In conſidering this operation, however, as carried on by nature, we will ſoon find, that it proceeds in a manner very different from what takes place in our chemical operations. In the latter, evaporation is merely the effect of heat; and the proceſs cannot go on without a conſiderable degree of it, eſpecially if the veſſel containing the fluid be cloſe. In the natural way, on the contrary, the proceſs goes on under almoſt every degree of cold we know; the vapours aſcend to an height which has never yet been determined; and, from the extreme cold which they ſuſtain, ſhow evidently that they are connected with our atmoſphere by means of ſome other agent beſides heat.

9 Dryneſs of the upper regions of the atmoſphere.

From the continual aſcent of vapour indeed, if the operations of nature were of the ſame kind with thoſe of art, the upper parts of our atmoſphere would be always involved in a fog, by reaſon of the condenſation of the vaſt quantity which continually aſcends thither; but ſo far is this from being the caſe, that in thoſe elevated regions to which the vapours continually aſcend, the air is much drier than at the ſurface of the ground.

10 Surpriſing inſtances of this dryneſs.

This was experienced by M. de Sauſſure and M. de Luc in their journeys up the Alps. The air was there found to be exceſſively dry, and evaporation to go on much more rapidly than below; ſo that the ſurface of their bodies was parched up, and an exceſſive thirſt took place by reaſon of the great abſorption of the moiſture. The ſame dryneſs was manifeſt by the hygrometer, which could ſcarce ever be brought to indicate any moiſture, even when our travellers were ſurrounded with clouds, hail, and rain. From many experiments, indeed, it is evident, that water, after being reduced into a ſtate of vapour, is capable of undergoing a certain change, by which it lays aſide its fluidity entirely, and even to appearance its ſpecific gravity; ſo that it becomes, as far as we can judge, a ſubſtance totally different from what it was before.

11 Water ſometimes changes its nature.

This may be underſtood from the common operation of ſlacking lime; for in that caſe, the water unites with the lime ſo intimately, that the whole aſſumes the form of a dry powder, extremely greedy of moiſture, and which cannot be reduced to its former ſtate of quicklime without undergoing a much greater degree of heat than the water by itſelf could bear. The ſame thing is manifeſt from mixing dry plaſter of Paris with water; for thus a vaſt quantity of the water is fixed, and becomes in a manner ſolid. A ſtill more remarkable inſtance is in ſending the ſteam of water over red-hot iron; for there the fluid unites in ſuch a manner with the metal, that it cannot be expelled from it even by the heat of a burning-glaſs. Other inſtances are mentioned under the article WATER: here we are to conſider the changes which the element undergoes after being reduced to the ſtate of vapour.

12 Partic... account ... natura... evapo... tion.

The firſt of theſe is, its aſſuming the appearance of ſmoke or fog when mixed with the common atmoſphere; which ſmoke, when examined by a microſcope, appears to be compoſed of an infinite number of ſpherules of water, hollow, and filled with a fluid ſpecifically lighter than air, by which means they aſcend in it. As long as the aqueous vapour retains this viſible form, it retains alſo its humidity, and will again become a liquid, and wet whatever comes in its way; and this the more readily, while it retains any ſenſible degree of heat. As the vapour cools in the atmoſphere, it gradually aſſumes an aerial ſtate, mixing itſelf with the air ſo as to be no longer diſtinguiſhable from it. In this ſtate the air itſelf does not by any means appear to become more moiſt, but continually drier the more water it receives. This, however paradoxical it may ſeem, is a certain fact: for in ſummer, though we are aſſured that evaporation goes on very rapidly from the ſurface both of the ſea and land, yet the air, ſo far from being moiſt, is much drier than at any other time; and yet we know that the whole quantity evaporated is ſome how or other received by the atmoſphere. After the water has attained to this ſtate, our inquiries concerning it muſt in a great meaſure ſtop. We know not now, whether it has the form of ſmall hollow ſpherules, or whether it really becomes part of the atmoſphere itſelf, and aſſumes the form of what we call *dephlogiſticated air*.

13 Is cap... of be... compo...

From ſome experiments in which that kind of air is produced from water, we are certain, that part of this element is converted into air: but in theſe operations, the evaporation of the water is prevented by being carried on in cloſe veſſels; ſo that we cannot tell whether that which would be mere ſteam in the open air, becomes dephlogiſticated air in cloſe veſſels or not. From the immenſe waſte of dephlogiſticated air, indeed, and the vaſt quantity which always ſurrounds the earth, we may ſuſpect that the water, after undergoing the natural proceſs of evaporation, does really become changed into this aerial fluid; and thus we will have a more ample ſource of it than can be derived from vegetation, or any other cauſe with which we are yet acquainted.

