public versus commercial broadcasting, serious papers versus tabloids (→ Tabloid Press), national and international politics versus local interest and gossip, public versus private or personal issues, public versus aesthetic interest, information versus entertainment, facts versus opinion, hard news versus → soft news, factual reporting versus feature writing, objective versus emotional style (→ Objectivity in Reporting), and high versus low credibility (→ Credibility of Content). In all of these, the dimension coded as masculine is regarded as the norm, conferring prestige and professional status, whereas the dimension coded as feminine carries low prestige and is equated with a lack of professionalism.

In feminist media studies, the claim that in recent years there has been a marked feminization of media professions and media content has been the focus of much *critical analysis and commentary*. One point around feminization has focused on → news and → journalism. It was not until the second wave women's movement, which emerged in many western countries from the late 1960s onwards, that the underrepresentation of women in journalism met with sustained criticism from communication scholars. Within the profession, some feminists began to call for hiring quotas for women in order to redress gender imbalances and schemes to promote women journalists and media workers so as to challenge sexual discrimination within media organizations (Carter et al. 1998; → Gender and Media Organizations).

Initially, it was hoped that as more female journalists were hired, the underrepresentation and discriminatory portrayal of women in media content would change as a result. Taking the claim of a "feminine journalism" as their starting point, researchers investigated whether women practiced a "different" journalism to that of their male colleagues. This claim has not yet been substantiated; however, it does appear that, similar to other counter-hegemonic discourses, the gradual emergence of feminist public spheres, and feminist publications catering to them, is influencing and challenging sexism in the mainstream media (Klaus 1998, 190ff.).

Some feminist researchers have concluded that increases in the number of women journalists from the 1980s onward has not led to a different style of journalism. On the contrary, according to van Zoonen (1998, 45), it may well have been changes in media genres and content produced in part by increasing commercialization and a growing market orientation, with its emphasis on human interest and soft, emotional, or sensational news, that has paved the way for more women entering the field of journalism (→ Commercialization of the Media). Those who point to its Eurocentric assumptions have called this hypothesis into question. Researchers point out that there has long been a high proportion of female journalists working in (formerly) socialist countries such as China or the eastern European states (until their recent transformation, in any case). Some suggest that this situation can be explained by the greater role accorded to gender equality within the state ideology of these nations. Examining media in such countries thus provides examples of organizations with large numbers of female journalists working in newsrooms where media content primarily was focused on politics, and was noncommercial and non-market-driven (Lünenborg 1997).

As in other professions, it has been the emancipation of women generally that has led to more women gaining admission to journalism and related fields. This has been reinforced by a growing media differentiation, such as public and commercial broadcasting, local and transnational coverage, and new formats in the print media, public relations, and online journalism (→ Diversification of Media Markets). In this process, the employment opportunities open to men and women have not been equal. In the newer professions, e.g., in public relations and various newly emerging commercial media, there have been certain areas where men had not yet "staked out their claim," thus making it easier for women to enter them. In these areas, as in → online journalism, the share of women has been growing at a much faster rate than in the more traditional and prestigious media, due mainly to a greater demand for new labor. The debate about "feminine values," a "feminine style," or "new" → genres merely served to legitimize the continually increasing

share of women in the field (Dorer 2005). Nevertheless, gender-based horizontal and vertical segregation remains a reality in these occupations. Female journalists more often work on less prestigious news beats and departments, they still earn less than men, and they more rarely rise to the top of the profession (Neverla & Kanzleiter 1984; Chambers et al. 2005).

The interlinked meanings of feminization produce an associative link between the two, thereby constructing a hierarchic dichotomy based on gender, with the masculine assigned a higher and the feminine a lower social status. As long as this discursive link remains unchallenged, existing gender differences can be reproduced and confirmed instead of being subjected to critical questioning and deconstruction.

## **Festinger, Leon**

*Wolfgang Donsbach*

*Dresden University of Technology*

Leon Festinger was one of the most important figures in modern psychology and contributed several theories that are still important today for our understanding of the communication process, particularly the individual's exposure to communication and

processes of opinion formation and judgment (→ Cognitive Dissonance Theory; Exposure to Communication Content; Social Comparison Theory). Born in 1919 in Brooklyn, New York, as the son of Russian immigrants, Festinger received his first training in psychology at the University of Iowa under the famous German-born social psychologist Kurt Lewin. After World War II he followed Lewin as an assistant professor to the Research Center for Group Dynamics at the Massachusetts Institute of Technology. There, in a group of other avant-garde psychologists, Lewin and Festinger developed the standards for modern experiment-based research on perception and group dynamics. It was during his time at MIT that Festinger authored his theory of informal social communication (1950), in which he described the influence of group pressure on the individual's attitudes and behaviors.

One year after Lewin's death in 1947 Festinger moved to the University of Michigan's Institute for Social Research and another three years later to the University of Minnesota. There he developed his *theory of social comparison processes* (1954) in which he suggested not only that the social group affects the individual's opinions but that there exists a drive within the individual to evaluate his or her opinions and abilities by comparison with those of others. Besides its relevance for processes of personal communication, the theory also applies to mediated communication. First, the mass media are one major source for the individual's assessment of what others think in a society. Second, journalists' decisions on media content, particularly in the area of news on politics and current affairs, usually lack objective criteria for news value and are often the result of similar social comparison processes, in which journalists compare their judgments with those of their peers (Donsbach 2004; → Objectivity in Reporting).

In 1955 Festinger became professor at Stanford University. It was during this period that he published his most famous contribution to social psychology, the *theory of cognitive dissonance* (1957). Building on the general paradigm of consistency existing at the time, Festinger endeavored to establish the individual's drive for consistency among the cognitions as a general biological law explaining most other phenomena, such as → persuasion, decision-making, and exposure to information (→ Consistency Theories). The theory became one of the most acknowledged and at the same time one of the most controversial in the history of social psychology. Hundreds of empirical studies have been carried out since 1957 and it is now fair to say that Festinger's ambition to establish this theory as a general law has failed, but at the same time the motivation to avoid or reduce dissonance is now recognized as an important driving force behind the individual's behavior.

In 1968 Festinger left Stanford to become a professor at the New School of Social Research in New York City, thus returning to his hometown. This move was accompanied by a sharp shift in his research interest. Partly because he was disappointed by the reception of his cognitive dissonance theory in the scientific community ("I never really understood the emotionality of the controversy," Festinger 1999), he now turned his interest to physiological processes of visual → perception. His research on the interaction between the eye and the brain in representing reality was primarily of a neurological nature, although he still focused on the structure and dynamics of the cognitive system.

In 1979 Festinger left the field of psychology and the laboratory and turned to such different fields as the impact of archaeology on mankind and societies, and the history of the Roman church. On the one hand this again showed his frustration with some of his

research agenda: “It is natural for me to talk as if the laboratory was at fault, but a laboratory is only a collection of rooms and equipment. It was I who conceived of and worked on narrower and narrower technical problems. That is not a proper occupation for an aging man who resents that adjective” (Festinger 1983 in Schachter 1994, 105). On the other hand this change shows the universal intellect and broad research interest of one of the greatest social researchers. Among many other awards, he received in 1959 the distinguished scientist award of the American Psychological Association, in 1978 an honorary doctorate from the University of Mannheim, Germany, and in 1980 the distinguished senior scientist award of the Society of Experimental Social Psychology. As Schachter (1994, 107) wrote: “The psychological world is a different place because he lived.”

Festinger’s theory of cognitive dissonance had a great impact on the development of communication research and particularly media effects research (→ Media Effects). For normative reasons it was welcomed as a tailor-made explanation for → selective exposure and perception and hence as an argument against strong media effects (→ Selective Perception and Selective Retention). Although the author was not uniquely interested in media-related phenomena he thus had a considerable influence within the discipline.

## **Fetishization**

*Jonathan E. Schroeder*

*University of Exeter*

Fetishization refers to a process of imbuing an object or idea with power. A fetish object is often associated with sexual gratification, desire, and worship. Fetishization marks a

cultural, psychological, and social technique of fetishizing things by making them appear larger than life, animate, or sexually desirable (→ Sexualization in the Media). It is argued that this process has profoundly influenced contemporary consumer culture (Fernbach 2002; Jhally 1987; Schroeder 2002).

### THE CONCEPT AND ITS APPLICATIONS

Fetishization is a useful concept for analyzing communication processes – it illuminates important aspects of consumer’s relationships with media, as well as how popular communication creates objects of desire. In an economy based on attention, → images, and → information, fetishization – as displacement, as dysfunction, and as deviance – contributes to a larger project of linking products with psychological fulfillment, emotional satisfaction (→ Emotion), and sexual gratification.

The word *fetish* has come to be associated with subaltern sexuality, or a fetish lifestyle organized around wearing fetish clothing and engaging in fetishized practices and rituals. Fetishization within popular communication draws upon these cultural associations to create associative connections for products, brands, and organizations. Fetishization, as used here, encompasses these concepts, but also refers to a broader cultural process of fetishizing objects via communicative technologies.

Fetishization in popular communication is often associated with *commodification* – associating objects and humans with markets and mass consumption. For example, → advertising often fetishizes goods by eroticizing and *reifying* consumer goods (→ Advertisement, Visual Characteristics of; Advertising, Emotions in; Reification). Products and → brands are worshipped for their ability to complete the self, to help consumers gain satisfaction – or even ecstasy – and revered for their capacity to project desired images (→ Branding). In this way, consumer goods function similarly (in a psychoanalytic sense) to the fetish object, which promises gratification but ultimately is unable to deliver, forever displaced within a fetishized relationship.

Fetishized objects often *symbolize control* and release, power and helplessness, sexuality and infantilism. In psychoanalytic terms, a fetish may be a dysfunctional response to sexuality, eventually replacing human contact for arousal. Further, a fetishized relationship, in some cases, interferes with the ability to have more “human” relations. Typically linked to sexuality, fetishized items are often contextually isolated – the shoe that by itself arouses, the disembodied body part, or the black stocking unconnected to any recognizable body. Visual communication often further displaces these objects via fetishization, by which an image replaces the physical object. The study of fetishization can be particularized by focusing upon clothing items, but widespread communication processes are also implicated.

Fetishization is associated with *displacement and disavowal* – sexual energy becomes directed toward something other than the genitals – a substitute charged with sexual power and attraction. Examples, of course, abound, but mainstays of the visual culture of fetish are sexually inflected clothing, such as high-heeled shoes, tight corsets, and lingerie. In popular terms, fetishism often refers to a psychological relationship or an intra-individual practice, but fetishization can fruitfully be considered a kind of communicative process or a cultural discourse.

## FETISHIZATION IN VISUAL COMMUNICATION

Visual communication and fetishization work together to create fantasy images of desire and inaccessibility. Fetishism has been discussed from many perspectives, including psychology, anthropology, and Marxism (Apter & Pietz 1993). Visual communication draws on each of these, creating objects of desire through visual techniques and symbols. Psychoanalytic theory holds that fetishization is based on paradoxical repulsion and attraction, which charges fetish objects with power as it simultaneously represents attraction and taboo. Visual representations of fetish objects – made possible by photographic reproduction, mass media, and digitization (→ Digital Imagery) – add another dimension to the fetish concept. Fetishization emerged as an important tool of advertising, via direct representations of fetish objects, and the fetish-like worship and power of consumer goods inherent in contemporary advertising (Schroeder 2002).

Photographic techniques such as close cropping, lighting, and depth of field help fetishize objects by isolating and reifying them. Two factors underlie the visual power of fetish: associations made through repeated usage of stock items in fashion, photography, and pornography and what has been called the *liminal* element of fetishization (Schroeder & Borgerson 2003). The word *liminal* reflects a gap, a space between, or an edge. Liminal zones are often spaces of uncertainty, creativity, danger, and passion. The space between – a space to be entered or crossed – can be exciting and unnerving simultaneously. Many fetishized objects – particularly items of clothing – represent a powerful liminal zone. Shoes, boots, corsets, and stockings are typical fetishized items – usually colored black or bright red. In popular discourse fetish clothing is usually desired by men on women.

The visual vocabulary of fetish has become a staple of the culture industries, television, fashion, film, music video, comic books, and advertising, which often draw on the cultural stereotype of the fetishist, a male whose sexual identity is linked with the fetish object. This projection – of lust, of desire, and of want – onto a fetish object seems the simplest way to present such imagery, which is usually recruited to lend an edgy sexuality to the advertised product. Ads for many products, from cologne to telecommunication networks, feature fetish themes of high-heeled shoes, stockings, tight leather, S&M, and bondage (e.g., Reichert & Lambiase 2006). Often these motifs are invoked with a wink to the knowing audience, a hip sign that the viewer understands – and appreciates – what might be implied by the image of a handcuff, an extremely high heel, or a leather corset.

These ads draw on motifs developed by *photographers* such as Helmut Newton, Horst, and Jean-Loup Sieff, who featured women in corsets, leather, and lingerie in their photographic work for mainstream fashion magazines. In the 1970s this trend accelerated, pushed by the art world, a growing awareness of “underground” sexual practices, and a market hungry for extreme imagery. By the 1980s fetish imagery had established a firm place in the visual pantheon of fashion, music video, and film, as adopted by celebrities as such Grace Jones, Madonna, and Annie Lennox, and showcased in the photography of Robert Mapplethorpe. Today, fashion companies such as Thierry Mugler, Versace, Jean-Paul Gaultier, and Sisley regularly include fetish-themed apparel in their clothing lines and ad campaigns, media icons like Kate Moss and Britney Spears are photographed

**Figure 1** The Absolut Au Kurant ad

Under permission by V&S Vin & Sprit AB (publ). Absolut®Vodka. Absolut country of Sweden vodka & logo, Absolut, Absolut bottle design and Absolut calligraphy are trademarks owned by V&S Vin & Sprit AB (publ). ©2005 V&S Vin & Sprit AB (publ).

in fetish garments, and mainstream movies and television shows like *The Matrix*, *Underworld*, *X-Men*, and *Buffy the Vampire Slayer* feature fetishized outfits as standard hero equipment.

The long-running and spectacularly successful Absolut vodka advertising campaign provides a classic example of fetishization in visual communication (Fig. 1). In a fairly simple and straightforward image in the Absolut Au Kurant ad, Absolut links itself to leather corsets, fetishism, alternative sexuality, and sexual allure. The message of the ad centers on the resonance between opening an Absolut bottle and consuming the product and opening the black corset and consummating a relationship. The lace bottle opens up the person within, undressing for potential intimate activity. The Absolut bottle serves as the key prop for sexual readiness. The magic, fetishized properties of the Absolut bottle are hinted at by these elements, a common theme in liquor advertisements (Goldman & Papson 1996).

Fetish clothing interacts with visual representation in intricate ways, supported by contemporary advertising photographic practice. Photography supports a fetish relationship with things by representing items devoid of context, reifying objects, and visually emphasizing tactile qualities like shininess (Mercer 1997). The language of photography, moreover, reinforces a dichotomous conception of black/white, inscribing racial categories with technological markers, in a process of racial fetishization. Fetishization also occurs via the use of composition, cropping, and color. In the Absolut Au Kurant ad, the fetishized bottle is given a contrasting lavender detail color to accentuate and isolate it as a graphic element. Advertising images often support fetishization processes by visually focusing on garments over bodies, things rather than humans, objects over relationships. Although most consumers do not exhibit classic fetishism – foot worship, for example – the relationship promoted between consumer and goods has many fetish-like tendencies. Moreover, many objects can and have been fetishized within contemporary visual communication.

### CONSUMPTION AND FETISHIZATION

The fetish relationship – object worship, delusional belief in the power of the fetish, and substitution of human relations with fetish relations – are also invoked in the broader dimensions of consumer culture and its aggressive object worship. Advertising appropriates and harnesses the power of fetishism to sell goods. Moreover, advertising creates meaning and values via photographic techniques, injecting new associations into the circuit of culture. Researchers attempting to understand its meaning-making capabilities miss a great deal by relying solely on information-processing models for themes and insights; fetishization represents a cultural, social, and psychodynamic process that often eludes cognitive-based approaches (→ Meaning).

Marx introduced the commodity fetish concept over a century ago and his analysis of the relationship between consumer goods and the market remains important. Marx may not have fully anticipated an economy based on image, one in which the dialectic of fetishization relies less on material things than on symbolic ideas. Advertising's use of photographic technology accelerates this process in a way that seems both readily apparent and relatively understudied. Contemporary consumption is highly visual: websites crave eyeball capture and advertisers work to break through the clutter. Fetishization offers useful conceptual tools for understanding how popular communication works in an economy that is attention-focused.

Fetishization may attract the eye to products or services in an economy fueled by obtaining consumer attention, but fetish themes have also been criticized as perpetuating stereotypes – women are most often the objects of the fetishistic attention, or women are portrayed as slaves to fashion (Reichert & Lambiase 2006). This critique suggests that fetishization with popular communication may reveal some transgression of sexual stereotypes that are mainly in the service of entrenched visions of human relationships – woman as object, black as exotic, fetishized sex as deviant (Schroeder & Borgerson 2003; → Women in the Media, Images of).

Further work would be useful to delineate how fetishization works in a wide variety of communication contexts, and how fetishism has developed as advertising shorthand for

various desirable attributes to be associated with brands and products. Key questions remain about how fetishization creates value. Just as art historians and literary scholars have been adept at tracing the history of icons, types, and characters, so communication researchers could show how these types migrate into advertising and photography, as well as how advertising generates new type and tropes.

## **Fiction**

*Marie-Laure Ryan*

*Independent Scholar*

Fiction is intuitively understood and widely used, both in the public at large and among specialists of literary theory, to refer to a representation not committed to the truth. Yet, the concept is as difficult to define technically as it is easy to recognize. Unlike lies, fiction is not deceptive, and unlike honest error, it is not mistaken (→ Fantasy–Reality Distinction).

The specification of the concept of fiction involves at least three questions. First, what are its relations to narrativity, a concept with which it is easily confused, as the tendency to equate “fiction” with “narrative fiction” demonstrates? Second, how can it be described in pragmatic terms, i.e., as a use of signs? Third, is it a concept specific to language, or can it be extended to other media?

### FICTIONALITY VERSUS NARRATIVITY

Fiction is commonly taken to mean “narrative fiction” (→ Storytelling and Narration). The overwhelming majority of fictions are, indeed, narratives, but not all narratives are fictional (e.g., news or biographies), and fictional texts do not always tell stories, as postmodern novels have demonstrated. The narrativity of a text or message is a semantic issue, i.e., a matter of content, and the audience can decide whether or not the text tells a story by simply decoding its meaning. Fictionality, by contrast, is a pragmatic issue, i.e., not a matter of what the text is about, but a matter of how it is used in social interaction.

Judgments about fictionality, thus, have far greater cognitive and practical consequences than judgments about narrativity. In the first case, the judgment can be right or wrong, and a wrong categorization would lead people to take the false as true, or the true as false. In the last case, we can read a story without asking ourselves, “is it or isn’t it a narrative,” and still process the text correctly.

There may be some semantic restrictions on the content of a fiction; for instance, it can be argued that a fiction must be about particulars and not general ideas, but there are no positive conditions that specify a certain type of subject matter. Even though literary critics have detected “signposts of fictionality,” or stylistic features that betray fictional status (Cohn 1999), these features are not mandatory. A given text could be read, at least in principle, either as a fiction or as a report of facts, as evidenced when Orson Welles’s 1938 radio dramatization of *The War of the Worlds* as a present-day invasion of the US from Mars reportedly created a public panic (Cantril et al. 1940). What tips the user to the fictionality of a text is usually a so-called paratextual device, such as the labels “novel,” “short story,” or “drama” (→ Text and Intertextuality). These labels instruct the user how to process the information of the text.

### PHILOSOPHICAL APPROACHES TO FICTION

In the Renaissance, Sir Philip Sidney characterized the stance of the author of fiction in these terms: “Now for the poet, he nothing affirms and therefore never lieth.” Two centuries later, Samuel Taylor Coleridge captured the phenomenon from the point of view of the audience, by describing the attitude of the reader of poetry as a “willing suspension of disbelief.” There is, however, more to a theory of fiction than the combination of a lack of truth and a non-deceptive intent. Both these features also describe figural language, such as → metaphor, as well as the counterfactual statements of everyday conversation, such as “If the referee had seen that this player was offside, we would have won the game.” Moreover, if fictions are generally false, they often contain accurate statements (e.g., historical novels). They could also be true entirely by accident, as

suggested by the need for disclaimers in fiction films which indicate that any resemblance to real people or events is coincidental.

Interest in the nature of fictionality was renewed in the 1970s as an outgrowth of *speech act theory* and other analytic philosophy. Philosophers of the analytic school were attracted to fictionality because it poses basic questions of truth and reference. Austin (1962) described fiction as an “etiolated” and “parasitic” use of language that does not entail the normal consequences of the speech acts it represents: an actor who makes a promise on stage is not held to honor it. This idea was further developed by Searle (1975) in his pathbreaking essay “The logical status of fictional discourse.” For Searle, fictionality is an operator that affects the status of assertive speech acts. In writing a novel, authors are only pretending to make assertions, or imitating the making of assertions. Though the language of fiction is often indistinguishable from the language of nonfiction, readers are protected from taking its statements to be genuine information because they recognize the author’s act of pretense.

Whereas the notion of fiction as pretense has been widely accepted, Searle’s account had difficulties handling the statements *within* fiction that refer to real-world entities. According to Searle, Conan Doyle pretends to make assertions when he refers to Sherlock Holmes, but he makes serious assertions when he refers to London. It is hard to reconcile this patchwork of fiction and nonfiction with the homogeneous impression that the world of the Sherlock Holmes stories makes on the reader.

Lewis (1978) offered, instead, a theory based on the idea of a plurality of worlds. He defined fiction as a story told as true about another world than the one we regard as actual by a narrator situated within this other world. A nonfictional story, by contrast, is told as true about our world by one of its members. The difference between fiction and nonfiction, then, is a matter of different reference worlds. In Lewis’s model, members of the actual world have counterparts in alternative possible worlds, so that when a novel refers to Napoleon, it does not describe the historical individual, but imports an alter ego of the emperor, possessing somewhat different properties, into its fictional world. For Lewis, the world of the Sherlock Holmes stories is not created by a mixture of fictional and nonfictional statements, but by a fully fictional discourse that describes a possible world linked to the actual world through many common features (or counterpart relations). This idea of counterpart relations solves the problem encountered by Searle when the text refers to actual entities. One of the most important implications of Lewis’s account of fiction is the self-denying quality that it attributes to this mode of expression: fiction is not just a product of the imagination, but an invention that passes as a report of facts. An overt prescription to the imagination (“think up a one-eyed, one-horned flying purple people eater”) and *if . . . then* counterfactual statements are not fiction, because they construct a world explicitly flagged as “other.”

While Searle’s and Lewis’s accounts were designed for fictions in verbal language, Walton (1990) put the theory of fiction on a transmedial track by relying on the notion of make-believe. Drawing an analogy between a certain type of children’s game and the representational arts in general, Walton defines fiction as a “prop in a game of make-believe” – an object that inspires imagining rather than belief. Just as children playing cops and robbers adopt imaginary personae and pretend that a certain tree is the jail, spectators of a painting of a ship pretend that they are facing a ship, and readers of literary

fiction pretend that the text is the description of a world that exists independently of the text, when they know that this world is in reality the product of the author's discourse. In all three examples, fictionality derives from a decision by the "player" to take something as something else.

## FICTION IN DIFFERENT FORMS OF MEDIA

As demonstrated in the case of language, fictionality is not a feature inherent to semiotic media, i.e., media understood as a type of signs associated with particular sense modalities (→ Media; Modality and Multimodality; Semiotics). Just as verbal texts can fall on either side of the divide, the concept of fictionality is applicable to the uses of other signs, modalities, and technologies in a number of distinctive ways.

Fictionality is a relevant analytical concern for all technological and institutional media that involve a language track: film, drama, opera. It is because the actors of *film and drama* engage in an act of pretense that these media can be considered fictional. In drama, pretense is inevitable, but in film, it is optional, since the camera is able to record both authentic and simulated events. Film (television, video), consequently, can be either fictional or documentary (→ Film Genres). As a form of make-believe, fictionality also cuts across gestures and other embodied communication: pantomime and acted silent movies are fictional, practical action is not, and dance is fictional only when the dancer impersonates a character. In purely instrumental music, a medium which cannot articulate a specific content, the distinction becomes inapplicable, at least in a literal sense.

*Photography* can be considered fictional when it captures role-playing models rather than people "being themselves" (→ Photography). In the case of → painting, the concept of fictionality is more controversial. One could regard as fictional the pictures of models who pose as historical or mythological creatures, or pictures illustrating stories (in which case their fictionality would be derived from a verbal text), and as non-fictional realistic portraits of real individuals. This categorization, however, leaves most paintings in a conceptual no-man's land between fiction and nonfiction: the fictional status of a Picasso portrait of a specific person in Cubist style is not only undecidable, but irrelevant to the understanding of the painting.

The concept of fictionality is better applicable to the images of film and photography than to painting because they are obtained through a mechanical recording device that gives them documentary value. They become fictional when this value is playfully subverted. The necessary condition for a type of signs, with any supporting technologies, to be considered as fiction is that they can also be used to make truth claims.

## **Fictional Media Content**

*Emily Keightley*

*Loughborough University*

Media content takes many forms and is differentiated by → code and convention, → genre and technology. The term “content” refers to the nature of the representations that are communicated by media genres and technologies rather than the medium in which they are carried. Fictional media content is one such classificatory grouping, signaling a similarity in the nature of the content on the basis of its intended relationship to a given reality, regardless of the specific media genre or technology in which the content is conveyed. This type of media content has received varying degrees of academic attention in communication, media, and cultural disciplines (→ Media Production and Content).

### **DEFINITIONS AND FORMS OF “FICTION”**

Etymologically, the term “fiction” derives from the Latin root *fict-*, which in its original usage referred to an activity rather than cultural content. However, in contemporary culture fictional media content refers to all media output that is not concerned with representing events or issues as they are lived or experienced in the real world.

Media fiction commonly refers to content with a narrative structure in contrast to the singular use of images, for example. Most commonly, this covers media content that takes the form of a story, ranging from literary novels to television drama (→ Drama in Media Content). Some fictional content takes the form of a discrete, one-off story-narrative that can vary in length and is characterized by the introduction of a setting and collection of

characters, a set of main events or developments in the plot, and a conclusion where the plot is resolved, such as in feature films, radio plays, and novels.

Alternatively, the narrative structure of fictional media can take an *episodic form*, where short sections of narrative are broadcast or published in succession. This would include → soap operas or → comics, where an indefinitely continuing narrative is constructed. Cast members may be introduced or may leave, but the core themes and settings of the program or publication remain the same. For instance, the British soap opera *Coronation Street* has run continuously since 1960. Other narrative forms of fictional content include the serial, where a story-narrative is divided into several episodes that build toward a conclusion in a final episode, commonly called a “series.” The more popular series may introduce subsequent series using the same characters or themes. Televisual forms of these narratives are particularly lucrative as they can be released in DVD/VHS format (→ Digitization and Media Convergence).

Fictional media content involves many *cultures of production*, ranging from the relatively solitary to the collective. However, most fictional media production begins with a written narrative. In the production of fictional literature, this is the main stage of production and it is followed by an editorial process. The writing of fictional literature is traditionally conducted by a solitary writer; however, it is becoming increasingly common for popular fiction novelists to co-author work, for instance the popular fiction writer Clive Cussler has co-authored several novels with his son. Popular fiction of this kind has received popular and academic criticism for its tendency toward formulaic plots, encouraged by the commercial pressures of the publishing industry.

The production of fictional feature films and television fiction frequently involves the production of a *written narrative* (→ Storytelling and Narration). This takes the form of a script or screenplay and, like fictional literature, this can be produced by a single writer, or as part of a writing team. In fictional content for the broadcast media, this is the first stage of the production process. It is followed by the practical planning of the production process, including costing and location planning. Choices at this stage play a crucial role in determining key features of the finished fictional content. The creative construction of the fictional content is then further developed in the processes of production by various members of production teams including actors, producers, and directors. Similarly to fictional literature, this is then followed by an editing process.

Fictional content is determined in relation to its conventional *conceptual opposite: factual content*. Whereas factual content claims to naturalistically represent real-world events, as for instance in current affairs programming, representations involved in fictional content refer to invented happenings despite bearing the recognizable conventions of narrative meaning. This means that although fiction may have a recognizable referent, such as a person or event, that referent may never have existed in lived experience. For instance, although the British soap opera *Coronation Street* features a recognizable community in spatial and communicative terms, it has not existed, nor will it ever exist, outside of the televisual text. Fictional media content is also contrasted with factual content on the basis of its narrative structure, where fictional features such as plots, characters, and scenes are set against nonfiction mass media content that features a non-narrative structure, such as the current affairs program, the news, or documentary (→ Documentary Film).

## THE LEGACY OF LITERARY CRITICISM

The distinction between factual and fictional media content has had considerable implications for the ways in which fictional content has been studied. The critical repertoire for assessing fictional content is largely derived from literary criticism. As well as providing evaluative terminology, such as labeling discrete representational content as “texts,” literary criticism has shaped the critical attention paid to fictional media in important ways. It has institutionalized the *separation of factual and fictional content* and as a result fictional media content has since been evaluated in these dichotomous terms. The development of this division in the evaluation of written or dramatic content has been maintained and applied to new forms of media content as they have developed through the nineteenth and twentieth centuries.

Particularly in early media studies, this critical legacy is easily visible. Fictional media content has often been evaluated on the basis of form and internal structure in relation to other fictional forms. Their subversive and political potential was, in the early period of media criticism, largely overlooked given their perceived disconnection from the reality of public and social life. In contrast, nonfiction representations have been considered in their relation to lived reality and their representational attributes have only more recently become subject to investigation.

Although having a long history in literary criticism, this separation was shared by media studies as it emerged in the early twentieth century out of the social commentary and philosophy of the *Chicago School*. The focus on the mass media’s role in political communication and participatory democracy resulted in the critical elision of fictional media content in early media studies in favor of a focus on the news and current affairs media (→ New Journalism). Fictional media content, like written fiction, was considered a superficial counterpart to the serious business of civic participation. The examination of media content was adjudicated through the criteria of realist aesthetics, espousing either recognizable political credentials or aspiring to an ideal of objectivity. Fictional media content, certainly in its most popular forms, could make precious few claims to these rationalist benchmarks of cultural value and so received limited critical attention until well into the twentieth century.

The second bequest of literary criticism is the *distinction between popular and literary fiction*. This involves superimposing a hierarchical framework onto literary texts, creating a canon worthy of critical attention with the others cast aside as mass entertainment. F. R. Leavis in the 1920s and 1930s is one such literary scholar who has propagated this distinction. A cultural pessimist, he decried popular genres with mass appeal, such as romance fiction, as evidence of a crisis in literary standards, in contrast claiming the qualitative value of particular “classic” forms. Ward (1989) tracks the associated pessimism regarding mass mediated culture emanating in large part from the Institute of Social Research in Frankfurt. The Frankfurt School positioned mass entertainment, which was largely fiction, as antithetical to political engagement. So, where literary criticism allowed for a canon of elite texts based on formal textual attributes, the Frankfurt School evaluated media texts on a similar conservative textual basis, casting the vast majority of fictional media as de-humanizing and appealing to the lowest common denominator.

In elite, conservative circles, attention to fictional media content was framed largely as fiction's potential to incite criminal or antisocial behavior in the working classes. Springhall (1998) discusses this form of critique in relation to anxiety over crime and gangster movies of the 1930s and their potential effect on the young. Popular concerns over the effects of fictional media content continue to be prevalent and are largely premised on the assumption that fictional media can elicit a direct response from their audience. For example, there have been moral panics over so-called "video nasties" and violent behavior in children, fuelled by a few high-profile criminal cases such as the murder of James Bulger in 1993. In Marxist circles, critique was framed rather differently, centering on potential inaction rather than unregulated behavior as popular entertainment was perceived as threatening the possibility of radical thought and public engagement (→ Popular Culture).

### **FEMINIST CRITICISM**

In contemporary consideration of fictional media content, the evaluative dimension of textual analysis applied to fictional texts has largely been abandoned, at least in academic circles, as a result of several related shifts. Feminist media theory, particularly in film studies, has been one of the central intellectual movements away from hierarchical frameworks of cultural value applied to fictional media content. It has attacked the lack of attention paid to fictional content and exposed the gendered nature of the omission (→ Feminist and Gender Studies). The division of fiction and nonfiction media content has not only been premised on the putative cultural value of fact and fiction, but on the gendered affiliations of those two forms. Masculine genres coalesce around nonfictional forms, particularly in terms of television and literary media, while fictional content, particularly soap opera and romance fiction, has been considered to be feminine in its modes of appeal. This gendered division has meant that feminist critique has loomed large in the intellectual consideration of fictional media content. Bearing many of the technical hallmarks of literary criticism, such as a focus on the text as a carrier of meaning, feminist media criticism has seriously considered previously ignored forms of popular entertainment as worthy of critical attention, evaluating fictional works not in hierarchical terms relating to their mass appeal but on the basis of their relative textual attributes and psychological or other benefits to the (female) consumer (→ Women's Media Genres).

Some of the early work in this domain focused critically on the gendered nature of fictional media content, for example considering how stereotypes are drawn on and reified in the texts, comparing gendered reality with gendered representations (→ Gender: Representation in the Media; Women in the Media, Images of). Much of the work on gendered stereotypes considered television soap opera and Latin American telenovelas as well as prime-time content. For example, Jenrette et al. (1999) give a comprehensive account of the stereotypes of Hispanic women deployed in daytime soap operas and measure them against their own account of Hispanic women. In the field of film studies, the gendered nature of fictional content was also receiving burgeoning attention. Mulvey (1975) has been central to this movement, repositioning the female critic in relation to the masculinized text. Here, fictional content is considered a dimension of political interaction rather than disconnected from everyday politics (→ Film Theory). The content

of media fiction is seen as connected to everyday reality, bringing fiction and nonfictional realities into view of one another. Film theory has also provided a plethora of alternative frameworks for analyzing fictional media content including “auteur” theory, genre analysis, and narratology. These approaches share a resounding emphasis on the meaning of the fictional text in itself.

### **CULTURAL STUDIES APPROACHES**

Cultural studies approaches to media content form a second strand of the critical assessment of fictional texts, involving a shift away from the meaning-inherent-in-text mode of analysis. This shift is not completely distinct from feminist media research, as many theorists belong to both intellectual fields. From the Birmingham Centre for Contemporary → Cultural Studies emerged a new approach to media texts that emphasized a new relationship between the audience and the media text. This became known as the active audience approach. Hall et al.’s (1980) encoding/decoding model suggested that meaning does not inhere in the fictional text but is a result of a negotiation between the audience and the text. This theoretical development was a watershed in the consideration of fictional content. Rather than being considered as a reflection of a given reality, fictional texts were involved in its constitution. Fictional content in this sense is allocated an equally important role in the construction of lived reality as nonfiction, therefore legitimating fictional content as worthy of critical attention. Dethroning the formal properties of the text and contextualizing fictional content in everyday life has resituated fiction within lived experience.

This has positioned cultural studies as central in redressing the critical imbalance between fiction and nonfiction media content. Feminist theorists have been keen to exploit the new seriousness with which “female” genres are being considered. Hobson (1982) has considered the practical and imaginative pleasures of the soap opera *Crossroads* and Hermes (1998, 166) has suggested that consuming popular fiction can have as much potential in the articulation of cultural citizenship as traditional, masculinized forms of communication. This engagement with fictional content has not revolved solely around the everyday politics of gender. The politics of class and ethnicity alongside gender and their intersections have also been key features of the cultural turn toward fictional content. Fictional forms are seen as resources for the construction of plural identities and also as providing literal and imaginative space for their articulation. The polysemic nature of fictional content makes it suitable for appropriation as resources for resistance and the subversion of dominant ideologies. In this theoretical perspective fictional media content is afforded the same active potential for constructing progressive meaning as nonfictional forms (→ Cultural Studies: Feminist Popular Culture).

### **BOUNDARIES BETWEEN FICTIONAL AND NONFICTIONAL MEDIA CONTENT**

Alongside the rebalancing of fiction in its relationship with factual content, there has been a parallel challenge to the very nature and premise of this distinction. This involves retracing the boundaries between genres of media content, specifically documentary form and drama. In early work of this nature, features of fictional content such as narrative

structure were considered to be migrating across formal boundaries, resulting in hybrid genres such as dramadoc and docudrama. The boom in “reality television” alongside historical content heavily reliant on dramatic techniques of reconstruction has intensified this debate, stimulating consideration of the implications of increasingly blurred boundaries between fictional and factual media genres. This has historically been met with pejorative accusations of falsehood and fakery in academic and popular forums (Petley 1996). Fictional imperatives of entertainment were perceived as compromising the validity of factual genres. However, this view is being revised, taking into account the constructed nature of both factual and fictional representational forms and problematizing outright rejections of cross-fertilization between factual and fictional genres. Winston, for example, suggests that previous accusations have failed to appreciate the “symbiotic connection between documentary and ‘reconstruction’” (2000, 106).

Postmodern critics have taken this blurring of boundaries a stage further to suggest that any differentiation between factual and fictional content has been removed altogether and that a disconnection of representations from their referent, factual or fictional, has rendered any evaluation on the basis of a connection to reality impossible. In this sense the organizing principle of mediated content is pastiche, and simulacra replace authentic signs, making coherent narratives or claims to lived experience redundant. Accounts of past lived realities cannot be separated from fictions, rendering accounts of the past subject to endless play and limitless revision. In postmodern media studies, the integrity of the criteria of fictional and nonfictional content has been compromised. While postmodernist critique is useful in undermining the rigid adherence to the critical dichotomy of fact and fiction, clearly it does matter for many people whether we have accurate, credible reporting of wars or financial fraud, or whether the Holocaust is represented as myth by anti-Semitic revisionists (→ Postmodernism and Communication).

A less radical response to the blurring of factual and fictional content has been to separate the notion of “truth” from fiction and nonfiction. The common-sense assumption that factual content can make claims to truth where fictional content cannot is re-evaluated, particularly in respect of historical accounts. Rather than tying the notion of truth to life as it was lived, truth is about making a contextual meaning of the past that has efficacy and resonance in the present. Stella Bruzzi (2000) argues that in documentary there are two kinds of truth: the factual images that we see and the meaning that can be generated from them. The reality depicted in a documentary remains a representation and is more than a collection of facts; claims are made to broader truths beyond the boundaries of the literal textual content. In this sense, fictional content can also make truth claims. John Steinbeck’s portrayal of the American dust bowl of the 1930s in the novel *Grapes of wrath* is perhaps one of the most moving and “truthful” evocations of the historical moment of the Depression. It makes sense of a period that speaks beyond those fictional experiences to a broader sense of truth. In contemporary filmic forms debates move away from the “facticity” of dramatized history to the nature of the truths that emerge. Spielberg’s historical drama *Schindler’s List* and Lanzmann’s documentary *Shoah* have been subject to these debates over claims to truth.

The relationship between fictional and nonfictional media content is becoming increasingly complex, but the intensifying intellectual debates surrounding it are generating ever more nuanced and sensitive accounts of media content and the politics of its classification and

evaluation. This increased critical attention in terms of both importance and definition of fictional media content has re-charted traditional attributions of value in media studies and forced the categorization of media forms to be substantially revised.

# Field Research

*James A. Anderson*

*University of Utah*

Field research is a somewhat dated term that is used to describe research conducted under the naturally occurring contingencies of unmanipulated or naturally manipulated contexts. In this usage it is contrasted with laboratory research, which is to be conducted under highly controlled circumstances and in fully manipulated contexts. In this contrast, field research is considered to provide relevance to everyday life, and laboratory research rigor to the conclusions drawn. In the traditions of law-seeking sciences, laboratory research returns findings of the highest generalizability and, therefore, of greater value. This attribution, of course, politicizes the relationship between different → research methods and the sciences that depend on them.

## TYPES OF FIELD RESEARCH

Setting the political issue aside for the moment, old-school field researchers catalogue objects, places, and spaces, do content analysis (→ Content Analysis, Qualitative; Content Analysis, Quantitative), perform → surveys, do → case studies, hold → interviews, conduct focus groups, do protocol analysis, perform nonparticipative → observation of naturally occurring behavior, or use similar research methodologies. The cataloguing of objects, places, and spaces generally has to do with their role in some activity. Objects might be a tool, a ceremonial element, or ritual implement; a place might be a geographical or architectural configuration that facilitates an enactment or set of beliefs, for example, a study of the cathedrals of Europe as a cultural expression or the role of the ancestral Puebloan ruins of Chaco Canyon (New Mexico) in New Age practices; a space might be a classroom or office designed to materialize practice of control or the expression of status.

Content analysis focuses on the components and elements of texts of every sort – written, spoken, visual, linguistic, and nonlinguistic. A survey is a descriptive methodology that, as its geological and geographical heritage suggests, attempts to catalogue the demographic and/or psychographic attributes and traits of a group of people or ideational domain. A case study is an extensive description of a (usually) single exemplar of some social behavior, group, organization, etc. It ordinarily involves nonparticipant – and sometimes covert – observation of the targeted behavior and individuals. Interviews can be highly structured short-form, where the answers require little additional coding prior to analysis, or open-ended long-form, with answers of several paragraphs that require extensive coding prior to analysis. Focus groups are usually conducted by bringing individuals of interest to the researcher together for a session in which they will participate in a guided discussion on a researcher-chosen topic. Protocol analysis takes a variety of forms, but each involves collecting information during the process of some respondent-initiated, ongoing activity (protocol) for the purpose of learning something about the activity itself or the activity's consequences for the practitioner. Nonparticipant observation is any sort of covert (e.g., behind a two-way mirror) or overt (fly-on-the-wall) observation, in which the observer is neither part of the group nor a participant in the activity being observed.

### METHODOLOGICAL STATUS

The significant *components in all of these methods* are: (a) the targeted object, place, space, or text is considered an actuality whose existence does not depend on the research; (b) the respondent retains a high level of autonomy of action; (c) the researcher is considered a neutral element and not a stakeholder in the object/place/text/action; (d) the relationship between the researcher and the respondent is not part of the results; (e) the respondent's behavior is unconsidered and not deliberately enacted to achieve some agenda (other than the researcher's); and (f) the responses given are (therefore) ingenuously true. The purpose of the researcher is to collect information about an object/place/space/text, the respondent or the respondent's state of mind, and/or about the course or consequences of some action. The data are descriptors of the respondent and/or the action, and the findings are considered descriptive rather than causal in character.

The fundamental *limits of the sort of research* are that the findings are always contingent on the particular – the particular objects, persons, or actions that are the source of the data. Given proper sampling procedures, one is justified in generalizing to larger populations but one is still limited to the particular conditions of that population. Populations shift, attitudes change, social practices evolve, technology intrudes, economies fail, governments fall out of favor. One would be hardly justified in using a survey of political attitudes taken as few as 10 years ago to describe a current situation. The findings may still be applicable, but the evidence would be missing.

The generalized claims that are advanced from descriptive data are considered tentative until they can be demonstrated under controlled experimental conditions conducted in the laboratory (gold standard) or in the field (lesser quality; → Experiment, Field; Experiment, Laboratory). Field experiments attempt to take advantage of differences that develop across some natural divide. For example, we might be interested in attitudes toward aggressive behavior for families with video game technology (VGT) and families without. Based on claims in the literature that participation in violent video games leads to a desensitization toward aggression, we might hypothesize that families with VGT will show more accepting attitudes toward aggression than families without VGT.

Such field experiments suffer from a common vulnerability in that the respondents self-select into the treatment categories. In our example, the very circumstances that led one family to buy VGT and another not may be associated with attitudes toward aggression. People who say “oh, it's all harmless fun” might be very different from those who say “I will never allow that stuff in my house.” Laboratory experiments would achieve much higher rigor by being able to randomize assignment across the “harmless” and “never” folks, but in turn their findings would lose relevance to how people actually live.

### POLITICS OF METHOD

The debate between rigor and relevance occurs across all science disciplines, but it is particularly pointed in the human sciences where laboratory, field, clinical, and applied sciences all vie for attention and funding. Most of the research generated in the history of the communication discipline has been traditional field research with content analysis and survey methods leading the list (a notable exception has been the message effects

studies). This characteristic would put the discipline in the prescientific category using the traditional criterion of ranking sciences by the clarity with which they can attain causal explanations. Communication would be considered still in its descriptive stage with the fundamental axioms of the discipline yet undiscovered and its paradigmatic configuration yet unresolved. Causal claims are certainly advanced, but they are routinely challenged as well (→ Communication as a Field and Discipline).

Naturally, there are practitioners who do not care to think of communication as pre-scientific. Some of these would argue that solid experimental work is being done and good, causal theory developed. Others might pick up the sociology argument that the relationships of interest are not materially determinant ones but rather contingent, social processes. If that argument is true, then the relationship between field approaches and laboratory approaches reverses itself because the laboratory work can never achieve the relevance necessary to make its findings of value. By being a field science, we are at the top of the game.

### CHANGING CHARACTER OF FIELD RESEARCH

In the early 1970s, most of social science was marked by what was called “*the interpretive turn*” and a distinction between objectivist and interpretivist research began to come to the fore. The term “field research” came to be associated with objective methodologies, and such terms as “naturalistic inquiry” and “hermeneutic empiricism” with interpretive approaches. An additional layering was introduced as postmodern sensitivities for power relationships began to question the justification for imposing researcher-driven meanings on respondent actions and answers. In this paradigm, the researcher was no longer considered neutral but an obvious stakeholder in the outcome; the relationship between the researcher and respondent became a significant element in the character of the data; and the research itself became a social process available for analysis on its own. The respondent lost the cloak of ingenuity and became a modal actor in the research text. The position of postmodernism (to the extent that postmodernism can take a position) was that there was no place for the researcher to stand in order to objectively observe and describe the condition of the other (→ Objectivity in Science; Postmodernism and Communication).

This epistemological variation has been called a paradigm shift, in what has been so far shown to be a gross overstatement. There is an engaging group of scholars, who support interpretivism, postmodernism, one or both, but they have hardly swept the field. What has happened is that the term “field research” became further politicized. Now it is burdened not only by being “descriptive” but also by being “objectivist” and “modernist.” The ostensibly harmless, “Oh, I see you are doing field research,” can be akin to throwing down the gauntlet.

### INTERPRETIVE FIELD METHODS

The principal difference between interpretive field methods and objective field methods is the former’s commitment to member understandings and the latter’s dependence on some form of literal meaning. Interpretivists hold that nothing reads itself; the meaning of things is rarely obvious; and what can be understood through impersonal observation is merely a surface reading. To understand objects, space, place, texts, beliefs, and actions,

one must be involved in the social processes that are the source of their → meaning. Consequently, passive observation becomes participant observation (surveys, especially attitude surveys, are rarely used); texts are understood not only in their content but also in the activation of that content; and objects and space are considered not only in their static properties but also in their dynamic use.

Participant observation begins by establishing membership with the social grouping that sustains the action or belief set of interest. Interpretivist epistemology holds that it is the relational terms of the group that establish the meaningfulness of what the group does or holds true, or what group members acting as members do or believe. Consequently, to tap into that meaningfulness, the observer must achieve some level of a member's understanding through participation.

A similar prior assumption directs the analysis of texts (→ Discourse Analysis; Text and Intertextuality). The facts of the text (this word rather than that word) are necessary to know, but are insufficient to understand, the force or power to influence of the text. That information comes through analyzing the interpretive processes through which the text is activated or made available to the action. Further, these processes are not simply cognitive engagement; interpretation does not begin and end "behind the eyes." It is in the social processes of interpretation that texts achieve their full significance.

Objects, space, and place are treated in the same way as texts: an inventory of the static components cannot by itself lead to an understanding of their meaningfulness. That meaningfulness arises and is made apparent when the object/space/place is put into play.

### **STATUS AND POLITICS REVISITED**

If one were to do field research on the techniques and tactics of objective versus interpretive field researchers, one might find, in the middle of things, little difference in what they do. It is not a question of a special set of methods that defines the two groups, although there are some clear differences. The primary difference in method is the prior preparation of membership required of the interpretive approach, but there is a behind-the-scenes, epistemological structure that turns the whole thing upside down.

In interpretivist epistemology, field research is always preferred to laboratory research, and grounded approaches that move up from the action are always preferred to hypothetical-deductive approaches that move down from prior theory. This configuration seems to echo the sociology argument about the primacy of field methods, but, in fact, objectivists and interpretivists will both make the sociology argument and then disagree on epistemological grounds. The result is a mutual rejection of what the other holds dear. Ideas compete and so do their adherents. In the real world of science, things are neither neat and tidy nor necessarily friendly.

## **Film Genres**

*Catherine Preston*

*University of Kansas*

A working definition of film genre depends on the purposes toward which it will be applied. The audience approaches genre as it is generally defined as kind, sort, or style. Categorizing films this way has been in use going back to the advent of film production and consumption (→ Film Production). For example, the “actuality” (early documentaries; → Documentary Film), the “comedy” (*The Waterer Watered*), and the “Western” (*The Great Train Robbery*) were all references that theaters used to advertise the film that accompanied the vaudeville show of the week (→ Cinema). Early filmmakers learned to cinematically code a narrative as early viewers learned how to understand these new codes, and the film company duly noted their response (→ Code). This relationship has continued to the present day. Genres offer fairly reliable means by which the industry can attempt to repeat and capitalize on previous box-office successes. They also provide audiences with knowledge they can use to organize their own viewing. In this sense, the rationale behind film genres has always been that of production balanced by consumption, and like the study of → stars, genre has always transcended the traditional boundaries of film studies.

The study of film adopted a more specific definition inherited from the study of art (→ Art as Communication) and literature. This schema categorizes films according to specific structure or thematic content through a consideration of the narrative and stylistic or formal aspects, setting or mise-en-scène, costume, character, and → cinematography. “The problem has always been to search for agreement about which elements or characteristics are essential to the category named, whether ‘idyll’ or ‘melodrama,’ ‘epic,’ or ‘tragedy’” (Chatman 1999, 52).

Hence, some film genres have their origin in literary genres: comedy, tragedy, and melodrama. Others are based more specifically on cinematic capabilities such as actualities, tableaux, travelogues, animated cartoons (Stam 2000, 14; → Animation). Genre criticism as an area of film study has historically been concerned with mapping the boundaries of each class, and determining which films belong where, while ignoring larger issues such as to what extent genres are “transcultural,” and whether “genres” exist beyond the critics’

→ discourse. In the 1990s many critics understood that what was at stake in defining film genres was the ability to organize and control the discourse around film. “The central assumption of genre criticism is that a work of art and communication arises from and is inserted into a specific social context and that its meaning and significance is constrained and limited within this context” (Ryall 1998, 328).

## EARLY DEFINITIONS

The introduction of genre criticism into the field of film studies represented a “tactical attempt to think beyond auteurism” (Anthony Easthope, cited in Hutchings 1995, 59). During the 1960s film critics, both within and outside academia, were attempting to legitimize the study of film within the university. Those interested in genre criticism argued that all film had far-reaching sociological, cultural, political, and economic implications for society and as such constituted a valuable object of study. Genre study was seen to be more systematic than the auteur approach (Gledhill 2000, 222). It offered a reliable classification system for film that was less subjective and more inclusive than that offered by auteur theory, and it was the advent of a serious consideration of popular film as art within the purview of the academy. In other words, the focal point of film studies shifted, “from film’s aesthetically ‘transformative’ and medium-specific attributes toward a more empirically based sociological interest in relations between style, popular narrative, and myth” (Berry-Flint 2004, 28).

Paul Watson has usefully suggested that the development of genre criticism can be divided into three areas: text, industry, audience. Each of these has been treated as sources of the meaning and significance of genre by researchers who have typically focused on only one at a time (Watson 2003, 152, 154). As in other areas of media and cultural studies, film scholarship has conceived → “meaning” as a discursive construction that occurs within a particular historical context and is related to other social, political, and aesthetic formations. In reference to the study of film genres, this has meant an ongoing conceptual broadening of the relations between genre aesthetics, industry, and audience expectations.

## AREAS OF GENRE CRITICISM

### Text

As a theory and method adapted from the study of literature, genre criticism has primarily focused on the Hollywood film text, and specifically on narrative and → iconography, themes and motifs (→ Hollywood; Film Theory). An early model argued that narrative (→ Storytelling and Narration) and iconography are structured to communicate cultural myths.

Attributing the popularity of the Western to myth, Bazin argued in the 1950s that myth manifests itself in the Western through the portrayal of Manichaeic struggles between the forces of good and evil. The mythic quality stands in a “dialectical” relationship with the Western’s specific historical settings, and because of this it takes on epic and tragic qualities. Thus the Western’s formal attributes are “simply signs or symbols of its profound reality, namely the myth” (Bazin 1971, 142; → Sign). Other critics also asserted

that, through iconography, particular “genres” addressed and attempted to resolve in imaginary terms the needs and contradictions of American society (Warshaw 1954). Iconography was identified as predominant in analyzing generic identity.

When genre criticism was taken up in the 1970s, the exceedingly formulaic Western and gangster films were used as exemplars of genre in general for their narrative and iconography. From these categories, genre critics elaborated the tone, purpose, subject, and audience, and the thematic identity that bound them as a text. In other words, genres were what critics said they were. The repetition of genre motifs can only be experienced intertextually (→ Text and Intertextuality). Genre studies set out to define and codify such intertextual fields. In this way, it created its own objects rather than simply discovering them. Early theorists argued that genre conventions are found in the films. Later theorists argued that genre categories are imposed (Tudor 1974, 135; Berry-Flint 2004, 27).

The next step in the development of genre analysis was the incorporation of Lévi-Strauss’s work on myth. Jim Kitses in *Horizons west* (1970) laid out a series of oppositions such as individual/community, nature/culture, law/gun, that structured the Western. Will Wright’s *Sixguns and society* (1975) sought to identify structural formats within the historical progression of the Western and relate these to broader shifts in American society (→ Structuralism in Visual Communication). Both models maintained that genres signified myths “crystallizing our fears and desires, tensions and utopias” (Stam 2000, 126). A further development of this divided Hollywood genres into films that re-establish social order, such as the Western and the detective film, and those that work to establish social integration, such as the melodrama, comedy, and musical. This “gendered” model argued that genres function as “cultural ritual,” either integrating fractured communities or restoring order, often through mediation, to conflictual groups (Schatz 1981). Problematic in this approach was the application of thematic analysis to genre definition because of its overinvestment in the Western. For example, melodramas lacked the visual and iconographic unity of the Western and were largely left unanalyzed. In the acceptance of form/content distinction most of these avenues reverted to a form of auteurism. Other sources of meaning, most notably the audiences’ relation to themes or iconography as sites of meaning were not considered.

In the late 1970s, genre criticism was influenced by ideological and psychoanalytical theories applied to classical Hollywood film (Willemsen 1994). In an effort to move beyond use of myth and ritual as primary operations of genre, critics argued that identity of genres depends on the specific relations established between a range of elements rather than on the selective representation of particular motifs (Gledhill 2000, 224). Popular genres represent patterns of repetition and difference, in which difference is crucial to the continuing industrial and semiotic existence of the genre. Proposing a model based on the balance between generic verisimilitude (ensuring audience recognition) and cultural verisimilitude (ensuring a film’s relevance to the audience), Stephen Neale argued that genre studies consider the changing historical context within which genres are produced. (Neale 1981). The attention to history in genre criticism raised the question of the impact of contemporary theoretical frameworks on genre analysis, such as postmodernism and postcolonialism (→ Postmodernism and Communication; Postcolonial Theory). Is there a distinctly “postmodern” genre or is it more accurate to refer to the impact of postmodernism on film as a style? The postmodern genre was characterized by irony, parody, hybridity, bricolage, and pastiche (Collins 1993). *Blade Runner* was referred to as the

classic postmodern film. But since most films contain these elements to a greater or lesser degree, genre criticism was yet unable to demarcate different classes of film.

In light of the insights of postcolonialism and transnational identity, Janet Staiger has suggested that the term “hybridity” is a misnomer for the kind of genre mixing that goes on within American film (→ Hybridity Theories). She proposed substituting the term “inbreeding” in recognition of the dominant role Hollywood has played in globally exporting cinematic style and form through genres. Applying the term “hybridity” to postcolonial and transnational films that are a *mélange* of global influence organized around the “cultural dominant,” Staiger acknowledges their creative force and ingenuity. She reserves “inbreeding” as a descriptor of the American film industry’s lack of cinematic creativity as production becomes increasingly cannibalistic through seemingly endless sequels, prequels, and remakes (Staiger 1997).

### **Audience**

The advent of audience studies in the early 1990s defined genres as “socio-discursive frameworks” brought to the viewing experience (→ Audience). Genres are provisional and malleable conceptual environments, in which viewers participate in construction of meaning and modify frameworks. They refer to cognitive repositories of images, sounds, characters, events, stories, scenarios, expectations, etc. (Berry-Flint 2004, 27). Genre definition is part of a larger question concerning cultural perception and structures of → visual communication. Approaching genre from an audience perspective is to study how cinematic artistic value and use value is constructed by the audience. It is an implicit communication between producers and consumers, allowing the audience to approach any given film from a “horizon of expectations” within which the film is comprehensible (Neale 1990; Watson 2003, 160).

The concept of genre helps explain the use of conventions and → stereotypes (→ Social Stereotyping and Communication; Stereotyping and the Media) and their function in the social world of the audience, without assuming a fixed set of codes for representing reality (Gledhill 1997, 351). Acts of communication are intelligible only within the context of shared conventional frameworks of expression, a contract between viewer and producer so that particular expectations occur, which then allow the acceptance or deviation from previous modes of intelligibility (Culler 1975, 147). It is a “conceptual space,” in which issues of texts and aesthetic overlap with those of “industry and institution, history and society, culture and audiences” (Gledhill 2000, 221). Reframing Robert Altman’s argument that filmic excess is an organized system of meaning, Linda Williams argued for “body genres” as made up of those films whose success is measured by “the degree to which the audience sensation mimics what is seen on the screen (Williams 1998).

### **Industry**

Genre is also analyzed as an economic method of producing, marketing, and distributing film and thereby attempting to control the ongoing uncertainties of the business. For some critics, the appeal of studying genre is that it offers the opportunity to deal with

cinema, and Hollywood cinema in particular as both an industrial and a popular medium (Hutchings, cited in Watson 2003, 151; → Political Economy of the Media).

From the audience's point of view, there are so many films available today on the web and in the form of DVDs that, in the absence of a title, generic categorization is the primary means of accessing the medium whether the location be a library, archive, catalog, or the web (→ Internet). Thus, while the critic might start with an individual film in seeking to understand its place in the generic regime, the audience learns to identify and thereby choose films through an industry-defined classification system that then becomes the frame through which both significance and value are determined.

Critics who analyze genre through the industry look at how global cultural flow has impacted film production. The increased production of genre films specifically for export to a global audience is one way the industry has attempted to deal with diminishing domestic ticket sales. Action films are so expensive to make that producers will not expect to recoup the cost from the domestic audience. They will create the film intending to export it, and these become identifiable in part by their lack of dependence on dialogue for narrative progression.

Hollywood genres perform two interrelated functions: to provide pleasure and meaning for viewers and to minimize risks of industrial production. There need to be innovation and difference within a generic regime in order to continue to appeal and be relevant to an audience. Genre provides for an atmosphere of reduced risk (Neale 1990). However, since digital technology brings less expensive equipment and the ability to bypass the major distributors by uploading and distributing film over the Internet, the American film industry faces sharply heightened risk as pressure to innovate the Hollywood product is directly proportional to dwindling box office.

## NEW DIRECTIONS IN FILM STUDIES

An example of the effect of new technology on definition of genre is an argument that in the virtual online game, *The Sims*, players rely on the conventions learned in “real life” (Nutt & Railton 2003, 589). It is applied here as a set of codes and practices by which game creators write and game players understand the game play. Genre is not only the categorization of a film but enters into an analysis of the practices of film viewing and film production.

The previous nomenclature used to refer to film types may not be such useful delimiters when it comes to specifically digital production (→ Digital Media, History of). Much genre criticism emerges from analysis of Hollywood classical period and cannot easily be transposed to the contemporary situation. Genre criticism has to do with understanding precisely the “rule”-governed practices of cinema as a mass entertainment medium (Watson 2003, 152–153). If the “cinematic” technology changes those rule-governed practices and if the “cinematic” technology is no longer a mass entertainment medium, is “genre” a term useful to criticism? Contemporary film resembles less the standard texts of the classical Hollywood system and more “multipurpose machines” that initiate “an endless chain of other cultural products” (Schatz 1993, 9–10). In that case, genre becomes an almost meaningless term as there is little that would not be included.

Digital media scholars are considering the usefulness of “genre” within the intensified mode of visual digital culture where genre becomes merely nominal, and the notion of seriality is “coming to replace or subsume genre in more recent manifestations of mass visual culture (Darley 2000, 126; → Digital Imagery). “Serial mode” is seen as a useful term because of Hollywood’s tendency toward sequels, prequels, series, follow-ups, and franchises. Not intended to reference the industry’s aesthetic deficiencies, mode is a more adequate reference to contemporary production trends. It indicates the “most potent distillation of the economic imperatives” having to do with innovation and difference. “Blockbuster,” “event cinema,” “summer movies,” and “special effects movies” describe a mode of filmmaking *and* a mode of viewing. These production trends fall outside the traditional generic method of organization. The term “intermedia” is offered as more appropriate to the “bidirectional system of aesthetic commodification exchange” involving merchandising, product tie-ins, product placement, branding, TV spin-offs, video games, and novelizations (Watson 2003).

Films of the last 20 years exhibit an array of technological, formal, thematic, and stylistic affinities with other media forms (Watson 2003, 153). The term “intertextuality” has also been suggested by several critics as a replacement, though “genre” itself remains a useful conceptual tool both for audiences and those studying the relationship between American film, international film, and global culture (Stam 2000, 129; Berry-Flint 2004). In at least one case, the uses of technology define categories of genre as well as narrative, character, setting, etc. Machinima (machine+cinema) is the term given to film production in a virtual world and it is often referred to as a new “genre” of film. As machinima is neither animation nor live-action filmmaking, it falls outside current understandings of genre. If we make machinima of a class held by a Harvard law professor in the virtual world, *Second Life*, is that a documentary? Andrew Darley argues that in a postmodern culture of intertextuality and radical eclecticism brought about by new technological developments “genre has a far more limited structural role to play,” referring to nothing more than “the general level of a form itself – narrative cinema” (Darley 2000, 144).

# Film as Popular Culture

*Mary-Lou Galician*

*Arizona State University*

*David Natharius*

*Arizona State University*

In the relatively short time since their invention at the end of the nineteenth century, movies have rapidly evolved from a temporary novelty to the most dominant visual form of modern popular culture worldwide. Unlike the print mass media (→ Book; Newspaper; Magazine), which require literate audiences, or even → radio, which requires audiences who understand the originating language, film is an almost universal language of moving visuals that was immediately embraced and popularized not only in the US, but also around the world.

In → Marshall McLuhan's "global village," twenty-first-century films are made by a kaleidoscope of countries and cultures. Virtually every developed culture in the world produces or presents films for theatrical release or home-viewing. In addition, movies specifically made for → Internet distribution can be accessed from every part of the wired world. Using digital video technology on personal computers, even amateurs can be filmmakers (→ Amateur Photography and Movies).

If popular culture is indeed "the culture of the people," then such worldwide popularity justifies the consideration of film as perhaps *the* iconic media form of popular culture. Although film is an art form and a political tool as well as a medium for → news and documentary reporting (→ Documentary Film), movies are the dominant form of entertaining and educating audiences about the human condition or providing a means of escaping from it. A century after its invention, film continues to both reflect and shape the popular culture of individual nations and the global village.

## THE APPEAL OF FILM AS STORYTELLING

The major appeal of movies has always been their ability to give a visual presence to storytelling (→ Storytelling and Narration). From their beginning, movies became a major source of entertainment for the burgeoning movie-going public, first in Europe and then in the US. Film also took its place as a major medium for preserving and reflecting popular trends and expressions of the cultures in which they were created, as well as for influencing and shaping them.

In 1894 in the US, Thomas Edison invented motion pictures that could be seen through a "kinetoscope" by one person at a time. However, the next year in France, brothers Auguste and Louis Lumière created the "cinematograph," which both captured moving images and, for the first time, projected them for multiple persons at the same time. Storefront neighborhood nickelodeons were soon replaced by sumptuous movie theatres that were "the people's palaces."

At the beginning of the twentieth century, the darkened *silent-movie theatre* represented a place where troubles and worries could be forgotten, and where dreams and even

fantasies could come to life. Movies created the kinds of images that could never be constructed in live theatre. Combining wish-fulfillment desires with thrilling action, adventure, and even sensationalism, this new technological miracle transported moviegoers not only to real places with real people – both famous and ordinary, past and present – but also to worlds with characters and creatures that never were or would be. As they watched, audiences could believe that they were actually in places and meeting people most could only imagine before the invention of film. In fact, when moving pictures were first shown in 1895, scenes of trains caused several audience members to jump out of their seats to get out of the way. The moving visuals – and the stirring music – made even pure fiction seem so real (→ Reality and Media Reality).

Moreover, the film actors and actresses who portrayed a culture's heroes and heroines became the twentieth century's *most popular celebrities*. The intimacy of a new technique, the close-up, turned performers – e.g., Mary Pickford (“America’s sweetheart” and then “the world’s sweetheart”) and Charlie Chaplin (“the little tramp”) – into both stars and friends. On larger-than-life screens, they literally and figuratively became larger than the heroes they portrayed. And, in the new symbiotic relationship of film and popular culture, new heroes and heroines were created in new narratives that worked well on the screen.

Thus, visual storytelling supremacy passed from the single community storyteller to the live stage to the movies. The first audiences came mostly from the working classes, but as movies developed, they became popular with all social strata.

## A GLOBAL POPULAR-CULTURE MOVEMENT

By the end of the first decade of the twentieth century, film was a global phenomenon, offering the public stories that were deeply embedded in the cultures in which they were created. Italian filmmakers created lavish sets and gave visual splendor to the classical history of Rome. French filmmakers created both comic and serious stories that reflected their culture's conflicting values, including Sarah Bernhardt in *Elisabeth Reine d'Angleterre*. The British introduced extensive film-editing to cinematic storytelling with *Rescued by Rover*. The Russians created sweeping historical dramas that had the look of documentaries. Denmark and Sweden made contemporary stories reflecting introspective self-reflective points of view, pioneering an approach stimulated by the psychoanalytic theories of Freud.

With D. W. Griffith's *The Birth of a Nation*, first shown to audiences in 1915, the US began its meteoric rise to becoming the film center of the world. Critics now vilify the film as blatantly racist, but when the cultural context in which it was created is considered, the film can be understood as a prime example of how cinema reflects the popular attitudes of its time. Other countries also reflected their contemporary culture in the landmark films that remain icons of cinema greatness, such as Sergei Eisenstein's *Battleship Potemkin* (1925), a reflection of the Russian culture's transition from monarchy to socialism/communism, and Fritz Lang's *Metropolis* (1927), an archetype of German expressionism, which emerged from a culture of artistic and social exploration in a society attempting to stabilize after a failed war.

The 1920s also witnessed the advent of “talking” pictures or “talkies,” which were at first ridiculed by critics but nevertheless adored by audiences worldwide, signaling the

end of the silent era. Full-length animated features like *Snow White and the Seven Dwarfs* also became a cherished part of the popular culture, enlivening culturally embedded fairy tales for audiences of all ages (→ Animation). Advances in full-color presentation made movies even more real.

By the end of the first half of the twentieth century, film was the most popular entertainment medium in the US. As television challenged cinema over the next decades, the content of cinema evolved: Fiction and fantasy still reigned, but there were more examples of the naturalistic reality that was sweeping the world. Partnering with the new popular medium of television, movies provided content as well as production facilities. Ultimately, the accessibility of home video in home theatres ensured the survival of film as popular culture by bringing cinema directly to the people. And in the twenty-first century, non-professional members of the public began to make movies accessible worldwide, expanding the popular culture exponentially.

### **FILM AS CULTURAL MIRROR AROUND THE WORLD**

In spite of recent advances in interactive visual media, films retain their place as the dominant mirror of the society in which they are created – reflecting the popular culture as they simultaneously create and change it. Movies represent the contemporary state of a culture and remain the foremost expression of popular culture. Sweden and Denmark, for example, became known for their stream of consciousness narratives, minimizing the linear development of traditional storytelling. Filmmakers in India, China, Japan, and Hong Kong developed visual styles that continue to be among the most remarkable on film, reflecting the cultures in which the smallest nuances of visual communication are important.

Some of the most important films have come from nations experiencing significant political and social change, such as the dramatic shifts in filmmaking after World War II in Germany and Italy, as well as Japan and China. Japan transitioned from a relatively closed culture to an open market deluged with Western influences, epitomized by Akira Kurosawa, whose films are lauded internationally because of their universal themes that integrate Japanese and Western cultural mythologies.

The French “new wave” films of the 1960s ushered in a new approach to filmmaking that minimized narrative while developing rich and unforgettable characters, and that brought international acclaim to such directors as Jean-Luc Godard and François Truffaut. Reflecting the post-World War II Italian culture, Federico Fellini and Bernardo Bertolucci presented unsettling 1960s and 1970s cinema images of persons in struggles for identity and purpose, which have become international archetypes.

Many of the films produced in the US in the 1970s reflected the cultural conflicts emerging from the country’s struggle and increasing disillusionment with the political decisions of US leaders, such as the decisions behind the Vietnam War and the Watergate scandal. Hollywood’s “A” list directors Francis Ford Coppola, Brian de Palma, George Lucas, Martin Scorsese, and Steven Spielberg all started their careers in the upheaval of the Hollywood studio systems that began in the 1970s (→ Culture: Definitions and Concepts).

## HOLLYWOOD: WORLD CAPITAL OF FILM AS POPULAR CULTURE

Although Europe was the dominant center of film production and distribution until the beginning of World War I, the US has been the center of filmmaking ever since. US movies are often the highest-attended films in other countries. US blockbuster films like “Titanic” have grossed billions of dollars, which speaks to the “popular” in popular culture. Few countries or film studios outside the US have the economic resources to spend one to two hundred million dollars on the production of a movie. The US generates 90 percent of the world’s revenue from film but actually produces only 15 percent of the world’s films: India produces more than twice as many films annually, and the film industries in many countries around the world are vital components of their country’s economic structure.

Despite the importance of the worldwide film industry, films produced in the US have the largest impact on world cinema and its audiences. Cultural critics complain about the resultant “colonizing” of the rest of the world by the US popular culture that → Hollywood both creates and reflects, which is increasingly violent and commercial, and includes rampant product placements for US goods and services (→ Cultural Studies).

# Film Production

*Gianluca Sergi*

*University of Nottingham*

The term “film production” has routinely been used as a way to indicate the stage in the making of a movie where actual filming takes place. While this usage is shared by both the public and filmmakers, it is somewhat misleading in that it draws attention to just one aspect of filmmaking at the expense of a fuller understanding both of the different stages of production and of the key relationships at the heart of the filmmaking process (→ Collective Action and Communication).

## PRE-PRODUCTION STAGE

The earliest stage of production, also known as pre-production or development, involves a handful of people who are in a position to shape a film project. Traditionally an idea is developed or picked up from existing material (be it in the format of newspaper news, books, previous films, etc.). There are several people who are in a position to develop the initial idea and bring it to the attention of a studio. Producers, writers, actors, and directors all have a share in this process, though the relative contribution of each will vary substantially from case to case. In particular, the actual influence of the director at this stage of the process is rather difficult to quantify. He or she could be the very initiator of the whole project (though this is not very common). More likely, a director will be hired once the main features of the story have been sketched out and the studio expressing an interest in acquiring the project begins assembling what they see as the right team for the project. Apart from the director, writer(s), and producer(s), actors, especially recognizable names, are attached to the project as early as possible to enhance its financial attractiveness.

This stage is a very *delicate* one; despite lengthy negotiations involving a number of professionals, many projects never get past this first hurdle. Indeed, it is not uncommon for directors to be replaced at this early stage, and for projects to change hands within a studio or even go to a different studio altogether. This instability can become problematic since financial backing needs to be secured, and this depends heavily on how effectively studio executives and filmmakers can present their case to potential backers. When the ever increasing cost of production is factored in, it becomes easier to see why this phase of production should be one of the most complex, difficult, and often frustrating aspects of filmmaking. The popular belief that → Hollywood operates according to a “cookie cutting” approach does not adequately account for the complications and pitfalls of the film development stage. While it is true that studios and filmmakers sometimes opt for the apparently “easier” option, often due to the huge financial risks involved in mainstream production, this does not guarantee them a smoother ride to success than that which filmmakers going against the grain will endure.

Pre-production is also one of the *least standardized stages* of the production process. Time, budget, and, most significantly, individual personality combine in a number of potential combinations so great that it would be unwise to even begin to suggest “the way

Hollywood does things.” The director and the producer are usually in charge of the project at this stage. The distinction between financial and administrative duties (the domain of the producer) and creative tasks (understood as the domain of the director) that is traditionally understood as regulating this key relationship is somewhat artificial.

The nature of the working relationship that some producers have with directors with whom they have collaborated on other projects goes well beyond such a schematic division of duties. It is fair to say that some producers will stand aside and let the filmmakers get on with their job (so long as they remain on schedule and on budget), while others will choose to be more involved throughout production to ensure that the director and other key personnel are given the opportunity to deliver the best possible film. The enduring image of the overbearing, dominant, crass producer hell bent on making money at the expense of artistic endeavor is mostly a caricature of reality. While there are producers who fit that mold in some sense, the vast majority of producers today do not exhibit those characteristics. Despite these variations in practices, there seems to be agreement on one point: the producer is perhaps the only figure who can ensure that all the filmmakers involved in the production of a film work to the same brief and find some common ground where the same “language” is spoken.

The ultimate aim of pre-production is neither entirely clear nor obvious. On the one hand, engendering a common sense of purpose (something that filmmakers often refer to as “vision”) of what the film would ideally ultimately feel, look, and sound like would appear to be a basic requirement (→ Cinema). However, even this “basic” aim often proves difficult to achieve due to lack of proper communication, clash of personalities, or a lack of a properly developed script idea. On the other hand, there are filmmakers who meticulously plan their production in order to enter the filming stage with as few variables as possible. Extensive storyboarding, early discussions with the key members of the cast and crew, and working toward achieving a workable script are all part of this process (for a fuller account of the key individual roles in filmmaking, see Goldman 1985). Both approaches present their advantages and pitfalls, and other variables, such as the composition of the filmmaking team (some directors and producers prefer to work with the same skeleton crew, whenever possible, to be able to establish a close working relationship that can be replicated on different projects), budgets, and the time allocated to the project, can mean the difference between failure and success.

Despite these variables, there would appear to be universal agreement on one aspect: the *quality of the script* is paramount. Cinematographer John Bailey summarizes this perfectly when he says: “The more experience I get the more I see that a problematic or mediocre script in the hands of a brilliant director is still going to have problems. A brilliant script in the hands of an okay director can still be a very good film” (Schaefer & Salvato 1984, 68). Indeed, in most cases the lack of a properly developed script is likely to cause serious tensions among cast and crew, leading to confusion, misunderstanding, delays, and budgetary issues. Despite this general agreement among filmmakers about the importance of scriptwriting, there is still a prevailing view among some critics and the general public that the making of a film is in the filming, where directors can put their vision into action. Screenwriter Caroline Thompson makes this point forcefully: “screenwriters work really hard at what we do, and it’s a very distinct job. I did feel hurt by the pieces written about *Edward Scissorhands* when it was always Tim Burton’s vision, or

ninety percent of the time it was Tim Burton's vision. There was a lot of me in that movie, and anybody who knows me can see me in it. But to the public at large, it wasn't mine at all, it was Tim's completely" (Schanzer & Wright 1993, 238).

## PRODUCTION STAGE

Once the production team has been assembled, locations have been selected, and a draft version of the script is available, the project moves into the filming stage, also known as "production." As in pre-production, individual and artistic personalities will determine how filming is organized. While there are producers and directors who wish to take as active a part in every stage of filmmaking as possible, there are others who are content with delegating creative decisions to key members of the crew. This distinction in approach has less to do with budget constrictions than it has with individual preference. To mention two notable examples, James Cameron prefers to be involved in virtually every decision that is made during the filming stage whereas Steven Spielberg prefers to delegate to trusted members of the crew, especially those with whom a working relationship has already been formed in previous films.

Key relationships form at this stage, the most important of which are the director-actor and the director-production designer-cinematographer relationships (→ Cinematography). Production designer Richard Sylbert illustrates the latter thus: "I take care of how the picture looks. The cameraman takes care of the lighting. And the director takes care of the emotions" (Heisner 1997, 159). Once again, filmmakers involved in this stage of the production are quick to point to the script as the key: a poorly developed or badly written script can make life very difficult: "One of the big challenges for this movie [*Silence of the Lambs*] was, how do you depict some of the shocking scenes described in the screenplay. Like when the police officers burst into the room in Memphis to discover their fallen partners. Ted [Tally] wrote 'What greets them is a snapshot from Hell.' Thanks Ted." (Heisner 1997, 159).

Interestingly, many directors indicate this stage as the least enjoyable phase of the filmmaking process. This view is mostly due to the huge pressure that is placed on filmmakers, directors especially, to make a great deal of decisions in a very short amount of time. Indeed, many see the cumulative effect of the inevitable mistakes that are made along the way as a direct threat to the ultimate success of the project. Director Spike Lee illustrates this issue very effectively: "a director is asked five million questions every single day. And you've got to make all those decisions very fast. And over the course of eight, nine, ten weeks, an accumulation of the wrong choices and your movie is fucked up!" (Breskin 1997, 179).

A further key reason for identifying filming as the least pleasurable part of filmmaking is the difficulty in rationalizing a process where a badly timed poor weather front can nullify in a matter of hours the months of careful preparations that had taken place in pre-production, while sending budgets spiraling out of control in the process. There are countless examples where weather inclemency threatened to derail an entire project and some have been very publicly documented. Eleanor Coppola, wife of director Francis Ford Coppola, shot a documentary on the making of *Apocalypse Now*. The documentary,

*Hearts of Darkness*, remains one of the best accounts of the difficulties of making a film in hostile weather and terrain conditions. There are clearly too many variables at work in this stage of the filmmaking process to suggest that there is “one way” of doing things. To state the obvious, each project and each set of filmmakers will present different challenges; this requires a flexible system, one that, though based on established hierarchies, is capable of accommodating change and innovation.

## POST-PRODUCTION STAGE

Once filming has been completed, the film moves into its final stage of production. Often referred to in the industry as “editorial,” this stage is most commonly known as “post-production.” Crudely, this is divided into two areas, *image and sound*. The image part of this process will involve mainly image editing and visual effects, whereas the sound part will involve sound editing, designing, and mixing as well as music composing. As before, practices vary substantially according to who is in charge of the project. Some directors and producers prefer to have film and sound editors on board a project very early on, sometimes during the development stage.

The majority, however, still follow a longstanding approach whereby editors put together a rough edit of the film (using a temporary sound track), to which both the composer and the sound team will work. Some filmmakers suggest that, though evidently viable, this approach is fraught with problems. Their argument is that early involvement in the filmmaking process would ensure a smoother and less troublesome (hence more cost effective) transition from stage to stage. In particular, bringing in key personnel, such as editors, sound designers and composers, and visual effects, so late in the project will inevitably limit what they can achieve. Sound designer Randy Thom illustrates this eloquently: “[Directors] tend to ignore any serious consideration of sound (including music) throughout the planning, shooting, and early editing. Then they suddenly get a temporary dose of religion when they realize that there are holes in the story, weak scenes, and bad edits to disguise. Now they develop enormous and short-lived faith in the power and value of sound to make their movie watchable. Unfortunately it’s usually way too late, and after some vain attempts to stop a haemorrhage with a bandaid, the Director’s head drops” (Thom 1999).

This sense of having to put things right that had gone wrong in previous stages of the filmmaking process is felt strongly among all filmmakers involved in these late stages of the process, as this rather sanguine quote from film editor Peter Frank confirms: “The picture editor is responsible for the film being a success, period. No matter what it takes. Sure, he can hide behind the director and the writer and the producer, but the mandate is simple. He’s just supposed to make it work, and if it was shot wrong, he’s still supposed to make it work. If it was misconceived, he’s still supposed to make it work. And if it was miswritten, yep, he’s supposed to fix that too. There is really no limit to the responsibility, in the ultimate sense, of the film editor” (Oldham 1995, 238).

This already difficult situation is compounded by the rather limited time available to the post-production crew. Often working to accelerated schedules due to a combination of unchangeable release dates and delays in finishing filming, the editorial teams face a

constant race against time. It is also not rare at this stage of the project for the director and other members of the original crew to have begun work on a different project. This in effect means that a considerable amount of delegation of responsibilities may have to take place from the director to the film editor and the supervising sound editor. This is one of the key reasons why so many directors prefer to work with the same crew wherever possible: the relationship they develop over the years ensures that working to the same brief does not require their constant presence at every stage of the production. Put succinctly, key decisions concerning the look and sound of a film will likely be taken by filmmakers other than the director.

### **FILM PRODUCTION AS TEAMWORK**

Although in film studies scholarship the figure of the director has traditionally been singled out as in effect shaping the whole production process through his or her “vision,” actual filmmaking practices in vigor in Hollywood today would seem to suggest a much more complex situation (→ Film Theory). The unstable nature of pre-production, the quantity and nature of the choices that need to be taken during filming, and the highly accelerated post-production schedule films need to follow to meet release dates paints a picture that is manifestly too broad and complex to be understood as managed by the director or any one person alone. Similarly, it would be unwise to underestimate the importance of directors: they are ultimately held responsible for their choices, and their decision-making power is accordingly larger than those of other crew members.

Ultimately, whatever the objectives of any film project and the relative creative input of cast and crew, film production remains a hugely complicated enterprise involving hundreds of people, several specialist languages, different creative and personal sensibilities, and extremely large sums of money, even in the case of an average mainstream film (→ Film as Popular Culture). In this sense, the complexity of film production is one of the very things that set cinema aside from other media: put simply, no other creative enterprise of any kind requires anywhere near the amount of people, money, and organization (with their attendant risks) than filmmaking. Perhaps it is no accident that the most effective way that filmmakers have to signal the complexity of film production is to compare it to another hugely complicated, expensive, and risky enterprise: going to war.

# Film Theory

Warren Buckland

Oxford Brookes University

Film theory is a form of speculative thought that aims to make visible the underlying structures and absent causes that confer order and intelligibility upon films. These structures and causes, while not observable in themselves, are made visible by theory. The ultimate objective of film theory is to construct models of film's nonobservable underlying structures.

Because the invisible structures are unknown they cannot be discovered by means of inductive procedures such as taxonomies. At the same time, the structures are not unknowable, for they can be represented as a system of theoretical hypotheses, concepts, or propositions, which have only a tentative or speculative status. Theories therefore offer explanatory depth rather than mere empirical generalizations. A particular theory enables the analyst to identify specific aspects of a film's structure, and to look at and listen to the film from the perspective of its own values. The aim of "theory" in this particular understanding is to construct different conceptual perspectives on a film, each informed by a specific set of values. A biased or value-laden theory is not only inescapable, but is also the condition of knowledge (→ Critical Rationalism for other conceptions of "theory").

Academic film studies has created a specialized theoretical vocabulary around the → cinema in order to talk about the invisible structures underlying films. This vocabulary represents the film theorist's unique way of seeing and thinking, which exceeds the immediate, commonsense view of films (their consumption as harmless entertainment) and begins to ask a set of questions that common sense has no need for. Film theorists are experts who develop a passionate interest in theories, and ask seemingly strange and difficult questions about films. Where do these questions come from? Why are they important? What do you need to know to ask such a question, let alone answer it? To understand the questions film theorists ask we need to place cinema in the context of twentieth-century thought.

## THE LANGUAGE ANALYSIS TRADITION

Twentieth-century thinking is marked by a shift from idealist philosophy to language analysis (→ Semiotics). The structural linguist Ferdinand de Saussure and the American semiotician C. S. Peirce initiated a radical critique of Descartes's and Kant's idealist philosophy of the subject. In this critique, language and → signs replace mental entities

as the locus of knowledge. Language analysis rejects idealism, transforming its focus on private mental events (as in Descartes's method of introspection) to the public perspective of language and signs.

The language analysts' assumption of indirect access to one's own thoughts via language replaced the idealists' assumption of immediate access to thoughts. In the late 1950s cognitive processes made a decisive return within the language analysis tradition, beginning with Noam Chomsky's transformational generative grammar. Chomsky created a synthesis of both idealism and the intersubjective nature of language. This history of thought in the twentieth century is encapsulated in film theory.

### SCHOOLS OF FILM THEORY

The values inherent in all film theories have directed theorists' attention to particular aspects of film's general nature. *Classical film theory*, which dominated from the 1920s to the early 1960s, tried to define film as an art and attempted to achieve this from an idealist perspective by focusing on film's ontology, or "essence." Different classical film theorists located film's essence in two incommensurate, diametrically opposed qualities of cinema: its photographic recording capacity (e.g., Siegfried Kracauer; Stanley Cavell; André Bazin 1967) and its unique formal techniques that offer a new way of seeing (e.g., Lev Kuleshov; Sergei Eisenstein; Vsevolod Pudovkin; Rudolf Arnheim 1957). For realists, film automatically (that is, mechanically) records and reveals reality. Filmmakers therefore have a duty, the realists argued, to maintain film's relation to reality by privileging its recording capacity (→ Realism in Film and Photography). *Formalists*, on the other hand, regarded film as a modernist medium that offers a new view of the world, and therefore urged filmmakers to exploit film techniques (montage, camera movement, etc.) to create a view of the world unique to the cinema. Auteur criticism is an offshoot from formalism. It examines the way individual directors use film techniques to manipulate film content in order to express their unique vision.

From the perspective of *language analysis*, which became prominent in the 1960s, film semioticians such as Christian Metz did not conceive "film" to be a pre-given, unproblematic entity, nor did they try to define its essence. Instead, they aimed to define film's specificity by constructing a general model of its underlying system of codes (→ Code; Sign Systems). Metz's first semiotic model was the *grande syntagmatique* (1974a) which (he believed) designated one of the primary codes underlying and lending structure to all narrative films. It represents a set of finite sequence (or syntagmatic) types from which a filmmaker can choose to represent filmed events. Metz defined each sequence according to the spatio-temporal relations that exist between the events it depicts. He detected eight different types of sequences in total, each of which is identifiable by a specific spatio-temporal relationship existing between its images. Metz's second semiotic model, developed in *Language and cinema* (1974b), attempted to define filmic specificity in terms of a specific combination of five overlapping codes – iconicity, mechanical duplication, multiplicity, movement, and mechanically produced multiple moving images.

Out of this semiotics emerged *modern film theory* of the 1970s (sometimes called the second semiotics or contemporary film theory) of (again) Metz, Jean-Louis Baudry, theorists centered around the journal *Screen* (Stephen Heath, Colin McCabe) and feminist film

scholars (Laura Mulvey, Mary Ann Doane, Teresa de Lauretis) (see Rosen 1986). They combined the Marxism of Louis Althusser with the psychoanalysis of Jacques Lacan to examine the underlying ideological, social, psychical absent causes that structure mainstream films and create the illusion of spectators as free, coherent subjects. They then mapped out the space for an oppositional avant-garde cinema that would break the ideological hold over mainstream film.

*Cognitive film theory* emerged in the 1980s as an alternative to modern film theory. Cognitivists share with the modernists a focus on the specific nature of the interface between film and spectator. But whereas the modernists examined the way a film addresses the spectator's irrational/unconscious desires and fantasies, the cognitivists analyzed the knowledge and competence spectators employ to comprehend films and engage them on rational and emotional levels (Bordwell 1985; Branigan 1992; Tan 1996).

### RECENT DEVELOPMENTS

The New Lacanians (most notably Slavoj Žižek) are united by a new concern with what has been called the "ethics" of psychoanalysis and its contemporary political ramifications, which revolve around democracy, totalitarianism, universality, and multiculturalism. Instead of concentrating on the imaginary and the symbolic when assessing the film experience in relation to a spectator, the New Lacanians focus on the imaginary and the real. This shift is a double one: it tries to free film studies from its obsession with vision, illusion, and representation, especially as elaborated around sexual difference, and it tries to repoliticize the cinema, by tracking the various permutations of the symbolic order under capitalist globalization (Elsaesser & Buckland 2002, 236–248).

Film scholars not persuaded by psychoanalytic or Marxist film theory, but equally dissatisfied with the cognitivists' analysis of rational and emotional reactions to films, have in recent years turned to the French philosopher Gilles Deleuze. Deleuze's two cinema books (*The movement image* [1986] and *The time image* [1989]) offer an alternative conceptualization of the film experience as an embodied, spatio-temporal event. Deleuze is not a film theorist in the commonly accepted sense, for he theorizes *with* rather than *about* the cinema. What seems to have drawn him to the cinema is the relation of bodies, matter, and perception, seen as a traditional philosophical problem, and in the twentieth century most vigorously explored by phenomenology (Elsaesser & Buckland 2002, 261–283).

### PIECEMEAL THEORIZING

Film theory, then, is a system of interrelated hypotheses, or tentative assumptions, about the unobservable nature of reality (a reality assumed to be a regular, economical, cohesive structure underlying chaotic, heterogeneous, observable phenomena). It unveils the scope and limits of human reasoning. This is Film Theory in the singular, written with a capital T.

For David Bordwell and Noël Carroll (1996), localized, middle-level (or piecemeal) theories should replace this singular Film Theory. They argue that to theorize should be conceived as an activity that is problem-driven rather than doctrine-driven. There are two immediate responses to this reconfiguration of film theory, one serious, the other less serious. First, piecemeal theorizing sounds like the story of the elephant and the six blind

men. The one who felt the elephant's leg said that it was like a tree trunk; the second who felt its tail said it was like a rope; the third who touched the elephant's trunk said it was like a hose, and so on. Piecemeal theorizing may not be able to see the forest for the trees if it completely abandons the tendency to develop a unifying theory.

Second, and more seriously, Theory and piecemeal theorizing are not incompatible. The initial stage of the theoretical activity involves the *simplification* (abstraction and idealization) of the domain under study. Simplifying is the necessary first step in constructing a theory. The early stages of any theory are governed by attempts to obtain the maximum amount of simplicity by studying only the essential determinants of a particular domain. But as research progresses, those determinants deemed inessential and irrelevant at the early stages take on a greater importance, and make the research domain complex, in the negative sense that the theory cannot successfully subsume important factors within its framework. For research to progress, this "negative complexity" must be translated into "positive complexity" – the theory must expand to take into account these additional factors.

Film Theory followed the simplicity principle and attempted to reduce, by as much as possible, the negative complexity of its research domain, by studying only those characteristics of the cinema posited to be specific to it (the spatio-temporal articulations of the *grande syntagmatique*, or the five overlapping codes outlined in *Language and cinema*). This process of simplifying eventually and inevitably leads to a crisis, as the so-called inessential phenomena take on importance. Modern film theory embraced positive complexity by including in its domain of research additional absent structures and causes – ideology, society, and the unconscious. To recognize and break down general theoretical problems into smaller, piecemeal theoretical problems does not necessarily involve a rejection of Theory, as Bordwell and Carroll suggest, but represents its next stage of development.

Film theory is valuable to the extent that it does not study film as an unproblematic, pre-given entity, but as a complex and little understood medium with its own properties, and cultural and social effects (→ Film Production). Film theory therefore challenges and goes beyond the commonsense ideological understanding of film as a mere form of harmless entertainment, and instead maintains that it is an intrinsically significant medium integral to contemporary society (→ Visual Communication).

## Financial Communication

*Holly R. Hutchins*

*University of Houston*

Financial communication entails all of the strategies, tactics, and tools used to share financial data and recommendations with investors and other interested parties. Around the world, companies need strong, proactive financial communication competencies to successfully help shape the evolution of capital markets for themselves and their industries. In return, companies likely will see the benefits in stock price and operating performance.

Thompson (2002a, 1) defines *investor relations* (IR) as “a strategic management responsibility that integrates finance, communication, marketing and securities laws compliance to enable the most effective two-way communication between a company, the financial community, and other constituencies, which ultimately contributes to a company’s securities achieving fair valuation.” The field is described here on the basis of its development in the US and with examples of the US economy.

### BEGINNINGS

Financial communication evolved during the 1960s and 1970s with, as Mahoney (1991) wrote, a promotional flare. Annual reports became costly showpieces. “Dog and pony shows,” the euphemism for multimedia presentations to security analyst and stockholder meetings, became the trademark of full-service public relations (PR) departments. Financial communicators were technicians, leveraging their communication skills to create the

necessary tools, such as reports, speeches, and multimedia presentations, to inform the investment community.

The “Age of Impressionism,” as Mahoney (1991, 3) described it, came to a sudden and unnerving end in the early 1980s with the emergence of a most unlikely influencer – the corporate raider. Individuals such as T. Boone Pickens, Ivan Boesky, and Carl Icahn in the US created a battleground unlike any ever experienced in corporate America.

Traditional → public relations practitioners, functioning as IR representatives, found themselves involved in financial discussions with corporate leaders. Those who understood the financial markets moved easily into the dialogue. In a matter of months, the IR/PR practitioner experienced a major reality jolt. Priorities went from producing bland press releases and glitzy annual reports to battling in the takeover trenches: giving daily reports from the field on how the battle was going, assessing the friends and foes, identifying and facilitating direct contact with shareholders who were hidden behind brokerage or bank accounts, doing quality research on the bidder, leading or conducting media contact or providing the information that went to reporters, determining the strategic content of information that would sway investors and analysts, and preparing and disseminating the actual communications materials (→ Strategic Communication).

By the 1990s, the takeover battlefield became considerably quieter as corporate managements had pretty well learned their lessons. Managements became more aware of enhancing shareholder value and incorporating it into strategic growth priorities. In the process, senior corporate executives recognized a very different role for IR, the more specific and strategic tools of monitoring investor attitudes and actions, and communicating corporate valuation programs and results.

Subsequently, IR moved from the PR or → corporate communications departments to the chief financial officer’s group, or even as a direct report to the chief executive officer. The people who occupied the posts were highly credentialed and often consisted of former business journalists, PR executives who possessed strong communications skills but also thoroughly understood business and finance, and perhaps a research analyst, an accountant, or a line business manager. They were working in a field that had become well defined as focusing on the investor constituency to enhance valuation.

### **ENTER THE BULLS OF THE 1990S**

The next major life-changing event for IR was the bull market that led Wall Street virtually throughout the 1990s and into the twenty-first century. The boom led to two developments that dramatically altered the financial communication landscape. First, the *competition for capital and for market visibility* became intense. IR pros were charged with developing initiatives that would break through the clutter on Wall Street and other capital markets, improve their company’s market visibility, and open the door to low-cost capital to fuel growth. This prompted the marketing discipline to drive IR. Marcus and Wallace (1997, xvii) argued that IR always had been a marketing function: “It has always been a process of understanding the needs of the target audience, and of casting the information about a company in ways that persuade the investor that a dollar invested in my company will appreciate faster than a dollar invested in somebody else’s company.”

Any process that relates a company's products or services – or even cogent information about that company – to the needs of the buyer is marketing.

Second, the boom of the 1990s rudely forced aside the notion of investing for long-term value and replaced it with a very *short-term focused approach* that worried about satisfying capital markets quarter to quarter. With this shift came the “managed earnings syndrome,” where corporate managements, through the accounting process, attempted to meet or beat the previous quarterly earnings to satisfy analyst expectations. The culprit here, as Louis M. Thompson (2002a, 12) wrote, was the reality that a “penny missed” could have devastating results on a company's stock price.

The combination of these two developments – vying for the attention of Wall Street and managed earnings – brought the investment community and IR to the brink of another dramatic sea change.

### **THE CRASH OF CORPORATE CREDIBILITY**

Except for the 2000 passage of Regulation Full Disclosure, which restricted the selective disclosure of material information to analysts and investors prior to making it available to the general public, Congress and the SEC basically stood aside as corporate America maintained its managed earnings practice. Financial scandals at Enron, Global Crossing, WorldCom, Tyco International, Adelphia Communications, and other blue-chip companies argued for new standards of financial communication. Multiple issues were blamed: aggressive accounting practices to meet quarterly earnings “consensus” expectations, conflicts of interest between research and investment banking, weaknesses in board oversight, a compensation system ill designed to align managements' interests with those of their shareholders, and conflicts of interest between auditing and consulting in major accounting firms.