14 Obſer... tions of M. de L.

On this ſubject M. de Luc has ſome very curious obſervations, built principally upon the new doctrine of the compoſition of water; which, though a poſition maintained by the antiphlogiſtians, is by no means inconſiſtent with the exiſtence of phlogiſton, but rather a proof of it. Our author firſt began to alter his ſentiments concerning the *aqueous* exiſtence of vapour in the atmoſphere, from the circumſtance already mentioned concerning the great *dryneſs* of the upper atmoſpherical regions already taken notice of.

A very remarkable inſtance of this was, that the ferule of his cane dropped off during his journey up one of the Alpine mountains, which he never had obſerved it to do before. It is obſerved likewiſe, that the air in theſe elevated regions is ſomewhat drier in the night than in the day-time; for which M. de Luc gives the following reaſon, viz. that the air on the plains being condenſed by the cold, the ſuperior air muſt ſubſide, and the air on the mountains of courſe be replaced by the drier air from above them; though he thinks that this dryneſs may alſo be imputed in part to ſome other cauſe. This increaſe of dryneſs in the night, however, ſeems leſs conſtant than that in the day-time. Our author has often arrived at the tops of mountains before ſun-riſe, and ſometimes found the graſs covered with dew; though he never had the good fortune to be able to determine the ſtate of the air for want of an hygrometer: nor indeed could the appearance of dew be any certain indication of the ſtate of the atmoſphere, there being ſtrong reaſons to believe, that dew is occaſioned in great meaſure by vegetables themſelves; for graſs, when covered with glaſs plates, was found to become moiſt as well as that which had been expoſed to the open air. In this caſe, the plates became moiſt both on the upper and under ſides; but when ſuſpended a foot above the ground, they were found to be covered with dew only on the upper part.

5 [...]uſ[...]re[...] [...]f ac[...] [...]dry[...] [...]f the

The dryneſs of the air on the tops of high mountains was otherwiſe accounted for by M. Sauſſure.— When on Mount Blanc, at the height of 7200 feet above the level of the ſea, he found, that from ſix in the evening till half paſt five next morning, his hygrometer moved 21 degrees (the whole ſcale containing 100) towards dryneſs. But this he accounts for by ſaying, that from ſunriſe to three or four in the afternoon, the quantity of vapours in the neighbourhood of the earth is continually diminiſhing, becauſe they *aſcend* in the atmoſphere, either in virtue of their own levity, or by means of a vertical wind, which he ſuppoſes to be produced by the heat of the ſun; that, from the time juſt mentioned till next morning, their quantity increaſes in the lower ſtrata, becauſe the upper vapours re-deſcend in proportion as they condenſe; and that in the higher regions of the atmoſphere, the reverſe ought to be the caſe, as the upper ſtrata are then left drier by the previous deſcent of the vapours. This argument, however, is contra-

6 [...]ient

dicted by M. Sauſſure himſelf in another part of his work; where he ſays, that in the middle of the day, when the ſun is hotteſt, the air in the neighbourhood of the earth contains really more *water* than it does at the moment when a refreſhing dew falls. It is beſides impoſſible that a *vertical* wind can ever be occaſioned by the heat of the ſun; for this produces only a general expanſion of the whole body of the atmoſphere, as a condenſation of it is occaſioned by the action of cold: neither could any conſiderable quantity of vapour (ſuppoſing with M. Sauſſure that it is a chemical ſolution of water in air) deſcend in the night-time; for, according to him, this compound differs very little from common air in its capacity of being expanded and condenſed. Neither, according to M. Sauſſure himſelf, can any part of the water with which the air is combined deſcend at all, until ſome portion of the former becomes ſuperſaturated with it, that is, till it has received more than it can hold in ſolution. But if this ſhould happen to be the caſe, the ſuperfluous quantity would then appear in the form of a miſt or cloud, and the hygrometer would indicate extreme humidity; whereas the contrary indication conſtitutes the difficulty.