Were the IR officers in these companies aware of the alleged fraudulent practices? If so, is it that they voiced their objections and no one listened? Whatever they did or did not do “obviously reflects on our profession,” remarked NIRI's president and CEO Louis M. Thompson, Jr (2002a, 11). Enron's collapse, exacerbated by the other scandals, triggered the most extensive congressional legislation and SEC regulations seen on Wall Street in 60 years (Thompson 2002b, 2). Heading the list was the Sarbanes-Oxley Act, passed in July 2002, which in its simplest definition requires public companies to validate the accuracy and integrity of their financial management.

### **INVESTOR RELATIONS RETURNS TO ITS PUBLIC RELATIONS ROOTS**

Fast forward to today and we see IR again evolving, this time seemingly back to its PR roots. Shane McLaughlin, senior writer at Best Practices in Corporate Communications, maintained that IR and PR are once again converging: “With renewed calls for information in the wake of corporate scandals and new financial reporting standards . . . there is more reason than ever to combine the functions of investor relations and corporate communications” (McLaughlin 2003, 9).

Also, McLaughlin (2003) argued that it is only natural that as companies open up more channels to send information, corporate communications will play a central role in

preserving consistency and content. Even if a company has not integrated the two functions of IR and PR, the people on these two sides need to be joined at the hip: “That way communications is systematically involved way before a matter becomes a public issue” (McLaughlin 2003, 9).

Roger S. Pondel (2002) argued that the debate essentially is over. Those who do not understand that IR and PR are converging are seriously weakening their companies’ valuations. The two management disciplines of IR and PR are being brought together more closely, Pondel maintained, because of heightened disclosure regulations and exploding technology around the Internet and related telecommunications.

Jeffrey Greene, global vice chair of corporate finance at Ernst and Young, suggested a new view of IR before a symposium of IR professionals in 2003. He called it “investor relationship management,” whereby IR officers move beyond providing data to facilitating a dialogue with the investor community on how best to value their companies. Greene added that the IR officer’s job is to manage relationships – internally and with the investing community – communicating but also educating and coaching: “It’s a two-way dialogue, and it requires integrated communications” (Berstein 2003, 4).

### **INVESTOR RELATIONS DESTINED FOR NEW RESPECT**

This turf battle among the disciplines promises to prevail for decades. Regardless of where IR lands, corporate managements appear in agreement that the role and responsibilities of the financial communication executive will continue to expand. Specifically, *five developments are singled out* for fueling the future growth of IR: (1) a greater need to satisfy more stringent disclosure requirements; (2) a broader communications role in the company; (3) a more proactive attitude by corporate managements toward IR; (4) more involvement in the strategic planning process (aside from all the disclosure requirements dictated by Sarbanes-Oxley, the recent rash of executive stock option postdating incidents strongly suggests that IR executives need to be “in the know” in order to effectively firefight these and other issues); and (5) greater information needs from institutions and portfolio managers.

Since Sarbanes-Oxley’s inception, its onerous enforcement impact on the New York Stock Exchange has led many corporate executives, particularly those heading up-and-coming entrepreneurial companies at home and abroad, to consider the New York market as an obsolete place to do business. They are flocking to exchanges in Europe and Asia instead. Around the world, corporate managements have a great opportunity to elevate IR to a more strategic and valuable role in response to today’s turmoil in capital markets and corporate governance.

## Fleet Street

*Michael Bromley*

*University of Queensland*

Running between the Strand and Ludgate Circus in London, Fleet Street is synonymous with the national newspaper industry of the United Kingdom. Though from the mid-1980s all the major newspaper offices were relocated, the name was still used to denote this type of newspaper and journalism. The most common explanation for this synergy was that since its development in the fourteenth century Fleet Street has connected the City of London with the City of Westminster, and thus governmental, financial, and commercial activities – traditionally staple sources of news.

When the first printing press was installed in Fleet Street by Wynkyn de Worde in 1500, the area was already a religious and legal center, settled from the twelfth century by the Knights Templar. In the 1340s, the royal courts moved permanently to London. Both the church and the law increasingly relied on documentation, and the streets, courts, and alleys in the area were populated by scribes and clerks. Books, pamphlets, tracts, treatises, official records, and plays provided the impetus for a printing industry, and an area extending east–west from St Paul's Cathedral to Whitehall was the location for publishers, booksellers, printers, binders, and other related traders. Much of this printing was conducted under royal license and noble patronage. The King's Printing House was near Blackfriars Bridge, and the Stationers' Company controlled the book trade. Another, more popular print culture, producing cheap handbills, pamphlets, and chapbooks, and more focused on the goings-on at the Old Bailey assizes and Newgate prison, emerged, too. Although sold in Fleet Street, these artifacts were produced elsewhere, including Cripplegate, where the term Grub Street evolved to describe the kind of “hack” writing associated with them.

Serial print publications, *corantos*, published in continental Europe, appeared in English translations in the early seventeenth century. They contained gossip, rumor, and sensation,

as well as commercial intelligence. The English Civil War encouraged the production of political propaganda, often spiced with scandal. At the same time, administrative control over Fleet Street, which lay outside the City walls, practically collapsed, and the area became a prime location for the publication of salacious and subversive, as well as conformist and respectable, material.

If print production fostered a supportive material infrastructure, writing required a set of intellectual relations. The inns and taverns of the Fleet Street area provided the basis for these, attracting the likes of William Shakespeare and Ben Jonson, and later the diarist Samuel Pepys and Dr Samuel Johnson. Coffee houses, too, began opening in Fleet Street in the 1650s. As well as facilitating the verbal exchange of ideas, news, and gossip, they published their own newsletters.

State control of all print publication under the 1662 Licensing Act lapsed in 1695, and attempts to close coffee houses failed (→ Freedom of the Press, Concept of). After the Great Fire of London in 1666, the rebuilt Fleet Street area was characterized by its inns, taverns, coffee houses, and burgeoning serial print publications. By the 1720s there were 12 London newspapers in circulation, including the *Daily Courant* (1702). At mid-century, Fleet Street was both the main distribution center for most London newspapers and “the central meeting-place for newsmen,” as well as “a gossip factory” (Boston 1990, 41).

The period of the long nineteenth century (the establishment of *The Times* in 1785; the development of popular Sunday newspapers in the 1840s; the repeal of taxes on newspapers in the 1850s; the emergence of a popular cheap press, particularly between 1896 and 1910; the industrialization of newspaper production) is popularly connected with the final cementing of Fleet Street with newspapers and the ideology of a “free press” (→ Newspaper, History of).

The enormous expansion in newspaper publishing in the second half of the nineteenth century attracted distributors, advertising agencies, and telegraph offices to the Fleet Street area. Between 1868 and 1900 purpose-built offices were erected for a number of papers. Railway access was improved and Fleet Street was widened and realigned several times. The embanking of the River Thames and the demolition of existing buildings opened up a freehold estate south of Fleet Street in the 1880s, where many of the new cheap newspapers (notably the *Daily Mail* and *Daily Mirror*) were located. This second rebuilding of Fleet Street continued into the 1930s.

In the twentieth century, most of the major national newspaper offices were located in these streets south of Fleet Street (Bouverie, Carmelite, Whitefriars, and Tudor). To the north of the street, a myriad of alleyways and courts, such as Bell Yard, Cliffords Inn Passage, and Wine Office Court, housed radio broadcasters, magazines, news agencies, book publishers, and related organizations and bodies. After 1945 the only major national newspaper offices actually in Fleet Street itself were those of the *Telegraph* and *Express*. After the exodus began with NewsCorp removing its titles in 1986, it was completed within four years. Ancillary premises well away from Fleet Street had been used for more than 70 years. The last remaining news organizations in Fleet Street were not national papers, but Reuters (which relocated in 2005), Agence France Presse, and the provincial press and comic book publisher DC Thompson.

The use of Fleet Street as a synecdoche for newspapers was largely a post-1900 practice, as the concentration of activities fostering shared interests developed into a collective

identity. Fleet Street was, as the editor Henry Massingham said, more “a habitation of the mind,” cultivated by a persistent informal culture, centered on its many public houses, and more formal institutions, such as the Press Club (founded in 1875). One origin of Fleet Street as cultural reference was Philip Gibbs’s 1909 novel, *The street of adventure*, although other journalist-novelists, such as Evelyn Waugh and Michael Frayn, have since taken a more sardonic view of what the satirical magazine *Private Eye* called “the street of shame.”

## **Foreign Correspondents**

*Christopher D. Karadjov*

*California State University, Long Beach*

The “classic” foreign correspondent had become an identifiable occupation by the second half of the nineteenth century, supporting an increasing need of European and US newspapers to cover overseas military and civilian developments (→ Journalism, History of). Ever since, foreign correspondents have been considered an elite among news professionals. The numbers of “classic” foreign correspondents reached a peak worldwide between the 1950s and 1980s, but have been falling since because media organizations have increasingly been using local reporters to provide international news to their audiences (→ International News Reporting). Competition, financial constraints, and technological advances have democratized the field of international news gathering and the profession of the foreign correspondent.

Foreign news has a demonstrable impact on foreign policies and → public opinion of every country (→ International Communication; Foreign Policy and the Media). In one formulation, the press acts as a “strategic center” that transmits facts about foreign policy between political systems (Cohen 1963). Mediated foreign news, particularly television

and photo imagery, has shaped public opinion around the world, often bolstering governments' resolve for action. The so-called "CNN effect" (Livingston 1997) stipulates that global real-time media have exerted a profound influence on diplomatic conduct and on foreign policy in the United States and perhaps elsewhere (→ CNN). The effect, also dubbed compassionate cosmopolitanism or electronic empathy (Hannerz 2004), has precipitated western-led interventions in various locations. On the flip side, foreign news is also among the most tightly controlled imports in countries without free media (→ Censorship).

Reporters on international assignments were assumed to have the freedom of travel around the world as requested by their editors, seeking ways to understand what is happening there, and recounting that intelligence as a critical but also sympathetic story (Hess 2005). This foreign correspondent of the "classic" model has been labeled "a cosmopolitan among cosmopolitans" in a somewhat romanticized image because of their assumed ability to adapt to new environments and situations, reporting from any location of interest to home-country media (Cohen 1963).

Recent social, occupational, and cultural changes in the uses of existing technology, such as the emergence of → bloggers, have made it possible for virtually anyone to send dispatches from abroad. Media have also liberalized their hiring practices, thus altering international news-gathering routines, although perhaps at the expense of professionalism.

## THE EVOLUTION OF THE FOREIGN CORRESPONDENT

An early glamorized image of the profession comes from Alfred Hitchcock's 1940 patriotic caper, *Foreign Correspondent*, where reporters are called "soldiers of the press . . . who are writing history from beside the cannon's mouth." Most countries still use or presume professional classifications of foreign correspondents that include an expectation of special training and a permanent station in a foreign city – a status not unlike that of diplomats. A pre-Internet study of US foreign correspondents (in Erickson & Hamilton 2006) found that compared with their peers in the US, four times as many foreign correspondents had graduate degrees and twice as many had attended private colleges.

These assumptions are no longer universally valid. A marked trend worldwide has been the disappearance of the correspondent stationed in a foreign city for a pre-assigned "tour of duty" of three to five years. Instead, many news organizations send their representatives directly to the country of interest and retrieve them back home when the newsworthiness of the location wanes. Another trend is the increasing use of "local" foreign correspondents living permanently in one country and contributing to news organizations in another, who can be freelancers or permanent hires, but rarely move to their publications' home office (Hess 2005).

The bulk of foreign news reporting today falls to news agencies, such as the *Associated Press*, *Reuters*, Russia's *TASS*, and China's *Xinhua* (→ News Agencies). Large, usually western, news organizations maintain permanent correspondent bureaus abroad, such as the major broadcast networks (→ BBC and CNN, for example) and weekly news magazines (the *Economist*, *Der Spiegel*, and *Newsweek*), as well as major newspapers such as the British *The Times*, the US *New York Times*, the French *Le Monde*, and the German *Frankfurter Allgemeine Zeitung*, among others.

Sending a reporter abroad, let alone maintaining a foreign bureau, is expensive. Every correspondent requires financing for travel, equipment, accommodation, and local assistance, in addition to salary and benefits. The cost is prohibitive to smaller news outlets in the developed countries and to all but the largest media from economically weaker countries. Media that cannot afford in-house international reporting must instead rely on news agency information or syndicated stories provided by major newspapers, or, increasingly, use local reporters who contribute stories on demand.

Western editors were initially apprehensive of hiring foreign nationals out of fear that they may be culturally detached from home audiences. A recent survey of US foreign correspondents found that today only 31 percent of US foreign correspondents are American citizens (Wu & Hamilton 2004). Data is limited for other nations, although the trend in the western media seems to be toward a decrease in the Eurocentrism of reporters' postings abroad. Some research findings indicate that institutional foreign correspondents share relatively similar → news values across the globe, as expressed through the topics and events that receive most media attention (Wu & Hamilton 2004). Such shared news judgments may result from a worldwide Americanization of news production or the appearance of universal news values related to the emergence of a profession (→ Professionalization of Journalism), or they may be a study artifact. No data exists on news values of local reporters who file stories for overseas media, but it could be expected that a more diverse field of contributors will increase the variety of viewpoints, but at the same time making quality control more difficult.

Foreign news organizations can rarely match domestic journalists in resources or access to political leaders and institutions, especially for coverage of breaking news. Local politicians and authorities are seldom interested in catering to the out-of-country constituencies served by these reporters, although under certain circumstances foreign news outlets may be preferred as a venue for political announcements when the creation of international resonance is an intended goal.

As a matter of tradition and convenience, foreign correspondents worldwide have relied heavily on local media for story tips, contacts, and news verification (Hess 1996). This has led to criticisms that few foreign press corps members venture outside of their offices to interact with natives. Lack of language proficiency is a related problem: while over three-quarters of correspondents reporting from Europe and North and South America report high levels of host-country language proficiency, this proportion dips to half for Russia and China, and below a quarter for Africa, the Middle East, Asia, and Eastern Europe (Hess 1996). This imbalance is changing with the increasing numbers of local journalists entering the field.

Foreign correspondents can have a direct effect on the fortunes in their host country. For instance, the Hollywood Foreign Press Association in the United States, which is a bastion of "classic" foreign correspondence, distributes the Golden Globe movie award, which can shape film marketing outcomes. Similarly, many foreign press organizations award prizes or hold events devoted to journalistic, civic, cultural, and even political achievements in their host countries.

Overseas business and financial news has supplanted foreign political news reporting in recent years (Hachten & Scotton 2002). The proportion of business and financial reporters has been growing among the foreign press corps members stationed in developed

and developing countries alike, leading to an increased demand for journalists specializing in business and financial stories.

### CHALLENGES IN FOREIGN CORRESPONDENCE

Numerous external pressures affect the way foreign correspondents cover the world, such as restricted access, suspicion from local authorities and citizens, along with cultural and language differences. Nondemocratic governments control the access for journalists as a rule, but even countries with otherwise free media have practices that often impede foreign reporters' work through limitations on questions, bans on the attendance of background briefings with officials, and other formal and informal restrictions.

Foreign correspondents may also find themselves torn between their understanding of what are the most important stories in the country they are covering and what their editors back home think is newsworthy. Because of such perceptual differences, foreign correspondents may not always succeed in portraying important events, despite their preparation and best intentions (→ Journalists' Role Perception). Superficial reporting, stereotyping, and "groupthink" on the part of foreign correspondents have been identified as major constraints of international news coverage, which makes it all the more important for news organizations to diversify their sources.

Editors have expected that the "classic" foreign correspondent living in a country for a set time would combine insiders' knowledge and outsiders' independence, allowing him or her to avoid partisan or vituperative edges that local media may exhibit. A foreign correspondent, however, usually provides a less nuanced interpretation of the host country or region than is available through local coverage, because of the correspondent's domestic audience's assumed lack of in-depth knowledge or interest.

A recent anthropological study followed *parachute journalists* covering various hot spots, finding that this practice does not seem to be as detrimental to reporting quality as journalism purists often portray it to be. Often involved in such parachute journalism are seasoned professionals whose beats and stories have taken them abroad to continue their work in a foreign setting (Hannerz 2004). The unexpected downside of this practice is the decreasing numbers of women sent to cover the world for their countries, most likely because of the inconveniences and risks associated with frequent travel to conflict areas (→ Gender and Journalism). No data exist on the gender structure of local stringers serving international audiences, although anecdotic evidence suggests that at least in conflict areas these contributors are overwhelmingly male.

Today, many individuals without formal media affiliations have adopted technology to become *de facto foreign correspondents* by posting regular online dispatches, especially from conflict or disaster areas (→ Citizen Journalism). Bloggers or other individuals who venture into foreign correspondence "informally" do not face the same editorial limitations as their institutional peers. The main challenges such freelancers face are attracting sufficient audience and financing themselves.

*Safety concerns* have been another issue in modern foreign correspondence. Nonprofit organizations such as the *French Reporters without Borders* and the *US Committee to Protect Journalists* estimate that between 15 and 25 percent of journalists killed worldwide from 1992 to 2007 were either foreign correspondents or local reporters freelancing for foreign news outlets (→ Violence against Journalists).

Special cases of foreign correspondence are → war correspondents and the institution of *embedded reporters*, which has existed in practice since World War II but became prominent with the US-led war in Iraq of 2003 (→ Embedded Journalists). These journalists reporting from conflict zones face the gravest professional risks among their peers.

Although foreign correspondents of the “classic” model are still influential in filtering the news from a country to the rest of the world because they can decide the angle, tone, and extent of coverage, the sheer diversity of news sources at editors’ disposal today deprives foreign correspondents of the exclusivity they once enjoyed.

## **Foreign Policy and the Media**

*Monroe E. Price*

*University of Pennsylvania*

There are at least two salient questions when thinking about foreign policy and the media. The first is whether foreign policy is affected by media considerations: have modern technological developments meant that foreign policy is increasingly affected by media concerns? The second is whether there is what might be called a foreign policy of media

structures, namely an interest by an individual state (or the international community) in the mode by which media is developed through an interdependent set of nations (→ Media Policy). The answer to both questions is yes, and the issues are interconnected.

## **MEDIA AND DIPLOMACY**

The term *CNN effect* is used to describe a variety of putative consequences of new media technology for foreign policy (→ Technology and Communication). The term was first used during the Gulf War of 1990. The argument was that because of the rise of → CNN and its style of reporting, leaders learned more from television than from their own officials about what was going on both on the battlefield and in the diplomatic sphere. By conducting diplomacy in real time and in the fishbowl of a global news service, leaders could directly reach past official and autocratic gatekeepers to broad civil publics (→ Globalization of the Media).

Stephen Livingston (1997) has listed three elements of this phenomenon: (1) → agenda setting (trumping the agenda-setting effort of the government); (2) an impediment to policymaking (where the existence of the media effect narrows or forecloses options open to the government); and (3) an accelerant to policy decision-making (where the impact of media coverage forces the government to take an action it might otherwise not have been inclined to do; → Media Logic; Mediatization of Politics). “Instant reporting,” it has been said, “requires instant response.” With the CNN effect, whatever leisure for decision-making that might have existed has been truncated.

There has been much controversy over the *extent of the CNN effect* and its transformation of the relationship between state and society. Several conclusions can be drawn. First, most of those who seek to shape multiple foreign policies – those who would react to the CNN effect – have internalized the phenomenon of global news services and have adjusted their behavior. What was most novel about the supposed impact of media in the early 1990s was its innovative qualities. Like militaries seeking to cope with new weaponry, diplomats had to adjust to an altered media world. Once they did so, once they could more consciously calibrate the consequence of various appearances on global news services, the transformative impact of the new technology was lessened. Second, it is no longer just a CNN effect, it is also an Al Jazeera effect (→ Arab Satellite TV News); networks are competing among themselves to have the most stunning breakthrough, and therefore the most impact on foreign policy. While the first factor works toward reducing the effect, the second works toward increasing it.

An important area for inquiry has involved a consideration of when use of broadcasting is most effective in transforming foreign policy. James Hoge (1994) has argued that the impact is greatest during a humanitarian crisis when there is an effort to mobilize a domestic community to press its officials into taking action (→ Crisis Communication). *Imagery* is also an important factor: the effect of broadcasting is most conspicuous when a broadcast shows, to a government’s domestic audience, a sustained set of images that, through their tragic and dramatic force, undermine the narrative of success that officials have proclaimed (→ Visuals, Cognitive Processing of). Here such a broadcast narrative can impede or accelerate government action or can alter the agenda (→ Narrative News Story).

The issue can be put differently. The ubiquity of media and its capacity to provide unfiltered access to harsh global events increases *emotional impact* – and an emotional impact not constructed or controlled by the government or its menagerie of gatekeepers (→ Emotion; Emotions, Media Effects on). This is not to say that foreign policy was previously based solely on reason and conducted in an environment wholly immunized against → public opinion. But, at certain times, and subject to the varying skills of international players, media can foreshorten time for reflection and spectacularly raise the way the stakes are perceived and governments are measured.

### **MEDIA AND SOVEREIGNTY**

Even leaving aside this described impact on media (but certainly in light of it), individual states as well as the international community have an interest in the structure and functioning of transnational media. Precisely because of the CNN effect and its now far broader incarnation, states wish to have unimpeded *access to foreign audiences* to present their priorities and their visions of the world; simultaneously, they wish to control efforts by other states to reshape, counter, or block that message.

Historically, states have had a tacit agreement that the media of one state would not persistently permeate the boundaries of another. The International Telecommunication Union (ITU) was, in a sense, created to help police the allocation of the spectrum so that, for the most part, radio (and then television) signals would be contained within national boundaries (→ Telecommunications: Law and Policy). Short-wave efforts designed at first to reach subjects around a colonial world were an exception to this general rule. While there were accepted and less accepted violations of the general principle, it was only with the arrival of the satellite (and to a lesser extent cable) that the general understanding disintegrated (→ Satellite Television; Cable Television). And even then, there were attempts at the UN and elsewhere to transfer to the satellite regime the state-protective elements of terrestrial radio and television.

International human rights norms, such as Article 19 of the Universal Declaration of Human Rights, which gives the right to receive and impart information, can be said to be part of an international “foreign policy” of media structures. States have utilized Article 19 to press for a greater range of domestic voices, especially in societies that are thought to be authoritarian or oppressive of domestic minorities. The general proscription against hate speech, and bilateral agreements to adjust media use in the interest of peace, are another example. In 1947, Pakistan and India agreed (though the history of this agreement is not consistent) to modulate speech that might instill enmity to the other within their borders. In the ill-fated Oslo Accords, there were mutual undertakings by Israel and the Palestinian authority to seek a media sphere that was more conducive to sustained amity.

### **PUBLIC DIPLOMACY AND INTERNATIONAL BROADCASTING**

States have also undertaken persistent and large-scale efforts to subsidize radio (and later television) that would alter the flow of ideas in a target society. Some of these efforts are called “*international broadcasting*” and include → Deutsche Welle, the → Voice of America and the → BBC World Service. But the process of developing government-subsidized

efforts for radio and television that reach a global audience has altered greatly. Serbia, as an example, invested in a satellite service to reach its diaspora and gain moral and financial support for its position in the 1990s. Hungary, after the transition, created Duna TV to reach ethnic Hungarians in Transylvania (Romania).

The strongest of these international services, like the US-funded Voice of America and RFE/RL (→ Radio Free Europe/Radio Liberty), and the BBC World Service, financed by the UK Foreign and Commonwealth Office, had extensive ambitions that were tied to foreign policy goals (sometimes only the goal of greater access to information, but sometimes more). RFE/RL was established as “surrogate radios” in the Cold War, ostensibly to provide information-deprived populations with access to news and information about their own society. In the early twenty-first century, the US foreign policy question was which of these Cold War services to maintain and at what level, or whether to use scarce resources to reach, inform, and persuade another “demographic.”

Patronage, foreign aid payments, transfers through non-governmental organizations – subsidy on a relatively large scale – is often deployed to determine what groups to persuade or influence, using what languages and what technologies. Qatar, in a novel use of funds, established Al Jazeera and altered the media face of the Middle East. Other governments in the region, including Saudi Arabia, saw to it that their satellite presence was bolstered. Even independent satellite services are tied to government-related interests. For the west, there is a determined notion of using media to reach the “hearts and minds” of Arabic youth across boundaries. The BBC launched an Arabic-language television service; the French promised to do likewise; and the US limped along with Al Hurra, its entry into the competition among Arabic satellite channels for the privilege of defining “news” and presenting a stronger image of the US or a view of the world as defined through the management of the channel and its relationship to Washington officialdom.

Beginning with the post-Soviet transition, western nations have subsidized or invested in the *development of an indigenous media in the transitioning societies* as part of the process of democratization. Without being too reductionist, the US has emphasized the development of “free and independent media” as an integral part of this process, while the UK has focused on strengthening public service broadcasters. In some transitional contexts, this odd Great Powers contestation has led to temporary stalemates. It is not clear that there is a formula that works.

### **RESTRICTIVE STATE RESPONSES**

It is an element of domestic policy (with foreign policy overtones) to limit or prohibit foreign ownership of internal communications technologies or to limit foreign-originated channels on cable or satellite channels that serve domestic audiences.

In the → Internet era, government policies vary in terms of surveillance, limiting access to the Internet and prohibiting certain kinds of use. From these variations, foreign policies arise, as one country seeks to pressure another (usually) into expanding use of the Internet and, through that, access to a greater bank of information. Some countries have foreign policies that would condition access to international finance or to regional alliances on their fostering of Internet technology.

We now see a broader interplay among leaders, governments and publics than was identified in connection with the CNN effect. That phenomenon somehow located the broadcaster as the independent variable, and the impact on leaders, governments, and publics as dependent. But the examination of a foreign policy of the media sphere demonstrates how almost all aspects are interdependent, including the broadcaster itself. Major players – finance, government, international goals, human rights – are interconnected. The mixture of foreign policies of media space provides the background against which daily media practice emerges.

# Fourth Estate

*Daya Kishan Thussu*

*University of Westminster*

The term “fourth estate” has been used to refer to the press since at least the early 1800s. It has become shorthand to denote the role of the public media as a pillar on which the smooth functioning of a democratic society rests, together with the other three estates – legislative, executive, and judiciary. A free press is also a counterbalance to these powers, a watchdog guarding the public interest, and providing a forum for public debate – a public sphere – that underpins the processes of democracy.

## ORIGIN OF THE IDEA

The idea of the fourth estate has a long history, parallel with that of the democratization of political processes, with its origins in the European Enlightenment and the French Revolution. The origin of the term “fourth estate” is attributed to the eighteenth-century English political philosopher and commentator on the Revolution, Edmund Burke, referring to the three sections of the French Estates-General, an assembly consisting of representatives from the clergy, the nobility, and the commoners (in practice, the bourgeoisie), whose gathering in 1789 is said to have paved the way for the French Revolution. The ideas of freedom and democracy enshrined in the Declaration of the Rights of Man and Citizen, passed by the French National Assembly after the 1789 Revolution, also inspired the First Amendment of the United States Constitution, which, in 1791, proclaimed the sanctity of “the freedom of speech, or of the press.”

The term was given wider currency by the nineteenth-century British historian Thomas Carlyle, another great chronicler of the French Revolution: in his book *On heroes, hero-worship and the heroic in history*, published in 1841, he wrote:

Burke said there were Three Estates in Parliament; but, in the Reporters' Gallery yonder, there sat a Fourth Estate more important than they all. It is not a figure of speech, or a witty saying; it is a literal fact. . . . Printing, which comes necessarily out of Writing, I say often, is equivalent to Democracy: invent Writing, Democracy is inevitable. . . . Whoever can speak, speaking now to the whole nation, becomes a power, a branch of government, with inalienable weight in law-making, in all acts of authority. It matters not what rank he has, what revenues or garnitures: the requisite thing is that he have a tongue which others will listen to; this and nothing more is requisite. (Carlyle 1841, 141)

In this context, Carlyle was referring to the three estates of the British parliament: the Lords Temporal, the Lords Spiritual, and the House of Commons. The quotation indicates Carlyle's view of the growing power of newspapers in shaping the public agenda in nineteenth-century Britain as well as acting as a check and balance on the possible abuse of power by the other three pillars of the state. Such champions of liberalism as John Stuart Mill, in his book *On liberty*, published in 1859, also argued that a liberal press was necessary for “the public good” (→ Freedom of the Press, Concept of). According to the German sociologist and philosopher → Jürgen Habermas, the wider availability

of printing facilities and the resultant reduction in production costs of newspapers stimulated debate in eighteenth-century Britain and led to the emergence of a “bourgeois → public sphere,” an arena that was independent of the state and the church, dedicated to rational debate, accessible, and accountable to the citizenry, in which public opinion is formed (Habermas 1989; → Political Discourse; Public Opinion). During the nineteenth century, greater freedom of the press was fought for and achieved in parallel with struggles for parliamentary reform.

The British press had a profound effect on its colonial territories, such as India, where the first regular newspaper, the *Bengal Gazette*, was founded in 1780 by James Augustus Hicky, an employee of the East India Company, who described the journal as “a weekly political and commercial paper open to all parties, but influenced by none” (quoted in Rau 1974, 10). The *Times of India* came into existence in 1838, while in 1858 the *Straits Times*, southeast Asia’s premier newspaper, was started as a daily newspaper from Singapore.

Advances in printing technology meant that newspapers in non-European languages could also be printed and distributed (→ Printing, History of; Newspaper, History of). By the 1870s, more than 140 newspaper titles were in circulation in various Indian languages, representing the linguistic diversity of the subcontinent. Though many of these were launched as commercial enterprises, a growing number were also inspired by a public information and fourth estate function, despite having to operate within undemocratic political systems.

*Al-Ahram*, the newspaper that has defined Arab journalism for more than a century, was established in Cairo in 1875, while Japan’s most respected newspaper, *Asahi Shimbun* (“Morning Sun”), was founded in 1890.

A socially responsible agenda was part of the nascent media, and newspapers were also used to articulate the emerging nationalism in many Asian countries.

## THE CASES OF INDIA AND CHINA

Despite strict colonial press laws, which severely curtailed freedom of expression, newspapers played a crucial role in anti-colonial movements, especially in India, where many nationalist leaders were involved in campaigning journalism, most notably Mahatma Gandhi. Writing in *Young India* (later named *Harijan*) in 1920, Gandhi, who was to become the “Father of the Nation,” defended the right of newspapers to protest against press laws: “The stoppage of the circulation of potent ideas that may destroy the Government or compel repentance will be the least among the weapons in its armoury. We must therefore devise methods of circulating our ideas unless and until the whole Press becomes fearless, defies consequences and publishes ideas, even when it is in disagreement with them, just for the purpose of securing its freedom” (Gandhi 1970, 59).

The fourth estate function of the media contributed to India’s transformation from a feudal colony to a modern nation-state with a stable, mature, and multiparty democracy. A democratic polity ensured that the government tolerated criticism of its policies on the editorial pages of the national press, providing the space within which the media could engage in critical debates on socio-political and economic issues. More importantly, the proactive and often adversarial role of newspapers contributed to a discourse of social

justice through, for example, the evolution of an early-warning system for serious food shortages and thus a preventive mechanism against famine (Ram 1990).

According to the *Hindu*, India's most respected newspaper, the long-term Indian press experience, set in larger context, suggests a set of functions that serious newspapers have performed with benefit to society. These are (1) the credible-informational, (2) the critical-investigative ("watchdog"), (3) the educational, and (4) the agenda-building functions (→ Agenda-Setting Effects; Investigative Reporting; Journalists' Role Perception). Summarizing its own principles, the newspaper said in a special editorial to mark its 125th anniversary, in August 2003: "*The Hindu* has worked out for itself a set of five principles as a template for socially responsible and ethical journalism. The first is the principle of *truth telling*. The second principle is that of *freedom and independence*. The third component of the template is the principle of *justice*. The fourth principle is that of *humaneness*. The fifth principle is that of *contributing to the social good*" (*The Hindu* 2003, italics in the original).

This fourth estate role of the media was also recognized in China, where the nationalist leader Sun Yat Sen founded *Chung-kuo Jih-pao* ("China Daily News") in 1899. In the first decades of the twentieth century, the discourse of Chinese journalism had a marked "social responsibility" bias, with such names as Liang Qichao (1873–1929), one of the most "exalted editor journalists" in the Chinese world, bringing a "rational and responsible" journalism to the Chinese public sphere (de Burgh 2003, 204).

### THREATS TO THE FOURTH ESTATE ROLE OF THE MEDIA

The liberal fourth estate functions of the media were undermined by the state control of media under communism, while in the capitalist world, hypercommercialism, indicated by a ratings- and circulation-driven media system, has eroded the democratic potential of the mass media. During the Cold War years the two competing models of media – state controlled and market driven – set the parameters of the extent to which the media could perform their fourth estate functions. In communist countries as well as in most developing countries they were little more than the mouthpiece of the ruling parties or of dictatorships – whether of right- or left-wing political orientation (→ Media Policy).

With the globalization of the US model of the media – one largely dependent on commercial → advertising – the → public interest has come under strain in most countries, evident in the decline and fall of public service media across the world (→ Public Service Broadcasting: Law and Policy). However, globalization has also provided transnational connectivity, enabling the creation of what has been called a "mediapolis," defined as the "mediated public space where contemporary political life increasingly finds its place, both at national and global levels, and where the materiality of the world is constructed through (principally) electronically communicated public speech and action" (Silverstone 2007, 24; → Globalization Theories). Unlike Habermas's conception of the public sphere, with its rational debate and argument, the mediapolis is more inclusive, because within it communication is "multiple and multiply inflected" (Silverstone 2007, 34).

Given the global nature of the → Internet, it has emerged as an increasingly important communication forum, providing opportunities for developing and strengthening a

transnational network of journalists and information activists to cooperate and exchange ideas. The “journalism domain” within the Internet, it has been argued, “is a core element of the public sphere on the Internet” (Dahlgren 2005, 153; → E-Democracy). In the age of the Internet, journalists can incorporate various viewpoints in their reports: in foreign reporting such access can be particularly useful in providing more balanced coverage on contentious international issues (→ Foreign Policy and the Media). It is the case that much of the online connectivity has been colonized for e-commerce, and yet the fourth estate functions, undertaken by activists and information mavericks, have enriched the transnational public discourse by providing alternative voices and perspectives on crucial contemporary issues.

In the 1990s the Internet was used effectively to mobilize international support against the US-sponsored Multilateral Agreement on Investment (MAI), which would have given unfettered powers to transnational corporations to move capital from one country to another. A concerted campaign was able to thwart the MAI. The growing importance of blogging in political communication as well as such “user generated” media outlets as *Current TV*, the channel made of clips created by viewers and producers and run by Al Gore, the former US vice-president, could be said to be “democratizing the media” (→ Blogger). Such globalization of news media has prompted scholars to extend the Habermasian idea of a public sphere into a global arena, facilitated by the unprecedented growth in transnational satellite news networks and online journalism, creating a global public sphere (McNair 2006).

The conception of a single, rational public sphere to promote the fourth estate function appears hard to sustain in the twenty-first century 24/7 multimedia world. In a “globalized public sphere” various versions of the public interest are circulating in a media ecology characterized by increasingly fragmenting and rapidly proliferating news and information outlets (McNair 2006, 143). The notion of a fourth estate too needs to be broadened to take account of our globalized media production and consumption patterns.

## Framing Effects

*Dietram A. Scheufele*

*University of Wisconsin-Madison*

There is no single commonly accepted definition of framing in the field of communication. In fact, political communication scholars have offered a variety of conceptual and operational approaches to framing that all differ with respect to their underlying assumptions, the way they define frames and framing, their operational definitions, and very often also the criterion variables.

Previous framing research can be classified based on its level of analysis and the specific process of framing that various studies have focused on. In particular, Scheufele (1999) differentiated *media frames* and *audience frames*. Based on these two broader concepts, he distinguished four processes that classify areas of framing research and outline the links among them: *frame building*, *frame setting*, *individual-level effects of framing*, and *journalists as audiences for frames*.

### TYPES OF FRAMES AND FRAMING PROCESSES

#### Media Frames vs Audience Frames

Media frames are defined as “a central organizing idea or story line that provides meaning to an unfolding strip of events” (Gamson & Modigliani 1987, 143). Media frames are important tools for journalists to reduce complexity and convey issues, such as welfare reform or stem cell research, in a way that allows audiences to make sense of them with limited amounts of prior information. For journalists, framing is therefore a means of presenting information in a format that fits the modalities and constraints of the medium they are writing or producing news content for (→ Media Production and Content; Framing of the News; Media Logic; News Routines) and that also makes it possible for audiences to make sense of the information and integrate it into their existing cognitive schema (→ Information Processing; Schemas, Knowledge Structures, and Social Interaction).

Some view news frames as tools of spin and manipulation (→ Spin and Double-Speak; Spin Doctor). Frames can certainly be used to manipulate the interpretation of messages by audiences. But it is important to note in this context that for most journalists framing is a tool that allows them to reduce complexity of issues and present them in a way that is easily accessible to wide cross-sections of the audience. Or as Tuchman says, “The news frame organizes everyday reality and . . . is part and parcel of everyday reality . . . , [it] is an essential feature of news” (1978, 193). Media frames serve as working routines for journalists that allow them to quickly identify and classify information and “to package it for efficient relay to their audiences” (Gitlin 1980, 7).

### Individual Frames

Media frames work as organizing themes or ideas because they play to individual-level interpretive schema among → audiences. These schemas are tools for information processing that allow people to categorize new information quickly and efficiently, based on how that information is framed or described by journalists. Framing research has often used the term “audience frame” to describe these schemas, defining them as “mentally stored clusters of ideas that guide individuals’ processing of information” (Entman 1993, 53; → News Processing and Retention).

Two types of frame of reference can be used to interpret and process information: global and long-term political views on the one hand, and short-term issue-related frames of reference on the other hand. Goffman’s (1974) idea of frames of reference refers to more long-term, socialized schemas that are often socialized and shared in societies or at least within certain groups in societies (→ Attitude Functions). But in addition to these more long-term and broadly shared schemas, there are also short-term issue-related frames of reference that are learned from mass media and that can have a significant impact on perceiving, organizing, and interpreting incoming information and on drawing inferences from that information (Pan & Kosicki 1993).

### The Interplay of Media and Audience Frames

The Price and Tewksbury (1997) applicability model of framing offers a theoretical explanation of how media frames and audience frames interact to influence individual perceptions and attitudes. They argue that frames work only if they are applicable to a specific interpretive schema (→ Schemas and Media Effects; Media Effects). These interpretive schemas can be pre-existing ones that are acquired through socialization processes (→ Socialization by the Media; Political Socialization through the Media) or other types of learning (→ Observational Learning). But they can also be part of the message itself. For example, a news message may suggest a connection between tax policy and unemployment rates. The news message may suggest that the best way to think about whether higher or lower taxes are desirable is through a consideration of whether one wants higher or lower unemployment. Thus, the message has said that considerations about unemployment are applicable to questions about taxes.

Price and Tewksbury’s applicability model does imply that when audience members do not have an interpretive schema available to them in → memory, and the schema is not

provided in a news story, a frame that applies the construct in a message will not be effective. Framing effects therefore vary in strength as a partial function of the fit between the schemas a frame suggests should be applied to an issue and either the presence of those frames in audience members' existing knowledge or the content of the message (Scheufele & Tewksbury 2007).

## **THEORETICAL EXPLANATIONS OF FRAMING**

This applicability model is consistent with the two larger theoretical or historical contexts within which researchers commonly examine framing: psychological approaches and sociological approaches.

### **Psychological Approaches**

Psychological approaches to framing research are often traced back to Daniel Kahneman and Amos Tversky's notions of bounded rationality, more broadly, and prospect theory, in particular (e.g., Kahneman & Tversky 1979). In 2002, Kahneman was awarded the Nobel Prize for his contributions to this collaborative effort, and in his acceptance speech he nicely summed up the basic premise of prospect theory: "Perception is reference-dependent" (Kahneman 2003a, 459). The idea of reference dependency assumes that a given piece of information will be interpreted differently, depending on which interpretive schema an individual applies. More importantly, however, different interpretive schemas can be invoked by framing the same message differently. Kahneman's experimental work focuses mostly on the impact of framing on economic and risk-related choices, but the implications for communication research are obvious.

A good example is the coverage of the death of Rachel Corrie. Both Reuters and the Associated Press ran news releases, outlining the basic facts. Corrie, a member of the International Solidarity Movement, was run over and crushed to death by an Israeli army bulldozer on Sunday, March 16, 2003 while she was trying to stop it from tearing down a building in the Rafah refugee camp in the Southern Gaza Strip. The difference between the two news releases was that the AP release was accompanied by a file photo of Corrie burning a mock American flag, surrounded by Palestinian children, her face contorted with anger. The Reuters photograph instead showed her lying on the ground after being run over by the bulldozer, still covered in sand, surrounded by fellow protesters, with blood running down her face.

Similar to Kahneman's example of ambiguous letters and numbers, this example highlights the idea of perceptions being reference-dependent. The written news story about Corrie's death can be interpreted quite differently, depending on which visual image is used to frame the account of events. The image, in other words, sets the context for or "frames" any subsequent information processing.

### **Sociological Approaches**

Sociological approaches to framing are often traced back to Erving Goffman's (1974) notion of frames or primary frameworks. Goffman assumes that individuals cannot

understand the world fully and therefore actively classify and interpret their life experiences to make sense of the world around them. An individual's reaction to new information therefore depends on interpretive schemas Goffman calls "primary frameworks" (Goffman 1974, 21). In particular, Goffman distinguishes between natural and societal frames similar to Heider's (1978) notion of attributions (→ Attribution Processes) to personal or environmental factors: natural frames help to interpret events originating from natural and non-intentional causes, whereas societal frames help "to locate, perceive, identify, and label" actions and events that stem from intentional human action (Goffman 1974, 21). Based on Goffman's ideas, there are various ways in which journalists can portray any given event in news coverage. And which portrayal is chosen depends on the framework employed by the journalists (→ Exemplification and Exemplars, Effects of).

### FRAMING AS A MULTILEVEL CONSTRUCT

The term "framing" has been used almost interchangeably to describe individual-level media effects, macro-level influences on news content, and other related processes. At least four interrelated processes involving framing at different levels of analysis have been identified (Fig. 1).

The first of these processes is *frame building*. Frame building refers to the linkages between various intrinsic and extrinsic influences on news coverage and the frames used in news coverage. These influences include the personal predispositions of journalists, organizational routines and pressures, the efforts by outside groups to promote certain frames, the impact of other parallel issues or events, and the type of policy arena where decision-making or conflict might take place (Shoemaker & Reese 1996; → Instrumental Actualization).

*Frame setting*, the second process, refers to the process of frame transfer from media outlets to audiences. Some communication researchers have suggested that

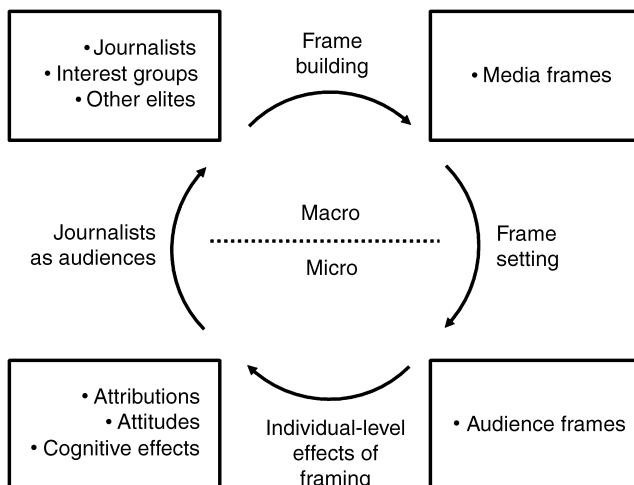

Figure 1 Typology of framing processes

this frame-setting effect is conceptually similar to the transfer of salience hypothesized in the agenda-setting model (→ Agenda-Setting Effects). Recent research, however, has shown that the two processes rely on distinctly different theoretical premises and cognitive processes (for an overview, see Scheufele 2000; Scheufele & Tewksbury 2007).

Most communication research has focused on a third process: *individual-level effects of framing*. These individual-level outcomes include attributions of responsibility, support for various policy proposals, or citizen competence (Druckman 2001; Iyengar 1991). Unfortunately, while making important contributions in describing effects of media framing on behavioral, attitudinal, or cognitive outcomes, most of these studies have not provided systematic explanations as to why and how these variables are linked to one another. Price and Tewksbury's (1997) notion of applicability effects outlined earlier provides a first step in this direction.

The last process related to framing that political communication scholars have explored is the idea of *journalists themselves as audiences for frames*. Without directly referring to the idea of framing, Fishman (1978; 1980) suggests that, similar to “regular” audiences, journalists are indeed susceptible to frames set by news media (→ Reciprocal Effects; Journalism: Group Dynamics). Fishman's study demonstrates how news coverage of isolated crimes in a community was framed as a “crime wave against the elderly” by initially a small number of local media and how that frame was soon picked up by other journalists and spread across other news outlets and communities. Fishman labels this phenomenon a “news wave.”

## UNRESOLVED ISSUES IN FRAMING RESEARCH

Framing research continues to struggle with at least three unresolved issues related to how the concept has been defined or measured.

### Framing as a Type of Agenda Setting?

Some scholars (e.g., McCombs 2004) have argued that framing is just a conceptual extension of agenda setting. Similar to agenda setting, they argue, framing increases the salience of certain *aspects* of an issue and therefore can be labeled “second-level agenda setting.”

A number of scholars, however, have rejected that notion (for an overview, see Price & Tewksbury 1997; Scheufele 2000; Scheufele & Tewksbury 2007). Rather, agenda setting is based on the notion of attitude accessibility. Mass media have the power to increase levels of importance assigned to issues by audience members or the ease with which these considerations can be retrieved from memory if individuals have to make political judgments about political actors (→ Priming Theory). Framing is based on the concept of context-based perception, that is, on the assumption that subtle changes in the wording of the description of a situation might affect how audience members interpret this situation. In other words, framing influences *how* audiences think about issues, not by making aspects of the issue more salient, but by invoking interpretive schema that influence the interpretation of incoming information (→ Attitudes, Values, and Beliefs, Media Effects on).

### Is there a Consistent Set of Frames?

The second unresolved area of framing research concerns the different *types* of frames identified in previous research. Scholars have operationalized media frames along dichotomies, such as episodic vs thematic frames (Iyengar 1991) or issue vs conflict frames (Cappella & Jamieson 1997) or game schema coverage (Patterson 1993). Other studies examined frames along content areas, such as conflict frames, human interest frames, or consequence frames (Price et al. 1997). What has been missing, however, is an examination of a set of frames that could potentially be applicable across issues. By taking an inductive approach, previous research has identified unique sets of frames with each new study. As a result, communication researchers continue to have only a limited understanding of the specific frames that can trigger certain underlying interpretive schemas among audiences and therefore lead to various behavioral or cognitive outcomes.

### Framing in the Lab vs Real World?

The final challenge for communication researchers is the inherent conflict between the different approaches to framing research that originated from the psychological and sociological foundations of the concept outlined earlier. In particular, Kahneman's (2003b) early experimental research focused on a very narrow but highly internally valid approach to studying framing. For Kahneman, framing a message means to keep the content absolutely constant and to manipulate only the mode of presentation or the context within which the information is presented (→ Strategic Framing). Based on more sociological approaches, however (e.g., Tuchman 1978), it is questionable to what extent it is possible to create real-world examples of news articles that are framed in different ways, but do not differ in terms of content. In short, framing in everyday journalism probably means a mixture of changes, both in terms of content and mode of presentation. And externally valid studies of framing effects will have to balance the desire for internally valid designs with the need for externally valid stimulus materials. Message effects in the real world are confounds of persuasive content effects (→ Persuasion) and modality- or presentation-based framing effects.

# Framing of the News

Zhongdang Pan

University of Wisconsin-Madison

Framing of news has become a lively interdisciplinary research area in recent years. The sprawling growth of this research area has its roots both in the intellectual ferment spurred by the “linguistic turn” of social theories and political practices in the era of mediated politics. Although the extant framing studies vary in precise conceptual definitions and theoretical foci, one can find some general agreements; that is, framing is a process of social actors using symbolic means to structure the social world (Reese 2001).

## CONCEPTUALIZING NEWS FRAMING

Among various definitions of framing, the most widely circulated comes from Robert Entman: “Framing essentially involves *selection* and *salience*. To frame is to *select some aspects of a perceived reality and make them more salient in a communicating text, in such a way as to promote a particular problem definition, causal interpretation, moral evaluation, and/or treatment recommendation* for the item described. Typically frames diagnose, evaluate, and prescribe . . .” (Entman 1993, 52; italics original). Focusing on the cognitive underpinnings associated with salience, this definition describes how varying salience is accomplished (via selection), where a frame resides (in text), and how such a text produces real political consequences (proving certain problem definition and policy prescription). In essence, frames are templates (ideas and principles) embedded in news texts; they are used to organize, and are also signified by, various symbolic elements (e.g., catchphases, images, metaphors, etc.; Gamson 1988).

While such a definition was offered to place news framing research in a coherent theoretical framework, others point out that news framing is a research program that has benefited from and is currently operating in the interfertilization of multiple paradigms (D’Angelo 2002). This is because framing is a *multifaceted phenomenon* with social, cultural, and political dimensions; it cannot be completely reduced to the cognitive level. Selecting what to include or emphasize in a news story is often ideologically motivated and politically charged; news text, regardless which frame structures it, is a physical embodiment of an ideology and is embedded with organizational and institutional rules and procedures of news production; and both information selection and problem definition are strategic acts performed by political actors situated in the spatio-temporal configuration of political and economic interests. Because of all these, as Gitlin points out, framing of news is an ideological process. It involves the construction of a discursive representation “about what exists, what happens, and what matters”; framing makes “the world beyond direct experience look natural” (Gitlin 1980, 6–7; → News Ideologies).

Framing of news is a *joint operation of journalists and various other social actors*. These social actors operate as sources that supply journalists with not only information but also the primary definitions and vocabularies concerning an issue or event that is to be represented in news stories. In this collaborative process, journalists play a more

subordinate role in defining the reality and their reports often “index” the opinions of political elites. In a pluralistic society, these social actors are not monolithic. Rooted in different interests and playing different roles in democratic politics, they engage in a discursive contestation in the recognition, definition, and labeling of issues, events, and problems (→ Agenda Building). By incorporating both the strategic and discursive aspects of these social actors’ actions, the concept of news framing is at the very center of developing an integrated perspective on public discourse (i.e., its structure and order, its articulation with the enduring values and the political climate of any moment, and its formation as shaped by the promotional or advocacy activities of various social actors, including social movement organizations that aim to promote their agendas through collective action; → News as Discourse).

We also need to add to Entman’s definition the conceptual meaning of framing in Kahneman and Tversky’s (1979) *prospect theory on risky choices*. In this theory, framing refers to organizing the presentation of equivalent information in different frames, which lead decision-makers to arrive at different choices through two mechanisms: first, the “gain” and “loss” frames correspond to different nonlinear value functions; second, there is a concave weight function for different levels of probability ranging from 0 to 1. These two mechanisms lead to a risk-averting tendency under the condition of certain gain and a risk-seeking tendency under the condition of uncertain loss in individuals’ decision-making. The theory makes it clear that, independent of *what* information is included, *how* such information is presented invokes a particular template through which the information is experienced. Framing, therefore, refers to the structuring of symbolic representation that sets in motion a distinct “train of thoughts” in individuals’ reasoning (Price et al. 1997) and their ways of discussing an issue.

These explications of the framing concept make it clear that framing is a process at the intersection between → political discourse and psychological effects. Therefore, the research on framing of news recognizes the “double lives” of frames and explores the connection between the two. As interpretive structures, frames are congealed in political or media discourse; as cognitive structures, they are part of individuals’ mental representations.

## NEWS FRAMING RESEARCH

News framing research to date can be roughly grouped into two broad categories: (1) identifying frames and framing devices in news, and (2) examining the effects of news framing. The former involves mostly some forms of content or textual analysis of news texts, whereas the latter often involves experiments, either taking place in laboratories or embedded in surveys. This body of literature attests to both the heuristic value and theoretical imprecision of the framing concept.

In the first category, researchers have analyzed *news texts*, often in connection with analyses of other discourses, to address a host of theoretical issues. Research has examined how an issue is framed in the news, how the framing of an issue in the media has evolved over time, the ways in which the representations of an issue are connected across the private and public arenas in a society, how the news media situate other political actors’ frames of an issue in news narratives, how journalistic → news values are manifested as organizing templates across media outlets or platforms, issues or events, and so on.

In the second category, researchers have not only examined a range of *effects* manifested as outcomes among individuals who are exposed to news frames but also proposed various accounts of the cognitive mechanisms involved. The effects range from causal attributions; internal consistency of an individual's belief system; political opinions (evaluations and preferences) on politicians, policies, and political process; ways of talking about politics and political issues; likelihood and levels of participating in civic as well as political lives; and so on. The following theoretical accounts have been proposed. First, framing affects individuals' outcomes by changing relative degrees of salience among different aspects of an issue or different considerations. Second, framing effects occur through the mediation of news frames reconfiguring the importance ranking of various principles from which individuals' judgments, evaluations, and inferences are derived. Third, framing involves reconfiguring the semantic associations among the relevant concepts stored in one's memory (e.g., increasing their proximity and strengthening their associative paths). And fourth, framing effects occurs through the application of the frame-related concepts stored in one's long-term memory. All these ideas are based on the associative network model of memory and point to transitory shifts in accessibility, applicability, prominence, and/or proximity among the concepts in such a network (Higgins 1996), presumably generated by news frames (→ Framing Effects; Media Effects).

Despite the mushrooming empirical studies on news framing, there has been little consensus on how to differentiate various frames and which frame classification system to use in various research settings. Six different *systems of frame classification* can be identified in the research literature: gain vs loss frames (sometimes simplistically referred to as positive vs negative frames), drawn from the prospect theory; thematic vs episodic frames in television news on their effects on voters' responsibility attributions (Iyengar 1991), and its more substantive extension, individual vs societal frames, based on the level of narrative foci (Shah et al. 2004); strategy vs issue frames in media coverage of election campaigns and policy debates; value frames (i.e., some enduring values functioning as "central organizing ideas" in news texts), drawn from the works of Gamson and developed further by others; news values such as human interest, conflict, and consequences functioning as frames (e.g., Price et al. 1997); and mental templates based on familiar social institutions being used metaphorically in representing unfamiliar or more complex issues (Schlesinger & Lau 2000).

Because researchers have differentiated frames in the context of addressing their own research questions, it is not clear how these systems can be integrated. Several typologies of different frames have been proposed for the purpose of studying effects (e.g., Druckman 2002; Levin et al. 1998). But they have not been useful for studying news content and its production. How to map news texts in connection with other types of public discourse remains a major theoretical and methodological challenge in news framing research. Pan and Kosicki (1993) differentiated the structural dimensions of news discourse – syntactical, script, thematic, and rhetorical structures – providing some heuristic suggestions.

## NEWS FRAMING AND DEMOCRATIC POLITICS

News framing has become a key construct in *understanding democratic politics*, based on the recognition that political actors have become increasingly sophisticated in their uses

of language and other means of signification. As a result, democratic politics increasingly involves contestations in the realm of representation, and journalists are more frequent targets of strategic framing by their sources (→ Political Communication). As a theoretical construct, news framing connects to the traditional formulations about news production and information control (e.g., → gatekeeping). But it goes beyond these confines by situating the analysis of news in the context of discursive formation of issues, policies, opinions, and engagement.

News framing also clearly relates to media effects in the → public opinion process – e.g., agenda-setting and priming (→ Agenda-Setting Effects; Priming Theory) – and news as a form of knowledge or window to the world. But it cultivates a much more expansive conceptual space to situate effects as micro constituents of democratic politics and to go beyond the informational effects of news. Further, the framing construct also raises questions about the practices of democratic citizenship, both in terms of citizen competence, interactivity between elite and the mass public's discourses about complex public issues, and the participatory potentials of individual citizens in policy deliberation and collective action.

## France: Media System

*Philippe J. Maarek*

*University Paris XII*

In its 543,965 square kilometers and some overseas dependencies, France has a population of 63 million. Currently under its Fifth Republic, a semi-presidential, semi-parliamentary political system, and a founding member of the European Union, it is a democracy of long standing. As early as 1789, freedom of speech was one of the main claims of the French Revolution, with its famous article 11: “Freedom of speech and opinions is one of the most precious Human Rights; any citizen may then freely speak, write, print, unless he has to answer for an abuse of that freedom in the specific cases determined by Law.” Nevertheless, the French media system’s independence from the state came only at the end of the twentieth century. As a consequence, nowadays, the French media system is sometimes still unbalanced by its new freedom.

### LEGAL FRAMEWORK

Print media – mainly the printed press, but also posters, etc. – have been ruled by a set of laws and government decrees based on the law of July 29, 1881, which established freedom of the press and printed material as a principle. The only limits are set by specific laws protecting minors or protecting individuals from defamation. For the audiovisual media, the case is different: freedom of radio and television is not a very natural state of affairs in France. Television and radio were a state monopoly for most of the twentieth century. The system started to come apart in the 1960s, when these media were reorganized under the sole aegis of the Office de Radiodiffusion Télévision Française (ORTF), which was nevertheless still subject to the Ministry of Information.

The end of the state monopoly, and the appearance of private radio and television stations, came when socialist politician François Mitterrand became president in 1981. After several short-lived and controversial reforms at the beginning of the eighties, the regulation of audiovisual media reached some level of stability with the September 30, 1986, law on freedom of communication. This established a fully independent regulating body for the audiovisual media, the Conseil Supérieur de l’Audiovisuel (CSA). Its area of competence is very extensive: it may issue rules, enact them, and even sit as an administrative court.

Its control is very thorough, though sometimes criticized as being more or less politically minded, since its nine members are designated by the president of the Republic and the presidents of the two chambers of the French Parliament, with some inevitable side-effects.

French audiovisual media regulations are currently facing two main problems. First, the increasing use of the Internet in many new kinds of ways is establishing it more and more clearly as a competitor to the “classical” audiovisual media. Second, there are frequent conflicts of competence between the French legal system and the decisions coming from the European Union authorities.

Taking the Internet first, it was initially understood that it would be ruled by the body of laws and regulations specifically intended for telecommunications, namely the July 26, 1996, law on telecommunications regulation. This established an independent authority in charge of that field, the *Autorité de Régulation des Télécommunications* (ART), which in 2005 became the *Autorité de Régulation des Communications Électroniques et des Postes* (ARCEP). But the increasing use of broadband to convey television is generating a conflict of legal competence yet to be resolved: in this area, should the CSA or the ART/ARCEP decide?

The second main problem comes from the discrepancies between the French and the European Union legal systems. One of the cornerstones of the European Union regulations on media, the *Television without Borders Directive*, is a particularly frequent source of conflict, because it throws the French legal system into disarray: it stipulates that a television channel legally authorized in any country of the European Union is then automatically authorized in the rest of the Union. This means that while the owners of a new channel need to go through a severe screening by the French CSA, they may seek an authorization to another less demanding country of the Union, and then be retransmitted in France through cable, Internet, or satellite (→ European Union: Communication Law).

## PRINTED PRESS

The French printed press is split into two main kinds, which follow quite different paths: daily papers on one side, magazines and other non-dailies on the other. National and regional daily papers are rather weak and have trouble staying in existence. French dailies' circulation (about 2.6 million copies) is very small compared with that in other similar countries, with a ratio in proportion to the population about half that in Germany or the UK, for instance.

Two of the dozen or so remaining French national daily papers (out of more than 80 a century ago), *Le Figaro* and *Libération*, have recently been bought by wealthy industrialists seeking influence and ready to take on their debts. In 2006, in spite of this help, *Libération* was put into receivership. The renowned evening daily *Le Monde* has been in a chronically difficult financial situation for some years, as have two smaller-circulation, narrowly focused newspapers, the Communist *L'Humanité* and the business-oriented *La Tribune de l'Économie* (with sales of under 100,000 each). Three profitable morning national dailies are *L'Équipe*, a successful sports daily with sales over 366,000; *Les Échos*, another business paper, selling around 100,000; and the Catholic *La Croix*, again with a rather small circulation of around 100,000 copies. (*Le Monde* and *Le Figaro* average 350,000 copies.) As for the formerly popular evening daily *France-Soir*, it is on the verge

of closing, while the tabloid *Aujourd'hui en France* is in fact a barely different version of the regional paper *Le Parisien*.

The situation of French national dailies has grown even worse recently with the launch of two free morning papers, *Métro* and *20 minutes*, as successful here as everywhere else. Both seem to have become profitable after only a few years and have taken away a considerable share of the advertising market from the traditional dailies. In 2006, another French businessman, Vincent Bolloré, launched the first free evening daily, the tabloid *Direct Soir*, and intends to launch a free morning daily, associated with *Le Monde*. French regional dailies have also had some difficulties. *Ouest France*, prevalent in the western part of the country, is the most important, and is profitable, with about 780,000 copies a day. This is not the case for many other regional dailies. *Le Monde* has been forging alliances with a few of them, in order to try and obtain financial and industrial synergies. In contrast to the dailies, French weekly and monthly magazines benefit from a stronger readership and from steady profits, even if advertising is slowly declining here in favor of the Internet.

Television magazines have had the highest circulation for decades: here, *Télé 7 Jours* has traditionally been the leader since the 1960s, with 1.7 millions copies a week sold in 2005 – about the same as pocket-sized *Télé Z*. But the free TV program guides included as supplements with some national and regional dailies at the weekend are threatening them: the highest circulation figure (4.5 million copies) is that of the weekend giveaway *TV Magazine*.

The new trend in recent years has been gossip magazines, with the successful launch of *Closer* coming after the success of *Voici*, *Public*, and *Gala* (with a circulation of 300,000–500,000 copies). Women's magazines are also very strong, with trendsetter *Elle* and also *Marie-Claire* (300,000–400,000 copies), but the leader is again an end-of-the-week giveaway common to several national and regional dailies, *Version Femina*, with a circulation peak of more than 3.6 million copies. *Femme Actuelle* is the biggest-selling regular popular women's magazine, with a circulation of more than 1.1 million copies.

The leading magazine publishers is Hachette Filipachi Media (HFM), a subsidiary of the Lagardere group, with its internationally known titles such as *Elle* or *Première*. Its main challenger is the German-origin Prisma group, created by expatriate Axel Ganz with considerable success. A third main publisher of French magazines, British-origin Emap/France, has recently sold its assets to Italian-bred Mondadori.

## RADIO

The economics of radio in France are still very much a consequence of its longstanding situation as a state monopoly. Of the four biggest radio groups, three remain the same as before the 1980s. First, there is state-owned Radio France, inheritor of the radio holdings of the former ORTF (i.e., the generalist France Inter, cultural France Culture, classical France Musique, etc.). Then there are two private radio groups, RTL and the Lagardere-owned Europe 1 group, that have been in existence since the 1950s: they were initially tolerated because they had been incorporated and were broadcasting in neighboring countries.

Their only recent contender is the NRJ Group, a popular radio station which arose from the hundreds of so-called “free radio” stations authorized in 1981, when the Socialists won the elections. Most of the other newly founded stations did not survive,

remained local, or did not manage to form a media group going much further than their main station. To compensate for their weakness, several so-called “independent” radio and television stations have formed a lobbying structure, the *Syndicat Interprofessionnel des Radios et Televisions Indépendantes* (SIRTI).

## TELEVISION

The structure of French television has changed considerably since the mid-eighties, although state-owned France Television is still a major player. But it is the TF1 group that is dominant, with its main asset, TF1, bought by industrialist Francis Bouygues when the 1986 conservative government decided to open television up to competition by privatizing the leading channel. The TF1 group is by far the most profitable television group, with TF1 audience market share steadily at between 30 percent and 40 percent, and its share of the advertising revenues at over 50 percent.

The two other major players in television are M6, initially dedicated to music but now a strong generalist channel, and Canal Plus, the first and dominant pay-TV channel. There is strong competition among these groups. State-owned France Television, TF1, and M6 even formed an alliance to build up a satellite pay-TV service, TPS, against Canal Plus’s satellite pay-TV programs, Canal Satellite. But in 2006, when the newly arrived free digital transmissions started to put satellite pay-TV in the shade, the three private groups, TF1, M6, and Canal Plus, formed an alliance, unifying their satellite and pay-TV subsidiaries under the banner of Canal Plus. They were joined by the Lagardere group; France Television had already left the alliance two years earlier.

## INTERNET

Here, the leader in terms of subscriptions is still Orange/France Telecom, the former monopoly in telecommunications, now privatized through its Internet subsidiary, also called Orange. An independent Internet player, Free, is a vigorous challenger, inventing a multimedia terminal, the Freebox, which is the first that can deliver ADSL broadband Internet and television (and now also Wi-Fi and phone) simultaneously, and for a much lower price than its competitors. Tiscali and Cegetel Internet subsidiaries are other important contenders in the market, while AOL’s French subsidiary completely misfired, and sold its operations in 2006 to Cegetel.

Thanks to the strong competition among Internet providers in price as in service, about 11.1 millions homes had broadband access at mid-2006, a figure more than 40 percent higher than a year earlier.

Less developed than in other countries, the cable providers have now all merged under the banner of UPC-Noos, but remain a minor player (about 6 percent of Internet access).

# Francophonie

*Jean-François Polo*

*Institute of Political Studies in Rennes*

Commonly, “francophonie” carries three meanings: linguistic (those who have French in common); geographical (the peoples whose mother tongue, fluency, or administrative language is French); and a more mystical meaning, signifying membership of a collective community. But “Francophonie” (capital F) designates the movement and institutions initiated by French authorities after World War II in favor of the French language, in the context of its former colonies’ independence. France tried to promote a French “commonwealth” and a special relationship with ex-colonies to protect the language. France was very often accused of maintaining neo-colonial relationships, but the movement for Francophonie was also supported by leaders of the new independent states as a means to build new relations with the former colonizer. Were these, then, actions to support the French language worldwide, or to protect French political and economic interests in its former colonies? This debate has been at the core of the history of Francophonie. Nowadays, through its institutions and agents, Francophonie strives to propose an alternative to a homogenizing globalization process, by promoting cultural diversity (→ Culture: Definitions and Concepts; Globalization Theories).

## HISTORY OF FRANCOPHONIE

Invented at the end of the nineteenth century by French geographer Onésime Reclus in his book *France, Algérie et les Colonies*, to categorize French speakers on the national territory and in the colonies, the term immediately bore ambiguity: “We consider as Francophone all who are or appear destined to remain here, everyone who seems to stay or to become participants in our language: Bretons and Basques of France, Arabs and Berbers of Tell, of whom we are already the Masters.” However, even if the movement was initiated by the French state in the 1950s to contain its colonies’ demands for independence, its founding fathers were predominantly political leaders of the new African states.

Indeed, during the 1950s, France elaborated various projects to establish a French Commonwealth (such as the project of a French Community in 1958), which failed because of the strong desire for emancipation in the colonies. Concurrently with these state initiatives, numerous nongovernmental associations emerged to assemble French language specialists in various disciplines. In 1952 the International Association of French Speaking Journalists was created in Paris, and in 1954 the French Cultural Union. In 1961, the Association of Partly or Totally French Speaking Universities was founded in Montreal, which extended Francophonie beyond linguistic disciplines and marked Canada's entrance into Francophonie (Quebec proclaimed itself during the provincial elections of 1960 as a "French speaking nation"). In 1962, the French review *Esprit* published a special issue on "Francophonie," which consecrated the African continent to Francophonie through its herald, the poet and president of Senegal, Léopold Sedar Senghor. An institutionalization process then got under way, with international conferences of ministers of French-speaking countries (on education, sport, and youth), and the creation of administrative bodies (such as the High Committee for Defence and Expansion of the French language).

But the true foundation of the *political project of Francophonie* is due to the initiatives of three African political leaders who strove to foster close cooperation first within the African French-speaking area, then beyond Africa. In 1960, Léopold Sedar Senghor (Senegal), Habib Bourguiba (Tunisia), and Hamani Diori (Niger) proposed to gather together the newly independent countries wishing to keep relationships based on cultural and linguistic affinities with France. But this project was not welcomed by all the countries (Morocco and Algeria were reluctant or refused). In 1967 the International Association of French-Speaking Parliament Members (AIPLF) was created (the future Parliament of Francophonie). Finally, thanks to the initiative of the three African leaders, plus Prince Norodom Sihanouk (Cambodia), the Treaty implementing the Cultural and Technical Cooperation Agency was signed on March 20, 1970, the first intergovernmental organization of Francophonie. Yet the very first international "Francophone Summit" took place in Versailles only in 1986, which brought together 42 participants and set up the institutional basis of Francophonie.

### THE INSTITUTIONS OF FRANCOPHONIE

The Heads of State and Government Conference, with French in common, is called the "Summit" and is the highest authority of Francophonie. The Summit is held every two years. At the Quebec Summit (1987) five sectors were defined: agriculture; energy; culture and communication; scientific information and technological development; and language. The next summit added three additional axes of cooperation: education and training; the environment; and democracy and the rule of law. Succeeding summits were held in Dakar (Senegal) in 1989, Paris in 1991, Mauritius in 1993, Cotonou (Benin) in 1995, Hanoi (Vietnam) in 1997, Monckton (Canada) in 1999, Beirut (Lebanon) in 2002, Ouagadougou (Burkina Faso) in 2004, and Bucharest (Romania) in 2006. Quebec was scheduled for 2008. The summits establish the orientations of Francophonie, decide on admission of new members, and elect the Secretary-General of Francophonie.

The *International Organization of Francophonie* (IOF) is the key multilateral institution under the authority of the Secretary-General and acts through the Francophone Agency. The IOF implements the intergovernmental cooperation of Francophonie, supports the member states in elaborating or consolidating their national policies regarding Francophonie, and implements multilateral cooperation projects. The IOF acts also in favor of peace, democracy, and human rights among the Francophone members. As of 2007, it included 53 member states and 10 observer states on all continents. French (spoken by around 200 million people) is the official language, on its own or combined with other languages, in 32 IOF member states. In 2005, the IOF budget was €83 million, to which the main contributors were France (54.5 percent), Canada (21.5 percent), Quebec (4.1 percent), Belgium (8.6 percent), and Switzerland (6.6 percent). The IOF headquarters are located in Paris (with 367 agents of 36 different nationalities), but it has four permanent representatives, in Addis-Ababa (at the African Union, and the UN's African Economic Commission), in Brussels (at the EU), and in New York and Geneva (at the UN); and three regional desks (West Africa, Central Africa, and Indian Ocean).

The *other institutions of Francophonie* are the Permanent Council, in charge of preparing and following up the summits, chaired by the General Secretary and composed of representatives of member states; and the Conference of Ministers, which maintains policy continuity between the summits, composed of the Foreign Affairs or Francophonie ministers of member states. There are four additional *Francophonie agencies*: (1) the University Francophonie Agency (AUF), which aims to build academic cooperation in French by supporting faculty and student exchange programs among over 600 research centers and universities in 70 countries on all continents; (2) TV5 Monde, a multilateral TV channel based in Paris, which diffuses cultural programs, movies, and news in French in 202 countries, 24/7; (3) Senghor University in Alexandria, Egypt, an international French-language postgraduate university to educate top executives to work in development priority fields; and (4) the International Association of French-Speaking Mayors, which promotes decentralized cooperation, good governance, and the strengthening of local democracy.

### **DEBATES AND CONTROVERSIES: NEO-COLONIALISM OR CULTURAL DIVERSITY?**

Mainly initiated by pro-independence African leaders, Francophonie emerged as a large movement associating former French colonies and partially or totally French-speaking states across all continents. But the relationship between France and its former colonies was not unidimensional.

Since independence, their relationship has been ambiguous, where under cover of a special relationship involving privileged cooperation and technical assistance, political and economic interests were sought to be secured by playing the part of Africa's policeman. Development cooperation was not simply to preserve past advantages. It took place in a strong political project of power and influence urged by President de Gaulle. France used its aid policy and also its culture to transform a sovereign area into a zone of influence. Thousands of technical aid workers and French teachers were posted to the former

colonies to diffuse the language. But the intention was also to educate French-speaking elites who could become potential partners and clients for the future. These actions encouraged the newly independent states to adhere to French culture. Thus, French global cultural influence was a major instrument of its political influence.

But at the same time, it is interesting to point out that de Gaulle remained aloof from the Francophonie project, probably in order to avoid giving ammunition to those who attacked France's African policy as neo-colonialist. For over 40 years, this policy was maintained by hidden interests and clientelist networks, using Africa as France's "game-preserve," stigmatized by the term "Françafrique" (Verschave 1998). At the end of the twentieth century, France's Africa policy, with its involvement in episodes such as the 1994 genocide in Rwanda, was fiercely criticized. Those attacks led to formal institutional change in 1998, with the absorption of the ministry of foreign aid (for Africa) into the Ministry of Foreign Affairs. In the following years, Franco-African relationships lost their specificity with the decline of a specific development budget and a rise in multilateral projects. Cultural cooperation was also transformed in the same direction, with the emergence of new actors, such as nongovernmental organizations or local associations, which sought to promote different forms of cultural exchanges (Visier 2003).

The movement in favor of Francophonie has been influenced by the evolution of Franco-African relations and more broadly by the international context. The dynamics of globalization have generated new anxieties prompted by the growing decline of French language influence and the inexorable rise of English in global communication and international organizations. While the promotion and defense of French remain clear goals for the IOF, its new target has become to defend cultural diversity. The problem is not that English is imposing itself as an international language, but to protect and promote other living languages around the world. The Francophone authorities made this goal their chief priority. They strongly supported the → UNESCO Convention on the Protection and Promotion of the Diversity of Cultural Expressions (adopted in 2005). This Convention is a binding international legal instrument (since March 18, 2007) which aims to reaffirm the sovereign right of states to draw up cultural policies, to recognize the specific nature of cultural goods and services as vehicles of identity, values, and meaning, and to strengthen international cooperation and solidarity so as to favor the cultural expressions of all nations (→ Cultural Products as Tradable Services). Francophonie supported the Convention because it shared the same principles (IOF 2006). For some authors, Francophonie is a unique chance for globalization to encourage cultural diversity against the threat of standardization or cultural domination (Wolton 2006).

Along the same lines, Francophonie began a dialogue with other linguistic areas, notably Hispanophone, Lusophone, and Arabophone, to develop concerted initiatives to promote cultural and linguistic diversity in their own territories. At the national or sub-national levels, IOF seeks to support the global south in elaborating cultural policy in favor of traditional music forms, or training lawyers specializing in anti-piracy efforts. The IOF also supports the valorization of vernacular languages that coexist with French. Following sociolinguists' analyses, it supports states which wish to develop and protect the use of dialects or creoles, termed "partner languages," to facilitate their engagement in written forms in harmony with French (Calvet 1999). These initiatives take the form of publishing journals in vernacular languages or of French/Partner-Language dictionaries.

Recently, French-speaking novelists adopted a manifesto “for a world literature in French,” but freed of its exclusive pact with France (Rouaud & LeBris 2007).

From the postcolonial project of promoting French to the protection of cultural diversity, the Francophonie project has sought to renew its philosophy while developing its institutions. However, the means remain limited and dependent on contributions from richer member states of Francophonie. M. Abou Diouf, Secretary-General of Francophonie, commented sourly in an interview with *Le Monde* in March 2007 on the paradox of lukewarm interest in Francophonie among the French. At the same time, current French immigration policy was perceived in Africa as an ongoing disjuncture between the theory and the reality of Franco-African cooperation (*Politique Africaine* 2007).

## **Free Flow of Information**

*Emile G. McAnany*

*Santa Clara University*

The free flow of information has been a key policy as well as a political aspect in the US government's approach to → international communication since World War II. There has often been a conflation of the term between a principle of democratic governance found in many national constitutions and United Nations agencies' charters (→ UNESCO), and the political principle of promoting free trade status to the export of news and entertainment

content across national boundaries (→ Cultural Products as Tradable Services). The historical review of the term “free flow of information” made by Schiller (1981) showed that the US Associated Press (AP) news agency had for decades before World War II argued against the European cartel of British, French, and German → news agencies that controlled the dissemination of international → news. At the end of World War II, the US emerged as the dominant economic and military power and began to promote the free flow policy as a universal principle of democracy for other nations. The US was among those nations that proposed and approved the inclusion of rights to free speech and information flow in the United Nations charter. As the Cold War got started in the late 1940s, the issue of free flow took on a whole new character, making it into an enduring political factor that included both the issue of government control of information and the export of news and entertainment to other countries.

The history of the term was complicated by the Cold War standoff between the US and the USSR but also by trade and technological developments. In the early 1960s the US launched experimental communication satellites that were geostationary, that is, remained in fixed positions over the equator at such a distance that they rotated in sync with the earth (→ Satellite Communication, Global). This meant that with three satellites the entire world could in theory receive messages from anywhere. By the late 1960s the US and other western countries had started such an international system with the consortium called Intelsat. The USSR and its allies saw this as a direct → propaganda threat that might feed unwanted → television programs into their territories. The fight within the United Nations was a standoff, but the consequence was that nations agreed to honor the territorial integrity principle in their satellite communication for the next two decades. At about the same time, the free flow principle emerged in another context within the United Nations agencies.

The United Nations Educational, Scientific and Cultural Organization (UNESCO) was an agency that had from its beginning in 1945 promoted the free flow principle and had also placed mass communications squarely into its most basic efforts to promote international development (→ Development Communication). As recently freed colonial countries joined the agency as members, the issues and focus began to change. The expansion of mass communication infrastructure, including communication satellites, was joined by the issue of the dominance of foreign content on the new television systems. The proposal to institute national communication policies to plan for more national news and entertainment content as well as limiting the import of foreign content touched on two important issues: the control or even → censorship of content by national governments, and the trade status of information that circulated among nations. The fact of US dominance in the international trade of both news and entertainment became a contentious point in the ensuing New International Information Order (NIIO) debate within UNESCO (→ New World Information and Communication Order [NWICO]). The conflation of freedom of information and the free trade of content made for complications in settling the dispute. The US government, which through its State Department had promoted both free trade and freedom of information, opposed many of the policies proposed by the report of the MacBride Commission in 1980 (2004) to resolve the issues. Eventually the US withdrew from UNESCO in 1985, only rejoining in 2003.

In the aftermath of the withdrawal, many scholars analyzed the factors that led to this political decision. Giffard (1989) provided the most compelling data about the coverage of the NIO debates in newspapers and on television. He showed that there was biased coverage by the news organizations that subverted the very principle of free flow that these same organizations were vigorously advocating (→ Bias in the News). The issue of trade dominance in export of content remains unresolved although the World Trade Organization (WTO) has been moving in the direction of greater freedom for trade in information. The solution is not clear as there remain a number of national and regional policies that limit the import of foreign content based on cultural integrity, including Canada's "cultural exception" principle in the North American Free Trade Agreement and the European Union's Television Directive of 1989 (Communication Law and Policy: North America; European Union: Communication Law; NAFTA and International Communication). The issue of the right of countries to control access to content that is deemed dangerous culturally or politically confronts the increased availability of this content through free trade pressure as well as more sophisticated technologies. The resolution will not likely be easy.

## **Freedom of Communication**

*Brian Winston*

*University of Lincoln*

The *annaliste* historian Fernand Braudel asserts that dealing with the concept of liberty, "in all its connotations including 'taking liberties,'" is the distinguishing mark of western civilization, the socio-political problem that most persistently occurs from the fifth

century to the present. The liberty to communicate, to impart and receive information of all kinds, is at the heart of the western idea of liberty. “This process has never been peaceful; yet it is one of the secrets that explains Europe’s progress” (Braudel 1993). The struggle for the practice of free “mass” communication begins with the emergence of newspapers in the seventeenth century, but the press freedoms gained over the next 300 years have been limited to print (→ Newspaper, History of; Freedom of the Press, Concept of). Even in the west a media-blind right of free expression has never been established, and newer media from film through broadcasting and beyond have been subject to the imposition, or the attempted imposition, of specific controls.

## ROOTS

Freedom of expression as a right was born in western Europe as a consequence of a desire to practice religion, within the bounds of Christianity, according to the dictates of one’s own conscience. The matter was not one of private thoughts and activities being policed. Rather, it was the making public of unorthodox opinions – the publishing of them – that was at issue. It was not that, for example, Galileo had privately observed proof of a heliocentric planetary system through his telescope in contradiction to the church’s teaching, but that he published his findings in *Nuncius siderius*, that caused him problems (Galilei 1980). The demand that publication in any form be permitted as a right received its first serious secular expression through the means of mass communication during the wars of religion between Protestant and Catholic in the early seventeenth century.

By then the ambiguities of the technology of the press were much in evidence. On the one hand, printing allowed for uncorrupted religious texts of the Bible and the Psalter and enabled authority more efficiently to communicate with its subjects; on the other hand, dissidents of all persuasions from heretics to astronomers could also use printing from type to promulgate their alternative views (→ Printing, History of). Authority attempted to control the press to its own advantage with licensing systems of various degrees of sophistication. Monopolies of licensed printers were established and the physical presses were also licensed. The texts to be printed were further subjected to control via → censorship procedures including vetting and registration. Despite all this, these censorship regimes were, as often as not, very leaky. Within a polity, unlicensed presses, being small enough to put on a handcart, were hard to discover and cross-border traffic in printed materials was equally difficult to monitor.

In 1644, during the English Civil War, the poet John Milton wrote an unlicensed pamphlet in praise of the then illegal procedure of divorce. After he was hauled before Parliament to explain himself, he published his defense, deliberately unlicensed: *The Areopagitica: A speech of Mr. John Milton for the Liberty of UNLICENS’D PRINTING, to the PARLIAMENT OF ENGLAND*. “Give me the liberty to know,” he wrote, “to utter, and to argue freely according to conscience above all liberties.” It was, he claimed, “as good almost kill a man as kill a good book” (Milton 1951). The *Areopagitica* was, however, no plea for unbridled free expression. Milton did not envisage, nor did the majority of those who succeeded him in holding free expression dear, a libertarian free-for-all. Necessary constraints upon expression would remain in place. The law would still move against those who directly harmed their neighbors by slanderous speech or libelous writing or

printing (→ Libel and Slander). Expression deemed to jeopardize the safety of the state was still sedition, and unorthodox religious opinions publicly expressed were blasphemy. Obscenity, variously defined, was still forbidden. The penalties for these crimes and civil actions remained, often draconian and sometimes capital. What was new in the seventeenth century was the demand that the operation of control take place through legal procedures after the expression had been published and not by censorship before.

This essentially permissive interpretation became the basis of press freedom – liberty from what came to be known as “prior constraint.” In 1695, MP Edward Clarke, using arguments furnished by his friend the philosopher John Locke, spoke in the House of Commons against an attempt by the crown to restore the pre-Civil War censorship regime exactly along these lines: because of the general law, he claimed, specific legislation “for the restraint of printing” is “very needless” (Winston 2005). This became common law doctrine but was significantly a more limited approach than that which radical opinion was beginning to formulate. In 1720, the London journalists John Trenchard and Thomas Gordon, writing together under the pen-name “Cato,” argued for a more general right of free expression: “Freedom of speech . . . is the right of everyman, as far as by it he does not hurt or control the right of another; and this is the only check which it ought to suffer, the only bounds it ought to know” (Trenchard & Gordon 1995, letter 15). Such a broader principle, although still constrained by the injunction to do no harm, remained a matter of radical, if not revolutionary, demand, even where, as in Britain and its American colonies, the technical legal prohibition against prior constraint existed. Thus, although the British press was protected from censorship, the British stage, for example, was not. A court official, the lord chamberlain, was empowered by an act of 1737 to censor and license all public performances. This act was not abolished until 1968.

Despite the failure to establish a media-blind right of free expression, by the end of the eighteenth century the principle was being written into radical constitutions. Partially in Denmark in 1761 and more comprehensively in Sweden in 1766, right of free expression statutes were imposed on weak kings, albeit only to have them repealed when the kings in question died. Article XI of the Rights of Man and of the Citizen, passed in August 1789 at the outset of the French Revolution, finally makes the rhetoric of “Cato” into law: “The free communication of thoughts and opinions is one of the most precious of the rights of man. Every citizen can speak, write and publish freely, only to answer to an abuse of this liberty in a scheduled action at law.” Some three years later, this right was abruptly declared *interdit* by a new constitution. Free speech was over. Longest lived of these eighteenth-century statutory rights is the First Amendment of the constitution of the United States, adopted in 1791: “Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or of abridging the freedom of speech or of the press; or the right of the people peaceably to assemble, and to petition the Government for the redress of grievances.” This is still in force.

## FREEDOM OF COMMUNICATION AND CONTROL OF MODERN MEDIA

With the coming of the new media of the twentieth century – → cinema, → radio, and → television – the tendency was to follow the model of the stage rather than of the press. The cinema was seen simply as a mechanization of the theatre and therefore the usual

range of prior constraints, the licensing of premises and of the films themselves, were put in place in essentially the same form in all western countries. Radio signals, unlike the press or cinemas, where a proliferation of publishers or sites could be established without overlap, demanded some form of centralized control if stations were not to interfere with each other. Moreover, the technology had emerged from naval experimentation and was initially of primarily military interest, another strong reason for state control. However, control of the infrastructure by the licensing of wavelengths did not automatically require further control of content. Yet control of content, as with the cinema, became the norm. All this was carried over into television, and various reasons were brought forward as to why what was “very needless” for the press was required by broadcasting (→ Radio: Social History; Television: Social History).

The underlying justification for the specific content controls that emerged is that the liberty afforded the press is inappropriate to these newer media. These, it is held, are far too persuasive and pervasive not to need special constraints. However, it can be argued that the press in the eighteenth century, for example, when at least 13 million newspapers a year were sold in Britain, had significant penetration into what was a much smaller literate elite. Certainly nineteenth-century newspapers could bring down a government. Other arguments for the specific control of modern media, such as the fact that broadcasting enters the home and could therefore be an “unwanted guest,” are even less compelling. The reasoning that holds that the regulation of infrastructure tends to create monopolies that need content control is a self-fulfilling prophecy, because such technological considerations have all too often resulted in unnecessarily centralized systems, even at the beginning of radio. With the proliferation of channels and platforms in the twenty-first century, these arguments become irrelevant. It is anyway illogical in societies that have supposedly adopted free speech as a human right to then put in place specific controls because media have influence. This is in effect to make free expression consequent upon its ineffectiveness. An Edward Clarke might well be justified in arguing that such controls are “very needless” in an age of media abundance just as they were in an age of comparative media scarcity.

The contradiction between a fundamental right of expression and the control of specific media remains unaddressed. Article 10 of the European Convention on Human Rights (1950), for example, states in a fashion to be found widely repeated in both international declarations and national laws since World War II (→ European Court of Human Rights): “Everyone has the right to freedom of expression. This right shall include freedom to hold opinions and to receive and impart information and ideas without interference by public authority and regardless of frontiers.” Yet this article goes on in overtly contradictory language to allow a state to require “the licensing of broadcasting, television or cinema entertainments” without specifically excluding content regulation by prior constraint (Anon. 1992). The conflict between basic principle and specific regulation can be seen as being at the heart of national broadcasting institutions such as the → BBC, which exist in the crease between free expression and state control, exactly reflecting the confusions of Article 10 of the Convention. It is therefore still the case that filmmakers and broadcasters are subject to specific content regulation and licensing via the agency of statutory or quasi-statutory bodies, such as the Office of Communications (OfCOM) in the UK or the → Federal Communications Commission (FCC) in the US, although these

potentially overt censors are normally inhibited by the tradition of press freedom, despite the fact this does not apply and on occasion is ignored, albeit controversially (→ Television Broadcasting, Regulation of). Moreover, it is not the case that new media – the → Internet, say – are, because of their technological formation, automatically free of specific control either. Witness Google’s or Rupert Murdoch’s relationship with the Chinese authorities or the action of the Iranian government in denying access to certain sites (→ Internet Law and Regulation). The systems for controlling the Internet are indeed leaky – but they exist and are in operation just as was the leaky system of controlling the press five centuries ago. And the controls constantly threaten to expand.

### **NEW THREATS TO FREEDOM OF EXPRESSION**

Up to the present the concept of free expression has remained limited, constrained by general laws and the principle that expression shall cause no legally measurable harm; by the nature of the medium involved; and by the changing social determinants of what constitutes expression sanctioned by community standards. These last are, of course, fluid and change over time. Hence the concept of obscene expression moved radically in the twentieth century. In the secularized west, laws against blasphemy are to all intents and purposes dead letters. Conversely, specific prohibitions against, say, publishing the names of children involved in legal proceedings or of rape victims have been enacted (→ Morality and Taste in Media Content).

This fluidity speaks to a more fundamental change as the west has become increasingly sensitized to the issue of human (and, it can be noted, even animal) rights in general. The old common law sense of “harm” being limited to demonstrable material damage is being rapidly amended to embrace nonmaterial damage, such as distress. At the same time the distinction between insult (which has no necessary harmful consequences) and incitement (which is designed exactly to produce such harm) is being eroded. Given the failure to establish a general right of free expression across all media, the new sensitivity to expanding the original concept of “hurt” to embrace an ever-greater degree of distress is a matter for concern. While obviously welcome in many ways, this growing sensitivity, and the changes it is bringing in train, have a chilling effect on the basic principle of free expression. It is a paradox that the test of the existence of free expression – that is, expression beyond upsetment but without some measure of demonstrable actual harm – has to be that society countenances it on occasion causing offense. If expression is never offensive, how can we be sure it is free?

Given that the principle of media-blind free expression has never been established, the moves toward controlling distressing speech, even if the anti-censorship mechanism of no prior constraint exists, has a chilling effect that might be considered threatening to the fundamental right. That this is underway at a time of extreme liberal community standards in certain areas, such as obscenity, is a further paradox. The liberalism of the one area of expression does not remove the threat of constraint to other, perhaps more significantly political, areas.

Alexander Hamilton, a Federalist father of the American constitution, had argued against the passage of the First Amendment that “whatever fine declarations may be inserted in any constitution . . . [Liberty of the Press] must altogether depend on public

opinion, and on the general spirit of the people and of the Government,” and that this could not be written down. Without this support Hamilton felt constitutional guarantees were worthless. There are worrying signs that this “general spirit” is not what it was. For example, a survey conducted on the bicentennial of the First Amendment in 1991 found that a majority of Americans felt that First Amendment protections should be watered down. Editorializing during a political campaign should not be automatically protected; nor should the press be allowed special privileges in covering the sexual behavior of politicians or publishing graphic photographs. Even the prohibition against prior constraint should be abolished for the reporting of security matters. Those surveyed “displayed an alarming willingness to remove legal protection from forms of free expression they merely disagreed with or found offensive” (Wyatt 1991). However much public appetite for sexual explicitness in expression drives the western media market, such a lack of an underlying appreciation of the principle of free expression, as well as the inappropriateness (as it might be argued) of continued media-specific content controls in an age of information abundance, are worrying signs that a four-century march toward establishing free expression as a general human right is in danger of being halted.

Hamilton’s essential point should not be forgotten: freedom of communication depends on the “general spirit”; technology, even global twenty-first-century computer-based networks, however sophisticated, can never be more than a necessary condition of free communication. It cannot, of itself, guarantee free communication, whose efficacy as an agent of freedom still depends more on societal forces than on technological wherewithal.

# Freedom of Information

*Martin E. Halstuk*

*Pennsylvania State University*

During the latter half of the twentieth century, the world's established democratic nations – along with those nations seeking to adopt democratic principles – experienced a sea change in governance with the rise of transparency, the idea that the workings of government should be visible. This global movement is grounded in the accountability principle of a representative democracy – namely, that in an open and democratic society citizens must have a right of access to government-held information so they can hold government responsible for its actions, and make informed decisions pertaining to self-rule. As of 2006, a public right of access to the vast stores of information gathered by governmental administrative bodies has been created in 68 nations under the general rubric of “freedom of information” laws.

The general principle of transparency can be traced to the eighteenth century. Sweden was the first nation in the world to recognize openness as a constitutional right when it created its Freedom of the Press Act in 1766, which granted a right of access to official government documents. The notion that public officials and bureaucrats should be accountable to the public was explicitly stated in the Netherlands in its 1795 Declaration of the Rights of Man, which declared that the public has the right to require that “each functionary of public administration” disclose “an account and justification of his conduct.”

The legal bases for the modern right to freedom of information today vary widely from nation to nation. In some countries, freedom of information is embodied in laws that protect freedom of expression and freedom of the press. In other nations, it is a separate and distinct right. Some nations contain constitutional provisions for access to public records and documents, while others provide for transparency by legislation or in a statute. For example, the United States Supreme Court has ruled that a right of public and press access to government information and facilities does *not* have constitutional protection, unlike freedom of speech and freedom of the press. America's right of freedom of information was created by Congress in 1966 in the Freedom of Information Act (FOIA). Additionally, open-records laws have been approved by legislatures in each of the 50 states and by the District of Columbia. On the other hand, many nations, such as Austria, Belgium, the Dominican Republic, Georgia, and Slovenia, to name a few, recognize a general principle of public access to information in their constitutions.

## **TRANSPARENCY LAWS VARY**

Typically, constitutional protection for freedom of information is stated in only general terms or as a principle. Therefore, nations with constitutional protection for freedom of information have also enacted a statute or other form of legislation that sets forth specific procedures to implement and enforce the constitutionally protected public right of access. Procedural examples include requirements that the government set deadlines so that agencies respond to information requests in a timely fashion; promulgate administrative

rules and regulations in a widely circulated official publication or on the Internet; and enumerate specific exemptions under which information can be withheld.

The United States has led the way in fostering the philosophy of freedom of information throughout the world and providing a model for an effective public records statute. The global spread of *public access laws* was slow, however. By 1986, 20 years after the US FOIA was enacted, fewer than a dozen nations had adopted a similar law. After the Soviet Union's collapse in 1989 and the emergence of fledgling democracies in Latin America and Africa, freedom of information laws began to proliferate. By 2006, when the US FOIA marked its 40th anniversary, 68 nations had enacted open-government statutes.

Generally, an effective freedom of information paradigm in the twenty-first century has several *fundamental characteristics*. The *first and guiding principle* behind a freedom of information law is a presumption of openness supported by a policy that the law is intended to provide full disclosure. The Republic of South Africa's public right of access, embodied in its 1996 Constitution, is one of the most progressive in the world because of the "profound mistrust the apartheid era instilled in people regarding government" (Mendel 2003). The stated purpose of South Africa's Promotion of Access to Information Act is to foster "a culture of transparency and accountability" and to "promote a society in which the people of South Africa have effective access to information to enable them to fully exercise and protect all of their rights."

Second, the right of access should be *available to "any person" and for "any purpose"*; the reason for a request should be irrelevant. "Any person" is granted a right of access to public records and documents under the US FOIA, Japan's Law Concerning Access to Information Held by Administrative Organs (1999), Bulgaria's Access to Public Information Act (2000), and Denmark's Access to Public Administration Files Act (1985), among many others. The Croatian constitution (1990) provided journalists with a right of access to information, but it was not until the Act on the Right of Access to Information was approved in 2003 that "any person" had a right to obtain government-held information. Some nations impose restrictions regarding who can gain access to information.

For example, the Parliament of India enacted the Right to Information Act in 2005. The legislation applies to records held by the central government and also to public agencies under state and local jurisdictions, but India's right of access is granted only to Indian citizens. Likewise, Canada's Access to Information Act (1983) is limited to Canadian citizens, permanent residents, and Canadian corporations. Similarly, in Israel, the Freedom of Information Law (1999) allows any citizen or resident access to government-held information, but it limits access to non-citizens and non-residents to matters related to their rights in Israel.

Third, an effective freedom of information paradigm allows the government to *refuse disclosure only if the requested information falls under clearly stated and narrowly drawn exemptions*. Narrowly crafted exemptions are necessary in order to limit discretion by officials. Exemptions vary considerably from nation to nation. Although nations' exemptions vary, the most common exceptions to disclosure fall under the categories of national defense, personal privacy, law enforcement investigations, information that may jeopardize an individual's safety or life, and proprietary business interests and trade

secrets. Under the United Kingdom's Freedom of Information Act (2000), for example, there are three general categories of exemptions and twenty specific exemptions. The United States FOIA lists nine exemptions. Mexico's Federal Law of Transparency and Access to Public Government Information (2002) parses its exemptions into five categories of documents and records that can be withheld if disclosure would harm the public interest – and separate exemptions for other kinds of information such as trade secrets, and some judicial and administrative records. Albania is unusual in that its Law on the Right to Information for Official Documents (1999) contains no exceptions; the government can withhold documents only if disclosure is restricted under other laws, such as laws on privacy or classified information.