17 Aerial vapour cannot be condenſed by cold.

It is beſides evident, from innumerable inſtances, that mere cold will not by any means occaſion the condenſation of aerial vapour. A moſt remarkable example of this is given by M. de Luc, in an account of a ſtorm in which he was involved on one of the Alps. "Though the hygrometer (ſays he) was within $33\frac{1}{2}$ degrees of extreme dryneſs, or $66\frac{1}{2}$ from extreme humidity, thick clouds formed around us, which obliged us to think of retreating: in a little time the ſummit of the mountain was ſurrounded by them: they ſpread and covered the whole horizon: a premature night ſurpriſed us in a very dangerous road; and we ſuffered one of the moſt violent tempeſts I ever experienced, of wind, rain, hail, and thunder. The ſtorm laſted great part of the night, and extended all over the neighbouring mountains and plains; and after it had ceaſed, the rain continued, with only a few intermiſſions, till next day at noon. In one of theſe intervals, I examined the hygrometer on the outſide of our cabin; it ſhowed only $1\frac{6}{8}$ more humidity than before; and even this increaſe was no more than what the difference of heat was capable of producing. Nevertheleſs, new clouds continually rolled around us; and the rain, which preſently began again, accompanied us as it were by fits to the bottom of the mountain. When arrived there, we ſaw the clouds diſperſe entirely. I obſerved the hygrometer again in the open air; and though the earth was all drenched with water, and the heat of the ſun much leſs, the hygrometer was $1^{\circ}\frac{7}{16}$ drier than it had been two days before, after a courſe of fine weather. Where was all this water, and all the ingredients of the ſtorm, while the hygrometer ſhowed ſuch a degree of dryneſs in the very ſtratum where it was formed?"

18 M. de Luc's definition of vapour.

M. de Luc adopts the opinion concerning vapour which has been publiſhed in this work, under the articles CHEMISTRY, EVAPORATION, and many others, viz. that it is a combination of fire with water. By *vapour*, however, he does not mean the viſible ſteam iſſuing from heated liquids, but that inviſible and ſubtile fluid which is found to be formed even *in vacuo*, and which of conſequence diſproves the hypotheſis of thoſe who hold that vapour is a ſolution of water in air. Our author, however, gives a ſolution of the difference betwixt what he calls *fog* or *miſt* and vapour, which ſeems not founded upon any evident principle. According to him, this vapour cannot ſubſiſt unleſs the particles of water united to the fire be at a certain diſtance from one another. When this diſtance is leſſened, a decompoſition takes place by reaſon of the attraction of the aqueous particles to one another; and they then appear in their proper form of a liquid, the fire diſſipating itſelf through the atmoſphere. The ſmalleſt diſtance to which the particles can be brought without any decompoſition, varies

varies according to the temperature; but is always conſtant in the ſame degree. When the thermometer ſtands at temperate, or thereabouts, watery vapours, compreſſed into the ſmalleſt ſpace they can bear, are found to have between $\frac{1}{16}$th and $\frac{1}{36}$th of the elaſticity of air; but have leſs than $\frac{1}{150}$th of its weight. If ſuch vapour, however, be mixed with air, the minimum diſtance is greatly increaſed, by reaſon of the interpoſition of aerial particles; and thus it can ſubſiſt under a much greater preſſure than it could otherwiſe endure. In the heat of boiling water they can, without any mixture of air, bear the preſſure of the atmoſphere: for ebullition, under any given preſſure, cannot take place until the vapour produced in the liquor has acquired a degree of expanſive force ſufficient to raiſe the liquor into bubbles under that preſſure; and as long as the vapour retains this heat, it muſt continue capable of reſiſting the ſame preſſure. As the heat abates, a decompoſition begins; hence the opaque ſteam over boiling water, which, by becoming vapour again by uniting with the fire it meets with in a larger ſpace, is diffuſed by its expanſibility.
19 Evaporation of the clouds. Thus, vapours are continually undergoing decompoſitions and new vaporifications. This evaporation of the clouds after they were once formed, M. de Luc obſerved very evidently; ſome parts being continually detached, and gradually diminiſhing and diſappearing, while new ones are formed; ſo that the clouds do not continue the ſame for two moments together; and the evaporation goes on ſo faſt, that a cloud could not ſubſiſt without conſtant and large ſupplies.—Theſe phenomena appear to be independent of heat and cold: for ſometimes clouds form ſuddenly in the middle of a hot day; and after they have poured down their water, all is clear again: and ſometimes they evaporate after ſunſet, gradually vaniſhing in the calmeſt weather without any change of place.—The appearances are ſuch as would be produced by a large maſs of water in violent ebullition, ſuſpended inviſibly in the atmoſphere; and the ſimilarity of effect naturally points out an analogy in the cauſe; that is, a ſource of vapour in the atmoſphere itſelf. It is only when the vapour is produced too abundantly and too rapidly to be diſperſed by evaporation that rain is formed; the veſicles in this caſe running together, and the water falling to the lower part, as it does in ſoap-bubbles, till they become thin enough to burſt.

20 Remarks on M. De Luc's obſervations. With regard to this explanation, however, though it may account for the artificial production and decompoſition of vapour, it does not ſeem to anſwer for that produced in the natural way. That the latter is certainly in a ſtate of dryneſs, cannot be denied; but it cannot be proved that ever any artificial ſteam is ſo, let the heat be what it will. Though the approach of the aqueous particles to one another, therefore, by a diminution of temperature, may occaſion the decompoſition of artificial ſteam, it does not ſeem to be ſo in the natural way; nor is there any ſource from which we can reaſonably infer a very great and ſudden acceſſion of vapour from the earth to the upper regions of the atmoſphere in particular places, which might increaſe the proximity of the aqueous particles, and thus bring on rain according to M. de Luc's hypotheſis. It muſt likewiſe be remembered, that, according to the doctrine upon which M. de Luc founds his ſyſtem, water, when decompoſed, is not converted into one ſpecies of air, but into two, viz. the dephlogiſticated and inflammable, each of which contains a quantity of undecompoſed water; ſo that there is ſtill ſome ambiguity in the experiments; and as the two ſhrink up into very little bulk by their union, there ſhould ſeem to be danger of producing vacuums of immenſe extent by the ſudden union of the two airs in the high atmoſpherical regions.—Theſe vacuums, were they to extend over the whole ſpace occupied by a large cloud, might occaſion dreadful concuſſions by the ruſhing in of the air to ſupply them: or even if we ſuppoſe them to be diſperſed interſtitially, they muſt certainly affect the barometer very greatly; which does not appear to be the caſe. M. Sauſſure, who paſſed ſeveral nights on one of the Alps, at the height of 10,578 feet above the level of the ſea, does not mention any conſiderable variation of the barometer, though he was frequently involved, during that time, in the moſt violent ſtorms of hail, wind, ſnow, thunder, and lightning. In the warm climates alſo, where we ſhould think that the vaſt deluges of rain would often ſink the barometer to an amazing degree, yet we ſeldom hear of any remarkable variation. M. de Prielong, in his account of Meteorological Obſervations made at Goree in 1787, informs us, that there were 16 or 18 hurricanes; and that the greater part of theſe raiſed the barometer from one twelfth to a ſixth part of an inch; others ſunk it as much, and ſome did not at all affect it. Another cauſe muſt therefore be concerned, which diminiſhes the rarefaction, or condenſes the air as faſt, or nearly ſo, as the condenſation of the vapour would rarefy it: and that another cauſe really is concerned, we learn from M. Reynier, who has made a great number of obſervations upon the vapours formed on the Alps, and gives us the following account. 21 M. Reynier's obſervations. "In the morning, the vapours condenſed by the coldneſs of the night riſe along the mountains in proportion as the ſun riſes above the horizon.—When the weather will be fine, they glide uniformly on the brink of the mountain, and riſe over it by a regular motion, ſomewhat ſlow. When rain impends, the motion is irregular: they are alternately attracted and repelled by the mountain, and riſe like elaſtic bodies rebounding. In a ſtormy ſeaſon, particularly when there will be hail, the motions are ſtill more rapid and irregular." "This obſervation (add the Monthly Reviewers, from whom the above quotation was taken) may be confirmed in the mountainous countries of Great Britain; we have ſeen it among the mountains of Cumberland, particularly in the neighbourhood of Keſwick. M. Reynier obſerves, and the obſervation is ſufficiently near the ſurface not to be overlooked, that the appearance is electrical."

22 Conſideration on the nature of the fluid into which water is reduced by vaporation. Before we proceed to give any ſolution of the *decompoſition* of vapour, it will be neceſſary to conſider a little farther the nature of that fluid or fluids into which water is converted when it aſſumes a dry ſtate in the atmoſphere. In the experiments of Lavoiſier and others, it ſeems with great probability to be reduced into the two different kinds of air already mentioned; but M. de Luc does not think that the atmoſphere

mosphere naturally contains any such fluids. Air, when artificially decomposed, does not contain inflammable, but phlogisticated or mephitic, air, mixed in a certain proportion with the dephlogisticated kind. These have different specific gravities; and our author is of opinion, that two fluids of this kind could not mingle uniformly with one another without separating through time: and as the dephlogisticated air has the greatest specific gravity, it thence follows, that the under parts of the atmosphere ought to be almost entirely composed of that kind, and the upper strata of the mephitic or inflammable kind. But this does not appear to be the case; so that M. de Luc concludes, that air is an homogeneous fluid, every particle being similar to every other, and consisting of all the ingredients that we extract from the mass, together, probably, with others yet unknown to us. Though a mixture of vital and mephitic air produces many of the effects of atmospheric air, we cannot thence conclude their absolute identity: the one may suffer a decomposition in order to the production of these effects, while the other produces them immediately. The mixture may support life for a time, but will it equally maintain health also? Though mephitic air by the mixture of one-third of vital air is prevented from being immediately fatal, we are not authorised to conclude that it is altogether innocent. On the whole then, if it is not in the immediate product of evaporation that rain has its source; if the vapours change their nature in the atmosphere, so as to be no longer sensible to the hygrometer or to the eye; if they do not become vapour again till clouds appear; and if, when the clouds are formed, no alteration is observed in the quality of the air; we must acknowledge it to be very probable, that the intermediate state of vapour is no other than air; and that the clouds do not proceed from any distinct fluid in the atmosphere, but from a decomposition of a part of the air itself, perfectly similar to the rest."