### EXEMPTIONS TO DISCLOSURE

Fourth, a freedom of information law should provide for an independent review when government refuses to disclose information. In Germany, an appeal can be made internally to the agency denying disclosure. If that appeal fails, requesters can go to a federal commission on freedom of information. Requesters can also appeal to the courts. France and Bulgaria are examples of nations that have no internal appeals process. In France, complaints go directly to a national commission that is charged with freedom of information oversight; disputes must be decided by this national commission before an appeal can be made to the courts. In Bulgaria, appeals go directly to the courts. Under the US model, appeals are made internally to the agency, and, if unsuccessful, requesters can then go to the courts.

A review and *appeals process should comprise a two-step analysis*. First, a determination must be made to confirm that the requested information does, in fact, fall under the exemption claimed by the government. Second, a balancing test must be conducted to weigh the harm of disclosure against the public interest in disclosure. Harm standards vary. Ideally, the degree of harm should be substantial harm.

A fifth characteristic is an *affirmative duty to publish certain information without the need for a request*. The US FOIA, for example, requires that agencies publish – both in the widely available Federal Register and on the Internet – their organizational plans, regulations, annual reports, statements of agency rules and policy, and instructions on how to use the FOIA. The rationale behind affirmative disclosure is to guard against the development of agency “secret law” – rules and regulations known to government officials but not to the general public.

Finally, in keeping with the spirit of a right of access to “any person,” fees for copying records must be reasonable. Otherwise, information would be accessible only to those who can afford it. (A right of public access to meetings of official bodies is also an essential component of open government. However, provisions for the public to attend meetings of administrative bodies usually are covered under separate statutes, and are beyond the scope of this article.)

One of the most significant recent advances in freedom of information is the development of a public right of access to information *pertaining to the environment*. More than 40 nations, mostly European, signed the Aarhus (Denmark) Convention in June 1998. It was sponsored by the United Nations Economic Commission for Europe (UNECE) and

went into effect in October 2001. The Aarhus Convention provides a public right of access to environmental information. It has also been ratified by the European Union, which has begun applying Aarhus principles in its legislation.

An increasing problem in terms of gaining access to government-held information is the *clash between the equally legitimate and important rights of public access*, on the one hand, and personal privacy, on the other. This conflict arises when someone's need for a government record results in the disclosure of private information about an individual who is identified in the record. Privacy concerns have mushroomed as technological advances make it possible to gather personal, even intimate, information about people. Identity theft and the Internet's potential for the instant and mass dissemination of information that could invade one's privacy have also inflamed concern. Governments with freedom of information laws nearly all contain exemptions protecting personal privacy. The problem is that an administrative agency can withhold information that is embarrassing to the government, or information that contains evidence of inefficiency or corruption, under the guise of protecting someone's privacy.

Perhaps the most challenging obstacle to implementing a broad philosophy of full disclosure by governments is the *scourge of terrorism* worldwide. After the terrorist attacks of September 11, 2001, for example, the US government removed huge amounts of potentially sensitive information from the websites of dozens of agencies. Some of this information was of high public interest because it pertained to public health and safety.

Despite obstacles, freedom of information worldwide is on an upward trajectory. Increasingly, economic reasons are the bases for more freedom of information laws; as more developing nations seek to participate in international trade, they will be encouraged – if not required – by prospective trade partners or the World Bank and the International Monetary Fund to make the workings of their governments visible. Nonetheless, the spread of government transparency will remain a process for a long time as both established and developing democracies seek to break free of the outmoded presumption of secrecy and replace it with a presumption of openness.

# Freedom of the Press, Concept of

Joseph Russomanno

Arizona State University

Virtually since the dawn of civilization and the establishment of authority-wielding institutions, what people can say and write has been challenged. There is a universal impulse to control expression, particularly statements or opinions contrary to the views, policies, or dogma of those in power (→ Censorship). As is typical within repressive regimes, a justification for the suppression (though not expressed publicly) is the desire to preserve power. This desire to control information continued up to and through the era of the modern press. The phenomenon is not restricted to authoritarian nations in Asia, Africa, and Latin America. Even liberal-minded countries, such as the United States, that provide for some kind of speech and/or press freedom have histories of not only struggling with the interpretation and implementation of freedom of expression, but also histories of speech and press suppression (→ Freedom of Communication; Freedom of Information).

## WHAT KIND OF FREEDOM?

Any analysis of freedom of the press immediately begs several questions, among them: Freedom from what? Freedom to do what? These questions evoke the *concepts of negative and positive freedom*. Traditionally, freedom of the press is perceived negatively, as freedom from external restraint. But some perspectives, such as that articulated by Theodore Peterson (1956), suggest this negative approach is inadequate. A positive point of view advocates that freedom must also mean the liberty to attain goals. In the case of the press, this is generally summarized as the ability to inform and entertain. This positive perspective, which is more widely accepted in many nations in Europe, Asia, Africa, and Latin America, moreover, asserts that press freedom is not a passive activity, but must be actively promoted – for example, through regulations that enable the press to attain its goals (→ Media Policy).

Returning to the question “Freedom from what?” and the notion of negative freedom, the source of external restraint at issue is typically in the form of a government (though throughout history, sometimes religious institutions also have assumed the role of information censors; → Censorship, History of). When the popular press emerged in western Europe, most governments were authoritarian. Thus, these controlling principles became the basis for a system of the press. An authoritarian press system, however, does not necessarily mean a state-owned press. Instead, it means a system in which the state can and does exert control and influence, insuring that the press supports and advances government policies. Censorship often occurs when criticism of government policies or officials is published or is about to be. Licensing of the press is also common within these systems.

## THE RISE OF LIBERTARIANISM

Historically, a rebellion against authoritarian control or influence (not merely of the press, but also of society and the citizenry, in general) ultimately led to libertarian press

systems coinciding with the establishment of democratic governments (→ Media History). These are in place today in many nations, including throughout western Europe, much of the Americas, and in several Pacific Rim nations.

While censorship's roots predate recorded history, Europe of the Middle Ages serves as a quintessential model, where both church and state exerted control of individuals. *England*, for example, was notorious both for its anti-sedition laws prohibiting criticism of the monarchy and laws requiring press licensing. That is, publishing required government approval. Accordingly, those who were granted permission to publish tended to be those predisposed to favor the crown. England's laws controlling both press and speech illustrate the inextricable link between these areas. Other nations followed similar patterns.

As attempts to suppress expression grew, in many instances becoming commonplace, intellectual voices began challenging that accepted wisdom. The benefits – to both societies and individuals – of writing and speech free of restraints were reasoned, usually in writing. Among the positive outcomes of free press that were articulated was the notion that people cannot fully develop as individuals absent the ability to express themselves. Societal benefits focus on self-governance – that people need to be able to openly discuss issues, including criticism of government and government officials, in order to exercise their votes wisely.

Many sources (e.g., Hatchen & Scotton 2006) agree that serious, intellectual reasoning against repressive institutions and their inclination to proscribe expression began with John Milton's 1644 work *Aereopagitica*. Published within the Age of Enlightenment, *Aereopagitica* not only ridiculed England's licensing, but also noted that a product of free expression is the discovery of truth. That is, by allowing all ideas and opinions to be expressed and then fully considered, only then can truth – or at least a close approximation – be realized. This notion of an open "marketplace of ideas" in which both spoken and written ideas are free to enter has remained a classic paradigm justifying free expression. John Stuart Mill picked up this torch in the nineteenth century, *On Liberty* being his exemplary work, and passed it to the US Supreme Court and Justice Oliver Wendell Holmes, Jr. Holmes wrote in 1919 in a dissenting vote in *Abrams v. The United States*, "the ultimate good desired is better reached by free trade in ideas – that the best test of truth is the power of the thought to get itself accepted in the competition of the market."

This marketplace of ideas model and the attainment of truth is one of several rationales for free press and speech that have been articulated over time. Other perspectives include individual self-fulfillment, participation in decision-making, the ability to maintain a balance between stability and change, and the checking value that free expression can have in limiting the abuse of official power. Encompassing many of these models is one that recognizes the contribution that a free press makes to a self-governing democracy. This system of government assumes a citizenry that is informed and that considers issues rationally (→ Political Discourse; Public Opinion). A press that operates independently of government influence serves as a significant provider of the information required to make reasoned decisions.

Conversely, absent such a press system, citizens are likely to be uninformed because of a lack of information or, perhaps even worse, misinformed by information that is distorted through the lens of the government or other institutions. Without a full range

of information supplied by a free press, decision-making is weakened and often unsound. Moreover, when the suppression of ideas is permitted, it is possible that the truth will be among those censored. The importance of a free press to a democratic society is highlighted by the label the → “fourth estate,” a term attributed to eighteenth-century British philosopher and politician Edmund Burke. Not unlike the American Founding Fathers who followed him, Burke recognized the significance of the checking power of a free press, consequently bestowing on the press an unofficial status as a branch of government.

In addition to Burke and Milton, other *Enlightenment philosophers* are credited with developing a progression of thinking that challenged authority and the notion that societies were better off when the opinions of their citizens were silent and unprinted. John Locke suggested that rather than belonging to the state, individuals possessed natural rights. Jean-Jacques Rousseau wrote that citizens enter into a sort of social contract with their government that requires sacrificing some liberties in exchange for the security government can provide. In turn, however, this contract places limits on the state, requiring it to provide not only protection, but also freedom. Voltaire also advocated individual freedom, but added that it was freedom of expression that enables citizens to participate in their government. Another prominent influence was a group of essays published in the 1720s under the pseudonym Cato. Written by two Englishmen, *Cato’s Letters* denounced tyranny and specifically advanced free expression as a means of criticizing government to make it more responsive to the will of the people. “Cato” asserted that freedom of speech was “the great bulwark of liberty,” protecting the people against tyranny by preventing and exposing abuses of power.

The expression and circulation of these ideas were influential in governments’ granting of various forms of rights protection, including England’s *Bill of Rights* in 1689. Though different in substance and scope, the document was a predecessor to the Bill of Rights, passed a century later, which amends the United States Constitution. In turn, the French government passed the Declaration of the Rights of Man and of the Citizen in 1789. Like the US rights, the French Declaration specifically included freedom of speech and of the press.

In establishing protection for the press, the architects of the *US Constitution* and its First Amendment were influenced by precedent, the writings of philosophers and statesmen (some described above), as well as how other governments considered handling the various issues. Thomas Jefferson, for example, voiced concern that a Constitution absent rights that protected individual liberties such as speech and press freedom was incomplete and improperly weighted. That is, merely outlining the structure of the federal government, as the body of the Constitution did, was inadequate; the anti-federalists also wanted protection for individuals from the power of that government. Specifically, Jefferson was a passionate advocate of a press free from government control or influence. Only when the press is free, he believed, can the people be well informed, and “whenever the people are well-informed, they can be trusted with their own government” (Koch & Peden 1972, 418).

## **FREEDOM OF THE PRESS NOT ABSOLUTE**

Even a libertarian perspective, however, can be illusory. First, professed freedom guarantees can mask authoritarian practices, both covert and overt. For example, in the US,

questions were raised regarding whether its news media were free in the wake of the terrorist attacks of September 11, 2001. Were they pressured to refrain from any questioning of government policy rather than voicing a healthy skepticism? The potential for repressive government influence was evident when, two weeks after the attacks, the White House press secretary responded to the words of a television commentator by saying that all Americans “need to watch what they say, watch what they do. This is not a time for remarks like that; there never is” (Fleischer 2001).

Second, and less subtly, governments may place limitations on press freedom through laws and regulations enacted by assemblies or agencies, approved by an executive, and upheld by courts when challenged (→ Communication and Law). These laws are meant to balance press freedom against other interests, many of which revolve around protection of individuals, other institutions, or society. For example, nearly every society makes the press liable, whether civilly or criminally, for → libel and slander, → privacy, and other personal harms. More often than not, the balancing process reflects the socio-political and cultural traditions of a country. In the US, libel law is exceedingly media friendly, whereas in the UK, it is far less so.

From an international and *comparative law perspective*, press freedom is still evolving (Fiss 1996). The journalist’s privilege to protect confidential sources as a right to free press is a case in point. While a growing number of democratic countries recognize the journalist’s privilege, the US backtracks on its actual or perceived protection of journalistic sources. As communication technology evolved beyond the publication and distribution of the printed word, freedoms and privileges granted to the press have often been extended to these newer mass media (→ Internet Law and Regulation). However, it is not uncommon that those freedoms are established at a lower level than those granted to printed publications. For example, in the US, the UK, and many other countries, the owners of broadcast stations must obtain a license from the government in order to operate in the public interest (→ Television Broadcasting, Regulation of).

Pressure on the press can originate with nongovernment sources, as well. In some environments, the *economic marketplace* may serve to constrain press freedom as much as anything. Within press systems that are advertiser supported, the power to withhold or withdraw monetary sustenance can be significant. Similarly, the press may be inclined to self-censor for fear of alienating advertisers or audiences. In addition, another freedom-limiting dynamic may surface simply through the practice of another press perspective: social responsibility. It may be suggested that if freedom carries with it an obligation to be responsible, by definition, the acknowledgment and implementation of that obligation (for example, codes of ethics) obstruct freedom (→ Commercialization: Impact on Media Content; Commercialization of the Media).

The concept of freedom of the press is just that – a concept. Nowhere is the freedom absolute. It is a concept that many have suggested is worth striving for, but it remains elusive. Moreover, a press system that is absolutely free – that is, unchecked either by government, marketplace forces, or a sense of social responsibility – is undesirable, largely because of the absence of accountability. Even governments that choose to grant freedom to the press struggle with defining that liberty. The debate over how and where to place the boundaries that divide acceptable and unacceptable uses of the press is ongoing.

# Friendship and Communication

*William K. Rawlins*

*Ohio University*

Communication within friendships is important for human development throughout life. Beginning in childhood, friendships shape and reflect developments in social cognition, perspective-taking abilities, moral comportment, and cooperation as equals. During adolescence and younger adulthood, friendships cultivate ethical sensibilities, and understandings and practices of intimacy, identity, and sociability. Across life people describe three benefits of close friendship: somebody to talk to; to depend on and rely on for instrumental help, social support, and caring; and to have fun and enjoy doing things with. Communication with friends relieves loneliness and contributes to physical and psychological well-being.

Despite consistent features, changes occur in the communication of friends across developmental periods due to differences in persons, their gender, concrete socio-cultural circumstances, and opportunities for and actual participation in friendship. Friendships persist to the extent that individuals treat each other in mutually fulfilling ways, according to shared definitions of required contact, evaluative standards, and appropriate actions. The interaction of friends helps us understand inherently valued communicative practices, as well as how and why people negotiate voluntary, free-standing allegiances with others or include a “friendship component” in diverse personal and social bonds including those with spouses, parents, siblings, children, relatives, neighbors, co-workers, and fellow citizens (→ Friendship and Peer Interaction).

## NATURE AND TYPES OF FRIENDSHIP

Robust friendships take time to develop and maintain, and the time available for friends fluctuates depending on the simultaneous demands of other normatively sanctioned relationships and commitments – such as school, family, and extra-curricular activities during youth; and career, family, and community ventures during adulthood. Despite their fundamental reliance upon private negotiation for continued existence, friendships are highly patterned culturally and contextually. While the ideals of friendship include free choice, personalized responsiveness to others’ intrinsic qualities, and equality, mutuality, and affection, actual patterns of friendship reflect social stratification and economic disparities (Rawlins 1992).

Gender-linked differences in friendship have been identified across life although they lessen in males’ and females’ closer and more enduring bonds (Monsour 2002). In general, females learn and practice emotionally supportive and personally involving friendships, termed a “communal” style, earlier in life than males. Women more frequently describe sustained attachment with close same-sex friends throughout their lives, even when married and working. Males typically describe their first intimate friendships somewhat later than females, and fewer males mention close same-sex bonds across life. Male friendships are typically not as disclosive, emotionally involving, or affectionate as female dyads. Whereas

female friendships emphasize interwoven lives and extensive self-disclosure, male bonds feature autonomy and activity-orientation, termed an “agentic” style, with married men often relying primarily on their wives for intimacy and close friendship. Depending on the socio-cultural circumstances of their earlier lives and adult relationships, women or men may develop friendships of either style or combining their attributes.

### CHILDHOOD FRIENDSHIPS

Children’s capacities to communicate with friends develop over the first 15 years of life, reflecting a dialectical interaction of cognitive abilities and concrete social experiences. Changes occur at somewhat different rates for particular children on the basis of their specific aptitudes, gender, and experiences. In contrast to surface perceptions of friends’ observable features and possessions, children develop a psychological appraisal of friends’ personal qualities. In the *early to middle elementary school* years, young persons typically choose friends of their age and gender, who share their physical characteristics and enjoy doing the same activities together (Smollar & Youniss 1982). Over time, discussions of subjective thoughts and feelings supplement talk about common activities or items. From a materialistic, object-centered basis for interaction, later childhood friendships evolve an intersubjective, person-centered core.

During the *later years of elementary school*, self-oriented and one-sided views of incidents between friends shift to mutually derived conceptions of interactions, emphasizing interdependence, shared experiences, and goals. Children learn how to see matters from their friends’ and society’s perspectives as well as their own (Selman 1981). The potential of peer friendships to comprise distinctive, mutually negotiated, moral spheres begins to emerge. For much of childhood, young persons must adapt themselves to patterns of interaction primarily determined by adults and older siblings. In contrast, friendships and peer interactions involve the collaborative and cooperative development of procedures for interacting between equals who lack the power to impose preferences unilaterally. The reciprocal exchange and perspective-taking necessary for such collaboration tend to enhance children’s sensitivity to others and their capacity for expressing and experiencing affection with an equal. A transitory conception of social relationships converts into an awareness of their endurance over time.

By *early adolescence*, around ages 12–14, young persons typically have developed the rudiments of friendship. Friends are equals deserving sensitivity and fair treatment; they reciprocally help and share with one another and may cultivate intimacy through personal discussions. Even so, friendships remain nested in same-sex cliques that exert strong conformity pressures and preferences for similar others.

Adolescent friendships transpire within the interconnected worlds of family, peers, school, and the larger society. Friendships provide contexts for learning about intimacy, developing one’s identity and sense of personal values, gaining autonomy from one’s family of origin, and dealing with multiple social orders and systems of evaluation (Youniss & Smollar 1985; → Intimate Talk with Family and Friends). In managing ethical issues and behavioral choices, young friends rehearse the moral alternatives of adult friendships. Adolescents learn that they are judged by the company they keep and their objective achievements; there are both societal and intimate constructions of self.

While pursuing the goals and expectations of self, family, school, and peers, adolescents negotiate various types of friendships across a continuum of personal and social domains. Since tensions between private knowledge and public exposure of self are fundamental concerns, adolescents are preoccupied with trust and confidence in their “true” or close friendships, which mediates their selection of friends and their distinctions among them (Rawlins 1992).

In their private discussions friends learn how to co-construct and respect discretionary boundaries between each other as well as between their friendship and other people. Importantly, friendships require an investment of self in their own production and articulation, and one’s choices of friends comprise significant judgments. Along with their possibilities for enhancing each individual’s sense of personal identity, adolescent close friendships can embody pro-social values and social responsibility and serve as a foundation for egalitarian relationships in adulthood (Berndt 1996).

The developments of puberty and sexual urges complicate adolescents’ feelings of affection. Participants and third parties may second-guess the caring experienced in same- and cross-sex friendships, viewing friendly feelings as possibly veiling sexual interests. How same- or cross-sex friends are treated once dating begins is a significant concern. Over time, culturally endorsed gender differences, and ideologies and practices of heterosexuality, homosexuality, and romantic love, transform the young person’s entire social arena.

### **FRIENDSHIPS IN YOUNGER ADULTHOOD**

During young adulthood persons explore the roles their friendships will play in adult life. Developmental tasks include preparing for and entering the adult world of work, developing personal relationships of varying degrees of intimacy and commitment, and integrating one’s identity. Friends may provide crucial input regarding one’s education, career options, romantic relationships and/or marriage, community involvement, and recreational activities. Individual and negotiated decisions regarding such matters influence self-conceptions and begin to articulate networks of human relationships within which one’s values and priorities are continuously enacted. Simultaneously, these pursuits also generate constraints shaping the forms and functions of one’s friendships at any juncture, owing to their contingent status and reliance on voluntary effort for continued existence.

Moral visions and friendship practices that transcend gender may thrive but also persistently align themselves with gender divisions. Consciously or not, normative roles and codes enacted in the workplace and associated by both sexes with marriage and raising children can reinforce these disparities. Consequently, the ways in which friendships are managed, the bases for distinctions among friends, and the overall significance of friendship in an adult’s social world are strongly indicative of that person’s self-defining values. Work settings may embody values that compete with the ideals of close friends as well as separate them in time and place. Marriage may introduce the couple as the unit of friendship, with compatibility now a matter of two pairs of people getting along. The ironic functions of friendships during young adulthood involve mutual enjoyment while helping each other make life decisions, which ultimately may constrict the opportunities for involvement with friends.

The adult years involve ongoing trials and impediments, which are socio-economically and culturally patterned although not strictly tied to age. Consciously and unconsciously, friends are sorted out, with social calendars, role commitments, and career moves functioning as both facilitators and disqualifiers of friendships (Matthews 1986). Negotiating busy schedules, physical separation, and friendship's voluntary and conditional standing in their role clusters, many adults' bonds persist because of the flexibility of their friendships. The friendship of spouses may assume importance during mature adulthood if or as they replace role-related perceptions of each other with an appreciation of each other's independence, companionship, and shared life experiences (Rawlins 1992). Work settings also persist as sources of friendships for women and men at least until retirement. Friends who have stood these "tests of time" and circumstances assume special status, and close friendships increase in stability across the life course.

### **FRIENDSHIPS IN OLDER ADULTHOOD**

As reservoirs of shared histories and experiences, old friends are narrators and curators of the long-term coherence and significance of each other's lives. In contrast, throughout life, new friends foster and reflect change and adaptation to altered conditions, while also being implicitly compared with a person's "populated biography" of past relationships (Matthews 1986). Talking and judging with trusted friends gets the weighty matters of adulthood off of a person's chest, helps articulate the meaning and implications of actions and choices, jointly establishes what is important to self and affected others, and provides nurturance and enjoyment to keep life's challenges and tragic inevitabilities in perspective.

Later adult friendships exhibit continuities and discontinuities with earlier patterns and normative contours evident across the life course. Friends are close enough in age to share analogous generational experiences; and they are usually alike in race, gender, and marital and occupational status, all of which promote comparable lifestyles and values. Modal gender differences in friendship activity are also evident in later life. Even so, friendship profiles remain diverse across this developmental period for many reasons. First, the period spans several decades. People also enact disparate personal styles, decisions, and initiatives in conducting their social lives. Friendship in later adulthood involves sustained connection with select individuals, consecutive sets of friends associated with changing residences and social circumstances, or a pattern of preserving certain long-term friendships as well as developing new ones as personal situations alter (Matthews 1986). Areas of diminishing individual control, such as persons' social capabilities, health, and mobility, as well as friends' proximity, abilities to interact, or mortality, become salient at varying junctures and are associated with continuities and discontinuities in friendship practices.

Functions, strains, and assortments of friendships persist in later life. Despite their limitations, friends typically play vital roles in sustaining older persons' feelings of well-being and life satisfaction. As long as personal capacities and situational factors allow, people turn to friends to talk about a wide range of topics, confide in and relate troubles, enjoy spending time together, and rely on for assistance and moral support. Contacting and being contacted by friends alleviates loneliness, connects individuals to larger communities, and fosters their ongoing enjoyment of life.

## **Friendship and Peer Interaction**

*William K. Rawlins*

*Ohio University*

Friendship refers to a broad category of interpersonal relationships communicatively accomplished with peers and characterized by voluntary, reciprocated, nonromantic affection and good will. These relationships range in depth and duration from superficial, transitory bonds developed from situational associations, such as residential, educational, or workplace proximity, to profoundly dedicated lifelong attachments spanning time and distance.

### **NATURE OF FRIENDSHIP**

Friendships involve five characteristics to varying degrees, depending on social and cultural circumstances, interaction patterns, and individuals' inclinations. First, communicating as friends is voluntary; persons choose to view and treat other persons as friends (→ Friendship and Communication). While social stratifications dictate opportunities to interact, persons elect to communicate and experience another's behaviors as friendship. This feature contrasts with the blood bonds of kinship, contractual and economically determined associations such as labor relations or partnerships, and religiously and legally sanctioned bonds such as marriage. These relationships occupy social categories

with requirements transcending individuals' preferences. In contrast, friendships persist to the extent that friends fulfill each other's particularized expectations for interactions and may be unilaterally dissolved.

Second, friendship is a personal relationship involving regard for each other as a specific individual with unique qualities, not as a member of a category. Third, friendship involves nonromantic affection for another person. Friends display their affection through encouraging each other's freedom to fulfill themselves as individuals. This quality contrasts with the possessive and exclusive nature of romantic love or the self-gratification of sexual loving. Fourth, friendship strives for equality based on the corresponding validity of each person's subjective experiences. While friends may be unequal in certain objective respects or abilities, communicating as friends involves identifying the means and areas within the relationship to treat each other as equals. Fifth, friendship is a mutual relationship reciprocated between persons. Mutually shared good will, understanding, trust, and support are hallmarks of enduring friendship. One-sided offerings of friendship do not constitute a viable relationship.

Friendships are contextually negotiated between persons. Accordingly, friendships may be developed as free-standing relationships, or they may be pursued as an added dimension of other relationships already serving required functions within the social structure. Because of their minimally determined status in the normative hierarchy of role relationships, peers develop friendships that complement, fuse with, compete with, and substitute for other interpersonal relationships (Hess 1979). For example, communicating as friends may complement the daily activities of two co-workers but compete with the requirements of a superior-subordinate relationship. The behaviors and expectations of friendship can fuse so extensively with a spousal or sibling relationships that it becomes difficult to determine when and whether persons are communicating as spouses or siblings or as friends (→ Intimate Talk with Family and Friends). Finally, with no close kin nearby, friends may substitute for one's family.

## THEORIES OF FRIENDSHIP

Recognizing the significance of interpersonal communication in achieving and defining friendships between peers as well as the importance of communication as an activity friends enjoy sharing, researchers have devoted increasing attention to friendship over the past 25 years. This work displays differing *approaches* to defining friendship for research purposes. Investigators developing generalizable theories tend to specify the definitions of friendship employed by participants in offering their responses to research questions. In contrast, inquirers emphasizing that definitions and practices of friendship differ according to the context and relationship allow their participants to define the relationship for themselves in providing responses. A second issue distinguishing researchers is whether they examine specific behaviors, communication skills, personal attributes, or provisions associated with friendships, or they study more holistically a constellation of experiences or communicative situations recounted by participants. Some projects combine the assessment of specific indicators with general descriptions of participation in friendships.

As to the *empirical methods* employed, investigations of communication and friendships have utilized exclusively and in combination survey questionnaires with fixed and/or

open choices, structured interviews, open-ended and narrative-based interviews, participant journals, ethnographic field notes, and auto-ethnographic reflections, as well as audio- and video-taped activities of friends.

Research concerning communication in the formation, maintenance, and dissolution of friendships emerged in the 1980s in response to social attraction studies examining personality variables or residential propinquity as static features of friendships (→ Relationship Development). Prior to this time, friendship appeared mostly as a residual category of social participation in demographic and sociometric studies, contrasting friendships (often termed “other”) with family and work relationships. Scholars began examining friendship as a relationship with characteristic demands and benefits in conjunction with a developmental perspective on communication in interpersonal relationships. This view assumes that what brings people together may not ensure the continuation of the relationship and that communication in relationships changes over time. Static conceptions of relationships say little about what makes friendships function on an ongoing basis or why their continued interaction holds mutual significance.

Closely associated with a focus on the communicative development of friendships is the recognition of dialectical tensions shaping and emerging from their interaction (→ Relational Dialectics). Whereas earlier work typically described friendship in benign terms and conceived relational growth as a linear process of increasing breadth and depth of disclosure, time spent together, intimacy, and satisfaction, a *dialectical perspective* challenges such notions. It argues that relating as friends involves inherent contradictions, antagonistic features of relational life that simultaneously presuppose and oppose each other. Several dialectical tensions of friendship have been reported. The dialectic of the ideal and the real describes the tensions between the abstract ideals of communication associated with friendship and the troublesome realities or unexpected rewards arising from its ongoing, concrete accomplishment. The dialectic of the freedom to be independent and the freedom to be dependent describes the cross-cutting requirements of availability and obligation in light of friendship’s voluntary basis. Friends must continually reconcile autonomy and interdependence within their relationship as well as enveloping social connections and circumstances. The dialectic of affection and instrumentality describes tensions arising from caring for a friend as an end in itself or as a means to an end. Friends rely on each other for emotional and practical assistance, but different meanings of friendship arise when someone feels befriended primarily for utilitarian reasons vs unqualified personal regard.

The dialectic of judgment and acceptance involves the recurring dilemmas in friendship between providing objective appraisals of a friend vs unconditional support. People expect acceptance and encouragement from their friends but also look to them for tough truths and wise counsel. Compassionately objective reactions combining evaluation and support are experienced as constructive criticism. The dialectic of expressiveness and protectiveness describes opposing tendencies to speak candidly with a friend and relate private thoughts and feelings, and the simultaneous need to restrain one’s disclosures to preserve privacy and avoid burdening one’s friend. Many persons consider confiding a distinctive privilege of their closest friendships. But revealing sensitive information makes persons vulnerable, and the responsibilities imposed on others not to misuse intimate disclosures make confidence and trust problematic achievements. Friends develop

trust through carefully managing the conflicting requirements of expressiveness and protectiveness.

## RESEARCH FINDINGS

Despite the challenges that friendships present as ongoing achievements, the communication of friends often distinctively embodies social ideals of shared good will, loyalty, trust, pleasure, assistance, personal validation, and moral comportment as equals. Considerable research examined how the outlook and practices of friendship are negotiated communicatively as dimensions of other relationships, and how other social bonds develop into relations that members consider friendships. For example, in the *family context* communicating as friends emerges between parents and children across the life course to the extent that they come to view their interactions as chosen and not compulsory; they address each other outside of the parenting role or the self-centered child's role; they speak more respectfully as equals; and they emphasize the pleasures instead of the obligations of interaction. Between siblings transitioning to friendship involves emphasizing personal validation and cooperation over competition and hierarchical, role-based interaction.

The *workplace* is an important site for making friends of varying degrees of closeness between peers. Persons in similar jobs often share physical proximity, overlapping work schedules, and common interests and projects, which can facilitate routine contact and friendship formation. How persons communicate their availability, caring, assistance, and judgment in workplace friendships affects their viability both as friendships and as occupational arrangements. The transition from co-workers to friends involves developing common ground and choosing to socialize outside the work setting; becoming closer friends involves discussing personal and work-related problems, sharing confidences about life events, and the passage of time (Sias & Cahill 1998). Despite the potential benefits of workplace friendships for individuals and organizations, the objective demands, occupational mobility, or disappointments of either person's job and conflicting expectations between friends can jeopardize and ultimately undo friendships, with negative repercussions for former friends and work settings.

*Gender-linked patterns* of communicating in friendships have been identified across the life course (→ Development, Gender, and Communication). Female same-sex friendships are characterized by extensive disclosure of personal thoughts and feelings, routine displays of affection, significant emotional involvement, instrumental assistance, and interweaving of daily lives and concerns. Talking together is considered a characteristic pastime of female friends. By comparison, male friendships are characterized by easy-going sociability, conversation about common interests, minimally binding instrumental help, and respect for each other's autonomy. Male friends enjoy doing shared activities with a secondary focus on emotional sharing.

Scholars disagree about the precise nature and extent of these gender contrasts. Some argue that these gender-linked patterns imply qualitatively different forms of friendship offering comparable satisfaction and potential for intimacy for their participants. Others observe that gender-linked contrasts in friendship diminish in the closer and more enduring bonds of both males and females throughout life. Moreover, specific same-sex

friendships of males or females may deviate significantly from these patterns depending on their social circumstances. While prevailing socio-cultural arrangements statistically link males and females with the patterns described here, the continual social construction of gendered relational practices in concrete circumstances and cultural systems of interpersonal relationships appears more crucial than biological sex.

Research addressing *cross-sex friendships* illuminates multiple issues in the communicative achievement of friendship. In such bonds females and males must negotiate desired communication styles and gendered practices for a person of each sex in a relationship including members of both. Meanwhile, a widely recognized benefit of cross-sex friendships includes gaining an insider's perspective on the other sex. Such relationships frequently must communicate boundaries between friendship and romantic love, address sexual desire, sexual orientations, and sexual identities, and orchestrate public perceptions of the friendship. Cross-sex friendships clearly illustrate the always contingent position of friendship in social life.

These understandings of friendship derive from research primarily addressing white, North American, middle-class participants. Until recently, Robert Brain's *Friends and lovers* (1976) presented one of the few surveys of cross-cultural and ethnic variations of friendship. Important areas of emerging and future research include: cultural and sub-cultural similarities and differences in meanings and practices of communication in friendships; how friendships shape and reflect individual and collective identities; the communicative achievement of interethnic and interracial friendships; communication skills for forming, sustaining, and withdrawing from friendships; the impact of communication technologies on friendships; the interrelationships of friendship and health; the roles of friendships in health care, education, and mentoring; and the contributions of friendship to community building and conflict resolution.

# Frustration Aggression Theory

Jürgen Grimm

University of Vienna

Frustration is defined as a state that sets in if a goal-oriented act is delayed or thwarted. The instigation remains even though the chances of realization are constrained by interfering influences. Under these frustrating conditions aggressive behavior is stimulated to an extent that corresponds with the intensity of the instigation and the degree of blockage of goal attainment. Aggression is defined as the deliberate violation of an organism or an organism substitute. It is primarily directed toward the cause of frustration, but may be redirected toward any other people or objects. The inhibition of aggressive behavior represents in itself a factor of frustration and can reinforce aggressive tendencies.

In its first general definition the frustration aggression theory (or hypothesis, hence "FA-H") proposes that aggression is always the result of frustration (Dollard et al. 1939). This corresponds with the following two postulates: (1) aggressive behavior requires the existence of frustration, and (2) the existence of frustration leads to some kind of aggressive behavior. Manifest aggression reduces aggressive tendencies and results in "catharsis." However, this only applies to that part of aggression caused by inhibition of aggression, not to aggression caused by the original instigation. The latter lasts as long as the frustrating conditions continue. A "catharsis" in its comprehensive meaning will only be achieved if aggression eliminates exactly those obstacles in the way of the original goal (→ Catharsis Theory).

FA-H is based on Freud's and Hull's drive theories. In contrast to mere drive theories, FA-H presupposes a frustration-inducing external incident that can be interfered with. It thereby transcends the defeatism and the implicit justification of violence contained in biological approaches, explaining aggression via law of nature as a condition of self-reproducing physical privation. For decades, FA-H was seen as the ultimate aggression theory and has become part of commonsense knowledge. Its *scientific and socio-political attraction* results from the combination of an empirically tested universal causal explanation of aggression and a correspondingly high socio-technological importance: whoever wants to avoid aggression and violence has to change or abolish frustrating social circumstances. FA-H therefore offers good reasons for the development of social programs expected to prevent criminal behavior and political violence. In the 1960s, FA-H was used as an argument when criticizing repressive moral values, more recently it was used as an explanation for certain aspects of terrorism (Mirdal 2003; → Mediated Terrorism).

*Criticism of FA-H* concentrated mainly on the general → validity of the assumed relation between frustration and aggression. Baron (1977) shows that the blockage of goal attainment leads to aggressive behavior only if the blockage occurs unexpectedly (→ Goals, Cognitive Aspects of). Moreover, it seems to depend on mediating factors, such as proximity of the goal, whether frustration actually leads to aggressive behavior. Berkowitz (1989) therefore suggested a *reduced version of the hypothesis*: frustration increases the likelihood of emotional aggression. The absence of aggression after frustration can always

be traced back to thwarting conditions or to inhibition of aggression. However, better compatibility with empirical findings also provided critical arguments against a reformulation. Berkowitz's variant of the hypothesis was said to have been made irrefutable, thereby losing in explanatory value. There are types of aggression that are not linked to the condition of induced frustration: goal-oriented aggression in order to gain an advantage, martial acts, and so on. Today, therefore, frustration is seen as a possible condition for certain forms of aggression (primarily impulsive anger) with personality traits (general fear, locus of control, and others) determining if the reaction to frustration is aggressive or, alternatively, depressed.

In *communication research* FA-H became primarily relevant in the area of research on media violence. Berkowitz & Geen (1966) assume in their "eliciting-cue" hypothesis that every aggression has two roots: (1) the existence of frustration, and (2) the presence of aggressive cues (e.g., a violent movie). It is telling that Berkowitz does not rely on frustration alone or on media violence alone to trigger aggressive effects (→ Violence as Media Content, Effects of). The eliciting-cue hypothesis therefore reacts to empirical findings that reject a law-of-nature occurrence of aggression after frustration. At the same time, potential learning effects of the recipients of media violence are linked to the condition that there is already an aggression-inducing emotional disposition to frustration present. In order to measure the influence of filmic depictions of violence, test arrangements were chosen in which the subjects were first deliberately provoked by verbal abuse or electric shocks and then shown films with violent content (→ Test Theory; Experiment, Laboratory).

This test arrangement was also used by Feshbach to verify the catharsis thesis. Feshbach (1955; 1956) is still very much linked with drive theories insofar as he claims that pressure can be alleviated by aggressive acts. A third variant of this combination – this time with arousal – is offered by Tannenbaum (1972) and Zillmann (1982). The authors show that frustrated media recipients can be reinforced in their aggressive attitude by arousing film stimuli independent of the content (→ Emotional Arousal Theory).

The uncritical acceptance of FA-H as a universal aggression theory in media violence research led for a long time to the use of two-factor-test concepts, where the isolation of media influences and the separation of personal and situational influences are difficult. At the same time, pre-receptive measuring did not take place, and formal aspects as well as evaluation in context were largely neglected. This caused a situation where the effect quality of media violence could not be clarified despite extensive research (Kunczik & Zipfel 2006).

In *research on aesthetic and dramatic means*, different effects on the viewer led to new evidence regarding the topicality of FA-H. It was particularly in dramatic films where the recipients were not offered a satisfying solution after stressful victim scenes, such as punishment of the villain, that aggression was provoked. In such cases, media-induced frustration concerning the end of the film led to an increase in violent attitude. What causes the violent reaction of the recipients is the shift from empathy with the victim to an aversive attitude toward the villain ("Robespierre affect," Grimm 1998). In contrast to the postulates of the eliciting-cue hypothesis, these results indicate that it is not aggressive film cues such as successful perpetrator models and the availability of weapons that are relevant for the effects of media violence, but the aesthetic and dramatic contextualization of the depiction of the victim. The aggressive shift occurs as a result of emotionally

stressful victim images that, together with the lack of a satisfying filmic solution, induce frustration plus moral outrage. Both together then provoke aggressive behavior.

## **Functional Analysis**

*Michael Kunczik*

*Johannes Gutenberg University of Mainz*

Functionalism regards society as an interdependent and self-regulating social system tending toward equilibrium. The goal of functional analysis is to establish to what extent the parts (subsystems) contribute to the functioning of the system as a whole (→ Systems Theory).

With functionalism, the theoretical emphasis moves from causes to consequences. No effort is made to derive a given social phenomenon from specific causes. Instead, the question becomes which functions have to be fulfilled, through particular social actions, so as to guarantee the maintenance of the system. The results of actions, thus, are interpreted *teleologically* in terms of their contribution to the stability of the system. According to Robert K. Merton (1968, 84), the theoretical framework of functional analysis requires a specification of the units for which a given social or cultural item – e.g., mass-mediated messages – may be functional, allowing for diverse consequences – functional and dysfunctional – for individuals, sub-groups, and the social structure and culture as a whole. Functional analysis, further, focuses attention on a causal loop through which the results of specific courses of action act back on the items and units under study, bringing about persistence or modification (Cosser 1976, 146).

### HISTORY OF FUNCTIONALISM

The origins of functional analysis can be traced back to the ideas of Herbert Spencer and Émile Durkheim. Spencer developed the view that society, like an organism, is a self-regulating system consisting of subsystems which have to contribute to the survival of the system. Spencer was probably the first to use the terms “structure” and “function.” Durkheim argued in *The division of labour in society* (*De la division de travail social*, Paris 1893) that social order should be explained not by the self-interest of individuals, but by social solidarity based upon collectively shared values. Social anthropologists Bronislaw Malinowski and Alfred Reginald Radcliffe-Brown extended this idea to develop a method of “functionalism” in order to explain the contribution of customs to the maintenance of social systems. Societies were regarded as consisting of parts related both to one another and to society as a whole. Societies have stable structures and functions; i.e., the contributions of partial activities relate to the total activity of which they are a part, so that each custom has a function within the total society (system). In “On the concept of function in social science” Radcliffe-Brown (1935, 397) argued that the function of a particular social usage is the contribution it makes to social life in its entirety. He emphasized that a social system (the total structure of a society together with the totality of social usages in which that structure appears, and on which it depends for its continued existence) has a certain kind of unity, which he called functional unity.

Talcott Parsons, whose ideas had been strongly shaped by biologists, had a determining influence on structural-functional analysis. Parsons and Edward A. Shils (1951, 197) defined a social system as a system of the actions of individuals, the principal units of which are roles and constellations of roles. *Roles*, which are regarded as the junction points of individuals with the social system, are the elements building the structure of the social system. Internal differentiation, which is a fundamental property of all systems, requires integration. The existence of the system depends on the coordination of differentiated roles, either negatively in the sense of avoiding disruptive interference with each other, or positively in the sense of contributing to the realization of certain shared collective goals through collaborative activity. The integration of the value orientations of various actors can be regarded as one of the most important functional prerequisites for the maintenance of the social system.

Parsons wanted to develop an all-embracing functional theory. Merton (1968, 39), a student of Parsons, suggested that research is not yet ready for a total system of sociological theory. He focused attention on *theories of middle range*, i.e., theories intermediate between the minor working hypotheses that evolve in abundance during the daily routines of research, on the one hand, and on the other the all-inclusive speculations that make up grand conceptual schemes from which one may hope to derive a very large number of empirically observed uniformities of social behavior.

### KEY PRINCIPLES OF FUNCTIONAL ANALYSIS

The following basic assumptions of functional analysis can be outlined (e.g., Hagedorn & Labovitz 1973, 38–42; Kinloch 1977, 215; Merton 1968, 79–91):

- 1 The social system possesses an independent existence and consists of subsystems that mutually influence each other.
- 2 The system has a certain number of basic needs that must be fulfilled; otherwise, the system breaks down.
- 3 For the maintenance of the system's equilibrium, the needs of the subsystems must be met.
- 4 The subsystems can be functional (contributing to stability), dysfunctional (decreasing stability), or irrelevant with regard to the stability of the system as a whole.
- 5 A specific need of the system can be satisfied in different ways (through functional equivalents).
- 6 Society adapts to its environment while trying to control the environment.
- 7 Society is integrated by culture.
- 8 Only institutionalized (regularly recurring) patterns of behavior lend themselves to functional analysis.

Structural-functional analysis, Philip Selznick (1948) argued, is especially suited to the analysis of adaptive structures or processes, because this method places currently variable behavior (functions) in relation to an assumed stable system (structure). Functions are short-lived processes that quickly run their course. By contrast, structures are stable, long-lived processes. Functions are those observed consequences that make for the adaptation or adjustment of given structures; dysfunctions are those observed consequences that lessen adaptation or adjustment.

Merton (1968, 105) further distinguished between *manifest functions* (objective consequences contributing to the adjustment or adaptation of the system, which are intended and recognized by participants in the system) and *latent functions*, which are neither intended nor recognized. Latent functions, then, refer to the “unintended” consequences of various kinds of behavior. There has been a tendency, however, to use the concept of latent functions particularly as way of giving seemingly irrational behavior (e.g., prayers for rain) a rational basis (for instance, strengthening social solidarity).

A main weakness of structural-functional analysis is its lack of clear criteria for answering the question: what is functional; what is not? This occasionally results in an

uninformative formulation of the framework of interpretation. Consequently, there is a danger that the individual researcher's value orientations will determine the answers to the research questions. At the same time, the emphasis on systemic equilibrium implies that functional analysis contains within itself a conservative perspective, one justifying the status quo. If a specific social system, regardless of its degree of social injustice, is regarded as being in a state of equilibrium, then unrest, rebellion, and revolution will easily be classified as upsetting the equilibrium, and accordingly as dysfunctional (→ Critical Theory).

## FUNCTIONALISM AND MEDIA

The functioning of any social system depends crucially on the internalization of its dominant value patterns by individuals. The motives of the individual and the values of the culture must be in accord to a considerable extent; the value patterns also must accommodate the individual needs of social actors. A prerequisite for the continued existence of a social system is the integration of the system's demands in terms of values with the individual's dispositions in terms of needs. In this regard, every social system, according to Parsons, must resolve four basic issues: (1) adaptive functions (means), (2) goal attainment functions (values), (3) integrative functions (norms), and (4) latent pattern-maintenance and tension-management functions.

In complex social systems, each of these functions is ascribed to a specific subsystem; thus, to the economy, adaptive problems; or, to the law, normative directions. And it is assumed that social systems can differentiate themselves further in response to increased demands regarding the fulfillment of the four basic functions. In Parsons's framework, however, there is no specific subsystem of mass communication. The question arises, then, to what extent mass communication is to be regarded as an aspect of the subsystem of the economy (e.g., stabilization of demand through advertising), of policy (e.g., mobilization of political support through manipulation), of the integrative subsystem (e.g., media contributing to socialization), or of the subsystem of pattern maintenance (e.g., resolution of tension via escapism). Parsons and Winston White (1960), in one treatise, did concern themselves explicitly with mass communication but, interestingly, without reference to system-theoretical considerations.

Functionalist approaches to the relationship between mass media and society have sought to delineate the contribution of a *subsystem of mass communication* to the functioning of the social system as a whole. A strict functionalist position was formulated by → Harold Lasswell (1948, 118), who stated that he was less interested in dividing up the act of communication than in viewing the act as a whole in relation to the entire social process (→ Models of Communication). Lasswell emphasized the system-stabilizing function of communication, which (termed ideology) supports dominant value structures. He detailed the following functions of mass communication: *surveillance* of the environment, disclosing threats and opportunities that might affect the values of the community and its component parts; *correlation* of the components of society in responding to the environment; and *transmission* of the social heritage from one generation to the next. A function of entertainment was added by Wright (1960, 610), who formulated the "classic" question of functionalist mass communication research: "What are the (1) manifest and (2) latent (3) functions and (4) dysfunctions of mass communicated (5) surveillance

(news), (6) correlation (editorial activity), (7) cultural transmission, (8) entertainment for the (9) society, (10) subgroups, (11) individual, (12) cultural systems?”

Building on Merton's (1968) conception of functional analysis, Wright (1960, 606) called for an investigation of those consequences of social phenomena – such as media – that affect the normal operation, adaptation, or adjustment of a given system: individuals, sub-groups, social and cultural systems. Whereas allegations concerning the conservatism of functionalist approaches have often been rhetorical rather than substantial, the conservative orientation of Wright's analysis was manifest in his argument that the media's contribution to social stabilization should be categorized as functional, while he applied “dysfunctional” to news of better societies that might threaten stability. In a more descriptive and explanatory vein, Melvin L. DeFleur (1970) asked how television contributes to the stability and permanence of American society as a whole. He concluded that low-taste content on television can capture audience members' attention and persuade them to purchase the advertised goods. Low-taste content thus functions to maintain the financial equilibrium of a social system that is tightly integrated with the whole of the American economic institution.

A great number of *lists of the functions* of mass communication are found in the literature. As paradigms or models, they provide theoretical orientation and under certain circumstances structure the research process. Some studies have addressed the communication between groups actively participating in the socio-political process – lobbies, interest groups, political parties, and so on. Other authors locate the dominant functions of media in relation to the political system. Especially after the death of Parsons in 1979 and Merton in 2003, the influence of functionalism in the field of media and communication research has been reduced. Today, there exists a potpourri of theories of which functionalism forms only a part (Bryant & Miron 2004).

# Fundraising

*Kathleen S. Kelly*

*University of Florida*

Fundraising is an organizational function and high-demand occupation unique to nonprofits, or nongovernmental organizations (NGOs). Although the term *fundraising* sometimes is used to describe the act of raising capital for for-profit businesses, and fundraising is conducted to finance electoral campaigns for government positions, the function is identified most commonly with raising gifts for charitable nonprofit organizations. Thus, this entry concentrates on what most accurately can be called “philanthropic fundraising.”

Simplistically defined, fundraising is the process through which charitable nonprofits generate income in the form of gifts from individuals, foundations, and corporations. Recent developments in research and theory building provide a richer perspective. Scholars and practitioners now subscribe to the principle that fundraising is more about relationships than it is about money. Definitions, such as Kelly’s (1998), have gained increased acceptance: fundraising is the management of relationships between a charitable organization and its donor publics. The new perspective holds that fundraising concentrates on the juncture where the interests of donors and the organization meet. Rather than simply generating indiscriminate income, fundraising is a staff function that counsels senior management on how to most effectively manage environmental interdependencies with donors (→ Stakeholder Theory; Systems Theory). The purpose of fundraising, then, is not to raise money, but to help charitable nonprofits manage their relationships with donor publics who share mutual interests and goals.

## **HISTORY, INSTITUTIONS, AND FUNDRAISING SCALES**

Fundraising as an organized and organizational function marks its beginning at the start of the 1900s in the US (Cutlip 1990). It evolved through distinct eras of professionalism, with responsibility for the function moving from volunteers and general managers to external consultants to specialized staff practitioners. The first commercial fundraising

firms emerged at the close of World War I, and the first internal staff fundraisers were hired at the end of World War II. Today, there are an estimated 100,000 full-time fundraisers in the US and about 80 percent of them are employed as staff practitioners. Although fundraising has spread to almost all countries, it is more advanced and pervasive in the US, where a favorable tax system supports an extensive nonprofit sector and fosters philanthropy through exemptions and deductions.

Nonprofit organizations primarily are defined as being entities that are neither businesses nor government agencies. Often referred to by various names, including *third sector organizations*, nonprofits cover a diverse collection of organizations, ranging from local daycare centers to major research universities to international disaster relief charities. Their missions represent all aspects of society, including the arts, education, the environment, health, human services, and religion. Nonprofits share only a few common characteristics: (1) they are private, which distinguishes them from government, (2) they do not distribute profits to those who control the organization, which distinguishes them from business, and (3) they are voluntary and self-governing.

There are approximately 1.6 million nonprofit organizations in the US, of which more than 1 million, or 67 percent, are designated “charitable nonprofits.” Nonprofits are exempt from federal income taxes, as well as such other taxes as property taxes, and are classified into 27 categories under Section 501(c) of the Internal Revenue Code. Nonprofits that have been granted charitable status are usually classified under the 501(c) (3) subsection. The primary difference between them and other nonprofits, such as chambers of commerce, is that gifts to charitable nonprofits are deductible from donors’ taxable income, whereas gifts to non-charitable nonprofits are not. As stated earlier, fundraising is a function of those nonprofits classified as charitable. It is important to note that *charitable organization* is a legal term and does not mean that all organizations classified as such deal with charity, or alleviating suffering of the needy. Indeed, charity constitutes a small portion of the work of US charitable organizations; most deal with philanthropy, or promoting human progress. The largest charitable organizations in terms of finance are those with missions in education and health, and hospitals and universities employ the largest number of fundraisers.

Giving in the US totals billions of dollars each year (\$260 billion in 2005) and represents almost 2 percent of the country’s GDP. Individuals traditionally give more than 80 percent of all gift dollars, and foundations and corporations provide the rest. To sustain and increase this high level of giving, US fundraising is organized into four programs: annual giving, major gifts, planned giving, and capital campaigns. The first two are primary programs; the second two actually are strategies to raise major gifts. Focusing on the two primary programs, annual giving raises lower-level gifts, whereas the major-gifts program raises large gifts. Dollar amounts defining the two gift types differ among organizations; however, a common dividing point is \$10,000, although annual gifts typically are less than \$100 and major gifts often exceed \$1 million. For most charitable organizations, annual giving produces the greatest number of gifts, but the major-gifts program accounts for the vast majority of gift dollars. The “principle of proportionate giving,” based on the unequal distribution of wealth, dictates that approximately 80 percent of all dollars raised will come from 20 percent of all gifts. The principle has been upheld for almost a century and fundraisers design their work around it.

## RESEARCH ON FUNDRAISING

Research and theory on fundraising is very new. Serious scholarship on the subject dates back only to 1991, when several ground-breaking books were published (for example, Burlingame & Hulse 1991). Unlike other aspects of philanthropy and nonprofit management, fundraising had not been claimed by any academic discipline. Knowledge of the function came from practitioners and consisted primarily of “how-to” advice based on anecdotal evidence. Advances in public relations theory starting in the 1980s, particularly excellence theory and a paradigm shift to organization–public relationships (→ Excellence Theory in Public Relations; Organization–Public Relationships), provided a framework for building theory on fundraising. Several public relations scholars have contributed to advancing knowledge on fundraising, but Kathleen Kelly (1991; 1998) is most closely associated with the endeavor.

Kelly and others conceptualized fundraising as a *sub-function*, or specialization, of *public relations* (→ Public Relations), which was defined as the management of relationships between an organization and the publics on whom it depends for success and survival. Donors were identified as a strategic enabling public of charitable organizations, similar to investors of publicly owned corporations. To be effective, fundraisers should rely on two-way communication and strive for mutually beneficial outcomes, or symmetrical effects. Theory holds that fundraising generates gift income by ensuring that the organization develops and maintains relationships with donors, who give freely due to relationships built on commitment, trust, satisfaction, and control mutuality. Fundraising should be integrated with other sub-functions of public relations so the organization can effectively manage its interdependencies with all strategic publics, including consumers of its program services.

A few scholars, as well as many practitioners, approach fundraising from a *marketing perspective* (→ Marketing). However, they do not conceptualize fundraising as part of the marketing function of nonprofits, but as a function separate from others. The leading proponent of the marketing approach is Adrian Sargeant (2004), a British professor of nonprofit marketing who in 2007 came to the US to assume the first endowed chair in fundraising, which was established the same year at the Center on Philanthropy at Indiana University. Sargeant has written several books and conducted research on various facets of fundraising, including public trust and confidence in charities (→ Trust of Publics), donor commitment, and branding. His greatest contribution thus far has been in the area of retention of annual-giving donors. He provides empirical evidence that building loyalty in people who already are giving saves organizations money and time. Regardless, the marketing perspective provides a limited view of fundraising. For example, Sargeant’s work concentrates on annual-giving donors and pays little attention to major-gift donors, who provide the majority of dollars raised in the US. The flaw is understandable given marketing’s traditional focus on mass consumers of products and services. Furthermore, in countries such as the UK, major-gift fundraising is only now emerging.

## FUTURE DIRECTIONS

In the last 20 years, the practice of fundraising has grown dramatically around the globe. For example, the Association of Fundraising Professionals, headquartered in the US, has

16 chapters and almost 3,000 members in Canada. It has strategic alliances with the Institute of Fundraising in the UK and the Fund Raising Institute of Australia. Fundraising also has spread to developing countries in response to the rapid growth of NGOs.

The increase in nonprofit organizations was documented by a team of researchers from Johns Hopkins University's Center for Civil Society Studies, led by Lester Salamon (Salamon et al. 2004). The comparative nonprofit sector project, launched in 1991, is an ongoing effort to analyze the scope, structure, financing, and role of the nonprofit sector around the world. Findings from the first stages of the project showed that nonprofit organizations are present in virtually every part of the world and the nonprofit sector is a major economic force. Based on a cross-section of 16 advanced industrial countries, 14 developing countries, and 5 transitional countries in central and eastern Europe, the researchers found that giving as a share of GDP ranged from a high of 1.85 percent for the US to a mid-level of 0.41 percent for Slovakia to a low of 0.04 percent for Mexico (unavailability of data on giving to religious organizations reduced the latter's percentage). If expenditures of all nonprofits in the 35 countries were calculated as a separate nation, the nonprofit sector would be the seventh largest economy in the world, ahead of Italy, Brazil, Russia, Spain, and Canada and just behind France and the UK. The researchers concluded that a massive upsurge of organized, private voluntary activity was underway.

The growth of nonprofit organizations has resulted in a demand for fundraising practitioners that has outstripped the supply. It also underscores the need for more knowledge regarding the fundraising function. Theories developed in the US must be tested and adjusted to accommodate different cultures and their legal, social, and political environments.

# Gag Orders

*Susan Dente Ross*

*Washington State University*

Governments prevent information from being made public through restraints on speech called “gag orders.” Government executive orders and court injunctions impose gags to restrict the flow of certain types of information to achieve specific government objectives. For example, many national governments enact laws or adopt executive orders to prevent the distribution of official government secrets, details of ongoing military actions, and national security data. Similarly, courts around the world impose injunctions and nonpublication orders to prohibit, or enjoin, public distribution of information that might prejudice the outcome of ongoing litigation. Gag orders are a form of prior restraint because they prevent the exchange of information before any harm occurs rather than imposing punishment in response to specific harms caused by speech. While some gag orders target individuals, many gags are imposed on the media as the messenger that disseminates information most widely.

Different nations and cultures have distinct histories and traditions related to the freedoms of speech and press (→ Freedom of the Press, Concept of). One foundational distinction rests upon a nation’s embrace of libertarianism or authoritarianism. More authoritarian nations tend to view press law as a means to advance the self-interest of the state, which includes maintaining law, order, and civility. More liberal nations see a more independent role for the press to provide external oversight of government to prevent political abuses and maintain an informed citizenry. These differences lead to divergent national presumptions about the costs and benefits of gag orders that suppress the exchange of information.

*Canada*, the *United States*, and *Australia*, for example, all trace their fundamental understanding of free-speech values back to England and share a strong common law presumption disfavoring prior restraints on speech (→ Communication Law and Policy: North America). In these nations, judges are required to protect the integrity of court processes and enforce procedural safeguards to limit their own discretion and the power of government officers to impose gags on the media. Nonetheless, Australian and Canadian courts presume that media coverage of ongoing trials prejudices jurors and irretrievably damages the fairness of proceedings. As a result, Australian and Canadian judges routinely impose gag orders on the media to prevent distribution of information about ongoing trials. In the United States, however, court orders preventing the media

from publishing information are presumed to violate the US Constitution and are subject to the most stringent standards of judicial review. US courts, therefore, commonly rely on prior restraints that stop attorneys, jurors, and other individuals engaged in the trial from sharing potentially prejudicial information with the media. In some instances, US courts uphold bans on reporters' access to public officials to prevent continued unfavorable coverage or disclosure of leaked government information.

Many governments consider official control of the content of speech to be a legitimate function of the state and impose prior restraints and prohibitions on a wide range of subjects. The Press Ordinance in *Palestine* and *Israel's* Defense Regulations give government the power to censor as well as to license, revoke, or suspend publications without court review. The *Philippine Press Institute* has fought government initiatives there to regulate media content by suspending or revoking broadcast authorizations. *Venezuela's* Law on the Social Responsibility of Radio and Television is a criminal statute that prohibits the press from attacking or insulting government and punishes journalists who undermine state values and ideology (→ Television Broadcasting, Regulation of). Both German and *European Union* standards prohibit denial of the Holocaust (→ European Union: Communication Law), and *German* law permits prior restraints on the press to avoid harm. In *Paraguay* and *El Salvador*, judges have extensive authority to impose gag orders to protect public morals and state security.

In rare cases, prior restraints reach beyond national boundaries. US Presidents Ronald Reagan and George W. Bush imposed a global gag rule that prohibited any non-US family planning organization that received US funds from disseminating information about abortion or lobbying for relaxation of anti-abortion laws. Members of the US Congress, the Council of Europe, and family planning experts across the Balkans, Africa, and the Americas opposed the so-called Mexico City Policy for its chilling effect on free speech and its negative impact on global women's health.

National standards and policies related to gag orders are not static, yet overall trends are difficult to assess. In general, more restrictive laws are adopted by authoritarian governments and during periods of national strife or insecurity. Political shifts toward democracy and international engagement tend to relax national policies on gag orders. For example, *Panamanian* government officials at the start of the twenty-first century moved to repeal key provisions of its decades-old criminal defamation laws that gagged the press and imposed severe penalties for criticism of government. The laws had been enacted under authoritarian military rule. Similarly, *Thai* courts revoked injunctions that prevented media from criticizing government officials as a means to preserve public peace and order. In addition, the interconnection of nations through a global communication network undermines the utility and effectiveness of gag orders that prohibit only information flows within national boundaries. Particularly in high-profile situations, international coverage of banned information as well as national reportage on the ban itself may increase, rather than reduce, interest in and attention paid to the prohibited speech.

## **Gatekeeping**

Wayne Wanta

*University of Missouri-Columbia*

Sociologist Kurt Lewin first used the term *gatekeeping* to describe how food purchasing habits of a population affected social change. After noting that not everyone had the same impact on which foods a population ate, he used “gatekeeping” to refer to those who transport, buy, and prepare food items because they acted as gates, allowing certain items to pass while holding back others.

### **THE CONCEPT**

The first to apply the term to news production was David Manning White (1950), who observed the news selection decisions of a US wire editor at the *Peoria Star* in Illinois. He concluded that “Mr. Gates” was “highly subjective” (→ Bias in the News; Objectivity in Reporting) in his decisions (p. 386). The editor did not allow some stories to run in his newspaper because they were “not interesting” or “B.S.” or because he didn’t care for them.

Since White’s study, gatekeeping has been a popular theoretical framework in communication. Researchers have examined the types of content that gatekeepers allow into the media, the selection process gatekeepers employ, and the background and biases of the gatekeepers themselves.

The area of research has a rich and extensive tradition, but also has several *shortcomings*. Much gatekeeping research has tended to be descriptive rather than analytical. Research has described the content produced through the gatekeeping process, for example, instead of rigorously testing propositions related to the process. The term “gatekeeping” has provided researchers with a convenient theoretical framework for their studies, and some analyses deal with gatekeeping only by assuming that content must have passed through a gatekeeper (→ Media Production and Content).

A second common criticism is researchers' tendency to view gatekeeping as a single stage in isolation from other factors. Pamela Shoemaker (1991), in a comprehensive discussion of gatekeeping, developed a model in which advertisers, public relations practitioners, pressure groups, → news sources, and news managers all influence content (→ Issue Management; Issue Management in Politics; Media Events and Pseudo-Events; Public Relations: Media Influence). Gatekeeping often involves group decision-making, with multiple editors deciding which stories will receive prominent coverage. Audience expectations and production costs also influence the process (→ Audience; Cost and Revenue Structures in the Media).

### THE GATEKEEPERS

David Weaver and Cleveland Wilhoit have conducted several studies examining the personal backgrounds and opinions working journalists hold (most recently, Weaver et al. 2006). In general, they conclude that the typical US journalist is male, Protestant, liberal, college-educated and middle class. Research elsewhere has noted similar demographics. A survey of journalists at the *Times* of London found that many shared news values but that cultural differences could affect their news selection (Peterson 1979; → United Kingdom: Media System).

Weaver and Wilhoit also found that journalists see themselves as much more than mere gatherers and disseminators of factual information; instead they see their role as interpreting what is news (→ Journalists' Role Perception). Other survey research has found the same tendency, revealing that journalists incorporate sense-making and interpretation as key job functions, which arguably increased in importance with the emergence of the → Internet and its unlimited volume of information.

Recent studies of content production on the Internet suggest that the role of gatekeeper shifts to the individual user, who has ultimate control over the information being received. A comparison of journalists' weblogs and news stories (Singer 2005), however, found that journalistic standards appear to persist online. Although expressions of opinion appear in blogs, journalists seek to retain their gatekeeping role by linking mostly to other mainstream media sites (→ Blogger; News Story).

Scholars have applied gatekeeping to several areas of the newsroom. For example, an examination of visual gatekeepers, through a content analysis, personal observations, and interviews with photo editors (→ Photojournalism; Visual Communication), found that individual opinions, conventions, and organizational structure all affect the process (Bissell 2000). The study concludes that newsworthiness and objectivity were not as important as the subjectivity of the editors (→ News Values).

US television journalists surveyed about their attitudes toward international news indicated that two factors influence the gatekeeping process: market demands and local relevance (Kim 2002; → Television News; Supply and Demand in Media Markets; Local News). Network journalists held a more global view of the news, selecting stories with diverse themes, but local television journalists tended to select international news stories with local angles. Timeliness and US involvement were important values for both groups.

Gatekeepers at international news media have also been the focus of research. Foreign news editors at the *Times* of London held news values very similar to those proposed in

previous research (Peterson 1979). A recent examination of international news agency coverage of the debate before the Iraq war found that nonwestern news agencies included more nonwestern viewpoints (Horvit 2006).

Finally, recent studies have attempted to link gatekeeping with other theoretical areas such as agenda setting (→ Agenda-Setting Effects). A study comparing patterns for newspapers with either a large or a small percentage of females in managerial positions (Craft & Wanta 2004) showed that male and female reporters covered different categories of stories only in newsrooms with predominantly male editors. In newsrooms with a high percentage of male editors, men covered more hard news stories and women covered more feature stories, contrary to previous findings (→ Media Management; Gender and Media Organizations). A replication of White's study with a female wire editor found no effects of news selection bias attributable to the editor's gender, and another study discovered no differences in the sense of personal autonomy of male and female journalists based on the number of women in a newsroom (see Craft & Wanta 2004). Overall, studies comparing gatekeeper gender have produced mixed results (→ Gender and Journalism).

## THE PROCESS

Hundreds of studies have examined the news selection process, many published well before White's (1950) initial work, such as → Walter Lippmann, who wrote in his classic book *Public Opinion* about how the news media paint pictures of the world for readers to imagine (→ Media Effects, History of).

More recently, Shoemaker and Stephen D. Reese (1996) proposed a *hierarchy of news* model, in which five levels of factors influence the content that ultimately appears in the media: journalists, their routines, media organizations, news outsiders, and society (→ News Routines). Shoemaker and Reese note key studies at each level. Journalists can influence media content merely by selecting certain potential story topics while ignoring others (White 1950). Journalistic routines include strategies such as demonstrating → balance and fairness, a process Gaye Tuchman calls a *strategic ritual*, which uses objectivity to defend the news product from critics. Management and the ownership structure of the place of employment constrain reporters by teaching them what is acceptable to avoid being fired and to win the rewards of raises and good assignments, through a process Warren Breed calls newsroom socialization (→ Ownership in the Media). Outside influences, such as advertisers (→ Advertising) and news sources, affect media organizations as businesses that must make money to survive. Finally, social influences occur as media organizations maintain the status quo by providing only content that hegemonic forces in society deem acceptable and appropriate (→ Political Economy of the Media). Much of gatekeeping research is concentrated in levels one or three of the model, examining individual gatekeepers and media organizations.

## THE CONTENT

Gatekeeping has an important influence on the information available to the public, as several studies have shown. Guido Stempel (1985) compared news content from several US newspapers and found that a few publications, notably the *New York Times*, influence

the news coverage of other media by acting as → opinion leaders (→ Newspaper Journalism; Agenda Building). Its morning edition has a significant influence on subsequent news coverage on evening broadcasts of US network news as well.

Several researchers have applied gatekeeping to international news flow. A → meta-analysis of the research found that traditional gatekeeper factors, along with newsworthiness, socio-cultural structure, and organizational constraints, affected news selection (Wu 1998). The gatekeeping process varies dramatically from culture to culture and country to country.

Online gatekeeping may differ from that of traditional media. An investigation of whether online newspaper gatekeepers provided readers with information identical to what traditional media provide found that online content tended to concentrate on local news (Singer 2005). Internet gatekeeping has also been examined in countries such as Greece, Egypt, and South Korea (→ Internet News; Egypt: Media System; South Korea: Media System).

Research on the gatekeeping process grows in importance as researchers move away from traditional media to examine content and the production process with information on the Internet. A focus on the production and the producers of media messages has had much to offer for half a century, and gatekeeping will likely continue as an important theoretical framework in mass communication research.

## Gay, Lesbian, Bisexual, and Transgender Media Studies

*Anita Chi-Kwan Lee*

*University of Hong Kong*

The subject of this entry is the field of study that examines the representation of gay, lesbian, bisexual, and transgender (GLBT) people in the media. GLBT media studies employ theories and methods from the relatively new field of GLBT and queer studies that started to appear in academia at the beginning of the 1990s. It is concerned with how the sexual identity categories of "gay," "lesbian," "bisexual," "transgender," "queer," and "straight" are constructed in the media; how minority sexualities are represented; and why they are so represented. "Queer media," "queer representation," "queer media representation," and "queer cultural production" are terms frequently used in the field.

### GLBT, LGBT, AND QUEER

The use of the initialism GLBT is still under much debate. One critical point of contention is that promoting the use of this term and its variants serves to reinforce a prevalent concept based on the binary opposition of "straight" as the norm against the rest as "the other," ignoring their inherent differences and the different issues faced by each group. There are variations to the term, which is an adaptation of the abbreviation LGB (or "lesbigay"). While it is used more in the United States and Australia, LGBT is more widely accepted and adopted by cultural and social service units catering to the needs of gay, lesbian, bisexual, and transgender groups in most English-speaking countries.

In existence since the 1970s, when the gay liberation movement started to appear on the agenda, GLBT studies examine how sexual minorities have been represented in history and culture, and how gender and sexual orientation have been constructed. Considered very important to GLBT studies are two essays by Gayle Rubin, "The traffic in women" (1975) and "Thinking sex" (1984/1993), which establish the theory that gender difference is different from sexual difference, though the two are related. Judith Butler

further explores the interrelatedness of gender, sex, and desire in her ground-breaking text *Gender trouble* (1990), which has become very important in queer studies.

There is also much controversy regarding the term “queer,” which has been re-appropriated since the late 1980s as an umbrella term for the marginalized sexual minorities, from an expression of homophobic abuse in the past. The first theorist to use the phrase “queer theory” in print was Teresa de Lauretis, whose essay of that title was published in 1991. Meanwhile, the text considered most influential in the development of queer studies is Michel Foucault’s *History of sexuality* (1978). Foucault argues that sexuality is constructed through religion, politics, and economics, so that no form of sexuality can be something natural or universal (→ Discourse). Embracing fluidity, “queer” is an open entity. In its resistance to the normative codes of gender and sexuality, “queer” rejects binaries like heterosexual/homosexual. As such, there is no consensus as to who is included and who is not under the term. Eve Kosofsky Sedgwick (1990) distinguishes “queer” as “universalizing” instead of “minoritizing.” As queer theory has developed in academic scholarship, “queer” has been interpreted not as a fixed category, but has instead been read all over culture. It is concerned with affirming otherness and differences that are characteristic of marginalized groups, rather than adhering to strict oppositional dichotomies.

The concern of GLBT studies and queer theory are somewhat different. First, the former has been occupied with the query of whether nature or nurture is the cause of homosexuality, while the latter is less interested in this. Queer theory looks at how the construction of the different categories of alternative sexualities functions in culture (→ Cultural Studies), while GLBT studies are more concerned with identity affirmation of the different sexual minority groups for the advancement of the GLBT political movement (→ Identity Politics). From the focus of GLBT studies on the social construction of categories of normative and deviant sexualities, queer theory has emerged to challenge essentialist notions of homosexuality and heterosexuality, questioning cultural assumptions that are often immersed in heterosexist presumptions (→ Heterosexism and the Media).

## **THEORETICAL CONCEPTS AND APPROACHES**

Gay, lesbian, bisexual, and transgender media studies investigate the ideological functions of GLBT and queer media representations by employing critical and theoretical methods from gender, psychoanalytic, semiotic, and film theories to interpret meaning in these representations (→ Film as Popular Culture; Film Theory). It is interesting that GLBT media studies have also engaged queer theory in media analyses, and there is a tendency for the former to appropriate the latter in order to contribute to the liberation movement (→ Civil Rights Movement and the Media). With a premise quite different from earlier culture theories, like the Frankfurt School (→ Critical Theory; Culture Industries), which view → popular culture as immutable and audiences as passive receivers (→ Affects and Media Exposure; Audience Research), queer theory argues for the possibility of multiple readings because of the increasingly complex relationship between readers/audience/viewers and cultural productions.

Before the 1960s, there were very few representations of homosexuality in American films due to the Production Code (also known as the Hays Code) that had been in force since 1934. A set of industry guidelines, the Production Code gave details of what was and was not considered morally acceptable in the production of motion pictures for a public

audience. The “Particular Applications” of the principles forbade references to alleged “sex perversion,” such as homosexuality. The early 1960s saw the release and screening of a few daring British films in America which offered commentary about homophobia. The American gay rights and civil rights movements then started a heated discussion about the Code’s restriction of the representation of themes that included sexuality. When enforcement had become impossible, the Code was abandoned entirely in 1967 in favor of the new Motion Picture Association of America (MPAA) film rating system, which went into effect on 1 November 1968, but which contains no reference to homosexuality or queer.

When GLBT representation started to appear in the *American cinema*, media studies work in this area began to flourish, with books published on the topic: *Screening the sexes* (Tyler 1972), *Gays and film* (Dyer 1977), and *The celluloid closet* (Russo 1981). The oldest lesbian and gay film festival in the world, the San Francisco International Lesbian and Gay Film Festival, was first launched in 1977. By the early 1990s, there was a body of queer films that won critical acclaim in the Sundance Film Festivals. They were grouped under the term “New Queer Cinema,” coined by theorist B. Ruby Rich, which was soon to be used arbitrarily to denote independent films with gay and lesbian content. Then, in an interview in May 2004, Rich proclaimed that New Queer Cinema was over, as its characteristic of defiance had been replaced by commercial blandness catering to a niche market. While the field of GLBT and queer film studies has been more developed, the most observant media watch concerning television, radio, popular music, advertising, and other forms of mass media has been offered by the gay, lesbian, and queer press in their reviews and articles (Doty & Gove 1997). That said, there is also a very powerful media watch organization in the US called GLAAD (Gay and Lesbian Alliance Against Defamation).

Though Doty and Gove (1997) think that there has consistently been some kind of *queer representation on television* since the late 1940s, other media scholars have until very recently lamented the rarity of mainstream media depictions of GLBT people, especially on television (Gross 1995). In the first decade of the twenty-first century, gay and lesbian characters became common on US prime-time television. Also available are programs produced by and for gay and lesbian people on television and radio, and representations found in the popular music arena, advertising, magazines, and newspapers. There is now a profusion of mainstream, alternative, and “in-between” sources of GLBT and queer media representation, although journalism and comic strips remain in two completely separate media worlds of the heterosexual mainstream and the GLBT and queer alternative. Meanwhile, same-sex erotic passions are suggested or directly referenced in popular music for the effect of transgression. These preoccupations with and connotations about sex appeal to the GLBT community, who express an intense dedication to popular music (Doty & Gove 1997).

Regarding *research methodologies* typically employed by GLBT media scholars, Worth (1993) notes a tendency toward difference in research areas, with gay men often engaging in historiographic archival work, while lesbians appear to typically conduct textual analyses (→ Historiography). For more than twenty years from the post-Stonewall period in the early 1970s, both media scholars and critics had been preoccupied with the question of “positive” and “negative” representation, which investigates how stereotypes are portrayed in the media, and the range of GLBT images on offer (Dyer 1993; Gross

1995; → Stereotyping and the Media). Related to this critical approach are the differences in how gay and lesbian images are read and interpreted by the different groups of straight and queer audiences (Doty & Gove 1997; Erhart 1999; Raymond 2003). Doty & Gove (1997) explain that the gay, lesbian, and queer images on television can either be presented overtly in the text through dialogues or sexual behavior of the characters, or the queerness of a character's sexuality can be understood on the basis of other signs. Erhart (1999) details previous scholarly discussions of what constitutes a queer image or narrative. From these discussions, she provides an oppositional definition of "queer" as contrasted with "heterosexual," and which stands for the imagery of alternative sexualities that are found outside of hegemonic representation. Both Erhart (1999) and Raymond (2003) comment on the growing involvement of lesbian, gay, or queer writers, authors, and directors in the production of GLBT media images. Such programs could also be performed by actors who are openly queer, or whose sexual orientation is enigmatic. With such ambiguity, viewers are open to multiple levels of reading performances, resorting to their fantasies and imagination, while simultaneously decoding elusive references, to capture the "queerness" that is on offer by the images.

### CRITICAL DEBATES

The increasing number of gay and lesbian characters in the different English-language contemporary media, especially those of the US, has prompted the question of whether their visibility represents a certain kind of political victory. In an active challenge of the prevailing tenets of visibility politics, queer cultural production is seen to offer new possibilities for queer "world-making" (to use the term of Henry Jenkins [2006], meaning the creation process of multiculturalism to sustain consumer franchising). Yet, it is doubtful whether the significantly white, middle-class, and gender-conforming gay and lesbian images offered by the mainstream media in the west, e.g., *The L Word* (Showtime 2004–), result in the normalization of queerness to serve the economy-driven neo-liberal political agenda.

Raymond (2003) thinks television programming that includes homosexual content has to appeal to mainstream liberal viewers, who, though mostly heterosexual, must know one or two homosexual colleagues, friends, or relatives. Commonly found up until the 1990s, the stereotypical or negative representation of GLBT people "as victim or villain" (Raymond 2003, 101) has been replaced by this normative interpretation of sexual difference. In addition, as Kellner (1995) puts it, difference sells. As a sign of opposition, difference helps create desire and sell commodities. This points to the trend to promote gayness as a lifestyle, and gay personalities as fashionable, stylish, and having cultured tastes, as portrayed in the very popular US Emmy award-winning television reality program *Queer Eye (for the Straight Guy)* (Bravo TV 2003–2007) and the sitcom *Will and Grace* (NBC 1998–2006). Raymond (2003) argues that the subversive potential that media critics tended to consider for resistant interpretations found in the images once created by independent directors are now undermined and weakened by the mainstreaming of these images offered in the mass media.

As much as the media are part of culture, debates in GLBT media studies also arise from the intertwining differences in culture, gender, and sex. Despite the recent

development of lesbian and queer studies into established fields of studies in the western world, such progress elsewhere is still very much in the initial stages. If media representation is about power and identity, nonwestern viewpoints are very much different from the western ones. Media studies in these areas reflect public awareness and acceptance of the issues. *Islamic countries, India and Greater China*, for example, all have different cultural values in gender relations and family structures, as opposed to the Freudian–Lacanian psychoanalytic tradition of the west that centers on the nuclear family. Quite a few examples of films that have been produced in recent years by filmmakers from Israel, Iran, and India still depict the suffering of women as a result of the unfair treatment and reactionary misogynist attitude of the people because of the local cultures and religions. Meanwhile, Confucian teachings have effectuated a very closely knitted parent–child relationship on Chinese families. Chinese children have to fulfill the expectations of their parents to carry on the family name and lineage through heterosexual marriage and reproduction, so that the act of coming out by a Chinese gay man or lesbian with the parents is more difficult than coming out with friends. Moreover, the gender relations in Chinese societies still pertain to a male-privileged hierarchy.

With the debased social *status of women*, who are treated as the peripheral to men – the core – which is still very much the case in a large part of the world, lesbianism is doubly marginalized. For that matter, bisexual and transgender people are both more than doubly marginalized, and their identities even more submerged. Raymond (2003) comments on the absence of bisexuals even in prime-time US television programs, which are full of gay and lesbian characters, while Doty and Gove (1997) also assert that bisexual desires cannot be fully recognized in the gay and lesbian images offered by mainstream media. Considering power as the site of oppression, the power disparity is significant here. As such, gay and lesbian representations in the nonwestern mass media have to deal with quite different issues, putting aside the cultural productions by the local GLBT circles, for the reasons of low circulation in the public arena and too much self-awareness.

Because of globalization and the rise of regionalism, the one-way traffic of media flow from the US and European core to the periphery has been replaced by the increasing flow back of nonwestern media productions from the peripheral to the core (→ Globalization of the Media). For example, Mexican film productions are exhibited in Spain, while Chinese films have started to penetrate western markets; with very strong and nationwide distribution, Korean and Indian films have started to wear down the overseas markets of → Hollywood. As Arjun Appadurai (1990) puts it, the current mediascape is much more diversified than the cultural homogeneity found in traditional media theory. With the multifaceted media flow that is replacing the old dichotomy between Hollywood and the rest of the world, media studies have to accommodate different perspectives from nonwestern countries in relation to gay and lesbian representations.

# Gaze in Interaction

Julien C. Mirivel

University of Arkansas at Little Rock

When communicators interact with one another, they necessarily gaze (or look) at each other or gaze separately or together at objects, artifacts, or events in the perceptual world. Gazing, scholars in language and social interaction have shown (→ Language and Social Interaction), is a fundamental mechanism through which people manage, coordinate, and choreograph their communicative activities. Gaze-in-interaction, then, is the term of choice to refer to these multiple activities, including the ways in which people use gaze as a resource for accomplishing specific interactional goals.

In general, people may gaze each other “in the eyes” (“mutual gaze”), gaze at specific bodily parts (e.g., a pointing gesture) or toward objects or artifacts, gaze at their own gestural behaviors to bring recipient’s focused attention to such activities (“gaze-shifts”; see Streeck 1994), or look in a direction established by another (sometimes called “triadic eye gaze”). These activities, researchers have shown, serve important functions; they “do” things.

When looking at another, a communicator may signal interaction readiness, thereby making himself or herself available, or asking the other, for human contact: this is a first *function of gaze* (Goffman 1963). A second function of gaze is to regulate interaction and monitor another person’s behavior (Kendon 1967). For instance, speakers cue recipients when it is their turn to talk (→ Conversation Analysis). Prototypically, a person looks away as they start to speak, presumably to hold their turn of talk, and gazes toward the recipient at the end of their utterance to relinquish the conversational floor or to enable participants to produce smooth transitions in turn-taking sequences. In some interactional contexts, speakers may precisely time their gaze toward listeners to provoke an audible feedback cue, and when a response is offered, their gaze is terminated (“gaze window”; see Bavelas et al. 2002). In short, participants gaze to regulate the flow of conversation. Third, people gaze to convey emotions and relational-intimacy-immediacy cues (→ Nonverbal Communication and Culture). Depending on the duration, frequency, and intensity of a gaze, participants may display dominance, liking, or attraction, and when juxtaposed with other nonverbal behaviors such as facial expressions, gazing may convey myriad emotions such as anger or happiness. When people gaze, then, they do not just look at people or objects, but instead, subtleties about how looking is done will perform important, interactionally implicative functions.

In addition to serving multiple functions, gaze also is something people *interpret* in particular ways. Across cultures, we find, for instance, that people agree on the meaning of a stare by interpreting it as a sign of assertiveness, suggesting that maintaining gaze and averting or withdrawing may be taken as signs of dominance or weakness. Much work has been done to decipher how gazes may be interpreted. For instance, an early study by Burgoon et al. (1984) about the perceived communicative meaning of gaze evidenced that communicators interpret frequent eye gaze as conveying greater intimacy, immediacy, dominance, persuasiveness, and aggressiveness, while gaze aversion shapes interpretation in the opposite direction. As a later study (Burgoon et al. 1985) also showed, gaze aversion negatively influences job interviewers’ interpretive judgment about a prospective

employee, including his or her credibility, competence, or sociability, and decreases the likelihood that they will be hired. How people gaze, then, carries both relational and institutional consequences.

Although gaze activities shape cultural members' interpretive-perceptual judgment, some research has examined how people interpret, orient to, and react to a particular gaze in the course of naturally occurring interaction. One recent study, for instance, showed how children interpret and differentiate the meaning of caregivers' multiple kinds of gazing activities (Kidwell 2005). As the author illustrated, young children differentiate caregivers' "mere looks" from "the look" by orienting to the gaze's implication on subsequent actions, particularly the likelihood that caregivers will intervene on sanctionable activities. How to interpret a gaze, then, is not just a matter of perception, but becomes meaningful, and collaboratively achieved, in and through interactional actions performed "in the moment."

To date, research on gaze-in-interaction has offered a rich descriptive account of how people coordinate their communicative activities to accomplish particular interactional (e.g., taking turns at speaking), relational (e.g., cueing intimacy and attraction), and institutional tasks (e.g., disciplining children or being compliant with and resistant to therapy). Interestingly, findings about how gazing operates in human interaction have been influential, shaping the design of accurate gazing behaviors from conversational agents operating within virtual environments or mediated conversation.

## Gender and Discourse

Ann Weatherall

Victoria University of Wellington

Scholarship on gender and discourse has a long, interdisciplinary history. Anthropologists in the seventeenth and eighteenth centuries documented differences between women's and men's speech in non-European cultures. However, gender differences within cultures have never been sufficient to constitute separate women's and men's languages. Around the early twentieth century, academics' attention also turned to the English language. Gender and language variation was an early research topic for linguists. One bold but inaccurate view was that a larger variability in articulateness among men than women was evidence of men's greater intelligence. Psychological studies dating from the 1930s and 1940s charted the emergence of sex differences in language use. A longstanding but still controversial claim is that of an innate female superiority in verbal ability (Weatherall 2002).

A feminist concern with language and communication also has a long history (→ Feminist Communication Ethics). Publications from the first *women's movement* in the late nineteenth century noted the use of diminutive terms to address women and not men. The significance of women changing their name on marriage was also criticized. However, it was the second women's movement starting in the 1960s that generated research on the relationships between gender, language, and power. Feminists documented how language, in both structure and patterns of use, encoded dominant beliefs about women's inferiority. Outside feminist and academic circles there has also been a sustained interest in the topic. Journalistic articles are regularly published that discuss gender-related language issues such as the use of "Ms," marital name-changing, and the use of gender-marked terms (e.g., "air hostess" vs "cabin attendant"). Some self-help books offering advice on how to communicate better across the so-called gender divide have reached bestseller status. It should be noted these books are largely targeted at a female audience and they suggest changes to the ways women should talk, but not men.

### RESEARCH SUBJECTS

A landmark publication was Robin Lakoff's (1975) *Language and woman's place*. She argued that women's social place was reflected in their speech, which she described as ingratiating, hesitant, and weak. Women's secondary status was also revealed in reference terms, which were more frequently negative and sexual than were terms for men. Pairs of terms that illustrated the kinds of bias she documented include mistress/master, bachelor/

spinster, and tomboy/sissy. The two topics identified by Lakoff – gender differences in speech and sex bias in language – dominated scholarship until the last decade of the twentieth century. An important and ongoing debate straddling those two topics was whether language merely reflected gender inequality or whether it also maintained and reproduced sex-based discrimination. Scientific studies have shown that language customs can perpetuate discrimination. For example, jobs advertised using male words tend to attract fewer female applicants than the same jobs advertised using gender-neutral terms. Research on the significance of language bias has been used to support policies that prohibit sexist language practices such as the use of “man” to refer to people in general.

Over time there has been a diversification of subject matter in this area (e.g., Holmes & Meyerhoff 2003). For instance, *women’s talk* has been studied not just comparatively but for what it reveals about women’s lives – their relationships with each other and their unique gendered experiences as mothers, daughters, and so on (→ Women’s Communication and Language). Likewise men’s talk has been examined in investigations of maleness and masculinities. The study of gender in language has also broadened. For instance, different contexts such as sports commentary and wildlife documentaries are now studied. There is a general consensus that *changes in gender representation* have occurred. For example, women are no longer as invisible as they once were. Less encouraging is that representations of women and men continue to be overwhelmingly consistent with sex stereotypes (→ Sexism in the Media). A vital new area of research is gender and computer-mediated communication. A key issue is whether established trends in gender and language research are reproduced or transformed by the new technologies.

Another important way subject matter has expanded is a consideration of language in terms of “queer” or *non-normative gender and sexual identities* (e.g., Livia & Hall 1997). Gender is pervasively conceptualized as a binary, so there is a notable absence of ways of talking about those who are transgender or intersex. Furthermore, past research on gender and language has largely assumed heterosexuality. More recently consideration has been given to marginalized sexual orientations and language use. Some research on sexuality parallels that on gender and language by asking questions about what is distinctive about the speech of those who belong to gay communities and how homosexuality is marginalized as a topic in talk and texts. However, other queer-focused research is characterized by a new way of theorizing the relationship between language and social identities (→ Identities and Discourse).

### THEORETICAL APPROACHES

The new way of thinking about language and identity that is evident in some of the sexuality literature marks a fundamental theoretical shift in conceptual thinking (Cameron 1998). The change is part of a broader movement across the social sciences that has been referred to as the “discursive turn.” Here, “discourse” does not refer to the everyday sense of the term as conversation, nor does it carry with it the technical linguistic meaning of language structure above the level of the sentence (→ Discourse Analysis). Rather, it alludes to a rejection of ideas regarding language as a simple system of representation. Instead, language as discourse *produces* meaning and knowledge. Furthermore, this new

sense of “discourse” captures the idea of power as truth, manifest in cultural givens about, e.g., gender and sexuality.

Discursive research continues an earlier interest in the relationships between gender, language, and power but examines them in new and innovative ways. Instead of asking how language reveals and perpetuates gender-based inequality, a discourse analytic study might ask about the ways meaning systems produce and reproduce cultural values. For example, discourse analytic studies have examined how dominant cultural notions such as liberalism and individualism are mobilized to deny gender inequality in the workplace and to justify a lack of affirmative action (→ Discursive Psychology). An ongoing concern for those following the discursive turn is a current rise in neo-Darwinian ideas, which reifies biology as the cause of complex gender-differentiated behaviors such as those relevant to communication. A critique of those neo-Darwinian ideas requires two types of expertise: a mastery of scientific discourse itself and an appreciation of a discursive critique of that same science.

The discursive turn brings with it a landmark change in the way *gender* is conceptualized. Early work on gender and language rested on essentialist ideas whereas discursive work embraces constructionist ones. To oversimplify, gender essentialism posits that relatively stable biological and/or social factors cause differences between women and men. Questions asking about gender differences in speech are typically essentialist because they assume some biological or social origin of gender differentiation. In contrast, *constructionism* views gender differences as a *product* of cultural meaning systems. So knowledge and beliefs about gender are produced by historical and social practices organized by a two-sex system. According to a constructionist perspective a gender identity is accomplished, at least in part, by talking and behaving in ways that are consistent with the sex label one has been assigned.

An important source of support for constructionist ideas is transgender studies. That a person can successfully pass as a different gender is, at least, evidence that gender is not entirely something that one is. Rather it is a social accomplishment requiring cultural knowledge about gender and a high level of skill and competence at enacting that knowledge. In cases of individuals who are born intersex, Kessler (1998) considered medical practices for what they revealed about the power of cultural beliefs to “make sex.” For example, social norms regarding penis functionality (i.e., ability to penetrate a vagina) are used to guide surgical decisions to feminize babies born with ambiguous genitalia. So the study of non-normative gender identities has launched challenges to long-held assumptions about the naturalness and inevitability of sex. The theoretical concept of language as discourse helps highlight the power of culture to shape understandings of natural phenomena such as biological sex.

## RESEARCH METHODOLOGY

Methodological changes in research on gender, language, and discourse also cut across theoretical distinctions. Put roughly, there have been trends toward naturalistic data and an increasing use of qualitative analyses (→ Qualitative Methodology). Also there has been a move away from treating gender as a feature of individuals and toward analyzing it as a social identity that may be more or less relevant in different interactional contexts. Overall, a complex array of research approaches exists. An advantage of the theoretical

and methodological diversity is that it characterizes a vibrant and exciting field of research. However, a disadvantage is a lack of common ground upon which to base discussion and debate. For example, a lack of definitive answers to questions about gender differences in speech motivates some researchers to pursue studies of difference, but it is used by others to reject the legitimacy of the questions. Such fundamentally incompatible positions are seemingly irreconcilable.

Compatibility issues aside, a range of contemporary approaches found in the literature are worth briefly mentioning. One is a → Communities of Practice (CoP) perspective. Typically associated with sociolinguistics, a CoP approach investigates how speech patterns develop in relation to gender-differentiated membership of social groups. For example, specific workplaces have different gender divisions of labor. Detailed qualitative and quantitative analyses can reveal how gender-differentiated speech patterns are linked to particular job-related activities. The ways that gender, alongside other social identities such as age and ethnicity, influence speech styles in interaction is also a chief concern of research grounded in → Communication Accommodation Theory (CAT), which is motivated by social psychological concerns. Another distinctive methodological approach evident in the published research literature is Conversation Analysis (CA), which attends to micro-features of talk-in-interaction. A CA study might examine when speakers observably orient to gender as relevant to the interaction, and might consider what those orientations accomplish in terms of social actions such as complimenting or complaining.

The richness and diversity of theory and methods in research on gender, language, and discourse belie simple predictions about possible directions future research might take. Currently, there is a substantive rift between language research based on essentialist ideas about gender and that based on constructionist ones. The establishment of *Gender and Language* in 2007, a journal devoted to publishing work on the topic, may help close that rift. Alternatively, approaches such as conversation analysis might gain ascendancy, approaches that side-step theoretical commitments about the nature of gender. Certainly, lay understandings of gender and its relationship to language largely rest on essentialist notions. Thus it behooves those endorsing constructionist ideas to make them more widely available and relevant to the concerns of contemporary society.

# Gender and Journalism

Marjan de Bruin

University of the West Indies, Jamaica

Gender and journalism became a popular area of study in the mid-1990s when gender in media studies gained recognition as a powerful variable defining feminine and masculine roles and behavior and structuring everyday life and work. Earlier feminist media studies had paid attention to women in journalism and their peculiar position in a male-dominated professional world with strong preconceptions about women journalists (Van Zoonen 1994). The growing realization that culturally determined gender role expectations exert influence led to the conceptual shift that added a *gender* perspective to journalism studies. Despite being common for years in gender studies (→ Feminist and Gender Studies), this perspective had not fully entered some fields such as media studies or organizational studies.

## RESEARCH HISTORY

In media studies this insight begins from the premise that gender notions color what journalists consider appropriate professional behavior for women and for men. Such notions may structure power relations in media work, influence the division of labor, determine access to promotion and status in media organizations, and affect journalists' interaction and communication with sources, colleagues, and supervisors.

Earlier accounts of women in the media were *autobiographies of female pioneers*, who related their survival strategies in an overwhelmingly male world. In the late 1970s and early 1980s other reflections on women in journalism began to appear, referring as well to alternative media. Several women initially excluded from journalism, who later gained acceptance on condition of surrendering to male newsroom norms, were motivated to develop their own media (→ Alternative Journalism).

In the 1970s, scholarly journals began to pay more attention to the *position and occupation roles of women in media hierarchies*. The 1975 Mexico Conference for the first UN Decade for Women helped set the research agenda in three areas: women's underrepresentation in the news (→ Gender: Representation in the Media), trivialization and sex-role stereotyping in content (→ Sex Role Stereotypes in the Media), and women's underrepresentation in decision-making positions. The driving force behind these priorities was the belief that a greater presence of women in the media would influence the media agenda (→ Agenda Building), which, in turn, would stimulate the inclusion of more women's issues in public debate.

Studies during the 1970s and 1980s began to compare women's and men's *tasks and responsibilities in media organizations*, trying to identify possible differences in their performance. Did male and female gatekeepers respond differently to news stories about women? Did women's or lifestyle page editors turn out different final products? Did men and women show differences in job satisfaction? Did they have different goals and achievement orientations? Did female television news anchors perceive any career barriers? There was even a replication, 40 years later, of White's (1950) classic on → gatekeeping, referring this time to Ms. Gates.

Studies on gender in the early 1990s were mostly descriptive research on media, rather than on journalism. Initial research on gender patterns in media employment concentrated on descriptive accounts of male and female *presence in organizations*, with numbers and percentages dominating the discussions (Creedon 1993; Gallagher & Quindoza-Santiago 1994; Gallagher 1995). These studies painted an overall picture showing that in the media workforce of many countries women formed a minority, occupying a small fraction of middle management, especially in news organizations, and an even smaller fraction in senior management. This serious underrepresentation still exists, although some countries have made slight changes for the better. US women journalists gained managerial responsibility and influence during the 1980s, especially in weekly newspapers and magazines (Weaver & Wilhoit 1996). On the other hand, a lower percentage of women than of men have a great deal of influence where power really matters: in hiring and firing (→ Journalism).

In the late 1990s several authors attempted to correlate women's presence in media organizations with *qualities of content*, as some research topics of the period reflect. Did female writers choose particular topics for stories? Did they have different priorities? Did the greater presence of women's writing on some front pages have anything to do with what appeared to be a wider range of stories of special interest to women? The assumption that a greater presence of women in the media workforce would lead to changes in their portrayal seemed to oversimplify the relationship between producers and content. It ignored the influence of the culture of the work environment – the media organization – on content as well as on content producers (→ Media Production and Content; Quality of the News).