This opinion of M. de Luc appears the more probable, that the two ingredients into which water is artificially resolved, by the late experiments do not by any means re-compose atmospherical air by simple mixture; for these explode with extreme violence on the application of flame: the common atmosphere, also, when decomposed, does not resolve itself into dephlogisticated and inflammable air, but into the former, and what is called phlogisticated or the mephitic kind, the difference of which in specific gravity is much less than between dephlogisticated and inflammable airs, though it is probable that even these are connected either by means of a chemical union, or by some other ingredient we do not yet know. By this union the qualities of both may be in some measure changed, and a third kind of substance formed, as neutral salts may be made out of acids and alkalies This third substance, which we call the common atmosphere, is proper for preserving both animal and vegetable life, which neither of the two ingredients are capable of doing; for plants wither and die in dephlogisticated air, and animals are suffocated in a moment by the mephitic kind; nor, indeed, do we know whether the dephlogisticated kind be altogether proper for the sustenance of animal life for any considerable length of time. It certainly will sustain it much longer than an equal quantity of atmospherical air, even the purest we are acquainted with; but it is equally certain that animals confined in it die much sooner than according to its apparent purity they ought to do. It is not an unreasonable hypothesis, therefore, that though water may be artificially separated into the two fluids called dephlogisticated and inflammable airs, yet in the natural way the decomposition does not proceed beyond a certain point, which we may, in a subject of such an obscure nature, call a *chemical union*, or a state in which the two ingredients exist, and are capable of being separated when the air comes into contact with certain substances. Hence, when the atmosphere is taken into the lungs of an animal, some of the dephlogisticated part may enter the blood, and the phlogisticated part combining more intimately with the rest, may form fixed air or part of it appear in its proper form. In like manner, when the common atmosphere comes in contact with a vegetable, it is possible that the phlogisticated part may be absorbed by it, and the dephlogisticated part set free, which in the atmosphere may form new combinations, &c.

25
Air and water convertible into each other.

Granting this to be the case, and we can scarcely hope for a more probable conjecture on the subject, the decomposition of the vapour will be easily accounted for. If by any natural process the water can be converted into air, and if the latter is only water partially decomposed; then, by an inversion of the process, air may be instantly re-converted into water, and will become visible in fog or mist, or be condensed into rain, consisting of greater or smaller drops, according to the degree to which this inverted process is carried. With regard to the means used by nature for carrying on these two opposite processes, we can say very little; because the agents concerned in them are entirely beyond the reach of our senses. From M. Raynier's observation, indeed, of the clouds being attracted by the hills, it would seem probable that electricity was ultimately concerned, but in what manner we cannot determine. On this hypothesis, however, we may explain the phenomenon taken notice of by M. de Luc and others, viz. that even during the time of excessive rains the hygrometer showed scarce any signs of moisture, and that the clouds were in a constant state of evaporation or dissolution in the air. The hygrometer, we know, cannot show signs of moisture, unless it absorbs it, and it cannot absorb, unless the air around it really contains more vapour in an aqueous form than the hygrometer itself does. But in very elevated regions this can scarce ever be the case. So much of the pressure of the atmosphere is then taken off, that the water contained in any substance resolves itself into vapour with the utmost facility. Hence bodies brought from the lower regions into the higher will undoubtedly part with a great deal of the moisture they contained in the lower parts of the atmosphere, and which was kept in it by the superior pressure of the atmosphere in these parts. For the same reason, though the air in the upper regions should be made ever so moist, a body such as the hygrometer can never absorb so much as it would otherwise do, because the water in these regions has a natural tendency to fly away from it. It appears, however, that there was in reality *some* variation of the hygrometer, though small; and had it been possible to conſtruct an hygrometer of materials found on the top of the mountain, which might be ſaid to be naturalized to the climate, the ſcale of variation might probably have been larger, though there is no reaſon to think that it ever would be ſo large as on the plain. For the ſame reaſon, as ſoon as the proceſs has been inverted, by which water was converted into air, the evaporation inſtantly takes place in the vapour that has been produced. We are to conſider, that the atmoſphere is never diſpoſed to let fall *the whole* of the vapour it contains, for this would amount almoſt to an annihilation of it. Both proceſſes go on at once; and it is only in particular parts that the reverſe proceſs takes place. Thus clouds are formed: but as theſe ſeldom continue ſtationary, they no ſooner come into a ſituation where the contrary operation is going on, than they begin to evaporate; and even in the very ſame place, as ſoon as the condenſing proceſs has ſtopped, the other begins; as we ſee that even in the moſt damp and moiſt weather there is a conſtant evaporation going on; ſo that during the very time that rain is falling, the atmoſphere is taking up what lies upon the ground.—Hence alſo we may ſee why the hygrometer indicated a greater degree of dryneſs in the night than in the day time, viz. becauſe the evaporation from the earth is leſs during the night than in the day time.