Most studies up to the late 1990s took the working environment of journalists as a gender-neutral condition; they conceptualized gender mainly as a fixed attribute within media organizations, and not so much as a relational quality within the organization. Until the mid- to late 1990s, authors noted a lack of systematic research on gender and media organizations, or gender and journalism, although organizational studies in general suffered from the same deficit.

In the late 1990s, organizational studies developed a more sophisticated approach by breaking away from the idea of organizations as gender-neutral entities and by recognizing that the behavior of employees is the outcome of much more complex processes involving interaction and practices (→ Organizational Culture). Gender is only one of the major determinants.

### **CURRENT RESEARCH FOCI**

Recent debates on gender and journalism also reflect this new approach, with less emphasis on counting bodies and describing employment patterns and more on gendered substructures shaping processes. To study gender and professionalism as variables in

media production, the catchphrases became “gender orientation in journalism” or “gendered professionalism.” “Newsroom culture” and “journalistic culture,” and more specifically, “gendered professional practices in the newsroom,” finally became a center of attention.

Professional values and newsroom practices, as part of newsroom culture, were seen to have an unavoidable gender bias, given the preponderance of male decision-makers. Studies began to identify gendered substructures, such as *topic selection*, in which male priorities set the media agenda, or *division of work* in the allocation of beats, because in many countries, sports, crime, or war are still topics that only men cover. Gender also influences the treatment of stories from particular angles and styles: women take up human interest features and men dig into hard news. News discourse, as part of newsroom culture, shows the selective privileging of masculine over feminine ways of knowing, preferring logic over emotion, or science over intuition (Kitzinger 1998).

Some gendered substructures are difficult to recognize in daily life; they have become part of the social fabric in newsrooms and are the norm – that’s-how-we-do-it-here (→ News Routines). Studies show that female journalists can make contradictory statements, indicating that gender has not been important in their careers but at the same time has had a negative impact on salary and on career opportunities, such as running into the *glass ceiling*. Sexual harassment in newsrooms, and sometimes from sources, continues for many female journalists.

The increasing personalization of news, sexualization of news presentation, growing emphasis on infotainment, and tabloidization of media, some say, have offered women more job opportunities. Others blame market-led feminism for promoting a materialistic version of femininity and feminizing news (→ Feminization of Media Content).

Perceptions by journalists of the core values and roles in their profession differ considerably worldwide, and sometimes even within one region, country, or media organization (→ News Ideologies). It may therefore be misleading to speak about gender and journalism as if journalism represents one set of orientations (→ Journalists’ Role Perception). A professional identity depends on individual, social, cultural, and economic factors. Looking at journalism through a gender lens magnifies the influence of cultural and economic conditions even more, because gender itself is a culturally specific social construction.

Studying a range of realities, through country or region studies, for instance, is important for understanding gender and journalism, but also exceptional (Gallagher 1995; Weaver 1998; De Bruin & Ross 2004; Chambers et al. 2004). Most research, however, has shown a bias toward resource-rich, first-world countries, with a serious underrepresentation of regions outside of Europe and North America.

Comparing the national and international studies is often difficult, not only because of the geographical imbalance, but because studies lack a common framework: some researchers focus on women’s overall share of media jobs and look at entire media organizations, but others limit themselves to news departments.

In recent debates about gender and journalism, three concepts figure prominently: professionalism, media organization, and gender. Debates use the terms *professional* and *organizational* inconsistently. Sometimes *organizational* refers to the newsroom but at other times to the whole media organization, and the two settings appear interchangeably. Searching for a conceptual framework, authors have now turned to another concept:

social identity. Identity offers a way to capture and explore the dynamics among gender identity, professional identity, and organizational identity.

## **Gender and Media Organizations**

*Donnalyn Pompper*

*Temple University*

Theorizing about gender and organizations has proved a complex challenge, resulting in a body of literature that is "patchy and discontinuous" (Ashcraft & Mumby 2004, xiii). Yet, around the globe, feminist scholars tend to agree on one universal impediment to gender equity: reality emerges from the male standpoint, which shapes organizations and meanings. For the past 50 years, few organizations have attracted more scholarly attention with regard to gender dimensions than those of the mass media industry.

## ISSUES

Fundamentally, the relationship between gender and media organizations affects individual consciousness and collective social life (Tuchman 1979), so that the organizational milieus in which media products are created invite serious feminist analysis. Women's limited share in the ownership and control of media organizations, combined with their low employment in key decision-making roles, underscores why gender inequality undergirds the media industry worldwide (de Bruin 2000; Watkins & Emerson 2000; → Ownership in the Media). As a *minority in the middle- and senior-management media workforce*, women are unable to effect significant organizational change, shape media content, or influence hiring and firing decisions (Weaver & Wilhoit 1996). They want to keep their jobs, so they must please those with more power inside and outside of the organization. Overall, Milkie (2002) suggested that too little research systematically examines the struggles and processes of gendered media systems – the workings of cultural power.

For example, while the number of women employed in US media organizations' lower-level positions may have improved in recent decades after federal Equal Employment Opportunity Commission (EEOC) legislation was enacted, scholars argue that the socio-economic organization of media and its *routines and conventions, which reinforce sexism*, have not. Social, technological, and economic change since the 1970s has forced media organizations to reinvent themselves in order to consistently show a profitable return on global conglomerates' investments – often by modifying strategies appealing to the female labor force. Also, mass media workers' routines shape media content, reinforcing gender stereotypes by constructing symbols and images that define gender and ultimately women's identities (→ Sex Role Stereotypes in the Media).

## WOMEN IN DIFFERENT MEDIA

Women's marginalized workplace status and gender-stereotypical messages permeate a wide variety of mass media organizations. In particular, feminist scholars have been highly critical of five general mass media organizations and products: news, advertising, television, motion pictures, and magazines.

First, *newsroom* gender issues have culminated in numerous sex-discrimination lawsuits and out-of-court settlements. De Bruin (2000) described a "macho culture of newsgathering" – an environment that often excludes women journalists and positions them as inconsistent with the "true news professional." Since the 1970s, female workers' relegation to "women's pages" and support staff functions has been widely noted. Bagdikian (1990) argued that concentrated power and focus on profits detrimentally affect news content and inspired the news media's shift to entertainment mode. Importantly, this trend seems to offer women more opportunities in journalism – even though many researchers have noted gendered salary discrepancies and female reporters routinely assigned to cover soft news such as famous women with cancer (Corbett & Mori 1999; → News).

Second, the symbiotic relationship between *advertisers* and corporate media organizations has drawn sharp criticism from feminist circles. Advertising's omnipresent messages and

images demean women and perpetuate their disadvantage (→ Advertising). Clearly, media organizations are heavily dependent on advertising revenues, so they work hard to woo advertisers. Strategically, media organizations package content that fosters a “buying mood”: commodities that avoid upstaging the ads (Gamson et al. 1992). As a shortcut to satisfying advertisers, media organizations reproduce past practices, prevent innovation, and maintain the status quo. For women, this results in reinforced stereotypes, or → “symbolic annihilation” (Gerbner 1972). Women’s disadvantage is created and maintained through such narrow, harmful images that “enter everyday practices and discourses” (Milkie 2002, 839).

Third, → *television* in the 1970s saw an employment spurt for women – yet gender equity continues to elude television organizations. The foundation of television programming is gendered, in terms of structured time and space coordinates that determine network programming schedules (e.g., daytime, prime time, late night). A narrowcast philosophy of programming means that networks green-light content that will capture specific demographic audiences during specific time parts – and women represent a significant portion of network viewers. In addition, → genre forms and character types are gendered – so much so that televisual representations of gender have changed modestly since broadcast radio created the family sitcom and detective shows, gendered work roles, and character types such as dumb blondes and brawny males (Watkins & Emerson 2000). Unfortunately, television writers and executives invite only the most liberal of feminist traditions in sanctioning content that will appeal to advertisers and viewers. For example, a television sitcom’s female character may work as a lawyer, but she works a second shift as primary caregiver to her children.

Fourth, feminist scholars also have closely examined the *motion picture* industry, both as an employer of women and as a mass medium communicating gendered messages. Women may have dominated the screenwriting profession in → Hollywood during the silent film era, but men have controlled corporate channels of production, distribution, and exhibition since filmmaking became more industrialized. Consequently, numerous Hollywood actresses have reported limited career options. Rosanna Arquette’s documentary *Searching for Debra Winger* features interviews with international award-winning actresses – all of whom tell of gender and age discrimination, resolving that greater diversity in onscreen female types can occur only when women assume roles behind the camera and in film studio executive suites (Walters et al. 2004). Film actresses’ sentiments concur with the findings of feminist scholars who report that the organizational structures and routines of the film industry are more likely to reward those individuals whose work appeals to masculine sensibilities. In her seminal essay “Visual pleasures and narrative cinema,” Laura Mulvey (1975) introduced the notion of “the male gaze” in feminist film theory (→ Spectator Gaze). Mulvey argued that the male point of view is privileged; that the masculine perspective shapes the film-viewing experience and socializes women into identifying and complying with patriarchal ideologies that reinforce women’s marginalization.

Finally, a rich body of feminist scholarship has examined *women’s magazines* (→ Women’s Media Genres). Many US consumer magazines target a particular gender group, since marketers promote their products as gender specific. Researchers have found that editorial pages of women’s magazines focus more on dieting and weight loss than serious

health problems. Fashion magazine covers, ads, and editorial content imply that being thin is associated with being happier, sexier, and more loveable (Malkin et al. 1999). Thus, → magazines may propagate a slender ideal that – at best – elicits women’s dissatisfaction with their own bodies, and – at worst – influences unhealthful behaviors. On the other hand, women’s magazines tend to employ a large number of women – who claim to have little control over the images and page content. For example, editor gatekeepers described a “symbolic constraint” wherein photographers and artists set the standards for aesthetic judgment of femininity (Milkie 2002, 854). Magazine editors also have blamed advertisers and “culture” for establishing readers’ expectations. In fact, feminist and magazine publisher Gloria Steinem (1990) said she battled constantly with advertisers before dropping advertising from the pages of *Ms*.

### **RACE AND CLASS**

Feminist scholars have illustrated how gendered organizational forms also are raced and classed (e.g., Ashcraft & Allen 2003). Ashcraft & Mumby (2004) suggested that in gender-organization studies, gender becomes relevant to organizations only when (white) women enter them. In terms of television programming, feminists suggest that the liberal tradition often fails to acknowledge the race and class differences between women because it is defined mostly by white, middle-class women (Watkins & Emerson 2000).

Moreover, Hochschild (1990) argued that the mass media offer women and other marginalized groups extensive cultural prescriptions in the form of advice about how to look and act to please powerful groups – without considering harmful outcomes. Indeed, mass-mediated messages about disadvantaged groups may frame a gender or racial order as natural (Hill Collins 1991; → Black Feminist Media Studies; Latina Feminist Media Studies; Feminist Media Studies, Transnational; Popular Communication and Social Class).

### **GOVERNMENTS AND NONGOVERNMENTAL ORGANIZATIONS**

Both governments and nongovernmental organizations (NGOs) in recent years have recognized women-and-media issues around the globe. At the 1995 Fourth World Conference on Women, the Beijing Declaration and Platform for Action (UNGASS) was adopted and signed by nearly 200 governments, identifying significant areas of concern – ranging from increasing women’s media access to eradicating gender discrimination. In 2000, a Global Women’s Media Team was organized at the United Nations General Assembly Special Session to review implementation of UNGASS. Worldwide, women also have formed NGOs in order to improve the position and portrayal of women in media. For example, NGOs work with and use media to promote women’s human rights across Africa, to encourage gender-fair reporting in Asia and the Pacific, to research the status of female media workers in Australia, to integrate a gender approach to policymaking in Arab countries, to support gender-sensitivity journalism training in Canada, to “invade” the → Internet with media by and for women in Europe, and to monitor mainstream media’s gender perspectives in Mexico.

In sum, greater awareness of media organizations' gendered nature is warranted – as is a systematic theory of deeply embedded gender and organizations. Importantly, it must be recognized that the creation of sexist media content is not gender specific. It has been argued that change happens far too slowly because organizational structures in industrial capitalist societies are erroneously viewed as gender neutral. Gender is not an addition to ongoing processes; rather, it is an integral part of those processes, which cannot be properly understood without an analysis of gender (Djerf-Pierre 2005). According to Creedon (1993, 79–80), “[T]he cutting edge of feminism is no longer about convincing anyone that sexism exists . . . Women want to name their experiences on their own terms; they want to have their voices heard and make their own meaning.”

## Gender: Representation in the Media

*Dafna Lemish*

*Tel Aviv University*

The study of representations of gender in the media understands gender to be socially constructed – an ongoing process of learned sets of behaviors, expectations, perceptions, and subjectivities that define what it means to be a woman and what it means to be a man. The main assumption of these studies is that a cultural ordering that presents gender differences as biologically determined and “natural” conceals the working of patriarchal ideology. “One is not born a woman, but becomes one” is Simone de Beauvoir’s formative statement that captured the essence of this process (1989, 1st pub. 1949). Accordingly, gender is not viewed as something originally existent in human beings, but rather it is a representation produced by how we relate to our bodies through behaviors and social relations in the practices of daily life. As such, gender is distinct from the biological, sexual differences characterizing humans from birth. It is understood to be a product of “social technologies” (de Lauretis 1987), including media texts, the arts, and institutionalized discourses. For example, while it is a biological fact that women can give birth, it is a social construction (→ Constructivism) that women in most societies are expected to be better suited to be the dominant caregivers of children.

### **MEDIA AND GENDER**

The media are central mechanisms in this process of construction since representations of femininity and masculinity are produced, reproduced, and circulated by them as part of a shared culture. Media are deemed an influential socializing force through which people learn to define themselves and others by their gender and through which they develop their own subjectivities (→ Socialization by the Media). As a result, the media have become a central focus of analysis and critique by feminist scholars.

The *theoretical point of departure* is the premise that media representations are grounded in contemporary ideological assumptions and discourses about worldviews and belief systems, in general, and gender in particular. Thus, gender representations are understood to be signifiers of dominant modes of ideology in which they are rooted, as well as at the same time the practices of these ideologies. They have been blamed for reaffirming and supporting gender hierarchies existing worldwide, maintaining the social status quo and the general subordination of women by reproducing social perceptions that legitimize dominant ideologies (such as patriarchy, capitalism, and colonialism; → Media and Perceptions of Reality).

However, given that representations are discursive constructions, they are also assumed to be able to take different forms and meanings in different places and times, under varied political, cultural, social, and economical contexts, and within diverse ideologies. As a result, gender representations are understood to be dynamic – always being fluid, changeable, and contesting social practices and perceptions. Analysis of representations thus becomes a central way of understanding gender and part of the feminist project of problematizing and critiquing our ways of knowing.

## **REPRESENTATIONS AND REALITY**

The complex relationships between gender representations and reality have been the focus of much academic contemplation and debate, particularly in the → cultural studies tradition in general, and more specifically that which developed in the UK from the 1950s onwards, including attention to the formation of social and cultural feminist thought, drawing insights from → structuralism and poststructuralism. These approaches take the view that representations do not have an original, authentic “reality” that can be represented or misrepresented accurately, but rather that gender is a form of “performance” of expected social scripts (Butler 1990).

Since gender itself is understood to be a construction, rather than a material reality, gender representations in the media are understood themselves to be *representations of representations*, standing for the → meaning of the original subject, rather than the material subject itself (Rakow & Wackwitz 2004). In contrast to studies of sex-role stereotyping and images of women, it does not assume that there are right or wrong, good or bad ways of representing a woman or a man. Rather, this perspective moves the emphasis from concerns for individuals to the larger categories of femininity and masculinity and shifts the burden of responsibility from the critique of “accuracy” of representations to challenging the systems that construct and create them, their political economy, power hierarchies, ideological infrastructures, and goals (→ Media and Group Representations).

A related argument builds upon Spivak’s development of Marxist theorization and claims that gender representations in the media have two complementary meanings (Ganguly 1992). One meaning refers to representations as “portraits,” or the “making present” of women and men and their gendered realities in the media. This meaning of representation calls attention to those ideologies, interests, life circumstances, and privileges (be they class, race, sexuality, or others) that influence the way gender is constructed. The second meaning relates to “proxy,” or “speaking out for” women and

men. In this regard there is a need to ask: who gets a voice in the media? Who speaks on behalf of whom? And, who gets to represent themselves?

The difference between these two meanings and their interdependency can be illustrated by a discussion of *women and* → *news*. The first refers to women as subjects in the news – the ways in which they are being portrayed (e.g., as victims, as trophy wives, as celebrities). The second refers to women as producers of news (e.g., reporters, editors, spokespersons for organizations). These two meanings are clearly interrelated, combining issues of culture and politics and challenging dominating power systems that influence both how gender is “made present” and who is making it present, as well as who is “speaking for” themselves and others, and how they are “speaking for” them. Following Michel Foucault, the study of representations thus recognizes that power operates in cultures through its various discourses and is located in the analysis of the symbolic systems through which people communicate and organize their lives.

However, what unites many of the intellectual readings of representations is the premise that representations are related to subordination and oppression in the material world. More specifically, in regard to certain genres of representations, as in the case of pornography (→ Pornography, Feminist Debates on), the debate over the interrelationships between reality and representations becomes compounded, since in the process itself of producing pornography, women are abused, humiliated, harassed, and raped not only the symbolic but in the material world (Russo 1992).

## **FEMININITY VERSUS MASCULINITY**

A central critique of gender representations is the well-entrenched, historical construction of femininity and masculinity as binary as well as hierarchical oppositions (Cirksena & Cuklanz 1992). While men have been mostly presented as the “normal,” representing the majority of society, women have been presented as the minority “other,” the “second sex” – the exception, the incomplete, the damaged, the marginal, and sometimes even the bizarre. Such a dichotomization can be tied to other forms of dualistic thought rooted in the Enlightenment worldview, including such divisions as those constructed between rational/emotional, spirit/body, culture/nature, public/private, subject/object, west/east, modern/traditional. Systematically, men and women have been constructed as inhabiting the opposing sides of the dualities, with the masculine associated with the highly valued rational-spirit-culture-public-subject-west-modern, and the feminine with the devalued body-nature-private-object-east-traditional.

Critical examinations of media representations throughout the second part of the twentieth century revealed the existence of these very same fundamental principles of patriarchal thinking around the world, including relegating the feminine to the private sphere, restricting presentation of women to the bodily functions of sex and reproduction, and locating women within the world of emotions where rational thought is lacking and behavior uncultivated. Personality traits of women are depicted as being fundamentally different in nature from those of men: on the whole, women have been represented as less logical, ambitious, active, independent, heroic, and dominant.

In contrast, they have been represented as more romantic, sensitive, dependent, emotional, and vulnerable. Such representations have been accused by critics of perpetuating another

form of dichotomy – the one reserved in patriarchal culture for women: the “madonna” on one hand and the “whore” on the other. As “madonna,” women are cast in the role of mothers, the one who gives birth, nurtures, raises, sacrifices herself, and finally the one who mourns her loved ones. As “whore,” they are pressed into the mold of sexual object, the essence of whose existence is tantalizing and threatening to the male, and whose ultimate fate is to be punished as a victim of violence and exploitation. Such media representations, claim critics, legitimize the de-humanization of women and relate to them as objects lacking consciousness or individuality (→ Femininity and Feminine Values).

*Hegemonic masculinity*, too, has been constructed as a “natural” state of being, commonly conceived and framed within several normative expectations: physical domination and subordination of others (humans and nature alike); occupational achievements and a purposeful and rational attitude; familial patriarchy, the man being the protector and provider; daring and staying outside the domestic sphere; sexual lust with heterosexuality as the dominant model (Hanke 1998). Deviation from these norms is prohibited, both socially as well as psychologically, as any departure is seen to be threatening to hegemonic masculine identity.

As a result, media representations emphasize a masculinity associated with the public sphere and world of occupation, competition, achievements, and social status. In comparison with women, men have been largely portrayed as more rational, individual, independent, having difficulty with expressing emotion or displaying weakness. They are shown to be more culturally and technologically oriented than women, exercising self-restraint, and tending to dominate both women and nature. They demonstrate the bonding of “men in arms” through expressions of solidarity, loyalty, determination, and a sense of purpose. They are constructed in association with action, adventure, aggression, competition, and preoccupation with vehicles and weapons. Their subordination of women is presented as related to their sexual drive. In contrast to the emphasis on women’s appearance, men are defined by their action: women “appear” and men “do” (→ Masculinity and the Media).

One important mechanism through which these constructions of femininity and masculinity are maintained and perpetuated is the *development of social “myths,”* in the sense explained by Roland Barthes (1957). Accordingly, myths are understood to be ways of conceptualizing gender within particular historical and cultural contexts, in ways that make it seem natural, a taken-for-granted commonsense way of what it means to be a man or a woman. In this way, myths perform as mechanisms that disguise ideologies and the power systems behind them. The media produce and reproduce these myths in the gender representations they offer to their audiences (→ Popular Mythology).

One such prevalent myth is the most popular *beauty myth* (Wolf 1991). It constructs a certain kind of femininity and masculinity, and a relationship between them according to which women are defined by their beautiful appearance and men by their desire to conquer such women. This emphasis on a particular form of beauty (largely rooted in white femininity, and characterized by a limited range of physical attributes) has been accused of sending women on an endless quest for an appearance that is unattainable and guarantees a life of frustration, feelings of inadequacy, and a wasteful exploitation of emotional, intellectual, and material resources, as women’s happiness and self-fulfillment becomes dependent on her appearance.

The glorification of women's external appearance as the most central characteristic of a woman's essence is directly related to the media's overemphasis on portrayal of women as sexual beings whose central function is relegated to being objects of male sexual desire and pursuit. Thus, such dominant media messages continue to promote restrictive ideologies of femininity, glorify heterosexual romance as a central goal for women, encourage male domination in relationships, and stress the importance of beautification through consumption, while dismissing the validity of women's own sexual feelings and desires apart from masculine desire (→ Sexualization in the Media).

## DIFFERENCE AND DIVERSITY

However, developments in feminist theorizing recognize that gender is an unstable and highly contested social category, and that gender experiences and identities are heterogeneous, fluid, ambiguous, incoherent, and ever-changing. Gender is always situated in a particular cultural context and historicity, and conflated with other social categories such as race, class, ethnicity, religion, and sexuality. As a result, the process of gender representation is strongly linked to other socially constructed systems of difference and exclusion. The problematization and rejection of binaries, including Said's (1978) critique of east/west and traditional/modern divisions, brought to the forefront an interest in *multiculturalism and diversity*. The challenge to social systems that privilege men's representations of women and men speaking for women has been expanded and reconceptualized to include critique of other forms of subordination. This includes the analysis of texts in which the colonizer represents and speaks for the colonized, and the resulting process of "internalized colonialism" through which the subordinate incorporate such constructions into their self-imagined subjectivity. This way, as Stuart Hall (2003) argues, dominant regimes of representations have the power to impose on audiences a perspective on themselves as "other," much in the same way that women are taught to view themselves as "other" in relationship to men (Valdivia 1995).

Such contributions of postcolonial and postmodern theorizing to feminist studies of representation bring forward the need to confront the challenge of representing marginalized others, unraveling the relationship between diversity and inequalities, between representations and the power systems that make them possible (→ Postcolonial Theory). The discussion of a need to "decolonize" representations and for development of a transnational perspective (Hegde 1998) is also related to the question of representational "silences," i.e., what and who is not represented, what and who is missing (→ Feminist Media Studies, Transnational). Critical analyses of "white femininity" as reproduction of the supremacy of white culture for example, as is evident in a variety of cultural icons (e.g., from portrayals of the late British Princess Diana, the American soldier Jessica Lynch, or the many prime-time American serials and commercial heroines traveling globally), highlight the conflation of gender and race and the complexities of the power systems involved. Women around the world do not have the same options and choices, as their location in the power structures vary. As a result, the gaps between popular representations and the life of the majority of women around the world are often inconsolable.

The growing diversity of gender representations and the construction of multiple variations for what it means to be a woman and a man in popular culture have resulted in

an array of gender options and contradictions (Meyers 1999; → Identity Politics). Attributes of such media representations that are often coined “postfeminist” include portrayals of females who are complex and distinct from one another on a variety of variables (including those mentioned above – such as race, ethnicity, sexuality, class, and religion – but also education, age, marital status, motherhood, personal abilities and disabilities, and the like; → Postfeminism). The breaking down of dualities include, for example, female characters who “want it all” rather than making a choice between family and career; who refuse to choose between feminism and femininity, i.e., leading an active and independent life but choosing to cater to traditional requirements of appearance, and the like. *Representations of “power feminism,”* moving away from women’s oppression to a celebration of women’s abilities and achievements, are becoming more commonplace in popular media. Deconstructing binary categories of gender and sexuality, in particular, and perceiving them to be flexible and indistinct, allows the growing experimentation with representations of gay, transgender, transsexual, and bisexual lives. Contemporary struggles faced by women are raised and examined, including explorations in issues of gender politics and feminism and its goals (Lotz 2001).

The emergence of innovative representations of women as well as men has also been explained by the *influences of commercial forces*. Such, for example, is the assertion that the growing emphasis on “career women” or “sensitive men” and the presentation of sexually active women and men as objects of desire reflect as much the pressures brought about by consumer culture as deep structural changes in ideological underpinnings (→ Commodity Feminism). As a result, the new type of strong woman is deemed acceptable as long as she is not only strong, but also sexy, and the new type of sensitive man is becoming more acceptable as long as it is clear that he is not only sensitive but also successful.

Despite such developments, change is rather slow, and there is an overall agreement in the study of gender representation that this form of patriarchal ideology serves to naturalize and justify male domination as well as contribute to the internalization of this ideology through the acceptance of differences between men and women as real, essentialist, and natural. It is argued that as a whole, this representational system has been detrimental to both women and men, in varying degrees, since it teaches both to adopt particular perceptions, roles, and practices that reinforce their differing placements in the social hierarchies as they continue to perpetuate the supremacy of white men. Feminist analysis of gender representations thus points toward a need to engage in reflexive critique and deconstruction not only of representations but also of the institutions that produce them.

## Generalizability

*Klaus Krippendorff*

*University of Pennsylvania*

The essence of generalization is simplification by omission of irrelevant details. *In logic*, a concept A is a generalization of concept B, if and only if every instance of concept B is also an instance of concept A, and there are instances of concept A that are not instances of concept B. For example, a cockroach is an insect, which in turn includes insects that are not cockroaches. Talking about insects omits the distinctions among cockroaches, beetles, flies, etc. Logical generalizations are based on sets whose instances have one or more attributes in common. They give rise to taxonomies, such as the Linnaean classification in

biology. Logical generalizability is the ability to find meaningful common attributes among disparate sets of instances. Except for their membership in the same set, this may not be easy. For example, it would be hard to find a common attribute among cockroaches, artifacts, poets, and scientific theories. The inability to find a conceptual basis for a set of instances limits logical generalizability.

According to *category theory*, A is the prototype of a category of instances B if and only if all instances of B belong to the same category, and A is judged to be the most typical among them. A prototype can be considered a generalization of B inasmuch as it possesses the defining characteristics of instances in B. Unlike in logic, where all members of a set are assumed to possess the same attributes, category theory acknowledges that membership in a category can be graded. For example in the US, among birds, robins turn out to be most typical, pigeons a little less so, with parakeets far from being prototypical. Penguins probably are the least typical birds, sharing few features with other birds. The prototypicality of the instances of a category can be obtained by systematic pair comparisons: "Which is the more typical bird, a or b?" Such comparisons identify the prototype as the most typical of its kind, surrounded by increasingly less typical instances, its periphery showing instances that may well belong to, and may therefore be easily confused with, other categories. Encyclopedias that illustrate a concept invariably choose something close to its prototype. Roles in movies are cast by typical mothers, typical criminals, typical heroes, whose deviation from their prototypes may have mere dramaturgical motivations. Not all sets of instances have meaningful prototypes. This led researchers like Eleanor Rosch (1978) to define three kinds of categories. Basic categories have visualizable prototypes, for example, chair, shirt, house, and spoon. Subordinate categories are distinguished by attributes of basic categories, for example, baby chair, dress shirt, outhouse, and serving spoon, whereas superordinate categories do not have clear prototypes and tend to be constructed logically, for example, furniture, apparels, buildings, and tableware. While cartoonists, advertisers, and political → spin doctors have a knack for finding prototypes of what they wish to promote, oppose, or generalize, category theory suggests how this ability is limited.

*In written discourse*, generalization concerns *propositions* and is a special case of logical generalization. A general proposition A semantically subsumes several lengthier propositions or complex narratives B, omitting irrelevant details while preserving what serves a particular purpose. A proposition concerning a ball generalizes propositions involving, for example, a soccer ball, made up of white hexagons and black pentagons. It retains only references to the attributes and behaviors of ball. Typically, scientific articles have a title and an abstract, followed by a body of text. Abstracts offer readers propositions that generalize the text. Titles may not be more than noun phrases abstracted from the text. Propositional generalizability is limited only by the meanings of the words available in language.

*In statistics*, a generalization A is sustainable by contrast to its logical complement  $\bar{A}$  if and only if the overwhelming majority of instances in B are instances of A as opposed to  $\bar{A}$ . Null hypotheses, for example, whether one variable has no effect on another, are meant to rule out that one falsely accepts a hypothesis when its logical opposite could be true as well. The measure of statistical significance expresses the probabilities of either hypothesis or generalization to be acceptable (→ Statistics, Descriptive; Statistics, Explanatory).

*In sampling theory*, a sample A of instances, selected from a larger population B of instances, is taken to be representative of B, if all relevant attributes of instances in B occur in A as well and in the same proportion as in B. A sample is not usually considered the generalization of a population. However, it is a simplification that omits irrelevant details and allows the researcher to examine the sample in place of a population (→ Sampling, Nonrandom; Sampling, Random).

Generalizations are obtained by induction and are subject to any of the errors of inductive inference.

*Hasty generalization* is the fallacy of examining only a few instances and generalizing from them to the whole set of instances. For example, someone might conclude, “everyone likes this movie” after talking to a few friends. Sampling always entails the possibility of a hasty generalization. Statisticians seek to circumvent this fallacy by relying on the law of large numbers. This law states that the larger the size of a sample, the closer do the averages calculated from that sample approximate the averages in the population. Coupled with a measure of the smallest acceptable imprecision and an assumption of the probability of the rarest incidences in the population, the law suggests sample sizes that keep hasty generalizations within tolerable limits (→ Election Polls and Forecasts; Election Surveys; Public Opinion Polling; Survey).

*Excessive exception* is the fallacy of a generalization that may well be correct but only under the condition of excluding a large number of its suggested instances. For example, “everyone can read the *New York Times* except children, the blind, and non-English speakers.” Using undergraduates as “human subjects” in psychological experiments can yield findings that are valid for this small population – although the researchers may have generalizations to humans in mind.

*Sampling bias* and *slanted propositions* occur when the method of sampling from a population favors incidences that support one or another hypothesis to be tested. For example, studying the literacy of a population by means of a written test systematically excludes those unable to read and write. Asking the members of one political party about the problems of their country biases the sample in favor of these party members’ opinions. Similarly, abstract propositions may be slanted by particular interests, for example, when polling data are interpreted by candidates for political office, or when literature on the effectiveness of a drug is selectively reviewed and published by its manufacturer.

*Part-whole confusion*, also called the fallacy of composition, is the mistake of generalizing knowledge across different levels of organization without considering the nature of the organization that integrates parts into their wholes. Examples are generalizing interpersonal relations to relations between countries, or using biological models to understand social enterprises (e.g., by distinguishing between functional and dysfunctional actions according to whether they preserve the existing structure of society).

*Concretizing the abstract* is the fallacy of attributing qualities to abstractions that belong to what the abstraction generalizes; for example, attributing agency to abstract concepts, such as in claims that unemployment caused unrest, a corporation failed to pay taxes, or “the White House says. . . .” Only people can create unrest, perhaps because they are without a job. Decisions to pay or not to pay corporate taxes are made by the employees of a corporation, and the White House cannot speak, only people can, and may do so in its name.

*Stereotyping* is the fallacy of taking the mean or mode of a distribution of the characteristics, usually of a group of individuals, by nonmembers, for that distribution, effectively ignoring the diversity of its spread. It confuses the mean or mode with a prototype; for example, claiming someone to be a “typical Frenchman” when there are millions of atypical Frenchmen living in France, or reporting the existence of correlation between particular variables at the expense of acknowledging how many instances do not fall on the regression line of that correlation (→ Correlation Analysis). Social scientific research can create → stereotypes when its findings are published and enter a population eager to accept theories as facts. For example, Marx’s theories of social classes created his oversimplified class distinctions. Stereotypes of minorities, professions, and pathologies may well be of scientific origin but can become exaggerated in use (→ Social Stereotyping and Communication; Stereotyping and the Media).

## **Genre**

*Paul Cobley*

*London Metropolitan University*

The English term “genre” derives – via French – from the same Latin root as “general,” “genus,” “gender,” “genesis,” “generate,” “genius,” and “gene.” Etymologically, then, it is bound up with the idea of generating complex configurations from a basic underlying pattern. The concept of genre is important to communication research because it designates not only specific kinds of messages, but also their characteristic social uses by audiences.

“Genre” was traditionally used in the arts to categorize texts with reference to their distinctive language and subject matter, such as poetry, drama, and the novel. The literary theorist Mikhail Bakhtin held that the novel – irrespective of the great variety of novels – is one genre (Bakhtin 1981). In this broad sense, short stories and nonfiction forms such as autobiography (usually narrative) and essays (usually non-narrative) all qualify as

genres. Other scholarship has understood genres to be types of text *within* such broad categories of composition. Already in ancient Greece, tragedy and comedy were recognized as genres, being constituents of the wider genre, drama. These categorizations, further, existed alongside other kinds of textual definitions: the epic, for one, was categorized according to its composition as well as key themes such as heroism. In both narrow and wide conceptions of the term, however, genre refers to a set of basic textual patterns that generate many and varied concrete texts. The vast majority of traditional works about genre have aimed to identify such underlying textual formulae (→ Text and Intertextuality).

## HISTORY OF THE GENRE CONCEPT

Genre theory effectively stayed in a steady state for 2,000 years after Aristotle's death before accelerating into flux during the twentieth century. Mainly as a result of Aristotle's legacy, genre theory has sought not only to lay bare textual formulae, but also to provide prescriptions. Aristotle's fragmentary observations in the *Poetics* (c.330 BCE) framed the classic genres in terms of a best practice that could guide the act of composition as well as supporting post hoc evaluation.

After the rediscovery of Aristotle's works in the late Middle Ages, Renaissance poets and dramatists during the two centuries after 1450 re-envisioned the classical world from within their own spheres of interest. Sir Philip Sidney in his *Defence of Poesie* (1595) invoked a wealth of classical authorities to both defend poetry as such and prescribe a humanist conception of poetry. In the classical and Renaissance periods, genre theories operated with a limited number of genres. Different kinds of speech were commonly appraised in terms of rhetoric in both periods (→ Rhetorical Studies), and genre tended to be associated with written forms, or with those oral forms that had made their way into writing and now often appeared first in writing, such as poetry.

From the Renaissance onwards, print technology in Europe facilitated the growth and diversification of genres such as diaries, confessions, romances, novels, ballads, and newssheets. By the end of the nineteenth century, the novel had fragmented into a multitude of genres, catering to an expanding and increasingly socially differentiated readership. And, in the audiovisual media of the twentieth century – on radio, in film, on television, and in cyberspace – narrative genres flourished in unprecedented amounts and variants.

The most common understanding of genre in the contemporary world focuses on the many popular genres that are consumed in quantities not previously witnessed in history (→ Popular Communication). Such genres include romances, thrillers, science fiction, → soap opera, and fantasy in the realm of → *fiction*, but also → *news*, → *advertising* and documentary (→ Documentary Film): both factual and fictional genres can have narrative form. Furthermore, all these genres are distributed across a range of interrelated media: print, → radio, → television, film, the → Internet (→ Cinema; Intermediality). Also in everyday language, each genre is commonly said to consist of a characteristic "formula." This understanding may be reinforced by the media themselves when "genre" as a mode of expression and reception is conflated with "format" in the process of production. By the end of the twentieth century, the term served as a shorthand for movie-goers, novel readers, TV viewers, and others to classify and anticipate media texts.

## TWENTIETH-CENTURY GENRE STUDIES

The twentieth-century proliferation of genres stimulated genre theory and communication theory that was cognizant of genre. In general, genre theory took a synchronic and formalist perspective. Spread across a number of countries and disciplines in the humanities, this perspective was developed in the work of Vladimir Propp and the Russian formalists; C. K. Ogden, I. A. Richards, William Empson, and F. R. Leavis in Britain; the new criticism, → Harold Innis, → Marshall McLuhan, and Northrop Frye in North America; the structuralists in France (→ Structuralism); the Prague linguistic circle in Czechoslovakia; and the Copenhagen School in Denmark – all of whom made direct or indirect reference to the concept of genre. Much of this work, however, especially when couched in terms of “mass culture,” was resolute in its criticism of those industrial classifications of texts that seemed to use genre to package artifacts for mass consumption. In the writings of formalists, genre became not just a form of textual organization, but a patterning of meaning with critical social implications (→ Critical Theory).

The formalist understanding of genre changed when academia began to embrace film as a legitimate object of study. As → *film theory* matured, searching questions were asked of genres, such as whether they were constituted by visual elements (iconography), or by stock situations, or by plot elements; whether the industry repeated formulae by audience sanction, and whether individual *auteurs* were responsible for the construction of meaning also in genre films. Many studies of film as well as print genres such as the western, the thriller, and the adventure story, were indebted to Propp (translated 1958; in book form 1968). His key idea was that some texts have not so much a formula but a *structure* that can be repeated time and again with rather different contents. This might resolve the problem of explaining the variable and changing “content” of texts belonging to the same genre: perhaps “structure” is always the primary carrier of meaning that will ultimately shape the concrete “content” (e.g., Wright 1975).

However, the equation of genre with structure proved a dead end as the serious study of popular forms of culture indicated the complexity of, for instance, popular fiction. Two new understandings of genre arose, both of which recognized genre as a far more prevalent phenomenon than had previously been assumed, even before the twentieth century. First, genre should not be reserved to describe “artistic” communications. In everyday communication, speeches, technical instructions, debates, letters to the editor, telephone manner, oaths, new year resolution lists, road signs, and a whole host of other forms constitute genres, as emphasized by analysts of language and communication (e.g., Martin & Rose 2006). That notion had already been anticipated by Bakhtin, who named these communicative phenomena *primary genres* (1986, 65). This social reframing of genre was developed by sociolinguistics and → discourse studies, and became a major growth area in international research.

Second, also regarding “artistic” forms, genre theorists re-emphasized the content of texts as crucially important, not just to the producers of generic texts, but to their consumers. One impetus was contemporary investigations into the responses of audiences for both literature and mass communications, suggesting that readers will bring to texts – including generic ones – much background knowledge. This may make readers largely impervious to the structural messages of texts that academic textual analysis has believed

to be implicit and effective (e.g., Seiter et al. 1989). Moreover, such research has established that all texts, even the most lowly, carry a multiplicity of meaning or *polysemy* that makes them open to interpretation.

### FROM TEXTUAL TO SOCIAL GENRES

Some theories of readership still assumed that markedly generic texts were somehow exempt from polysemy, and scholars sometimes seemed to suggest that such texts were, in fact, eternally limited in meaning. The film theorist, Rick Altman, for example, argued that generic texts invite a form of reading that is “short-circuited” (1987, 4). However, as part of the general reorientation of contemporary genre theory toward readers and their social uses of texts, Altman also explicitly acknowledges the role of the reader in any process of short-circuiting. For Altman (1999), a genre is “made” through the actions of readers who harbour expectations about it. Audiences’ uses of the term “genre” probably grow out of their familiarity with primary genres, as identified by Bakhtin, but also with *secondary genres*, or the kinds of literary commentary and other discourses that are promulgated by the media industries producing narrative genres. Ultimately, audience expectations are the products not just of secondary publicity or primary genres but of social and cultural knowledge, values, attitudes, emotions, and pleasures.

The idea that a genre is a formula was traditionally paired with a view of genres as self-contained. Yet, clearly, many modern popular genres are hybrid in nature. In addition, some recent work has advocated abolishing strict boundaries between genres in favour of examining what may be “nomadic” tendencies in people’s reading of hybrid genres as well as of distinct, yet interrelated texts (Bloom 1996). Such work also implies that, in the multimedia environment of the present, it is important to promote audiences’ awareness of genres and their hybrids as a crucial component of → *media literacy*. In sum, whereas a genre was previously defined by its “formula,” so that an analysis of a generic text could be carried out as an immanent and neutral undertaking, genre now is understood more as an idea or expectation, implemented by readers through readings that are interested and contextual (e.g., Copley 2000).

## Gerbner, George

*Joseph Turow*

*University of Pennsylvania*

George Gerbner (1920–2006) was one of the most perspicacious students and critics of the social and political effects of television. Of half-Jewish descent, he grew up in Budapest as a recognized poet and lover of folklore. Forced to flee fascist Hungary to the US in 1939, he studied journalism at the University of California, Berkeley. After serving in the US military, Gerbner worked briefly as a journalist and then received a PhD in education from the University of Southern California. He taught briefly at a junior college, then from 1956 at the University of Illinois's Institute for Communications Research. In 1964, he became dean of the University of Pennsylvania's Annenberg School of Communications, where he remained until 1989.

On the surface, his perspective on media and influence was not that different from that of many Marxist-inflected political economists (→ Political Economy of the Media). But while Illinois colleagues such as Dallas Smythe, Herbert Schiller, and Thomas Guback were convinced they could best understand the American media by noting how the capitalist system shaped them, Gerbner focused on the actual materials that capitalism's industrial apparatus created. He believed it was crucial to look closely at what (echoing anthropologist Hortense Powdermaker) he called mass-produced daydreams because they likely influenced the hierarchy of values as they developed in people's minds (→ Attitudes, Values, and Beliefs, Media Effects on). Gerbner insisted that because → popular culture is mass produced, it should be analyzed as a system of industrially patterned, rather than idiosyncratic or artistic, messages. With the "message system" as a central concept, communication research should pursue three fundamental goals: explore the forces that shape the pattern of messages, examine the overall nature of those message patterns, and understand the social roles or functions that those patterns play in society.

Through content analyses he showed that media themes and portrayals were sharply patterned (→ Content Analysis, Quantitative). From his analyses of the media industries, he argued that the content patterns are not objective reproductions of reality. Rather, the mass media's "system of messages" results from media firms' need to satisfy advertisers

and politicians who benefit from showing people certain views of reality and not others (→ Media and Perceptions of Reality).

The patterned messages that served the goals of large symbol-making industries, he argued, were generally not those that would cultivate an educated and egalitarian society. His research found, for example, that pressures on television producers led them to consistently and inaccurately depict insane people as violently dangerous in ways that would undermine medical leaders' call for more humane approaches to the mentally ill. He showed that the industrially created popular culture's portrayals of teachers as either impotent or dangerous were part of a pervasive, enduring negative image of education. This "hidden curriculum" created an illusion of caring about education while actually serving private enterprise's interests in undermining schools' "political capital and popular aspirations for mobility, equality and social reform."

He stirred social controversy when he turned his attention to television violence (→ Violence as Media Content, Effects of). His critics pointed out that his definition of violence lumped together realistic cases of physical harm with humorous battles by cartoon animals. But Gerbner's definition derived from his view that the central problem was not that children and adults would commit violent acts as a result of seeing them on television; most, he noted, would not. Rather, he was concerned with what ideas TV violence reinforced about the world for most viewers. Gerbner and his colleague Larry Gross (1976) developed this concern into what they called → *cultivation theory*. Comparing → survey answers of individuals who watched lots of television with those who were light viewers, Gerbner, Gross, and colleagues consistently found that heavy viewers overestimated their chances of being victims of violence. Because heavy viewers were likely to see a great deal of violence in news and entertainment, they concluded that television was helping to reinforce and extend a view of the world as mean and dangerous (→ Cultivation Effects).

Critics pointed out that this causal explanation could easily be reversed: people who were afraid of the world would stay at home and watch a lot of TV, and the presence of TV violence had little or nothing to do with it. Gerbner and Gross replied to these critiques with elaborations on their cultivation model that have sparked much research.

Observers who dwell on these issues, however, miss a larger point: some of the later Gerbner and Gross studies, read carefully, reveal a far more critical, even subversive, conclusion about television violence. Gerbner insisted that the most widespread and socially significant negative consequence of a person's exposure to mass media is their reinforcement and extension of discriminatory cultural norms that serve the interests of elites and media industries while undercutting the democratic values they pretend to espouse. He saw media violence as the most elemental *form of symbolic control*. It didn't matter to him whether such actions were in news or dramas, live-action shows or cartoons. His cultivation studies suggested that they all presented a message of mayhem that led heavy viewers to worry excessively about their world (→ Fear Induction through Media Content).

Gerbner saw the hands of private and government power working together to amass symbolic influence. Violence attracted viewers for media firms and votes for politicians: insecure, angry people may be prone to violence but are even more likely to be dependent on authority and susceptible to deceptively simple, strong hard-line postures. They may

accept and even welcome repressive measures such as more jails, capital punishment, harsher sentences – measures that have never reduced crime but never fail to get votes – if they are likely to relieve their anxieties.

After his retirement from Annenberg, Gerbner started the Cultural Environment Movement to encourage grassroots activities that would demand greater public participation in decisions about cultural investment and cultural policy.

## **Germany: Media System**

*Jürgen Wilke*

*Johannes Gutenberg University of Mainz*

Germany is the most populous country in Europe, with 81million inhabitants. Since 1990, it has been a federal republic consisting of 16 states. Until then the country had been separated into two states as a result of World War II (1939–1945). Next to the Federal Republic of Germany (FRG), established in the western occupational zones, there existed the German Democratic Republic (GDR) on the territory of the former Soviet zone of occupation. Through reunification in 1990, five new federal states were added.

Germany is a parliamentary democracy with a multi-party system. The administrative authorities are divided between the federal government and the federal state governments. This division of power is also of great importance for the German media system. According to the typology of Hallin and Mancini (2004), Germany is located in the area of the “north European or democratic corporatist model”: characterized by high newspaper circulations, external pluralism of the press, a great level of professionalization among journalists, and state regulation particularly with regard to the public broadcasting system.

### **HISTORICAL DEVELOPMENT**

Germany is regarded as the birthplace of the modern mass media. In the city of Mainz, Johannes Gutenberg invented the printing press around 1450 (→ Printing,

History of). And it was in Germany, at the beginning of the seventeenth century – after several preliminary stages – that the first periodical papers were developed (*Relation* in 1605, and *Aviso* in 1609; → Newspaper, History of). At this time the German Reich was a federation of more than 300 territories. As a result, more newspapers were published here than in all other European countries combined. At the end of the seventeenth century there were already about 70; at the end of the eighteenth century the number had risen to more than 200. Special periodicals emerged for a lot of interests.

As early as the sixteenth century, → censorship had been introduced as a means of controlling the printing profession, and it was also expanded to newspapers. In Germany, the implementation of freedom of press took longer than in England or the United States (→ Freedom of the Press, Concept of; Censorship, History of). Only in 1874, after the German Reich had been founded as a nation-state, was the freedom of press legally guaranteed. When the Nationalist Socialists seized power in 1933 and erected a totalitarian regime, the press (together with all other media) was subjugated to a strict controlling system, which only came to an end after Germany's defeat in World War II.

The very first → radio program in Germany was broadcast on October 29, 1923, in Berlin. The telecommunications prerogative lay in the hands of the state, so that radio was put under the custody of the postal service. In 1923/1924 nine regional broadcasting organizations were established. Private investors also participated. Yet the majority of the stakes remained in the possession of the state postal service. The leading basic idea was to create a nonpolitical educational and entertaining broadcasting service. In 1932, the private investors were expelled and broadcasting was handed over completely to the state. This facilitated the takeover of the broadcasting system by the Nationalist Socialists in 1933. They centralized broadcasting and put it under the control of the propaganda ministry (→ Propaganda; Propaganda in World War II). The beginnings of → television also fell into the period of Nationalist Socialist rule. The first public presentation took place on March 22, 1935.

In 1945, a completely new period in the history of the German media system began. The fundamental decisions were made by the Allied victors. In the three western zones the occupying authorities wanted to set up a free and democratic media system to prevent future misuses by propaganda. In the Soviet occupational zone the media were again tied to the state government and the party leadership, in accordance with Marxist–Leninist theory. The western Allies issued licenses for newspapers (and magazines) to private investors. Thus, 144 papers had come into existence by 1949. In the Soviet occupational zone licenses were almost exclusively issued to parties and organizations. Private ownership of newspapers was prohibited.

At first, the occupying powers also organized radio services. In 1947/1948, still under the influence of the Allies, German laws for those radio stations were created. They were modeled on the British pattern of the public institution → BBC. For the supervision of programming, a broadcasting council (“Rundfunkrat”) consisting of representatives of socially relevant groups was deployed. Representatives of the state and of the parties were (at first) designated only in limited numbers. The public stations were given a programmatic mandate, which comprised information, entertainment, and education.

And they were obliged to provide a fair balance of content (internal pluralism; → Public Service Broadcasting: Law and Policy).

## LEGAL FRAMEWORK

The constitution of the Federal Republic of Germany, founded on May 23, 1949, guarantees in Article 5 freedom of opinion as well as the freedom of the press, the freedom of broadcasting, and the freedom of film. Also guaranteed is → freedom of information; censorship is forbidden. These liberties are restricted only by the general laws, especially by personal rights and the protection of youth.

According to the regulation of competences in the constitution, the federal states are responsible for creating the judicial basis for broadcasting. The central government has only to provide the technical infrastructure. By developing the broadcasting system, the federal states have agreed to regulate certain aspects of electronic media in a similar or common way in accordance with the Broadcasting Treaty (“Rundfunkstaatsvertrag”). An important role for media legislation and the media structure is fulfilled by the Federal Constitutional Court (→ Television Broadcasting, Regulation of).

## PRINTED PRESS

Germany has a well-developed press system. Most prevalent are – in accordance with the federal tradition – regional newspapers, covering larger areas. They are predominantly delivered on subscription. Typically, these newspapers possess a more or less large number of local editions. Apart from this, there are only a few newspapers with a nationwide circulation (such as *Frankfurter Allgemeine Zeitung* and *Die Welt*).

Also, the number of tabloid papers (→ Tabloid Press) sold on the streets is limited. The biggest of them is *Bild*, at 3.5 million copies the newspaper with the largest circulation in Germany. In 2004, 138 independent “editorial units” (“Publizistische Einheiten”) – i.e., independent newspapers that produce local, national, and international news independently in all editorial areas – were published in Germany. These editorial units produced a combined total of 1,538 different editions. The total circulation of the daily press amounted to 21.5 million copies. The number of readers per 1,000 is about 315, a figure between those for countries with high and low newspaper circulations.

## RADIO AND TELEVISION

For decades, an exclusively *public broadcasting system* existed in Germany. Initially after World War II there were six radio stations. The number increased to nine by the end of the 1950s. In 1960, two national broadcasting stations were established, too, one for West Germany and the GDR (*Deutschlandfunk*), and two foreign broadcast services (*Deutsche Welle* and *Stimme der DDR*).

In 1950, a consortium of public broadcasting stations (*Arbeitsgemeinschaft der öffentlich-rechtlichen Rundfunkanstalten* or ARD) was founded. On this basis television in the Federal Republic of Germany was built up. The regular start of the first channel followed on November 1, 1954. The broadcasting stations of the federal states contributed

proportionally to the joint programming. In 1962, the federal states agreed to bring into being a joint second national TV station (*Zweites Deutsches Fernsehen* or ZDF), which started to operate on April 1, 1963. Since that time a public duopoly has existed in German television. The ZDF is also organized by the principles of public control by a supervising board with representatives of several social and political groups, associations, and parties.

New technologies gave the starting signal for the *dual broadcasting system* in Germany. Today it consists of two pillars: the still powerful public broadcasting organizations and the numerous private program providers. ARD and ZDF broadcast one main TV program each and a common culture, children's, and parliamentary channel. In addition both are also offering their own digital programs. Each of 11 broadcasting stations in the federal states possesses yet another TV channel. A joint venture by ARD and ZDF is *DeutschlandRadio*.

Besides the public sector there exists a multifaceted *private broadcasting* sector in Germany. The licenses are issued by a telecommunication agencies at the level of the federal states. These are also supervised advertising regulations and certain content requirements. Today, all in all more than 200 German radio programs and 30 German TV channels can be received. Nationwide operating radio stations have established themselves in part; however, there have also been attempts to introduce local radio stations.

Two big commercial TV organizations, RTL and SAT.1/ProSieben, emerged. In Germany *RTL group* (a member of the Bertelsmann group) owns, in addition to its main program channel, several other channels (RTL 2, Super RTL, Vox, and n-tv). The *SAT.1/ProSieben* media company owns the programs Sat.1, ProSieben, Kabel 1, and N24. This group constituted the core of the German media corporation of Leo Kirch, which went into insolvency in 2002. It was sold to American Haim Saban, who resold it in 2006 to other foreign investment groups. Apart from the full programs, there are also special news and sports channels (→ Media Conglomerates; Globalization of the Media).

A third pillar of the German TV system is *pay-TV*. Yet this format, due to the sheer size of the free TV market, has not managed to become widely accepted. The channel *Premiere* has been attempting since 1999, with a number of special interest programs (sports and movies), to gain ground in the pay-TV market and was listed at the stock exchange in 2005.

## INTERNET

In the mid-1990s, the Internet was introduced in Germany for general use, and it expanded quickly. In 2006, 60 percent of the population used the Internet at least occasionally. Differences do still exist according to age. Nearly all young people go online, but only 20 percent of people over 60 years old.

Today, almost all German daily newspapers and numerous magazines are present on the Internet with their own websites (→ Online Media). Yet in the beginning many publishing houses hesitated to go this way and did not invest too much, because they were afraid of "self-cannibalism." Radio and television stations developed their websites, too, the private ones with a lot of additional material, whereas the public stations are restricted to giving only material complementing their programming. Newcomers in the field intend to offer IPTV (Internet Protocol TV).

## CURRENT ISSUES OF THE GERMAN MEDIA SYSTEM

Since the middle of the 1950s there has been a growing tendency toward *press concentration* in Germany (→ Concentration in Media Systems). Today, the 10 largest publishing houses are responsible for more than half of the total newspaper circulation. The degree of concentration is particularly high in the new federal states of former East Germany, since former party papers were sold to newspaper proprietors from West Germany. Apart from losing advertising to the Internet, German newspapers have also constantly lost readers, particularly among the younger generation. The total circulation of the German daily press has seen a gradual decline.

The *radio and TV market* is also facing substantial problems. The public broadcasting organizations are trying to defend their privilege of double-funding by license fees and advertising revenues, particularly against the policies of the European Union (→ European Union: Communication Law). Their regular demands to increase the fees have always been a political issue. The competition for attractive programs requires high expenditures. Further, some critics have accused the public broadcasting organizations of neglecting their quality program obligations by adapting to commercial programming (“*convergence*”; → Commercialization: Impact on Media Content). The private providers are totally dependent on advertising revenue, which they would like to monopolize for themselves. The ownership structures are also in flux. Ownership in commercial TV is limited by a maximum audience share of 30 percent.

# Gestures in Discourse

Jürgen Streeck

University of Texas at Austin

The communicative roles of gestures during talk in interaction are partly a function of their placement within unfolding turns and action sequences. Gestures occur both as free-standing unit-acts and as components of multimodal turns.

A *facial* gesture, usually enacted with eyebrows and/or the mouth, can occur in the role of operator on a concurrent or imminent unit of talk when it is performed by the speaker, and qualify its deontic and pragmatic status (e.g., serious or ironic, assertion or tease) and the *stance* that the speaker adopts toward it (eyebrow raises occur as components or minimal versions of shrugs and can display the speaker's distancing from a proposition), as well as the type of uptake it should preferably receive. When performed by listeners, facial gestures (e.g., a brief raising of the brows) may mark the status of an ongoing or just-completed utterance as new or old information, as surprising, amusing, or depressing: recipients' facial gestures often convey affective messages in addition to their discourse-organizational roles. Providing the speaker with ongoing feedback about the reception and effects of talk, facial gestures also contribute to its further course. While there has been a considerable amount of research on listeners' facial actions, we still know relatively little about the communicative work of the speaker's face (→ Facial Expressions).

*Head* gestures such as nods, shakes, and tosses are common conventional listener responses as well, notably in the roles of affirmation and negation, but also as "continuers" or acknowledgment tokens during ongoing turns at talk. There has been a considerable amount of research on these gestures, but we know less about other, more subtle motions of the head, e.g., tilts and turns that do not amount to signs of affirmation or negation (→ Gestures and Kinesics).

*Vocal* gestures, also called interjections and "response cries" are conventional vocal acts that are quite diverse in their functions; they can serve to beckon, to display an attitude toward what is being said or done, to comment upon one's own mishap as speaker, or to regulate the actions of another. Vocal gestures typically show phonological features otherwise uncommon in the producer's language; many are formed by *ingressives* (or *clicks*) – sounds that occur as phonemes only in a single language family of Southern Africa (→ Paralanguage).

One might also consider certain linguistic units as gestures, for example, tokens that are commonly placed at turn-beginnings, e.g., "well" or "okay"; agreement and disagreement tokens; and turn-completers and re-completers, e.g., *tags* such as "right?" "no?" "know-what-I'm-sayin'?" because they foreshadow illocutionary roles or regulate uptake – functions that they share with various types of bodily gestures (→ Discourse Markers).

The most important and, by far, most diverse kind of gestures in discourse are *hand* gestures, i.e., acts performed by movements of the hands. A number of different basic genres of communicative activities are carried out by motions of the hand, which can be distinguished in terms of the ways in which these motions figure in situated ecologies of action, cognition, and perception. Thus,

- 1 *pragmatic* gestures display the speaker's imminent or ongoing communicative act (its *illocutionary force*) or aspects of its structure and relation to prior discourse or the topic at hand;
- 2 *interaction-management* gestures mediate and regulate transactions, by allocating turns, displaying intended speakership, or establishing or marking relations between (the talk of) participants;
- 3 *conceptual* gestures or *cepts* manually construe ideational content that the speaker seeks to convey, without, however, showing how something looks;
- 4 *depictive* gestures depict phenomena in the real or some possible world; and
- 5 *indexical* gestures direct attention to and provide or reveal structures of objects and settings at hand, or of the world within sight, for example by various forms of pointing, tracing, and discerning.

Types 1 and 2 are about the processes of interaction and communication, 3 and 4 about the world that is thematized in the discourse, and 5 and 6 are about the proximal and distal setting within which the interaction takes place. Gestures of types 1, 2, and 3 are often metaphorical in that they construe abstract content or the process of communication according to models of manual action and experience in the physical world: they bring embodied knowledge – “haptic” knowledge of the world and manual know-how – to bear on communication and linguistic action.

It is important to realize that the term “gesture” refers to various orders of phenomena: to the practice of gesturing (when used as a mass-noun) or to individual instance of gesturing (when used as a count-noun). The latter, however, can be either a token of a type – when a conventional gesture is instantiated – or a creative, impromptu act of symbolic invention – this is often the case when speakers *ceive* or *depict* real-world or abstract phenomena. The fact that these distinctions are covert can lead one to falsely believe that all gesture is conventional, drawing from cultural repertoires (lexicons) of stable form–meaning pairs. But the improvisational character of much gesticulation – which does not seem to impede its intelligibility – is a feature that makes it particularly interesting for communication theory. It demonstrates, among other things, the importance of context and sequence to the ways in which bodily acts contribute to talk in interaction.

## Gestures and Kinesics

Laura K. Guerrero

Arizona State University

Kinesics is the study of bodily movement, including gestures, posture, and movement of the head, arms, legs, or torso (Birdwhistell 1970). Some scholars also include → facial expression and → eye behavior as kinesic behavior. However, because these behaviors are discussed elsewhere in this encyclopedia, this entry focuses primarily on gestures and bodily movement.

In their classic work, Ekman and Friesen (1969) argued that kinesic behavior can be distinguished on the basis of origin. Some kinesic behaviors are *symbolic* because there is an arbitrary association between the behavior and the referent (what the behavior refers to). For example, an up-and-down head nod means “yes” in many places around the world. However, the relationship between nodding and the word “yes” is arbitrary; indeed in some regions nodding to one side means “no” rather than “yes.” Like language, symbolic nonverbal behavior developed within specific cultures. Other kinesic behaviors are *iconic*, meaning that the nonverbal behavior resembles the referent. Pointing to the left when giving directions, reaching up to show how tall someone is, and pretending to swing a bat are all examples of iconic kinesic behavior. Because these behaviors resemble their referents, they are more easily understood across cultures than are symbolic behaviors. Finally, *intrinsic* behaviors, such as crying and smiling, have biological origins and often reflect people’s internal states. Intrinsic cues are therefore the most easily understood across cultures.

Ekman and Friesen also identified five general categories of kinesic behavior: emblems, illustrators, affect displays, adaptors, and regulators. These categories are based on the origins and usage of kinesic behavior. The five categories provide a useful framework for organizing both classic and contemporary work that examines how kinesic behaviors function in interpersonal and intercultural communication contexts (→ Nonverbal Communication and Culture).

### EMBLEMS

Emblems are symbolic forms of kinesic behavior that function to substitute for or repeat verbal communication. Emblems are culturally specific and operate independently of speech. Take the following gesture as an example: the thumb and index finger are shaped in a circle while the other three fingers are pointed up with the fingertips curved slightly

downward. This gesture means “A-OK” or “all is good” in the US, “money” in Japan, and “worthless” in France. It is also an obscene gesture in some parts of the world. Similarly, the US “come here” gesture (which involves moving one’s fingers and palm back and forth toward one’s body) means “good-bye” in regions of Italy, China, and Colombia. In Algeria, the wave that signals “good-bye” and “hello” in North America and parts of Europe means “come here.”

As these examples illustrate, emblems have direct verbal translations. Like most verbal communication, emblems are processed primarily digitally (as a single word or phrase) in the left side of the brain rather than holistically as most other nonverbal messages are. Although emblems become symbolic within a given culture, they often have iconic origins. For instance, the “A-OK” gesture used in the US resembles the letters “O” and “K.” This same gesture represents a coin, the number “zero,” or private body parts, which correspond to various meanings of the gesture across the globe. Thus, although emblems become symbolic when they are integrated into the communication system of a particular culture, they often start out as iconic representations of the idea or object they represent.

Emblems substitute for spoken words when verbal communication is difficult or awkward. For instance, verbally saying good-bye to someone who is beyond the security checkpoint at a busy airport would be difficult, if not impossible. Waving accomplishes the goal of saying good-bye much more efficiently. Similarly, obscene gestures are often used to convey negative affect in situations where it would be difficult or inappropriate to verbally confront someone (e.g., while driving). Emblems can also serve a bonding function for couples and groups. Secret handshakes, emblematic signals between members of a minority group, and private messages communicated via gestures all send messages of solidarity.

## ILLUSTRATORS

Illustrators typically complement or clarify parts of a verbal message by adding description or emphasis. Examples include pointing in a certain direction, drawing something in the air, showing height or width, and pretending to kick a ball. *Batons* or *punctuation gestures* are a specific type of illustrator that emphasizes words or phrases. When people move their hand up and down while making an important point, they are using a baton gesture. Illustrator gestures are often iconic, making them somewhat interpretable across different cultural contexts. Yet there are cultural differences in how people use illustrator gestures. Middle Eastern, Mediterranean, South American, and Caribbean cultures display more frequent and expansive gestures than people from central Europe, northern Europe, and North America. Thus, the former cultures are regarded as more kinesically expressive. Kinesic expressiveness appears to be learned. For example, second-generation Italian Americans use fewer illustrator gestures than do first-generation Italian Americans, presumably because they have adopted the norms of the new culture.

Illustrators also send messages related to dominance and liking. Burgoon et al. (1996, 315) noted that “Large, sweeping gestures extend the individual’s spatial sphere of control and add an air of dynamic energy,” as do pointing gestures and a rapid walking pace. Other studies have shown that along with smiling and eye contact, illustrator gestures are a primary nonverbal cue associated with liking (e.g., Palmer & Simmons 1995). Illustrator gestures are also a nonverbal immediacy cue that shows interest and enthusiasm (→ Teacher Immediacy).

## AFFECT DISPLAYS

Affect displays show → emotion. As such, they are often intrinsic and understood across cultures. Planalp et al.'s (1996) research demonstrated that people rely on four types of kinesic cues to decode the emotional states of others: *facial cues* (e.g., rolling eyes, smiling), *body cues* (e.g., clenching fists, jumping up and down), *activity cues* (e.g., throwing things, going for a walk), and *physiological cues* (e.g., blushing, crying). Of these kinesic behaviors, people rated facial cues as the most important indicator of emotion, followed by body cues, physiological cues, and activity cues. All four of these kinesic cues were rated as more important for decoding emotion than was verbal communication. When people recognize that another person is experiencing an emotion, they often respond by showing emotions themselves. *Motor mimicry* occurs when a person displays emotion in response to something that happens to another person, such as wincing when a girl skins her knee or smiling when a colleague wins an award (Bavelas et al. 1986). *Emotional contagion* occurs when people “catch” the emotions of others, often through mimicking kinesic behaviors (Hatfield et al. 1994).

Research has also examined profiles of kinesic behavior associated with specific emotions (Guerrero & Floyd 2006). Affectionate emotions such as love and liking are associated with mutual gaze, smiling, general facial pleasantness, head tilts, direct body orientation, forward lean, and reinforcing head nods. During courtship, attraction is communicated via many of these cues plus primping or preening (e.g., touching up one's makeup or standing more upright) and demure downward gaze. Liking and equality are also communicated through *postural congruence*, which occurs when two people share the same posture or position, such as sitting with their legs crossed the same way or walking in unison. Hostile emotions, such as anger and contempt, are associated with attacks on objects (e.g., pounding a tabletop, slamming doors), furrowed brows, tight muscles, heavy walking or stomping, clenched teeth or jaw, threatening gestures, clenched hands or fists, defensive behaviors (e.g., arms crossed against chest), lack of eye contact, and the “evil eye.” Sadness is associated with narrowed or dull eyes, frowning, trembling mouth, juttled or trembling jaw, downward glances, reduced eye contact, slumped posture, defensive body positions, and less overall gesturing.

## ADAPTORS

Adaptors are idiosyncratic behaviors that help people release tension and feel more comfortable. These behaviors are typically used when people are bored, nervous, or physically uncomfortable. People often control their use of adaptors in public, especially when other people are watching them. Adaptors have been classified into three sub-categories. *Self-adaptors* involve manipulating one's own body, such as twisting a strand of hair, or biting one's nails. *Object-adaptors* involve manipulating an object that a person is wearing or holding, such as tugging on an earring or repeatedly tapping a pen on a tabletop. *Alter-adaptors* involve correcting another person's appearance (e.g., tucking a tag into someone's shirt collar; licking one's finger and removing a smudge on a child's face). Because alter-adaptors involve invading someone's personal space, they can be perceived as threatening, leading to angry responses (→ Proxemics). However, when a

person welcomes alter-adaptors, this acceptance usually signals that a relationship is intimate.

Adaptors can signal nervousness or boredom. Conversely, a lack of adaptors can reflect composure and confidence, especially when complemented by illustrator gestures. Relaxation and composure are communicated nonverbally through a set of nonverbal behaviors that includes less random leg and foot movement, fewer adaptors, less swiveling, more body openness, and more expansive gesturing. This same combination of kinesic cues is associated with perceptions of dominance.

## REGULATORS

Regulators function to manage interaction by initiating, maintaining, and ending interaction. Common kinesic behaviors that help initiate interaction include forward leans, walking toward someone, and making eye contact. Common leave-taking behaviors, which signal a person's desire to end an interaction, include decreasing gaze (which is sometimes preceded by mutual gaze), facing away from a partner, gathering possessions, and looking at one's watch or a clock. When a receiver fails to recognize a person's leave-taking attempts, the person in the leave-taking position sometimes displays adaptors, such as tapping one's foot. Similar behaviors have been reported during conflict situations when one partner wishes to withdraw from the interaction. Studies examining demand-withdrawal patterns in marital interaction have shown that husbands who withdraw exhibit more head turns away from their wives, less gaze, more head-down positions, and fewer open body positions. People also use adaptors when trying to withdraw from conflict.

Kinesic behavior also helps regulate turn-taking. People who want the conversational floor engage in behaviors such as leaning forward, raising one's hand, opening one's mouth slightly, and nodding rapidly. When people wish to relinquish their speaking turn, they often lean back and settle into a relaxed position and/or gesture toward the person who should speak next. People subtly refuse speaking turns by sitting back and nodding slowly to encourage a speaker to continue talking. Importantly, the ability to control the conversational floor is related to power and dominance. As Cappella (1985, 70) stated, power can be established and maintained "by controlling one's own and others' ability to present information." Kinesic regulators are one key to obtaining this type of control, just as kinesic cues in general are a critical component of effective interpersonal communication.

## Girl Culture

Sharon R. Mazzarella

Clemson University

Within the discipline of communication there has been a long history of studying the relationship between girls, media, and other cultural artifacts. Until recently, however, the focus of such studies has been almost solely on girls as consumers of media and other products and/or as passive victims of mediated portrayals of femininity (→ Gender: Representation in the Media). For example, the norm for academic studies of girls has, until recently, been to define girls as potential victims of the culture that surrounds them – a definition guiding much of the research examining how girls are affected by teen magazines, romance novels, popular music, and other cultural artifacts.

This tendency of the academy to label girls as victims of mass culture found a parallel in public discourse as well, a predisposition that was evident throughout the twentieth century and particularly during the 1990s. At that time several influential and high-profile studies of girls were published addressing such issues as girls' declining self-esteem, negative body image, and poor school performance. Paramount among these was Mary Pipher's controversial book *Reviving Ophelia*, in which Pipher argued that girls were living in a "girl poisoning culture" (1994, 12).

### “GIRLS' STUDIES” IN THE ACADEMY

What was missing, until very recently, however, were studies of girls as able to resist and negotiate cultural messages as well as girls as active producers of their own cultural artifacts. Indeed, recent scholarship, grounded more in → cultural studies and feminist theory, particularly in third wave feminism, has changed the way we in the academy think about and study girls (→ Cultural Studies: Feminist Popular Culture; Feminist and Gender Studies). Dubbed “girls' studies” (as opposed to simply studies of girls), this field has its roots in women's studies and represents “a sub-genre of recent academic feminist scholarship that constructs girlhood as a separate, exceptional, and/or pivotal phase in

female identity formation” (Wald 1998, 587). As a result, in the early years of the twenty-first century, girls have achieved a new visibility in the academy as a whole and within the discipline of communication in particular.

This visibility is groundbreaking since, until the latter half of the twentieth century, academic and clinical studies of females were virtually absent. Much of what we know (or thought we knew) about youth as a generation has come from male scholars studying male children and adolescents. As feminist scholar Carol Gilligan reminds us, those theories guiding the public and media discourse on youth development throughout much of the twentieth century told us nothing about girls as a distinct group. Gilligan’s own work, notably the groundbreaking *In a different voice* (1982), has gone a long way toward showing us the unique ways female youth develop as well as the ways in which girls and women communicate and reason, and notably that they speak in “a different voice” (→ Developmental Communication).

While Gilligan focused on the biases inherent in longstanding psychological theories of youth development, Angela McRobbie reminded us that these same biases and absences were extant in theories of youth culture, in particular youth subcultures. Grounded in both feminist and cultural theories, McRobbie’s own work on girls has expanded the dialogue about girls and girl culture and, like Gilligan’s, has had a profound influence on the development of girls’ studies as a field. Her book *Feminism and youth culture* (1991) is generally credited with laying the groundwork for cultural studies of girls’ lives.

In addition to shifting the focus of youth studies away from solely boys, Gilligan’s and McRobbie’s contributions to the development of girls’ studies have also been methodological, specifically advocating the need to listen to the voices of girls themselves rather than relying on adult academicians’ interpretations of girl culture. Girls’ studies scholars often rely on qualitative and cultural methods of studying girls, including focus groups, one-on-one interviews, and ethnographies. Such methods enable girls to speak for themselves.

## GIRLS AND POPULAR CULTURE

Paralleling and contributing to the growing academic and public discourse about US girls in the 1990s, girls proved to be a highly profitable audience for the media industries, a phenomenon initially attributed to the movie *Titanic*, whose financial success has been linked to repeat viewings by pre-adolescent and adolescent girls. But it was not just *Titanic* that benefited from a newly powerful young female audience (→ Audiences, Female). Girls helped insure both the financial and cult success of such youth-oriented television programs as *Buffy the Vampire Slayer*, *Party of Five*, and *Dawson’s Creek*, not to mention a new wave of pop music acts such as the Spice Girls, the Backstreet Boys, Britney Spears, and Christina Aguilera, to name just a few.

Given girls’ clout with the popular culture industries, it is not surprising that girl-oriented popular culture has generated extensive academic scrutiny. The television program *Buffy the Vampire Slayer*, for example, has been the focus of countless articles, chapters, and entire books, many focusing on the role of the teenaged Buffy Summers as a transgressive and empowering role model for girls. Moving beyond knee-jerk reactions to controversial portrayals and/or messages, girls’ studies scholars typically offer nuanced and theoretically grounded deconstructions of such cultural texts.

This upsurge of academic studies of girls' cultural artifacts, while still grounded primarily in content analysis methodology, differs greatly from previous studies of cultural artifacts targeted at girls. First, they are not limited to studies of print media such as teen girl magazines, thereby acknowledging the range of media producing cultural artifacts representing and targeting girls. Second, they do not begin with an assumption that cultural messages are harmful to girls and that girls are the hapless victims of the culture industries. Indeed, it is this movement away from defining girls as victims that leads to the most compelling area of current girls' studies scholarship – studies that listen to the voices of girls themselves.

Following from Gilligan and McRobbie, many girls' studies scholars remind us of the need to go beyond even the most nuanced deconstructions of cultural artifacts, and to move toward including the voices of girls themselves in the dialogue – to hear how girls actively negotiate and even resist these cultural artifacts. Yet, while it is important to listen to the voices of girls as they tell us about their relationships to cultural artifacts that we, as adult scholars, would likely miss or misinterpret without their help, it is equally, if not more, important to listen to, to see, and to read their voices through the cultural products they themselves create. Technological innovations such as digital video/filmmaking and the → Internet have enabled young people to produce their own media messages – a phenomenon that is particularly prevalent in girl culture (→ Internet Use across the Life-Span). But even such low-tech pursuits as publishing a handmade zine that has been photocopied and handed out at a concert is an important form of cultural production for girls (→ Zines).

Nearly a decade ago, Mary Celeste Kearney (1998, 285) labeled the “emergence of girls as cultural producers” as “one of the most interesting transformations to have occurred in youth culture in the last two decades.” While writing at a time when others both in the academy and the media were focusing on girls as victims of media content, Kearney advocated seeing girls as active and capable of doing more than consuming media content. She reminded us, “If scholars involved in the field of Girls' Studies desire to keep current with the state of female youth and their cultural practices, we must expand the focus of our analyses to include not only texts produced for girls by the adult-run mainstream culture industries, but also those cultural artifacts created by girls” (1998, 286).

In response, the field of girls' studies has generated a plethora of studies documenting girls' active production of culture (both media and otherwise), including music, zines, websites and blogs (→ Blogger), films, the riot grrrl movement, and skater girl culture, to name only a handful of examples. But it has been the area of girls' creative production on the Internet that has generated the most prolific body of work. While at one time there may have been a gendered digital divide such that boys were more likely to use computer technology than were girls, that divide no longer exists, at least in the United States. In fact, in many ways US girls are more active Internet creators than are boys, especially when it comes to such things as blogs. According to a recent study conducted by the Pew Internet and American Life Project, 38 percent of US girls aged 15 to 17, versus only 29 percent of US boys in this age group, create and share such self-authored content as photos, artwork, videos, and stories. While the first studies of girls and the Internet focused on websites created *for* girls or other Internet content *about* girls, recent scholarship has moved toward examining websites, blogs, and instant messaging created

by girls. Specifically, scholars have examined the Internet as a space fostering girls' self-expression, community building, identity play, and expressions of girl power (→ Cyberfeminism).

## GIRL POWER

Indeed, one cannot discuss studies of girl culture without addressing this highly contested and controversial concept of girl power. Certainly, the phrase has been associated with everything from the riot grrrl movement (a now international movement, grounded in feminist politics and a punk aesthetic, designed to empower girls and young women through music, self-publishing, and community building) to the Spice Girls to the animated *Powerpuff Girls* (→ Feminist Media). But its origins are less well known. The independent Welsh band Helen Love first included the phrase in a song, "Formula One Racing Girls," in 1993, and the pop-punk duo Shampoo released an album and single titled "Girl Power" in 1995. But no one did more to popularize and commodify the term and to link it to girl culture than did the Spice Girls – the prefabricated, all-girl, British pop group whose music was purposely targeted at young girls. Adopting the girl power slogan, the band has been criticized for redefining the phrase to focus on physical appearance, sex, and shopping. No matter what the phrase's origins, it is significant that the *Oxford English Dictionary* began including it in 2001, defining it as "a self-reliant attitude among girls and young women manifested in ambition, assertiveness and individualism" (BBC News 2002). Indeed, this definition captures the spirit of the way in which girls' studies scholars and girls themselves use the term.

In her call for girls' studies scholars to study girls as cultural producers, Kearney (2006) makes it clear that she is not dismissing the role consumerism plays in girls' lives. Rather, she is attempting to broaden our focus to include areas of scholarship and ways of defining girls' relationship with media that had been previously neglected. Specifically, such studies, she argues, enable us to redefine adolescent girls as active agents, acting on their world. As the culture, technology, and society evolve, so too must the questions we as academics ask and the methods we use to answer them. Indeed this has been one of girls' studies major contributions to the study of the relationship between youth and cultural artifacts.

# Global Media, History of

*Dwayne Winseck*

*Carleton University*

The first phase of a truly global media network ran from the 1860s through the 1920s. Two major interpretations of this era are available. One, long established, emphasizes how aggressive nation-states deployed communication firms to further their own economic and political goals in carving up the planet (→ Cultural Imperialism Theories). Another, more recent, reads the period as one of capitalist cosmopolitanism, noting the international cartels and other multinational enterprises that in actual fact dominated the growth of the first global technical infrastructure for communication. However, growing nationalism and protectionism over the 1920s put paid to early proposals for a constructively regulated global communication system.

## **BRITAIN'S INITIAL LEAD IN COLONIALISM AND GLOBAL COMMUNICATION**

The flow of → news and → information has followed channels of trade, migration, and cultural contact for millennia. Media historians, however, usually look to the period between the second half of the nineteenth century and the turn of the twentieth, when a global media system emerged consisting of a worldwide network of submarine cables and → news agencies interlinked with urban and national telegraph systems and national commercial press systems (→ Telegraph, History of; Telegraphic News). While access was limited to financiers, traders, diplomats, and military strategists, the rise of these global media coincided with the birth of the commercial press, whose mass appeal and extensive foreign news coverage, even by the standards of our own time, brought these facilities within reach of a larger general public (→ Newspaper, History of).

The maturation and consolidation of the telegraph industry in Britain, Europe, and North America by the mid-1860s led to the initial steps to wire the world. Expanding commerce, especially in the transatlantic economies, combined with the British Empire's commercial, diplomatic, and military reliance on fast and secure → international communications, added further momentum. For the first time in history, worldwide electronic

communication networks and the mass production and dissemination of news, financial information, and diplomatic correspondence brought distant events to far-flung communities almost instantaneously. This simultaneous shared experience of distant events provided at least a thin basis for a mediated global culture (→ Culture: Definitions and Concepts).

British firms, especially the Eastern Telegraph Company – the biggest multinational of its time – led the efforts to create a sprawling network of telegraphs and submarine cables to Europe (1850s), to the Middle East, India, and North America in the 1860s, to South America and Asia in the next decade, and finally encircling Africa in the mid-1880s. Simultaneously, three European-based wire services – Reuters, Havas, and Wolff – emerged. These firms were early and prominent multinational corporations whose operations served as the informational underpinnings of global capitalist → modernity, or liberal internationalism as it was referred to by contemporaries. The news agencies, in essence, broadcast news over the wires to big city newspapers and their influence on press development was strong in Europe, the Americas, and the Middle and Far East. Their standardized service simultaneously underpinned the new journalistic principle of objectivity (→ Objectivity in Reporting) and attracted specialized and mass → audiences alike, while their policy of giving exclusive service to one newspaper per city (except in China) reinforced the drift toward local press monopolies (Boyd-Barrett & Rantanen, 1998; → Competition in Media Systems; Concentration in Media Systems). From as early as 1869, Reuters, Havas, and Wolff divided the world's news markets into mutually exclusive areas and set the rules governing news exchange and cooperation among them. The Associated Press was included in 1893 in recognition of its growing standing in North American and European news markets (→ News Agencies, History of).

The fact that the largest communications company – the Eastern Telegraph Company – and most powerful news agency – Reuters – were based in London gave Britain unparalleled hegemony over world communications. Control over both the medium and the message conferred enormous commercial and strategic advantages, a power that British officials refused to yield lightly. Britain's free trade policy was explicitly designed to attract cables and capital to London in a bid to reinforce its status as the world's communication hub. In foreign markets, British officials used diplomatic prowess and ties to local elites to preserve the monopolistic concessions acquired by British companies since the 1850s, which remained a prominent feature of the global media system until the 1920s. Huge subsidies were given to firms, mostly the Eastern Telegraph Company, to extend cable systems to commercially unviable places within Britain's vast territorial empire.

By 1900, however, France, Germany, Japan, and the United States began to build their own international communication systems, engaging, according to Hills (2002), in a "struggle for control of global communication." Communications media were "weapons of politics" for powerful nations in the worldwide competition for territory, wealth, and power (Headrick 1991). This was especially true following the "scramble for Africa" in the 1880s. Parts of Asia and the Caribbean met a similar fate. Fast, reliable, and secure communications became an essential element of imperial administration, diplomacy, and conflict among the imperial powers as well as between them and those they controlled. World War I magnified this strategic role, as surveillance, → censorship and → war propaganda became systematic elements in military conduct (→ Censorship, History of).

Britain was slowly displaced by the United States as the locus of world communication, initially as a consequence of the latter's rapid commercial, political, and military expansion, but also due to the ravages of World War I. This decline accelerated quickly after the costs and consequences of World War II led to the dismantling of British and European territorial imperialism.

### REVISIONIST HISTORICAL ANALYSIS

However, new historical scholarship suggests the need to refine this perspective. It is important to cast the analytical lens beyond competition between powerful nations, especially Britain and the US, for control of world communication and beyond conflating the history of global media with the history of imperialism (Bayly 2001; Jones 2005; Winseck & Pike 2007). Studies written after World War I reread the past through the excessively nationalistic prism that defined much scholarship and the public mood in the decades following. However, the half-century prior to World War I can be better interpreted as "cosmopolitan" in nature, an era of liberal internationalism that deeply shaped the structure and operations of the global media.

As Jones observes, "London was exceptional in the degree of cosmopolitanism in the nineteenth century, [but] the lack of concern about the nationality of ownership was general. This stance did not shift with the intensification of nationalistic rivalries in Europe before World War I" (Jones 2005, 282). The structure of the global media business exemplified his argument. First, while London was home to many important cable firms, in particular the Eastern Telegraph Company, just because capital poured into the city during the cable-building boom years (1870–1910) does not mean that the firms that emerged were British. Indeed, many of the most important firms contained a mixture of British, European, and North American capital, and their boards of directors reflected this fact. The French Atlantic Cable Company in the 1870s illustrates the point, with its combination of French and British capital and two boards of directors, one in London, the other in Paris. The Great Northern Telegraph Company, the Western and Brazilian Telegraph Company, and the Commercial Cable Company were other notable firms with similar features. This is obscured by most studies which refer generically to firms as British, American, German, French, Japanese, with the inference that they were tools of their respective states. In fact, many firms took an opportunistic stance toward their national identity. The Commercial Company was a master at this, claiming to be British when it successfully sought subsidies for two "British" affiliates that it owned – the Halifax and Bermudas Telegraph Company (1890) and Direct West India Cable Company (1898) – and "all-American" when standing before Congress to promote its bid to lay the first American-owned cable across the Pacific (1904).

From its inception in 1888 until the 1920s the Commercial Company displayed its indifference to national identity by leading alliances with several European cable companies in the transatlantic market, while joining with an affiliate of the Eastern Telegraph Company and the Anglo-Danish Great Northern Telegraph Company for its Far East operations. This reveals another crucial aspect of the cosmopolitan character of the global media: the *dominance of cartels*. Cable firms formed cartels throughout the world in the 1870s, cutting deeply across national lines. The ring-circle agreement of 1869 created a

global news cartel consisting of Reuters, Havas, and Wolff (and Associated Press from 1893). The big four commercial wireless firms – Marconi, Compagnie Générale de Télégraphie sans Fil, Radio Corporation of America, and Telefunken – adopted the same methods after World War I. Hogan (1977) calls these cartels “private structures of co-operation”; they were critical to efforts made by companies and governments to avoid “ruinous competition” and to negotiate among foreign policies of nation-states. The news cartel collapsed only in 1934, the wireless cartel in the mid-1940s, while the cable cartels have continued, albeit in different form, to the present day. All of this suggests that it was the *internationalization of control*, rather than the struggle for control, that characterized early globalization.

The most important communications and news markets were between Europe and North America, a few key cities in Atlantic South America, and in certain Chinese and Japanese cities (→ Markets of the Media). This is where the cable companies and news agencies focused their efforts. However, usually through state subsidies and sometimes through state-owned cables, these firms extended their operations into the zones carved out by Britain, European powers, Japan, and the United States in Africa, the Caribbean, and Asia, though these newer areas were some of the least-connected, worst-served places in the planet. In them too the collaborative nature of imperialism was on display, despite episodic flashpoints between the imperial powers. From the mid-1880s to just after the beginning of the twentieth century, the imperial powers worked together to a remarkable extent, most notably as France, Germany, Spain, and Portugal all gave subsidies to affiliates of the British-based Eastern Telegraph Company to meet the commercial and imperial communications needs in Africa.

### THE “EMPIRE OF CAPITAL” AND MOVES FOR REFORM

Beyond the colonized territories lay a much vaster capitalist imperialism, where “informal imperialism” intersected with national modernization discourses to shape the relationship between local and global communication media. These areas included the post-imperial nation-states of South America and the faltering regimes of the Ottoman, Persian, and Chinese empires. In each, nation-builders, business leaders, reformers, and technocrats vied with opportunistic cities, thieves, and culturally conservative forces to define the terms upon which telegraph systems and the nascent commercial press would be integrated into the global media system. Unlike those areas where either markets ruled or “territorial imperialism” rode roughshod over the local population, the empire of capital was based on a loose → discourse of modernity and of creating a harmonized global space for capital accumulation.

Initially, the terms upon which the countries just mentioned were integrated into the empire of capital involved long-term monopolistic concessions, high rates, and little attention to developing local telegraph agencies and the press. Over time, however, these countries began to gain greater control over the terms of cable concessions, to create their own telegraph administrations, and to oversee the emergence of a relatively vibrant, locally controlled press. Such achievements, however, were short-lived. A combination of financial debts and the perceived failure, in the eyes of western commercial and political interests, of these countries’ modernizing initiatives resulted in their fledgling media,

along with much else, often being brought under the de facto rule of foreign interests – a process not reversed for decades. This was not universal though. Argentina, Brazil, and Chile possessed wealthy and influential newspapers, such as *La Nación* and *La Prensa* in Buenos Aires, and by the 1910s a cadre of adroit officials who pushed to nationalize domestic telegraph systems, and to liberalize international communication markets. These countries benefited by playing the once all-powerful foreign cable companies and news agencies off against each other, and their efforts strongly influenced the rebalancing of power that took place among US and European cable companies and news agencies after World War I.

In short, the idea that imperialism meant one-way exploitation by imperial states and corporations is unduly simplistic. The politics of these global media involved local and foreign interests, and the dynamics differed between territorial and informal imperialism. It was not only “developing countries” that chafed at monopolistic concessions, cartels, and exploitative arrangements, but also individuals drawn from the ranks of social reformers that emerged across the North Atlantic countries between the 1880s and 1920s. Among these individuals were those drawn from parliaments, engineering, → journalism, academia, and other walks of life, who set their sights on the monopolistic telegraph and cable companies, cartels, and news agencies whose high rates and collusive behaviors they saw as choking the flow of information and preventing the new means of communication from being turned into vehicles of mass communication. Since the 1880s, this “global media reform” movement pushed to eliminate monopolistic concessions and cartels, for rate reductions, and sometimes for state-owned cables, with one testimony to their success being the state-owned Pacific Cable jointly constructed and owned in 1902 by the British, Canadian, Australian, and New Zealand governments. While their gains were limited, the fact that they achieved a measure of support in, for example, the *New York Times*, *The Times* (London), and the conservative *Economist*, kept the cause alive and arguably put downward pressure on rates that had remained prohibitively expensive for nearly half a century. In 1912, the British government finally came to agreement with all transatlantic cable firms to implement new “cheap rate” services to enhance popular use of long-distance communication – a practice soon copied worldwide.

The reformers’ grievances were exacerbated by the extensive surveillance and censorship of cable traffic, and collusion among news agencies, press, and governments for propaganda purposes, during World War I. The movement was broadened among journalists, as Reuters and press barons revealed their willingness to continue to produce “tainted news” even afterwards. The reform movement agenda converged with a willingness to include communication issues within the 1919 Versailles peace talks. While Britain and Japan sought a narrowly focused review of how to deal with several German cables captured by the Allies during the war, the US, France, China, and a few others sought a more expansive review of the global media system. While the latter initiative has often been dismissed as a “cloud of high-minded rhetoric” (Headrick 1991, 174), this misses the point that many believed a comprehensive review of the barriers to world communication – monopolies, cartels, high rates, hidden subsidies, and propaganda – was long overdue. An agreement was reached for just such a review to be held in Washington in 1920, but continued wrangling over the agenda led instead to the issues being dealt with more bilaterally over the 1920s. In the end, this piecemeal approach and the overall relative failure of Versailles, coupled with a turn to a more nationalistic climate over the

following decade, signaled the end of an era. The 1930s Depression thereafter put the final nail in the coffin of early modern globalism, and with it the first period in which elements of a truly global media system were in place.

## **Globalization of the Media**

*Daya Kishan Thussu*

*University of Westminster*

Like many other spheres of contemporary life, the mass media have been profoundly affected by the processes of globalization (→ Globalization Theories). During the 1990s, the global media landscape was transformed as a result of the deregulation and privatization of broadcasting and telecommunication, enabling a quantum leap in the production and distribution of media products across continents and in real time.

The globalization of media, and especially of visual media, is helping to make → Marshall McLuhan's dream of a "global village" a reality. In the era of "real-time" communications, people all over the world can watch live as events unfold, such as the terrorist attacks on New York and Washington on 11 September, 2001, the tsunami that overwhelmed southern Asia in 2005, or major sports events such as the football world cup or Olympics.

With the convergence of → television and the → Internet and the growing availability of broadband, media consumers today can share information and entertainment

programs and, with digital devices, even generate and distribute their own media content (→ Convergence of Media Systems). Whether the audience is enjoying sports or watching → news reports of military conflicts or natural disasters (→ Disasters and Communication), → music videos, → soap operas, or game and chat shows, the globalization of the media has enabled the creation of a thriving international market, which now encompasses the globe (Thussu 2007).

### **OPENING UP THE MEDIA MARKET**

It has been pointed out that the globalization of the media is not entirely new: during the nineteenth century the world was connected by cable and wireless telegraphy, and → news agencies such as Reuters were early examples of global media (Boyd-Barrett and Rantanen 1998). However, in almost every country, the media, historically, were considered a national institution. The state played an important role in the development of the private press (through subsidies) and especially in the growth of → radio and television, key media for national integration and a sense of cultural identity, with a remit to inform and educate as well as entertain. In the communist world, the mass media were considered part of the legitimate state → propaganda machinery. In many developing countries, too, the mass media were used by ruling elites to retain their hold on power (→ Development Communication). Before media globalization, with the possible exception of broadcasters from major powers such as the United States, television networks, for example, traditionally saw themselves as operating within and for the nation-state, making programs for citizens rather than consumers (→ Audience). With the globalization of the liberal model of the media, national broadcasters no longer have a monopoly on the airwaves. This has meant a dynamic media, challenging state → censorship and widening the → public sphere, while at the same time also leading to the concentration of media power in a few, unelected, transnational corporations (Herman and McChesney 1997; Baker 2007; → Concentration in Media Systems).

The political and economic opening up of markets at the end of the Cold War, through international agreements under the auspices of the World Trade Organization (WTO) in order to encourage privatization and deregulation, relaxed restrictions on media ownership. The subsequent rush of mergers and acquisitions led to the concentration of power in a few large media corporations mainly based in the USA and Europe (Herman and McChesney 1997; Bagdikian 2004; Boyd-Barrett 2006; Thussu 2006; Baker 2007). At the same time, new markets opened up: the former Soviet bloc and emerging economies in Asia provided a growing and increasingly affluent class of media consumers (→ Media Conglomerates).

Benefiting from globalization, transnational media corporations, such as → Disney, AOL-Time Warner (→ Time Warner Inc.), and → News Corporation, came to dominate the global media industry by virtue of their ownership of multiple networks and production facilities and the huge increase in transnational traffic in media products. The USA leads the field in the export of audiovisual products. Through its political and economic power, its media are made available across the globe in English or in dubbed or indigenized versions. From news and current affairs (→ CNN, available in 260 million households worldwide, and Discovery, available in 180 million households worldwide)

through youth programming (MTV, the world's biggest television network, reaching 418 million households), children's television (Disney), feature films (→ Hollywood), and sport (ESPN) to the Internet (Google; → Search Engines), the United States is the global giant (Thussu 2006).

The USA is particularly strong in exporting filmed entertainment: Hollywood films are shown in more than 150 countries worldwide and dominate market share in most countries (→ Film Production). In 2005, more than half of the US film industry revenues came from foreign markets. According to the Motion Picture Association, in 2004, the worldwide box office was worth \$25.24 billion, with the world's top 10 grossing films being produced by Hollywood (Miller et al. 2005).

### **SATELLITES AND THE GROWTH OF GLOBAL TELEVISION**

The globalization of the media has been made possible by digital technologies and the growing availability of affordable communication satellites (→ Digital Media, History of; Satellite Television). During the 1990s – the decade of globalization – more geostationary satellites were launched than in the previous three decades combined, enabled by international agreements on telecommunications, especially the WTO's Fourth Protocol (also referred to as the Basic Agreement on Telecommunications Services; Thussu 2006).

The resulting proliferation of satellite and → cable television has led to unprecedented growth in new television networks. In Latin America, for example, *PanAmSat*, the first private satellite service for the continent, launched in 1988, revolutionized broadcasting, providing direct-to-home (DTH) television services. In Asia, the launch in 1990 of *AsiaSat* made such broadcasters as STAR (Satellite Television Asian Region), part of News Corporation, a possibility. In less than a decade from its launch, STAR could claim to be setting the pace of media in Asia, broadcasting 40 services in eight languages and reaching more than 300 million viewers in 53 countries. In the Arab world, the regional satellite operator *Arabsat* enabled beaming of programs across the region and among the Arab diaspora, as with the pan-Arabic entertainment network Middle East Broadcasting Centre (MBC), as well as news organizations such as Al Jazeera (→ Arab Satellite TV News). All these networks are now supported by online and mobile delivery mechanisms (Thussu 2006).

One reason for the growing demand for transnational media is the result of a huge movement of people through migration (→ Migration and Immigration). According to a report of the UN Global Commission on International Migration, the world had nearly 200 million migrants in 2005, partly as a result of the globalization of commerce and communication (UN 2005). Transnational satellite broadcasters and online media companies have tapped into these emergent geocultural and linguistic groups (Chalaby 2005).