24 Electricity of the atmoſphere conſidered.

II. Having now in ſome meaſure explained the phenomena of natural evaporation, we muſt next conſider thoſe of the *Electricity* of the atmoſphere. Under the article ELECTRICITY, the nature of that fluid is ſo fully diſcuſſed, and its identity with the ſolar light rendered ſo probable, that there ſeems no farther occaſion for entering into ſpeculations upon the ſubject. We ſhall therefore, without taking any notice of the arguments of M. de Luc for its being a compound fluid, proceed to conſider, according to the principles laid down in that article, how far electricity is concerned in producing the phenomena of meteorolgy.

25 Different agents concerned in producing all meteors.

In this inquiry we muſt obſerve, that as none of the agents by which thoſe phenomena are produced can act by themſelves, but muſt always be aſſiſted by the reſt, ſo we are not to aſcribe any one phenomenon to the influence of a ſingle agent without the reſt.—Thus, though in evaporation heat is principally concerned, and though evaporation is the principal cauſe of the appearance of clouds, &c. yet we do not find that heat is the *ſole* cauſe of evaporation; neither is evaporation the ſole cauſe of the appearance of clouds. In like manner, though electricity is the principal cauſe of many of the more grand phenomena of nature, yet electricity does not act by itſelf, but in conjunction with aqueous vapours; and when the atmoſphere ceaſes to contain any of theſe vapours, it is highly probable that it ceaſes to manifeſt any of the common effects of electricity alſo.

26 Electricity of the earth explained.

The general electricity of the earth has, under the article ELECTRICITY, been ſhown to depend upon the abſorption of the rays of the ſun by the land and water, eſpecially by the latter. As this abſorption muſt undoubtedly be ſtrongeſt in thoſe places where the greateſt quantity of rays fall upon the ſurface, it follows, that the emiſſion muſt be greateſt where the feweſt are abſorbed; that is, at the poles. Hence, were there no obſtacles, the electrical fluid would iſſue forth in vaſt quantities at each pole, very little being emitted in the intermediate ſpaces. By reaſon of the reſiſtance made by the great body of the earth, and the immenſe fields of ſnow and ice with which the polar regions are conſtantly enveloped, and which are much leſs perfect conductors than liquid water, the electric fluid, once abſorbed, has no free paſſage through any particular part of the globe, and therefore forces out every where throughout the whole ſurface. This paſſage is facilitated by the moiſture contained in the atmoſphere; and thus the proceſſes of evaporation and electricity aſſiſt one another: for where the air has for a long time been very dry, we find that the electric fluid cannot readily paſs, and violent thunder and lightning, nay ſometimes earthquakes, are ready to enſue. Hence alſo the common obſervation relative to thunder, viz. that there is ſeldom much thunder when it begins to rain before the thunder comes on: The reaſon is, that the rain, being an excellent conductor, facilitates the paſſage of the electric matter through the air, and keeps up the equilibrium without any violence or exploſion.

As the electric matter gets out of the earth, it is naturally driven upwards to the higher parts of the atmoſphere, where it probably aſſiſts in the decompoſition of air, or reſolving air into water, as has been already ſaid. When clouds are formed, it preſſes ſtrongly upon them by reaſon of their conducting nature: and hence all clouds, whether high or low, are found to be electrified; as are likewiſe all fogs, of whatever kind. The fluid getting ſtill higher and higher, at laſt aſcends beyond the regions of our atmoſphere, into the unknown ſpaces which are the reſidence of thoſe firſt of all created agents which conduct the planets round the ſun, and act as the *primum mobile* of nature.

Thus there is a circulation in the electric fluid as there is in the water. It deſcends originally from the ſun; pervades the whole ſubſtance of the globe; and perſpiring, as it were, at every pore, aſcends beyond the clouds; and, paſſing the extreme boundaries of our atmoſphere, returns to the ſun from whence it came. As the ſphere of its action in returning, however, muſt always increaſe, it follows, that after it has got beyond the bounds of the atmoſphere, the ſigns of its action muſt continually become leſs and leſs, nay, moſt probably vaniſh entirely; becauſe it is there oppoſed by an immenſe quantity of ſimilar matter, acting in an oppoſite or different direction from itſelf.