### **GLOBAL MEDIA: FLOW AND CONTRAFLOW**

The resulting growth of multichannel networks has made the global media landscape more complex: it is now multicultural, multilingual, and multinational (Sinclair et al. 1996; Thussu 2007). Digital communication technologies in broadcasting and now

broadband have given viewers in many countries the ability to access simultaneously a vast array of local, national, regional, and international media. A whole range of television networks is now available to viewers around the world: news (CNN, BBC World, France 24, CNBC, Bloomberg, → BBC World Service), regional news networks (Sky News, Star News Asia, the pan-Arabic news network based in Qatar, Al Jazeera), documentary (Discovery, National Geographic), sports (ESPN); and entertainment (Cartoon Network, Disney, HBO, Paramount, MTV), to name the most prominent genres (→ International Television).

Though the media flow from the west (mainly the US) to other parts of the world has increased, there is a small but significant flow in the other direction, from the *non-western world*. Such countries as China, Japan, South Korea, Brazil, and India have become increasingly important in the circulation of cultural products. Japanese → animation, film, publishing, and music business was worth \$140 billion in 2003, with animation, including manga (comics), → anime, films, videos, and merchandising products bringing in \$26 billion, according to the Digital Content Association of Japan. South Korea has emerged as a major exporter of entertainment – film, television soap operas, popular music, and online games – especially within east Asia, prompting commentators to speak of a Korean wave (the “*Hallyu*”) sweeping the region.

One key example of transnational media flow is the Latin American soap opera, the *telenovela*, which has become global in its reach: by 2005 the telenovela had developed into a \$2 billion industry, being broadcast in 50 languages and dialects and reaching 100 countries from Latin America to southern and eastern Europe, to Asia, Africa, and the Arab world (Martinez 2005).

Another major non-western presence in the global media market is the growing visibility of India’s \$3.5 billion Hindi film industry, which, in terms of production and viewership, is the world’s largest: every year a billion more people buy tickets for Indian movies than for Hollywood films. More films are made in India each year than in Hollywood, but their influence is largely confined to the Indian subcontinent and among the South Asian diaspora, though in recent years many “cross-over” films have changed this situation (Kaur and Sinha 2005). The unprecedented expansion of television in the 1990s and early 2000s has also boosted the movie industry, with the emergence of many dedicated film-based pay-channels. The globalization of → *Bollywood* has ensured that Indian films are increasingly being watched by an international audience as well as a wider diasporic one: Hindi films are shown in more than 70 countries and are popular in the Arab world, in central and southeast Asia, and among many African countries.

In the arena of news and current affairs, such *contra-examples* may include the pan-Latin American news channel *Televisora del Sur* (“Television of the South,” Telesur) based in Venezuela; Russia Today (RTTV), the round-the-clock English-language global television channel launched in 2005; and CCTV-9, the English-language network of China Central Television, in operation since 2003. Al Jazeera, which since its launch in 1996 has redefined journalism in the Arab world, is the most prominent example of contraflow in global media products. By 2006, this pan-Arabic 24/7 news network was claiming to reach 50 million viewers across the world, challenging the Anglo-American domination of news and current affairs in one of the world’s most geopolitically sensitive areas. If the live broadcast of the 1991 US military action against Iraq contributed to

making CNN a global presence, the “war on terrorism” catapulted Al Jazeera into becoming an international broadcaster whose logo can be seen on television screens around the world (Lynch 2006). With the launch in 2006 of *Aljazeera English* – and its claim of “setting the news agenda” – the global news-scape is likely to become more diverse.

## MEDIA GLOCALIZATION

Aljazeera English is an interesting example of media glocalization, drawing on the professionalism of the → BBC’s public service ethos but aiming to privilege a southern perspective on global issues. Such hybridization is not uncommon and helps in a better understanding of strategies being adopted by the major western media corporations to maximize their entry into emerging markets around the globe (Robertson 1992). Conforming to what Sony once characterized as “global localization” – content and services being tailored for specific cultural consumers – a glocal media product is an inevitable commercial imperative. Glocalization strategies exemplify how the global can co-opt the local in order to maintain its dominance. This localization trend is discernible in the growth of regional or local editions of western or, more specifically, American → newspapers or → magazines; the transmission of television channels in local languages, and even producing local programming, as well as having local-language websites.

Major Hollywood studios are increasingly using local production facilities in Europe, Asia, and Latin America. Columbia TriStar, Warner Brothers, and Disney have set up international TV subsidiaries to produce English-language co-productions, to be followed by country-specific programming. Sony has contributed to local-language film production in Germany, Hong Kong, France, and Britain, and television programming in eight languages. Global media companies are particularly keen to consolidate their position in the world’s two largest, and hitherto not fully explored, markets: China and India. Cartoon Network has indigenized operations in India, producing a series based on the Hindu religious epics, the *Ramayana* and the *Mahabharat*, while Disney Consumer Products has established more than 1,800 “Disney Corners” in Chinese department stores.

STAR TV has aggressively adopted the policy of indigenization in offering localized channels, including STAR Chinese Channel (for Taiwan), STAR Japan, STAR Plus and STAR News (for India), and VIVA Cinema (for the Philippines). Among the business television channels, too, Asia is a priority area. By 2006, CNBC Asia, CNBC-TV18 (India), and Nikkei-CNBC (Japan) were available in more than 34 countries across the Asia-Pacific region. CNBC also had an alliance with China Business Network, a subsidiary of the Shanghai Media Group.

In the Middle East, western or westernized TV platforms such as Orbit and Viacom’s pay-TV joint venture Showtime are increasingly localizing their content, as well as using subtitles for American programming and moderating language and depictions of nudity and sex. In Latin America, prominent US brands include MTV Latin America, Canal Fox, CNN En Español, Fox Kids Network, and Fox Sports Americas.

In *print media* the localization process is well established. *Newsweek* has a network of local-language publications in Japanese, Korean, Spanish, Arabic, and Polish. The regional editions of major US business publications such as the *Asian Wall Street Journal*, *Far Eastern Economic Review*, *Fortune Asian*, and *Fortune China* have a small but

influential pan-Asian readership. In Latin America, US presence includes the *Wall Street Journal Americas* as well as *Time* magazine, published as a supplement in leading newspapers in nine Spanish-speaking countries. *AmericaEconomia*, a Dow Jones publication, is Latin America's leading pan-regional business magazine, published bi-weekly in Spanish and Portuguese, while *Fortune* has a Latin American edition, *Fortune Americas*. Many international media brands publish multiple international editions of magazines, like *Reader's Digest*, *Esquire*, and *Good Housekeeping*. This localized content is supported by regionalized advertising, increasingly deploying regional and national languages and using cultural values to sell consumer and other products through the different media.

As US-led western media conglomerates have regionalized and localized their content to extend their reach beyond the elites in the world and to create the "global popular," many southern media organizations have benefited from synergies emerging from this process. Some have skillfully used their position within a media conglomerate, drawing on technological and professional expertise to grow into global operators. In addition, the globalization of western or western-inspired media has contributed to the creation of professional careers in media and cultural industries. The localization of media content and outsourcing of digital media for transnational corporations – from Hollywood post-production to animation and digital data management – have provided the impetus for the formation of important global hubs for creative industries: by 2005, for example, India had emerged as a key destination for outsourcing media content (UNESCO 2005).

### CHALLENGING DOMINANCE?

During the 1970s and 1980s, → UNESCO studies, conducted amid heated debates about the → New World Information and Communication Order (NWICO), suggested that there was generally a one-way traffic, mainly in entertainment-oriented programming, from the major western exporting nations to the rest of the world, resulting in a global imbalance in the media.

In the era of globalization, it has been argued that the one-way vertical flow has given way to multiple and horizontal flows, as non-western media content providers have emerged to service an ever-growing geocultural market. However, a word of caution is advisable. The prominent examples of media flows from India, Brazil, and Qatar may give the impression that global media have become more diverse and even democratic. A careful analysis of the reality of global media flows would demonstrate a more complex process.

Despite the growing trend toward contraflow, the revenues of non-western media organizations, with the exception of Japanese animation, are relatively small, and their global impact is restricted to geocultural markets or at best to small pockets of regional transnational consumers. None of the Latin American telenovelas has had an international impact comparable with the cult following of *Friends* or *Sex and the City*, and, despite the growing presence of Indian films outside India, their share in the \$200 billion global film industry (valued in 2004) was negligible.

As trade figures demonstrate, the circulation of US media products still continues to define the "global." One result of the privatization and proliferation of television outlets and the growing glocalization of US media products is that American film and television

exports witnessed a fourfold increase between 1992 and 2004 – from \$2.5 billion to \$10.4 billion (US Government 2005). The extensive reach of US-based media, advertising, and telecommunications networks contributes to the global flow of consumerist messages, helping the US to use its “soft power” to promote its national economic and political interests (Nye 2004; → Americanization of the Media).

Critical theorists have argued that the transnational corporations, with the support of their respective governments, exert indirect control over the developing countries, dominating markets, resources, production, and labor (→ Critical Theory; Political Economy of the Media). In the process they undermine the cultural autonomy of the countries of the south and create a dependency on both the hardware and software of communication and media: “transnational corporate cultural domination” is how one prominent scholar defined the phenomenon (Schiller 1992, 39; → Dependency Theories).

In such an analysis of global media flows, however, the audience and media content were largely ignored: that the content can be interpreted differently by different audiences and that southern countries may be able to innovate and improvise on the western products were discounted. While some have argued that the global-national-local interaction is producing “heterogeneous disjunctures” rather than a globally homogenized culture (Appadurai 1990), others have championed the cause of cultural hybridity, formed out of an adaptation of western media genres to suit local cultural conventions (Kraidy 2005; → Culture: Definitions and Concepts).

Such hybridization of the media takes shape within a broader new-liberal ideological framework. It could be argued that globalized media are contributing to a culture that celebrates the supremacy of the market and liberal democracy, as defined by the west. That the message is in local languages may in fact be a more effective way of legitimizing the ideological imperatives of a free market system: one that privileges the private and undermines the public media.

# Globalization of Organizations

Cynthia Stohl

University of California, Santa Barbara

Most generally, globalization is defined as “the widening, deepening, and speeding up of worldwide interconnectedness in all aspects of contemporary social life” (Held et al. 1999, 5). Globalization is produced and maintained through communicative action. Political, cultural, social, and economic events are no longer bound by time or space. The free flow of goods, services, money, and ideas, facilitated by emerging technologies, strongly influence and are influenced by organizational communication practices. No longer circumscribed by socio-geographic borders, organizational identities transcend nation-states. The complexity of contemporary issues such as AIDS, global warming, and

terrorism implicates organizational interdependence. No matter what their mission, structure, or physical location, all types of organizations must address the complexities of operating within a multicultural communicative, legal, moral, and social context (→ Globalization Theories).

Although the word globalization first appeared in Webster's dictionary in 1961, it was not until the mid-1990s that globalization became a noteworthy concept in organizational communication studies. Until that time, organizational communication scholars primarily addressed issues of structural convergence (exploring how organizations were becoming more similar), or organizational divergence (focusing on cultural variability) (Stohl 2001). Little work addressed the dynamic tensions associated with increasing global interdependence and volatility.

Today, organizational communication literature addresses a broader range of *organizational types* than ever before, including multinational corporations, nonprofit, nongovernmental, and governmental organizations, and international institutions. Across organizational types and sectors, the need for flexibility, responsiveness, and speed, and efficient knowledge production, reception, and diffusion have resulted in the emergence of networks as the quintessential organizational form (Monge & Fulk 1999). Globalization theories highlight networks as “the new social morphology” of society (Castells 1996).

## THEORETICAL PERSPECTIVES

The ubiquity of globalization in all aspects of life has shaped a diversity of theoretical perspectives. In one perspective, globalization is framed as the triumph of capitalism, the free market, and democracy. New communication technologies, social exchanges, and competitive markets are seen to open up organizational processes. Within this perspective, research focuses on the dynamics of globalization that explain the macro-restructuring of global sectors and the creation, maintenance, and dissolution of specific types of micro-organizational networks (e.g., Doerfel & Taylor 2004; Shumate et al. 2005).

In contrast, scholars operating within a *critical theoretical framework* (→ Critical Theory) view globalization as a transformation in labor markets, immigration patterns, and communication structures that exacerbates the distance between the “haves” and the “have nots.” The enactment of inequality (Ganesh et al. 2005), the changing nature of corporate social responsibility (May et al., in press), and concern with how marginalized groups manage/resist tensions associated with the new world order and changing social contracts are major research topics (e.g., Papa et al. 1995).

Researchers who view communication as an interpretive symbolic process approach globalization as intersubjectively constructed. In their view, globalization contributes to new formations of identities that challenge traditional definitions of who we are and what we do (→ Corporate and Organizational Identity). Globalization transforms our work and our social lives. Workplace discourses represent processes of power and control (Holmer Nadesan 2001), and the shift to network structuring is theorized to result in the weakening of social bonds and the loss of trust and commitment.

Although theoretically diverse, most organizational communication scholarship reflects the *transformationalist thesis* of globalization (Held et al. 1999). Globalization is a central driving force behind the rapid political, social, economic, and cultural changes

taking place, but the valence of these changes is indeterminate. Organizational practices and collective actions are primary means by which individuals and groups influence the trajectory of globalization. Globalization is a dialectic process (Giddens 1990); organizations adhere to their own cultural patterns but simultaneously adapt patterns and structures to accommodate differences in and pressures of the global system. Globalization may marginalize and disempower large segments of societies, but the same dynamics may redress the imbalance of power and provide new opportunities that will improve the lives of all.

## DYNAMIC PROCESSES OF GLOBALIZATION

Across theoretical perspectives there are six globalization dynamics that have important implications for the study of organizational communication. Following the discussion of Stohl (2005) we can trace many pathways where communication scholars contribute to the understanding of organizing and globalization.

*Dynamic 1: Dramatic increase in economic interdependence.* Increasing interdependence means that new forms of cooperation are being forged across local and global contexts and organizational types. Organizational networks are dynamic and flexible, no longer locally bound by sector, geography, or past relationships. New types of partnerships are being forged among corporate and public sectors, NGOs and IGOs, and nonprofit and for-profit enterprises. Intersectoral collaborations are enacted without traditional forms of trust and connectivity (Stohl & Stohl 2005), thereby opening up possibilities for entirely new forms of alliance and coalition building.

*Dynamic 2: Intensification and deepening of material, political, and cultural exchanges.* The escalation of exchange has created enormous opportunity for multicultural learning and the expansion of local diversity, while, at the same time, increasing homogeneity and cultural convergence. The consolidation of media ownership (→ Globalization of the Media), for example, is associated with global news coverage and format becoming more similar and entertainment-driven. Yet, the enormous reach, resources, and influence of these organizations may be counteracted by increased exchanges found on the web and the explosion of e-magazines, blogs, and other alternative forms of communication.

The intensification of exchanges also means that many problems can no longer be solved within one nation or sector. There has been an exponential growth in international nongovernmental and governmental organization as people strive to cope with the challenges of globalization. Moreover, the escalation of global linkages through practices such as outsourcing and offshoring has created new forms of global cities. Distance may be disappearing, but location still matters. Places like Bangalore and São Paulo are becoming sites of increased immigration, diverse work cultures, and multicultural exchanges. These environments provide greater visibility for marginalized groups and potential opportunities for international labor movements and the development of civil society (Kaldor 2003).

*Dynamic 3: Global and rapid diffusion of ideas and knowledge enabled through new information technologies.* Network flows are the core of globalized social structures enabling rapid diffusion of information and ideas. New communication technology makes traditional models of knowledge management outdated. In this “global information revolution”

(Friedman 2005), organizations and their members have the potential to exchange information in ways that were never before possible. People need not be physically co-present, and work can be dispersed geographically and temporally. As a result, models of power, privacy, and surveillance have been altered.

The widespread availability of new communication technologies also means that individuals are no longer constrained by the high transaction costs of coordination. The relative ease and low cost of communicating with large populations lead to changes in strategies and meanings of organizational membership. Whether the transformation of contemporary organizing is linked to declines, increases, or new distributions of social capital is still unresolved (Bimber et al. 2005).

*Dynamic 4: Compression of time and space.* The invention of the telegraph resulted in symbols moving independently of geography and faster than mechanical means of transportation (Carey 1989; → Telegraph, History of). The widespread diffusion of → television enabled dispersed people to experience events at the same time. No longer reliant on organizational infrastructure, today's broadening reach and increased speed of communication have produced even greater changes in the way we organize, experience, and interpret events. Non-co-located individuals are able to simultaneously interact, influence, and interpret events.

Thus, globalization not only changes what it means to be present or absent but what is considered and experienced as inside and outside, home and away, them and us. Under these conditions, organizational and personal identities become more ethereal, volatile, and problematic (→ Information and Communication Technology, Development of).

*Dynamic 5: Disembedding of events and institutions permitting new realignments and restructuring of social interaction across time and space.* Many globalization theorists note that more and more people "live in circumstances in which disembedded institutions, linking local practices with globalized social relations, organize major aspects of day-to-day life" (Giddens 1990, 26). Human interactions are "lifted out" of local contexts and repositioned within network flows, creating new linkages. Local organizations, which heretofore had primary responsibility for the inculcation of values, the establishment of civil society, the production of commercial partnerships, the education of the populace, and the development of relationships, are being replaced by distant linkage and "virtual" experience. Symbolic tokens and expert systems are able to distribute knowledge across far-flung groups of people who become connected in ways more powerful than those within their own local networks. Disembeddedness thereby contributes to the creation of new perceptions of ourselves, our organizations, and the world in which we live (Monge 1998).

*Dynamic 6: Increases in global consciousness through processes of reflexivity.* Most theories of globalization suggest that people today establish their identities and position themselves in relation to the global system, rather than to national or local sectors. Organizational choices and experiences are increasingly processed within a global perspective, challenging local cause and effect, expanding relevant stakeholders, and broadening legal and cultural constraints and opportunities. Even when individuals and groups consider themselves different from the rest of the world, they establish their position in relation to the global system, a process described as relativization (Robertson 1992). This reflexive dynamic is embodied in changes in discourses of identity and the constant re-examination of social practices in light of new identities, information, and relations.

Global reflexive processes are oppositional; a heightened appreciation of the global community is coupled with the organizing of social movements designed to counter the new world order. Organizational identifications transcend the nation and help establish an evolving global civic culture. At the same time communal identities are strengthened as people communicate inwardly, sharply distinguishing between in- and outgroups, and resist economic, social, cultural, and political integration (Castells 1996).

## FUTURE DIRECTIONS

Organizational communication scholarship and globalization theory require an understanding of past and present economic, socio-cultural, political, and organizational practices and a sensitivity to ethical and social consequences of organizational action. The complexity of the phenomenon calls for studies utilizing qualitative, ethnographic, survey, network, and parametric statistical approaches. Cross-cultural communication studies are particularly vulnerable to methodological parochialism, and it is a challenge to make sure that methods and data are comparable and appropriate across contexts. The interconnected nature of language and cultural identity highlights a methodological challenge and the significance of language in globalization studies. Understanding organizational communication will play a central role in how we address the challenges and opportunities inherent in globalization.

## Globalization Theories

*Annabelle Sreberny*

*University of London*

An interconnected set of terms – globalization, global, globality – dominated analytic discourse toward the end of the twentieth century. The considerable disagreements among theorists are set out below. Then the specific issue of cultural globalization and its debates are addressed.

### KEY DEBATES ABOUT GLOBALIZATION

One argument queried whether globalization was an *old process, or a contemporary one*. The *Communist manifesto* of 1848 (Marx & Engels 1990) put forward an analysis of the dizzying reduction of space and time and of the transnational force of capitalist processes, as the growing bourgeoisie sought raw materials and labor power in the further reaches of the European empires. Some globalization skeptics, such as Hirst and Thompson (1999), have argued that, at least in international trade, the world was more globalized toward the end of the nineteenth century than at the outset of the twenty-first (→ International Communication). The exhibition *Venice and the Islamic World, 828–1797*, organized by the Metropolitan Museum of Art, New York, and the Institut du Monde Arabe, Paris (Carboni 2007), provided vivid material evidence as to how much had been

lost in the two centuries since Napoleon's invasion of Egypt in terms of interaction and information between western Europe and the Middle East.

A second line of argument revolved around *globalization's chief components*. Social theorists agreed that it is best thought of as a skein of interlocking processes but not on what those processes might be. Appadurai (1990) developed the notion of a set of "scapes" – technoscape, ideoscape, ethnoscape, mediascape, financescape – to which further glosses included a sacriscape, a genderscape, and a linguascape. Giddens (1990) suggested that globalization involved industrialization, capitalism, the nation-state system, and technological diffusion, and that modernity's juggernaut pressed toward transnational connectivity (→ Diffusion of Information and Innovation). Held et al. (1999) suggested that four comparative spatio-temporal dimensions marked out the contemporary period: the extensity of global networks; the intensity of global interconnectedness; the velocity of global flows; and the impact propensity of global interconnectedness. Thus, globalization processes are argued to stretch political, social, and economic relations beyond clear territorial principles of organization, challenging the deeply embedded notion in the social sciences of the national society as the central unit of analysis. Yet the analytic issue remains: what is the *key* driver producing such effects?

A third line of argument hinged on *globalization's outcomes*. Many analysts saw globalization as the expansion of transnational practices, especially practices that originate with nonstate actors and cross state borders, or simply the development of global social relations. Some theorists considered the complex skeins of economic and cultural connectivity that tie different parts of the world together now constitute a new post-societal era (Urry 2000).

Some feared a homogenization of culture as western, materialist values and desires spread around the world, while others suggested hybridization to be a key process (Kraidy 2005); historicized argument recognizes that all cultures have been hybridized through time and questions the natio-centric definition of "culture" that often pertains in such arguments (→ Culture: Definitions and Concepts; Hybridity Theories). Many theorists pointed to globalization's contradictory outcomes, producing both homogenization *and* heterogenization (Hannerz), deterritorialization *and* reterritorialization (Held), fragmentation *and* integration (Rosenau).

## GLOBALITY AND GLOCALIZATION

A closely allied term was "globality," coined and defined by Robertson (1991) as the increasing awareness that the *world is, indeed, a single place*. He argued that the consequences for new claims to identity formation were among the key issues facing the twenty-first century, so that an analysis was needed of new forms of collectivity and the individual. Thus, contemporary issues such as global warming and nuclear power were seen as problems that no single state could solve but which required coordinated action across the system of states, with involvement of the global citizenry. The notion of "global civil society" itself was challenged as a chimera (Sparks 2006), while others saw it as a "multitude," embodying and coordinating a wide range of ecological, peace, and social justice movements (Hardt & Negri 2000).

Another imagining of the "global" was of *spatial connectivity*, moving into the universe from the "I" outward through the local, the national, and the regional, to the ether, the

atmosphere that we all breathe. This was powerfully invoked by Castells' (1996) notion of the Internet as a global network whose functioning at any one point in time was probably impossible to map but which potentially connected individuals to others through a variety of forms of communication, the closest humanity has come to inventing a global brain. However, with the spread of Internet connectivity, there is little use in an analytic hierarchy of space that makes the global not only the largest spatiality but also the most remote: for those with access, the global is only a click away.

Everywhere in the world is impacted by globalization processes, even if the impacts are highly differentiated. Hence, macro-level globalization processes have to be studied in specific locales as place-specific. Robertson (1991) notes that it was Japanese economists in the 1980s who coined *dochakuka*, "glocalization," for the emerging Japanese business practice in which goods and services were produced and distributed globally according to particularistic, local criteria. This argument countered fears of homogenizing processes since any ideas or values must adapt to local circumstances if they are to stick. He honed "glocalization" to mean the simultaneity of universalizing and particularizing tendencies, echoing some arguments about hybridization processes.

### CULTURAL GLOBALIZATION AND SOCIAL THEORY

Theorizing about globalization triggered significant rethinking about the foundational notion of state, nation, culture, and society as homologous, neatly bounding the same terrain. With global migrations, what constituted the "national" also became diasporic for many people. Cultural products move even more easily across state boundaries, particularly in the form of mediated content. Older terms needed re-specifying, the "international" becoming more closely linked to solely state-based relationships. "Trans" emerged as a useful prefix, with "transnational" being used for movements of peoples and things across national borders, "transcultural" suggesting personal encounters, and "translation" opening up the analysis of linguistic exchanges and adaptations. "Cosmopolitanism" was increasingly invoked as a positive embrace of global multiculturalism.

Media and communications were centrally implicated. First, communications technologies of various kinds provided the visible and invisible *skeins of connectivity* on which other processes of globalization rely (→ Technology and Globalization). Global finance became the processing of digitized information, as did the scheduling of transnational travel and the purchasing and distribution of goods. Huge data-processing industries grew in Costa Rica and India, such as call centers and data archiving.

Second, press and broadcasting remain key carriers of → *news*, and were thus powerful *socializing agents of the new globality*. Here the problematic of the unequal political economy of international communication may still have resonance, as western → media conglomerates pump out content that circulates around the world carrying images of middle-class consumption and the prejudices of western countries (→ Political Economy of the Media). Resonances with the argument about cultural imperialism are evident (→ Cultural Imperialism Theories).

Yet there were many rapidly developing media industries in the global south (Brazil, India, China, Egypt), so that media analyst Jeremy Tunstall, who in 1977 had published *The media are American*, in 2007 published *The media were American* (Tunstall 1977,

2007). Indeed, the 2000s seemed to augur the severe erosion of US cultural hegemony, challenged by the new voices in the Middle East, such as the television stations Al Jazeera (Arabic and English), Al Manar, and Al Arabiyya, along with other forces (→ Arab Satellite TV News; China Central Television Channel 9 [CCTV-9]; Francophonie; Independent Media Centers Network; Internet Law and Regulation; Korean Cultural Influence; TeleSur).

A third argument regarding cultural globalization focused on *media formats*, especially in entertainment, where a western show transmutes to suit a different cultural location. Lebanon's *Star academy* TV show kept its contestants segregated by gender, though Bahrain's version of *Big brother* was cancelled in response to clerical outrage. Such translation of formats made the world's screens perhaps more similar than was once thought, while still producing a form of mediated hybridity (Kraidy 2005).

A fourth and final argument focused on *technological convergence* through digitization, whereby the dividing lines between the media industries, telecommunications, and computerization blurred and offered novel spaces for participation. Social network sites initially popular in the mid-2000s, such as *YouTube*, *MySpace*, and *FaceBook*, became showcases for global creativity, involving millions of nonprofessional content items, as well as platforms for political commentary and satire that could evade national censorship practices. Diasporas and home populations could actually share virtual spaces for engagement and dialogue, with unknown potential for reshaping national politics, while citizen journalists and bloggers challenged mainstream media content from their own countries and beyond (→ Convergence of Media Systems; Digitization and Media Convergence).

## THE CONTRADICTIONS OF GLOBALIZATION

Yet, while some celebrated a "borderless" world, others reminded us of inequalities of gender, class, and race within the power dynamics of globalization. It was argued that the neo-liberal globalization of western consumerism and mass production had increased inequality around the world, and that World Bank and World Trade Organization (WTO) policies exacerbated global inequality. In 2007, when the first person made a million US dollars selling virtual land on the *Second life* website, nearly three billion people still lived on less than two dollars a day, and it was estimated that the GDP of the poorest 48 nations was less than the wealth of the world's three richest people combined.

Yet despite or even because of its frequent use, "globalization" as a single word became an empty signifier. It now seemed to require a qualifying term, e.g., "economic globalization" or "cultural globalization," to anchor it. Perhaps the time had arrived to no longer praise globalization but to bury it. Increasingly it was recognized that to study the processes of globalization required analysis at the local level, the "glocal" (Hemer & Tufte 2007). We might anticipate more nuanced usage of the term and recognition that even if we all share some transnational processes, we do not all feel their effects in the same way. As global social justice movements grew, critical of neo-liberal policies, so global capitalist logics in China and India rapidly produced new wealth, greater integration into the world economy, and growing internal inequality.

While the economic logic of capital is a central driving force of globalization, as Marx and Engels recognized a century and a half ago, giving the term a hostile usage, its unfolding has produced contradictory impacts and responses, not least because of the

increased visibility of global processes via communications. Further analysis of grounded real-world processes of globalization should produce more refined theorization and the repudiation of simplistic totalizations.

## **Goals, Cognitive Aspects of**

*James Price Dillard*

*Pennsylvania State University*

The term “goal” refers to a future state of affairs that a person wishes to attain or maintain. Goals prompt planning, which, in turn, serves as the basis for action. From

these simple premises, it is apparent that the core function of goals is to regulate behavior and that communicative goals and plans fall under the broader conceptual umbrella of behavioral goals and plans.

Theories that invoke the goal concept also embrace *three general principles* (Powers 1973). First, goals are arranged hierarchically and, therefore, necessarily vary in their level of abstraction. Second, regardless of hierarchical level, goal-directed behaviors are responsive to feedback concerning the discrepancy between the current and desired future states. Finally, goals are abandoned when they are achieved or when the expectation for success falls below some individually determined threshold.

### THE CONCEPT OF GOALS

A person's goals are structured in *hierarchies*. As an example of hierarchy, consider that a person who possesses the goal of maintaining good health might intend to consume fruits and vegetables, to exercise regularly, and to get periodic check-ups. Each of these aims, in turn, generates various lower-level goals: avoiding fast food, learning to cross-country ski, and making an appointment with the physician. Each of the action sequences associated with these lower-level goals can themselves be decomposed ad infinitum.

Goals also prompt action. When an action is carried out, the consequence of that action is compared to the goal. In this way, *feedback* is provided to the *cognitive system* that monitors progress toward the goal (→ Cognition). However, the fact that multiple goal-feedback cycles are occurring simultaneously at different levels in the goal hierarchy introduces a degree of complexity. To regulate behavior at any given time, the cognitive system needs to coordinate goal-feedback cycles across levels in the goal hierarchy. Difficulty arises because lower-level goal-feedback cycles occur more rapidly than higher-level goal-feedback cycles.

Coordination among the goal-feedback cycles at different levels is achieved through two means: top-down control and inhibition. One top-down process operates by activating cognitive mechanisms attuned to the goal. In the perceptual realm, this mechanism is captured by the adage, "All the hungry man sees is food." Goal-relevant information in memory also becomes more accessible once the goal is adopted. The second mechanism – inhibition – involves suppression of competing goals. This occurs by circumscribing action tendencies that might work in opposition to the prepotent goal.

Goal-based models of communication typically incorporate a comparative mechanism that assesses the discrepancy between the goal and the current state of affairs. When that discrepancy reaches zero, the goal has been achieved and no further effort is required. However, *goals may be abandoned* for reasons other than success. In particular, lowering the estimations of success may diminish motivation to achieve the goal. Such changes in likelihood often result when multiple attempts to achieve the goal are met with failure. Berger (1997) has demonstrated that our desire to conserve cognitive resources can work against the need to alter our behavior in the face of goal failure. Because of the greater effort required to change major components of the behavioral plan, individuals sometimes alter trivial elements (e.g., volume) that are unlikely to increase the efficacy of the action.

## GOALS IN ACTION

A cognitive perspective on goals emphasizes their psychological qualities insofar as they reside in individuals (→ Goals, Social Aspects of). On this basis, some writers have asserted that goals may explain action, but not interaction (e.g., Bavelas 1991). The argument is premised on the observation that individuals do not seek to attain their aims in isolation, but rather they must co-construct a conversation with another individual who surely has their own set of goals. From this perspective, then, goal-based explanations fail to illuminate communicative interaction because of their focus on the individual. They may explain monologue, but not dialogue. Such an argument makes sense only if we assume that individuals' goals remain static over the course of the conversation. Empirical research shows that this is a dubious assumption.

Waldron (1997) had dyads interact with one another for 8 minutes, after which time he separated the research participants and asked them to review a tape of their conversation. An experimenter stopped the tape every 30 seconds and participants rated the importance of five goals for the preceding time period. His analysis revealed that 30 percent of the intervals showed a significant shift in goal importance. Using a similar method, Keck & Samp (2007) found that 66 percent of the intervals in their investigation showed goal shift during a conflict interaction. The Keck & Samp study made another important contribution to research on goals by demonstrating the effect of partner behavior on individuals' goals. For example, when one person behaved in a distributive fashion, the other interactant subsequently rated their own other-identity goal as less important. In sum, just as goal-based theories of message production predict (e.g., Dillard 1990; Berger 1997), the evidence supports the notion that interlocutors adapt their goals and behavior to one another during conversation.

## GOAL FORMATION AND MULTIPLE GOALS

Cognitive models of → message production assume that individuals possess knowledge of a range of interaction goals as well as the circumstances that might facilitate or threaten goal achievement. This information is stored in → memory, where memory is modeled as an associative network (→ Memory, Message). Wilson (1995) proposes the existence of cognitive rules that link interaction goals to information about the situation that is relevant to particular goals (see also Greene 1997; Meyer 2000). Such rules are activated by a match between the situational features associated with the rule and the perceived features of the situation in which the actors find themselves. For example, a message source is likely to form the goal of "enforcing an obligation" when (1) an individual of lesser status (2) fails to perform a promised behavior that (3) has consequences for the source (Wilson 2002, 169). A goal is likely to be formed to the extent that there are more, rather than fewer, relevant features perceived to be present in the situation or, equivalently, to the degree that the circumstances *fit* the rule. In addition to the fit criterion, the likelihood that a rule will result in goal formation depends on the *strength* of the rule and the *recency* with which it has been activated. The strength of a rule can be conceived of as the degree to which the set of situational features demands a particular action.

Social interaction frequently requires interlocutors to manage *multiple goals*. Individuals are not only trying to achieve their objectives, but they may also be trying to demonstrate

respect, minimize imposition, control their anxiety, or avoid damaging the relationship. From this, it follows that coordinating multiple aims is a more challenging undertaking than the pursuit of a single objective. Indeed, there is evidence that, relative to single goals, managing multiple goals is more effortful and consumes more cognitive resources (e.g., Greene & Lindsay 1989).

## **Goals, Social Aspects of**

*James Price Dillard*

*Pennsylvania State University*

A goal-oriented perspective on communication entails the assumption that social interaction is an instrument for achieving objectives. Communication is the means by which something gets done.

Goals have several *features*. They vary in their level of abstraction (→ Goals, Cognitive Aspects of). For example, a person who is seen typing at a computer may be writing a research paper, attempting to build a case for tenure, or contributing to communication science. Individuals have the capacity to form and maintain goals at varying levels of abstraction. Goals also show variability with regard to their importance. Certain aims are crucial to life satisfaction for some individuals, whereas others might view the same objective as trivial. Third, some goals are more challenging than others. Achieving a challenging goal demands more resources from the social actor, which may take the form of time devoted to planning.

A distinction can be drawn between *primary and secondary goals* (Dillard et al. 1989). The primary goal provides the explanation for the social episode. It is the answer to the question: what are the interactants doing? Secondary goals are all of the concerns that follow from consideration of the primary goal. For example, if one individual wishes to give advice to another person, the message source may be concerned about appearing overbearing and thereby giving offense.

*Primary goals* serve two social functions. One is motivational. They lie at the beginning of the goals-plans-action sequence. Thus, they are primary in the sense that they initiate the process that results in message production. Primary goals also serve a social → meaning function. They imbue the social episode with meaning by offering a culturally viable explanation for the communicative transaction. In so doing, they also enable individuals to identify the beginning and ending points of the social episode. Segmentation is valuable for making sense of what might otherwise be viewed as an undifferentiated outpouring of behavior. Although a goals perspective assumes that primary goals have the capacity to provide social meaning, it does not claim that they invariably do so. Sometimes, individual actors have different understandings of the meaning of a particular social episode. In other instances, one party may have a secret agenda that defines the interaction for him or her, but is not shared with the other actor. Finally, the end points of a social episode may be fuzzy. On certain occasions, individuals explicitly mark the start and finish of the episode, but other times they do not.

As noted, *secondary goals* are concerns that follow from the consideration of a primary goal. One such concern is face. When a speaker wishes to know the time, she may use various linguistic constructions to lessen the threat to the hearer. "I'm sorry to bother you, but . . ." recognizes that individuals have a right to be left alone and that a request for information intrudes upon that right. By including the phrase, the speaker has crafted a message request that will not only obtain the desired information, but also will achieve the goal of respecting the other social actor. Different writers have produced different sets of secondary goals (→ Message Editing).

Berger and Kellermann (1983) specify the existence of *two meta-goals*. Efficiency can be conceptualized as the ratio of outcome to effort, where higher values indicate greater efficiency. Social appropriateness is the degree to which a behavior is suitable or fitting in a specific interaction. Meta-goals are distinct from primary goals insofar as they are cross-situational concerns that influence how a primary goal is achieved. The notion of meta-goal shifts the focus from outcome to process.

There are three ways in which *primary and secondary goals relate to one another*. In the first case, goals are incompatible. One party may wish to end a relationship, but without

inducing any negative affect in the other. Another possibility is that secondary goals are irrelevant to the primary goal. Third, primary and secondary goals may be compatible. Relational initiation offers one context in which goal compatibility might occur. The norm of reciprocity demands that individuals repay favors provided to them by others. When one person asks another for help (e.g., a ride to the grocery store) that he or she cannot immediately repay, the message source is signaling a willingness to enter into a relationship in which reciprocity will occur over a lengthier time period. Such is a defining feature of friendships. The speaker may obtain a ride and, in so doing, also enhance a budding relationship.

The third case is the most desirable of the alternatives, but it is also the least common. Most interactions are a blend of cases one and two. Because there are multiple secondary goals, it is likely that some of them create opposition to the primary goal, while others will be irrelevant. In most instances, the *set of relevant secondary goals* will constitute a counter-dynamic to the primary goal. To the extent that concern for the set outweighs the desire to achieve the primary goal (and any compatible secondary goals), the individual may view engaging the other as unduly risky and choose not to engage the other person. Knowledge of the relationship between primary and secondary goals can help explain why individuals choose to communicate or to remain silent.

## **Goffman, Erving**

*Wendy Leeds-Hurwitz*

*University of Wisconsin-Parkside*

Erving Goffman was a sociologist, but what he studied was communication. He established the “interaction order” as a legitimate topic of study; in doing so, he provided the logic for why, and the method for how, to study face-to-face behavior. People construct the social world through language and interaction, he argued, so if we are to understand the social world, we must examine the act of social construction, i.e., specific behavior. His method was careful attention to details of naturally occurring contexts of *co-presence* (when people are physically together). Interaction socially constructs meaning, even when it appears nothing noteworthy is occurring. Language and social interaction (LSI) scholars analyze the same everyday behaviors, whether or not they explicitly acknowledge Goffman’s

influence (→ Language and Social Interaction). The main strands of research in LSI today are all different ways of studying Goffman's interaction order (→ Conversation Analysis; Ethnography of Communication; Ethnomethodology; Language and Social Psychology).

Goffman was born in Manville, Alberta, Canada, in 1922. In 1945 he received his BA from the University of Toronto. He received his MA in 1949 and his PhD in 1968 from the University of Chicago. He taught at the University of California, Berkeley, from 1958 to 1968, and then at the University of Pennsylvania until his death in 1982.

Goffman was an especially graceful writer who wove together his observations (often of the Shetland Isles or St Elizabeth's Hospital) with the reports of others. His emphasis on description over theory makes his work unusually accessible. He developed extensive taxonomies for understanding the structure underlying interaction. These attributes brought his work substantial attention; his books became bestsellers during his lifetime, remaining widely read today.

His publications all explored essentially the same topic: *the social construction of the self, relationships, and social reality through language and interaction*. He always used the same method of micro-analysis (attending to details of behavior). Each work emphasized a different aspect of interaction, providing new terminology for the study of the self, relationships, and social reality.

Goffman was intensely interested in the *self* as a social product. *The presentation of self in everyday life* (1959) introduced the concept of → impression management, attending to information one participant conveys to others (Self-Presentation). He divided behavior into information one *gives* (deliberately) and *gives off* (inadvertently). He distinguished between *front stage* (where the self is visible, as in the dining room) and *back stage* (where it is hidden, as in the kitchen). The social self can be examined in a wide range of contexts. *Asylums* (1961) studied selves within a *total institution* (a place to live and work, cut off from society); *Stigma* (1963) considered the plight of someone with a *spoiled identity* (any attribute that discredits them). Goffman occasionally examined the construction of social categories (gender, race, class), as in *Gender advertisements* (1979), but the majority of his work examined the self as constructed in public, in the presence of strangers.

For Goffman, social selves were always interacting with others; relationships connected individuals to the social world. *Behavior in public places* (1963) divided contexts of *co-presence* into *gatherings* (when people are co-present, but not necessarily interacting) and *occasions* (social events having temporal and spatial boundaries, with participants likely to interact). In either, *face engagements* exist as a joint focus, such as a conversation. Any time someone wishes to hide an activity or discourage involvement, they can make use of an *involvement shield*, such as reading a newspaper; use of shields permits *civil inattention* (not paying obvious attention to others). *Encounters* (1961) emphasized *social roles* (activities required by a position): people can stay *in role* (behaving appropriately) or *break role* (behaving inappropriately). *Strategic interaction* (1969) examined the various *moves* and *styles of play* available to the *players* of the game. *Interaction ritual* (1967) examined the *rules of conduct* binding actors together, specifically, *face* (positive social value a person claims) and *facework* (actions taken to maintain face), *deference* (actions conveying appreciation of others), and *demeanor* (nonverbal behaviors conveying one's desirable qualities). *Relations in public* (1971) examined the link between relationships and public life, introducing a *single* (person alone), a *with* (person obviously with another), and *tie-signs* (evidence of

relationship). He included *remedial work* (efforts to repair interaction) such as *accounts* (explanation of what occurred); he discussed *social identities* (membership in categories, including age, race, gender), and their associated *social norms, rules, and interpersonal rituals*.

Goffman also examined the construction of social reality more generally (→ Constructivism). First, he proposed three metaphors for understanding interaction: theatre, ritual, and game. These thread through various books; the major statement of life as theatre can be found in *The presentation of self*, life as ritual in *Interaction ritual*, and life as game in *Encounters*. The theatre metaphor is widely studied in communication as “dramaturgical theory.” Second, he analyzed how interaction rules create reality. *Encounters* distinguished between *focused interaction* (when people cooperate to sustain a focus of attention, as in conversation) and *unfocused interaction* (when people glean information through observation, as in noticing a stranger’s clothes). Because social rules are easily broken, our sense of reality can be easily shattered. Finally, he studied the *frames* (contexts within which language and behavior are understood) used to make sense of behavior. In *Frame analysis* (1974), his focus was on *keying* (the way in which a frame can be reinterpreted) and *strips* (a piece of the stream of behavior). In *Forms of talk* (1981) he introduced *response cries* (interjections, like “oops!”) and *footing* (participants’ alignment). Talk was always one of Goffman’s topics, for he took conversation to be the central act of communication; it was most clearly the focus in this, his final, book.

# Government Speech, Law and Policy on

*Kevin R. Kemper*

*University of Arizona*

Governments, by the nature of their functions and purposes, communicate with people inside and outside of their jurisdictions. This process may be called “government speech.” The “law and policy of government speech” in different countries typically depends upon the nature and type of each government and how much that government controls its press systems. Globalization and related changes to governments more and more influence how those laws and policies are shaped (→ Globalization Theories). Whereas the press during the twentieth century, particularly in the United States, was a “primary conduit for information” about government to the people, governments now regularly use media in alternative conduits to exert control over that information, with negative implications for democracy, as Braman and Nerone (1995, 162–176) have argued (→ Political Communication Systems).

The law and policy of government speech for a particular nation may in fact be defined by the limits that nation puts on the government for communication. “Government speech” is viewed in the context of the transition to democracy by numerous countries around the world. Fundamentally, the issue revolves around the limits on expression a constituency can put upon its own government. Government speech can at times be → propaganda, which has a more negative connotation than simple → persuasion.

And some governments – including the US government – explicitly have had checks and balances to minimize the propagation of propaganda to its own people. Legal issues arise, including the extent to which a country’s government can propagandize to its own people; the ability of a ruling party to do this may keep minority parties and other voices from being heard, and thus undermine democracy. While the particular nuances of government speech in US law may provide a template for discussion, each country in the world has unique characteristics in how it handles legally the issue of whether and how to control government speech.

## GOVERNMENT SPEECH IN THE UNITED STATES

Historically, the United States has provided checks and balances on its own speech. The Smith-Mundt Act (1948), for instance, has forbidden domestic propagandizing, though such restrictions might undermine the free “flow of information.”

Recent decisions by the US Supreme Court have given the federal government more latitude to express itself to its own citizens. And common practice is for the US government to fund a multitude of expressions like art, music, and broadcasting. But the Court also has narrowed the expressive rights of government employees. Generally, government speech in the United States has been addressed in a series of cases since *Rust v. Sullivan* (1991), when the US Supreme Court held that the prohibition on government funding of communication about abortion does not violate the First Amendment rights of those communicating about abortion. The Court reasoned that the federal government can hold and communicate a particular viewpoint, if Congress has approved that

viewpoint and its communication. In *Johanns v. Livestock Marketing Association* (2005), the US Supreme Court held that the funding of particular advertising by the federal government “was ‘government speech,’ not susceptible to First Amendment compelled-subsidy challenge.” The Court reasoned that, since Congress chose to fund the promotion of beef and related products as part of the political process and thus “subject to democratic accountability,” and since the government speech was not attributed to the respondents, the respondents’ First Amendment rights were not violated (→ Freedom of Communication).

The United States now has narrowed the free expression rights of government employees in particular circumstances, placing upon them the government’s controls if they speak as part of that government, even while criticizing it. In 2006, the US Supreme Court in *Garcetti v. Ceballos* used a two-part test from earlier cases to hold that the government could restrict the speech of one of its employees – despite First Amendment’s general guarantees of freedom of expression for even government employees – if the employee did not speak “as a citizen on a matter of public concern” and if the government had “an adequate justification for treating the employee differently from any other member of the general public.” The Court also said, “So long as employees are speaking as citizens about matters of public concern, they must face only those speech restrictions that are necessary for their employers to operate efficiently and effectively.” This appears to mean that government employees, speaking as government employees, have slightly diminished First Amendment rights and thus can be punished by the government if they express themselves in a way that undermines certain government purposes.

Thus, the US Supreme Court has established a precedent that government speech – as long as Congress has decided through the political process to fund or express that speech – does not violate the First Amendment rights of US citizens who may disagree. This has caused concern among scholars, who argue that the overwhelming power of the government could subsume other parties and violate constitutional rights.

## **GOVERNMENT SPEECH BY INDIGENOUS TRIBES IN THE UNITED STATES**

Indigenous tribes in the United States provide concrete examples of governments adopting policies of controlling the media to accomplish what they view as for the good of the tribes. This has raised concerns, though, about whether such controls violate the rights of freedom of expression for tribal citizens and for the tribal government employees who function as journalists, especially when those media outlets are owned and operated by those tribal governments.

Tribes in the United States are considered to be “domestic-dependent nations,” having at least some measure of sovereignty. The US Congress in 1968 guaranteed free expression rights for tribal members in the Indian Civil Rights Act, but the US Supreme Court in *Santa Clara Pueblo v. Martinez* (1978) held that tribes have the obligations to enforce those provisions. Thus, tribes may well decide to assert their own rights of government speech to control the expressions of others. This would be theoretically consistent with the US Supreme Court holdings that allow the federal government’s democratic decisions to fund certain speech, despite the claims by individuals and groups that such speech undermines their own expressive rights (→ United States of America: Media System).

## **GOVERNMENT SPEECH IN AUSTRALIA**

The High Court of Australia recently touched upon its law and policy of government speech in a case about whether the federal government had the necessary authority to pay for a nearly \$4 million advertising campaign to push reforms of industrial relations in Australia. In *Combet & Anor v. Commonwealth of Australia & Ors* (2005), the High Court held that the expenditure was indeed appropriate under constitutional taxation and spending provisions, and did not reach the question of whether the Australian government had the authority to engage in such blatant propaganda to its own people.

The *Combet* Court instead considered issues of efficacy, or whether the particular advertising campaign achieved its intended effects, which were argued to be necessary to justify the public expenditure. Justice McHugh argued that the advertising should have a “rational outcome,” or some measure of efficacy. The plaintiffs in the case had argued that the expenditure should have been authorized by Parliament, rather than by the administration of Prime Minister John Howard.

Though the case focused upon the power of expenditure of Parliament, some have voiced a common concern that government speech needs to have checks and balances. A minority opinion by Justice Kirby cited the US Supreme Court’s opinion in *Johanns* and a quotation from President Thomas Jefferson, who had said that “to compel a man to furnish contributions of money for the propagation of opinions which he disbelieves, is sinful and tyrannical” (→ Australia: Media System).

## **GOVERNMENT SPEECH IN CHINA**

In China, the state views itself as the nexus for speech. Article 35 of the Constitution of the People’s Republic of China (1982) guarantees freedom of press and speech, but Article 22 asserts the government as the primary impetus for “the development of literature and art, the press, broadcasting and television undertakings, publishing and distribution services, libraries, museums, cultural centres and other cultural undertakings, that serve the people and socialism, and sponsor mass cultural activities.” Chan and Qiu (2002, 36) note how this state control of expression has liberalized more and more because of “commercialization, improvisation, bureaucratization, internationalization, and technologicalization.” But this does not necessarily mean that China is adopting a libertarian model of the press.

In China, the state owns the media, but the media also are commercial. The Central Propaganda Department of the Communist Party controls the content and functions of all traditional media at all levels. Thus, there is no separation of press and state. Any speech is supposed to be government speech, under the Constitution and related statutes and cases. For instance, newspapers must “propagate the path and policies of the Chinese Communist Party and the People’s Republic of China,” according to one national statute (→ China: Media System).

## **THE CASE OF RWANDA**

An egregious example of government speech out of control is the role of a former Rwandan government’s use of the mass media to espouse hate speech and genocide

(→ Hate Speech and Ethnophaulisms). Former Rwandan radio and newspaper executives Ferdinand Nahimana, Jean-Bosco Barayagwiza, and Hassan Ngeze – each with personal and professional connections to the former Rwandan government of President Juvenal Habyarimana – were appealing in 2006 their 2003 convictions of various crimes against humanity by a United Nations war crimes tribunal, the first such convictions of media personnel since Julius Streicher’s conviction and execution in 1946 for his role as a newspaper editor in promoting the genocide of Jews and others in Nazi Germany during the early twentieth century.

The International Criminal Tribunal for Rwanda noted that the president and the ruling party at the time primarily owned Radio-Television Libre des Mille Collines – the main tool of Nahimana, Barayagwiza, and Ngeze for promoting genocide (→ Africa: Media Systems).

# Graffiti

Jeff Ferrell

*Texas Christian University*

Broadly speaking, graffiti denotes the array of words, figures, and symbols illicitly inscribed in public space. Over the past three decades this phenomenon has taken on special salience as the graffiti of youth sub-cultures has emerged as a pervasive form of public communication. Because of this, graffiti has become perhaps the most potent and visible symbol of delinquency and danger, with political authorities and the public regularly associating public graffiti with gang activity. In reality, the contemporary role of graffiti as a form of public communication, and as a communicative component within youthful sub-cultures, is far more complex than a simple equating of graffiti and gangs (→ Popular Communication).

Throughout the United States, Canada, Europe, and beyond, the most prominent and publicly visible form of contemporary graffiti is in fact not gang graffiti, but *hip hop graffiti*. Hip hop graffiti developed during the 1970s in the United States as a component of a larger hip hop youth scene that also incorporated rap music, break dancing, and other cultural innovations. As street-level alternatives to gang life and gang conflict, hip hop music, dance, and graffiti offered new media for contesting identity and acquiring status (→ Youth Culture). Then as now, hip hop graffiti “writers” and their “crews” wrote their “tags” (nicknames) in places of public visibility, and painted elaborate public “pieces” (murals), as markers of artistic innovation and sub-cultural “fame.” In this way hip hop graffiti came to operate as a stylized form of ongoing public communication, with writers employing graffiti to offer aesthetic challenges to other writers, to inscribe artistic declarations and manifestos, and to comment on the merits of existing graffiti (Cooper & Chalfant 1984; Ferrell 1996).

As hip hop graffiti has spread to Europe, Australia, and elsewhere (Chalfant & Prigoff 1987), its initial communicative dynamics have also continued to develop. Along with spray paint cans and ink markers, writers now utilize etching tools, stickers, and computer-generated images. They “tag the heavens” atop roofs and freeway overpasses to gain public visibility and to demonstrate sub-cultural commitment. Once attempting to “go citywide” with their tags and pieces, writers now “go nationwide” by tagging and piecing outbound freight trains, and “go worldwide” through hip hop graffiti websites and magazines (Snyder 2006). Increasingly functioning as the folk artists of ethnic minority communities, they also paint signs for local businesses and design “rest in piece” memorials for the departed.

*Gang graffiti* functions as a different medium of public communication, as youth gangs utilize graffiti to define membership status, demarcate contested space, and issue symbolic threat. Latino/Latina gangs, for example, often inscribe barrio walls with *placas* – stylized insignia that define gang and barrio boundaries, symbolize the collective presence of the gang, and warn away potential intruders. While such gang graffiti certainly signifies some sense of trouble or threat, it also references historical traditions of public communication and mural painting, and so signifies a sense of community solidarity and ethnic pride.

For other Latino/Latina and African American gangs, graffiti functions as a more direct demarcation of gang influence and power, and as a street-level advertisement of a gang's economic or territorial domination (Phillips 1999). Here the writing of a gang's graffiti is complemented by the symbolic degradation of rival gangs through coded threats or the "crossing out" of rival gang graffiti. Such symbolic provocations can invite physical violence – yet they can also displace the need for physical confrontation by demarcating urban space and setting cultural and territorial boundaries. The graffiti of skinheads and neo-Nazi youth, in contrast, seems clearly designed to communicate terror and threat while accompanying campaigns of physical violence against gays and lesbians, immigrants, and others.

The pervasive public visibility of hip hop and gang graffiti over the past three decades has spawned a variety of equally high-profile "anti-graffiti campaigns" or "wars on graffiti." Themselves exercises in carefully crafted public communication, anti-graffiti campaigns have been beset in particular by their persistent inability (and unwillingness) to distinguish hip hop graffiti from gang graffiti – or more specifically, their insistent definition of all graffiti as gang graffiti. Relatedly, these campaigns regularly propose that graffiti offers only a single public meaning: generalized threat and insecurity. This proposition not only misses the different meanings of hip hop graffiti and gang graffiti; it fails to note the multiple meanings that are negotiated *within* each of these graffiti types.

Two further developments reflect the persistent visibility of graffiti and the campaigns against it. First, anti-graffiti campaigns have often amplified the very phenomenon they have sought to suppress. For many hip hop graffiti writers, anti-graffiti campaigns have enhanced the public notoriety and illicit excitement of graffiti writing, and have pushed them toward greater anti-authoritarian militancy. The use of highly visible campaigns to police a highly visible form of youthful communication has also served to make graffiti increasingly prominent, and so to recruit new graffiti practitioners and to spread graffiti farther still beyond its origins (Ferrell 1996). Second, global corporations and their advertising agencies also have noted this proliferation of public graffiti – and in response have increasingly appropriated graffiti into clothing lines, CD covers, and advertising schemes in an effort to cash in on its illicit credibility (Alvelos 2004).

# Graphic Design

*Matthew Soar*

*Concordia University*

“Graphic design” refers, in essence, to the artful arrangement of images and text on a variety of surfaces and in a range of forms. Typical pieces of graphic design include: posters; → books; CD, DVD, and book covers; brochures and flyers; → magazines and → newspapers; logos, trademarks, → branding and corporate identity systems; product packaging; annual reports; T-shirts; signage and way-finding systems; websites; and motion graphics (e.g., film title sequences, TV station identifiers, and promos). Related and sometimes overlapping activities include product design, exhibition and information design, type design and → typography, and design for interactivity (websites, kiosks, DVD-ROMs; → Design; Interactivity, Concept of).

Graphic designers might work individually, or in small-to-medium-sized studio partnerships, or in service-oriented departments within larger organizations, in sectors such as book publishing, the music industry, highways departments, computer software, or pharmaceuticals. Apart from their applied creative role, designers may have other duties: commissioning and overseeing printing, liaising with clients, or developing strategic plans for business, branding, or marketing plans.

Graphic design is an increasingly *professionalized practice*, with associations in many countries, such as D&AD (the Designers and Art Directors Association) in the UK, the AIGA (American Institute of Graphic Arts), the SGDC (Society of Graphic Designers of Canada), and the SDGQ (Société des designers graphiques du Québec). The International Council of Graphic Design Associations (ICOGRADA) currently represents the interests of nearly 100 such entities in nearly 50 countries around the world. These associations cover only a fraction of those involved in the panoply of professional, trade, and artisanal practices that together constitute graphic design.

Despite these developments, the *term* “*graphic design*” has yet to receive broad acceptance and understanding beyond the confines of this emergent profession. As Mildred Friedman noted during her tenure as design curator at the Walker Art Center in Minneapolis: “graphic design has played a key role in the appearance of almost all print, film, and electronic media, as well as architectural and urban signage. Today it literally dominates our visual environment. Yet . . . there is only nominal acknowledgement of the significance of this least recognized visual art form” (Friedman et al. 1989, 9–10).

## HISTORY

The terms “graphic design” and “graphic designer” are widely believed to have first appeared in print in the US as recently as 1922, in an article titled “New kind of printing calls for new design” (Dwiggins 1999). That said, the word “designer” – although somewhat undefined – appears in documentation produced by the US Bureau of the Census “as early as 1890” (Thomson 1997, 10).

Regardless, the roots of graphic design are both broad and complex. Influences and precursors in Europe and North America include: the creation of → propaganda posters

during two world wars; commercial art; and various art movements and schools, including Futurism, → Constructivism, Arts and Crafts, the Secessionists, DADA, Bauhaus, and De Stijl (Hollis 1994; Meggs 1998; Weill 2004). The “ukiyo-e” movement was singularly influential in the development of graphic design practice in Japan, given that country’s extended cultural isolation until the nineteenth century (Meggs 1998; Weill 2004).

Some commentators have located the origins of graphic design in the prehistoric cave paintings of Lascau, France (Meggs 1998); in the development of the art poster and its associated printing technologies in Europe in the early 1900s (Hollis 1994); and in the emergence of printing and allied trade practices in the US in the mid- to late 1800s (Thomson 1997; → Poster; Printing, History of). Accounts such as these are sometimes marred by a singular identification with the careers of “great men,” great works, sweeping chronologies, or the triumphs of technology.

The history of graphic design is inevitably bound up in the development of printing, photographic, and typographic technologies (Thomson 1997). As Thomson notes:

Technological advances in printing type and reproducing imagery were part of a larger development. The mechanization of paper manufacturing and printing, the invention and improvement of the rotary press, advances in ink chemistry, the use of wood pulp to replace rag in paper, at least partially, and the introduction of wood engraving occurred in the first half of the nineteenth century. At the end of the century the relation between design and production was recast. For the first time, letters and pictures, text and image, could be printed together. (1997, 12)

## GRAPHIC DESIGN, ART, AND COMMUNICATION STUDIES

Graphic designers have often complained that, in spite of the ubiquity of their work, the profession is rarely identified by name in popular cultural discourse. Similarly, graphic design has been addressed only fleetingly, and often anonymously, in the communication literature. One exception is Dick Hebdige’s discussion of the *Face* magazine (Hebdige 1988). That said, graphic design has been *used* in highly memorable ways in the communication literature, as in *The medium is the message* (McLuhan & Fiore 1967), a collaboration between Marshall McLuhan and the designer Quentin Fiore. Formal encounters between graphic design and communication theory have been rare. An early exemplar was the appearance of C. Wright Mills at the International Design Conference in Aspen (IDCA), where he gave a talk titled “Man in the middle: The designer” (Mills 1963). The IDCA, which still runs annually, has at times provided a novel, if somewhat elitist, forum for the discussion of issues rarely voiced in the day-to-day practices of architectural design, industrial or product design, and graphic design (see Banham 1974). Mills’s essay brought an early, and much-needed *sociological eye* to the activities of designers, and also anticipated Pierre Bourdieu’s notion of the cultural intermediary: an individual whose function is to provide a bridge, or *liaison*, between two distinct worlds that can be variously labeled production and consumption, or manufacture and distribution, or commerce and culture (Bourdieu 1984; Nixon 2002).

More recently, *art historical scholarship* has highlighted the formative tensions associated with the movement of trained artists into an emergent commercial design sphere. The

contradictions and conflicts inherent in these dynamics are neatly captured in Michele Bogart's phrase "art for publicity" (Bogart 1995, 4): the continual attempt to meld a highly personal mode of expression with the broader needs of sales and marketing (→ Art as Communication). Patricia Johnston's *Real fantasies: Edward Steichen's advertising photography* (Johnston 1997) focuses on one artist in particular: Steichen was extraordinarily successful in adapting his skills to the needs of commerce. If he initially had difficulties reconciling the ethical implications of this relationship, Steichen still ended up making his name (and his fortune) out of it.

The development of graphic *design as a distinct practice*, and in relation to the principles and priorities of Modernism, has been explored extensively in Allen (1983), Friedman et al. (1989), Meggs (1998), Jobling and Crowley (1996), and Margolin (1997). Among the major institutions referenced in these studies are the Bauhaus, the New Bauhaus Chicago (ultimately renamed the Institute of Design), and the International Design Conference in Aspen (Banham 1974).

A connection is often made in these historical studies between the activities of artists, illustrators, photographers, art directors, industrial designers, and graphic designers and visions of social, cultural, and political change. Indeed, idealistic sentiments and utopian urges perhaps find their most intense realization at these "borders of art" (Bogart 1995). Jobling and Crowley contend that:

[t]he expression of such aspirations for the future implied a messianic role for the modern designer to prefigure a better world where visual communication would enlighten rather than simply reproduce the prevailing taste, attitudes and conditions of the day. Graphic design would, in [Bauhaus designer László] Moholy-Nagy's words, be "part of the foundation on which the *new world* will be built." (1996, 143–144)

Some of these studies stress the erosion of the political tenets of modernist art and design as the movement gradually migrated from Europe to the United States (Wild 1989). This appears to have been located less in the specifics of graphic form or appearance than in formative impulses and underlying intent. Indeed, it is perhaps a peculiarity of graphic design that slippages of this nature routinely occur; that one can easily mimic a particular radical aesthetic without any recourse to the political or cultural moment that generated it – and often for the most mundane or normative of purposes.

## **DISCOURSE OF GRAPHIC DESIGN PRACTICE**

The discourse of graphic design practice is overwhelmingly celebratory, promotional, and technique-oriented; the trade literature far outweighs the available avenues for more reflective, critical perspectives. That said, newer, more supple approaches to history and criticism are also reflected in recent writing and scholarship about graphic design (see, for example, Blauvelt 1994/1995). In addition, the commercial and corporate investments of the profession periodically come under attack from designers themselves. The two iterations of the *First Things First Manifesto* (in 1967 and 1999) are a case in point (Soar 2002). In this instance, a group of influential designers and design writers produced a short polemic excoriating the profession for its narrowly conceived vision of design as a commercial (and often highly trivial) practice. The fallout was inevitably divisive: arguments ensued over the true role of graphic design, a perception that the signatories were simply exploiting

their position of privilege, and the connotations of professionalism. Regardless, some graphic designers continue to use their skills to draw attention to specific political, social, and cultural issues, or to produce independent work on a variety of highly personal themes (→ Activist Media).

Key here has been longstanding arguments about what graphic design *should be used for*. In the 1930s, Otto Neurath introduced ISOTYPE (International System of Typographic Picture Education), a highly formalized graphic method for presenting complex statistical information using only pictorial icons. The system was used to present comparative information on child mortality and unemployment rates, standards of living and factory productivity. This approach has been highly influential in the development of information graphics, international signage systems, and computer icons (→ Infographics).

The general theme of social engagement is not a consistent aspect of graphic design. Paul Rand, for example, was an iconic designer responsible for developing logos for IBM, UPS, NeXT Computer, and Enron (→ Trademarks in the Media). For Rand, and for many of his contemporaries, design professionalism meant honoring the communicative aspirations of the corporations for whom he worked (→ Corporate Design; Brands). Questions about, say, ethical standards or environmental records were beyond the scope of the designer's role. A rising skepticism about this narrow approach has most recently been fueled by critiques such as journalist Naomi Klein's book *No logo* (2000).

Unlike the historically related practice of advertising art direction (→ Advertising), it is evident that graphic design has a demonstrably broad range of potential cultural and political commitments: while it is also intrinsically about information and persuasion, what we now call graphic design has long been used as a form of personal and political expression in, for example, the protest posters of John Heartfield, Grapus, and Gran Fury, and the recent rise of culture jamming (see McQuiston 1993). Through its ad spoofs and activist campaigns, the Canadian magazine *Adbusters* has championed culture jamming as a kind of visually oriented form of dissent; more importantly, it has recently targeted graphic designers and ad creatives as the avant-garde in a culture jamming revolution. While perhaps an exercise in hyperbole, this perspective underscores the ubiquitous if generally unacknowledged role of graphic design in commercial or consumer culture.

Graphic designers have occasionally developed *niche activities* that draw on their understanding of the relationship between text and image, but which are not static or print-oriented. One such example is "motion graphics," a broad term encompassing film title design, broadcast graphics, and computer animation (→ Digital Imagery). A celebrated moment in this realm is the work of Saul Bass, a graphic designer who developed film title sequences for Alfred Hitchcock, among others.

Graphic design practice has changed markedly with the emergence and take-up of digital media production tools. For example, the task of preparing finished concepts for print has been greatly simplified, both for the designer, who used to have to create accurate artwork "mechanicals," and for the printer, who would typically have an entire department set aside for "prepress": the process of taking the artwork and preparing it for proofing and printing. The emergence of the world wide web has required the development of new skill sets focused on programming, interactivity, and the design of user interfaces (→ Digital Media, History of).

## Grassroots Media

*Lisa Brooten*

*Southern Illinois University Carbondale*

Grassroots media are small-scale, developed by and accessible to members of a local community or group, and conceptualized as a key tool in the process of social change (→ Community Media). They have developed out of concerns with problematic representations of women and other marginalized peoples in mainstream media, as well as limited → access to the media and political participation for marginalized groups, especially women, around the world. Women’s movements worldwide have thus worked to develop grassroots media that are conceptualized and based locally and that operate very differently from mainstream commercial or state-run media. The goals of feminist grassroots media are varied, but generally involve the desire to strengthen the self-confidence of women and other marginalized peoples, and to empower them to challenge, change, and take charge of the media and their representations. Another increasing concern encouraging the development of grassroots media in the era of global capital is the protection and preservation of local cultures and cultural diversity.

### GOALS

Grassroots media have resulted from a vibrant history of struggle and research on gender and communication, focusing on representations of women and marginalized peoples in mainstream media and on women’s access to media. In Beijing in 1995, the media were included for the first time in the history of UN women’s conferences as a separate area of analysis, especially due to this history of concerns over lack of access to media and over mainstream media representations (Pandian 1999). Research has shown that there has been little improvement in recent years in the quality or quantity of news and information about women in the world’s news media, and that when such news does appear, portrayals of women are sexual in nature, focus on their victimization, or are confined to the private sphere (Gallagher 2005; Pandian 1999; → Sexualization in the Media; Women in the Media, Images of). In addition, feminists have continued to question the relevance of mainstream media content to the lives of women, arguing that it lacks useful information about women’s rights or the significant problems they face in their lives.

One result of these critiques has been the development of grassroots media that involve women and other marginalized peoples as central to their production. This is especially important as research on media and social change has led to the recognition that social change does not occur merely through the provision or diffusion of information via official or mainstream media channels. Social change, including processes of democratic decision-making, is best served through a variety of media, especially grassroots, participatory media that work to stimulate dialogue at the local level and to shift conceptualizations of power through empowering people at the grassroots (→ Social Mobilization; Planned Social Change through Communication). These shifting conceptualizations of power include the recognition of women and other marginalized peoples as significant social actors whose communication experiences and ways of communicating are varied, but always rooted in their daily experiences within specific social environments. These differences, therefore, must be recognized and heard in order to democratize the circulation of ideas and redistribution of power (Riaño 1994).

### PRINCIPLES OF ORGANIZATION

The emphasis in grassroots media on bottom-up or lateral forms of communication and social change developed from a typology of women's participation in communication and social change, described by Riaño (1994) in *Women in grassroots communication: Furthering social change*. The history of these developments begins with top-down forms of → *development communications*, generally originating outside the control of the community and aimed at mobilizing a community to change their behavior. Such projects have been seen as one of the most serious obstacles to the development of grassroots media, as a result of their top-down nature. They have been critiqued for their conceptualization of the local community as subjects to be mobilized by outsiders in processes in which participation is understood as acceptance of the message and the proposed set of corrective actions. The primary aim of such projects is not to empower the community to control the projects themselves or to question the hierarchical position of the sender and receiver of media messages.

This model was followed by conceptualizations of *participation as development*, in which women are understood to be participants in a two-way interaction that is still primarily controlled by the information source (→ Participatory Communication). This model does not recognize differences in power and access to resources, on both personal and societal levels, that make it difficult for people to participate as equals. Projects conducted using this approach can result in unequal distribution of resources, prompting the question of who ultimately benefits.

Arising out of the critiques of development communications and participation for development approaches to media use have been *alternative communication* models that encourage participation for social change, promoting a more horizontal communication model in which women at the local level conceptualize and develop their own media uses and define for themselves the social change they are working toward. This model encompasses forms of popular communication, including community media, group media, grassroots media, and → "citizens' media" (Rodriguez 2001), which are owned

and operated by nonprofessionals, and emphasize access to and participation in the production of media (Riaño 1994; → Citizen Journalism).

## **WOMEN'S GRASSROOTS MEDIA**

The trajectory of research and experience that moved conceptions of media use from more top-down development communication models to alternative, community-based models of media nevertheless did not consider gender as part of the analytical framework (→ Development Discourse). The ways in which gender influences participation in media production or mediates experiences of subordination for men and women were not considered in these models (Riaño 1994). As a result, feminist communication research began including a gender perspective in these analyses, conceptualizing women as active subjects of struggle.

Women's grassroots media movements have shifted over time. Critiques of second wave feminism found fault with its problematic, essentialist notion of global sisterhood in which all women were assumed to share the concerns of white, professional-class western feminists whose goal was to gain legal equality with men through the integration of women into the patriarchal → public sphere. These efforts corresponded to conceptualizations of the relevance and success of alternative media in terms of the extent to which they challenged or changed the messages or structures of mainstream media (→ Feminist Media Studies, Transnational). Feminism's "third wave" shifted focus from an essentialist understanding of women to a recognition of the need to embrace multiple identities, tactics, and causes. This led to the awareness of the impact of differences among women based on race, class, sexual orientation, and geographical location, and that everyone's different experiences of oppression affect their communicative interactions with others. The resultant emphasis on building solidarity across differences globally has occurred alongside shifts in structure from traditional social movements to new social movements, which are more loosely constructed and fragmented than earlier, more centralized structures, and to conceptualizations of grassroots media as key to the process of media democratization.

Many of these changes in theorizing communication and media have occurred in response to shifting conceptualizations of power, from a binary conception of the powerful and the powerless to more complex models of power as contextual, contested, and continually shifting. These more complex models conceptualize the individual as having multiple and shifting identities and degrees of power, depending on context. This view understands individuals as creating power by taking a stand when they engage in actions that shape and reshape their environments, rather than as passive recipients of rights provided and protected by the state. This model of power widens conceptions of political action to include efforts toward social change made in the quiet events of everyday life, a conceptual move that blurs the traditional public/private divide that has centrally concerned feminists.

Another fundamental shift in thinking about these issues is related to feminist critiques of the public sphere as conceptualized by → Jürgen Habermas. Feminists have critiqued the assumption that everyone can equally participate in the public sphere, arguing that such an assumption denies inequalities and differences and acts to strengthen patriarchal

hegemony in the public sphere. For example, Nancy Fraser (1992) has problematized the Habermasian notion of the public sphere. Her conceptualization of multiple public spheres and counter-publics provides a theoretical framework for understanding feminist grassroots media and how they interact with more traditional media and political structures to enact social change (→ Public Sphere, Fragmentation of).

A central contribution of women's grassroots media projects around the world has been the recognition that differences of race, class, gender, geographical location, and sexual orientation must be acknowledged in order to bring about individual and collective transformation. This has led to women's grassroots media movements around the world that are challenging existing hierarchies of power by foregrounding voices unheard in mainstream media, by providing women with access to resources, and by working to develop collective, consensus-based, and nonhierarchical → organizational structures.

### **PARTICIPATION AND OBSERVATION**

A major focus of grassroots media projects is their attention to process, where the emphasis is on marginalized people learning by doing through a process intended to be empowering to the community or the group involved. And yet this empowerment is arguably not the end stage of grassroots media production processes, which often give rise to complex new problems as the empowerment of previously marginalized peoples challenges existing power structures. The focus on process over product in grassroots media has included a challenge to the concept of objectivity and its tendency to dehumanize media representations, the blurring of the producer/audience dichotomy, the promotion of personal testimonials as valuable media content, and the recognition of indigenous knowledge as valuable (Cottingham 1989; Crafton Smith 1989; Riaño 1994; Sreberny-Mohammadi 1996; Werden 1996).

Grassroots media have incorporated participatory research methodologies as a means of involving women and other marginalized peoples in the process of identifying specific problems and coming up with possible solutions (→ Participatory Action Research). Media messages produced using participatory research methods involve collective processes in both the discussions that lead to problem identification and the collective production of media to address or solve problems at the community level. Grassroots media also promote participation in that they work to demystify the processes of production through training and skill-sharing workshops, so that the technologies become accessible to those who would otherwise not have access, including the illiterate. In just one example of many, grassroots video production has been very successful in the efforts of women, many of them illiterate, to increase their skills and advocate their rights. Producing → community videos has led women to develop themes centering on practical problems in their productions, which have then been used to influence policymakers.

### **PROSPECTS**

While research on grassroots media has demonstrated its usefulness for empowerment and individual and community identity-building, years of grassroots media activism do

not seem to have produced much noticeable change in regional or national communications policies, especially in the global south (Pandian 1999). Gender issues generally remain off the radar of mainstream media as well as the agendas of media policymakers globally. This includes development news, which remains a focus of much of the mainstream media in the global south and which does not often challenge the patriarchal attitudes of societies. The increasing privatization of media worldwide has not helped in this regard, either, as with increased privatization, the nation becomes less accountable to the concerns of its women regarding media (Pandian 1999). In addition, regional and national cultural differences regarding what kind of media content is seen as “decent” or “sexist” make it difficult to draft international or even regional codes of media conduct (→ Sexism in the Media). Nevertheless, the power of grassroots media to transform individuals and communities and challenge power structures continues to encourage the development of new grassroots media projects globally, as well as research on their impact in the age of globalization and → commercialization of the media (→ Globalization of the Media).

# Grounded Theory

*Bertram Scheufele*

*University of Jena*

In its original sense “grounded theory” stands for a methodology, research program, and method of qualitative research. In a narrower but also more practical sense the term describes a qualitative technique of text analysis comparable to qualitative content analysis (→ Content Analysis, Qualitative) and → discourse analysis. Barney Glaser and Anselm Strauss introduced grounded theory as a general research program for developing substantial (specific) or formal (general) theory by starting without (too) many assumptions and working immediately with the “data” (mostly text material) – this is what the term “grounded” refers to (→ Qualitative Methodology).

## BASIC ELEMENTS OF GROUNDED THEORY

Three observations are important to understand grounded theory adequately. First, several misunderstandings stem from the fact that the approach uses terms known from quantitative research in a totally different way. For instance, its authors speak of “data” not in the sense of a quantitative dataset, but in the sense of text (→ Text and Intertextuality) and even any material (“all is data”). Or authors speak of → coding not in the sense of measuring quantitatively but in the sense of summarizing and structuring, e.g., interview transcripts.

Second, Glaser and Strauss have walked different paths since their collaboration and their seminal book, published in 1967. Glaser still favors a strategy of strict induction and emergence – one might call this the “conservative” position of grounded theory. Strauss, however, favors a more “progressive” and practical position. Together with Juliet Corbin, he established grounded theory as a qualitative but nonetheless quite systematic method, e.g., for analyzing media coverage, interview transcripts, protocols of observations, and other material for the purpose of generating theory. Finally, grounded theory is a method of text analysis like qualitative content analysis or discourse analysis, but goes beyond these techniques since it also includes methodological aspects and a micro-sociological action theory. This becomes obvious, e.g., with the coding paradigm in the Strauss version of the approach.

As mentioned already, grounded theory aims at *generating theory from data*, i.e., mostly from text material such as observational protocols or transcripts of qualitative → interviews.

The discovery of a grounded, data-based theory comprises concepts and relations between them (e.g., causes of social action) in a set of hypotheses for a specific sector of reality. But the so-called substantive grounded theory generated by this is just a first step toward a formal grounded theory, the hypotheses of which claim to be general rules.

The crucial procedure of the approach is called “coding.” Here, one retrieves theoretical concepts (codes) from the text material (data) and provides examples (indicators) also from the text material. These provisional codes as well as indicators are continuously compared to the text material, which also changes as the research process progresses (theoretical sampling; see below). Concepts are classified and categorized step by step, and key concepts, called core variables (e.g., action pattern), emerge. Relations between these core variables are then expressed in hypotheses (e.g., about the causes of action). Strauss describes the principle of coding as neither inductive nor deductive but abductive, i.e., combining both perspectives in a research technique of parallel data sampling, data analysis, and theory development, with inductive and deductive steps supporting each other (→ Deduction vs Induction vs Abduction). This research process comes to an end when the emerging theory does not change any more (theoretical saturation).

## CODING

There are *three types of coding*, which take turns in the process of theory development. This can be illustrated for transcripts of interviews: One starts with *open* coding usually, i.e., with conceptualizing transcripts line by line. In this stage of theory emergence, one conceptualizes a lot of phrases and obtains many codes, which are compared to other material, merged, renamed, and modified. Strauss recommends asking for sociological categories like role or action in order to avoid mere paraphrasing and to find substantive concepts. The second technique is called *axial* or *substantive* coding. Here, Strauss recommends using a coding paradigm that is a scheme of social action including categories like causes and consequences. For instance, one searches for phrases in the transcripts (e.g., about job problems) helping to explain the behavior (e.g., alcoholism) mentioned by the interviewee. In doing so, one generates links between concepts and tries to establish hypotheses. Concepts, indicators, and hypotheses are saved in memos, category lists, and diagrams. Computer programs like Atlas/ti were developed especially to support such memos, lists, and diagrams. While coding axially, usually one or two core categories emerge. Then one should continue with the third technique, called *selective* coding. Here, one looks only at those parts of the interview transcripts relevant from the perspective of the core variable. In addition, category lists and memos are ordered theoretically, concepts are related to the core variable(s), and links between concepts as well as vague concepts are finally specified. This process ends with the above-mentioned theoretical saturation.

## THEORETICAL SAMPLING

Theoretical sampling is a key feature in coding. This term is misunderstood by many researchers who do a selective rather than a theoretical sampling though pretending to do the latter. Selective sampling means defining the criteria of qualitative sampling before

one starts to analyze the sample material, which is “fixed” with the sample criteria (→ Sampling, Nonrandom). Theoretical sampling, however, means continuous sampling and transforming of sampling criteria during the whole research process. Whether to take this or that part of an interview transcript, for instance, depends on the stage of theory development: With open coding in the beginning all material is important at first. But when a core category has been found, new material is chosen with this category in mind.

Another core principle applied in coding is comparable to → cluster analysis in quantitative research. In their joint work of 1967 Glaser and Strauss described minimizing and maximizing strategies. The minimizing strategy calls for searching for similar concepts and indicators in the material. The maximizing strategy involves the opposite. This is comparable to homogeneity within a cluster and heterogeneity between different clusters in quantitative cluster analysis.

## **TWO VERSIONS OF GROUNDED THEORY**

With the coding paradigm and several examples for the three types of coding, Strauss has moved grounded theory close to qualitative techniques of text analysis. Thus, his version of the approach is “open-minded,” in the tradition of qualitative research methodology, but also tries to establish a more systematic and at least partly deductive research technique than the Glaser version. Glaser emphasizes more the inductive aspects of grounded theory. He demands that researchers avoid research literature before starting to generate the theory and thus be really “grounded” in the data instead of sticking to preconceptions.

Nevertheless, a literature review is useful at a later stage of theory development. Besides, Glaser considers talking about an emerging theory to be counterproductive before ending the research process, since supporting comments as well as disapproval would end the motivation for writing memos and for comparing and refining categories, concepts, and the emerging theory. In the Glaser version of grounded theory, theoretical memorizing – i.e., writing down all ideas about concepts and relations between them, rewriting them, and sorting them – is the key principle of creativity in developing a substantive or formal theory.

# Group Communication

Lawrence R. Frey

University of Colorado at Boulder

The study of group communication focuses on (1) the nature and effects of symbol usage in relatively small collectivities (a minimum of three people) on individual, relational, and collective processes and outcomes, as well as (2) how groups and group processes themselves are products of such symbolic activity. The study of how groups employ communication and how that communication is affected by and affects phenomena is called a *symbolic-management focus*; the study of how the significant symbol of “group” and group processes result from communication is called a *symbolic-constitutive focus* (Frey & Sunwolf 2004). Both perspectives view a group as a significant site of communication; indeed, Poole (1998) argued that because a group is the minimum unit of analysis for the confluence of influence associated with both individuals and social contexts, the group should be *the* fundamental unit of communication research.

## THEORIZING GROUP COMMUNICATION

A number of theories have been developed to understand and explain communication in groups, including systems, functional, symbolic convergence, and structuration theories, as well as the symbolic-interpretive perspective. One of the most prominent ways of viewing a group is as a *system* comprised of *inputs* (variables that precede and potentially influence groups), *throughputs* (group interaction processes), and *outputs* (products resulting from group inputs and throughputs) (→ Systems Theory). From such a symbolic-management perspective, communication represents a throughput that is influenced by inputs (e.g., group members and relevant contexts) and affects outputs (e.g., decisions made and member satisfaction).

Another well-established symbolic-management theory that views groups through the input-throughput-output lens is *functional theory* (→ Group Decision-Making, Functional Theory of). Functional theory argues that effective group decision-making (the chief outcome studied) requires the satisfaction of fundamental tasks or requirements, called *functional prerequisites* (e.g., thorough and accurate understanding of the choice-making situation), with communication being the means of satisfying these critical requirements.

Symbolic-constitutive theories include (1) → *symbolic convergence theory*, which describes how recurring communication forms (e.g., fantasies, fantasy chaining, and fantasy themes) lead group members to share a common social reality (e.g., rhetorical visions), including the perception of being a group; and (2) → *structuration theory*, which draws on sociologist Anthony Giddens’s work to explore how group members’ enactment of structures (rules and resources) produces and reproduces the group system, a process called “structuration.” The *symbolic-interpretive perspective* is a more recent theory grounded in these and other theories (e.g., rhetorical and dialectical perspectives), and employing a variation of systems language to focus on relationships among symbolic predispositions (inputs), symbolic practices (e.g., specific forms of symbol usage such as narratives), and symbolic processes and products (e.g., developing group climate and culture, with processes and products linked to reflect their recursive and reflexive relationship).

## **STUDYING GROUP COMMUNICATION**

The study of group communication includes a focus on task and relational communication, investigations of laboratory and natural or bona fide groups, and the use of quantitative and qualitative methods.

### **Task and Relational Communication**

Historically, the study of groups emerged from an interest in (1) knowing whether groups (and group discussion) were more effective than individuals in solving tasks, and (2) employing effective practices to promote democratic group decision-making. Group communication scholars, thus, began by studying the relationship between communication and decision-making and problem-solving in task groups (→ Group Communication and Problem-Solving). *Process-oriented* scholars studied the communication processes by which decisions and solutions to problems developed, focusing, for instance, on distributional and sequential communication structures in decision-making groups, group developmental stages/trajectories, and group argumentation (→ Group Communication and Social Influence); *outcome-oriented* scholars studied the effects of communication on group decision-making, including group information processing, impact of group discussion procedures, and, later, effects of new communication technologies (e.g., decision support systems) on group decision-making (→ Technology and Communication).

Group researchers since the time of psychologist Robert Freed Bales have recognized, however, that groups also have a social or relational dimension. Historically, task and relational dimensions were seen as competing forces, but both are now viewed as necessary. Although some early researchers focused on how communication in laboratory decision-making groups affected outcomes such as member satisfaction, more recently, scholars have focused on relational messages (e.g., social support), processes (e.g., relationship development), and both positive (e.g., cohesiveness) and negative (e.g., groupthink) outcomes (see Keyton 1999; Barker et al. 2000) in many other types of groups, especially those in natural settings.

### **Laboratory versus Natural or Bona Fide Groups**

Although the study of groups in other disciplines, and some of the early studies in the communication discipline, focused on groups in their natural contexts, historically, because of its emphasis on the task, group communication was studied in the laboratory. For instance, Frey (1994) reported that his review of group communication research published during the 1980s, a prolific period because of the infusion of the theories described previously, revealed that the majority of that research studied student (72.3 percent), zero-history groups (64.1 percent), meeting once (72.3 percent), in a laboratory setting (59.6 percent); moreover, 50 percent of the research conducted in the field studied groups that were created for classroom purposes.

Although laboratory studies revealed much about group communication processes and their effects on decision-making and problem-solving, and some studies, such as those on new communication technologies were conducted in labs that mirrored natural settings

(e.g., technology rooms in organizations), numerous critiques of the external → validity of such research led communication scholars to start studying groups in their natural environments. In addition to natural task groups (e.g., organizational teams), researchers also started studying more relationally oriented groups, including families, friendship cliques, social clubs, support groups, children's groups, and church groups, as well as gangs, cults, terrorists, and other "dark-side" groups. These studies of natural groups led Putnam and Stohl (1990) to advance the *bona fide group perspective*, which challenged the typical "container model" of groups as relatively closed entities with fixed boundaries and borders and focused solely on internal group processes, by arguing that groups demonstrated two interrelated characteristics: *stable yet permeable group boundaries* and *interdependence with their relevant contexts* (→ Bona Fide Groups). Subsequent studies have explicated these two characteristics (see, e.g., the studies in Frey 2003).

### Quantitative and Qualitative Methods

In addition to conducting experiments and surveys to study group communication quantitatively, group communication scholars have led the way in the use of *interaction analysis*, the quantitative observational study of discourse. Starting in the 1930s, followed by the pioneering work of Bales's (1950) interaction process analysis (IPA), which coded for both task and relational communication, and Bales et al.'s (1979) extension of IPA, the system for the multiple level observation of groups (SYMLOG), and continuing to the present day, scholars developed numerous observational instruments to code and measure group interaction.

As scholars moved to the field to study natural or bona fide groups, they started employing more qualitative methods to study group communication; these include ethnographic methods (→ Ethnography of Communication), → discourse analysis, rhetorical analysis (→ Rhetorical Criticism; Rhetorical Studies), and performance studies. Today, many researchers conduct multi-methodological studies that combine various methods (→ Research Methods).

Studying group communication, however, poses some significant *challenges*, including: (1) a level-of-analysis issue of how much to focus on individual members versus the group as an entity (and the possible member relationships in between); (2) how to account for the fluidity and permeability of group boundaries and borders (as in the bona fide group perspective); (3) the unit of interaction to code (e.g., separate speech acts, complex combinations, or the entire group discussion); and (4) the designation of group variables (as the same construct, such as cohesiveness, can be an input, throughput, or output variable). Group communication scholars continue to debate how best to manage these methodological issues (see Poole et al. 1999).

### FACILITATING GROUP COMMUNICATION

Historically, the study of group communication was tied to practice – helping people to be more effective participants in democratic group decision-making. Scholars and practitioners have realized for quite some time that groups, when engaged in naturally occurring (free) discussion, often flounder and perform less effectively than might be

expected; consequently, groups need *facilitation* – which typically means employing *meeting procedures* that specify how a group should organize its processes to achieve a particular goal (→ Meeting Technologies). A plethora of group meeting procedures has been created, ranging from those that facilitate group creation, group conflict communication, group conversation or discussion, task group communication (e.g., from macro-level issues of planning, decision-making, evaluating, and promoting change to micro-level procedures that help groups to structure, analyze, create, and agree), to those that promote team communication (see, e.g., Sunwolf & Seibold 1999; Sunwolf & Frey 2005; Frey 2006). Research on the effects of those meeting procedures, however, has lagged far behind the development of procedures. What research does exist suggests that these facilitation procedures work because they structure the communication that takes place in ways that prevent groups from engaging in faulty processes and that harness the strengths of groups.

# Group Communication and Problem-Solving

Randy Hirokawa

University of Hawaii at Hilo

Interest in the relationship between group communication and group problem-solving performance has a long and somewhat controversial history (→ Group Communication). Many trace interest in problem-solving in the group context back to the early work of Maximilian Ringelmann (1861–1931). Ringelmann first measured the effort of a single individual working alone, then measured how much more effort was achieved by two, and then three, people working together. He found that the triad exerted the most effort, but the intriguing aspect of this finding was that the addition of each person did not increase the performance by the average effort of a single individual. Triads, for example, only exerted 2.5 times more effort than individuals working alone. In short, Ringelmann discovered an *inverse relationship* between the number of people in a group and the magnitude of individual performance on additive tasks. This finding contradicts the notion that groups work harder than individuals, and became known as the *Ringelmann effect*. Subsequent work carried out by Ingham and colleagues (1974) essentially replicated Ringelmann's original findings.

Since the days of Ringelmann, group interaction and communication have taken on increasing importance in the study of group problem-solving effectiveness. The presumed importance of group interaction is clearly implied in Steiner's (1972) oft-cited formula: "Actual productivity = potential productivity – losses due to faulty processes." This

formula highlights the potential for communication to detract from the effectiveness of group problem-solving, though research suggests that some communication in problem-solving groups also contributes to the effectiveness of the group effort.

## DEFINITIONAL PARAMETERS

### Problem-Solving Group

Group scholars have historically defined a *problem-solving group* as a collection of individuals who interact with one another in their efforts to arrive at a solution for an unmet need or objective. The literature differentiates between two types of group problem-solving tasks: intellectual tasks and decision-making tasks. *Intellectual* tasks require a group to choose an alternative whose “correctness” can be determined by applying culturally accepted standards of coherence and rules of logic. *Decision-making* tasks, on the other hand, require a group to select an alternative whose “correctness” is determined by a “consensus about what is morally right or what is to be preferred” (McGrath 1984, 64; → Decision-Making Processes in Organizations). In short, groups working on intellectual tasks produce outcomes that can be proven (objectively) to be of high quality, whereas groups working on decision-making tasks produce outcomes that can only be judged (subjectively) to be of high quality.

### Group Communication

The terms → “interaction” and “communication” are often used synonymously in the group problem-solving literature, but there are technical differences worth noting (→ Communication: Definitions and Concepts). Group *interaction* occurs when two or more group members do something together. As such, interaction involves *mutual influence*; that is, the behavior of one member (A), verbal or nonverbal, is affected by (because it is usually a response to) the behavior of another member (B, C, and so forth) and vice versa (→ Group Communication and Social Influence). Hewes (1996) uses the following equation to present a formalized, and widely accepted, definition of group interaction:

$$\text{Prob}[x_b(t+n) \mid y_a(t)] = \text{Prob}[x_b(t+n)]$$

That is, interaction is said to occur in a group when the likelihood (Prob) of person B’s (*b*) overt physical/symbolic activity or behavior (*x*) at any given time (*t + n*), given the presence of person A’s (*a*) overt physical/symbolic activity or behavior (*y*) at some prior point (*t*), does not equal the likelihood that person B would produce behavior *x* in the absence of person A’s behavior *y*. Stated in simple terms, interaction is said to occur between persons A and B when person A’s activity has an influence on person B’s activity, and vice versa.

*Communication*, in contrast, refers to the achievement of common (or shared) understanding among two or more interacting individuals in regards to the meaning (or referent) of symbolic behaviors – verbal or otherwise – produced and exchanged by those group members. To the extent that communication and interaction are obviously

inextricably intertwined, many group scholars tend to view the terms as synonymous, and hence use them interchangeably.

## GENERAL FINDINGS

Research shows that group communication affects group problem-solving performance in at least three general ways.

*First*, communication allows group members to *distribute and pool* available informational resources necessary for effective decision-making and problem-solving. Studies have found that group communication is especially important for successful group problem-solving when the group is characterized by the unequal distribution of crucial → information. In particular, group discussion facilitates effective group performance when it results in the effective centralization of information in the hands of people who need it to help the group arrive at a high-quality decision (Stasser 1992).

*Second*, group communication allows group members to *catch and remedy errors* of individual judgment. According to Taylor and Faust (1952), the principal reason why groups generally outperform individual problem-solvers is because the discussion of ideas, suggestions, and rationales for preferred choices tends to expose informational, judgmental, and reasoning deficiencies within individual members that might go undetected if those individuals were solving problems on their own. Moreover, group discussion provides the opportunity for members to point out and correct these problems before they can contribute to regrettable choices.

*Third*, group communication serves as a means for intragroup → *persuasion*. Shaw and Penrod (1962) found that group discussion provides members with the opportunity to present and support their decisional preferences and, in so doing, convince others to go along with those alternatives. According to Riecken (1958), the overall quality of a group's solution will often depend on the solution preference of the group's most persuasive member(s). His findings indicate that the presence of knowledgeable group members does not necessarily lead to high levels of group performance unless those individuals are able to persuade others to accept and utilize the information they possess in arriving at a group decision.

## FINDINGS REGARDING GROUP COMMUNICATION AND PROBLEM-SOLVING

While research provides evidence that group communication is related to group problem-solving performance, the available evidence suggests that the relationship is more complex than initially believed. Studies show that group communication is more than a convenient channel that group members use to distribute information or make their preferences known to others in the group. Communication appears to have its own distorting and biasing effects on group problem-solving performance (Hirokawa 2003), and the relationship between group communication and group problem-solving performance seems to be affected by at least two task-related contextual factors: (1) information distribution, and (2) information-processing requirements (Orlitzky & Hirokawa 2001; Hirokawa 1996; → Information Processing).

The relationship between group interaction and group problem-solving performance appears to be affected by the *distribution of relevant information* among group members (Hirokawa 1990). When information is equally distributed among group members, communication appears to be unrelated to group problem-solving performance (Leavitt 1951). However, when the distribution of information is skewed so that only a few group members possess the information needed to solve the problem, a positive relationship between group communication and group problem-solving performance emerges (Shaw 1964).

The relationship between group communication and group problem-solving performance also appears to be influenced by the *information-processing requirements* of the problem-solving task. Information-processing requirements refer to the extent to which (1) the validity or accuracy of relevant information can be objectively verified, and (2) the relevance of available information is clearly evident to group members. Research indicates that group communication is unrelated to group performance when information-processing requirements are low – that is, when the accuracy of information can be verified, and when the relevancy of the information is clear (Argyle & Cook 1976; Williams 1977). When information-processing requirements are high, however, a positive relationship between group communication and group problem-solving performance emerges (Hiltz et al. 1986).

In summary, we can expect group communication to have the greatest impact on group problem-solving performance when the group task is characterized by unequal information distribution and high information-processing requirements. Under other circumstances, the relationship between group communication and group problem-solving performance remains less clear.

# Group Communication and Social Influence

Charles Pavitt

University of Delaware

When a decision-making group comes into discussion intending to choose among a set of possible courses of action, any disagreement among the members of the group regarding the best option normally results in some form of social influence. We assume that group members enter discussion having formulated a “pre-discussion preference” for a particular option, that these members leave discussion with a “post-discussion preference” among the options, and that the group as a whole reaches a decision about the best option. Social influence occurs when there is a difference between individual member pre-discussion and post-discussion preferences and/or when the group decision differs from what would be predicted based on the members’ pre-discussion preferences (→ Attitudes; Persuasion).

## EARLY RESEARCH

Research relevant to social influence within groups has a long history. In fact, perhaps the earliest quantitative research (→ Quantitative Methodology) study published in a speech communication journal examined the process of preference convergence due to group discussion (Simpson 1939). Although conducted in relatively unrealistic settings in which

aggregates of research participants only voiced judgments in one another's presence, two early studies of visual perception deserve special note. Sherif (1935) placed participants in an inherently ambiguous circumstance, and observed that voiced comments at the early stages of the task resulted over time in the emergence of a consensual framework that was applied during subsequent judgments.

This study instantiates one of two avenues for social influence in groups, *informational influence*, in which persuasion occurs as the result of the content of arguments made for and against various options during discussion. Asch (1951), in contrast, used a relatively unambiguous situation and noted that research participants believing themselves to be in disagreement with a majority often were persuaded by that majority, even though the participants' original judgments were obviously correct. In post-study interviews, many of these participants stated that, no matter what they saw, the very presence of a disagreeing majority was persuasive. These findings reflect the second pathway for social influence in groups, *normative influence*, in which persuasion is due to minority members coming to believe that the majority must be correct due solely to their majority status (→ Social Norms). Normative influence should not be confused with compliance, in which minority members voice the opinions of the majority but do not in actuality come to agree with that majority view. By the end of the 1950s, these and other studies had led to three empirical generalizations: that group discussion usually leads to convergence of members' preferences, that the group decision reflects that convergence, and that group minorities normally are persuaded to conform to the majority point of view.