This laſt conſideration leads into a very curious ſpeculation, and in a very plauſible manner anſwers an objection, the force of which it would otherwiſe be very difficult to avoid. "If the electric fluid be no other than the light of the ſun abſorbed by the earth, and emitted from it again by innumerable ſmall vents, how comes it to paſs that it is not perpetually drained off from the upper regions as faſt as it arrives, without ſhowing any ſign of being reſiſted. The phenomena of thunder, of rain, nay of every meteor, manifeſtly ſhow that it often meets with very great reſiſtance; but this could not happen, unleſs there was without the atmoſphere ſomething capable of reſiſting and counteracting the vehement impulſe of all the electric fluid with which the earth is filled. This reſiſtance is very evident: for if there were none, there could

27 How the electric matter is confined in the atmoſphere.

could not be any accumulation of electricity in the upper regions of the atmoſphere, but a rarefaction in it would take place ſimilar to what there is of air in the ſame regions. But this is ſo far from being the caſe, that all the electrical phenomena are much ſtronger in the upper than in the lower regions."

To ſolve this objection, Mr Morgan, in a late paper in the Philoſophical Tranſactions, ſuppoſes that an abſolute vacuum, ſuch as he imagines the celeſtial ſpaces to be, is abſolutely *impenetrable* by the electric fluid. But this ſeems not far from a contradiction. Sir Iſaac Newton imagined the celeſtial ſpaces to be void of all matter, on account of the apparent facility with which the planets move through them; and we ſee that the rays of light, the impulſe of which is accounted ſcarce any thing at all, do penetrate them. To ſuppoſe, indeed, that a mere non-entity can act either by reſiſtance or any way elſe, is an abſurdity. How can any perſon imagine, that a perfect vacuum, which even a feather by its weight can cauſe it pervade from one end to the other, ſhould be impenetrable by a flaſh of lightning? It is true, indeed, that from ſome experiments it is found, that when the air is exhauſted very perfectly from a receiver, we cannot force an electric ſpark through it. But this, ſo far from proving that there is *nothing* in the glaſs, plainly ſhows that there is *ſomething* in it which makes a greater reſiſtance than we can overcome: and it is very probable that this ſomething is no more than the electric fluid itſelf; for as we are very certain that the electric fluid can *impell*, ſo we are equally certain that it can *reſiſt*. The truth is, that it is not in our power to move this fluid at all but by leſſening in one part the reſiſtance it meets with; in which caſe it moves very freely of itſelf: juſt as we can move the air with great facility, provided we allow the reſt to follow; but if we attempt to puſh a quantity of air before us, without allowing any to follow it to ſupply the vacuity, we will meet with a moſt violent reſiſtance. In the caſe of electric fluid, we can make it circulate from one part of the earth to another by means of conductors: but we cannot force any part of it to a diſtance from the reſt, nor can we cauſe a ſmall quantity expel a large one from any place, otherwiſe than by breaking the equilibrium; in which caſe the quantity which follows is preciſely equal to that which went before. In the caſe of a perfect Torricellian vacuum, we cannot diſcharge a bottle through it, without ſetting in motion all that quantity which is contained in the glaſs, as well as all that is connected with it, which it ſeems is more than the power of any machine can do. In like manner, the atmoſphere of the earth being ſurrounded by an immenſe and inconceivable quantity of electric matter, it cannot eſcape without putting in motion a quantity of that matter equal to what goes out. But this quantity, upon the whole, can never be greater than that which the earth every moment abſorbs from the ſun. Were a greater quantity to iſſue forth, it would be reſiſted by all the reſt, even to the utmoſt boundaries of the univerſe; a power which no created being could overcome. As matters ſtand at preſent, the reſiſtance is inconceivably great: for from the laws of mechanics it is evident, that action cannot exiſt without re-action; ſo that where there is no reſiſtance, there can be no effort. In all caſes we ſee that where the electric matter has a good conductor, it moves ſilently, and without ſhowing any marks of power whatever. If it meets with a ſmall reſiſtance it makes a ſmall effort, and a greater one if a greater reſiſtance is made, and ſo in proportion. The violence with which this fluid acts in ſome caſes, ſhows the ſtrength of the reſiſtance to it all around; for, like other fluids, we are certain that this one alſo acts with equal force all around it, and the exploſion is always made at the leaſt reſiſting part. The electric fluid of the atmoſphere, therefore, is confined by a very great power, which it is not by any means able to overcome, but which yields in a certain degree to its impulſe every moment, in proportion to the freſh ſupplies yielded by it to the earth, and which ſupplies come every moment from the ſun.