These three empirical generalizations are evident, for example, in *research on jury decision-making* (Davis 1973). As data based on real jury deliberations are at best difficult to obtain and in many cases illegal to use for research, workers have turned to *mock juries*, experimental simulations of jury deliberations usually based on convenience samples but occasionally using people called for jury duty but not assigned to a real case. Studies comparing pre-discussion preferences with group decisions reveal preference convergence and majority rule, with a two-thirds majority for either guilt or innocence usually decisive for a group decision. Mock jury studies of communication content during deliberation have been rare (→ Group Decision-Making, Functional Theory of).

## GROUP POLARIZATION

An important step forward in our understanding of social influence in groups began in the early 1960s with the employment of a relevant research paradigm, the *choice dilemma*. In choice dilemmas, group members must choose between two possible courses of actions, one relatively attractive but with some likelihood of failure, the other sure to succeed but with less attractive consequences. Early studies led researchers to infer that groups made riskier decisions than individuals, but this inference was the incorrect consequence of a research artifact. What was actually discovered was that groups make more extreme decisions than individuals.

This *group polarization effect* can technically be defined as the tendency for group decisions to be in the same direction as but more extreme than the mean of the members' pre-discussion preferences. In addition, the mean of members' post-discussion preferences also shift toward the extreme, evidence that actual social influence rather than compliance

is occurring. By the late 1970s, two theoretical positions, one relying on normative influence and the other on informational influence, came to dominate attempts to explain group polarization.

The normative influence explanation was an extension of → Festinger's → *social comparison theory*, in which, upon discovering where one another stands on the issue, group members shift toward the majority view. This generally leads to group polarization due to the fact that, at least in this research paradigm, group majorities are usually more extreme than minorities. The informational influence explanation, *persuasive arguments theory*, hinges on the notion that discussion leads members to hear arguments favoring their pre-discussion preference of which they were previously unaware, in turn leading them to support that preference even more strongly. This account, however, only works if the content of discussion is biased toward the majority preference; if discussion content reflects both sides, then arguments favoring each side would counterbalance one another such that no preference shift would occur. Research evidence does indicate a discussion bias in favor of the majority point of view. Both the social comparison and persuasive arguments explanations boast considerable empirical support, and any comprehensive model of group polarization must include both processes (Lamm & Myers 1978).

Two major research programs exploring group polarization have been instigated by communication scholars. First, Boster and co-workers discovered that the inherent tendency of items to elicit risky versus cautious preferences predicted talk time supportive of each option, but that majority view predicted perceived strength of arguments; as a consequence, Boster and Mayer (1984) proposed a multi-stage model of polarization including both normative and informational influence components. Second, both social comparison and persuasive arguments explanations rely heavily on pre-discussion knowledge and preferences to predict group decisions; in response, structuralist theorists (Meyers & Seibold 1990) have attempted to demonstrate the sufficiency of discussion independent of pre-discussion processes (→ Structuration Theory). These efforts have been indecisive but resulted in research on the relationship between categories of discussion argument and group decision.

### HIDDEN PROFILES AND MINORITY INFLUENCE

The next major advance in our knowledge about social influence in groups was again the result of another research paradigm, the *hidden profile*. Hidden profiles exist when research participants are given information about different options, manipulated so that the information each participant received favors the same option but, taken in total, all of the information provided favors a different option. This can be accomplished by, for one of many possible examples, supplying each member of three-person groups with the same four items of information favoring option A but two unique items of information favoring option B. We would assume that each participant would begin the discussion supporting option A. If all the information came up during discussion, then group members would eventually become aware of all six “unshared” items of information and change their support to the “objectively correct” option B.

However, as with group polarization, research has repeatedly demonstrated that discussion is biased toward information relevant to the originally favored option, so that

group members continue to favor and generally choose the “objectively incorrect” option. This occurs if for no other reason than the fact that an item of information is more likely to surface if many people are aware of it. In addition, however, shared items of information are more likely repeated during discussion, an indication that shared items of information are considered more credible (Wittenbaum et al. 2004). As with group polarization phenomena, the manner in which decisions are made in the hidden profile paradigm likely includes both normative and informational influence components. Regarding normative influence, there is strong evidence that the larger the proportion of group members aware of an item of information, the greater the influence of that item on the group’s decision. In the case of informational influence, there is counterbalancing evidence concerning the impact of unshared items of information mentioned during discussion on group decisions. Winquist and Larson (1998) proposed a parallel process model in which informational and normative influence have independent effects on post-discussion preferences, with the situation determining which of the two has the larger impact (→ Extended Parallel Process Model).

As noted earlier, majorities are usually successful in persuading minorities to conform to their point of view. However, exceptions have long been noted, and during the 1960s procedures were developed that produce a relatively high proportion of group decisions in which majorities give way to minorities. This discovery inspired the growth of a research literature on *minority influence*. Although majorities find it easy to discount the arguments of a sole deviant, minorities of two or more people are more difficult to ignore, particularly if the members of that minority remain steadfast in their voiced opinions and provide reasons that are consistent with one another. Research has shown that, along with occasionally convincing majorities to change their mind, minorities can be successful in improving the overall level of critical thinking in a group, such that additional options beyond those originally supported by the majority and minority may be uncovered (Nemeth 1986).

## Group Decision-Making, Functional Theory of

Dennis S. Gouran

Pennsylvania State University

The functional theory of group decision-making, while relatively recent as a formal theory, has origins dating well back into twentieth century (Gouran et al. 1993). One significant origin is the adaptation of American philosopher John Dewey's *method of reflective thinking* for use in the teaching of group discussion by speech teachers (Dewey 1997, 1st pub. 1910; → Speech Communication, History of). In Dewey's characterization, the method consists of five steps: (1) a felt difficulty; (2) its location and definition; (3) suggestion of possible solution; (4) development by reasoning of the bearings of the suggestion; and (5) further observation and experiment leading to its acceptance or rejection; that is, the conclusion of belief or disbelief. Early on, teachers interested in communication in groups converted these steps into a standard agenda for conducting decision-making and problem-solving discussions (see, e.g., Ewbank & Auer 1941). The presumption was that following these steps and cultivating the corresponding habits of mind would lead to better decisions (→ Group Communication; Group Communication and Problem-Solving).

A *second origin* of the functional theory of group decision-making was work by sociologist Robert Freed Bales (1950), who was a strong proponent of equilibrium theory as applied to groups. Bales posited that decision-making groups strive for equilibrium or balance in their efforts to satisfy task-related demands and the social and emotional needs of their members. Communicative acts, in his view, are the instrumentalities by which members of such groups become cognizant of any imbalances in the two domains and achieve equilibrium between them. Thus, communication has functional value for groups making decisions.

A third influence contributing to the emergence of the functional theory of group decision-making was Irving Janis (1972; 1982) and his inquiries concerning the causes

underlying some historically noteworthy and conspicuously poor American foreign policy decisions involving various governmental groups. Janis attributed these poor decisions to the *phenomenon of "groupthink,"* or the sacrifice of critical thinking that often accompanies the desire to promote harmony in groups. Specifically, Janis defined groupthink as "a mode of thinking that people engage in when they are deeply involved in a cohesive in-group, when the members' strivings for unanimity override their motivation to realistically appraise alternative courses of interaction" (1972, 9). Janis's research revealed that such decisions were almost invariably characterized by an absence of the attributes that Dewey (1997) identified as the method of reflective thinking.

Janis (1989) later introduced what he referred to as the *constraints model*, which he used to demonstrate how so-called cognitive, affiliative, and egocentric constraints lead the members of groups to resort to mental shortcuts, or heuristics, that contribute to the relaxation of sound critical judgment in choice-making situations. For instance, a group might be unduly influenced by the heuristic, "Don't rock the boat," if challenging a member's judgment were to threaten to inject disharmony into a group discussion. The constraints model had a significant impact on the more recent development of the functional theory of group decision-making.

Gouran and Hirokawa, drawing on various strands of the lines of thought summarized above, introduced the functional theory of group decision-making and problem-solving groups in 1983. Following that introduction, the theory became an object of considerable research and underwent a good deal of evolution (see Gouran 1999; Poole 1999).

### ASSUMPTIONS AND PROPOSITIONS

At its most fundamental and general level, The functional theory of group decision-making is predicated on a single premise. Specifically, effective decision-making and problem-solving in groups, the referent for which is "choosing appropriately," is in direct proportion to the extent that communication serves to insure that the members have adequately satisfied the requirements posed by their tasks. An appropriate choice is the one that "a group is obliged to make in light of its purpose, the requirements of the task, and what the analysis of information bearing on the available alternatives establishes as reasons for endorsing and rejecting each" (Gouran 1988, 257).

In its present form, the theory rests on 10 assumptions and comprises eight general propositions, one of which has five components. The propositions all relate to the functions that communication should or does serve in order to heighten the probability that a decision-making or problem-solving group will choose appropriately. To the extent that communication fails to serve these functions under the conditions assumed, in general, it is less likely that a group will, or even can, perform effectively in the sense noted.

The *assumptions* underlying the functional theory of group decision-making are as follows:

- 1 The members of a decision-making or problem-solving group are motivated to make an appropriate choice.
- 2 The choice confronted is nonobvious.

- 3 The collective resources of the groups in respect to the particular task exceed those of individual members.
- 4 The requisites of the task are specifiable.
- 5 Relevant information is available to the members or can be acquired.
- 6 The task is within the intellectual capabilities of the members to perform.
- 7 One or more of the members must be capable of recognizing and interpreting the signs of unwanted cognitive, affiliative, and egocentric constraints.
- 8 Communication is instrumental.
- 9 Members are aware of how well interaction is serving to satisfy fundamental task requirements.
- 10 Members will take steps to minimize and counteract sources of influence that limit prospects for adequately fulfilling fundamental task requirements (Gouran & Hirokawa 1996, 75).

Under circumstances in which the assumptions apply, the functional theory of group decision-making advances eight general *propositions*, positing that the likelihood of a group's arriving at an appropriate choice is at a maximum when the members:

- 1 make clear their interest in arriving at the best possible decision;
- 2 identify the resources necessary for making such a decision;
- 3 recognize possible obstacles to be confronted;
- 4 specify the procedures to be followed;
- 5 establish ground rules for interaction;
- 6 attempt to satisfy fundamental task requirements by
  - a. showing a correct understanding of the issue to be resolved
  - b. determining the minimal characteristics any alternative, to be acceptable (endorsable), must possess
  - c. identifying a relevant and realistic set of alternatives
  - d. examining carefully the alternatives in relationship to each previously agreed-upon characteristic of an acceptable choice, and
  - e. selecting the alternative that analysis reveals to be most likely to have the desired characteristics;
- 7 employ appropriate interventions for overcoming cognitive, affiliative, and egocentric constraints that are interfering with the satisfaction of fundamental task requirements; and
- 8 review the process by which the group comes to a decision and, if indicated, reconsider judgments reached, even to the point of starting over. (Gouran & Hirokawa 1996, 76–77)

## RESEARCH

To date, research has focused on proposition 6. Hirokawa and Salazar (1999) have summarized much of the pertinent scholarship. Among the findings to which they point are correlations of the assessment of positive and negative qualities of decision options, problem analysis, and identification of criteria with the appropriateness of the choices

groups make. Providing less support for the proposition has been research concerning the generation of decision options, as the number groups have identified does not appear to be predictive of whether or not they make good choices. Not receiving attention thus far is the part of the proposition involving the extent to which the members of decision-making groups assess the alternatives under consideration in respect to the criteria they select – at least, not in any systematic way.

In respect of proposition 7, Janis (1989) identified 20 hypotheses embodying a variety of leadership practices, having as their aim to counteract the negative influence of cognitive, affiliative, and egocentric constraints, but communication-based research to test them has not been forthcoming. Despite that, they provide a ready-made scholarly agenda that lends itself to such research.

As the functional theory of communication in decision-making groups stands, its principal value has been that it aids in accounting for instances of defective choice-making (see, e.g., Gouran et al. 1986; Hirokawa et al. 1988; Gouran 1990). Its predictive promise has yet to be convincingly demonstrated (Poole 1999).

## Gulf States: Media Systems

Carola Richter

University of Erfurt

The six Arab countries of *Bahrain, Kuwait, Oman, Qatar, Saudi Arabia*, and the *United Arab Emirates* (UAE) passed through similar development stages evolving comparable media systems. With the exception of Saudi Arabia, the smaller Gulf States had been British protectorates, gaining their independence only in 1971 (Kuwait in 1961). Since extensive oil production started in the 1950s, the region has been transformed from a remote area into one of the hubs of economic and technological globalization. Politically, it is still trapped between modernization and tradition. All six states are practically authoritarian, ruled by a dominating royal family despite established parliaments. Islam plays a major role in legislation and in the legitimization of the rulers. The contradiction between technological progress and political stagnation is reflected in the state-of-the-art media that may be privately owned but are normally loyal to the rulers and their politics (Rugh 2004). Because of a serious lack of skilled citizens, large numbers of expatriates work in the Gulf. Not only are they considerable target audiences for the media, fostering the development of English-language media and a pan-Arab orientation, but media production itself depends heavily on expatriate journalists, especially Arabs.

Compared to other Arab countries, mass media were introduced rather late, owing to a low level of development and small populations. Newspapers appeared in Saudi Arabia and Kuwait in the 1960s, while the first dailies circulated in the other Gulf States in the 1970s. Radio was introduced first in Saudi Arabia in 1949, and last in Oman in 1970. TV broadcasting started first in Kuwait in 1961, last in Oman in 1974.

Every Gulf State has elaborate press laws. Publications have to be licensed and are exposed to censorship; nevertheless the governments tend rather to exercise indirect control by issuing subsidies and placing ads. The foreign press is subject to import controls. Taboo topics are the ruling family, religion, and the basic lines of governmental

**Table 1** Media distribution in the Gulf States

<sup>a</sup> Percentage of population aged 15+.

<sup>b</sup> World Bank (2004).

Source: World Bank (2006)

politics. National news agencies disseminate official statements as guidelines for the media (→ Communication Law and Policy: Middle East).

As an effective tool to shape public opinion the *broadcasting* media were monopolized by the government. In each country except Qatar, the Ministry of Information still controls national broadcasting, normally operating one or two TV channels and several radio programs. The UAE have a federal system with each of the seven emirates operating its own channels. The exception to the loyalist rule is *Al Jazeera* news channel. Launched by the emir of Qatar in 1996, the channel has become the catalyst of a new Arab public demanding political reform (Lynch 2006; → Arab Satellite TV News).

The *press*, however, is predominantly privately owned, but passive in style and loyal to the government. Kuwait's press is the most liberal and diversified. The highest circulation is that of Saudi Arabia's *al-Riyadh* with 170,000 copies (Rugh 2004; see overview in Table 1).

The immense increase in oil prices in the 1970s boosted the Gulf States' revenues, resulting in the elites' search for new investment opportunities. The smaller Gulf States' determination to diversify their economy because of decreasing petroleum revenues in the 1990s ironically had similar effects: elites largely invested in media and information technology as a promising economic sector. Back in 1994, the Saudi government still prohibited ownership of satellite dishes, but the more effective means to control the media was to own them (Sakr 2001). Members of the Saudi Arabian royal family control the leading pan-Arab dailies *Asharq al-Awsat* (launched in 1978) and *al-Hayat* (1990), the ArabSat Satellite; the *MBC* broadcasting network (1991) including *al-Arabiya* news channel (2003) and the pay-TV networks *ART* (1994) and *Orbit* (1994). To avoid both arousing opposition from religious zealots and the strict national laws, these media were launched "offshore" from London and Rome. Furthermore, commercial pan-Arab media producers anticipate and obey Saudi Arabia's strict religious and political guidelines, since it is the largest and most profitable market in the region (→ Globalization of the Media; Satellite Communication, Global).

The smaller Gulf States are dependent on western and regional support and have adopted “a circumspect policy of cooperating with everybody” (Rugh 2004: 115). Comprehensive media freedom and tax exemption are guaranteed for international players in the 2001-inaugurated *Dubai Media City* (DMC) and *Dubai Internet City* (DIC).

The rapid expansion of the technological infrastructure in the Gulf – reaching standards like those in North America (Ayish 2002) – led to the highest *Internet* user rates in the region and a saturated telecommunication market. Nevertheless, the Internet is not free of control. With the exception of Kuwait, access to the Internet is only possible through a sole provider. Pornographic or un-Islamic content as well as sites from the political opposition are censored.

## Habermas, Jürgen

*Hartmut Wessler*

*University of Mannheim*

Jürgen Habermas (born 1929 in Germany) is one of the leading philosophers of the second half of the twentieth century. He has had and continues to have a decisive influence on communication theory and research internationally through his work on the public sphere and his theory of communicative action, as well as his theory of deliberative democracy and public deliberation.

In his book on *The structural transformation of the public sphere* (originally published in German in 1962, but available in English only in 1989, several years after his *Theory of communicative action* appeared in English, in two volumes, 1984 and 1987), Habermas describes, in an ideal-typical fashion, the emergence of a bourgeois → public sphere in Europe in the late eighteenth and early nineteenth centuries. The bourgeois public sphere opened a space for rational-critical discussion between private individuals about matters of common concern and thus constituted a social sphere separate from self-interested interaction in the marketplace, on the one hand, and the authority of the state, on the other. Habermas portrayed the development of public communication since the mid-nineteenth century as a process of increasing commercialization of the mass media (→ Commercialization of the Media) and a growing tendency toward publicity aimed at securing mass loyalty rather than critical debate (a process he called “refeudalization” of the public sphere).

This conception of the public sphere was criticized on several grounds (for an overview, see Calhoun 1992). Some questioned the historical accuracy of the account, some objected to the neglect of non-bourgeois (plebeian) public spheres, others questioned the very demarcation of the public as opposed to the private and the subsequent confinement of the conjugal family to the private sphere, or rejected what they saw as an overly rationalist conception of public communication. In response to such criticism, Habermas (1992) made *some revisions of his original account* and further elaborated his normative conception of the public sphere in the context of an overarching theory of deliberative democracy (Habermas 1996; → Deliberativeness in Political Communication). He now acknowledges a more ambivalent role for mass-mediated public communication in democratic politics by stressing the capacity of civil society to procure and withdraw political legitimacy at least in exceptional phases of heightened political conflict. He sees the public

sphere as a “highly complex network that branches out into a multitude of overlapping international, national, regional, local, and subcultural arenas” (Habermas 1996, 372). And he emphasizes the importance of informal public opinions rooted in the life-world functioning as an antidote to what he sees as the colonization of the life-world by the systems of money and administrative power (economy and politics; → Public Opinion).

More fundamentally, Habermas has turned away from concrete historical instantiations of the public sphere (i.e., its bourgeois type) as a source of normative potential and has developed a *normative model of rational-critical discourse* that is rooted in a reconstruction of the implicit presuppositions that humans make in everyday communication (→ Political Discourse). According to Habermas’s “theory of communicative action” (1984, 1987), speakers implicitly follow the rules of an ideal speech situation by counterfactually presupposing that contributions in discourse are comprehensible, true, sincere, and morally right. Even though these rules are violated all the time, they serve to normatively regulate communicative behavior by privileging communicative action, i.e., “action oriented to reaching understanding,” over “action oriented to success” (Habermas 1984, 285). Violations of the rules of discourse can be addressed in different types of discourses in which the respective validity claims are problematized and discussed – a process that creates procedural rationality. And Habermas insists that it is this procedural rationality created in discourse (rather than some dubious kind of alleged substantive rationality) that confers legitimacy upon political decisions, actors, and institutions, and that facilitates societal learning processes (Habermas 2006). Public deliberation, therefore, is vital for democratic politics, and cannot be substituted by success-oriented strategies of → public relations. Habermas’s writings on the public sphere and public deliberation continue to inspire both theoretical reflection and empirical investigation, particularly in the field of political communication but also beyond (see Butsch 2007; Peters in press). In addition to his theoretical work, Habermas has also emerged as one of Germany’s most prominent public intellectuals and a well-known international figure – raising his voice and triggering public debate about a wide range of issues including, for example, revisionist accounts of the Hitler regime, the ethical implications of genetic engineering, or the value of a Constitution for the European Union.

## Habituation

*Robert LaRose*

*Michigan State University*

Habituation is a decrement in response to repeated stimuli. It is a learning mechanism through which organisms are able to filter sensory inputs from their environment and thereby allocate scarce attentional resources to only the most relevant stimuli (Siddle 1991; → Attention).

Habituation involves both peripheral and central nervous system processes. In the peripheral nervous system, the orienting response that alerts humans to novel stimuli originates in the reticular formation, a complex collection of nuclei in the upper brain stem with connections to the thalamus, hypothalamus and cortex. The orientation response explains reflexive physiological manifestations of attention – such as bodily reorientation toward the stimulus, elevated heart rate, accelerated eye blinking, and “sweaty palms” – in reaction to breaking news events, blaring commercial interruptions, or attention-grabbing sequences of violent or sexual activity (→ Emotions, Media Effects on; Exposure to News). The orientation response must be suppressed, otherwise novel stimuli would never cease to be novel and completely occupy human attention, rendering the world a “buzzing confusion.”

Habituation of the orienting response is associated with a diminution of the P300 component (a cortical response that follows exposure to an external stimulus by 300 milliseconds) of the event-related potential in the brain’s cortex. Functional magnetic resonance imaging (fMRI) and positron emission tomography (PET) scan studies indicate that the amygdala, hippocampus, and medial/inferior temporal cortex are the locations in the central nervous system responsible for habituation in the higher brain centers (Fischer et al. 2003).

Affective habituation responses, or reductions in stimulus-evoked affective reactions as a result of previous exposure, may explain the “wear out” of popular media. Repeated exposure to unfamiliar stimuli produces an inverted U pattern. Pleasure initially increases from repeated exposure through reductions in fear and uncertainty, followed by a slow and linear decrease in pleasure with numerous repeated exposures, or habituation (Bornstein 1989). However, unlike the neutral and unfamiliar stimuli often used in habituation studies, highly valued and familiar stimuli, such as favorite songs or TV programs, habituate after only a few exposures and with no further increase in pleasure. Habituation

of valenced, familiar stimuli is a conceptual process that readily generalizes to similar stimuli (Leventhal et al. 2007). Thus, the decline in the popularity of “reality programs” might be said to be the collective effect of individual-level affective habituation to individuals’ respective favorites from that genre.

Affective *habituation to unpleasurable stimuli* may explain → desensitization to violence when narrowly defined as a reduction in emotion-related physiological reactivity to real violence (Carnagey et al. 2007). Within the general aggression model (GAM; Anderson & Bushman 2002), desensitization is thought to facilitate violent behavior as a result of suppressing initially fearful and anxious reactions to violence by repeatedly presenting violence in a positive context. In a controlled experiment, Carnagey et al. found attenuated physiological reactions to real life violence following a 20-minute exposure to a violent video game. Desensitization is also a factor in the effects of violent television (Bushman & Huesmann 2001; → Violence as Media Content, Effects of).

Media habits, defined as media consumption behaviors that occur automatically without active self-instruction, are thought to result from the same *economies of attention* that drive other forms of habituation. While media consumers actively attend to initial media selections, they become inattentive to repeatedly enacted behaviors, diminish their self-regulation, and automatically repeat their media selections (LaRose & Eastin 2004). Media habits are found in uses and gratifications research as ritualized (as opposed to instrumental) gratifications (Rubin 1984). Excessive media habits have been characterized as addictions (Kubey & Csikszentmihalyi 2002; → Addiction and Exposure), media habits that cause significant life crises. These studies have relied on self-reports of habit strength, while physiological measures of arousal are the norm in the psychological literature. Paper-and-pencil measures of habit strength that parallel those used by communication researchers have been validated against reaction-time measures that assess habit strength through word association tasks (Verplanken & Orbell 2003).

# Hacktivism

*Paul A. Taylor*

*University of Leeds*

The simplest definition of hacktivism is that it represents the conjunction of technologically knowledgeable *hacking* techniques with the values and communicational strategies of political *activism*. Whilst hacking involves the imaginative and unorthodox use of computers and their systems, hacktivism is the application of those techniques in the pursuit of political agendas frequently associated with new globalized social movements (→ Technology and Globalization). Behind these initial, relatively clear definitions, however, lie more ambiguous and less easily separated relationships between old-style hacking and its new applications.

## DEVELOPMENT AND FORMS

Hacktivism arose in the mid-1990s largely as an attempt to remedy hacking's innate political limitations that resulted from hackers' over-identification with the technology. The advent of hacktivism coincided with the increasing number of new social movements seeking to engage with a politics of globalization in which material conditions on the ground in any one place are affected by immaterial, but nonetheless powerful, informational processes. It shares with its predecessor, hacking, an interest in the manipulation and exploration of technological systems. However, in contrast to hacking's tendency to enjoy these activities for their own sake, hacktivism translates a fixation upon technical means into a diverse range of technologically informed modes of political protest using its expertise with global communications systems (→ Communication Infrastructure).

At the most *destructive end of its spectrum*, hacktivism may involve methods of electronic vandalism such as computer worms, viruses, trojan horses, email bombs and the defacement of websites (→ Crime and Communication Technology). In these actions, the technology is foregrounded. More typically and constructively, however, hacktivism seeks to subordinate the prominence of the technological component in order to raise the profile of its political causes. *Tactical media* refers to the attitude of ingenuity hacktivism applies to the media in order to produce actions that have a wider social and political

impact than are normally seen within hacking. It is, however, based upon the adaptable and inclusive basic notion of the “hack” (see Taylor 1999, 14–19; Jordan & Taylor 2004, 5–9), with which hackers sought to reverse engineer the basic functionality of a range of artifacts (of which computers are merely the most socially significant). This is a new form of hacking in which the technological means are adopted, not as an end in themselves, but in order to promote a political purpose. Examples of such actions include: *virtual sit-ins and denial of service* (DoS) attacks – as part of an ethos known as electronic civil disobedience, the purpose is to replicate in cyberspace the physical presence of a large number of politically motivated people. The *Electronic Disturbance Theatre* (EDT) group originally developed a project called *Floodnet* which depended upon a concerted mass effort to request web pages in order to overload the computer servers of specifically targeted organizations. In later versions the process has become more automated.

Although usually considered separately from hacktivism, *culture jamming* illustrates the porosity of the definitional boundaries in this field. Drawing upon the French activist tradition of Situationism, it relates to the act of reverse engineering corporate advertising, in effect, hacking semiotic codes rather than those of computers. This link with previous hacking culture is reinforced by the relative simplicity with which powerful effects can be achieved. For example, huge advertising budgets and designs can be undermined by billboard protestors armed with nothing more than ladders and spray cans. In a form of semiotic aikido, a few well-chosen additions or blacking outs with a spray can produces the opposite message to that originally intended. Ron English is one of the most famous guerilla artists who superimposes his own acrylic paintings over a well-known advertisement, e.g. painting a bloated Ronald McDonald on an existing billboard. Other groups include *Adbusters* and the *Billboard Liberation Front*. Beyond the still image, some other groups engage in *precision targeted satire*, whereby various forms of performance are created to promote a subversive message. For example, *RTMark* is a group that mimics a conventional stock exchange except it promotes investment in subversive activities, while the *Yes Men* have targeted organizations such as the World Trade Organization with tongue-in-cheek presentations at formal gatherings in order to satirize their free market values.

*Open Source* and *Free Software* are two groups that seek to undermine capitalist values by creating software that does not follow the frameworks of conventional proprietary rights (→ Open Source). Software is produced on the basis of a collective effort and made freely available to all users. In the early days of hacking, computers were viewed as an essential tool for empowering the citizenry of heavily technologized societies by encouraging its greater access to information (→ Communication Technology and Democracy). For example, Apple Computers was largely founded upon a desire to bring computing power to the masses. While this strand of the early politics of information-for-all has been superseded by the commercial pressures that have made Apple Computers a highly successful global corporation, it remains a feature of hacktivism’s network politics.

In political and legal terms the line between hacktivism as legal activism and as illegal vandalism tends to lie in the eye of the beholder (→ Code as Law). Hacktivist protests against large multinationals tend to be received well when they are based on satire or nondestructive methods, but activists who are prepared to disrupt the Internet connectivity of others are viewed much less charitably by those labeled the *digitally correct*

(see below). As with their forebears, hackers, who became increasingly subject to moral judgment and legislative action (see Taylor 1999), hacktivists have also tend to evolve along with society's growing dependence upon the technological systems and informational resources being disrupted.

### THE POLITICS OF INFORMATION

While a major strength of hacking is the ease and familiarity with which it manipulates information, the history of the activity suggests that both the notion of free access to information and the “kick” that derives from technological ingenuity all too often became ends in themselves. A perceived political limitation of the original hacker movement was its failure to make the most political capital out of its unrivalled familiarity with informational networks. For a period of time, hacking was arguably hamstrung by its tendency to identify too closely with the technical means of communication over the purpose of the communication itself – it fetishized the medium over the message. There are strong grounds to suggest that hacktivism has successfully compensated for hacking's frequent lack of a political perspective. It has married computing expertise with ingenious manipulations of various forms of the mass media in order to create its own political discourse. However, the hacker tendency to over-rely on the technological means continues within hacktivism. The disputed relative importance of the role played by technology within hacktivist actions gives rise to the competing strands of mass action and digitally correct hacktivism.

*Mass action* hacktivism emulates traditional forms of protest and applies them within cyberspace. *Electronic civil disobedience*, for example, seeks to involve large numbers of people who carry out acts that are technically simple but which derive their strength from the sheer weight of numbers involved. In a mass action denial-of-service attack, for example, large numbers of people seek to crash computer servers by simultaneously requesting information from a targeted site. *Digitally correct* hacktivism, by contrast, uses the technical features of cyberspace to amplify its message without disrupting the communicational potential of the Internet itself – the technological means are not subordinated by the desired social ends. Mass action hacktivism is technically inelegant, but its deliberately simple, manual nature means that it is good at encouraging active political involvement. It creates networks of coordinated people rather than more sophisticated technical techniques that may achieve the same end but involve less people. Ricardo Dominguez of EDT, for example, uses the pejorative term “digitally correct” to accuse certain activist groups of being more concerned about digital rights and the maintenance of bandwidth than with the human rights of those suffering in the offline world (Jordan & Taylor 2004, 91).

### INCORPORATION BY THE SYSTEM

While it is clear that hacktivists are more overtly political than their hacking forebears, they share with hackers a potentially problematic relationship with the system they are seeking to manipulate. An accusation made against hackers is that they are parasitical upon the health of the technological systems on which they depend for the site of their

playful explorations, and that this dependency has continued into hacktivism with the rise of the digitally correct. Beyond the question of the basic nature of the relationship with the technical infrastructure, however, is a larger question about the likelihood of successfully using media technologies to undermine the values of a society largely constituted by those same media.

Just as the original maverick hackers were ultimately recuperated as microserfs (see Douglas Coupland's novel of the same name) into Microsoft's corporate system, so hacktivists are faced with the problem of maintaining their critical, radical edge in their use of the artifacts and systems for political purposes. For example, insofar as hacktivism uses the techniques of satire and culture jamming, their efforts to re-engineer are themselves vulnerable to re-engineering by the system they oppose. Satire and culture jamming can themselves be co-opted and translated into the edgy pastiche that is frequently the raw material for sophisticated corporate advertising, making it unclear as to whether any critical political point is in fact being made.

In *For a critique of the political economy of the sign* (1981) Jean Baudrillard refers to "the mortal dose of publicity" that tends to accompany events designed to make an impact within the media. Like Daniel Boorstin's (1992) notion of a *pseudo-event*, Baudrillard's interpretation is that creating "real" political events has become increasingly difficult because events reported within the media event contain their own particular grammar. Rather than promoting political action, publicity stunts designed to create a media stir tend to be processed according to the media's own internal logic (such as the "funny" or add-on item within a news program). The net effect may actually be reduction in political content as it is translated into images and stories for the media's own particular forms of discourse.

We have seen that there is an innate difficulty faced first by hacking and then by hacktivism in their desire to reverse engineer either systems that are purely technological or that are a complex imbrication of the social and the technical. There is a tendency for actions that seek to subvert the technological and media systems to be re-absorbed back into the system. There is a growing consensus among communication theorists that the new global informational order creates a pervasive environment outside of which it is extremely difficult to step. Arguing that hackers occupy an inevitably parasitic position, Gunkel (2001, 5) asserts that "The parasite occupies a structurally unique position that is neither simply inside nor simply outside. It is the outside in the inside and the inside outside itself." Similarly, in the context of hacktivism and social movements, Hardt and Negri (2000, 46) describe global capitalism in terms of an *empire* and argue that "We should be done once and for all with the search for an outside, a standpoint that imagines a purity for our politics. It is better both theoretically and practically to enter the terrain of Empire and confront its homogenizing and heterogenizing flows in all their complexity, grounding our analysis in the power of the global multitude." Compared to hacking, hacktivism is much better suited to answering Hardt and Negri's call but its ultimate ability to achieve this aim remains open to question.

## Hate Speech and Ethnophaulisms

Terry A. Kinney

Wayne State University

One of the most controversial topics that a democratic society faces is the issue of regulating the speech of its citizens. As Delgado and Stefancic suggest in *Must we defend Nazis? Hate speech, pornography, and the new First Amendment* (1997), the notion of “free speech” in a democratic society is a misnomer, as social institutions place controls on what can be said, to protect the public. This is certainly the case when speech is classified as obscene, defamatory, slanderous, or hateful, and holds a reasonable potential to be harmful (Lederer & Delgado 1995). Hate speech, for example, is a form of verbal aggression (→ Verbal Aggressiveness) that expresses hatred, contempt, ridicule, or threats toward a specific group or class of people (Asante 1998). Hate speech encompasses verbalizations, written messages, symbols, or symbolic acts that demean and degrade, and, as such, can promote discrimination, prejudice, and violence toward targeted groups. Hate speech often stems from thoughts and beliefs such as hatred, intolerance, prejudice, bigotry, or stereotyping (Allport 1954). Common forms of hate speech include ethnophaulisms, racial slurs and epithets, sexist comments, and homophobic speech (→ Prejudiced and Discriminatory Communication).

### FUNCTIONS AND EXAMPLES

Hate speech functions to distort the history of targeted groups, to eliminate the agency of targeted groups, to create and maintain derogatory cultural, racial, and ethnic illusions about targeted groups, and as a vehicle for expressing pejoratives (Asante 1998). This class of communication represents some of the most noxious and often hurtful forms of communication that exist (Kinney 2003; Leets & Giles 1997). Examples of hate speech can be found in our earliest written records, including the *New Testament* (Titus 1:10–16), where derogatory statements are made against a class of people:

[10] For there are also many disobedient, vain talkers, and seducers: especially they who are of the circumcision.

[11] Who must be reprov'd, who subvert whole houses, teaching things which they ought not, for filthy lucre's sake.

- [12] One of them a prophet of their own, said, The Cretians are always liars, evil beasts, slothful bellies.
- [13] This testimony is true. Wherefore rebuke them sharply, that they may be sound in the faith.
- [14] Not giving heed to Jewish fables and commandments of men, who turn themselves away from the truth.
- [15] All things are clean to the clean: but to them that are defiled, and to unbelievers, nothing is clean: but both their mind and their conscience are defiled.
- [16] They profess that they know God: but in their works they deny him; being abominable, and incredulous, and to every good work reprobate.

Perhaps the most harmful form of hate speech from the perspective of society manifests when representatives of well-established social institutions use it to espouse their positions by oppressing, ostracizing, and demeaning others for political or power purposes. This form of hate speech can be used to justify why another group must be removed, discriminated against, or killed, as the contents of the messages often cast the other as the enemy, as subhuman, as immoral, or not worthy of existence. The Nazis' use of anti-Semitic propaganda during World War II is perhaps one of the clearest examples of hate speech, although hate speech tends to surface during most wars as a way to instill hatred and incite violence toward the opposing force (→ Propaganda in World War II; War Propaganda). Use of the terms "terrorist" and "axis of evil" are examples of how speech is able to cast a class of individuals (or entire countries) into the role of enemy, motivating derogatory thoughts and potentially inciting violence against them. Thus, one conclusion that can be drawn about the nature of hate speech is that it provides a window through which we can view aspects of ourselves (Allport 1954). As Berkowitz suggests in *Aggression: Its causes, consequences, and control* (1993), when we experience aversive affective states we are often driven to express them outwardly (→ Frustration Aggression Theory).

Social scientists have examined some of the social issues that underlie hate speech. For instance, Allport (1954) argues that individuals develop prejudicial tendencies and beliefs early in life as a direct result of being exposed to these notions from others (→ Bandura, Albert). In 1989, the Prejudice Institute undertook a national assessment of the extent and consequences of ethno-violence and other forms of victimization in the United States. The Institute defined ethno-violence as acts motivated by prejudice that are intended to do physical or psychological harm to persons because of their actual or perceived membership in a social category. Results showed that ethno-violence occurred at substantially high rates, and that the rates varied by social setting (community, work, school) and by target group (black, white, Latino, Native American, Asian-American, etc.). In addition, most ethno-violent acts were not reported to officials, and, as a consequence, the magnitude and severity of ethno-violence and its aftermath are largely unrecognized. Finally, the study revealed that victims of ethno-violence suffer greater trauma than do victims of other types of violence that is committed for reasons other than prejudice. While this is just one study, it does support the notion that hate speech may be prevalent in American society and that its consequences, while severe, are largely unrecognized, and underreported.

### JUSTIFICATIONS FOR REGULATION

The consequences of exposure to hate speech have been examined by social scientists, and the evidence suggests that such exposure can harm individuals psychologically, socially,

and physically. Hate speech holds power over aspects of our well-being due to the way that it is able to infiltrate our thoughts, affecting how we perceive ourselves, and due to its ability to activate physiological and affective responses. While the process of infiltration is complex, it starts with exposure to a negative message. At this point a host of psychosocial theories (→ Social Identity Theory; Symbolic Interaction) help to explain how the negative message enters the psychological system to produce cognitive changes that may activate affect (e.g., Higgins 1987), cause pain, elicit psychological harm, and incite aggressiveness (Lazarus & Folkman 1984).

These effects potentially move hate speech from protected speech into arenas in which it may be regulated despite democratic principles promoting freedom of speech. However, there are significant problems when regulating speech, including determining what is offensive, being able to separate speech that expresses thoughts, however negative and egregious, from speech that solely functions to demean and damage, and then being able to assess harm accurately. While there are specific instances of words and phrases that most individuals recognize as taboo because they are inflammatory (e.g., racial epithets), even these words can be reclaimed and re-engineered by specific groups in ways that alter their meanings, making them less offensive for some.

Currently, justifications for the regulation of hate speech center on the idea that hate speech is detrimental to social and racial harmony and may lead to forms of harm against recognized groups of individuals. As a result, several countries have enacted *laws* that ban forms of hate speech (e.g., United Kingdom, Canada, Iceland, Australia, New Zealand, France, USA). These laws are seen by some as a form of state-sponsored → censorship, and at the extreme end, a form of thought control. The most common form of regulation is to enact speech codes or codes of acceptable conduct (Lee 1997).

In addition to the socially oriented reasons to regulate hate speech, a second rationale for regulation is grounded in *social psychological theory*. Social scientists argue that motivations often influence behavior, and that motivations that activate strong emotions influence behavior more directly. Thus, the motives that tend to be associated with hate speech are seen as undesirable for individuals to harbor, including prejudice, bigotry, stereotyping, and cynicism. It is often the case that violence is driven by the motives that surround hate speech. As such, the cognitive consequences of these motives can breed discrimination and overt hatred, which can ignite anger and incite violence. Thus, if hate speech holds the power to instill hatred toward others, then hate speech holds the potential to promote overt and covert discrimination and violence, which suggests that it can be regulated.

### MESSAGE DESIGN ISSUES

The fact that we recognize that our self-concepts may be vulnerable to verbal and symbolic attacks and we are willing to develop and use forms of communication that target these vulnerabilities suggests that we understand how the self-concept is organized. The fact that we align ourselves along, and are connected to, our racial, ethnic, and national origins, our past, and our gender identification, makes us vulnerable to messages that attack these aspects of our selves. Understanding this connection makes us effective in being able to attack others. The use of hate speech suggests that the message source

believes that the target (1) deserves to be attacked, intimidated, or harassed, (2) is deficient or corrupt in some manner, and (3) is vulnerable to the message. These notions bring to the surface important aspects of communication research that allow for a deeper understanding of how messages do harm. The principles of message design are central to this area of communication scholarship, and research shows that the nature of the message makes an important difference in how it is interpreted and the type and magnitude of response that it generates (e.g., Calvert 1997). Thus, the design components of messages and the social contexts in which the messages are found are important areas to examine for communication scholars (→ Message Design Logics).

As societies become more diverse, manifestations of hatred can increase due, in part, to social tensions and perceptions of inequalities. In addition, technological advances that allow the dissemination of messages to mass markets in relative privacy serve to create new communication spaces where hatred can flourish, as is experienced on the Internet (→ Internet Law and Regulation; Mediated Terrorism; Terrorism and Communication Technologies). Empirical evidence suggests that exposure to expressed hatred and rejection can harm individuals (Rohner & Rohner 1980; Savin-Williams 1994). The effects illustrate that what others say and do holds tremendous weight. As such, the issue of hate speech is an important social phenomenon, but is especially controversial in democratic societies that must balance the rights of individuals against protecting the public from harm.

# Health Behavior Change, Transtheoretical Model of

Wayne F. Velicer

University of Rhode Island

The transtheoretical model is an integrative model of behavior change, combining key constructs from other theories. The model describes how people modify a problem behavior or acquire a positive behavior. It has been very influential in guiding the design of behavior change interventions during the last two decades. The central organizing construct of the model is the stages of change theory (→ Stages of Change Model). The model also includes a series of independent variables, the processes of change, which are 10 cognitive and behavioral activities that facilitate change, and a series of intermediate outcome measures, including the decisional balance inventory, self-efficacy or situational temptations scale, and behavior measures (→ Health Campaigns, Communication in).

The transtheoretical model is a *model of intentional change*. The specific focus of the model is on behavior change and the key constructs are dynamic variables, i.e., open to modification, whereas more static variables such as gender and past history are included only as moderator variables. In addition, the model primarily focuses on the decision-making of the individual where other approaches to health promotion study social or biological influences on behavior (→ Planned Social Change through Communication). The model has been previously applied to a wide variety of problem behaviors. Smoking cessation has been the most widely studied application and will be used for illustration here.

## STAGES OF CHANGE: THE TEMPORAL DIMENSION

The stage construct is the key organizing construct of the model. It is important in part because it represents a temporal dimension. Change implies phenomena occurring over time. Behavior change was often construed as an event, such as quitting smoking, drinking, or overeating. The transtheoretical model views change as a process involving progress through a *series of five stages*.

*Pre-contemplation* is the stage in which people are not intending to take action in the foreseeable future. In smoking cessation, pre-contemplation is the stage where the person is currently smoking and not intending to quit in the next six months. People may be in this stage because they are uninformed or under-informed about the consequences of their behavior. Or they may have tried to change a number of times and become

demoralized about their ability to change. Both groups tend to avoid reading, talking, or thinking about their high risk behaviors.

*Contemplation* is the stage in which people are intending to change their behavior. For smoking, contemplation is the stage where the person is currently smoking but intends to quit in the next six months. Contemplators are more aware of the pros of changing than pre-contemplators but are also acutely aware of the cons. This balance between the costs and benefits of changing can produce profound ambivalence that can keep people stuck in this stage for long periods. We often characterize this phenomenon as chronic contemplation or behavioral procrastination.

*Preparation* is the stage in which people are intending to take action in the immediate future, usually measured as the next month. For smoking, preparation is the stage where the person is currently smoking but intends to quit in the next month. They also have made some changes in the target behavior in the last year, such as reducing the number of cigarettes or making a quit attempt. These individuals typically have a plan of action, such as consulting a counselor, talking to their physician, buying a self-help book, or purchasing a pharmacological aid such as nicotine replacement therapy.

*Action* is the stage in which people have made specific overt modifications to the behavior. For smoking, action is the stage where the person has quit smoking in the last six months. The person will make numerous changes to their personal environment to maintain the change and, since action is observable, the behavior change will be recognized by others. The action stage is defined as lasting for six months because of the relapse curves reported across a wide variety of behaviors but this definition may need to be modified for behaviors such as mammography screening where women are recommended to undergo screening every one to two years.

*Maintenance* is the stage in which people have maintained the change for at least six months. For smoking, maintenance is the stage where the person has quit smoking and has maintained that change for at least six months. People in maintenance no longer have to work as hard to maintain the change, are less tempted to relapse and are increasingly more confident that they can continue their change.

Two different concepts are employed to define the stages. Before the target behavior change occurs, the temporal dimension is conceptualized in terms of behavioral intention. After the behavior change has occurred, the temporal dimension is conceptualized in terms of *duration of behavior change*. Regression occurs when individuals revert to an earlier stage of change. Relapse is one form of regression, involving regression from action or maintenance to an earlier stage.

## **DETERMINING WHEN CHANGE OCCURS**

Theories often focus on only a single outcome measure of success. From smoking cessation research, point prevalence smoking cessation serves as an example of a single outcome measure (Velicer et al. 1992). These measures are not sensitive to change over all possible stage transitions. Point prevalence for smoking cessation would be unable to detect an individual who progresses from pre-contemplation to contemplation, from contemplation to preparation, or from action to maintenance. In contrast, the transtheoretical model involves a series of intermediate/outcome measures, proposes a multivariate

outcome space, and includes measures that are sensitive to progress through all stages. These constructs include the pros and cons from the decisional balance inventory, self-efficacy or temptation, and the target behavior (Velicer et al. 1996).

The two constructs of the *decisional balance inventory* (Velicer et al. 1985) reflects the individual's relative weighing of the *importance* of the pros and cons of changing. It is derived from Janis and Mann's (1977) model of decision-making. A predictable pattern has been observed relating the pros and cons to the stages of change. In pre-contemplation, the cons of smoking cessation far outweigh the pros. In contemplation, these two scales are about equal. In the advanced stages, the pros of quitting outweigh the cons. However, a different pattern has been observed for the acquisition of healthy behaviors.

The *situational self-efficacy/situational temptations* construct represents the situation-specific confidence that people have in order to cope with high-risk situations without relapsing to their unhealthy or high-risk habit (Velicer et al. 1990). This construct was adapted from Bandura's (1977) self-efficacy theory. Research into relapse prevention can be measured with a confidence or temptations response format. The temptation format measures the intensity of urges to engage in a specific behavior when in difficult situations. The self-efficacy format measures the confidence of the individual not to engage in a specific behavior across a series of difficult situations.

The intermediate/dependent measure outcome space also includes *behavioral measures* that are specific to the problem ( $\rightarrow$  Attitude–Behavior Consistency). For example, in smoking cessation the behavioral outcome measure would include such widely employed measures as point prevalence smoking cessation, number of cigarettes, and time to first cigarette. These are sometimes described as measures of *dependence* or *problem severity*.

## INDEPENDENT MEASURES: HOW CHANGE OCCURS

The *processes of change* are the covert and overt activities that people use to progress through the stages. Processes of change provide important guides for intervention programs, since the processes are the independent variables that people need to apply, or be engaged in, to move from stage to stage. Ten processes have received the most empirical support in our research to date (Prochaska et al. 1988). The first five are classified as experiential processes and are used primarily for the early stage transitions. The last five are labeled behavioral processes and are used primarily for later stage transitions. Table 1 provides a list of the processes (together with alternative labels) with a sample item for each process from smoking cessation.

For smoking cessation, each of the processes is related to the stages of change by a curvilinear function. Process use is at a minimum in pre-contemplation, increases over the middle stages, and then declines over the last stages. The processes differ in the stage where use reaches a peak. Typically, the experiential processes reach peak use early and the behavioral processes reach peak use late.

## APPLICATIONS

The transtheoretical model has had a strong influence on all aspects of intervention development and implementation. It has been particularly appropriate for researchers

**Table 1** The processes of change, with alternative labels and sample items

---

I. Processes of change: experiential	
1. Consciousness raising (Increasing awareness)	I recall information people had given me on how to stop smoking
2. Dramatic relief (Emotional arousal)	I react emotionally to warnings about smoking cigarettes
3. Environmental re-evaluation (Social reappraisal)	I consider the view that smoking can be harmful to the environment
4. Social liberation (Environmental opportunities)	I find society changing in ways that make it easier for the nonsmoker
5. Self-re-evaluation (Self-reappraisal)	My dependency on cigarettes makes me feel disappointed in myself
II. Processes of change: behavioral	
6. Stimulus control (Re-engineering)	I remove things from my home that remind me of smoking
7. Helping relationship (Supporting)	I have someone who listens when I need to talk about my smoking
8. Counter-conditioning (Substituting)	I find that doing other things with my hands is a good substitute for smoking
9. Reinforcement management (Rewarding)	I reward myself when I don't smoke
10. Self-liberation (Committing)	I make commitments not to smoke

---

who want to intervene on total populations. One new intervention approach where the transtheoretical model has been widely employed is expert system or computer-tailored interventions (Noar et al. 2007; Velicer et al. 2006).

Use of the transtheoretical model can affect all aspects of an intervention: recruitment, retention, progress, and outcome. For recruitment, the model makes no assumption about how ready individuals are to change. It recognizes that different individuals will be in different stages and that appropriate interventions must be developed for everyone. As a result, very high *participation rates* have been achieved (see Velicer et al. 2006).

The model can produce high *retention rates*, since the model is designed to develop interventions that are matched to the specific needs of the individual. Since the interventions are tailored to their individual needs, people drop out less frequently because of inappropriate demand characteristics. The model can provide *sensitive measures of progress*, since it includes a multivariate set of outcome measures that are sensitive to a full range of cognitive, emotional, and behavioral changes and recognize and reinforce smaller steps than traditional action-oriented approaches. This is particularly important in the early stages where progress typically does not involve easily observed changes in overt patterns of behavior. The model can support a more appropriate *assessment of outcome*. Interventions should be evaluated in terms of their impact (recruitment rate X efficacy) since interventions based on the transtheoretical model have the potential to have both a high efficacy and a high recruitment rate.

The transtheoretical model should be viewed as a *work in progress*. It represents an attempt to integrate the diverse components of existing theories. One of the important advances that resulted from adding the temporal dimension, i.e., the stages of change, was that theories previously viewed as conflicting could now be integrated. However, an integrative theory cannot ever be viewed as finished, since an important new construct can emerge at any time, when a new version of the model will be required to integrate that construct. Beyond the addition of new constructs, the measures of the current constructs are being continuously evaluated and updated. New empirical evidence about the relationships between the constructs and the similarities and differences across different areas of application is an ongoing activity.

# Health Belief Model

*Usha Menon*

*University of Illinois at Chicago*

*Laura Szalacha*

*University of Illinois at Chicago*

The health belief model (HBM), prodigiously researched, has enjoyed sustained popularity amid evolving social norms, theories and models, and the recent developments of advanced technology influencing health behavior change (→ Health Communication; Planned Social Change through Communication). Developed by US Public Health Service social psychologists in the 1950s, the HBM was conceptualized to model the failure of individuals to engage in disease prevention or detection programs (→ Prevention and Communication). Around 1974, and later in the 1980s, additional components (knowledge about the disease, self-efficacy or confidence in one's ability to perform the action of interest, cues to action), such as those examining responses to diagnosed illnesses and symptoms and adherence to medical regimens, were added to the model (Janz et al. 2003; → Health Literacy).

The HBM has been studied both as separate components and in its entirety, with multiple illnesses and preventive health behaviors, using various multivariate analytic techniques. The *four basic components of the HBM* are: (1) perceived risk or susceptibility (defined as one's perception of vulnerability to developing a disease; → Risk Perceptions); (2) perceived severity (seriousness of the illness or consequences of not completing the behavior of interest); (3) perceived benefits (perceived efficacy of the action or behavior change of interest) and perceived barriers (tangible and psychological obstacles to completing the action or behavior change of interest); and (4) cues to action (strategies to activate behavior change) (Janz et al. 2003). In later formulations of the model, self-efficacy, the confidence in one's ability to take action or complete the steps of behavior change, was adapted from → *social cognitive theory* (Bandura 1986). Socio-demographics and knowledge about the desired action or illness to be prevented were also added, and hypothesized to affect perceptions and subsequently indirectly influence individual behavior as a result.

## THEORETICAL FOUNDATION AND MEASUREMENT

Rooted in cognitive and stimulus–response theories, the HBM can be understood as a value expectancy theory (→ Stimulus–Response Model). A value expectancy theory assumes that individual people are goal-oriented, and that the behaviors they perform in response to their beliefs and values are undertaken to achieve some end (→ Goals, Cognitive Aspects of). Value expectancy concepts, revised to fit within the paradigm of health behaviors, resulted in the present interpretation of the model. For example, examined within the context of breast cancer and screening using mammography, when individuals recognize breast cancer as serious (perceived severity), understand themselves to be at risk of developing breast cancer (perceived susceptibility), frame mammography as efficacious in detecting breast cancer (perceived benefits), identify few obstacles to

having a mammogram (perceived barriers) and are confident in their ability to complete all the steps necessary to have a mammogram (perceived self-efficacy), they will have a mammogram (→ Expectancy Value Model).

Descriptive, cross-sectional research on health behavior change usually assesses → perceptions and knowledge about a disease (e.g., cancer, diabetes, heart disease) and the behaviors that manage illness. Intervention studies investigate the effects of education about health promotion behavior using these key components of the HBM. For example, in a diabetes control or insulin adherence regimen study, education may be based on individuals' pre-education perceptions and knowledge. By changing perceptions and knowledge through a prescribed communication program, researchers expect to see post-education differences in perceptions and/or knowledge, and, correspondingly, an increase in adherence to insulin regimen.

### APPLICATIONS

There are many advantages to using the HBM as the *guiding framework for behavior change research*. First, the conceptualization of the various components of the model has been well established by application to a variety of diseases. Studies as varied as cancer screening, diabetes, exercise behavior, and smoking cessation have all been conducted using the HBM as the guiding theoretical framework. Most studies attempt to effect health behavior by changing → cognitions about relevant actions. Variations of the model, including the addition of culturally oriented variables, health-care access, and health service factors, have been published. Results have been mixed, with less than half of the variance in health behavior explained by the HBM framework. For example, the HBM variables together explain less than 50 percent of the variance in mammography screening behavior, leaving almost 50 percent of the variance unexplained. Unfortunately, the majority of the studies assess only linear relationships between HBM variables and outcomes, leaving unanswered questions about possible mediating or moderating relationships between variables (→ Statistics, Explanatory).

A second advantage of the HBM is that it can be adapted for use with other behavior change theories and models. For example, the key components of the *transtheoretical model of change* (TTM) and the HBM can be merged to predict or affect health behavior change (→ Health Behavior Change, Transtheoretical Model of). According to the TTM, behavior change is not a dichotomous event; an individual progresses through a series of stages while changing behavior (from not thinking about it, to thinking about it, to taking action, then maintaining the change; Glanz et al. 2003). At each stage, research indicates that perceptions (such as those from the HBM) may differ significantly, allowing communication to be tailored or targeted to each stage. In mammography screening, for example, a woman in pre-contemplation (not thinking about having a mammogram) may report low perceived susceptibility and low perceived benefits; a woman in contemplation (thinking about having a mammogram) may indicate she has higher barriers than those in pre-contemplation (Champion et al. 2007). Given this information, researchers may focus on changing different perceptions at different stages to encourage forward movement.

Another example of the HBM being integrated with other theories is with the *precede-proceed model* (PPM). The PPM is a nine-phase framework for guiding community-based

health programs (Glanz et al. 2003). Various phases deal with the individual, the community, organizations, evaluation, and policy. At the individual level, predisposing factors are defined as antecedents that provide a rationale for behavior change. The variables under this factor are not specified but left to the discretion of the model user. Researchers have inserted perceptions from the HBM under predisposing factors; further, a cue to action may be seen as an enabling factor – defined as external resources that facilitate behavior change (at the individual level) (Menon et al. 2003). Health communication may then be aimed at affecting change in perceptions (predisposing factors) and providing a cue to action (enabling factor).

### LIMITATIONS

The HBM, however, also has limitations, especially in regard to accounting for *cultural differences* among the audience. As boundaries between countries blur and advanced technology makes cross-over even easier, it is important to consider health in the larger contexts of culture and globalization. The HBM makes no allowances for cultural variations in beliefs. The underlying assumption of the model is that individuals will engage in preventive health behavior given the right set of beliefs. However, in cultures where preventive health orientation is lacking, fatalistic views of life are prevalent, or religion influences beliefs about health and death, the HBM would predict little or no health behavior (→ Culture and Health Communication).

Furthermore, the HBM assumes that health promotion technology or *health-care is available* to individuals. However, in economies where preventive tests, such as mammograms and glucometers, are not available to people, regardless of perceptions, health behavior change cannot occur. Additionally, even in societies where health insurance exists and covers costs of health promotion, many individuals are underinsured or uninsured, and without access to health-care. In countries where free national health plans provide for all citizens, long waits and plan-stipulated delays may incur. In all such instances, cognitive perceptions may end up having little to do with a woman's decision to have a timely mammogram or adhere to an insulin regimen.

Given the long and widespread use of the HBM, the *operationalization of concepts within the model is widely variable*, even when studying the same health behavior. Thus, comparison of the predictive value of the HBM across studies remains difficult and findings have been rather inconsistent. For example, perceived susceptibility to breast cancer has been reported to have had a positive, a negative, and no effect on mammography screening. The operational definitions of susceptibility were different in these reports.

A final limitation is that the model has rarely been extended to examine *moderating or mediating effects*. The majority of multivariate analyses have investigated HBM variables in linear regression models. There remains the possibility that the HBM variables may moderate or mediate the effect of each other or other variables from other theories.

The answer to such limitations lies in further adapting the HBM to accommodate cultural and system variables such as fatalism and health-care access, among others. Planned in-depth analysis of curvilinear relationships within the HBM may further add to its utility as the basis for health communication. While some HBM constructs may not directly influence behavior, they may still act as mediators or moderators of the relationships between beliefs and the outcome. For example, while fatalism may not

directly influence mammography use, it may act as a mediator of the relationship of barriers or benefits to mammography use. Inconsistent results when using the HBM underscore the importance of standardization of operational definitions of HBM variables within various disease foci. Despite these constraints however, the HBM remains a popular model, guiding behavior change and health communications for over six decades.

## **Health Campaigns, Communication in**

*Seth M. Noar*

*University of Kentucky*

Health communication campaigns have long been a tool used to influence the health of the public in countries around the world. Campaigns are an organized set of communication activities to produce health effects or outcomes in a relatively large number of

individuals, typically within a specified period of time (Rogers & Storey 1987). The history of campaigns in the United States provides a window into how the general health communication campaign literature has progressed, and is now presented along with some important caveats.

While health communication campaigns in the US can be traced back as far as the 1700s, the modern history of campaigns began in the 1940s and 1950s, when large-scale campaign efforts were carried out and seemingly resulted in minimal or no effects. According to Rogers and Storey (1987), this was an *era of minimal effects*. The 1960s and 1970s then ushered in a “*campaigns can succeed*” era, in which campaign successes, most notably the Stanford 3-City Heart Disease Prevention Program, brought new optimism to the campaign literature. Campaign scholars began to blame ineffective campaigns, rather than the recipients of those campaigns, for a lack of effects. Such scholars also began to uncover and formalize principles of effective campaign design, which paved the way for a new era of campaigns. This latest era of campaigns has been referred to as the *moderate effects era*, and is the period from the 1980s until today (→ Media Effects, History of). During this period, many additional campaign successes have helped campaign designers to better understand how campaigns work, in terms of both what makes them effective and what their limits may be. While we have witnessed a greater accumulation of campaign successes in this era, campaign “failures” still abound.

Although this historical perspective, put forward by Rogers and Storey (1987), is often presented as a basic history of campaigns, some scholars have criticized it as overly general and missing some important caveats. For instance, while early campaign evaluators may have found minimal or no effects of campaigns, such researchers tended to look only at general population effects. In fact, it is likely that many campaigns had effects but only among particular sub-groups (Ball-Rokeach & DeFleur 1976; Viswanath et al. 1991). From this perspective, it is not so much that early campaigns failed as that campaign effects were limited to particular sub-groups and this fact eluded many scholars at the time. Indeed, campaigns may have differential effects on individuals based upon a variety of factors, including social class (Viswanath et al. 1991), dependence on media (Ball-Rokeach & DeFleur 1976), and personality factors (Zimmerman et al. in press). This realization has led to a much greater focus on audience segmentation in campaigns, which will be discussed below.

## **CAMPAIGN EFFECTIVENESS**

While campaign effectiveness can be defined in different ways, typically determinations of campaign success are based upon whether a campaign’s goals were met and/or whether the campaign had a practical impact on the health issue at hand (→ Public Opinion, Media Effects on). What kinds of outcomes are health communication campaigns typically focused on? And what types of effects are campaigns capable of? Health communication campaigns are often aimed at modifying one or more of the following outcomes: (1) increasing knowledge and raising awareness about a health issue; (2) increasing positive attitudes about a particular health practice; (3) reinforcing and/or changing social norms surrounding a health practice; (4) increasing individuals’ intentions to engage in a health practice; and (5) impacting the health behavior or practice itself.

Traditionally, campaigns were thought to only be capable of raising awareness and perhaps improving the attitudes and social norms of a particular audience. More recent work, however, has provided evidence that properly designed and implemented campaigns can impact health behaviors and practices (e.g., Hornik 2002; Snyder et al. 2004; Noar 2006a). In fact, a large research synthesis of numerous health communication campaign studies conducted in the US revealed that such campaigns have improved health practices including seat-belt use, oral health, alcohol use, smoking cessation, heart disease, mammography screening, and sexual and other behaviors (Snyder et al. 2004). While the effects of such campaigns have tended to be small (i.e., impacting, on average, 8 percent of individuals in the campaign community), the impact at the population level could be significant. Reviews that have focused on or included campaign studies from countries throughout the world reveal similar conclusions with regard to small but meaningful effects of health communication campaigns (e.g., Piotrow & Kincaid 2001; Derzon & Lipsey 2002; Bertrand et al. 2006).

## PRINCIPLES OF CAMPAIGN DESIGN

Perhaps the most valuable lessons being learned in the campaign literature are the conditions under which campaigns tend to be most effective. These can be referred to as principles of effective campaign design, and many were originally derived from the → social marketing literature. They include: (1) conducting *formative research* with the target audience; (2) *using theory* as a conceptual foundation for a campaign; (3) *segmenting one's audience* into meaningful sub-groups; (4) using a *message design approach* that is *targeted* at the audience segment(s); (5) utilizing effective *channels* and *strategies* widely viewed by and persuasive with the target audience; (6) conducting *process evaluation*; and (7) using a sensitive *outcome evaluation design*. These principles and their application have been often written about and discussed within the campaign literature (Rogers & Storey 1987; Salmon & Atkin 2003; Randolph & Viswanath 2004; Noar 2006a; Palmgreen et al. in press). Each principle will now be discussed as it is applied in the campaign literature (→ Health Campaigns for Development).

### Formative Research

Formative research has been defined as a two-phase process. First, *pre-production research* is carried out. This includes gathering data regarding audience characteristics, the behavior at issue, and message channels. Second, production testing, or *pre-testing*, is carried out. This includes testing initial campaign messages with target audience members in order to gain feedback on the appropriateness and persuasive impact of those messages (Atkin & Freimuth 2001). No matter what the audience, behavior, or channels to be focused on, formative research is thought to be crucial to truly understanding the target audience. Information gathered from such research can help insure that campaign designers understand the target audiences' perceptions with regard to the attitudes/ behaviors at hand, develop messages that resonate with the target audience, and place messages in channels that the target audience has a high likelihood of viewing. Insights gathered from such research are traditionally used to help make critical campaign

decisions regarding channels and messages and ultimately may have a great impact on whether a campaign is successful or unsuccessful.

### **Theory-Based Campaigns**

Theories serve as important conceptual foundations for any health communication campaign. In fact, theories serve a number of important roles, including suggesting: (1) important behavioral determinants that campaign messages might focus on; (2) variables for audience segmentation (discussed below); and (3) variables to be used in evaluating campaigns (discussed below). In the health communication campaigns area, numerous theories have been used. These include those focused on individual-level determinants of health behavior change, such as the → health belief model, → social cognitive theory, theory of reasoned action (→ Reasoned Action, Theory of), and the transtheoretical → stages of change model, as well as those from media studies research, including agenda setting (→ Agenda-Setting Effects), exemplification theory (→ Exemplification and Exemplars, Effects of), and the knowledge gap hypothesis (→ Knowledge Gap Effects). Campaigns have also applied dual-model → persuasion theories such as the → elaboration likelihood model and heuristic systematic model as well as theories of community adoption such as diffusion of innovations (→ Diffusion of Information and Innovation).

### **Audience Segmentation**

A key consideration in any campaign has to do with defining a target → audience. Who is the specific audience that is being focused on with the campaign? A target audience is typically formed using audience segmentation procedures. This is accomplished by dividing the population of interest into smaller, more homogeneous groups. The ultimate purpose of segmentation is to create groups that have similar message and channel preferences, and can thus be targeted with persuasive messages specifically designed for those audience segments.

Segmentation can be conducted on a variety of variables, including demographic, behavioral, theoretical, individual difference, risk factor, and other variables. At times simple segmentation strategies are utilized, such as defining a target audience based upon basic demographic variables alone (e.g., gender, age). At other times more complex segmentation procedures are used. For instance, after segmenting on demographics, campaigns may segment on additional individual difference (e.g., → sensation-seeking) and behavioral (e.g., those experimenting with the problem behavior) variables. The question of *how* homogeneous audience segments need to be can be a challenging one for campaign planners, and different campaigns may use very different segmentation strategies.

### **Message Design**

Once a clear audience segment (or segments) has been defined, messages thought to be persuasive and effective with the audience segment can then be developed. Health behavior change theories (mentioned above in the *Theory* section) are often used to inform the content of intervention messages. However, additional theoretical perspectives can be used in order to inform the creation of messages that have the greatest likelihood

of being persuasive with the target audience. There are a variety of approaches to message design that are applied in health communication campaigns. Some examples include: (1) *fear appeals* – this approach suggests that messages high in levels of both fear and self-efficacy (building individuals' confidence that they can carry out the recommended behavior) are most likely to be effective; (2) *emotional appeals* – this approach suggests that messages that elicit particular kinds of → emotions from viewers may be effective (e.g., warmth appeals); (3) *message framing* – this approach suggests that positive (gain-framed) messages are most effective in impacting preventive behaviors, while negative (loss-framed) messages are most effective in impacting screening behaviors. This is different from the widely used conception of framing as mental structures that help people to interpret the world around them, often examined in political and news-related research (→ Framing Effects; Framing of the News; Strategic Framing); (4) *sensation-seeking targeting* – this approach suggests that messages high in novelty, intensity, drama, and a lack of preaching will be most effective with high sensation seekers; and (5) *narrative approach* – this approach, often used within an → entertainment education model, suggests that storylines that provide positive role models and reduce counterarguments may be most effective. Still other approaches that are not theory-based but that appear to have been effective include the Truth campaign's focus on the US tobacco industry's manipulative marketing practices and cover-ups by the industry.

### **Channel and Strategy Selection**

Health communication campaigns utilize a number of channels and strategies to reach and affect their intended audience. These include mass communication channels such as → television, → radio, and print media, as well as small media such as posters, billboards, bus signs, and other materials and outlets. Some campaigns include broader, community-wide components such as community events, workshops, → public relations activities, and coordination with school-based programs. Newer campaigns are increasingly taking advantage of the → Internet and creating campaign-related websites (→ Health Communication and the Internet), where television content can often be viewed and campaign-relevant articles and activities can be found. In addition, evidence exists that concomitant changes in the environment along with a campaign significantly increase the chances of campaign effectiveness, and campaigns sometimes use such a strategy (→ Media Advocacy in Health Communication). For instance, seat-belt campaigns are more effective when seat-belt laws are enacted and enforced (Snyder et al. 2004), and anti-tobacco campaigns are more effective when taxes on tobacco products are increased in concert with a campaign (Randolph & Viswanath 2004).

Key decisions for campaign planners include *which* channels and strategies to use in a campaign as well as *how to* strategically place messages so that the target audience has multiple opportunities for exposure to the messages (Salmon & Atkin 2003). Multiple channels are often used in campaigns in order to try and increase the chances of reaching a large proportion of the audience segment. Traditionally, many campaigns have suffered from low campaign exposure (Hornik 2002; Snyder et al. 2004). Newer campaigns, however, have been increasing both *reach* and *frequency* of exposure to campaign messages. This has been achieved by well-funded campaign efforts that have the resources

to buy significant media time, and through strategic placement of messages within those media channels (Randolph & Viswanath 2004; Noar 2006a). The term *reach* is typically used to refer to the percentage of the audience segment exposed to any campaign message, while *frequency* refers to how often those individuals were exposed.

### **Process Evaluation**

Process evaluation refers to the monitoring and collection of data on fidelity and implementation of campaign activities. Campaign designers may have a good campaign plan, but whether that plan was executed properly is a question that process evaluation attempts to answer. Did campaign messages air in the channels (and specific placements within those channels) in which they were intended to air? Was a significant proportion of the target audience exposed to the campaign messages? With what frequency were individuals exposed? Are there any mid-course corrections that can be made to elements of the campaign to improve reach and/or frequency of exposure to the campaign? These are the kinds of questions that get asked during a process evaluation. The answers to such questions will inform mid-course corrections for the current campaign and improvements for future campaigns. In addition, process evaluation aids in the interpretation of why a particular campaign was or was not successful. If process evaluation is not conducted and a campaign fails, there may be few clues for campaign designers as to why.

### **Outcome Evaluation**

Outcome evaluation is concerned with assessing whether a campaign had its intended impact. For instance, if a campaign was focused on raising awareness and increasing knowledge about a particular health issue, an outcome evaluation asks if this was accomplished. Similarly, if campaign goals aimed to change health attitudes and behavior of a certain proportion of the target population, an outcome evaluation asks whether or not these goals were met.

Outcome evaluation is one of the most challenging aspects of any health communication campaign. Unlike other kinds of health-related interventions that may lend themselves to well-controlled experiments, campaigns are conducted “in the field” and do not lend themselves well to controlled evaluation designs (→ Experimental Design; Experiment, Field). Consequently, most of the evidence for the effects of campaigns comes from research studies that leave open many threats to internal → validity (Valente 2001; Hornik 2002). Indeed, one finds a variety of evaluation designs in this literature, including both standard evaluation designs and variations on such standard designs (Valente 2001; Noar 2006a). Popular designs used to evaluate health communication campaigns include post-test-only designs, where a campaign is followed by a post-only → survey assessing campaign exposure and campaign-relevant variables, and pre-test–post-test designs, where a pre-test survey is given, the campaign takes place and is followed by a post-test survey. Some campaigns use designs that are more rigorous and thus decrease threats to internal validity, such as pre-test–post-test control group designs, which include a control community for comparison purposes, and time-series designs, where multiple surveys are given both before and after a campaign is executed.

Most campaign evaluations use cross-sectional or independent samples (→ Sampling, Random; Sampling, Nonrandom), where *different* respondents are surveyed at one or more points in time. However, in some cases panel samples are utilized, which are those in which the *same* respondents are surveyed over multiple points in time. Occasionally, studies that evaluate campaigns using panel samples will also use cross-sectional samples to get two different viewpoints on the outcomes of a campaign. Both cross-sectional and panel samples have unique advantages and disadvantages (Valente 2001), suggesting that both kinds of evaluation are advantageous where possible.

## FUTURE DIRECTIONS FOR CAMPAIGN RESEARCH

Although health communication campaigns have been used to influence the health of the public for decades, researchers are still learning much regarding the effective design, implementation, and evaluation of such campaigns. First, campaign researchers are increasingly looking back over the many published evaluations of campaigns for lessons learned. Research syntheses or → meta-analyses have recently appeared and helped to quantify average campaign effects (e.g., Derzon & Lipsey 2002; Snyder et al. 2004), and more of these kinds of reviews are likely to appear in the literature in the future (Noar 2006b). Meta-analyses, however, often cannot make up for weaknesses in the original primary reports, and thus have limits to what they can reveal about the literature. Although theories of health behavior change have been widely applied in campaign research, there has been recent discussion regarding the need for additional communication theories that can be applied to message design (e.g., Noar 2006a; Slater 2006). Such theories might better explicate how certain message features affect health attitude and behavior changes, and could guide campaign designers in the creation of more effective health-related campaign messages. Moreover, campaign evaluators are increasingly recognizing the limits of certain evaluation designs and at the same time suggesting ways to strengthen those weaker designs (e.g., Hornik 2002). In addition, health communication campaign evaluators appear to be increasingly applying more rigorous outcome evaluation designs (Noar 2006a). Thus, a trend for the future may be better outcome evaluations of health communication campaigns, which could have the effect of increasing the quality of the resulting data and the value of this literature as a whole. Finally, a trend that will no doubt continue is in understanding the role of the Internet and other new technologies within health communication campaigns. These technologies unlock seemingly limitless possibilities in terms of potentially affecting health, and their role in health communication campaigns is just beginning to be explored and harnessed.

# Health Campaigns for Development

Thomas Tufte

Roskilde University

Development communication engages strategic social change in a variety of areas, yet a great proportion of resources in this field are allocated toward the field of → health communication (Hemer & Tufte 2005; → Development Communication). There is no universal → strategic communication response to complex health-related challenges, but rather a framework of general principles, ranging from behavior change through mediated communication to advocacy communication directed toward policy and structural change, through the processes of → participatory communication (Nutbeam & Harris 2001). The practices engaged follow the standards invoked in → development communication campaigns (McKee et al 2000; → Media Advocacy in Health Communication).

In issues of health, a central challenge has been the replication of health campaigns across different communities and issues (Piotrow et al. 1997). The particular contexts of the health concern and the community at risk differ greatly. For example, the social marketing of individual behaviors (condom use) in family planning strategies in the 1970s and 1980s was very rapidly transferred into a dominant strategy in HIV/AIDS in subsequent decades. This happened in part due to HIV/AIDS being conceived as primarily a problem arising from certain kinds of sexual behavior. In more recent years there has been a growing recognition of the need to complement and replace → social marketing as the (exclusive) strategy in HIV/AIDS prevention, incorporating advocacy and → *entertainment education* approaches (Airhihenbuwa & Obregon 2000; → Prevention and Communication). Currently this issue has arisen in response to development campaigns addressing the health issue of avian flu. Many campaigns have attempted to reproduce behavioral strategies known from the earlier HIV/AIDS days by emphasizing consumer behavior at the expense of other potential approaches.

In the field of health, development communication campaigns might consider a variety of factors in articulating an appropriate strategy (Tufte 2007). First, a *distinction between types of health programs* should be made. For example, a communicable disease such as malaria would require a different approach from cardiovascular disease. The problem of malaria requires dealing with individual behavior vis-à-vis the risk of mosquito bites, but also attention to policies on access to both prevention (bed nets) and treatment, and ultimately and ideally attention to the waters where mosquitoes breed. Addressing cardiovascular disease, on the other hand, requires attention to lifestyle over time, physical activity, smoking patterns, food patterns, etc. It also requires attention to individual behavior, policies, and environmental factors. In other words, carefully tailored communication interventions should be based on a profound understanding of the health problem encountered while at the same time drawing on the generic options of individual behavior, policy, and environmental factors.

Second, *emergency diseases*, such as SARS or avian flu, need to be distinguished from more fairly *typical development-oriented health problems*, such as those directly related to conditions of poverty. This distinction relates to the difference between broad-based and narrow-based problems. With sexual or reproductive health, for example, one could focus

on a concrete practice, such as condom use, or more broadly based issues related to gender and power, poverty, and public health.

Development communication campaigns in the field of health should consider several criteria, beginning with the timing and duration of the intervention, from immediate and short-term to carefully (slower) planned long-term interventions. For example, emergencies require immediate and in the first instance short-term intervention, such as tackling food shortages in drought situations or required infrastructure to avoid cholera epidemics. In contrast, longer-term intervention is needed to insure sanitation in addressing long-term health issues.

Second, health campaigns in development need to consider the level of intervention, whether it is to be engaged at a local community, national, transnational, or global level. Third, the nature of the intervention – whether it should be addressed from a behavioral or from a socio-economic and political structural angle – should be considered. Fourth, the content of the intervention should be related to these issues, directing attention to specific messages or social processes, such as women’s empowerment and gender roles in considering family planning practices. Fifth, the expected outcome of the development campaign might include a recognition of the processes or focus on specific results.

Development communication campaigns in the field of health face *several challenges*. First, *more collaborative and comprehensive strategies* are needed to engage the complexity of health concerns. Many campaigns illustrate the fact that the core challenges of many health problems lie outside of the public health system and require cross-sectorial collaboration. The work of the FEMINA Health Information Project in Tanzania is one example. In countering the growing HIV/AIDS pandemic and other issues related to sexual and reproductive health, such as gender equality, they engage in formal and informal education, income-generating activities, and public debate (Fuglesang 2005). The South African health communication campaign “Soul City” is another example illustrating complex multilevel and multi-sectorial responses to HIV/AIDS. Responding to the complexity of health concerns has been acknowledged in WHO since the *Ottawa Charter for Health Promotion* was adopted in 1986 and even at a previous conference which resulted in the Alma Alta Declaration. The social determinants of health were already acknowledged at that time. However, the practice of health campaigns are still only gradually responding to these broader-based challenges. Second, a range of characteristics of *globalization* are today impacting upon health and will subsequently pose fundamental challenges in health campaigns for development (→ Globalization Theories). One case in point is the growing migration, for example in Africa, that is leading to the explosion of “modern” diseases, such as diabetes and obesity, in many developing countries. Another is the increased transnational mobility that leads to *epidemics traveling*, as in the case of SARS, avian flu, and HIV/AIDS. This requires stronger transnational collaboration in health campaigns.

## **Health Communication**

*K. Viswanath*

*Harvard University*

Health communication is the study and application of the generation, creation, and dissemination of health-related information, health-related interactions among individual social actors and institutions, and their effects on different publics including individuals, community groups, and institutions.

The challenges inherent in disease prevention and health promotion warrant a multidisciplinary and multilevel approach that examines the role of distal factors such as social and economic policies and health policies, near proximal factors such as neighborhoods and health-care organizations, and proximal factors such as individual lifestyles to explain individual and population health. Some have argued that communication is one thread that could connect the distal and proximal factors to explain individual and population health. Given this charge, health communication, though primarily a derivative field, draws from and contributes to such fields as mass communication, journalism, communication studies, epidemiology, public health, health behavior and health education, medicine, sociology and psychology, among others.

### **THE EMERGENCE OF THE CENTRALITY OF HEALTH COMMUNICATION**

The precise “origin” of health communication is difficult to pinpoint though its evolution could be traced to campaigns in public health to promote hygiene and immunization in

the eighteenth and nineteenth centuries, persuasion studies during and after World War II, and the → development communication campaigns in the 1970s. At the same time, the importance of communication in health-care delivery and health services provided the foundation for health communication that focused on patient–provider communication. Some recent developments in health communication, however, have contributed to its emergence as one of the more dynamic areas in communication studies. In many countries these developments include reports by major academic think tanks and professional organizations calling for communication to be included in curricula in medical and public health schools, for funding to be available from major national and international agencies, and for the inclusion of health communication goals in governments' national health agenda.

The Institute of Medicine (IOM), a major research organization in the United States, published several reports that highlight the centrality of Communication in health, including *Speaking of health: Assessing health communication strategies for diverse populations*, and *Who will keep the public healthy?*, a report on the future of public health education that identified communication as a cross-cutting area of critical importance for training future public health professionals. The IOM also released several research reports including *Unequal treatment: Confronting racial and ethnic disparities in healthcare*, *Health literacy: A prescription to end confusion*, and *Fulfilling the potential of cancer prevention and detection*, among others that clearly identify a role for communication in the health-care continuum of prevention, detection, diagnosis, treatment, and survivorship or end-of-life stages.

Major funding agencies in the United States including the National Institutes of Health (NIH), agencies in Europe such as institutions of the European Union, and international bodies such as the World Health Organization (WHO) and the International Bank for Reconstruction and Development (IBRD), also known as the World Bank, have recognized the contribution of communications to population health and, accordingly, have begun major funding initiatives in this area. In addition, in the United States, the National Cancer Institute (NCI) of the NIH established a branch dedicated to health communication research, the Health Communication and Informatics Research Branch (HCIRB) whose presence provided the impetus for increased funding and large-scale initiatives in communication research.

Two such initiatives are worth noting: the funding of four Centers of Excellence in Cancer Communications Research (CECCRs) and the start of a national survey of health communication behaviors of American adults, the Health Information National Trends Survey (HINTS). The latter, arguably, is the first public use dataset on health communication in the world. As a part of its “Futures Initiative,” the Centers for Disease Control and Prevention (CDC) recently established the National Center for Health Marketing, with communication playing a central role. The presence of formal health communication programs at the NIH and CDC, coupled with major funding initiatives from NIH and the United States federal government on anti-drug campaigns, heart health, anti-tobacco, and AIDS/HIV prevention campaigns among others has attracted funding and interest from a variety of scholars from many different disciplines including communication, public health, psychology, sociology, and epidemiology among others. The United States federal government's action plan for health, *Healthy People 2010*, devoted an entire chapter of its report to health communication. Finally, there are now at least two

major journals, *Health Communication* and the *Journal of Health Communication*, that exclusively publish research in this area in addition to other journals in social sciences and health that publish health communication research. These developments have precipitated and accelerated the establishment of health communication specialization in academic disciplines in major American and European universities.

### ORGANIZATION OF THE FIELD

There is no simple or complete way to organize the field of health communication though several sub-fields have existed depending on one's research interests, as well as due to adventitious and historical circumstances. While not necessarily perfect, a more heuristic way to locate one's interest is *along levels of analysis*: individual, interpersonal, social network, organizational, and mass or societal levels. Such an approach is not meant to be comprehensive but is a way to organize the large amount of research, as well as to locate the interests of a variety of practitioners as well as researchers.

In general, at the *individual level*, the focus is twofold: (1) how health cognitions, affect, and behaviors influence and are influenced by, health communications; and (2) how interpersonal interactions between patients, family members, and providers, and with members of their → social network, influence health outcomes. At the *organizational level*, some have studied the role of communication within health-care systems and how organization of media and the practices of media professionals may influence population and individual health. Finally, at the *societal level*, the focus is on large-scale social changes and the role of communication with such changes. For example, one might examine how → strategic communications as well as natural diffusion of information impact individual and population health; or how communication mediates and is influenced by social determinants such as social class, neighborhood, social cohesion and conflict, social and economic policies, and how that impacts individual and population health.

Even as these levels provide a useful organizing framework, *two caveats* are warranted. First, policymaking and research related to health may affect more than one level. For example, one might be interested in how communication between patients and physicians may influence patients' adherence and compliance with medical regimens, satisfaction, and quality of life. At the same time, advertising of drugs, or "direct to consumer advertising" (DTCA), on television may motivate the patient to discuss the drug with the physician thus affecting their interactions. Thus, while organizing the field along the different levels may be utile, one must be cognizant of actions and outcomes occurring across levels of analysis.

Second, interest in a level of analysis and pursuit of work at one level is not inconsequential. Locating a problem at one level, and studying it at that level has implications for the kind of policy or practice that is likely to emerge from that research. For example, if a researcher finds that social norms may lead an individual to abuse alcohol, a solution may focus on addressing those norms at the individual or interpersonal level. On the other hand, if it was found that advertising is responsible for influencing social norms and subsequent binge drinking, solutions may focus on the environment including communication policies and regulation of advertising. In short, choosing one's level of analysis is neither trivial nor inconsequential.

## **DIMENSIONS OF HEALTH COMMUNICATION**

Several dimensions of communication have been studied at the individual level, both focusing on psychological factors within individuals, as well as the interactions between individuals and among small groups and how they affect health.

### **Models of Health Behaviors**

Several theories from psychology and communication inform how psychosocial determinants such as health → cognitions, → emotions such as fear, beliefs, motivations, and perceptions among others influence individual behaviors insofar as they affect health. There are a variety of individual-level theories that have informed the work in health communication. These include expectancy value theories such as the → health belief model, the theory of reasoned action and the theory of planned behavior (→ Reasoned Action, Theory of; Planned Behavior, Theory of), the protection motivation theory, and the transtheoretical model (→ Health Behavior Change, Transtheoretical Model of), among others (→ Expectancy Value Model).

*Expectancy value theories* make a number of core assumptions. Health behavior is an outcome of a series of contingent conditions starting with beliefs and norms leading to behaviors. People have “expectancies” or beliefs about certain outcomes and these beliefs are either valued or not valued by them. In making their choices, people strive to maximize benefits and minimize costs. Individuals make rational choices affecting their health based on information available to them and the choices could be influenced by providing appropriate information pertaining to those beliefs. Fishbein et al. (2002) developed the “*integrated model*” of health behavior combining elements of several health behavior theories. They argued that there are only a finite number of determinants of behavior and they can be integrated to explain and predict health behaviors. An addition to the integrated model, self-efficacy from social cognitive theory, is worth noting.

While the expectancy value models treat environment as a background that works through individual norms, beliefs, and attitudes, → *social cognitive theory* (SCT) proposes that human behavior is a dynamic product of three sets of factors: personal, behavioral, and environmental (Bandura 1994; → Bandura, Albert). SCT assumes that humans are active agents capable of self-assessment, evaluation, and learning and react to, and in turn influence, their social environment. They can learn via “symbolic modeling” from the media or through interpersonal contacts. If they value a behavior and feel that it has positive consequences they are capable of imitating the behavior, but if they believe that it has negative consequences they may not adopt it. Lastly, they must believe that they are capable of engaging in the recommended behavior, i.e. have self-efficacy for the behavior in question.

### **Health Communication and Information Processing**

The impact of persuasive communications through communication campaigns, providers, or casual exposure to health information depends on how the information is processed by the recipient (→ Information Processing). Two dual-process models of information

processing, the → *elaboration likelihood model* (ELM) and the *heuristic systematic model* (HSM) (Chaiken 1980; Petty & Cacioppo 1996) have been popular in health communication. In essence, both models posit that change in one's attitude (in terms of both whether or not it happens and for how long) depends on the route through which the information has been processed, and the motivation and ability to process the information.

Many persuasive campaigns in health communications (→ Health Campaigns, Communication in) used the dual-process models to design and evaluate health communications. More recently, however, several advances in psychology call for a revision of conventional assumptions about attitude change (→ Attitudes; Persuasion), suggesting that: (1) there are multiple pathways in changing attitudes (e.g., Cohen & Reed 2006); (2) attitudes are less stable than originally assumed and they may vary across time and situation; (3) attitudes may be less enduring and may form quickly; (4) attitudes may be of two types: explicit attitudes reported more consciously and implicit attitudes that are more automatic and based on deeply held affect (Greenwald & Banaji 1995).

## INTERPERSONAL COMMUNICATION

Interpersonal communication, or communication among dyads or small groups, has a remarkable effect on several individual-level health outcomes (→ Interpersonal Communication). Much of the attention and energy has been focused on communication between health-care providers and consumers, and has attracted attention from a diverse range of disciplines including researchers from communications, health services, and primary care physicians, among others. Other dimensions such as the role of significant others in influencing social norms, providing social support, and social capital have also been pursued at this level.

### Consumer–Provider Communication

Extensive attention has been given to understanding the consequences of communication between physicians and patients on patient satisfaction, adherence, and quality of life. Even though most attention has been focused on the interaction between physicians and patients in a medical encounter, it is now recognized that the field of study should expand beyond physicians and patients to the context of the communication and the actors engaged in it (→ Patient–Provider Communication). For example, it is recognized that patients interact not just with physicians but also with other providers including nurses, specialists, pharmacists, patient navigators, and other clinical staff. In addition, patients are assisted by other family members whose presence influences medical interactions. Furthermore, larger social forces such as direct-to-consumer advertising and the burgeoning influence of the Internet are also influencing the nature of physician–patient interactions.

The research on patient–provider interaction runs along several streams. One theme is *who controls the interaction* between providers and patients, known as “relational control.” The traditional paternalist model, where the physician as an expert exercised greater control, is yielding to more participatory or consumer-oriented models, where patients seek a more active role in their treatment, leading some to focus on “patient-centered” communication.

A second theme focuses on the *outcomes of patient–provider interactions*. Extensive research has documented that patient–provider communication influences patient satisfaction which, in turn, is related to patient adherence and compliance to treatment regimens, ease of distress, physiological response, length of stay in the hospital, quality of life, and health status among others. In turn, providers also benefit from better communication where patients are less likely to change providers, fewer malpractice suits are initiated, and patients are more compliant with recommendations.

Third, recent examination of determinants of disparities in health-care paid attention to communications including patient–provider communications and *patient information seeking*. The health-care system is complex and patients typically are forced to deal with a remarkable array of health-care personnel making it difficult to navigate the system and negotiate care. Researchers have documented stark differences in patient preparation and access, and in care received and health outcomes, between social classes as well as racial and ethnic groups. For example, racial and class differences between providers and patients influence the duration and informative nature of discussions and the emotional support and question-asking by patients, resulting in shorter visits, less participatory decision-making, lower satisfaction, and lower compliance (Cooper & Roter 2003). This is likely to put the underserved groups at a disadvantage as they are much less likely to seek information from outside the medical encounter.

### **Social Support, Social Capital, and Social Networks**

The implications of interpersonal interaction in the context of families, friends, co-workers, and voluntary associations on health outcomes has emerged as one of the most dynamic areas of research in health communication. This topic has been pursued from diverse theoretical viewpoints by researchers focusing on social networks, social support, family communications, and social capital based on the researcher's disciplinary origins and research interests. It is a mistake to infer that social support and social capital are the same given their different theoretical underpinnings and intellectual interests. It is, however, reasonable to assume an overlap between these distinct areas.

In the context of patient health, *social support* mechanisms, through which relationships with others such as family members, friends, and co-workers eases stress, has a salutary impact on health (→ Social Support in Health Communication). Social support could be in the form of information on how to address problems, encouragement and support for behavior changes, or reinforcing healthy behaviors, and/or tangible support in the form of resources or services such as transportation to a clinic (House 1981). Patients endowed with such support generally do well and enjoy enhanced quality of life (QOL).

In addition to social support, interpersonal relationships among *social networks* may have other outcomes. Social networks can accelerate or decelerate diffusion of new information, and also influence how it is interpreted (Valente 1995). Members within networks can serve as role models for lifestyle behaviors such as in smoking and obesity.

Last, interpersonal interactions could *generate social capital*, defined as norms of reciprocity, interpersonal trust, solidarity, and cooperation, that seem to characterize most relationships within social networks or informal organizations (Putnam 2000; → Social Capital and Communication in Health). It is widely documented that social

capital is positively related to lower stress, lower risky behaviors, lower mortality, higher self-rated health, and lower psychological distress. Social capital is a product of interaction between two entities and the interaction is sustained by communication (Viswanath 2007). Social ties and the advantages emerging from those ties are related to media use, identification and involvement with the community, and promotion of interpersonal trust, allowing for the spread and interpretation of health information (→ Community Integration).

The emergence and spread of the → Internet has broadened the scope of interpersonal interaction and its influence in health communication by moderating the limits of geography. While one may still need geographical proximity to provide instrumental social support, the emergence of disease-focused support groups on the world wide web, provision of health information, and facilitation of electronic communication with family, friends, and physicians is a dynamic area that will attract more attention from health communication researchers.

### **Risk Communication**

Risk communication is a well-established area of research in health communication and its study cuts across all levels of analyses (→ Risk Communication). Risk is the probability of negative outcomes as a result of certain events or behaviors. Communication about risk may occur through interpersonal interactions from physicians, family members, and friends or through mass media. For example, a physician may try to communicate the likelihood, or “risk,” of a negative or adverse outcome to a patient. Or a news story on avian flu in the media may include discussion of the risk of its spread to humans. In general, the goal of risk communication is to increase the perception of risk, that is the possibility of negative outcomes with the hope of changing audience behavior (→ Risk Perceptions). As risk, by definition, deals with uncertainty, it involves explaining the determinants of risk, the likelihood of negative outcomes, and their consequences. The recipient of communication is expected to weigh these different components before deciding on a course of action. Clearly, this places a considerable burden on both the communicators as well the recipients. Much attention in risk communication has been given to communicating probabilities. Given that probabilities and other risk metrics are difficult for lay individuals to understand, alternative forms of communication are necessary.

Some work in risk communication has examined how community structural factors and social conflict (“outrage”) may influence how risk is framed and amplified, and the consequences of the coverage of risk in the media (→ Environmental Communication; Social Conflict and Communication). Overall, risk communication is an important area that connects conceptual work tightly with application.

### **MASS MEDIA AND HEALTH**

As will be evident from other entries in this encyclopedia, mass media emerged as one if not the most powerful agencies of socialization in the twentieth century. Mass media may be defined as organizations explicitly structured and organized to create or gather, generate, and disseminate news and entertainment, which distinguishes them from others

such as families, friends, or churches (Viswanath et al. in press). Media products range from strategic communications such as advertisements (→ Advertising) and press releases, entertainment products such as movies, → television programs and → books, and informational products such as news.

The *power and appeal of the media* stem from three sources. First, thanks to the technological revolution, media have penetrated the farthest corners of the globe, a reach that is virtually unrivalled to this point. Second, media institutions are organized to efficiently produce, process, and disseminate media products. Third, despite the strategic focus on catering to narrow segments of population sub-groups for marketing purposes, the appeal of media products, within reason, transcends boundaries of race, ethnicity, culture, and class. These reasons, in combination with emerging media platforms such as the Internet, mobile phones, and other mobile technologies will likely maintain the power of media over other ways to communicate and socialize (→ Mobility, Technology for).

In health, media influence may occur in two ways: (1) exposure to messages through routine use of the media, leading to effects on people's cognitions, affect, and behaviors and on institutions and groups in reaction to media messages; and (2) strategic use of media in health promotion and disease prevention. Both routine use and strategic use of the media have a profound impact on individual and population health as well as on institutions involved in health.

### **Routine Use of Media and Health**

The incidental and routine use of media for → news and entertainment serves four functions in health (Viswanath 2006). The *informational function* is served when casual use of media for news or other purposes may expose the audience to developments on new treatments or new drugs, alert them to risk factors, or warn them of impending threats such as avian flu.

Media serve an *instrumental function* by providing information that facilitates action. For example, in times of natural disasters the audience may learn about places where they should take shelter. Information of this kind allows for practical action.

Media defines what is acceptable and legitimate, performing a *social control function* that has been widely used in health promotion. For example, media have been enlisted to create new → social norms (e.g., engage in physical activity) or change existing norms (e.g., discourage binge drinking or smoking).

The *communal function* is served when media provide social support, generate social capital, and connect people to social institutions and groups. Media may promote trust in local institutions through its coverage. As discussed earlier, social support and social capital are associated with better health outcomes.

### **Purposive and Strategic Use of Media**

Strategic or purposive use of media may take several forms. Individuals may deliberately seek information to learn more about a health topic that is of relevance to them or their referent other. Public health agencies have extensively used media alone or media as a part of a larger arsenal to promote knowledge, or to change beliefs, attitudes, and behaviors that impinge on health (→ Social Marketing). Social movement groups, among others,

have engaged in *media advocacy* to draw the attention of policymakers to policies that affect population health (→ Media Advocacy in Health Communication; Social Movements and Communication).

### *Information Seeking*

Information seeking, as a construct, has gained greater currency in recent times as more information on health has become routinely available because of greater coverage of health in the media, the spread of health-related content on the world wide web, or the consumerist movement in health that promotes informed or shared decision-making (→ Information Seeking). It is widely assumed that some people under certain conditions actively look for health information to seek a second opinion, make a more informed choice on treatments, and learn in greater depth about a health problem that afflicts them or their friends or family members.

However, not everyone actively seeks information. Some look less actively but indulge in *scanning* the environment for information because of perceived salience (→ Information Scanning). Some avoid information, often characterized as “blunting.” Others do not seek at all, often those from lower socio-economic status groups. The consequence of actively looking or scanning for health information is that such strategic use may result in greater attention to and processing of media messages and, as a result, greater learning and behavior change.

### *Media, Agitation, and Advocacy in Health*

Some have drawn lessons from social movements in using the media to agitate and advocate for changes that may affect the health of populations and communities and in health policies. The rich history of collective action when activist groups confronted powerful institutions and interests to correct social injustice and rectify inequities has provided a fertile ground for activists in health (→ Collective Action and Communication).

Activists have drawn lessons from the experiences of social movements to speed up or even change drug approval policies in HIV/AIDS; drawn attention to the profound disparities and inequities in health where certain population groups and communities suffer disproportionately compared to others (→ Health Disparities, Communication in); and frequently agitated to draw attention to environmental factors such as polluting factories that seem to affect the dispossessed and the disenfranchised much more than others. In the initial stages, mainstream media were seldom hospitable to activist groups and some groups have even been derided and their concerns delegitimized, an experience faced by many groups including women’s, civil rights, and green movements.

The media have been integral to the strategy of activist groups who strived to attract attention, frame issues, and influence public opinion (→ Framing Effects). Activists have used a variety of tactics to attract attention including creating dramatic events, holding sit-ins, and disrupting routines. Often, movements created their own vehicles such as songs and music, newspapers or magazines, documentaries, books and recently websites, which (1) help to present their point of view, and (2) serve to inspire and mobilize supporters and maintain morale. Over time, movements have evolved into legitimated institutions funding research, communicating with policymakers, and mobilizing supporters as in the case of breast cancer, heart disease, or tobacco campaigns.

*Health Campaigns*

The most visible and popular means of strategic communications is through health campaigns which have become a critical arsenal in health promotion. A typical health campaign attempts to promote change by increasing the amount of information on the health topic, and by defining the issue of interest in such a way as to promote health or prevent disease. For example, an anti-drug campaign may attempt to make visible not only a message against illicit drugs but also the reasons why drug use is undesirable and not normative. The outcomes of focus in health campaigns include raising awareness about a problem, increasing knowledge, changing beliefs around behaviors that impinge on health, influencing social norms, and changing and maintaining health promotive behaviors.

Expectations of the effects of health campaigns have always been high, though in reality their actual impact has been more modest (Snyder & Hamilton 2002; Fishbein 1996). Comparing expectations in the commercial world, Fishbein argued that while marketers may consider a 3 to 4 percent increase in market share as successful, in public health an effect size in this range may be considered failures. Moreover, the campaigns are not designed to detect such small effects. A collection of case studies of successful campaigns as well as a review of campaigns edited by Robert Hornik (2002b) clearly demonstrates that: (1) campaigns to promote change can be successfully mounted even with modest budgets, as was shown in the anti-tobacco, seatbelt use, sudden infant death syndrome (SIDS), and heart disease campaigns among others; and (2) evaluation of campaigns calls for creative research designs that can document both intended and unintended changes.

Recent reviews of the vast literature on health campaigns have identified *conditions under which health campaigns can be successful* (Hornik 2002a; Noar 2006; Randolph & Viswanath 2004): (1) Insure “exposure” to the campaign messages, a problem that has plagued most health campaigns, which rely on limited budgets. In addition to exposure, it is essential that the definition of the issue at hand is favorable to the promoted topic. (2) Use social marketing tools to create the appropriate messages for distribution and dissemination, including formative research, audience segmentation, and creative media mix. (3) Develop messages, taking into account research in the areas of (a) executional elements such as message construction, and (b) determinants of health behaviors. (4) Facilitate changes in the environment that allow the audience to practice the recommended behaviors and reduce, if not eliminate, barriers to change.

In summary, strategic use of communications through health campaigns remains a promising means for practitioners to promote social change in health and for researchers to examine health-related social change.

### **Use of Media and Media Effects in Health**

At the outset, research has documented an association, of varying degrees of strength, between media use and media exposure and health outcomes, including beliefs and behaviors around sex, obesity, violence, smoking, and cancer screening among others. Research shows that exposure to violence on TV is associated with aggressive behavior in some children and acceptance of TV-portrayed reality, or *cultivation*, among adults (→ Violence as Media Content, Effects of; Cultivation Theory; Cultivation Effects). Exposure to portrayal

of smoking in movies is positively related to experimenting with smoking among teenagers. Lastly, a plethora of studies report that time spent watching television is associated with obesity and being overweight, though the studies are fraught with methodological problems (→ Research Methods; Validity). Nonetheless, it is reasonable to assume that exposure to some media content under certain conditions is likely to have some effects on a subset of people some of the time. It is also plausible to argue that the effects found in studies with defined populations or in experiments with small groups could be considered serious when projected to population level, a fact that is often overlooked in the debates about media effects on health (→ Experimental Design; Experiment, Laboratory).

Part of the explanation for the effects was discussed earlier under the theories of health behavior. But, more to the point, the effects of media on health could be due to the broad reach and hence exposure to media content, and perhaps also to the very structure of media messages. Irrespective of the genre of media content – news, soap operas, talk shows, movies, or opinion pieces – there are certain common message elements that can potentially influence how the information is processed and its impact on people. Some common message elements, including format or structure (how the messages are constructed), that are attracting attention in health communication research at present include → sensation seeking, fear appeals, narratives, framing, and exemplars among others (→ Exemplification and Exemplars, Effects of). While an extensive treatment of these message effects can be found elsewhere in the *Encyclopedia*, a brief definition is in order.

*Framing* in health messages emphasizes the consequences of adopting or failing to adopt certain health behaviors. It has also been conceptualized as a way to define or construct a health problem. *Narratives* are stories with meaning that appeal to an audience and offer symbolic models for behaviors to emulate (e.g., smoking in movies; → Narrative News Story). *Fear appeals* are messages with high negative emotions that are aimed at increasing perceptions of threat and severity of risk but are effective only when accompanied by messages that tell the audience how to reduce the threat. *Exemplars* are used to represent a general class of events as typifications and purport to be more effective than factual presentation in recall and learning. Finally, *sensation seeking* is a personality trait that is characterized by thrill seeking, the search for novelty and intense stimulation, which may lead to potentially risky behaviors such as the use of illicit drugs or unprotected sex.

The outcomes of exposure to different media content and formats are discussed extensively in the literature on → media effects. For example, research on *cultivation analyses* has shown that sustained exposure to media images may cultivate mediated reality among heavy viewers. A fear of crime as a result of exposure to violent programs may discourage the viewer from engaging in physical activity outside the home (→ Fear Induction through Media Content in Children). Exposure to news programs may influence the priorities people assign to the topics that receive attention in the media; this is called *agenda setting* (→ Agenda-Setting Effects). In fact, the media may define or frame how an audience may want to think about a given health issue and what they should do about it. The *knowledge gap hypothesis* proposes that media effects, particularly learning, are actually likely to be not uniform but different across audience sub-groups subject to individual and social factors (→ Knowledge Gap Effects).

The role of the mass media and its offshoots such as the Internet remains a subject of intense interest to the communities of practitioners and researchers in communication,

public health, and medicine, and is a significant area of contention between industry and the public health community.

### **SOME MAJOR PUBLIC USE DATASETS**

In keeping with its emerging central role in health, both public and private sector agencies are beginning to invest in surveillance mechanisms that can track health communication trends in the population, particularly in the United States. This may be in the form of a few questions on national surveys such as the Behavioral Risk Factor Surveillance System (BRFSS) of the US Centers for Disease Control and Prevention (CDC), or surveys devoted exclusively to health communication as with the NCI's Health Information National Trends Survey (HINTS), a dataset devoted primarily to tracking communication behaviors with particular reference to cancer control. The Pew Internet and the American Life surveys, one of the most visible and prominent surveillance mechanisms in understanding the role of the Internet in the US, also fields occasional surveys that focus exclusively on health and the Internet. Finally, efforts are underway to develop the tracking of patient information needs and behaviors through clinical informatics systems, which is sometimes discussed under "e-health." These public use datasets, which serve academic as well as practical purposes, may provide health communication researchers and practitioners with some useful surveillance information similar to what the public health community has enjoyed for decades.

### **EMERGING CHALLENGES/DIMENSIONS**

Some significant developments in the field of biomedical sciences and information technology have important implications for health communication. Four are worth mentioning here: informatics, consumer movement and decision-making, increasing disparities and communication inequalities, and research dissemination.

The combined impact of computers and telecommunications on society, needless to say, has been transformative, impinging on almost every facet of human life including art, culture, science, and education. Health communication is no exception. *Consumer informatics* integrates consumer information needs and preferences with clinical systems to empower patients to take charge of their health-care, bring down costs, and improve quality of care (→ Consumer Informatics). For example, the integration of electronic medical records with communications should facilitate communications between patients and providers, send automatic reminders to patients to stay on schedule, and help patients navigate the health-care system. Informatics also allows for more precise tailoring of messages to the needs of the intended audience (→ Tailoring, Communication and). It remains for the implications of fast-emerging informatics systems for communication and health to be investigated.

Technological developments are coinciding with the consumerist movement in health-care. The paternalistic model that characterized the physician–patient relationship is slowly being complemented by alternative models such as *shared/informed decision-making models* (SDM/IDM), which in essence means expecting or allowing the patient to take a more active role in her or his care. Another approach that has been advocated is

patient-centered communication (PCC). Some evidence suggests that a more participatory role could have positive outcomes on health, including greater patient satisfaction and QOL. The SDM/IDM movements have been facilitated by new developments in technology that allow patients to access more information outside the clinical context and be more proactive in their own health-care.

The significant investments in biomedical research enterprise in the developing world, and movement toward more evidence-based medicine, have led to calls for translation of the knowledge from the laboratory to the clinic and the community. This movement to bring knowledge from “bench to bed” and “bench to trench” is researched under the areas of knowledge integration, knowledge transfer, and → *research dissemination*. Funding agencies in medicine and public health in North America and Europe are investing resources to develop a science of “translation and dissemination,” and the impact of this area on population as well as practitioners bears watching.

Lastly, an urgent and a moral imperative in health is addressing the profound inequities in access to health-care and the disproportionate burden of disease faced by certain groups. These disparities are prevalent between rich and poor nations as well as between the rich and poor within nations. Complementing the health disparities are communication inequalities: differences in access to information, the benefits that accrue from it and the ability to act on information at the individual level, and the differences between social groups in generating, processing, and disseminating information. While the idea of inequity is not new in communication, the formalization and integration of research into a theory of → communication inequality is. Research is beginning to accumulate that shows that inequalities in communication could exacerbate health disparities. The primary determinants, precise mechanisms, and ultimate consequences of communication inequalities are yet to be investigated.

Communication is a central factor in the four aforementioned developments and health communication researchers should be vigilant in monitoring and understanding these developments and their implications for health.

The biomedical and information revolutions that characterize our time will have a far-reaching impact on personal and population health. The possibilities for providing access to information, improving physician–patient interaction, empowering patients, influencing the information environment on health, blunting the negative effects of media, and promoting pro-social change have never been more promising. Practitioners and researchers are looking toward health communication, both its study and its practice, to be a key player in the unfolding scenario to promote individual and population health. It remains to be seen how health communication practitioners fare in this central casting role.

## Health Communication, Ethics in

Nurit Guttman

Tel Aviv University

Ethics is at the heart of → health communication. Ethical issues are embedded in a wide array of health communication activities that aim to influence people's health-related beliefs or behaviors. These activities include disseminating information about particular health risks, persuading people to adopt healthy lifestyles or to persuade others to adopt healthy lifestyles, and modeling healthy behaviors. Invariably, such health communication activities raise a multitude of ethical concerns, in particular because they deal with deeply held personal preferences and social values, or aim to foster social norms opposed by certain groups.

Perhaps because the general intent of health communication interventions is to promote the health of individuals or populations, ethical issues embedded in these activities are often unacknowledged. However, all aspects of communication aimed to influence people's health involve ethical issues, from the choices made regarding which populations should be the "target" of the intervention, to the strategic approaches used. Health communication also involves addressing issues such as responsibility, risk, and social and cultural values (→ Risk Perceptions; Risk Communication). Further, some critics maintain that because health communication interventions have such a strong presence in society, they compete – along with commercial advertising – in an appropriation of the political, social, and moral realms of the → public discourse.

### ETHICAL FRAMEWORKS

Prominent ethical theories and principles defining the moral duties and obligations of practitioners in the health-care context offer guidelines and principles for identifying and addressing ethical issues in health communication interventions. A particularly influential framework is presented by Beauchamp and Childress (2001), in the field of bioethics. These ethicists present a *series of moral obligations* for health-care practitioners: (1) to do the utmost to better people's health; (2) to avoid doing them any harm (whether on a physiological, psychological, social, or cultural level); (3) to respect autonomy and privacy; (4) to ensure equity and fairness; (5) to provide for those who are particularly vulnerable or who have special needs; and (6) to maximize the greatest utility from the health promotion efforts, especially when resources are limited.

Harm may occur when messages create undue anxiety, label, or stigmatize. Respect for personal autonomy and privacy is another central ethical obligation, based on the premise that individuals have an intrinsic right to make decisions for themselves on any matter that affects them, at least insofar as such decisions do not bring harm to others. This precept is rooted in the liberal western tradition, which places strong emphasis on individual autonomy, and it has been the foundation for the development of important medical care codes such as patients' rights and informed consent (→ Communication Modes, Western). Other ethicists note that the respect for individual rights is considered a fundamental principle of health-care, but that individual rights may be superseded when it is believed that the state should intervene in order to assist in the protection of these rights. Some criticisms of this framework are that it represents mainly a western approach to the conception of moral issues, that it draws too much on assumptions of individualism and universalism, that it may be removed from the socio-cultural milieu in which moral choices actually take place, and that it does not reflect diversity in moral reasoning.

Additional stipulations that can help identify ethical issues in health communication interventions can be found in ethical frameworks in the *rhetorical and persuasive communication literature* (→ Rhetoric and Ethics) and more recently also in those presented by scholars and practitioners involved in → *social marketing*. These include: (1) the obligation to be truthful and not base claims on hidden arguments; (2) acknowledging alternative ways of framing and prioritizing the health issues; (3) ensuring that issues are truly relevant to the intended populations and not made to seem relevant; (4) offering accurate, complete, and relevant information on the health issue; (5) providing reliable,

correct, and accurate claims; (6) not exaggerating negative consequences or the magnitude of the problem, even if this would positively influence the intended populations; (7) not modeling inappropriate behavior; (8) not offending certain cultural norms and beliefs; (9) providing fairness and balance; (10) not stigmatizing certain behaviors or groups; and (11) avoiding → stereotypes, even if doing so seems to serve the goals of the intervention.

## ETHICAL ISSUES IN HEALTH COMMUNICATION

### Informed Consent

Whereas consensus exists about the need to obtain patients' or their guardians' informed consent in medical practice, and in many health-care systems it is mandated by law, in health communication this is not the case. Practitioners and scholars do not have official guidelines for obtaining informed consent from populations for whom health messages are intended.

A significant challenge is identifying who represents an intended population, particularly when it is a large group or a community. Further, within one group, some may want the health messages to be disseminated, whereas others may find them offensive. One mechanism for obtaining the equivalence of an informed consent in community or population settings is the use of advisory boards, which are often mandated by governments or funding agencies. An ethical concern raised by this mechanism is that the board members may not represent marginal groups or that they may hinder the efficiency of the communication intervention.

### Targeting Certain Populations

A major strategic approach in health communication, which draws also from the social marketing approach, is to identify groups of people with shared characteristics as "segments," and narrow the focus of the health communication intervention by "targeting" these particular groups. This means that the issues, themes, messages, information, and other aspects of the process of communicating with this population are designed according to its particular needs, beliefs, values, and behaviors, or the communication channels it uses. The underlying rationale for this approach may be utilitarian – to improve the chances that the communication intervention will be more effective and efficient in utilizing resources. A *utilitarian approach* may also serve as the rationale for decisions to focus on those most likely to adopt the health-related recommendations.

Alternatively, the decision of whom to "target" may be based on *considerations of equity*, and the intervention would try to reach disadvantaged groups, in particular those considered "hard to reach" and thus less likely to adopt the health recommendations. "Targeting" thus can serve ethical obligations of maximizing utility as well as equity, by attending to the particular needs of vulnerable populations. However, a common ethical concern associated with targeting is that, despite its utility, it can be unfair by excluding certain populations. This raises ethical concerns similar to those raised when making policy decision on rationing health-care resources.

### **The Use of Persuasive Appeals**

In order to help people adopt health-promoting beliefs and practices, health communication scholars and practitioners have developed theoretical and tactical approaches on how to make effective persuasive claims and appeals (→ Persuasion). Ethical issues are embedded in each approach because a persuasive tactic, by definition, is an attempt to influence a person, and this may infringe on people's rights not to be manipulated. In support of using highly persuasive tactics, some health communicators argue that such tactics are the most efficient way to help motivate people to adopt recommended health practices.

Further, some communicators feel that because health communication often takes place in a media-saturated environment, they need to employ strategies that "break through the clutter" in order to gain people's → attention, and that this justifies the use of some form of exaggeration, misrepresentation of information, or strong emotional appeals (→ Selective Attention). However, this strategic approach is likely to conflict with their obligation to be truthful and to respect people's autonomy by not using manipulative techniques.

### **Messages on Personal Responsibility**

Personal responsibility is a central theme in health communication. It can be viewed as epitomizing people's sense of autonomy, but also raises ethical concerns characterized as *victim blaming*. The notion of responsibility may refer to, for example, an obligation to talk to your children about drugs or to ensure your spouse adopts a healthy lifestyle. Such messages may be associated with social roles and serve to reinforce moral commitments to others. Responsibility may refer to making prudent choices in your food consumption, leisure activities, and sexual relations. People may be warned that they will become a burden to their family, or to society as a whole, if they are not responsible in their lifestyle.

A major ethical concern is that such appeals may elicit feelings of shame and guilt among individuals, who find that they are not able to adopt the recommended practices for varying reasons. This is referred to as "victim blaming"; when health-related behaviors are often not fully within the volition of individuals but are influenced by factors such as work and housing conditions, access to health-care, or pollution. Responsibility messages thus raise concerns regarding violations of the precept of "doing no harm." Further, they can have an impact on public opinion and health policies, with the consequence of requiring those viewed as "irresponsible" to pay more for the expenses of certain health conditions or to receive a lower priority for their health-care services. A different type of ethical concern is that, as pointed out by sociologists and anthropologists, a discourse on responsibility is ideologically and culturally based, and what is considered irresponsible depends on each society's selection of what it considers risky and its definition of social roles, behavioral obligations, sanctions, and rewards.

### **Labeling, Stigmatizing, and Stereotyping**

Communication activities aiming to promote health may have inadvertent negative outcomes. By warning against the risk of contracting a stigmatized medical condition or

by a negative portrayal of those who do not adopt the health recommendation, the message can stigmatize individuals or groups. This may even contribute to the creation of new types of negative stereotypes. Even humorous uses of presumably harmless stereotypes in health messages may have ethical implications. Communication activities can also serve to label people as “sick” and can negatively influence their sense of identity. Some critics suggest that one possible way to meet the challenge of developing non-stigmatizing messages is to focus on social and environmental risk factors rather than on disability as the dreaded outcome.

### **Inequity and Social Gaps**

Communication scholars note that, because of socio-economic differences, considerable gaps can be found between groups of people in the acquisition of pertinent information; this has been characterized as the knowledge gap (→ Knowledge Gap Effects). Occurrences of such gaps have been found regarding health information as well. Thus, the presumption that health communication activities invariably help to advance the health of disadvantaged groups may not be realized, and health communication activities may inadvertently serve to reinforce existing social disparities.

The perpetuation of social gaps can also occur when health communication recommendations call upon people to relinquish various practices they enjoy or that have cultural significance or emotional importance. Whereas those with economic means may find it easier to find substitutes for practices considered unhealthy, members of vulnerable groups may find that these “unhealthy” practices provide not only pleasure, but also they serve as an important coping mechanism that is not easily replaced.

### **CONSTRUCTING HEALTH AS A VALUE**

Scholars and health promotion ethicists have expressed concern that the growing profusion of health communication messages may result in people viewing health as a top priority, or turning the importance of health into an overriding value. This concern can draw on media studies that note that an important role played by the mass media is its “*agenda-setting*” capacity, and thus the coverage particular issues receive in the media, as well as the way they are framed, can result in the prioritization of these issues on the public and personal agendas (→ Agenda-Setting Effects; Framing Effects). Good health increasingly signifies virtue, and health communication interventions can appear to color the pursuit of health with moral overtones. Another concern is that such a prioritization can come at the expense of prioritizing other social issues, and may contribute to escalating expectations from medicine and health-care providers and industries. Ethicists suggest that this raises questions of equity, because the more powerful groups will demand that health-care systems meet their escalating needs, whereas members of vulnerable groups will continue to receive relatively fewer services.

With the advancing *professionalization of the practice of health communication* interventions and the adjacent field of social marketing, interest in ethical issues is growing. Though an official code of ethics has not yet been proposed, discussions of ethical issues can be found in journal articles, book chapters, and a few books entirely devoted to the topic. However, conceptual approaches regarding ethical issues – in particular those that

address health communication interventions that utilize games and new media channels, or entertainment-education approaches that increasingly include reality shows – must be explicated and developed. Ethical approaches in health communication may need to draw further on communication theory and address issues concerning diversity, ethical relativism, and the role of health communication in social change.

## **Health Communication and the Internet**

*Heinz Bonfadelli*

*University of Zurich*

The functions of modern mass media to give → information, to provide orientation, and to promote health-related behaviors are widely recognized within the field of → health communication. The media of → television, → radio, → newspapers, and → magazines influence intentionally or unintentionally, and mass media health campaigns are used purposively and effectively to change health practices (→ Health Campaigns, Communication in). Nevertheless, the existing empirical research evidence is mixed. Content

analyses (Will et al. 2005) and → cultivation effects research (Brown & Walsh-Childers 2002), e.g., on media images of thinness and eating disorders, seem to prove many dysfunctional health effects, especially by television (→ Content Analysis, Qualitative; Content Analysis, Quantitative). Even though there is some controversy on the effects of mass media in health promotion, there is a large body of work that documents the effectiveness of mass media public health campaigns. So the → Internet as a new platform gave rise to many new hopes, especially because of its unique features like convergence, interactivity, information capacity, and global reach (→ Interactivity, Concept of).

### UNIQUE FEATURES OF THE INTERNET

The Internet allows *interactive communications*, giving and receiving information and advice between users and/or providers of health information. The persuasive potential of the Internet is especially enhanced because interactivity allows targeting of health messages to the special problems and needs of the individual user (→ Persuasion).

The Internet has the potential to give immediate *feedback* to its users similar to → interpersonal communication. This feature can be used to target the information given according to the user's needs, to foster motivation, and to strengthen the persuasive impact of health messages.

The Internet requires the potential user to *actively search* for information in contrast to traditional mass media, which are directed more toward passive → audiences. On one hand, this is an advantage as users “tune in” to health messages based on their motivation and involvement. On the other hand, it may limit its reach as usually the more educated and more active people access the Internet.

Internet-based health services have the capacity to economically reach large and geographically diffuse audiences. Furthermore, the Internet can be used anywhere (at home, in schools, clinics, or community centers) and at any time during day or night (*unlimited reach and flexibility*).

In contrast to traditional mass media, the quantitative capacity of the Internet as well as the depth and specialization of the health information provided by the Internet is almost unlimited (*information abundance*).

Besides these opportunities and strengths, there are *risks and threats* as well. One problem is the reliability and trustworthiness of the health messages offered on the Internet because information providers or sources behind the information are not clear. As a consequence, it is not easy for users to estimate the credibility of the source (→ Credibility of Content; Credibility Effects). So there is an ongoing discussion on how to assess the quality of health information on the world wide web and how to improve it, e.g., by so-called “quality labels” (Eysenbach et al. 2002; Trepte et al. 2005). Then, there are *ethical problems* such as protective → privacy of medical records and conditions.

### HEALTH PROVIDERS AND APPLICATIONS OF THE INTERNET

There is an enormous and ever growing number of public and private providers of health information on the Internet at local, state, and international level, and the range of information provided by them includes → news (e.g., disease outbreaks), statistics,

advice and health tips on lifestyles, health promotion, and disease prevention. Besides, there are even more providers in the private area, such as insurance companies, health advisory services, and pharmaceutical firms. And last but not least, a large number of discussion groups and forums exist where many different health-related topics are discussed, and health information and personal health experiences are exchanged. The use of the Internet supports traditional health services and applications, but new services have also been created in recent years in the areas of e-content (e.g., health information and orientation, medical databases), → e-commerce (e.g., online pharmaceutical providers, etc.), e-connectivity (intranets of hospitals), e-computer applications, and e-care (e.g., telehealth monitoring, teleisurgery).

As a result, health-related web pages and Internet addresses can no longer be overviewed and summarized. Nevertheless, the existing health-related content on the Internet can be broadly differentiated into three general types:

- 1 *Health content*: the Internet user can search and download health-related information that can be accessed easily in so-called general health portals in a unidirectional way and without the possibility of communicating with other Internet users.
- 2 *Health communities*: there is the opportunity of horizontal and two-way communication with feedback possibilities in countless general or specialized health-related news and support groups, such as chatrooms or community health information networks.
- 3 *Health provision*: direct contact between patients as clients and various providers of health services via the Internet, such as health consultants, physicians, pharmaceutical firms, insurance companies, etc., as a form of e-commerce. Here, cost, quality of care management, privacy, confidentiality, and security are important quality criteria.

### **USAGE AND EFFECTS OF THE INTERNET**

It is difficult to estimate the number of users of the Internet but surveys conducted in the US estimate that between 50 percent and 70 percent of online users have sought health information on the Internet. The figures for Europe are significantly lower (Härtel 2003). For example, according to the 2004 Univox survey in Switzerland, although 70 percent had access to the Internet, only 23 percent of online users looked for health information, and 14 percent looked for information on a specific health problem. Then there are socio-economic differences concerning the education and income of users; there is evidence that health is one of the few topics of Internet use where women outnumber men. On the other hand, there seem to exist significant knowledge gaps (→ Knowledge Gap Effects).

Even though it is widely acknowledged that the Internet is used to gather health information, its effectiveness in health communication requires more empirical work. Theoretically, given its hybrid nature of combining mass and interpersonal communication features, the Internet should be a powerful medium for health communication (Cassell et al. 1998). But this sender-oriented perspective has to be complemented by a view from the user as well. And here there are various challenges and risks, such as unequal access to the Internet – the → digital divide – and the skills to use it. Although most of the users of health information on the Internet so far seem to be satisfied with the health content they are looking for, and rate the searched information as helpful, giving

new insights, and even believe it (Houston & Allison 2002), there is only very limited evidence so far concerning the far-reaching consequences of the Internet as a new information source and service provider in the field of health communication.

# Health Communication and Journalism

Jo Ellen Stryker

Emory University

The news media are an important source of health information, not just for the general public, but also for patients, for doctors and the medical community, for entertainment producers in search of story ideas, and for policymakers and funding organizations (→ Health Communication). Journalistic practices favor the use of established sources, so public health and medical journals are one of the principal sources for health reporting. Fundamental differences between the institutional norms of → journalism and public health and medicine create potential sources of misunderstanding and confusion among news consumers. Nonetheless, studies have demonstrated the effects of news media on knowledge, health behavior, medical practice, and public policy (→ Media Effects).

## PATTERNS OF NEWS SELECTION ON HEALTH ISSUES

Journalistic practices facilitate the routine construction of news, and affect how medical and health information is presented. For example, journalists favor *established sources* because their credibility can easily be confirmed, and because they can provide a steady flow of information to the journalist, which is useful for the continuous development of new stories (→ News Sources; News Routines). Medical and public health journals are an important established source for journalists because certain rules and practices of the journals have facilitated their use as sources for reporters. These journals are peer-reviewed publications, which takes the onus of establishing source credibility away from the reporter (→ Credibility of Content).

Additionally, certain practices ensure the “*newsworthiness*” of a medical story (→ News Values; News Factors). For example, most prominent medical journals have what is known as “the Ingelfinger rule.” Established in 1969 by the *New England Journal of Medicine*, the Ingelfinger rule posits that a given journal will not publish any article whose content has been previously reported. Enacted in part to increase the journals’ profitability via → advertising, the Ingelfinger rule also assures journalists that the information about which they are reporting is timely, and that no other journalist has the opportunity to “out-scoop” them. Similarly, many medical journals have a policy of a “news embargo,” under which journalists receive advanced copies of the journal with the promise that nothing will be reported until the journal’s release date.

Another mechanism that enhances journalists’ reliance on medical journals is the *use of the press release*. Typically, press releases are written for several of the journal articles in each issue. A press release aids the reporter because it highlights “important” issues, and saves the journalist the trouble of translating what can often be difficult medical language. Journalists have reported that the availability of a press release does increase the likelihood of their reporting medical research, and research has shown that journal articles for which press releases have been written receive more news coverage than those without.

## TENSIONS BETWEEN MEDICINE AND JOURNALISM

There is a documented tension between medicine or public health and the media that is due in large part to the disparity of norms between the two institutions. In the book *Selling science: How the press covers science and technology*, Dorothy Nelkin (1995) chronicled the tension that stems from differences in the production process. Epidemiologic findings, and the scientific process more generally, are based on replication over time; journalism is based on timeliness of the news event. The *need for drama* in news stories often results in emphases on aberrant findings, scandals, individuals of public notoriety, or misleading headlines (→ Drama in Media Content). A reliance on short narrative structures and “newsworthiness” criteria (which include timeliness and the need for novelty and drama) govern the ultimate selection and framing of news stories.

The factors affecting story selection and format often hinder optimal presentations of science and medicine in the news media. In particular, journalists *oversimplify medical research*, often omitting important contextual information. There tends to be a lack of follow-up in news reporting, such that the reporter, and by extension the media consumers, may not know how much importance should be placed on one particular study. Inaccuracies resulting from the decontextualized and sensationalized manner in which stories are reported are known as “errors of omission” (→ Sensationalism). Faced with reporting on new medical research that does not place it in the proper historical context, the public often feels confused because so many recommendations, often contradictory, appear in the news. Hence, health news reporting potentially creates a knowledge gap (Tichenor et al. 1970; Gaziano 1997) whereby individuals with greater education are better equipped to sift through and interpret seemingly contradictory information from health news stories (→ Knowledge Gap Effects). Accordingly, individuals with less education may become frustrated with health information in the news, and the gap between the health knowledge of high- and low-health-education individuals becomes exacerbated.

Errors of omission are conceptually distinct from, and tend to occur with greater frequency than, *factual errors*, known as “errors of commission.” For example, a study assessing the accuracy of breast cancer research reported in the news media found that 17 percent of stories contained erroneous information, while 38 percent contained errors attributed to misleading or decontextualized information (Moyer et al. 1995). Errors of any kind contribute to potential misunderstanding of medical information reported by the news media.

## EFFECTS OF MEDIA COVERAGE

Despite distortions in news coverage of health issues, there is an abundance of evidence to suggest that news coverage influences health knowledge, beliefs, and behaviors. Research to date suggests that frequent media users are more informed about health issues than their counterparts who do not have the same levels of media exposure. Beyond the informative dimension, media may also influence health behaviors. There are numerous pathways through which news coverage may affect health behaviors.

The news media are a primary source of health information for the general public. An *individual effects model* suggests that individuals exposed to news messages gain

knowledge about or change attitudes toward the behavior, with enough people exposed that changes can be seen at the population level (Hornik 1991). Alternatively, exposed individuals may share the information with others in their social network, who subsequently change their behavior. There is also a variety of other audiences for news messages: physicians and other health-care workers, policymakers responsible for passing laws and allocating funding for health, and entertainment producers in search of story ideas. Each of these audiences may indirectly influence health behaviors. Policymakers, for example, may be prompted by news messages about the dangers of drunk driving to introduce legislation for stricter drunk driving laws, which subsequently reduces the prevalence of drunk driving in the US (Yanovitzky & Bennett 1999; → Social Behavior, Media Effects on; Media Effects Models: Elaborated Models).

Evidence regarding the impact of news coverage on health behaviors can be separated into *short- and long-term effects*. A compelling event, such as a celebrity diagnosis of cancer, can generate substantial news coverage capable of producing temporary changes in health behaviors. For example, Katie Couric's public crusade to educate the public about colon cancer after her husband's death, including her on-air colonoscopy on *The Today Show* in 2000, resulted in increased colonoscopy rates after the program aired (Cram et al. 2003). Similar effects were demonstrated for mammogram rates following Betty Ford's and "Happy" Rockefeller's surgeries for breast cancer in 1974 (Fink et al. 1978), and for colorectal screening rates after Ronald Reagan underwent surgery to remove an intestinal tumor (Brown & Potosky 1990). In most cases, population changes in health behavior increase while media attention to celebrity illness is high, but decrease after the media spotlight wanes; i.e., celebrity effects on health behaviors tend to be of limited duration (→ Media Effects Duration).

The second conceptualization of news effects on health behavior entails more *gradual and cumulative effects* of exposure to health news. Comparable to agenda-setting research (→ Agenda-Setting Effects), the basic causal mechanism is that the quantity of news coverage about a health behavior produces changes in population-level behavior. However, in contrast to agenda-setting research, which posits that the amount of media attention influences perceptions of salience, some models of media effects on health behavior suggest that specific media "frames," albeit simplistic ones, produce different persuasive effects (Framing Effects; Framing of the News). For example, David Fan's ideodynamic model proposes that the population at any one point in time consists of adopters and non-adopters of beliefs, attitudes, and opinions with respect to a particular health behavior (Fan 2002). While the majority of individuals' beliefs, attitudes, or behaviors will only be reinforced by media messages, there is presumably a small population that would be induced to change because of news coverage. This persuasive force is a function of the ratio of messages supportive of healthy behaviors to messages advocating the unhealthy behaviors, which can function as deterrents to behavior change.

Studies of media effects on correlates of health behaviors include funding for AIDS research, → public opinion regarding AIDS and illegal drugs, and beliefs about AIDS transmission. Others studies have moved into the realm of health behavior and health outcomes, testing effects on breast cancer incidence, drunk driving, mammography utilization, cocaine use, marijuana use, and binge drinking. Slowly, evidence is

accumulating that news media messages affect secular trends in health behaviors. Mediating pathways through which behavior change may occur include public beliefs about performing the behavior; social norms; funding for medical research; and legislation.

## GARNERING MEDIA ATTENTION TO HEALTH ISSUES

The news media have the lofty goal of packaging and re-presenting medical and public health information to their audiences. There are different audiences among those affected, including “average” citizens, policymakers, and individuals in funding agencies (→ Audience Segmentation). Even those individuals in the medical profession reading medical journals are not exempt from being affected by the news media telling them what to think about regarding medical knowledge.

Journalists look for newsworthy medical research that will appeal to their readers. In so doing, the news media over-represent certain medical issues that conform to the normative necessities of journalism. For example, stories about prevention tend to receive less media attention than stories about treatment (→ Prevention and Communication). It may be that prevention does not conform to journalists’ conceptions of newsworthiness, including the need for novelty and drama. While there is no conceivable way to reconcile the conflicting norms between medicine and the media that contribute to imbalanced representations of illness and health, it is critical that public health practitioners keep a watchful eye on news producers by forging lasting relationships and taking steps to help shape the content of health behavior coverage.

In light of the growing body of evidence supporting news media effects on health behavior, the utility of *media-advocacy approaches* must be considered (see Wallack et al. 1993; → Advocacy Journalism). While media advocacy traditionally focuses on the strategic use of news media to advance a social or policy initiative, the term can be more broadly applied to include any purposive effort to help shape news coverage to positively impact health (→ Health Campaigns, Communication in).

There are numerous obstacles to garnering and sustaining media attention to an issue over time. There is a limited amount of time and space for health news, hence health issues must compete with each other for room on the media’s agenda. For example, while there has been an extraordinary amount of news attention to breast cancer, it has come at the cost of attention to other cancers. Moreover, the media tend to exhibit what has been termed the “issue-attention cycle,” whereby any given issue tends to receive substantial media attention for a limited time only, because journalists are motivated to constantly introduce new issues in an effort to maintain the interest of their audiences. While the successful implementation of media advocacy efforts often proves difficult, the potential for improving the public’s health provides a powerful incentive.

## **Health Disparities, Communication in**

*Vicki S. Freimuth*

*University of Georgia*

Eliminating health disparities is one of the most pressing global health issues. In the United States, health disparities have been examined primarily as differences in groups based on racial, class, and ethnic classifications. Globally, the issue focuses on the differences between developing and developed nations in health status and access to state of the art treatments. Harshly put, wherever in the world you live, if you are poor and a minority, you live sicker and die sooner (→ Health Communication).

The causal paths leading to these disparities have been more controversial. In the United States, Kawachi and colleagues (2005) identified three paths frequently described

in the literature. The first views race as a biologically meaningful category and racial disparities in health as reflecting inherited susceptibility to disease. The second treats race as a proxy for social class and blames socio-economic stratification for disparities. The third approach, and the one the authors strongly support as the most useful, accounts for the independent and interactive effects of both class and race. According to this approach, race is neither a biologically meaningful category nor a proxy for class, but is a separate construct from class. This approach suggests that race should not be used as a proxy for class, neither should racial disparities be analyzed without also considering the contribution of class disparities, and finally, class-based health disparities should never be analyzed without also considering the contribution of race and ethnicity (Kawachi et al. 2005).

### THE CONTRIBUTION OF COMMUNICATION TO HEALTH DISPARITIES

While communication cannot solve the social, economic, and political issues underlying these disparities, it can make important contributions to reducing health disparities. First, we must acknowledge that there are racial and class disparities in communication as well as in health. The way information is generated, manipulated, and distributed differs among social groups. Viswanath and Emmons (2006) propose the idea of “communication inequalities,” that is, there are differences in the way social groups access and use, attend to, retain, and act on relevant health information. Almost every study of health knowledge and health protective behaviors shows gaps based on social class. Those from lower social classes tend to know less about the health risk and are less likely to adopt behaviors to protect against the risk. This problem has been particularly frustrating because attempts to close these gaps have often actually increased them (→ Knowledge Gap Effects). Traditional health promotion programs are used more readily by those with more resources to act on the information. For example, rates of smoking fell far more quickly among the more educated following the US Surgeon General’s report on smoking, resulting in the current socio-economic status (SES) gradient in smoking (Adler & Newman 2002; → Planned Social Change through Communication).

Second, communication research needs to identify in much more depth the relationships between race and class and the responses to health risks of various kinds, the value placed on knowing more about the risk, the sources turned to and trusted when weighing what to do about a risk, and the way information is processed about the risk. Disadvantaged groups have poorer → information processing skills such as → health literacy (Kutner et al. 2006), may be more likely to use English as a second language, and have less experience with such communication skills as negotiation. They may be locked in an information ghetto where the only trusted information is internally generated and more likely to be inaccurate.

These disadvantaged groups often are portrayed as fatalistic people with a pervasive *sense of helplessness* (Bosma et al. 1999). They may use information channels differently than other social classes. While the disadvantaged have access to both informal and formal sources of information, they prefer the informal sources to meet specific information needs. Television is always reported as the source most frequently used by disadvantaged groups (→ Exposure to Television; Media Use by Social Variable). Much has been written about the way the → Internet has affected disadvantaged groups. The lower social classes

tend to have less access and less use, a phenomenon that is described as the → “digital divide.” There also is some evidence that social class impacts the way health risk information is processed. Several studies using quite different methodology have found evidence that lower social classes are more likely to process risk information heuristically rather than systematically.

Third, health communication scholars should examine the different strategies commonly used to enhance the health of individuals and communities to see what contributions they have and could make toward reducing disparities. The following sections begin this examination for health provider/client communication, social support, everyday interpersonal interactions, mass mediated health campaigns, entertainment education, media advocacy, and interactive health communication.

### STRATEGIES TO ENHANCE HEALTH

Street (2003) argues that the medical consultation is a socially constructed event and the primary activity is talk, i.e., the *interaction between the health provider and the client*. This talk between physicians and minority clients frequently misses the mark because of contrasting perceptions of physicians and patients, linguistic asymmetry, and self-fulfilling prophecy spirals (Perloff et al. 2006). Van Ryn and Fu (2003) suggest that providers may even contribute to health disparities by influencing clients’ views of themselves and their relation to the world, by differentially encouraging health promotion and disease prevention behaviors and services, and by withholding access to treatments or services and denying benefits and rights. They cite evidence of physician contributions to racial/ethnic disparities in both kidney transplant rates and cardiac procedures, in pain assessment and control, and in mental health services (Van Ryn & Fu 2003). They argue for interventions to help providers avoid these biases as one way to reduce disparities (→ Doctor–Patient Talk).

*Social support* is another communication behavior that has profound consequences for mental and physical well-being (Albrecht & Goldsmith 2003). Yet there is evidence that kinship support networks are deteriorating in low-income and minority communities due to unemployment, transience, and substance abuse. Virtual support networks are becoming increasingly important but access to the technology is an issue in underserved communities.

Cline’s (2003) argument for shifting the focus of interpersonal communication about health from formal to informal contexts such as *everyday talk* highlights a rich and untapped dimension of communication that could contribute to reducing disparities. These informal contexts occur much more frequently and these relationships may be much more significant to the individual. She focuses on HIV/AIDS to illustrate how the primary frameworks of meaning driving participants’ behaviors are social rather than health related. HIV prevention behaviors, for example, may be driven more by desire to avoid character judgments and relational discord than to promote health. These primary frameworks of meaning are embedded in culture and must be understood before effective interventions can be designed.

Segmenting audiences on the basis of race and ethnicity is one of the most common ways that *mass media health campaigns* address health disparities. Hornik and Ramirez

(2006) concluded after examining the race or ethnicity segmentation in health communication campaigns that there was no evidence that this segmentation, in any of its forms, reduces disparities. Yet they still defended segmentation as the most politically viable way of getting resources to reach disadvantaged segments of society. Even though race and ethnicity do not completely define disadvantage in US society, they may be the most politically respectable correlates of social disadvantage in a society where class politics are considered divisive (Hornik & Ramirez 2006). They do caution, however, that segmentation can have disadvantages – segmentation can increase costs, can be difficult to implement, and can have negative effects such as stigmatization on the people who are meant to be the beneficiaries.

Once audiences are segmented, messages need to be tailored for these segments (→ Audience Segmentation). Health communicators frequently equate culture in a simplistic fashion with race and ethnicity. The Institute of Medicine (2002) claims that culture has been poorly examined in the context of health communication, and asserts that to consider culture in health communication requires significant exploration beyond the typical variables of race, ethnicity, and SES. Resnicow and Braithwaite (2001) refer to this superficial approach as the surface structure of a culture. Addressing surface structure includes matching messages and channels to observable social and behavioral characteristics, including familiar people, foods, music, language, and places. They argue that it may be more important to address deep structure, which reflects the cultural, social, psychological, environmental, and historical factors that affect health for a minority community. Resnicow and Braithwaite (2001) argue that when health communication reflects appropriate surface structure, it increases the receptivity and acceptance of the campaign, but when it also addresses deep structure, it conveys true salience with the community it seeks to reach (→ Culture and Health Communication; Culture: Definitions and Concepts).

*Entertainment programming* on the media is a powerful way to communicate health information, especially for minority audiences, who are heavy consumers of this type of media (→ Entertainment Education). In developing countries, entertainment education frequently produces entertainment programming for the sole objective of influencing health behaviors. In the US, organizations exist that introduce important health topics to writers and producers and assist them in portraying these issues accurately to their viewers. Several research studies have demonstrated that even brief exposure to health information and behaviors can have strong effects. For example, in surveys conducted by Porter Novelli during 1999 and 2000, over half of regular prime-time and daytime drama viewers reported that they learned something about a disease or how to prevent it from a TV show. About one-third of regular viewers said they took some action after hearing about a health issue or disease on a TV show (Centers for Disease Control and Prevention 2006).

*Media advocacy* is the strategic use of mass media and its tools, in combination with community organizing, for the purpose of advancing healthy public policies (Institute of Medicine 2003, 338). It moves beyond the individual to address the social conditions that affect individual health. An early example of such a campaign is the Uptown Coalition in Philadelphia, which used the media and community organizing to defeat R. J. Reynolds' proposed campaign to market Uptown cigarettes in African-American communities (→ Media Advocacy in Health Communication).

*Interactive technology*, “computer-based media that enable users to access information and services of interest, control how the information is presented, and respond to information and messages in the mediated environment” (Hawkins et al. 1997, 2), has created new opportunities for health communication (→ Interactivity, Concept of). These applications can eliminate barriers such as low literacy and expand the opportunities to tailor and personalize information. One of the pioneer applications of this technology, the Comprehensive Health Enhancement Support System (CHESS), has impressive research evidence of its potential for reducing disparities. Fifteen years of research on CHESS have shown consistently positive effects on low-income African-American women’s health informational competence (Shaw et al. 2006). Yet access issues prevent an effective approach such as CHESS from achieving its full potential in reducing health disparities.

Health disparities are insidious global problems that communication scholars can and should address. Sensitivity to the race and class issues underlying these disparities is essential when studying or designing health communication interventions.

## Health Literacy

Emily Zobel Kontos

Harvard School of Public Health

The association between education and health outcomes has been well documented, and education has historically been used as an indicator for socioeconomic status in epidemiological studies (Pamuk et al. 1998). Researchers hypothesize that education may protect against disease by influencing lifestyle behaviors, problem-solving abilities, and values. Other researchers have demonstrated a strong association between education and health by exploring three explanations for this association: (1) education influences work and economic conditions; (2) education influences social psychological resources; and (3) education supports a healthy lifestyle (Nielsen-Bohlman et al. 2004). Although the demonstrated evidence of the association between health and education is strong, the explanations for this association and the underlying mechanisms have not been extensively studied. In the past decade, researchers, mainly rooted in the US, have begun to unpack education in an effort to investigate the factors that may more precisely predict poorer health outcomes and help to explain aspects of disparity (→ Health Disparities, Communication in). Literacy, specifically health literacy, emerged as a distinct area of research and construct to be examined as one possible pathway for the link between education and health.

In the report “Healthy people 2010,” the US Department of Health and Human Services (2000) defined health literacy as *the degree to which individuals have the*

*capacity to obtain, process and understand basic health information and services needed to make appropriate health decisions.* Health literacy focuses on the *interaction* between individual level skills and structural factors such as health sector demands. The need for a health-literate public has become more critical than ever because of rapid innovations in biomedical sciences and the proliferation of information in a variety of media and the movement toward informed and shared decision-making that promotes involvement of the patients in medical decisions (Rimer et al. 2004; Viswanath 2005).

## LITERACY ASSESSMENTS

At the individual level, variables such as background knowledge, experience, emotional state, efficacy, and literacy skills affect one's overall health literacy. Most of the attention and research to date has been on functional literacy skills required for tasks needed in the workplace and for full participation in the activities of everyday civic life, including *interacting* with health-care systems. The National Adult Literacy Survey (NALS) in the US and the International Adult Literacy Surveys (IALS) in 22 industrialized nations involved home-based interviews with 13,000 adults in the US and over 75,000 adults from other industrialized countries (Kirsch et al. 1993; Tuijnman 2000). The surveys examined adults' *functional literacy skills* – their ability to use the written word for mundane tasks such as locating information in a → newspaper or in a form. The tasks that adults were asked to perform ranged from fairly simple (locate a piece of → information in a text) to sophisticated (determine the amount of medicine to be given to a child of a specified age and weight based on a medicine label). The scores were reported for three different literacy scales: *prose literacy*, the knowledge and skills needed to understand and use information from texts that include editorials, news stories, poems, and fiction; *document literacy*, the knowledge and skills required to locate and use information contained in materials that include job applications, payroll forms, transportation schedules, maps, tables, and graphs; and *quantitative literacy*, the knowledge and skills required to apply arithmetic operations, either alone or sequentially, using numbers embedded in printed materials.

The findings from the 1992 NALS indicate that fully 47 to 51 percent of US adults have limited or low functional literacy skills and often cannot accurately and consistently locate and match information from newspapers, advertisements, or forms. This does not mean that they cannot read. Most of these adults can and do read.

In 2003, the National Assessment of Adult Literacy (NAALS) was conducted as a follow-up to the 1992 NALS in the United States. Although the educational attainment of US adults had increased between 1992 and 2003, prose literacy had decreased for all levels of educational attainment. As was true in 1992, literacy was lowest for adults who did not complete high school (Kutner et al. 2005).

In one of the earliest attempts to examine *health-related literacy tasks* (HALS), researchers identified 191 health-related tasks among the NALS and IALS → survey data and analyzed the health literacy of US adults. (Rudd et al. 2004). They found that some 12 percent (23 million of US adults) are estimated to have skills in the lowest level (Level 1) on the HALS, while an additional 7 percent (13.4 million) are not able to perform even

simple health literacy tasks such as locate dosage information on a medicine label. Those performing below Level 1 are about evenly divided between US-born and foreign-born adults. The results are alarming for at-risk and vulnerable populations; for example, among adults who have not completed high school, almost half scored at or below the lowest literacy level. Similarly, almost half of adults over the age of 65 performed at or below the lowest level. Minority populations, including adults born outside the United States, scored significantly below white adults and adults born in the United States, on average.

## RESEARCH ON LITERACY AND HEALTH

In a critical examination of the link between literacy and health outcomes, it was found that the health of children in developing countries was related to the literacy of their mothers (Grosse and Auffrey 1989). Subsequent empirical research in the area of health literacy has been conducted mostly in the US and has documented the mismatch between the literacy demands of health systems and the literacy skills of the people using the system. For example, a variety of health-related print materials have been assessed over the years, and researchers report that an overwhelming majority of the materials score at reading grade levels that far exceed the reading ability of the average adult (which is equivalent to the fifth or sixth grade level). International assessments of health materials, focused mainly on informed consent documents, echo these findings (Mathew & McGrath 2002).

Researchers were able to move beyond assessment of materials to better define the association between literacy and health outcomes with the development of *health-specific reading assessment tools* such as the Rapid Estimate of Adult Literacy in Medicine (REALM) and the Test of Functional Health Literacy in Adults (TOFHLA; Davis et al. 1991; Parker et al. 1995). These tools enabled researchers to assess patients' health-related reading skills and then correlate the readability/literacy levels with health outcomes in a clinical setting. This body of literature found that patients with low health literacy, defined as individuals with skills below the ninth grade level, are less likely to make use of health-care services such as screening (Davis et al. 1998), more likely to present in later stages of disease (Bennett et al. 1998), and more likely to be hospitalized (Baker et al. 1998), after adjusting for factors such as age, race, gender, socio-economic status, and self-rated health status. In addition, studies indicate that patients with limited health literacy skills who need to manage a chronic disease such as cancer (Merriman et al. 2002; Schillinger et al. 2002; Williams et al. 1998b) or asthma (Williams et al. 1998a) are less well-informed about the basic elements of their care plan and have measurable poorer health outcomes than those patients suffering from the same disease conditions but who possess higher levels of health literacy (→ Knowledge Gap Effects).

In addition to the ill effects on the individual patient, limited health literacy places a burden on health-care systems which in turn impacts the overall economic consequences to society. In the US, the National Academy on an Aging Society estimated that roughly US\$73 billion in additional health-care costs were attributable to low health literacy. This is due in part to higher rates of hospitalization and higher use of expensive emergency services.

## FUTURE DIRECTIONS

As the field of health literacy evolves more research is required to rigorously examine the full breadth of the construct as illustrated in its definition: *the degree to which individuals have the capacity to obtain, process and understand basic health information and services needed to make appropriate health decisions*. This definition goes beyond one's ability to read and identify health terms; it speaks more to one's ability to access health information, effectively navigate the information to retrieve relevant information, and then ultimately act on this information (→ Communication Inequality). To advance the field of health literacy, researchers must therefore go beyond the examination of reading skills and systematically assess and test interventions that address the other necessary skills, such as obtaining and using information as embedded in the health literacy definition. Health-care providers, creators of health information and education materials, and the health-care and public health systems bear a large part of the responsibility for having created materials, ways of communicating, and systems that are far too technical and complicated to meet the needs of the vast majority of the populations they serve.

## Heraldry

Clive Cheesman

College of Arms, London

Heraldry is a traditional display system for family and corporate visual identity, originating in late twelfth-century western Europe, based on the complex of design-bearing units known in English as a coat of arms (→ Code). The word “heraldry” originally indicated the entire business of the heralds, court officials who at first recorded coats of arms and later (from the fifteenth century, when the various European jurisdictions began to attempt to regulate the sector) administered, designed, and licensed (“granted”) them. The late medieval and early modern system of heralds granting arms to proprietors on behalf of the state, which then guarantees some degree of protection for the design, survives in only a few countries: notably parts of the Commonwealth, South Africa, and possibly Ireland, though some post-communist republics of eastern Europe have revived versions of the system.

The principal, and only essential, unit in any coat of arms is a *shield-shaped frame* (the “shield”), displaying a supposedly unique design. This → design, being two-dimensional in character, can be used on other flat display vehicles such as flags. The next most significant unit is the “crest” (a word sometimes misapplied to the whole coat of arms), which is defined by its location above the shield; notionally three-dimensional in form, it represents an item modeled and worn on top of the helmet by a medieval knight, and in full representations of a coat of arms it is depicted on a helmet. In fact the vast majority of crests never have been or will be modeled, but their potential three-dimensionality continues, mostly, to inform their design. Crest designs are not, in some heraldic

jurisdictions, required to be unique, though they are frequently displayed alone, without the shield to which they are technically subsidiary.

Shield and crest may be supplemented in a full coat of arms by the following: “supporters” (animal or human figures depicted holding the shield); a motto (a slogan-like phrase depicted above or below the main design); and various direct indices of social rank or status, such as coronets and the insignia of awards and decorations, the display of which is often guided by heraldic convention without their being truly heraldic in themselves. Supporters function as indirect status indicators, inasmuch as all jurisdictions restrict their use to individuals of certain rank, large corporations, and official bodies.

It is the combination of design elements making up the shield, known as “charges,” that most clearly identifies a coat of arms (→ Graphic Design). The repertory of charges ranges from purely geometric forms derived long ago from the shape of the shield, through a large class of more or less stylized representations of beasts, birds, monsters, and medieval implements, to images of modern artifacts (→ Visual Representation). The category is unlimited and anything capable of standardized, simplified rendition in easily recognizable form is appropriate. The charges’ mutual spatial relationship – to describe which heraldry uses a semi-fossilized terminology called “blazon” – is equally significant, and heraldic conventions in this area have been taken by some scholars to provide an analytical key for works of art, particularly of the Renaissance and baroque periods.

Together, choice of charges and their relationship create the identity of an individual shield, viewed as a type of which specific representations – which may vary considerably in artistic style – form tokens. Heraldry’s approach to type-identity is broad, certainly when compared with newer areas such as that of corporate trademarks. Color definitions, too, are loose: a limited number of colors are used and standard shades of each are considered identical. Thus behind heraldry’s large graphemic repertory lies a vast range of heraldically insignificant graphetic variations (→ Emic vs Etic Research). Proprietors of coats of arms may, of course, apply their own, narrower restrictions to give their heraldic identity a more consistent look than heraldry itself requires. This often happens in the corporate world, where the desire for a coherent, closely managed visual identity can lead to the privileging of specific representations.

In systemic terms, heraldic designs impart relatively sparse information about their proprietors. It is often mistakenly assumed that they encode complex data, but any references they make tend to be transparent, and not specifically heraldic; a mixture of graphic metaphors from religious art (e.g., a pelican for Christian piety) and archaic professional references (e.g., checkers for accounting or banking) are the nearest that heraldry gets to a symbolic approach (→ Symbolism). Family arms frequently pun on the family surname, while corporate arms often indicate the main business of the corporation, or its location. Cross-reference within the system is frequent, with one design repeating elements from another to suggest a connection between their respective proprietors (→ Sign Systems). This haphazard and unsubtle approach was one of the factors in the rise of the more esoteric and elliptical “device” or *impresa* in the sixteenth and seventeenth centuries.

In many ways the most eloquent statement made by a coat of arms about its proprietor is the extra-systemic one that this person or corporation is the sort to possess (and use) a coat of arms. Widely perceived associations between heraldry, social rank and conservatism color the usage of both corporate and private heraldry, and diminish the

potential reach and variety of the medium. It is perhaps surprising that in the early twenty-first century the two UK heraldic authorities should be required to grant as many as 250 to 300 new coats of arms a year. Still more indicative of the continuing prestige of heraldry, however, is the vast number of corporate trademarks in use across the world that, even if not actually well-formed expressions within the heraldic system itself, consciously resemble or recall coats of arms.

# Hermeneutics

*John Durham Peters*

*University of Iowa*

*Samuel McCormick*

*Purdue University*

“Hermeneutics” comes from the name of the Greek messenger god, Hermes – the patron of travelers, rogues, liars, and thieves. As the carrier of messages between gods and mortals, Hermes had to be fluent in both of their idioms. It was his task to build and maintain an interpretive bridge between alien worlds. Since he was also a trickster who could deliver messages in garbled form, the Greek verb *hermeneuō* meant to decipher cryptic or obscure meanings, and, more generally, to explain, translate, and express (Gadamer 1971). The term hermeneutics descends from this root, via the Latin *hermeneutica*, and has been used in English and German since the late seventeenth century. Today hermeneutics has two main senses: the art of reading texts, and the philosophy of textual interpretation and human understanding. However forbidding or exotic the term may sound, hermeneutics is a fundamental mode of inquiry into communication and its conditions. Indeed, hermeneutics and communication theory alike focus on how messages span the gaps of human togetherness (→ Communication Theory and Philosophy).

## **THE ART OF TEXTUAL INTERPRETATION**

Hermeneutics is traditionally understood as Biblical interpretation. However, it is an art relevant whenever a canonic text needs to be updated and applied to a concrete situation.

Any tradition of practical judgment anchored in classic writings calls for procedures of interpretation, whether in religion, law, or science. The hermeneutic problem is simple: how to draw dim and distant writings into the broad daylight of understanding? This problem faces any interpreter who is historically or culturally removed from a foundational text. Inasmuch as many cultures in the world have canonic texts, there is a great variety of hermeneutic traditions. Elaborate rules and methods of textual interpretation have developed, for instance, in Judaism, Christianity, neo-Confucianism, Hinduism, Buddhism, and Islam. Such methods guide the temporally remote interpreter's practical relation to authoritative texts. The imperative of interpreting classics is not unique to religious traditions. Hellenistic scholars developed methods for reading Homer and other ancient Greek texts, methods whose central task was the interpretation of allegory. These methods deeply shaped how the Christian church fathers and Jewish scholars read the Bible – traditions that are known as patristics and rabbinics, respectively – and decisively stamped the intellectual history of the west for the past two thousand years.

Though any reading of an old text in a new situation can be understood as a hermeneutic act, perhaps the paradigm case is legal interpretation, in which a particular case needs to be judged in the light of a textual corpus. The need to check the source raises diverse complexities. Before knowing how to read, one must determine what sources are relevant, how to harmonize their contradictions, and what parts of them are superseded or still in force. Hermeneutics can have legal, religious, literary, historical, ethical, linguistic, and philosophical dimensions. In the rabbinic and Muslim legal traditions, for instance, it is impossible to separate legal, historical, and religious interpretations. In the Anglo American common law, legal interpretation is always a reading of historical precedent. Taken as the art of interpretation, hermeneutics is a set of methods for determining legitimate readings. It is a collection of techniques for bridging the communicative gaps between classic texts and novel situations.

## **THE THEORY OF HUMAN UNDERSTANDING**

Because textual interpretation has often raised larger philosophical questions, the deep history of hermeneutics can be traced to diverse sources. But taken as a name for a more ambitious theory of interpretation and human understanding, hermeneutics started around two hundred years ago in Germany. This tradition, often known as “philosophical hermeneutics” (Grondin 1994), expanded the scope of hermeneutics variously to a method for understanding history, a justification of the disciplinary uniqueness of the humanities, and an account of human existence.

The broader context for the rise of philosophical hermeneutics was near-universal literacy and the rise of positivist paper sciences such as classical philology and history in late eighteenth-century Germany. Classical philologists powerfully felt and systematically discussed their cultural and linguistic distance from classical oratory, literature, and jurisprudence. Their efforts to recover and restore distant texts and traditions shed new light on the problem of historical remoteness. Hermeneutics was the philosophical ancilla for the massive scholarly labor of source criticism in such sciences and arts of text-constitution as philology, papyrology, paleography, archaeology, and historiography. The extremely influential doctrine of historicism made anachronism a hermeneutic crime,

thus emphasizing the temporal expanse across which the modern interpreter had to travel. One could no longer receive the *Iliad* or *Genesis* as a direct message; one had to read them as ancient productions designed for alien worlds and full of strange notions. Access to meaning became mediated by consciousness of historical distance and cultural difference. Biblical “higher criticism” was one key expression of this distance.

The hermeneutic developments of Protestant theology and the philological traditions of classical scholarship came together in the work of Friedrich Schleiermacher, who added a strong dose of Kantian and post-Kantian philosophy to the mix. For Schleiermacher, hermeneutics was a theory of understanding other minds that are problematically remote in time, language, or culture. He argued that the primary object of understanding is not the meaning entailed in a given text (grammatical content), but the intentional consciousness of its author (technical-psychological content). However, because authorial intention can only appear as an interpretive reconstruction, meaning is always only a function of interpretation itself. This insight led Schleiermacher to the radical conclusion that understanding can never entirely escape the potential for misunderstanding. As a “productive repetition,” interpretation required both a holistic immersion in the world of the original text and a lively sensitivity to the demands of the present.

Schleiermacher’s phenomenology of understanding informed Wilhelm Dilthey’s defense of the human sciences against the emerging dominance of the natural sciences. For Dilthey, hermeneutics was a universal theory of interpretation in and through which to understand sciences that depend crucially on meaning or consciousness (→ Idiographic vs Nomothetic Science). He called these sciences *Geisteswissenschaften* or human sciences, translating J. S. Mill’s term “moral sciences.” Unlike the natural sciences, which derive knowledge from observations of the outside world, the human sciences derive knowledge from “lived experience” (*Erlebnis*). Since the act of knowing is indistinguishable from the known object, the human sciences require *Verstehen* (interpretive understanding) in addition to *Erklären* (rule-based explanation) (→ *Verstehen* vs *Erklären*). For Dilthey, the task of hermeneutics was to disclose the vital link of subject and object in human knowledge, and in so doing to provide an epistemological-logical-methodological foundation for the human sciences. No longer would hermeneutics confine itself to transmitting the authority and normative validity of distant texts and traditions. It was Dilthey’s great achievement to redefine hermeneutics as the universal methodology for making sense of the entire social, historical, and psychological world.

Martin Heidegger took the argument one giant step further. If Dilthey used hermeneutics to free the *Geisteswissenschaften* from the *Naturwissenschaften*, Heidegger freed hermeneutics from the tradition of *Wissenschaft* altogether. The epistemological understanding of the human sciences, he argued, derives from a more basic hermeneutical understanding. Making sense of things was for Heidegger the ontological condition of human existence (*Dasein*). Understanding is “existential” because it is our fundamental, if often implicit, mode of being in, dealing with, moving through, and caring for the world. More specifically, understanding orients our ability to be in alternate positions in the world, our potential to pursue different life projects. Understanding is the being of this potentiality, and interpretation is its subsequent development. Prior to our possession of any given theoretical knowledge, Heidegger insists, we are inexplicitly yet affectively *involved* in the world. Thus, hermeneutics is not just a fancy name for what

scholars, judges, and clerics do with texts. It is what every human being does by living, thinking, choosing, and acting. Inasmuch as all humans live in time and have no choice but to choose, the human condition is hermeneutic.

More recent hermeneutic thought is dominated by Hans-Georg Gadamer (2004) and Paul Ricoeur (1981), who follow in Heidegger's wake. Both see hermeneutics as a unique justification for humanistic inquiry, and both see human existence as fundamentally communicative. In expanding the notion of "text" to include any field of enduring meaning, Ricoeur explicitly figures interpretation as an act of communication (→ Text and Intertextuality). Wherever there is unintelligibility, there is a hermeneutic problem. Hermeneutics, like communication, is the general theory of dealing with problematic meanings. It aims to decipher lost sense with an almost therapeutic mission of liberating meanings that have been frozen into muteness or madness by the passage of time or culture. Whereas the rhetorician asks, how will the audience receive this text (→ Rhetorical Studies), the hermeneut asks, how would the author have written this text if they were addressing us now? Hermeneutics is the talking cure for texts that have slipped into darkness, an inventory of ways to make them talk again – and yet again (McCormick 2003). For Ricoeur, hermeneutics is a form of dialogic textuality. It is like exchanging letters with someone who cannot write back, but whose old letters you treasure and whose voice you must supply (Peters 1999). Hermeneuts hold up both ends of a literary correspondence – the then of the text, the now of its recognizability. More specifically, they bridge historical, cultural, and linguistic gaps by mediating the original text through the production of another. In this sense, Ricoeur builds on Schleiermacher's insight that any reading is a "productive repetition."

### WIDER RELEVANCE AND CRITICISM

Philosophical hermeneutics has received diverse criticisms since the 1960s. For critical theorists, hermeneutics neglects the social conditions that sustain canonic texts and specialized interpretive labor, and thus has conservative political and methodological consequences (Habermas 1977; → Critical Theory). This criticism was echoed in the canon skirmishes of the 1980s with a more pointed gender and race dimension, claiming that hermeneutics enshrined an elite pantheon of European male authors. For poststructuralist media theorists, hermeneutics smuggles assumptions into its theories that are in fact reflections of communication systems; "humanity" and "literature" are historical by-products of data-processing networks (Kittler 1990; → Postmodernism and Communication).

For other poststructuralists, hermeneutics separates discourse too far from power (Said 1983), or problematically champions a metaphysics of presence (Derrida 1982). None of these critics denies the need for interpretation in some form; the debate is about its scope, assumptions, and mission. Partly responding to such criticisms, Ricoeur's notion of the "hermeneutics of suspicion" widens the field to include such central figures of modern thought as Marx, Nietzsche, and Freud. The textually deconstructive ambition of this broader sense of hermeneutics complements – or radicalizes – the textually restorative ambition found in the tradition running from Schleiermacher to Gadamer.

Hermeneutics has had some recognition within communication studies, but perhaps not enough. It received a particularly warm welcome in the 1970s, due in large part to the

philosophical support it lent to → qualitative methodology. With a greater interest in power since the 1980s, communication scholars tended to turn to critical and postmodern theories, though interest in hermeneutics persists as a key to understanding the curiously distanced communicative situation of broadcasting, and abiding questions in rhetorical theory (Hyde 2001). If communication is fundamentally a matter of distance and its bridging, and human existence is fundamentally interpretive, then hermeneutics holds a key to understanding communication in general. Whether taken strictly or broadly, hermeneutics still has much to say about basic communication problems.

## **Heterosexism and the Media**

*Elizabeth A. Suter*

*University of Denver*

Heterosexism “refers to the belief and expectation that everyone is or should be heterosexual” and the term “heteronormativity” equates heterosexual experience with human

experience, in effect “render[ing] all other forms of human sexual expression pathological, deviant, invisible, unintelligible, or written out of existence” (Yep 2002, 167). Heteronormativity provides a larger context for understanding how heterosexism influences cultural and social institutions, such as the media (→ Behavioral Norms, Perception through the Media).

Historically, mediated portrayals of gay, lesbian, bisexual, and transgender characters have been infrequent. When represented, they have tended to be portrayed negatively (e.g., as villains, as problems to be solved). Concurrent with the gay liberation movement, more positive portrayals emerged in the 1970s. By the 1990s, the frequency of media representation had increased dramatically. Yet, as critical media scholars point out, representation neither guarantees legitimacy, nor creates a panacea. Rather, visibility is complicated. Representations reflect the ideological frameworks and interests of agenda setters who generally appeal to an assumed heterosexist audience (→ Media and Group Representations).

Critical media analyses have begun to unmask how representations of gay, lesbian, bisexual, and transgender characters, particularly on television, but also on film, often end up renormalizing heteronormativity by reinforcing heterosexuality as “normal” and taken for granted, simultaneously constructing homosexuality as aberrant and as abnormal (→ Gay, Lesbian, Bisexual, and Transgender Media Studies). One mediated stratagem that has been highlighted by research is referred to as the *gay male/straight female pairing*, portrayed on mainstream films and television sitcoms, of which the US series *Will & Grace* (1998–2005) has been the most studied. Battles & Hilton-Morrow (2002) argue that *Will & Grace* fortifies heteronormativity via the techniques of equating gayness with a lack of masculinity, relying on sexual tension and delayed consummation between the gay male/straight female, infantilizing characters who subvert heteronormative conventions, and emphasizing characters’ interpersonal relationships over their connections to the larger social world (e.g., gay politics). Shugart (2003) argues that the show’s subtexts renaturalize heteronormativity by presenting the gay character Will as heterosexual (e.g., dressing and acting conventionally masculine) and his relationship with the straight character Grace as romantic, and granting him control over female sexuality, similar to that which occurs in heterosexual male privilege. The sexual tension between Will and Grace appears to appeal to heterosexist audience members and sustains the show’s popularity (Quimby 2005).

A second stratagem can be seen in the US version of the reality/makeover show *Queer Eye for the Straight Guy* (2003–present), where gay males are more competent in constructing conventional masculinity than the straight males they make over. Morrish & O’Mara (2004) argue that the show subverts the expectation that the gay male cast, the “Fab Five,” will feminize their subjects. Rather, by the end of each episode, the heterosexual male is rendered more confident in his masculinity, his heterosexuality, and made more pleasing to the heterosexual woman of his desire. *Queer Eye* repositions “White, urban, heterosexual masculinity as normative and dominant” (Clarkson 2005, 252).

Whereas most critical media scholarship examines mediated narratives that reinforce heteronormativity, analyses have begun to emerge arguing that selected mediated narratives can be read as denaturalizing heteronormativity. Cooper (2002) argues that the film

*Boys Don't Cry* (1999), which depicts the life story and eventual brutal murder of the transgendered teen Brandon Teena, normalizes Brandon's female masculinity and critiques conventional masculinity. In portraying Brandon Teena as a sympathetic individual, the film legitimates feminized masculinity, offering a challenge to heteronormativity's attempts to order a society that only accepts highly masculinized performances of male gender roles. Cooper & Pease (2002) critique an episode of *Ally McBeal* (1997–2002), "Boy to the World," that juxtaposes a narrative about a transsexual with a narrative about intolerance toward short people. This narrative structure equates bigotry toward short people with bigotry toward transsexuals, making society's intolerance for transsexuals seem as absurd as prejudice toward short people. In doing so, the episode challenges heteronormativity and validates non-normative (e.g., transsexual) sexual identities.

The US soap opera *All My Children* (1970–present) first introduced a storyline in 2000 about an out lesbian, Bianca Montgomery. The storyline disrupts the genre's underlying celebration of heterosexual romance. Whereas daytime television has historically led prime-time in addressing controversial issues, Bianca is the sole gay or lesbian character on network daytime (Harrington 2003). This storyline marks progress in that the producers have placed the storyline centrally (Bianca is the daughter of Erica Kane, one of the longest-running characters in daytime history) as well as written the narrative to normalize Bianca (e.g., depicting her in a gay bar; Harrington 2003). In doing so, the storyline destabilizes heteronormativity. However, the question remains whether other daytime shows will follow this lead, or whether the constraints of industry, genre, and audience expectations will effectively block additional positive (and potentially normalizing) representations of gays and lesbians on daytime television.

Communication scholarship examining heteronormativity and the media is sparse and most of it has been limited to examinations of US television programs and films. Much more research is needed that moves beyond the US media context. For instance, television networks in the UK, Australia, Spain, Italy, France, and Finland have all created their own versions of *Queer Eye for the Straight Guy*, with varying degrees of success. How might these versions of the same show, but for different audiences, vary in terms of how they fortify or call into question heteronormativity? Another area unexplored by communication scholars is heteronormativity in relationship to shows explicitly about gay and lesbian sexuality (e.g., the British or US versions of *Queer as Folk* [2000–present] and *The L Word* [2004–present]). Does the explicitly gay and lesbian-themed content of these shows offer alternatives to or replay heteronormativity?

## Historic Key Events and the Media

Rudolf Stöber

University of Bamberg

Historic key events are genuine events with historical importance. Four factors are important to consider in this regard. (1) Historic key events have a *short and distinct duration*. The event happens within a short time and it is clearly separated from later and earlier events. It is arguable whether wars and revolutions should be considered as historic key events; overall it seems best to regard them as chains of related historic key events (Wilke 1989). (2) Historic key events have a significant *impact on later times*. The historical dimensions of the political, social, economic, or cultural effects are sometimes obvious when the event happens, but at other times the importance of the event becomes clearer with the passing of time, when the significance of its effects can be evaluated differently. It is easier to regard political or economic events as key events than social or cultural events. (3) Historic key events are *not primarily created for media attention*. Their importance is independent of any media coverage. Even when some aspects of an event may have been planned in advance to attract media attention, its main purpose is not media effect. (4) Historic key events are *ambiguous and subjective* in many ways. Billy Wilder's film *One, Two, Three* (1961) started with a quote that provides a perfect illustration of the ambiguities of historic key events and media key events: "On Sunday, August 13th, 1961, the eyes of America were on the nation's capital, where Roger Maris

was hitting home runs #44 and 45 against the Senators. On that same day, without any warning, the East German Communists sealed off the border between East and West Berlin. I only mention this to show the kind of people we're dealing with – real shifty!" On the one hand, the mass media cover key events; on the other hand, media routines can be used for political or other purposes (→ News Routines). The ambiguous status of a key event is due to the point of view. The above quotation illustrates that the importance of a given event may be valued very differently: some events achieve the status of a historic key event, while others remain simply key events in media coverage.

### CHARACTERISTICS OF HISTORIC KEY EVENTS

Historic key events have to be *distinguished clearly from media events or pseudo-events*. A pseudo-event "is not spontaneous, but comes about because some one has planned, planted, or incited it . . . It is planted primarily (not always exclusively) for the immediate purpose of being reported or reproduced . . . The question, 'Is it real?' is less important than, 'Is it newsworthy?'" (Boorstin 1962, 11; → Media Events and Pseudo-Events). A historic key event is sometimes almost the opposite; some of them did not attract media coverage at all. The Hitler–Stalin Agreement on the division of Poland was a key event of twentieth-century history in that it gave Hitler the opportunity to start his war. Nevertheless, it was not covered by the media and even at the Nuremberg Trial the Soviet Union denied its secret amendment.

However, the importance of media in modern society means that most historic key events are *subjected to media coverage*. Under normal circumstances, the coverage of historic key events by the media is one indicator of the importance of the event in itself, but it is not the most important indicator. Media coverage simply indicates that the journalists consider a specific event to be relevant to their audience. For example, in 1996 a suicide bombing attack was covered over 72 hours nonstop on Israeli television. Television coverage of John F. Kennedy's assassination in 1963 lasted uninterrupted from November 22 to 25; it was the longest uninterrupted television coverage of an event until the events of 9/11. But not even in Israel is the suicide bombing of March 1996 recognized as being as important as JFK's assassination or the terrorist attacks of 9/11. Because key events are for the most part mediated events, they lead to follow-up coverage of minor events by the media (Kepplinger & Habermeier 1995), for example, even small incidents involving airplanes attracted greater media attention after 9/11 (→ Mediated Terrorism).

The status of an event as historic and key depends on its specific importance, which is *relative* not absolute. For example, in Egypt's modern history the assassination of Anwar El Sadat in 1981 was a key event, but its status as a key event in modern history in general may be doubted even though the international media covered the assassination broadly. Most of the historic key events of a particular nation are important for the nation's history but not necessarily for other nations.

The status of a key event also is related to the *bias of the significant effects* of the event in history. Many key events have positive effects for one interest group but create negative effects for others. The bias of the media coverage depends on the varying points of view (→ Bias in the News). For instance, that Sadat (together with Menachem Begin) was

awarded the Nobel Peace Prize (in advance) for his treaty with Israel in 1979 was commented on very positively by the press in Egypt, Israel, and in the west, but extremely harshly in Syria's *Al Baath* ("The Resurrection"), and in many Arab countries and in the east European communist press.

### THE ROLE OF SYMBOLISM

Historic key events become emblematic by way of the attribution of importance to them, which may be biased, and media coverage plays an important part in forging the → symbolism. The concentration of the distinct event in a short historic moment at a given place makes both media coverage and forging the symbol easy. The assassination of Archduke Franz Ferdinand in 1914, which led to World War I, was the symbolic end of the nineteenth and the beginning of the twentieth century. The murder of JFK marked the end of the American dream of "Camelot" in 1963. The raising and tearing down of the Berlin Wall in 1961 and 1989 marked the climax and the end of the Cold War in 1961 and 1989 respectively. The terrorist attacks of 9/11 upon the symbols of America's strength started the worldwide "war on terror" in 2001. Some key events were symbolic acts in themselves: in 1952 the coronation of Queen Elizabeth II began a Europe-wide taste for television spectacles.

Media coverage does overload some "historic" key events with symbolic weight. Whether they are really significant for the future may not yet be clear. The landing on the moon in 1969 serves as an example: it may be that in the distant future, when inter-planetary space travel has become routine, man's landing on the moon will be seen as the first important step toward other worlds, but so far the landing on the moon has not yet made any significant impact on life on earth. Other events were placed center-stage and overloaded with symbolism, for example, Chamberlain's return from the Munich negotiations in 1938: later "Munich" came to symbolize the opposite, not lasting peace but political weakness that led to war.

The most impressive key event of recent years, the terrorist attacks of September 11, confounds the rule that every historic key event is a genuine event. The symbolic nature of the attacks underlines its character as a media event: the Twin Towers as a symbol of US high finance, the Pentagon of its military strength, and the Capitol or White House of its political system indicate that 9/11 was arranged for the media. The attacks on America's symbols may not have been so choreographed in former times, when there were no TV networks or video cameras. If the terrorists had reckoned on this they had calculated on the routines of media coverage precisely. There is a time delay of a quarter of an hour between the impact of the first plane on the north tower of the World Trade Center and the impact of the second plane on the south tower: even if no TV cameras had covered the first impact the terrorists may have reckoned on quick and instant media reaction to capture the second impact, and they were right. The second plane crash was filmed live by many TV cameras in close-up and the pictures were broadcast all over the world.

### TRENDS IN MEDIA COVERAGE

In history media coverage of key events has followed some general trends. (1) The time delay between event and media coverage has been reduced dramatically. (2) Media

involvement in historic key event coverage has expanded. (3) The impact of the news media's coverage of key events on the audience has increased. (4) Key events are illustrated with the most impressive material. All these trends are related to changes in the media system itself.

### **Time Delay**

The media coverage of key events has progressively decreased to virtually *zero time delay*. At the beginning of the history of mass media, in early modern times, key events were covered with a delay of weeks or even a month. At the beginning of the twentieth century key events were covered by the next day or even within the same day. After 1920 foreseeable events were covered with little time delay. These days even the news of unforeseen events is disseminated throughout the world within minutes, as for example the events of 9/11 or the London bombings of July 7, 2005. Improvements in media infrastructure are the main cause of this trend.

At the beginning of early modern times most of the traffic on land and sea did not have a time schedule. Regular mail delivery was established as early as the sixteenth century on the main routes such as Amsterdam to Venice. These mail delivery systems expanded in the following centuries, and the frequency and speed of delivery improved. In the nineteenth century in many countries stage coaches ran according to schedules, and further improvements came with the development of the railway. The building of railroads after 1825 did not merely improve the speed of travel but (from the following decade) was also connected with the construction of telegraph lines: the new communication device helped to coordinate its schedule. Stockbrokers exchanged news of prices and news agencies spread news by the telegraph from the mid-nineteenth century onwards (→ Telegraph, History of).

Starting in the 1920s → radio communication by air wave enabled live reporting. Probably the first live report was transmitted even before regular radio stations were on air, and it was a false report: "All Titanic's passengers safe," in 1912. In the last third of the twentieth century multiplication of the channels intensified communication: satellites, cable and digital multiplexing wove a dense information network nearly all over the world. Today the infrastructure comprises not only the mass media but, due to the technological conversion, every mobile phone or video camera in private hands may become part of the infrastructure at any key event. The constant improvements have reached a point where no further minimization of time delay is possible (→ Information and Communication Technology, Development of).

### **Increasing Involvement of the Media in Key Events**

A second trend the expansion of media coverage of historic key events. In general, the events are covered by all existing media, where up till the nineteenth century the news of events was disseminated by all kinds of press reporting. Regular newspapers and non-periodical broadsheets, magazines with or without pictures, chronicles and books covered major events like the beheading of Charles I in 1649 and of Louis XVI in 1793. In 1914 the assassination of Archduke Franz Ferdinand was covered by all kinds of press, but also by newsreels. In the 1920s and 1930s live → radio reporting was added. When Neville

Chamberlain returned to London after the notorious Munich Conference, he delivered his famous speech on “Peace for our time” into radio microphones and waved the Munich Agreement in front of the newsreel cameras. In 1960s press, newsreel, radio, and the new television media spread the news of President Kennedy’s assassination and the landing on the moon around the world (→ Television News). While new media took over the actual coverage the older media switched to background coverage and specialized in “inside information” to deepen the audiences’ understanding of the event.

Any major event provides the public with special issues of newspaper or television magazines. The events of 9/11 provide an example of the broad approach of media coverage. After the first plane crash TV networks all over the world switched to live reporting. In Germany the highly respected public broadcasting system lost much ground to the private RTL station which went on air with the news within minutes and reported live for the rest of the day. The attacks were the main theme in the press and on television for nearly a month. But even very old media like books could be written and published quickly. Some of these did no more than reproduce rumors circulating on the Internet. The Internet itself became a major source of information, for example for those looking for missing relatives, but also for misinformation and conspiracy theories.

### **Increasing Effect of Media Coverage**

The third trend is related to the second: media coverage has become *more impressive, affecting and emotional* (→ Emotions, Media Effects on). Due to technological progress, the mass media’s capacity to address the human senses has improved. The press has traditionally used the written word to cover events, but it has also covered historic key events with pictures. These were printed using woodcuts in the sixteenth and seventeenth centuries and high-quality copper plates and steel engravings in the seventeenth and eighteenth centuries (e.g., events like the burning of Magdeburg in 1631 and the Lisbon earthquake in 1755). The reproduction of pictures became cheaper with lithography and wood engravings in the nineteenth century.

At the end of the nineteenth century Meisenbach’s autotype enabled photographs to be reproduced. Nevertheless, the poor quality of photographs and of their reproduction meant that many events continued to be illustrated by highly dramatic lithographs or engravings even at the end of the nineteenth century and on the eve of World War I, for example, in coverage of the explosion of the USS *Maine* covered by the Hearst papers in 1899 and the assassination of Archduke Franz Ferdinand in Sarajevo in 1914. Since the end of the nineteenth century historic key events were also captured on film. Because of the lack of authentic pictures sometimes faked material was used in news coverage. For example, Pathe’s newsreel on the Russo-Japanese War of 1905 illustrated the battles with ship models. As media technology improved, sound was eventually added: Fox Movietone Newsreel first combined picture and sound coverage of the news in 1927.

### **The Role of Pictures and Sound Bites**

A fourth and more recent tendency is the media’s reduction of a historic key event to its most *impressive picture or sound bites*. Examples are Winston Churchill’s “we shall never

surrender” and “blood, toil, tears and sweat” (1940); pictures of the assassination of JFK (1963); pictures and sound bites of Neil Armstrong’s first “small step” on the moon’s surface; and the the airplanes crashing into the World Trade Center. These and other examples are reproduced by the media so often that they begin to take on a life of their own. The use of the same pictures and sound bites depends on media routines and the expectation of the public (→ Photojournalism; Television News, Visual Components of).

The media need examples with great symbolic value and aims to depict events with the most impressive material. The public, captivated by such routines, gets so used to these examples that it constructs a direct connection between the historic key event and the most widely used coverage material. Some key events do not yield such impressive material because no media was present or because the event itself was very abstract. Media routines then tend to illustrate the event with material that has a connection not with the incident but with its consequences; for example, the Wall Street Crash of 1929 did not provide as impressive a photograph as long rows of unemployed workers.

## **FURTHER RESEARCH AND METHODOLOGY**

At present the principal methodology employed in research in historic key event coverage is content analysis, which has been used to study isolated events (→ Content Analysis, Quantitative; Content Analysis, Qualitative). But because key events are a combined result of media coverage, impressive symbolism, and audience reception, this kind of approach cannot cover all aspects of the field. Content analysis may be suitable for examining the content of media coverage, but it does not explain the motives of the communicators.

Therefore, historic key event research should take into account a combination of content analysis, reception research, media structure analysis, and historical criticism – a method developed by historians from Leopold von Ranke, Gustav Droysen, and others. Historical criticism takes into account, among other things, the context, → meaning, social background, and personality of communicators, and considers that very important historical sources are always missing, especially when intentional communication processes are involved. For example, when the Prussian chancellor Otto von Bismarck launched a → propaganda machinery in 1882 a top-ranking bureaucrat wanted to know whether he had to preserve receipts of the money he had spent, Bismarck’s answer was “Definitely not.”

Research also lacks long-range diagnostics, which would be very helpful in attempts to define historic key events, which, moreover, change over time and differ between one nation’s history and another’s. Furthermore, research lacks international comparison, whose main obstacle is probably the lack of knowledge of many different languages. It is clear that this research program is very ambitious.

## **Historiography**

*Michael Meyen*

*Ludwig Maximilian University of Munich*

The term “historiography” is used in a number of different ways. It can refer to writings that present the past as “history.” It can also refer to the way these writings are produced, focusing on the issues of method that are linked to the construction of history. Unlike historical novels, historiography is based on a systematic access to sources, and therefore often connected with a claim of truth. However, it should be considered that any evidence is revocable because new sources may be found and already known sources can be reassessed according to the present world’s interests (Jenkins 1995; Bentley 1999; Burke 2005).

Historical research that is conducted in the framework of a social science is confronted with *two problems*. First, studies of this kind will only be perceived as being in their particular discipline if links are established between the historical perspective and a systematic scientific interest in new findings for the discipline. Second, the acceptance of historical research is complicated by the fact that historians and social scientists have different viewpoints on science. This has an impact on the criteria used when assessing the quality of scientific work. Whereas most researchers in the social sciences, just like natural scientists, want to discover objective relationships and general laws, and search for knowledge that can be used practically, historical research is concerned with individual cases that are not repeatable, so that it can merely supply orientation knowledge that encourages reflection, e.g., upon one’s own existence or upon the basic values of a society (→ Research Methods; Communication Theory and Philosophy; Critical Rationalism;

Case Studies). Since historiography's interpretations are always subjective in nature, it cannot meet the social sciences' ideal of objectivity (→ Objectivity in Science). This explains why, in communication studies, the situation is anything but optimal for historical research (Curran 1991; O'Malley 2002).

Although communication studies in the German-language area were taken into the university by qualified historians at the beginning of the twentieth century, there is now a strong decrease in the number of historiographically based studies and in the number of professorial chairs dedicated to communication history or media history. Since the study of questions of method in historical research does not currently offer much benefit for an academic career in the discipline of communication, and since the techniques used were usually not addressed in studies dating from the discipline's founding period, this entry must necessarily be based upon the corresponding debate that has been going on in the discipline of history (→ Communication as a Field and Discipline).

### HISTORICAL METHOD

In order to make the results of historical research intersubjectively verifiable and thus to be able to legitimize history as a science, the discipline of history has developed a canon laying down *rules for the handling of sources* (Furay & Salevouris 2000; Burke 2005). Structured along the same lines as in the natural sciences, this body of rules is referred to in literature as the historical method. According to this method, anything produced by a human being is to be regarded as a source. The discipline of history distinguishes between unintentionally and intentionally transmitted sources. This distinction is important for the assessment of a source's value and for interpretation. Whereas intentionally transmitted sources owe their existence to the intention to provide posterity with information about certain facts or events and therefore have to be read in a particularly critical way (examples are chronicles, memoirs, or historiographical works), unintentionally transmitted sources originated under circumstances that become the focus of examination. Among these are material/object sources (buildings, works of art, articles of everyday use such as phonographic records or radio sets) and in particular all the documents written at some time in the past in order to satisfy the needs of the moment (records, legal instruments).

The distinction between *intentionally and unintentionally transmitted sources* is not always clear-cut; it also depends on how a question is formulated, as can be demonstrated with the daily press serving as an example. Editorials, for instance, were in the first place addressed to contemporary readers, and could therefore be classified as unintentionally transmitted sources and consequently as being of particular value for historiography (→ Editorial). The journalists knew, however, that the papers would be kept, and they also wanted to communicate "historical" knowledge about past events (→ Collective Memory and the Media; Historic Key Events and the Media) – these are indications of intentionally transmitted sources.

Since neither unintentionally nor intentionally transmitted sources give a direct picture of the past and since the results of historical research are greatly dependent on the type of sources that are used, the historical method provides rules for choosing, criticizing, and interpreting sources. These rules were developed as early as the nineteenth century. That is one of the reasons why they refer in the first place to written documents (official

records), but they can by analogy also be applied to other sources. The value of a source is mainly determined with the help of two criteria. First and decisive is the *proximity of the event* or the state that is to be explored. The word “proximity” refers here to time as well as to space. Normally, accounts from eyewitnesses or from co-acting persons that have been recorded immediately after an occurrence are of greater value than second-hand narrations. The second important criterion is *availability*. The value of a source always depends also on the kind of other additional sources that can be used. There is no point in producing one’s own sources by means of retrospective biographical interviews, for instance in the field of historical audience research, unless all transmitted sources are untrustworthy or do not allow a complete solution of the research problem under consideration (→ Qualitative Methodology; Interview, Qualitative).

*Criticism of sources* is the most important tool for historiography. The trustworthiness of sources has always to be questioned, and one has to ask about the relationship existing between the wording and the facts that are being described. In order to do so, one has to know the history of the origins of a given source – its purpose as well as the organization that has produced the writing – and the intentions of the author. In addition to source transparency, the central quality criteria applied in historiography are consequently: the diversity of sources, and the comparison of sources. In order to be able to open up and assess sources, the discipline of history has developed a number of complementary sciences such as genealogy (disclosure of descent) and paleography (decipherment of writings). In order to filter necessary information from sources, today one can also use the quantitative and qualitative techniques that were developed by the social sciences and, for some of them, also by the other humanities (→ Quantitative Methodology). That is why the historical method is usually a technique that combines several methods.

## **HISTORIOGRAPHY IN THE FIELD OF COMMUNICATION**

Within the discipline of communication’s framework, historiography deals with the historical dimension of public communication processes (→ Media History). In doing so, it can also examine isolated parts of these processes, the range extending from the origins of accounts to the media and media contents as well as to the audiences and to media effects (Stevens & Dicken Garcia 1980; Briggs & Burke 2002; O’Malley 2002). Examples of practical use are: the history of the journalistic profession (→ Journalism, History of), biographies of newspapers and magazines (→ Newspaper, History of; News Magazine, History of), the history of radio programs and radio institutions (→ Radio: Social History), as well as historical → audience and → media effects research. Through focusing on long-term contexts and by analyzing examples for particular cases, historical research can enhance the ability to perform reflection within the discipline and put the results of selective and short-term studies into a broader context.

Thornton (1998), for example, analyzed 45,000 “letters to the editor” in popular magazines and was thereby able to show how the *public discussion about journalistic quality in the USA* has changed. While at the beginning of the twentieth century the debate focused on public duty, 80 years later the credibility of the media was at the center of interest. Thornton knew for sure that his source did not provide an unfiltered view on the “voice of readers”; first, because only a distinct group of people writes letters of that

kind, and second, because the editorial office decides which of them are to be published. Thornton's arguments to support the use of this source were that the letters determined the agenda of the public discussion (→ Agenda-Setting Effects); furthermore, they represent what the readers were able to see; and beyond this, such letters "often [are] the only existing record of some public opinion" (Thornton 1998, 39), especially for more distant periods.

The historical audience research is confronted with similar problems. Using the case study of the introduction of television in Germany in the 1950s and 1960s, Meyen and Hillman (2003) discussed the *correlation between the use of media and the development of society*. What factors determine the changes in communication relationships and how do these changes affect society? The authors based their analysis on all available survey data from East and West Germany as well as the most important media services and a systematic cross-section of the media itself. They showed that the expectations of people in relation to the media are predominantly influenced neither by politics and media systems nor by concrete media contents. Primarily, their communication needs are dependent on working conditions and daily routines.

This second example shows that communication historiography has reacted to developments in the discipline of history. After a slight delay, communication historiography has reacted to developments in the discipline of history; it has opened itself up to the subject matters of social history and of everyday life history, and has also entered upon a discussion about method innovations (oral history, quantification).

However, unlike social scientists, most of the authors of historiographical papers still fail to disclose the way they proceed, and they do not submit their approach to discussion. In compensation they add a (usually implicit) reference to the historical method and an appropriate list of works consulted (this list being as extensive as possible). However, because of the success of the natural science model, the discipline of history, too, is now more conscious of the fact that no object exists without being the subject matter of research and that it is necessary to discuss the theoretical prerequisites and methodical steps that serve as a basis for historical interpretation. Moreover, historiography is unthinkable without historians. The questions that are put to history as well as the selection and interpretation of sources are never only determined by present-day interests, but also by the intentions of the authors and by their social position (Mruck & Breuer 2003). As historiography does not simply reflect upon a given past, the subjectivity of the authors should be discussed: their socialization, their conception of people and society, their relationship with the subject matter of the investigation, and the interests they possibly have. The historical method offers the best preconditions for undertaking this analysis. The criteria for dealing with sources that have been developed can be applied to theoretical elements, to methodical approaches, and to the subjectivity of authors.

## **Hollywood**

*Jan-Christopher Horak*

*University of California, Los Angeles*

Hollywood is the metaphoric, if not exactly the geographic, center of the American film, television, cable, music, and digital media industry. Ripe with symbolic meaning for media consumers across the globe, Hollywood exists almost purely in the collective imaginary, since it is neither incorporated as a city, nor definable by strict borders as a geographic location within the city of Los Angeles. Even in terms of its real geography, Hollywood was only one of several industry centers: of the major film studios, only Paramount (Melrose Ave), RKO (Cahuenga and Gower), and Columbia (Gower Street) maintained production facilities directly in Hollywood, while Universal Studios was located in the San Fernando Valley (Universal City), Warner Brothers in Burbank, 20th Century-Fox in West Los Angeles (Westwood), and Metro-Goldwyn-Mayer (MGM) in Culver City. Nevertheless, millions of tourists flock each year to "Hollywood," which has also had its ups and downs as a piece of real estate.

### **EARLY HOLLYWOOD**

Located approximately ten kilometers northwest of downtown Los Angeles, Hollywood got its name in 1887, when Mr Harvey Wilcox registered his ranch with the LA County Records authorities. In 1903, Hollywood officially became a city with 700 inhabitants.

A year earlier, the Hollywood Hotel had been opened by Hobart Johnson Whitley (sometimes known as the father of Hollywood) at Hollywood Boulevard and Highland Avenue, but it was under the ownership of Myra Parker Hershey that it became one of the premiere hotels of Hollywood in the silent era. In 1910, Hollywood was officially annexed by the City of Los Angeles, a legal status that has remained to the present day.

Although film companies based on the east coast started shooting in and around Los Angeles, beginning in 1906, when the American Biograph Company sent location crews there in the winter months, it was pioneering film director D. W. Griffith who first shot scenes within the boundaries of Hollywood, for his film *In Old California* (1910). According to a myth now considered apocryphal, American film producers first began producing films in Los Angeles County in order to escape easily to Mexico from the goon squads of the Pinkerton Agency, which had been hired by the Motion Picture Patents Trust to enforce their monopoly on motion picture production. In reality, it was merely *sunshine and the diversity of topographies* that lured filmmakers from New York and New Jersey to southern California. In the early days of the film industry, producers shot on outdoor stages in natural light, rather than utilizing electric light, so that dependable sunshine was a must. Southern California's mixture of seascapes, mountains, desert, and other topographies in a relatively limited area was thus a plus.

The *first permanent film studio* in Hollywood was established in the Blondeau Tavern at the corner of Sunset Boulevard and Gower Street by David Horsely's Nestor Film Company in 1911, when H. J. Whitley encouraged studio manager Al Christie to set up shop there. Within months, 15 other film production companies had established production facilities in Hollywood. A year later, the Idyll Hour Theatre, Hollywood's first → cinema, opened. Cecil B. DeMille directed his first feature film, *The Squaw Man* (1914), in Hollywood after leasing the Burns and Revier Studio at Selma and Vine; the "Lasky-DeMille" barn, which functioned as office and laboratory space, survives to this day as a museum across from the Hollywood Bowl. By 1913, then, Hollywood had over 8,000 inhabitants, many of them working in the budding movie industry.

### CLASSICAL STUDIO SYSTEM

By the 1920s, numerous companies and film producers had built permanent production facilities in Hollywood (→ Film Production). In 1913 William Clune opened a studio at Melrose and Bronson, destined to become a major rental studio in the 1920s, the Tec-Art Studios. This studio continued in the sound period under various banners (California, Enterprise, Horizon, Stanley Kramer, etc.); it still functions in the twenty-first century, as the Raleigh Studios. Today virtually all studio lots, including majors like Universal and Paramount, are also rental studios, catering to the demand of independent film and television. Fox opened its first studio at Western and Sunset in 1916, dedicating its expanded Westwood studio in 1928. Charlie Chaplin's mock-Tudor-style studio at La Brea and Sunset was opened in 1917 and is today home to Jim Henson Productions. Columbia Pictures built its studios in 1923 on Gower, the heart of what was considered "poverty row," where independent and low-budget "B" producers rented or owned small studios. Paramount established its presence in Hollywood relatively late (1926), having previously produced all its films in Astoria, New York.

Before 1903 producers sold their films outright by the foot, asking exhibitors to pay anywhere from \$50 to \$100 per title, which were run until the market was saturated. With programs changing at an ever-increasing rate, this system became economically untenable. According to conventional wisdom, Harry J. Miles of San Francisco came up with a solution to this dilemma in 1902 by purchasing films from the producer and then leasing them to individual vaudeville houses at half price. The development of exchanges meant that the distributor maintained film inventories, supervised the handling of films, and attended to the repair of damaged films. The exhibitor was thus relieved of these costs, without cutting into the profits of the producer. By 1907 more than 130 exchanges operated in various parts of the country.

In the cinema's earliest days, films had been projected only as an adjunct to live vaudeville performances. While it is still a matter of historical debate when exactly the first *store-front "nickelodeon" theaters* opened, some historians have credited Harry Davis of Pittsburgh, PA, with inventing the term "nickelodeon" in 1905, but it is probable that early store fronts opened in a number of locations in that year, bearing such colorful names as "Dreamland," "Bijou," "The Princess," "Electric," and "Bijou Dream." By early 1907 there were more than 2,500 nickelodeons in the USA. Many of the later movie moguls, including the Warner Brothers (who bought their first theater in Castle, PA, in 1906), Adolph Zukor (Paramount), Carl Laemmle (Universal), Louis B. Mayer (MGM), William Fox (20th Century-Fox), and Marcus Loew (MGM), began their careers as nickelodeon operators, eventually purchasing chains of theaters, exchanges, and production facilities. As the teens progressed, theaters increased in size and programs expanded. By the end of the 1920s, many movie palaces had been built on Hollywood Boulevard: Hollywood Theatre (1913), Fox Hollywood (1918), Sid Grauman's "The Egyptian" (1922), the El Capitan (1925), the Ritz (1925), Graumann's Chinese (1927), and the Pantages (1929). Such large-scale cinemas in Hollywood and in every other metropolitan area were soon controlled by the film companies. In the classical period from the 1920s to the 1950s, the film distributor supplied a complete program, including a "feature," a second short feature (B-film), a newsreel (important before the age of television), a short documentary (often a travelogue or educational short), and a cartoon (→ Film Genres).

Thus, by the time film production had been established in Hollywood, the *basic structure of the film industry* was in place, divided into production, distribution, and exhibition. The first vertically organized film combine, uniting all three levels of the industry, was formed by Paramount-Famous-Players in 1919, followed by Loew's-Metro in 1921 (→ Media Corporations, Forms of). The initial impetus for the Paramount merger was the growing strength of First National, a theater chain controlling over 639 screens, which had signed Charles Chaplin and Mary Pickford to production contracts, thus threatening Paramount's control over virtually all the major stars. However, it was a financial report by H. D. H. Connick to Kuhn, Loeb and Co. supporting a loan to Paramount that convinced company president Adolph Zukor of the wisdom of owning his own theater chain.

### **AN OLIGOPOLY INDUSTRY**

The 1920s, then, saw Hollywood and the American film industry dominate the world market by structuring itself as a vertically and horizontally integrated industry. Since the

huge American market allowed companies to amortize their product domestically, they could undersell the foreign competition abroad. No other country, except perhaps Germany, ever threatened *Hollywood's hegemony*. Hollywood became a worldwide brand name (→ Brands). In 1923, an enterprising real estate agent built in the hills above Franklin Street the now famous “Hollywood” sign, which originally read “Hollywoodland” in order to advertise a new housing development. In 1927 *the first Oscars* were staged at the Roosevelt Hotel. In the 1970s Hollywood, especially Hollywood Boulevard, degenerated to an area of drug pushers and prostitutes, but beginning in the 1990s, the street started to gentrify, and by the early twenty-first century had become prime real estate for redevelopment, again attracting legions of tourists.

One of the central ironies of the American film industry is that film production is both highly organized and ritualistic. While dependent on the exact coordination of literally thousands of people and the amassing of vast financial resources, the economic success or failure of a film is believed to be a matter of secret formulae, of luck smiling, of timing, talent, and guts (→ Communities of Practice). In its classical phase from the 1920s to the 1950s, Hollywood was a monolithic economic system, a multinational monopoly of corporations, whose structure of film production, distribution, and exhibition was based on laws of scientific management, an intense division of labor, the pioneering use of modern → advertising techniques, and complete control of the market (→ Concentration in Media Systems). Everything possible was done to minimize risk and maximize profits. Yet success was always thought of in magical terms. Naturally, as the captains of America's largest leisure industry, film producers were neither interested in exposing their own ruthless business practices, nor willing to undermine the social and economic status quo.

### CLASSICAL CODES

Hollywood's → discourse always supported a romantic mythology, because the very commodity this industry produced was fantasy and fictional narratives (→ Fiction). Film images sought to transport an audience from the real world into a universe of myth, where audience desires could find at least partial satisfaction (→ Uses and Gratifications). Long before economists thought in such terms, the film industry offered American consumers a service, leisure-time activity, rather than an industrial commodity, and thus foreshadowed the postindustrial, service economy of the late twentieth century.

Indeed, as early as 1917, according to most film scholars, Hollywood had instituted a highly conventionalized form for storytelling that is now subsumed under the label “classical Hollywood narrative” (→ Storytelling and Narration). In contrast to European “art films,” Hollywood movies naturalized the viewing process, imbedding the viewer through film technology and technique in the narrative, hiding artifice and any self-conscious reminders that the audience was indeed viewing a film (→ Visual Representation; Entertainment Content and Reality Perception).

In terms of film technique, this meant utilizing a *system of “invisible editing”* that would hide the breaks between individual shots, creating a seamless visual flow. Camera men and editors internalized a whole set of rules and regulations, including the 180-degree rule, the 45-degree angle rule, the use of establishing shots, and protagonist-centered plots. In terms of narrative, classical Hollywood demanded that character motivation and

plots followed the logic of generic convention and star persona, rather than a complex, three-dimensional reality: John Wayne appeared in Westerns, Judy Garland in musicals, Joan Crawford in melodramas (→ Stars). Dramatically, films had to traverse an arch from exposition to the building of conflict to a resolution through a happy end, with heterosexual union being the driving narrative force of practically every film story.

The “*star system*” had evolved in the early teens, just as Hollywood was ascending. While the Motion Picture Patents Trust discouraged naming actresses and actors in their publicity, in order to keep salaries low, the independent producer Carl Laemmle hired “the Biograph Girl,” Florence Lawrence, in 1910, successfully exploiting her name and image. It soon became apparent that selling “stars” was the most efficient means of selling films. By the late 1910s, stars such as Mary Pickford, Douglas Fairbanks, and Charles Chaplin were so important that they could start their own company, United Artists (1919). In the classical studio period, every major studio had a table of stars, controlled through long-term contracts and an elaborate system of publicity to build them up (→ Celebrity Culture). With the rise of independent film production, stars became their own producers.

### INTERNAL CENSORSHIP

Given continual threats of public and private → censorship, beginning with the establishment of municipal and state film censorship offices in the 1910s, the industry created its own rigorous, internal pre-censorship system through the Catholic-dominated Motion Picture Production Code “Hays” office under Joseph Breen in the 1930s. Hollywood film producers thereafter privileged hetero-normative romance in their fictions as an efficient means of avoiding – with rare exceptions – political and social controversies, and thereby circumventing the crossfire of politically charged public discourse. This avoidance of the political was not just a matter of choice, but of law: in 1916, in a landmark Supreme Court decision *Mutual v. Ohio*, the Court held that the production and distribution of movies was a business, rather than a matter of communication, and therefore, unlike the theatre or newspapers, *not subject to First Amendment guarantees of free speech*. This ruling was not overturned until the 1970s, leading to a period of liberalization in sexual and social content, yet even today a “Rating” system, enforced by the Motion Picture Producers and Distributors Association (the same MPEA of the Hays Office), restricts access to the commercial media market (→ Censorship, History of).

### ANTITRUST ACTIONS

For approximately 30 years, the period known as the classical Hollywood studio era, film companies were allowed to earn unprecedented profits. Their flagrant violations of anti-trust laws were called into question by the US Justice Department as early as the 1920s. The courts continued hearing cases for almost 30 years, before the “Paramount Consent Decree” of 1947 effectively ended the monopolistic position of the majors. In 1921 the Federal Trade Commission had filed its first complaint against Paramount & Co. In 1929, after the acquisition of First National and the Stanley Theatre chain, Warner Brothers was sued under the provisions of the Clayton Act, which forbade the acquisition of any

competitor with the intent of creating a monopoly. In a criminal case based on the Sherman Anti-Trust Act, the Justice Department in 1935 charged that Harry Warner, Paramount, and Fox had conspired to deny a St. Louis independent theater owner any first-run films, thus forcing him from the market.

When the government lost the case, they continued to prosecute in civil suit in two further courts. On July 20, 1938, the Justice Department filed suit against the five majors, accusing them of 28 separate offenses in violation of the Sherman Act, including block booking, blind buying, and the acquisition of theaters for purposes of creating a monopoly. The case was settled out of court, when a “Consent Decree” was reached in November 1940, which limited some practices, but kept the status quo intact. Not until the Paramount Consent Decree did the motion picture companies begin the process of divorcement, separating production companies from exhibition. Paramount split in 1949, RKO in 1950, 20th Century-Fox in 1951, and Warners in 1953. At the same time, the growing television industry threatened Hollywood’s hegemony in the domestic media market (→ Television; Television: Social History), while demographic shifts with suburbanization brought a predominantly youth audience to cinemas. Hollywood was never again the same.

### MULTIMEDIA EMPIRES

It took a few decades, but Hollywood eventually reinvented itself as a group of transnational, multimedia conglomerates that dominate all forms of media: Walt Disney Company (→ Disney), Paramount Pictures (Viacom), Sony Pictures, Universal Studios (General Electric), and Warner Brothers (AOL/Time-Warner) control film, television networks, cable channels and providers, digital media, Internet portals, recorded music, billboards, newspapers, and radio stations. Leading the way was Lew Wasserman, who turned Universal (after MCA bought the company in 1962) into a powerhouse by initiating a system of independent production whereby agents and producers, at their own risk, developed and produced films that were then distributed by Universal.

Wasserman’s Universal was the first major studio to move into *television production and syndication*, allowing independent producers to shoot on the lot, but again at their own financial risk, while also pioneering the production of so-called television movies. Finally, with *Jaws* (1975), Universal created the “blockbuster,” opening a film in thousands of movie theaters across the globe at the same time, generating billions of dollars, not only in ticket sales, but also through product tie-ins (merchandising), and the sale of television and video rights (→ Popular Culture). As a result of this blockbuster mentality, the average price of a Hollywood feature film had climbed by 2006 to US\$75 million, and films that generate less than US\$100 million are considered flops.

### THE VIDEO AGE

In the 1980s, then, film distribution companies quickly moved into new forms of presentation, as theatrical movie attendance continued to dwindle, supplanted by other moving image media, especially home video and, subsequently, DVD platforms. By the turn of the century, income from electronic media far outstripped that of box office, so that the industry once again evolved structurally. Sony, the giant Japanese electronics

company, bought Columbia-TriStar and the Culver City studios of MGM to create Sony Pictures.

Viacom, a television and cable-television provider that also owns CBS, bought both Paramount and Blockbuster, the leading home video rental outfit. Disney purchased ABC, created the Disney Channel on cable, and differentiated its film product through subsidiaries Hollywood Pictures, Touchstone, and Miramax. Rupert Murdoch, owner of the giant international → News Corporation (→ newspapers, → satellite television, → radio) purchased 20<sup>th</sup> Century-Fox and created the Fox Television network. Warner Brothers, which was a subsidiary of the Time-Life publishing empire, also owning HBO and other cable networks, was bought by AOL in 2001. Universal Studios, after no fewer than three management changes in 10 years (Matshusta, Seagrams, Vivendi), was acquired in 2004 by General Electric (GE), which also owns NBC; GE's yearly revenue, in excess of US\$130 billion, would dwarf those of AOL-Time-Warner, Disney, and Viacom were they combined.

These companies control and dominate virtually all public communications media, from newspapers to television news, from book publishing to entertainment film and television, cable, and digital moving image media, from the Internet to satellite communications, from Broadway theatrical shows to video/Internet games, from all forms of amusement parks to billboards and electronic advertising, even political campaign media (→ Culture Industries; Media Conglomerates). It remains a central question and issue of communications research to ascertain if and just how the democratic process can or does survive, given the massive domination of virtually all communications media by a handful of gatekeepers.

# Hong Kong Cinema

Anthony Fung

Chinese University of Hong Kong

The term “Hong Kong cinema” refers both to an industry and to a phenomenon. In its most concrete sense it denotes the cinematic productions based in the former colony and now Special Administrative Region of Hong Kong. But in a larger sense it also refers to a stylistic and cultural movement, and the influence of that movement regionally and globally (→ Cinema; Popular Culture). As a cultural influence Hong Kong cinema has experienced several different stages.

Hong Kong first became internationally known for its *kung fu movies*, which displaced the sword-fighting *wuxia* genre once widely popular in Chinese communities of the 1970s (Teo 1997, 103; → Film Genres). In the previous decades the Hong Kong industry had been dominated by large Mandarin-language studios such as Shaw Brothers and Motion Pictures and General Investment Film Company (a.k.a. Cathay). These companies moved to Hong Kong from Shanghai after the postwar communist victory and produced films reflecting the commercial modernization associated with the 1960s.

The 1970s, however, saw the decline of the major Mandarin studios. Former Shaw Brothers executive Raymond Chow started Golden Harvest, the studio that signed Bruce Lee. Lee developed his own Cantonese version of martial arts films, with himself as kung fu star, in *The Big Boss* (1971), *Fist of Fury* (1972), and *Way of the Dragon* (1973), gradually superseding the popularity of the Mandarin-speaking films produced by the Shanghai directors in Hong Kong.

The brutal fighting scenes and anti-racist and anti-western nationalist themes highlighted in Lee’s movies not only appealed to Chinese communities but, paradoxically, won great popularity in western markets, particularly the US, and led to the co-production of *Enter the Dragon* (1973) by Hollywood-based producers and Lee’s Hong Kong production team (→ Film Production). Lee became an icon as an Oriental hero, and the Hong Kong action choreography was not only well received by international audiences but came to influence the staging of fight scenes in → Hollywood films as well. Lee’s premature death led to a temporary decline of western interest in martial arts films, but during the late 1970s, Cantonese cinema continued to have local appeal with the kung fu comedy films of Jackie Chan and Sammo Hung, and the comedies of Michael Hui, which satirized the growing urbanized Hong Kong society. The martial arts movies of Chan and Hung further popularized a kung fu “acrobatic” style that translated into big box office in North America and led to a Hong Kong-American international “action style,” represented by such films as *Kiss of the Dragon* with Jet Li (2001) and *Rush Hour 3* (2007) with Jackie Chan.

What should be emphasized is that the development of Hong Kong cinema is closely tied to the *socio-economic and political changes of Hong Kong*. Thus, though Hong Kong kung fu movies exercised global appeal, after the mid-1970s they no longer satisfied the first generation of local-born Chinese in Hong Kong, who were experiencing major socio-economic and political changes. Alongside the popular kung fu movies in the 1970s to mid-1980s were movies of the New Wave, including *Private Eyes* (1976) by Michael Hui, which exposed the hardships of the Hong Kong lower classes, *Jumping Ash* (1976) by

Leong Po-Chih and Josephine Siao, which explored drug trafficking and police corruption, and *Boat People* (1984) by Ann Hui, which depicted the tragedies of Vietnamese boat people seeking refuge in Hong Kong waters.

A major factor in the transitional period after 1984 was the Joint Sino-British Declaration returning the sovereignty of Hong Kong to the People's Republic of China (PRC) by 1997. Fearful of impending communist control, a large number of Hong Kong movies portrayed Chinese mainlanders stereotypically (→ Stereotypes), as gangsters disrupting the law and order of Hong Kong (e.g., *Long Arm of the Law* [1984]), as people with insurmountable social and political differences (e.g., *Homecoming* [1984]; Yau 1994, 193–195), amplifying the sense of incompatibility between the pluralistic colony and the “uncivilized” motherland (e.g., *Her Fatal Ways* [1990]). These “realistic” movies, together with many local commercial movie fads about triad societies (e.g., *A Better Tomorrow* [1986] by John Woo), vulgar films featuring sex and gambling (e.g., films directed by Wong Jing) and the famous postmodern “meaninglessness” comedies of Stephen Chow (*Wulitou* [1997]; → Postmodernism and Communication) propelled Hong Kong cinema to its apex. Paralleling the global dominance of Hollywood, Hong Kong cinema had become another regional source of influence in Asia, especially Taiwan, Thailand, Indonesia, Singapore, Malaysia, and South Korea.

After 1997, Hong Kong cinema suffered a severe blow, ironically not due to political pressure but to the economic downturn resulting from the Asian economic crisis of 1997–1998. This was followed by the terror of the SARS (Severe Acute Respiratory Syndrome) epidemic in 2002–2003. Many of the famous Hong Kong directors and superstars took attractive offers from Hollywood to continue their movie careers abroad (Dannen & Long 1997). Among those are John Woo, who directed *Mission Impossible II* (2000); Tsui Hark, who directed *Knock Off* (1998); Ringo Lam, who directed *In Hell* (2003); flight choreographer Dannie Yen, who participated in *Stormbreaker* (2006); and artist Chow Yun-Fat in *Crouching Tiger, Hidden Dragon* (2000). While the lure of Hollywood might be regarded as a brain-drain problem for Hong Kong cinema, many Hollywood films, in particular action movies, now carry the stylistic mark of Hong Kong cinema (→ Globalization of the Media).

In the face of this economic downturn some Hong Kong filmmakers risked producing films with high budgets. The most prominent of these was *Infernal Affairs* (2002), the script and high concept of which were acquired by Hollywood and transformed into the American version, *The Departed* (2006), winner of the Academy Award for Best Picture in 2006. Other local filmmakers sought to partner with Chinese national and private film companies (e.g., *Hero* [2002]) or with international financiers to produce high-budget quality films with a Chinese edge. For example, *Kung Fu Hustle* (2004) was jointly produced with Columbia Pictures Film and Stephen Chow.

Nevertheless, the pull of an expanding China market *poses a dilemma* for Hong Kong cinema: Can films be produced for the Chinese market – with its regulations regarding sex, violence, and politics – and still perpetuate a distinct Hong Kong genre and culture (→ Culture: Definitions and Concepts)?

## **Horse Race Coverage**

*Frank Brettschneider*

*University of Hohenheim*

Horse race journalism is a controversial form of political coverage. It means reporting on politics with the help of sports metaphors. Horse race journalism is particularly prevalent in election campaign coverage, mainly in the context of opinion polls (→ Election Campaign Communication; Political Communication).

Horse race coverage looks approximately like this: at the beginning of the campaign, a candidate goes into the race with a head start, soon gets tired, regains strength only after a quarter of the race, loses speed again and falls back at the back straight, only to make the home stretch by a short head and win the race in the end. The race is exciting from the beginning to the end (Broh 1980). Election polls are useful to journalists drawing on this metaphor, since they can tell the “spectator” who is ahead in the race and whether a candidate’s position is improving or deteriorating throughout the race. With the increasing diffusion of → election polls and forecasts since the 1940s, horse race journalism has been on the upswing (→ Public Opinion Polling).

However, it has been around much longer than modern opinion polling. As early as 1888, the *Boston Journal* used the horse race image in its election coverage (Littlewood 1999). It has been criticized ever since, and with the emergence of modern polling techniques, the criticism has also been directed against election polls and the way journalists use them (→ Polls and the Media; Political Journalists). The following statement is typical of the prevailing criticism: “Instead of covering the candidates’ qualifications, philosophies, or issue positions, polls have encouraged journalists to treat campaigns as horse races, with a focus on the candidates’ popularity, momentum, and size of lead” (Atkin & Gaudino 1984, 124).

According to its critics, horse race journalism *trivializes politics* by reducing it to a sports event with gladiators and spectators. Thrilling entertainment therefore takes priority over factual information in campaign coverage (→ Politainment). Horse race journalism thus contributes to depoliticization and trivial spectacle. Polling results are hardly used to analyze the voters’ motives, but rather provide the material for a credible description of the horse race in the campaign. Today, the horse race coverage outshines every other campaign topic of substance – more time and space is attributed to horse race coverage of the US presidential campaigns than to all other issues combined (Farnsworth & Lichter

2003; Patterson 2005). In all other western democracies, the horse race coverage is not yet quite as dominant, though it is on the rise there, too.

Moreover, horse race coverage leads to a *focus on the frontrunners* in the campaign (→ Personalization of Campaigning). Aside from reporting on candidates' positions in the opinion polls, the media also cover their character and the composition of their image (→ Candidate Image). "While the character of the candidates is obviously of crucial importance for a meaningful democratic choice, the horse-race metaphor runs the risk of emphasizing beauty – some horses are gorgeous animals – and neglecting differences on issues of substance" (Broh 1980, 520).

Representatives of horse race journalism defend this kind of coverage, claiming that many people are not particularly interested in politics. Describing "distant" and "alien" politics with familiar sports language could raise interest in political events. According to the proponents of this kind of journalism, most voters are primarily interested in who is leading and who is behind in the campaign. This, they say, does not necessarily exclude coverage on political issues. Horse race coverage could even serve as a door opener for issue-related coverage. In addition, it has another advantage: journalists have a natural interest in portraying a race as "open" for as long as possible, since the interest in its result would otherwise slacken. This reduces the danger imminent in the mass media, that a premature declaration of the winner turns the campaign into a self-fulfilling prophecy (→ Bandwagon Effect; Underdog Effect).

Horse race coverage employs a number of *stylistic devices*. Aside from the sports analogy, comparisons are used to portray the campaign as a dynamic event. More often than not, polling results from different points in time are compared with each other, portraying the candidates' ups and downs in the campaign. Even minor changes in the polls are dramatized with the help of the horse race frame (→ Framing of the News); erroneous interpretations of polling data by journalists are not a rarity (Patterson 2005).

Polls are also used to describe the influence of individual campaign events on the race – for example the impact of → televised debates. Journalists use such media events in order to illustrate trends and changes in the voters' support (→ Media Events and Pseudo-Events). Changes in → public opinion are portrayed in conjunction with events. Incidents during the campaign therefore take on great significance for the candidate's position in the race: each and every mistake, appearance, and blunder can influence the candidates' image, boost them, or make them trip. Comparisons are also made between individual states or regions, so that the entire race is composed of numerous individual sprints.

## Hostile Media Phenomenon

*Albert C. Gunther*

*University of Wisconsin-Madison*

The hostile media effect refers to a perceptual bias in which partisans – people highly involved with an issue or interest group – tend to see media coverage of that issue or group as unfairly slanted against their own position (→ Involvement with Media Content; Bias in the News; Balance). Thus, for example, groups on opposite sides of a controversial issue, such as supporters and opponents of abortion, will each judge news stories on the abortion issue to be biased in favor of the rival point of view.

Any individual's judgment of unfairly biased media coverage might be called a hostile media perception. That this phenomenon is a perceptual bias is evidenced when two groups see the same content in opposite ways, or when a partisan sees media bias where a disinterested observer sees fair and balanced reporting. Virtually all professional journalists can recount anecdotal evidence of the hostile media effect (also known as the hostile media perception), pointing to audience accusations that news coverage is unfair. Though such audience complaints may be valid, attacks coming from both sides – such as liberals' complaints of right-wing bias side by side with conservatives' accusations of a leftist slant – are cited as evidence that the news coverage must actually be on neutral ground.

### ROLE OF THE CONCEPT IN COMMUNICATION RESEARCH

A central aspect of the hostile media perception is that it dramatically illustrates the subjective interpretation of content: different people perceive the same content in different ways (→ Selective Perception and Selective Retention; Information Processing). In this respect it fits squarely into the “active audience” paradigm, in which individuals on the receiving end of the communication process play a significant role in the construction of the message. The importance of this audience involvement also argues against simplistic early ideas about the undifferentiated mass audience, such as so-called “magic

bullet” or “hypodermic needle” models (→ Media Effects, History of; Models of Communication; Stimulus–Response Model).

The hostile media phenomenon adds a new piece to an interesting puzzle in social psychology: the apparently contradictory tendencies toward assimilation and contrast effects. In the contrast bias, individuals interpret information as increasingly divergent from their own positions; its counterpart is the assimilation bias, in which individuals see information as conforming more closely to their own point of view.

In communication research the *contrast bias* has generally been tested experimentally by using opposing groups of partisans and “neutral” stimulus material. Evidence for a hostile media perception, and the underlying perceptual bias, is claimed when both sides see bias in an “unfavorable” direction. Some research, however, has demonstrated a relative hostile media perception, in which there is a significant difference between group perceptions even though one group may not judge the content to have an unfavorable bias in absolute terms. This means that one group is not necessarily exhibiting the contrast bias per se, and the divergent judgments between groups become the focus of theoretical interest.

Some research findings suggest that identical information can stimulate either assimilation or contrast effects depending on the message context, and that the hostile media effect may be unique to mass media content. Experiments have shown that information presented to partisans in a mass media context, such as a newspaper article, elicits the hostile media perception (→ Experimental Design). But the same information presented in a format not intended for a mass audience, such as a college student essay, can eliminate or even reverse audience judgments of unfavorable bias, tending toward the assimilation effect (Gunther & Schmitt 2004). These findings suggest that, at least for a partisan audience, mass media may stimulate distinctive, perhaps defensive, processing mechanisms.

## THE PARTISAN AUDIENCE

In general, perception of disagreeably biased media content appears to be contingent on the individual’s involvement in the issue in question. Partisans, people who feel strongly about particular issues such as abortion or Middle East conflict or genetically modified foods, can be expected to see an unfavorable slant in media coverage of those issues, even though they consider media coverage more generally to be fair and balanced. People who feel neutral about, or do not attach great importance to, particular issues tend to find media coverage of those issues quite acceptable. Individuals who lean only slightly toward one side of an issue may find coverage more often in agreement with their own opinions.

Most research on this topic, particularly experimental research, has studied partisans by selecting them from groups that have a stake in the issues in question. Highly involved individuals can also be identified via sets of filter questions asking about the direction and strength of their opinions and then including for analysis only those with more extreme positions. It is generally accepted that partisans cannot be temporarily manufactured in a lab, since the intensity or depth of involvement needed to elicit the hostile media effect cannot be achieved via experimental manipulations (→ Experiment, Laboratory). Some research has included “neutral” participants, those without strong pre-existing opinions

on an issue, as control group members. Because identifying and recruiting partisans is often difficult and time-consuming, it is more labor intensive than most experimental research.

An additional difficulty is that, because partisans are recruited on the basis of their pre-existing opinions on an issue, it is impossible to exercise the principle of random assignment of individuals to groups, a characteristic of experimental research that is important for internal validity (→ Sampling, Random). As a result, there may be differences other than partisanship among partisan groups in an experimental design. These differences present potential rival explanations for differences in dependent measures. One remedy for this problem is to measure and test for other differences between groups – income, education, political, or religious positions would be some examples – and include them as co-variates in analysis.

An important question, however, is *what defines a partisan*. Or, more precisely, what defines the kind of partisanship that produces the contrast bias of interest here. Hostile media effect research to date has been more opportunistic than conceptually methodical in defining partisanship. It is not clear what level of involvement engages the contrast bias mechanism, nor what dimensions of involvement may be necessary or sufficient conditions. Such involvement may be related, for example, to extremity of attitude, to personal relevance, to perceived importance, to emotional engagement, or to other factors seemingly underlying the concept of partisanship.

## THEORY

Beginning with the earliest empirical study (Vallone et al. 1985), several explanations have been proposed for how and why the hostile media perception occurs (Fig. 1). The first group of explanations concerns how audience members process mass media content in a way that leads them to see disagreeable bias.

In one scenario an individual who favors gun control, for example, may be *more attentive* to, or simply notice more of, the content that supports opponents of gun control. Such disagreeable content may seem to receive more emphasis, as if appearing in boldface, or to take disproportionately more space. This mechanism has been called *selective recall*, though it might be better labeled as a type of selective perception. It implies that different individuals actually see a different reality in the same content.

A second mechanism, termed *selective categorization*, proposes that partisans may see the same content in the same way but categorize or evaluate it differently. For example, a phrase or sentence evaluated as neutral or unfavorable by a gun-control supporter may be judged favorable by a gun-control opponent.

The third mechanism, often called *different standards*, shares aspects of the latitudes-of-acceptance-and-rejection model associated with → social judgment theory. This mechanism proposes that, while partisans may see the same content and evaluate it the same way, they disagree about what constitutes acceptable, valid, or relevant material. In the range of facts, ideas, and arguments over gun control, for example, an opponent may argue that some content on the supportive end of the spectrum is false or irrelevant and that including such content in a news report unfairly favors the other side.

a. Information distribution in what a neutral observer would see as a balanced news story, with equal proportions of anti (A), neutral (N), and pro (P) content.

b. Selective recall; pro partisans remember disproportionately more unfavorable content.

c. Selective categorization; pro partisans evaluate relatively more content as unfavorable.

d. Different standards; pro partisans consider unfavorable content to be invalid or irrelevant.

**Figure 1 a–d** Illustration of the distinctions among three potential mechanisms for the hostile media effect; shown from the perspective of “pro” partisans

*Source:* Schmitt et al. (2004)

Since the mid-1980s, the definitions and measures of these mechanisms have been progressively refined, but evidence for them has been mixed. Selective recall has received little or no support, although recall-based measures may not be the best test for this perception-based hypothesis. Selective categorization, by contrast, has been supported in several studies (see Schmitt et al. 2004) as a mediating factor in the hostile media perception. In evaluating excerpts, one- or two-sentence morsels from the body of a news report, partisans on both sides of an issue perceived more excerpts as unfavorable toward their own attitudes and beliefs. The different-standards mechanism has also been dramatically evident in this body of research, but not as an explanation for the contrast effect. In two studies where the media (news article) vs non-media (student essay) sources respectively produced and erased the hostile media effect, evidence of a different-standards mechanism was equally robust in both conditions. This result suggests that people are indeed applying different standards in deciding what is acceptable content, but that it is not distinctive to the hostile media perception.

A second category of explanations concerns why partisans might process information differently when it appears in a mass media channel. One answer proposes that individuals bring a pre-existing belief in biased media coverage to their reading or viewing of issues in which they are highly involved (Giner-Sorolla & Chaiken 1994). Another view is that

the mass media context cues partisans to think about the potential impact of content on a vulnerable mass audience – an audience that may not be sufficiently well-informed and may thus be easily misled (Perloff 1989; Gunther & Schmitt 2004; → Third-Person Effects). Either or both of these conditions may put partisans in a defensive processing mode that causes them to perceive more disagreeable content.

## CONSEQUENCES

The hostile media perception is thought to have any number of consequences, most of them undesirable. For example, partisans who think media content is unfavorable may also think public opinion generally – presumably influenced by this “hostile” media coverage – will be less sympathetic to their own positions. It may also lead to increased polarization of extreme groups, and to an increased sense of alienation from other people and democratic processes.

Some studies suggest that the perception of hostile media coverage may cause partisans to lose confidence in conventional political avenues and resort to violence or other extreme actions (Tsfati & Cohen 2005). It is often argued that the information and ideas conveyed by mass media make an essential contribution to the quality of public discourse thought to be so essential to democratic processes. The hostile media perception presents a potentially important impediment to that contribution.

## Hovland, Carl I.

*Michael Schenk*

*University of Hohenheim*

One of the founding figures of communication science, Yale psychologist Carl Iver Hovland (1912–1961) was born in Chicago to Scandinavian parents. His mother, Augusta Anderson Hovland, had emigrated from Sweden, while his father, Ole C. Hovland, a child of immigrants from Norway who had settled in Minnesota, had left the family farm to become an electrical engineer and inventor in Chicago. Both parents were said to be deeply religious.

Hovland had a solid background in mathematics, physics, and biology, as well as in experimental psychology, receiving his BA (1932) and MA (1933) at Northwestern University (Shepard 1998). In 1934, he arrived at Yale University to become a member of faculty. He was recognized as an outstanding student, shy and self-contained, but gentle and musical (a piano player). He was found to be a very efficient administrator of research who never seemed to be bothered by details which he dealt with very quickly. He received his PhD with honors in 1936, under the prominent Yale learning theorist Clark C. Hull. Hovland rose quickly through the ranks of assistant professor (1937), director of graduate studies (1941), associate professor (1943, in absentia), to become full professor and chairman of the psychological department in 1945, at the age of 33, and Sterling professor in 1947.

During World War II, from 1942 to 1945, Hovland headed the Experimental Section of Samuel Stouffer's Research Branch under Major General Frederick Osborn's Information and Education Division of the War Department. The mission of the Experimental Section was to evaluate the training programs and films prepared for American troops in the United States and Europe. Hovland was responsible for guiding the work of more than 15 researchers, who did experimental work on problems of communication and social psychology (→ Experimental Design; Psychology in Communication Processes). The principal long-term researchers were Frances Anderson, John Finan, Irving Janis, Arthur Lumsdaine, Nathan Maccoby, Fred Sheffield, and M. Brewster Smith. The output of their research includes the highly influential book *Experiments on mass communication* (Hovland et al. 1949).

After his work for the War Department, Hovland returned to Yale to establish the *Yale Communication and Attitude Change Program*, on which he continued to work until his early death in 1961. Supported by the Rockefeller Foundation for over 15 years, the program, under Hovland, brought together over 30 co-workers and students who went on to become well-known professors of communication science or social psychology. Among the researchers were prominent names such as Robert Abelson, Norman Anderson, Jack Brehm, Jonathan Freedman, Irving Janis, Harold Kelley, Herbert Kelman, Abraham Luchins, Arthur Lumsdaine, William McGuire, Milton Rosenberg, David Sears, Fred Sheffield, Muzafer Sherif, and Philip Zimbardo.

The research program focused on how verbally presented messages change a recipient's attitudes, opinions, and beliefs as a function of experimentally manipulated variables, such as the credibility of the source, the order of presentation of arguments, the

recipient's prior position on the issue, the recipient's self-esteem, the recipient's emotions (especially fear), the time between presentation of a communication, and the assessment of attitude change (→ Credibility Effects; Order of Presentation; Sleeper Effect). The success of the Yale research program stems from Hovland's conceptual ability to deconstruct the complex relations between persuasive communication and attitude change and to reveal them using controlled laboratory experiment (→ Experiment, Laboratory). To this day the program remains a constituent part of → persuasion research even though further developments such as the elaboration likelihood model have advanced the field. By "establishing a structural-sequential mode of the input-mediating-output variables and processes involved, Hovland anticipated the later information processing approach that proved so valuable in cognitive psychology" (Zimbardo, quoted in Shepard 1998, 246). In the aftermath of Hovland's death, this body of work was acknowledged to be the largest single contribution to the field of communication ever made (Schramm 1963), the "biggest single force within psychology's communication-relevant attitude-change movement" (McGuire 1996, 43).

During his short life, Hovland published over 70 articles and was the editor or co-author of seven books. His activity was not restricted to within the university but also included consultancy work. He also played a crucial role in the formation of the *Bell Telephone Laboratories Behavioral Research Center* where he benefited from his early studies in the field of industrial psychology. He was one of the first leading figures to apply basic psychological research in an industrial setting.

# Human–Computer Interaction

*Bonnie A. Nardi*

*University of California, Irvine*

*Jannis Kallinikos*

*London School of Economics and Political Science*

Every computational device must allow for some form of interaction with its user. Human–computer interaction is the discipline that studies how people interact with computational devices and the implications that the design of the human–machine interface has for this interaction. The discipline also investigates wider communal and social implications associated with user interface design and the use of digital systems and artifacts.

## TECHNOLOGICAL STEPS

The earliest user interface to a practical computer was the punched card system devised by Joseph Marie Jacquard in 1804. This system (remarkably like the punched cards used for data entry well into the 1970s) enabled weavers to instruct a loom in the design of a textile. The first modern computers emerged in the mid-1940s. Shortly thereafter, human–computer interaction leapt forward when Grace Hopper, an employee at Remington Rand Corporation, invented the compiler around 1950. The compiler allowed programmers to write in languages closer to English instead of in machine code (directly comprehensible in the computer’s binary system of understanding). A series of new programming languages followed. Many languages still in use today, such as Fortran and C, date from the 1960s and early 1970s (→ Information and Communication Technology, Development of).

A number of breakthroughs in the 1970s began to open computing to non-programmers. Arguably the most revolutionary development was the invention in 1979 of *VisiCalc*, a *spreadsheet program* that moved accounting from paper ledgers to the computer. This program was embraced by ordinary people, who found countless uses for it from running small businesses, to planning the family vacation budget, to forecasting expenses in corporations. *VisiCalc*’s power was its user interface, which enabled people to view the rows and columns of numbers just as they would on paper. Even today spreadsheets are used by engineers, scientists, and businesses as a primary tool of calculation.

The other major development was a radical *redesign of the computer* to fit on a desktop. The Alto computer, invented at the Xerox Palo Alto Research Center in California, not only fit on a desk, it incorporated ideas such as the mouse (developed by Douglas Engelbart at SRI in Menlo Park, California, in 1964), WYSIWYG editors, and bit-mapped graphical displays to provide a graphical view of the user’s data and applications (→ Domestication of Technology).

## CONTRIBUTIONS OF THE HUMAN–COMPUTER INTERACTION COMMUNITY

### Emergence of the Community

In 1982, the Association for Computing Machinery’s SIGCHI Conference on Human Factors in Computing Systems was held in Gaithersburg, Maryland. This conference marked the

formal beginning of human–computer interaction as a distinctive intellectual community. Although the Conference referenced “human factors,” the concerns and methods of the human–computer interaction (HCI) community are only loosely connected to traditional human factors research, which is rooted in ergonomics and goes beyond computers.

The HCI community is a coalition of computer scientists, psychologists, sociologists, anthropologists, and artists, who share an interest in the design of technology as well as in analysis of its effects on people. Computer science and psychology are most heavily represented, but the community is open and interdisciplinary. It welcomes research from academia and industry as well as practitioners who confront issues of human–computer interaction in practical ways. The community is international, with many active members in North America and Europe, as well as in Japan, Latin America, and elsewhere. The HCI community, as it has developed since Gaithersburg, is best exemplified by scholars and practitioners who gather at conferences such as ACM SIGCHI (known as CHI), NordiCHI, Interact, and HCI International.

The proceedings of these conferences are a rich source of information on human–computer interaction. The CHI conference, for example, functions much as a selective journal (with a low acceptance rate) and showcases some of the most interesting work in human–computer interaction. The contributions of the human–computer interaction community can be roughly categorized in three areas: the design of new digital technologies, the evaluation of the usability of technologies, and cognitive and social analyses of the use of technology.

### **The Design of Technologies**

In 1998, Brad Myers at Carnegie Mellon University published a thoughtful review, “A brief history of human–computer interaction technology,” which addressed new technologies that have come from the HCI community (Myers 1998). Myers described the *provenance of familiar interaction technologies* such as overlapping windows, icons, drawing programs, text editors, hypertext, and speech recognition. He noted that tools for building user interfaces, such as user interface management systems and widget toolkits, are part of the legacy of the HCI community. Component architectures for user interfaces, predecessor to Web 2.0 techniques such as “mashups” (which combine data or procedures from more than one application) were pioneered at Carnegie Mellon in 1983 in the Andrew system. Myers observed that most important innovations were funded by government, primarily the US government, although industry also played a role. Practically all the inventions Myers analyzed were developed at universities, industrial research laboratories, or think tanks such as SRI or the Rand Corporation.

Since Myers’s review, one of the biggest successes from the HCI community has been *recommender systems* such as those used by Amazon.com to help prospective buyers evaluate potential purchases. Buyers are informed about what those with similar preferences purchase based on data which are clustered according to user characteristics. The earliest version of a recommender system was part of a project at Xerox PARC in the 1980s.

### **Usability**

The second major contribution of the HCI community is an activist one. Human–computer interaction researchers have insisted that computer users have the right to

well-designed applications that are easy to use. Don Norman has been especially vocal in defending the needs of users. The delightful cover of Norman's book, *The design of everyday things* (1990), depicts a teapot with the spout and handle vertically aligned. This image has become an icon for the need for sensible design.

Usability is held as one of the most important values of the HCI community. Several techniques for evaluating usability have been invented and are widely deployed in academic research and in industry. Formal, controlled laboratory studies are conducted in academic settings and at usability labs in companies such as Microsoft and Oracle. Other methods such as heuristic evaluation and cognitive walkthroughs provide less precise but more cost-effective results and have been shown to improve usability (Dix et al. 1993). Usability is not merely a good idea but a thriving practice that improves the products we all use. Of course, there is room for much improvement, and Norman described some of the organizational barriers in industry to usable design (Norman 1998; → Technology Assessment).

### **Analyses for Human–Computer Interaction**

The third contribution of the human–computer interaction community has been *cognitive and social analyses of human–computer interaction*. The most robust, integrated body of work is in computer-mediated communication, which examines how people communicate in digital media including email, video, instant messaging, blogs, wikis, websites, listservs, and social networking websites such as Facebook and MySpace (→ Network Organizations through Communication Technology).

For example, it has been found across several studies conducted in different countries that in non-work contexts, users of cell phones, instant messaging, and social networking websites communicate primarily with small groups of well-known friends and family. These technologies do not expand social life but deepen it with those already known. Studies have demonstrated that, rather than isolating people, participation in online communities provides important social functions such as support for people (and their families) with unusual medical conditions, or casual socializing in online gaming communities (a substitute for the corner bar, which no longer exists in many North American cities and suburbs). A large body of cognitive research investigates the ways people interact with specific aspects of the user interface such as menus and scroll bars or how speech interfaces influence the user experience (→ Virtual Communities).

### **THEORIES OF THE FIELD**

The most theoretical work in human–computer interaction examines issues of cognition and sociality. The cognitive analyses of Card et al. (1983) laid the foundation for usability evaluation. More recently, as the purview of human–computer interaction is taken to be the wider social context in which people interact with digital technologies, new theories have entered the community, in particular, distributed cognition, activity theory, and actor–network theory (→ Online Media). Distributed cognition and actor–network theory posit flat networks in which both people and technologies are “nodes” or “actants.”

These theories are concerned with informational flows and the propagation of changing state across networks. Activity theory comes from a psychological tradition based on Vygotsky's (1986) work and views relations between people and technology more asymmetrically, with technology mediating reality for people. Human abilities differ from those of things; thus activity theory is more open to discussions of creativity, imagination, and invention, which are distinctively human (Stahl 2006). Actor–network theory and distributed cognition, on the other hand, have drawn attention to the agency of things. Kaptelinin and Nardi discuss these theories in the context of interaction design (2006), proposing an extension to activity theory based on notions of agency derived from actor–network theory.

Human–computer interaction is a young field that can claim considerable success. It has advanced our understanding of relations between people and digital technologies and provided many of the technologies that we encounter on a daily basis. A void in this tradition is critical analysis of digital technology. The HCI community has taken a positive attitude toward technology for a variety of reasons. The connection to industry is an obvious reason and the love of technology is another. This bias has meant that scholars who are perhaps in the best position to provide critical analysis because they have both deep technical understanding and an orientation to human use of technology, have not examined the costs as well as the benefits of technology. The attitude is that one designs technology and the “marketplace” will correctly choose those technologies that meet social needs (→ Information Society).

### CRITICAL ANALYSES

Critical analyses are therefore a needed counterpoint to the unexamined enthusiasm for ideas such as → ubiquitous computing, embraced by the human–computer interaction community. Certainly, we must ask if every human experience should be mediated by digital technology. Another pertinent issue concerns the hidden trade-offs between usability (ease of use) and human choice. There is little doubt that smooth user interfaces facilitate the use of computers and are inviting, in the sense of inciting people to explore the possibilities computational devices offer. However, technologies influence human behavior not only by means of what can be done with them but through what cannot be accomplished by the functionalities they offer (Kallinikos 2002, 2004). Simplifying the user interface often implies that some options are eliminated. Human–computer interaction techniques may unwittingly contribute to a narrowing of the space of possible options. The history of skills in the course of industrial capitalism suggests that removing complexity from the interface and stacking it “underneath” is a double-edged gesture (Mumford 1952). Very little is currently known about these trade-offs (→ Technology, Social Construction of).

Apart from the social ramifications, there are externalities such as the *toxic waste produced by digital devices*, which has been shown to pollute groundwater as billions of devices are eventually dumped in landfills. Promising work that addresses environmental concerns proposes creating a practice of “sustainable interaction design” (Blevins 2007). In the future, considerations of social responsibility in human–computer interaction should extend from current concerns with providing technology appropriate for people with

disabilities and on low incomes to more problematic issues of restraining and reshaping technology.

## **Hybridity Theories**

*Marwan M. Kraidy*

*University of Pennsylvania*

Theories of hybridity entered international communication research at a time when the cultural imperialism thesis was ceding ground to the media globalization paradigm (→ Cultural Imperialism Theories; Globalization Theories). This has been controversial because “the idea of cultural hybridization is one of those deceptively simple-seeming notions which turns out . . . to have lots of tricky connotations and theoretical implications” (Tomlinson 1999, 141). Although usage of the term hybridity acquired critical momentum in Anglophone postcolonial studies – mostly focused on the British

colonization of India and its politico-economic-cultural aftermath, especially in the work of literary critic Homi Bhabha (1994) – the notion itself has many historical and scholarly antecedents (→ Postcolonial Theory).

### DEVELOPMENT OF THE CONCEPT OF HYBRIDITY

Historically, terms such as syncretism, creolization, *mestizaje* (Spanish), and *métissage* (French) have been used to describe various linguistic, racial, ethnic, and cultural mixtures in contexts as varied as ancient Egypt, post-independence Caribbean nation-states, and contemporary Latin America. Also, many scholars have used hybridity or variations on the term to explain artistic, cultural, and historical exchanges and mixtures in different parts of the world. These include the Argentinean-Mexican cultural theorist Néstor García Canclini (1995), the Spanish-Colombian media scholar Jesús Martín-Barbero (1993), the French historian Serge Gruzinski (2002), the French Guyanese literary critic Roger Toumson (1998), and the Saudi sociologist and novelist Turki al-Hamad (2001).

Although there is widespread recognition that cross-cultural fusions are historically and geographically pervasive, there is controversy about the meaning and implications of hybridity, which focuses for the most part on the nature of the connection between hybridity and power. In this regard, postcolonial theorists have sparred intensely about the advantages and pitfalls of using hybridity. Does the existence of cultural hybridity imply the subversion of political and cultural power? Does it merely celebrate the very specific experiences of migrant intellectuals? Or, more gravely, is the discourse of hybridity complicit with structures of inequality, as in the past it was a racist discourse used to justify colonial repression (Young 1995; Kraidy 2005)?

The field of communication imports its theories, methodologies, and some of its major debates and questions from the social and human sciences. It is not surprising, then, that the debate over hybridity in postcolonial studies translated into a parallel polemic in → international communication scholarship, where there have been major differences between, on the one hand, “dominance” perspectives and, on the other, “resistance” or “pluralism” approaches. After several decades where primary concerns were about → propaganda and then about → modernization and development, theories of cultural domination developed as a reaction to the western-centric assumptions of the modernization paradigm (→ Development Communication). “Cultural imperialism” and “media imperialism” approaches dominated discussions in the 1960s and the 1970s, but since the 1980s opponents have argued that dominance approaches rooted in the radical political economy tradition have lost their explanatory power due to the growing complexity of global communication and intercultural relations.

The result was an emergence of a variety of disconnected and sometimes contradictory lines of theory and research, most of them connected to the so-called “cultural turn,” a move away from political economy and social psychology and toward British → cultural studies, French poststructuralism, and American → film theory and criticism. The ensuing engagement with culture as a broad and important issue prepared the ground for the appearance of theories of hybridity at various levels in international communication research (→ Culture: Definitions and Concepts). From the perspective

of the traditional division of communication processes in terms of production, message, and reception, most hybridity research has emphasized media texts and reception, though a few studies have analyzed the links between production, message, and reception.

### THE CONCEPT OF HYBRIDITY IN RESEARCH

The British scholar Jeremy Tunstall (1977) may have been the first international communication scholar to use the adjective “hybrid” when he predicted three decades ago that regional media centers would produce “hybrid genres,” i.e., indigenized versions of programs developed in the west. Indeed, regional media production centers such as Brazil, Mexico, and Hong Kong have vindicated Tunstall’s prognosis and inspired research that engages with the notion of hybridity. One scholar identified four patterns of mixture in Hong Kong’s cultural industries: the *parrot* pattern described wholesale mimicry of foreign culture by local industries; the *amoeba* pattern referred to a modified cultural form with a non-changing content, such as the adaptation of a foreign movie for local consumption; the *coral* pattern reflected cultural products whose content is changed but whose form remains the same; and the *butterfly* pattern was a wholesale hybridization blending the local and the global (Lee 1991).

Some political economists of communication have toyed with the notion of hybridity, albeit indirectly, arguing that continental integration through free trade deals “does not portend a unitary North American monoculture” (Mosco & Schiller 2001, 4; → Political Economy of the Media). Indeed, hybrid cultural forms are compatible with the aims of globalization (Kraidy 2005), since market forces have shaped “an increasing hybridity of global culture, ever more complex and more commodified . . . everywhere more complex and more commodified in the same sort of way” (Boyd-Barrett 1998, quoted in Kraidy 2005).

One area of media research where hybridity has been a central notion is studies of migrant or diasporic media in western countries such as Australia, the United Kingdom, and the United States (→ Migrant Community Media). These include amateur, homemade media and the productions of professional media institutions. Migrants have used personal media such as video cameras and editing consoles, sound mixers, and increasingly blogs and the → Internet to represent the experience of migrant life (→ Blogger). For example, Croatian and Macedonian immigrants in Perth, Australia, produced videos of weddings and birthdays, video “family albums,” or raw scenes from the Yugoslav war to create “an iconic continuum” (Kolar-Panov 1997, quoted in Kraidy 2005) between host country and homeland. Similarly, media produced in “Tehrangeles,” the Iranian community in Los Angeles (Naficy 1993, quoted in Kraidy 2005), or media consumed by Punjabis in London expressed the tensions between two or more worldviews that shaped the hybrid culture of migrant life, drawing its affective energy from the native country while being concretely grounded in the host country.

The most nuanced treatment of hybridity in the context of communication processes is probably the Spanish-Colombian scholar Martín-Barbero’s expansion of the notion of *mestizaje* to include relations between ethnic groups, cultural expressions, social classes, and political constituencies, whose overlaps are best understood in the study of → popular

culture. According to Martín-Barbero, communication plays an important role in the formation of *mestizajes* because it is instrumental in the creation of meaning and not because of mere information transmission. As against media-centric theories of communication, Martín-Barbero (1993, 2) advocates an interdisciplinary approach more attuned to “the cultural realities of [Latin American] countries, the new combinations and syntheses – the *mestizajes* – that reveal not just the racial mixture that we come from but the interweaving of modernity and the residues of various cultural periods, the mixture of social structures and sentiments.” Hybridity in this case is a helpful entry point to understand media and popular culture as a struggle to define the social world, often drawing on myths from the past and aspirations for the future.

Hybridity has been useful for scholars in the field internationally. It remains a controversial notion, even though suspicions persist about its methodological practicality, theoretical usefulness, and ideological implications. In the end, it is still too early to determine whether theories of hybridity constitute a temporary fad or whether they will remain part of the debate over power and culture in international communication scholarship.

# Hypothesis

*Benjamin Fretwurst*

*Free University of Berlin*

Hypotheses are assumptions about empirical (observable) phenomena. They are formulated as empirical (experience-related) statements; thus they can be either true or false – i.e., they are testable. This implies that hypotheses are tentative: their validity (truth or falseness) is subject to empirical test.

In this general form, the definition also corresponds to the conventional, everyday meaning of “hypothesis.” In the social sciences – thus including social science-oriented communication sciences – the concept is more narrowly circumscribed: scientific hypotheses are empirically testable *universal* (nomological) propositions about *causal relationships*. They are stated in terms of either “if–then” or “the more–the more (or less)” propositions.

Example: “People learn from news media which are the most important problems facing their country” (→ Agenda-Setting Effects).

- This statement is an assumption which can be empirically tested.
- The statement can be translated into an “if–then” proposition: “If an issue is prominently discussed in the news media, then people will regard it as an important problem.” In this case, it can also be translated into a “the more–the more” proposition: “The more an issue is discussed in the news media, the more people will regard it as an important problem.”
- The statement applies not merely to a single media user, but to all media users; it is not limited in terms of time and place and is thus universal, and not singular.

Counterexamples:

- “Media use can lead to violent behavior.” Because of the “can,” this statement cannot be false and is thus not empirically testable (“If media are used, this may, or may not, lead to violent behavior”).
- “John likes to watch television.” This statement is testable, but it is singular and not universal.
- “Diversity of opinion is to be guaranteed.” This is a normative statement, not a proposition.
- “Everyone has the opportunity to get information from the mass media.” This statement does not refer to a causal relationship (if–then proposition) but describes an existing state.
- “The world wide web is a mass medium.” This statement is a definition and thus a denotation; unlike a hypothesis, it cannot be falsified (Definition). A corresponding hypothesis might read: “The world wide web is generally perceived as a mass medium.”
- “If television had not been invented, people would be more peaceful.” The if-component of this proposition is counterfactual and cannot be reproduced artificially. Therefore, the proposition cannot be tested empirically (many everyday claims about media effects have that quality).

## THE RELATIONSHIP OF HYPOTHESES AND THEORIES

In the realm of epistemology, the concept of “hypothesis” has a different meaning than in the context of social science methodology. In epistemological discourse, any testable proposition, according to the “general form” above, is called a hypothesis. That makes “hypothesis” a logically superordinate concept relative to “theory,” and indeed it is often used as a synonym, as, for instance, in Popper’s *The logic of scientific discovery*.

In social science discourse, the term “hypothesis” is reserved for specific statements rendered *directly* testable by virtue of measurements. A “theory” in this context is a system of (few) basic propositions and a large number of logical derivations. The basic propositions of a theory as well as the derivations must correspond to the fundamental form of social science hypotheses: they are universal propositions about causal relationships. This is a prerequisite for “backward” inference, from the results of empirical testing, via the derivations, to the fundamental propositions – i.e., the core – of the theory. A theory will, in principle, allow an unlimited number of specific hypotheses to be derived (deduced). Obviously, they cannot all be specified in advance. Therefore, specific hypotheses are spelled out only in the context of empirical studies.

The decision about the empirical validity of a derived hypothesis is tantamount to a decision about the validity (truth or falsehood) of the underlying theory in its current form; it is thereby *confirmed*, *modified*, or *rejected*. If a hypothesis derived from the basic propositions of the theory is confirmed, the theory is said to be *corroborated*. If the results of an empirical study contradict the hypotheses derived from the theory, it ought to be *rejected*. In practice, however, theories tend to be more robust than their derived hypotheses. Thus, if empirical results contradict the derived hypotheses, it is common practice to examine or discuss first the possibility of flawed derivations or faulty measurements, i.e., to examine whether logical or technical deficiencies might have occurred in conducting the test. If such deficiencies can be largely excluded, it still remains possible to *modify* the theory by adding limiting conditions which could explain the deviant observations. These added conditions, however, necessarily reduce the explanatory power of a theory since they restrict its range of applicability. If a theory cannot be “saved” by adding more and more limiting conditions, it will ultimately have to be rejected.

The decision about the validity of a theory is based on hypotheses derived from the theory. This principle is referred to as the hypothetico-deductive method.

## HYPOTHESIS TESTING

According to Popper’s *Logic of scientific discovery* (2006), the validity of universal propositions (general statements, including hypotheses) can never be proved (verified). To do this would require an examination of all conceivable objects to which the universal statement refers. This is logically impossible, if only because theories also refer to future observations.

While it is true that hypotheses are not verifiable, they are regarded as refuted (falsified) if specific observations contradict a hypothesis. Hypotheses always rule out some possible observations. The content, or power, of a hypothesis is based on the extent to which

conceivable observations are ruled out. A hypothesis is considered falsifiable if a *basic statement* can be formed which asserts the negation of the hypothesis. That is to say that a basic statement postulates the existence of at least one observable instance, anywhere or at any time (universally), that contradicts the hypothesis. Hypotheses, as universal propositions, refer to infinitely many phenomena and situations which can, in principle, never be tested in their entirety; but when a universal proposition – that is, a universal postulate of existence – can be verified, the hypothesis is falsified: “Whenever it is found that something exists here or there, a strictly existential statement may thereby be verified, or a universal one falsified” (Popper 2006, 49). Popper’s most famous example is this: the universal statement “All swans are white” is falsified if the universal existential statement “There exist (somewhere and sometime) non-white swans” can be empirically verified. Scientific research consists of the earnest search for observations which would falsify the hypotheses.

In this manner, the problem of falsification of a general hypothesis has been converted into the problem of verification of a falsifying existential statement. The question now becomes whether the hypothesis should be considered refuted by a single contradictory observation, or whether instead the validity of that observation should be cast in doubt. Since any observation is fallible, we should be trying to *replicate* it. A theory is considered to be falsified only “if a low-level empirical hypothesis which describes such an effect is proposed and corroborated (Popper 2006, 66).

Only universal existential statements can be replicated. Consequently, the confirmation of fundamental statements can be replicated, potential mistakes can be excluded with sufficient certainty, and theories thus falsified. Yet it will never be possible to confirm a sufficient number of existential statements (with errors safely excluded) to permit a universal statement, and thus a hypothesis, to be verified.

Observations, or empirical studies, can produce results of two kinds: the observations *correspond* or contradict the hypothesis. The principle of replication calls for repeated, independent observations in order to rule out errors with sufficient certainty. If the replications are in correspondence to the hypothesis, the *degree of corroboration* is rising. If the replications are in contradiction to the hypothesis, the *degree of falsification* is rising.

### Testing Social Science Hypotheses

The hypotheses derived from a theory are causal assumptions. Actually, causality is a rather demanding concept about temporally immediate cause-and-effect processes. If the assumed causal processes are in fact operating, they will induce corresponding relationships between variables in social science data (e.g., correlations or differences in means) that can be analyzed with the aid of statistical procedures.

In the physical sciences, hypotheses are statements that refer to individual instances. In the social sciences, by contrast, hypotheses are statements about quantities of cases. To illustrate, consider the agenda-setting hypothesis: “When an issue is prominently discussed in the media, there is a strong probability that it will be regarded as important by media users.” To falsify that hypothesis, it would not be sufficient to find *one person* who is using the media yet does not regard a media-emphasized issue as important. Statements about quantities of cases usually take the form of probability statements, and

they can be tested only in terms of empirical frequency distributions. Social science hypotheses are, therefore, tested on the basis of samples.

Potential samples, however, differ in terms of their composition. The set of all objects to which a hypothesis is to apply, called the population or sampling universe, determines the composition of the sample. The safest principle for generating a sample that represents the composition of the universe is a random sample. It implies that each element of the sampling universe has the same chance of becoming part of the sample ( $\rightarrow$  Sampling, Random). However, by using a random sample we no longer obtain exact measurements, but merely estimates of the assumed causal effects, with a specifiable degree of imprecision. Possible errors due to random deviations are represented and tested by means of statistical hypotheses.

### Statistical Hypotheses

By means of statistical hypotheses we can test whether observed relationships between two or more variables in the sample data might simply be the result of chance, i.e., of the random sampling procedures by which the sample was generated. This possibility, i.e., that *no* causal relationship exists in the population, is expressed statistically in terms of the so-called *null hypothesis*  $H_0$ . If the relationship in the data is very clear (*significant*), in a statistical sense,  $H_0$  is rejected, as that would represent a very unlikely case; instead, the (set of) statistical *alternative hypothesis*  $H_1$  – i.e., the substantive hypothesis that a causal relationship *does* exist – is maintained.

Regardless of whether or not  $H_0$  or  $H_1$  is accepted, an erroneous decision can never be ruled out with complete certainty. The two statistical hypotheses imply two possible types of error:

Type I error:  $H_0$  is true, but  $H_1$  is accepted erroneously;

Type II error:  $H_1$  is true, but  $H_0$  is accepted erroneously.

In the case of type II error, we draw no new inferences from the data. In the case of type I error, we are definitely drawing erroneous conclusions, as the apparent relationship observed in the data does not really exist in the population but is merely a result of chance fluctuations. The goal thus is to keep the *probability* of type I error (called  $\alpha$ ) as small as possible. When the probability of type I error remains below an acceptable level (in the social sciences commonly set at 5 percent), the statistical null hypothesis ( $H_0$ ) is considered to be falsified, and the statistical alternative hypothesis ( $H_1$ ) will be maintained. In that case, a statistically supported substantive causal relationship is assumed to exist.

### HYPOTHESIS GENERATION

Thus far, this entry has been concerned with the question of how hypotheses in the social or communication sciences can be evaluated by means of empirical data. In epistemological terms, this is sometimes called the logic of scientific discovery. The following is concerned with what is sometimes called the *psychology* of scientific discovery. In terms of process, a hypothesis has to be devised before it is tested. It is the testing, however, that is

decisive, because only the strict rules of hypothesis testing lead to scientific knowledge. By contrast, the *generation* of hypotheses is not subject to such rules. Science is productive as long as the generation of hypotheses is free. This is where Feyerabend's "Anything goes" (Feyerabend 1993) is appropriate. It is of no relevance whether the idea for a theory or hypothesis arises from a researcher's subjective impressions, or an inspirational dream, or inductively as a result of analyzing data.

Although there are no rules for the generation of hypotheses, some recommendations may be offered. A researcher need not wait for ingenious intuitions or inspiring dreams; it is certainly *permissible* to derive hypotheses from the analysis of empirical observations. Indeed, the results of empirical studies can and should be exploited for the generation of hypotheses. One of the most famous communications researchers, → Paul Lazarsfeld, in his landmark study of "people's choice," tested and refuted the thesis of direct persuasion, and then proceeded to develop his theory of the "two-step flow of communication" inductively, on the basis of his empirical results.

# Iconography

*Marion G. Müller*

*Jacobs University Bremen*

Iconography is both a method and an approach to studying the content and meanings of visuals (→ Visual Representation). In its colloquial use, the term “iconography” describes the motif of a particular picture or a specific group of artworks. A general distinction can be made between religious, mainly Christian iconography and secular or political iconography. In the context of visual research “iconography” is used to describe a qualitative method of visual content analysis (→ Content Analysis, Qualitative).

Originally devised in the context of sixteenth-century art collecting to categorize the particular visual motifs of paintings, iconography was first modernized by the art historian Aby M. Warburg (1866–1929) at the beginning of the twentieth century (Schmidt 1993; Diers 1995; Forster 1999; Rampley 2001). It was further refined by art historian Erwin Panofsky (1892–1968), who popularized this method of visual interpretation in the United States during the 1950s and 1960s.

Warburg used the term “iconography” in his early research, but in 1908 replaced this term with “iconology,” describing a particular method of visual interpretation (Schmidt 1993, 24). Panofsky, a colleague of Warburg, published a seminal article in 1932, introducing a three-step method of visual interpretation first labeled “iconography,” and later termed “iconology” (Panofsky 1955/1982). Panofsky himself did not give credit to his iconological predecessor (Schmidt 1993, 12), leading subsequent scholars to link the iconological method only with Panofsky’s name.

## **ICONOGRAPHY AS A METHOD**

Iconography can best be described as a qualitative method of visual content analysis and interpretation, influenced by cultural traditions and guided by research interests originating in both the humanities and the social sciences (→ Culture: Definitions and Concepts). In its Warburgian sense, iconography/iconology is an interdisciplinary comparative method, focused on the “visual interval” (Rampley 2001), both temporal and spatial.

Panofsky (1955/1982, 40–41) distinguishes between the first step, pre-iconographical description, the second step, iconographical analysis, and the third step, iconological interpretation. To this day, Panofsky’s three steps constitute the core of iconography as a

method. These three steps form the “act of interpretation.” Each of the three acts has a different “object of interpretation”; each needs different “equipment for interpretation” and follows a different “corrective principle of interpretation.”

*Pre-iconographical description* focuses on the primary or natural subject matter, which is usually the “world of artistic motifs.” *Iconographical analysis* is concerned with “conventional subject matter” – culturally shared visual → signs and connotations – and thus “the world of images, stories and allegories.” *Iconological interpretation* aims at unraveling the “intrinsic meaning or content constituting the world of ‘symbolical’ values” (Panofsky 1955/1982, 40; → Semiotics; Symbolism).

The “equipment for interpretation” changes from (1) mere practical experience and familiarity with depicted objects to (2) knowledge of literary sources to, finally, (3) “synthetic intuition,” “conditioned by personal psychology and ‘Weltanschauung’”

Panofsky’s (1955/1982, 41) reference to the German term *Weltanschauung* not only hints at his personal roots, but also reveals a primary influence on his thinking, fellow emigrant and eminent sociologist Karl Mannheim. In 1923, Mannheim published an article in German on “The interpretation of ‘Weltanschauung’” in which he not only defines *Weltanschauung* as “global outlook of an epoch” (Mannheim 1923/1952, 33) but hints at an interpretation method involving three levels of → meaning (“objective,” “expressive,” and “documentary”) as well as “objective correctives” of interpretation. Panofsky adapted Mannheim’s sociological method of interpretation to suit the needs of art history. Both sociology and art history are interested in understanding and unraveling how individuals as well as groups of people make sense of cultural artifacts and how, in turn, the visuals shape cultural belief systems at a given time. The method gives access to processes of meaning construction and meaning attribution to particular groups and motifs of pictures. Although systematic, iconography as a method is also highly subjective, raising questions about the validity of the interpretation result.

## ICONOGRAPHY AND ICONOLOGY

Many researchers use both terms interchangeably. But in Warburg’s and Panofsky’s understanding, iconology as a method went beyond iconography. While the iconographical analysis only constitutes the second of three steps in the interpretation process, iconology is the ultimate goal. Panofsky (1955/1982, 31–32) pointed to the difference between the two, hinting at the etymological origin of both terms. Iconography’s suffix “graphy” is derived from Greek *graphein*, meaning to write, thus stipulating that this is a merely descriptive method, aiming at an objective and neutral description and classification of depicted motifs (→ Objectivity in Science). Iconology, on the other hand, relates etymologically to the more encompassing concept of *logos*. Thus, Panofsky (1955/1982, 32) concludes, “iconology . . . is a method of interpretation which arises from synthesis rather than analysis.”

## ICONOGRAPHY AS AN APPROACH

Iconography in the Warburg tradition operates with a complex concept and understanding of the visual. Warburg himself enlarged the scope of art history by including “any visual

image,” regardless of its artistic quality. This meant that press photographs and other forms of mass-mediated imagery could be considered appropriate objects of study for art history (→ Art as Communication; Photojournalism; Visual Communication). The concept of iconography is closely linked to the German language. The key term of the German iconographic tradition – *Bild* (image, picture, visual) – cannot be fully translated into English. While the English language offers three different terms, there is only one word in German to describe visuals in the broadest sense. Warburg’s definition of *Bild* is twofold: any visual consists of a material and an immaterial dimension, in German conveniently labeled as *Abbild* (material image) and *Denkbild* (mental/immaterial image). For every material image, there are immaterial images corresponding to the material image. But not every immaterial image takes on a material form. Warburg was only interested in those visuals that have both dimensions, leading to the hypothesis that the material images can be used as sources to learn about the mental images of times past.

Scholars outside of art history have also used the terms iconography and iconology to denote not a method, but an approach. The most influential work in this respect is Mitchell’s *Iconology* (1987). He takes the word “iconology” literally, aiming at “a study of the ‘logos’ (the words, ideas, discourse, or ‘science’) of ‘icons’ (images, pictures, or likenesses)” (Mitchell 1987, 1). Van Leeuwen (2000) connects Panofsky’s approach with semiotics in the tradition of → Roland Barthes. Other works limit themselves to Christian religious iconography; that is, the classification and analysis of figures, poses, gestures, garments, colors, objects, and symbols that denote religious stories and theological concepts in European art (Büttner & Gott dang 2006; → Code; Religion and Popular Communication).

### POLITICAL ICONOGRAPHY

Largely unnoticed by the non-German-speaking academic community a “new Warburg school” has emerged since the early 1990s. The driving force behind this “Warburg revival” is the German art historian Martin Warnke, who, together with his Hamburg collaborators, initiated the renovation of the still existing original Warburg-Haus, which hosted the famous research center established by Aby Warburg – the Kulturwissenschaftliche Bibliothek Warburg (KBW). Warnke, inspired by Warburg’s image collection, recalibrated the iconological method to the topic of politics in its widest sense, creating an approach of his own, labeled *Politische Ikonographie* – “political iconography” (Warnke 1994). Warnke’s work is based on his collection of approximately 500,000 image cards, which are archived and accessible for researchers in the reopened Warburg-Haus in Hamburg. Due to the lack of translation, the international impact of this “new Warburg school” has been limited. At the beginning of the twenty-first century, the combination of visual interpretation as a method and political pictures as a topic appears to be experiencing a revival, reflecting the need for explanation of visual phenomena like the terrorist instrumentalization of visuals (→ Mediated Terrorism), the publication of torture images at the Abu Ghraib prison in Iraq (Eisenman 2007), or the controversy about the publication of Muhammad cartoons (Müller & Özcan 2007; → Conflict as Media Content; Caricature; Cartoons).

Iconology has the potential to better understand and explain the meanings of contemporary mass-mediated visuals. Its holistic approach, intrinsic subjectivity, and cultural focus on western traditions are both its strengths and its shortcomings.

## **Identification**

*Jonathan Cohen*

*University of Haifa*

Identification with media characters is a key component of viewers’ propensity to become engaged (→ Transportation Theory) and involved in media content (→ Involvement with Media Content). Identification is an imaginative process that is evoked as a response to characters presented in mediated texts, whereby → audiences feel as if they are part of

the world depicted by the mediated text (→ Media and Perceptions of Reality). When identifying with characters, audience members experience the events described by the plot not as external viewers, but rather from the perspective of the character with which they identify, and as if they were part of the story. Zillmann (2002) argues that because viewers often respond to characters they are obviously responding to them as witnesses (i.e., experiencing them from the outside), but this criticism is valid only if one assumes that the responses to characters are constant over time and across viewers and can take only one form. Most likely, identification and other forms of response (such as → parasocial interaction and relationships) are intertwined and people move in and out of these varying forms as they view (Wilson 1993).

Identifying with a character means feeling an affinity toward the character that is so strong that we become absorbed in the text and come to an empathic understanding for feelings the character experiences (→ Empathy Theory), and for his or her motives and goals. We experience what happens to the characters as if it happens to us, while, momentarily at least, forgetting ourselves as audience members, and this intensifies our viewing experience (Cohen 2001). Thus, identification has both affective (empathy) and cognitive (understanding goals and motives, perspective taking; → Cognition) components. Though the relationships audience members develop with characters can take other forms (e.g., parasocial interaction, liking, attraction, imitation), identification describes the most psychologically involving relationship, but one that, unlike some of its counterparts, is a process that is temporary and intermittent even if its effects can be long-lasting.

Studies of → media effects and reception have found that identification with characters has important effects on audiences. Such identification has been related to more arousal, → emotion, and pleasure (Fiske 1989). Identification also affects how viewers interpret TV series and increases the persuasive effects of celebrities (Basil 1996; → Persuasion; Celebrity Culture). Ethnographic work (→ Ethnography of Communication) has found that teens do not adopt values portrayed by their television heroes, but rather their identification with TV characters allows them to explore possible ways of achieving the values and roles they adopt from their families (→ Socialization by the Media). In sum, it seems that Morley (1992, 209) was correct when arguing that: “One can hardly imagine any television text having any effect whatever without that identification.”

Somewhat less clear than the effects of identification are its *causes*. Intuitively it is suggested that one identifies more strongly with characters that are most similar to oneself. However, studies of how children choose favorite characters point to choices that are based on similarity to what children aspire to, rather than on actual demographic similarity. Other studies show mixed results, suggesting that for some audience members certain kinds of similarity may promote identification, but in many other cases people prefer and identify with characters that are different from them in very fundamental ways. Overall, audience members have been found to select and identify with characters across gender, class, and age. People’s capacity for identification with characters who are very different from themselves is demonstrated by their ability to identify even with animated and animal characters (→ Animation).

Other factors that influence identification have to do with the depiction of the characters themselves. Logically, we are more likely to identify with characters that are

portrayed positively (Hoffner & Cantor 1991). Viewers tend to identify more strongly with heroes than with villains, and character traits such as strength, humor, and physical attractiveness have been identified as important in favorite character selection. However, if the narrative structure of a story supports identification with villains, audience members have shown the capacity to identify with them (a notable example was the identification with the evil J. R. Ewing in the 1980s series *Dallas*).

Because identification is so heavily dependent on perspective and empathy, *how stories are told* can influence who becomes the target of identification and to what degree such identification will develop (Livingstone 1987). Literary scholars suggest that allowing a character to narrate the story can increase identification with that character. Possibly, using a first-person perspective in film can produce similar effects. More subjective narratives should, then, promote greater identification with a hero, as should suspenseful narratives. Indeed, our ability to identify with the characters in a story is often used as a measure of our opinion of the quality of the narrative and the skill involved in its creation. Finally, because identification occurs in the minds of audiences, it depends on the proclivities and capabilities of individual viewers, listeners, or readers. Gender and age have been found to be determinants of the intensity of identification, as have individual capacities for empathy and relationship styles. On the other hand, the intuitive assumption that lonely people are most likely to identify strongly with media characters as a compensation for their lack of satisfaction from their interpersonal relationships has consistently failed to find empirical support (e.g., Rubin et al. 1985; Tsao 1996).

Though the research on identification is no longer in its infancy, it has yielded only limited understanding of this phenomenon. Lack of conceptual clarity, use of inconsistent definitions and measurement, and heavy reliance on self-report methodologies have plagued this area of research. One can legitimately question the validity of people's insight into and reports about deep psychological processes such as identification. However, the continued scholarly interest in this area, and the recognition of the centrality of identification to the social and personal significance of media in modern living, promise a bright future for the study of identification. New research tools will lead to new paradigms and greater understanding of this important phenomenon.

## Identities and Discourse

Charles Antaki

Loughborough University

Social scientists are not interested in identity in the sense of an individual's unique name and address. They are interested in identity in the sense of the category that an individual belongs to (or is made to belong to). All languages have explicit names which allocate people to a category of person (e.g., *madre* in Spanish, *umm* in Arabic, or *mother* in English), an occupation (*ingeniero*, *mohandass*, *enginee*, respectively), or a position in society that has loose definitional criteria (*gamberro*, *'ozbagui*, *hooligan*).

### DISCOURSE ANALYSIS

Much quantitative social science was (and is) devoted to “cover-sheet” identities like those, or still more general ones like gender, race, and class, and how they correlate with such variables as income, health, education, and crime. Social scientists who do qualitative research, however, take another tack. They believe that what is interesting about identities is how they are constituted – how society invents and perpetuates them. The way that society categorizes people, the laws it draws up, the visual images it promotes, the jokes it allows – all these are *discourses of identity*.

These discourses can be mapped in a descriptive way, to make a list of the features that society ascribes to any given identity category (one could, e.g., count the number of times the word “teenager” co-occurs with references to education, sex, television, and so on in the newspapers). Because that gives a rather static snapshot of the identity category, many

social scientists are turning instead to discourse as an active social practice – i.e., to seeing discourse not as static, but as doing some business rhetorically or interactionally. The emphasis is not on the list of features of the category, but on what it means to bring up the category at that place and that time, and in those terms. Most of that sort of research falls under the heading of → discourse analysis, which is a very varied set of analytic practices. Its five core features, applied to the study of identity, are these: (1) identities are to be understood not as essential and unchanging, but as subject to active *construction*, and liable to be imposed and resisted; (2) they appear in talk or text that is *naturally found* (in the sense of not invented or imagined by the researcher); (3) the identity words are to be understood in their *co-text* at least, and their more distant context if doing so can be defended; (4) the analyst is to be sensitive to the words' *non-literal* meaning or force; (5) the analyst is to reveal the *consequences* achieved by the identities conjured by the words' use – as enjoyed by those responsible for the words, and suffered by their addressees, or the world at large.

There are many ways in which those five criteria can be realized in the study of identity. I shall set them out in terms of their primary data; i.e., whether the discourse analyst looks for identities in people's own words in interviews, in the context of a locally researched site, in the wider political context, or in the organization of interaction.

### THE INTERVIEW AS RESEARCH METHOD

Interviews are still probably the method of choice for most qualitative researchers in the social sciences, on the proposition that they give respondents the freedom to express themselves, while at the same time allowing the researcher to probe specific questions that interest them. How one sets up the interview, and how one analyzes the resulting conversation, are a source of some debate in the literature. At one end are those who prefer the structured set of questions, and who treat the interviewee straightforwardly as an informant: thus a folklorist or oral historian might ask (say) community elders about their memories of their experiences as new immigrants, or about the customs of their particular sub-culture, and so on. The result is an enriched sense of identity issues as they are experienced by the people themselves, albeit filtered through memory and the demands of a retrospective interview.

At the other end are those researchers who look to the interview to provide evidence for further analytic work. The respondent's story might be subjected to a thematic analysis, a narrative analysis, an interpretive phenomenological analysis, or a free association method. These analyses differ among themselves, but they all look to find something "between the lines" of the respondent's account. A thematic analyst will look over a long account, or perhaps a set of accounts from different respondents, to find common themes of meaning – ways in which the respondent is making links between various parts of their identity. A narrative analyst will see how the respondent set her or his story out as a coherent narrative, using devices familiar from fiction to "plot" their life and people it with characters and events. The interpretive phenomenological analyst will use the interviewee's words to try to get "inside their head" and understand their phenomenological experience of themselves. A free association narrative method will approach

the respondent's words from a psychoanalytic perspective, trying to understand the inner forces that produce the person they express themselves to be (→ Interview, Qualitative).

## **RESEARCH CHARACTERISTICS**

### **Research in Local Context**

The ethnographically minded discourse researcher will be at pains to locate people's words in their context and culture. Interviews may form part of the researcher's toolkit, but principally as a way of informing the researcher of local meanings and codes; the analysis will be done on recordings of language as it is actually used, and identities as they come into play. Researchers in the ethnography of communication tradition, e.g., will look to see how speakers of different cultural identities signal those differences to each other, and how that affects (not always benignly) the success of their interaction.

Researchers in an ethnomethodological tradition will eschew interviews, and indeed any on-site material that is not brought actively into play by the speakers and participants themselves. The focus is on the ways that people publicly perform their reasonings about the world, such that they can prosecute their business with others: their reasoning is perforce available to all, without further interpretation or recourse to information not in the scene. So, e.g., in analyzing the way that a school student is judged to have a learning disability, Hugh Mehan (1996) analyzes not just the expert talk of the psychologist and the comparatively powerless talk of the parent, but also the props and furniture of the scene: the psychologists' notes and statistical tables, the boardroom and table, the seating arrangements, and so on.

### **Research in a Political Context**

Some discourse analysts prefer to approach their data from a given perspective on power and ideology in society, arguing that one must understand the social conditions of the production of a text before one can start reasonably to analyze it. The umbrella term "critical discourse analysis" shelters a broad family of analysts, but all are concerned to unpack the operation of power and ideology in discourse. Identities, their argument runs, are not always innocent, nor always under the control of the person identified; they can be oppressive, and the burden can be resisted.

Critical discourse analysts will not rely exclusively on one method or source of data. They may use research interviews with respondents, but their more common source of data on identities will be such "found" sources as newspaper and media accounts, political speeches, news interviews, and so on. The guiding principle will be to use linguistic and rhetorical scholarship to identify the metaphors, allusions, argumentative strategies, terminological choices, and pragmatic implications that converge to promote a certain vision of a group of people as falling under this or that socially significant identity. For example, a controversial identity like "asylum seeker" may be analyzed for how certain groups in society construct it to have – and other groups resist it having – politically and culturally negative implications. The work of the critical discourse analyst

is to find subtle expressions of racism and power, and to unravel their workings (→ Critical Theory).

### **Research in an Interactional Context**

Among those methods of analyzing discourses of identity that look first to what happens in interaction, the one that pays closest, and most exclusive, attention to the precise sequence of talk is → conversation analysis (CA). Its genesis was in the dissatisfaction of some sociologists in the late 1960s with the then dominant quantitative methodologies of their discipline, which were silent about how people actively realized the social world, in real time. In the 40 years since the pioneering work of the group around Harvey Sacks (whose lectures were published posthumously as Sacks 1992), CA has attracted a good deal of attention within sociology and outside it, and has developed into a multi-disciplinary enterprise.

CA's account of identities is to see them as being brought into active service in the particular moment of the interaction, for particular *interactional effects*. For a person to “have an identity” – whether he or she is the person speaking, being spoken to, or being spoken about – is to be cast (by a “membership categorization device,” which may be a term like “family” or the name of a profession, and so on) into a category with associated characteristics or features (the sort of thing you’d expect from any member of that category; their actions, beliefs, feelings, obligations, etc.). The force of “having an identity” is its consequentiality in the interaction – what it allows, prompts, or discourages participants to do or from doing next. For example, Dennis Day’s work (1998) on how people may allocate fellow-speakers to an ethnic group uncovers how mere hinting is enough to imply that someone is “not one of us,” and oblige them to take evasive action.

For CA, there is no need to go to the sort of abstract level favored by other kinds of discourse analysis, in their quest for the significance of identity talk: the speaker or writer’s use of (or hint at) an identity category is locally effective. If you call someone an asylum seeker (or hint that she or he is one) then you are doing it for local consumption, and the consequences will be interactionally visible. And this is true for mundane categories (like, say, “daughter”) as much as it is for more politically charged ones. In common with other discourse approaches, CA sees identities as constructed by language; its special emphasis is on language in use, at particular times and places.

## Identity Politics

*Usha Zacharias*

*Westfield State College*

Identity politics refers to the struggle for political recognition by marginalized social groups based on particular affiliations of individual identity, such as gender, sexuality, “race,” ethnicity, and nationality (→ Marginality, Stigma, and Communication; Symbolic Annihilation). Identity-based movements, as they grew in the west, challenged the limitations of political representation and citizenship offered within the liberal democratic state and institutions. Even as identity politics made visible more dominant social inequities, it also opened the door for rethinking and questioning within social movements based on identity, such as the movements for women’s liberation and feminisms in general (→ Social Movements and Communication). At the heart of feminist identity politics are the questions: who is the “woman” that is imagined as the subject of feminism or of women’s emancipation, and is there a singular significance to gender identity when the “woman” is embedded in a network of other social identities such as race, ethnicity, religious community, or nationality?

The Combahee River collective, an African-American lesbian feminist group, wrote one of the foundational feminist manifestos of identity politics, in which they insisted on the interlocking, intersecting nature of oppressions based on “race,” gender, class, and sexual identity. Gender politics, it followed from their argument, could not be analyzed through gender identity alone; it had to be mapped in and through the interlocked politics of racial identity, sexual identity, and class identity. Feminist work on “race” and gender in communication has constantly sought to unravel these intersections (see Bobo 1995), challenging work that solely focused on the white, middle-class, heterosexual woman as the subject of

feminist media studies. Rather than “race” becoming a marker for minority identity, the shifting colors of “whiteness” became important for feminist media studies.

Both British cultural studies and French postmodern theories of language and representation have played critical roles in the way the questions regarding identity politics have been rethought in gender and communication since the 1980s. The work of postmodern theorists such as Michel Foucault and Jacques Derrida, and postmodern feminists like Julia Kristeva, Eve Sedgwick, and Monique Wittig, questioned the very identification of “identity” with sameness and continuity of the individual self. Identity was reconceptualized not as an essence that belonged to the individual bounded by body and self, but as an *effect* of the working of language, modes of representation, and systems of signification that produce meaning (→ Postmodernism and Communication). Identity could no longer be thought of as the voice of individual or collective experiences; instead, identities themselves arguably emerged only through a play of differences in a network of signifying words and signs (Hall 1996).

For feminists, this was an important turning point, making it necessary to think not of sexual identity so much as sexual difference itself as an effect of language, representation, and signification. Clearly, this set the way for feminist media studies (→ Feminist and Gender Studies) to theorize media and communication processes as an important site for the construction of sexual identity and difference. The fluid, shifting constructions of sexual identities and differences through media representations, media texts, language, and symbolic systems that mutate in historical and cultural contexts became the single most significant theme in feminist media studies. New and emerging forms of femininities, sexualities, and sexual differences, as well as new cultural trends such as → postfeminism in the media could now be mapped through feminist critiques of representation (Dow 1996; McRobbie 2004). The concept of shifting, multiple, and contingent identities has proved to be particularly relevant to feminist research on new media (Sundén 2001).

The binary modes of thinking about sexual difference based on sex as biological nature, and queer theorists led by Judith Butler (1990), challenged gender as culture (→ Culture: Definitions and Concepts). These theorists argued that feminist identity politics could not be built on gender ontologies, or on foundational claims about gender that essentializes the differences between “natural” and “cultural” identities such as woman/man, feminine/masculine, homosexual/heterosexual, and lesbian/gay. The body, which had remained a biologically constant artifact for earlier feminisms, was no longer perceived to be a mute physical surface on which culture was inscribed (→ Body Images in the Media). Instead, the body was seen as something that fundamentally became intelligible only through sedimented knowledge, political contexts, and cultural meanings of sexual differences. Gender, Butler maintained, is performative; it is not a substantive reality belonging to the body nor is it a pre-existing social or subjective identity, but an act recreated through repeated performances by a body to produce cultural meaning. The argument led feminist scholars studying sexuality in communication to take both sexual subjectivities and the body as culturally constructed, and, as Henderson (2001) argues, as an arena for political struggle.

Given the centrality accorded to language and representation in postmodern feminism, women’s experiences were no longer authentic enough sources to validate feminisms. Thus, it became necessary to deconstruct the language of such experiences and subjectivities to show how they were mediated by history, culture, and politics. Since the

authenticity of experience was questioned, so were the feminist collectivities that relied on the shared experience of women's oppression as their ground, and the knowledge that was produced about women in academia. Processes of identification with another woman's experience were central to feminism's collective ground, and even to its academic knowledge production (→ Women's Movement and the Media). However, that was now open to question. Power relations between women of different classes or races were now regarded as just as significant as male/female power relations. This reflected on the world of learning, where women were privileged to produce knowledge about other women and to represent the experiences of other women. Feminist work in cultural anthropology, for example, has foregrounded the power relations between academic feminism and women who were the subjects of inquiry. In feminist media ethnography (→ Culture and Communication: Ethnographic Perspectives on; Ethnography of Communication), reflexivity, or the analysis of power relations between the woman academic and the women who formed the subjects of their research, became a key factor in the production of academic knowledge about women. The identity of the researcher, in terms of "race," class, gender, and sexual orientation was seen to significantly affect the research process itself.

If "race," gender, and sexual orientation were influential in creating discourses of identity politics from the start, postcolonial theory introduced a new dimension into the reconceptualization of identities (→ Identities and Discourse; Postcolonial Theory). Edward Said's work (1979) drew sharp attention to the frameworks of knowledge through which the west defined and produced an exotic, barbaric "Orient." Chandra Mohanty (1991) argued that colonial frames of knowledge that haunt feminist work represented the "third world woman" as a voiceless, passive subject of age-old tradition in contrast to her "liberated" western counterpart. Gayatri Spivak (1988), a central figure in postcolonial feminist theory, showed how the speech of the "third world woman" is impossible in the Anglo American academy (→ Communication Modes, African; Communication Modes, Asian; Communication Modes, Western). The voice of the "woman at the other end of the international division of labor," she argued, is forcibly muted through multiple filters of knowledge that the academy uses to understand her. Our knowledge about this underprivileged woman is always mediated by colonial or imperial ways of generating knowledge about the "east." Postmodern thought, which leans toward cultural relativism, can only highlight regional and national patriarchal ideologies of womanhood, so that the voices of marginalized women are not heard on their own terms. Spivak thus initiated postcolonial feminist criticism, which aims to expose not only colonial and imperial frameworks of knowledge, but also knowledge generated through regional and national patriarchies. While identity politics led Anglo American feminists such as Butler back to the body, postcolonial feminism now recast the body into its wider contexts of imperialism and globalization (→ Globalization Theories). In the context of the overlapping, multiple histories of colonialism, imperialism, and globalization, feminist work took on new, transnational dimensions that also questioned the first world location of feminist theory and practice. Transnational feminist media studies (Hegde 1998) involves the study of diasporic identities, immigrant identities (→ Migration and Immigration), and national identities inflected by transnational processes of colonialism, imperialism, and globalization, as well as by regionally dominant power networks that stabilize multiple patriarchies (Darling-Wolf 2004; → Feminist Media Studies, Transnational).

In the post-September-11 world, feminist media studies have particularly focused on how gender identity politics plays a role in the media's construction of the global "war on terror" (Cloud 2004) and in global militarisms (Weiss 2003). Identity politics is now being rewritten in feminist media studies over a very different map: one that no longer stops within Eurocentric boundaries of thought, and instead insists on theorizing gender through a transnational geopolitics of knowledge and location.

# Idiographic vs Nomothetic Science

Thomas R. Lindlof

University of Kentucky

For more than a century, two forms of explanation have been used in the social sciences: nomothetic and idiographic. These two kinds of explanation embody major differences in scientific logic, → *research methods*, and even understandings of how the world is constituted. The differences are so stark that they appear to some scholars to be unbridgeable, thereby threatening the prospect of achieving unity in the sciences. However, other scholars welcome both approaches, viewing them as complementary ways of studying and evaluating the same phenomena. At the heart of the nomothetic/idiographic debates is the question of whether the social sciences require different modes of explanation than the natural sciences. These debates persist to the present day, albeit at lesser intensity than before and with greater sophistication in the terms of the argument.

## HISTORICAL DEVELOPMENT OF THE CONCEPTS

While the roots of the duality reach back to Aristotle (Nagel 1961), the neo-Kantian philosopher Wilhelm Windelband is credited with creating and defining the terms. In a public address given at the University of Strasbourg, entitled “History and Natural Science” (1894/1998), Windelband set out to explore the question of where psychology fits as a discipline in relation to the natural sciences on the one hand, and the humanities on the other. Explanations in the humanities, he noted, take the form of an in-depth, descriptive account of “a unique, temporally circumscribed reality” (1998, 12). These explanations he called *idiographic*. In contrast, explanations in the sciences take the characteristic form of law-like statements about the mechanism for patterned, ever-repeating classes of events. These explanations, which enable one to predict the future occurrence of events, were called *nomothetic*. Importantly, Windelband characterized both types of explanation as empirical. Thus, psychology could use either the idiographic approach to interpret a person in all of his or her singular complexity, or the nomothetic approach to explain the regularities of behavior observed across many people.

Other contributions to the discussion followed in the early decades of the twentieth century. Max Weber argued that the nomothetic and idiographic did not necessarily correspond to scientific and nonscientific approaches, respectively. Rather, he viewed subjective meaning (or *verstehen*) as a unique object of study, with both nomothetic and idiographic approaches playing parts in advancing knowledge (Williams 2000; → *Verstehen vs Erklären*; Meaning). Gordon Allport’s *Personality: A psychological interpretation* (1937) reintroduced the idiographic/nomothetic distinction to modern psychology, where it had a significant influence on personality theory and research. Meanwhile, the social sciences at mid-century moved in two directions at once. The dominant movement was broadly positivist, and embraced the nomothetic goal of explaining behavioral and attitudinal regularities. A smaller movement of social inquiry began crafting idiographic strategies for studying self, society, and culture (→ *Symbolic Interaction*). Especially in anthropology, developments in ethnography elevated the importance of cultural interpretation (Geertz 1973).

By the 1970s, communication scholars began engaging in foundational debates about the theories, methods, and identity of the discipline. The nomothetic/idiographic distinction was often a main axis of these debates. Idiographic research in particular was vigorously championed – especially by scholars doing research under the broad umbrella of cultural communication studies (→ Cultural Studies) – as an alternative to the then dominant paradigms of behaviorism and functionalism (→ Functional Analysis). By the twenty-first century, a spirit of methodological pluralism in communication was ascendant, and open conflicts between proponents of nomothetic and idiographic approaches subsided. However, issues remain about the knowledge claims they produce, and how each relates to the other.

### NOMOTHETIC EXPLANATION

Nomothetic explanation in communication research and other social sciences is modeled on the natural sciences, especially the exact sciences of physics and chemistry. Other natural sciences, such as evolutionary biology and geology, are concerned with indeterminate processes and their theories lack the predictive power of physics. In addition, biologists and geologists often focus on historical records. Consequently, they tend to operate further to the idiographic side of the continuum. The nomothetic scientist seeks to explain human phenomena by means of a general law, often called a “covering law.” The structure of nomothetic inquiry is deductive (→ Deduction vs Induction vs Abduction; Critical Rationalism), such that the explanandum (the event to be explained) is the logical outcome of a covering law and some initiating event or condition, which are the explanans (the propositions that do the explaining). The strong form of a nomothetic explanation is deterministic: Given the law, “If event A occurs, then event B must occur,” the appearance of A will always cause B to appear (Porpora 1983). Because a law has universal scope, the causal relationships it specifies should hold everywhere and at all times. Experiments and controlled observations are the primary methods of discovering and validating these relationships.

For a variety of reasons, scholars in communication and other social sciences have failed to discover covering laws. For one thing, *the causes of human behavior tend to be indeterminate*. Unlike the world of physics, in which events occur invariantly in closed, homogeneous environments, human action occurs in open systems (Monge 1973). The effects that arise in open systems are often due to multiple causal paths that vary from moment to moment, making it nearly impossible to adopt the strong form of nomothetic explanation (Bernstein et al. 2000). Related to this point, *people’s reasons for acting* often have to be taken into account; as Porpora (1983) noted, there is no limit to the reasons that an actor can produce. Epistemological issues also undercut the ability of social scientists to develop law-like statements. Couched as they are in natural language, *social science theories lack point-to-point correspondence with the phenomena they try to explain*. In addition, theoretical statements can be meaningful apart from any operational definitions that might be devised (O’Keefe 1975). Consequently, human behavior can be explained through many different types of scientific account.

Laws may be beyond their reach, but communication researchers continue to strive to produce findings that can be generalized to a population with a known probability. As a

result, *ceteris paribus* propositions – i.e., stating a predictive relationship between events, with the qualifier “all things being equal” – are fairly widespread in communication research. Of course, all things are never equal. The use of statistical models, such as the inductive-statistical and the deductive-statistical models (Bostrom & Donohew 1992), allows nomothetic science to go on, subject to certain conditions (→ Quantitative Methodology). This approach to empirical research has led over the decades to the construction of communication theories of considerable scope, precision, and complexity.

### IDIOGRAPHIC EXPLANATION

Idiographic explanation concerns the particulars of one case, be it an individual, a dyad, a group, an organization, or a cultural system. The idea that *no two lives are the same* is one of its bedrock assumptions. This is not exactly the same as saying that the individual is of ultimate importance. Rather, idiographic analysts study the contexts in which the individual finds meaning for his or her actions (Anderson 1987). Another major assumption is that *human action does not arise from determinate causes*. Unlike the world described by the physical sciences, humans create their own cultural environments and are able to make themselves objects in conscious thought. Human action emerges in large part from the *motivation to “make sense”* of social and physical circumstances. The process of making sense is not individualized or abstract, but comes into being through the situated use of language and other kinds of symbolization. Thus, idiographic analysts treat behavior as a semiotic act that must be interpreted (→ Semiotics). If causal claims arise at all in idiographic research, they are likely to be specific to the social rules and codes of the case itself.