29 Of heat and cold as agents.

III. Heat and cold are very powerful agents in producing various meteors: but theſe are only relatives, and different modifications of the ſame fluid; the former being its action from a centre, the latter its action from a circumference to a centre. Though we do not know what connection there is between heat, cold, and what we call electricity, yet we know that this laſt is very much affected by them; for heat makes bodies more pervious to electricity than otherwiſe they would be, and cold makes them leſs ſo.—Hence the moſt violent electrical phenomena are obſerved in hot countries; while in the colder regions thoſe which depend on a more moderate electrification, as auroræ boreales, are more frequent. The prevalence of heat and cold in particular places, however, depends upon circumſtances which are altogether unknown to us; and therefore we cannot inveſtigate the modes of their operation in ſuch a particular manner as could be wiſhed. From what has been already ſaid, however, about the nature of the different agents concerned in meteorology, both in this article and in other parts of the work, we may take the following view of the cauſes of meteors in general.

30 Particular explanations of meteors.

1. Evaporation, combined with electricity, produces all the phenomena of vapour, fog, clouds, rain, &c.; and according as theſe two are joined to certain degrees of heat or cold, they produce dew, hoar-froſt, rain, hail, or ſnow.

The phenomena of dew and hoar-froſt ſeem to proceed from a quantity of aqueous and undecompoſed vapour which always exiſts in the atmoſphere; and which, being raiſed by mere heat, is condenſed by mere cold, without undergoing that proceſs by which water is changed into air. Hence it both aſcends and deſcends; for if we cover a ſmall ſpace of ground with plates of glaſs, they will be wetted both above and below. The reaſon of this is, that the evaporation from the ground does not ſtop immediately after the air begins to cool, eſpecially if it be covered with any thing which prevents the acceſs of the cold air, as the glaſs plates do in this caſe. The cold air, therefore, acting upon the glaſs, condenſes the vapour below it, in the ſame manner that the h[illegible] or the receiver of a retort condenſes the vap[illegible] riſe from the matter to be diſtilled. If the cold be very intenſe, hoar-froſt appears inſtead of dew; [illegible] nothing more than the dew frozen after it [illegible] the ground, in the ſame manner that the vapou[illegible] warm

warm room congeals on the inside of the windows in a frosty night. As this seems to be the whole process, it has not been observed that any electricity is concerned in the production of dew.

When the vapour has been thoroughly decomposed, and become invisible, it very frequently returns back to its pristine state, so far as to assume the appearance of mist or fog. In this case, electricity appears evidently to be concerned; for Mr Cavallo has observed that all fogs are electrified. When the process has advanced farther, and the water begins to collect into drops, the electricity is still more remarkable; and it is with great reason supposed that it is by means of electrical repulsion that the drops of rain keep at a regular distance from one another. When the cold is intense, and the electricity strong, the drops of water are frozen, and hail is produced: but snow indicates a more moderate degree of electricity; and a very violent cold, accompanied with a strongly electrical atmosphere, produces that excessively disagreeable vapour in the polar regions called *frost-smoke*, which is a general congelation of all the aqueous moisture contained in the atmosphere.

2. By violent electricity alone are produced the phenomena of thunder, lightning, fire-balls, ignes fatui, and the aurora borealis. In the phenomena of thunder, evaporation and the other agents by which rain and hail are produced are also concerned; though electricity is most remarkably so, and thunder and lightning of the most violent kind frequently occur without any rain. The ignis fatuus, aurora borealis, large fire-balls, and the smaller ones called falling-stars, seem to depend upon electricity alone, without any aid from evaporation, or from heat or cold. Aurora borealis, indeed, is most common in the northern and southern parts of the world, where the cold is intense; though this seems to be owing, not to the cold, but to the natural emission of the electrical fluid from the polar regions in much greater quantities than from others. The fire-balls commonly appear collected on the very extreme boundaries of the atmosphere, where, from the violent resistance already mentioned, the fluid is confined as it were in a concave shell, which it cannot by any means penetrate in great quantities in any particular place. Though these fire balls, therefore, contain an immense quantity of this fluid, they can only proceed in an horizontal direction, and never fly perpendicularly up from the earth, as those will sometimes do which are formed nearer the ground. The ignis fatuus seems to depend on the strong electricity of a certain portion of atmosphere, the cause of which is not well understood.

3. By the action of heat and electricity combined, are produced the phenomena of hurricanes, whirlwinds, and water-spouts. It is not, indeed, known in what manner those agents combine themselves to produce such tremendous effects; but it seems evident that electricity is concerned in them, as the sea-water becomes unusually clear before an hurricane, and many signs of electricity are likewise observed in the heavens.

4. The winds are supposed to proceed mostly from the heat of the sun rarifying the atmosphere, and occasioning a continual influx of fresh air to fill up the vacuum; but very violent winds are frequently observed where no such cause can be supposed to exist.—Thus, on the tops of high mountains the winds are commonly very violent; and mountainous countries, especially when cold, are for the most part also subject to high winds. As the tops of mountains, however, are known to be strongly electrified by their attracting and repelling the clouds, we must suppose that this electricity has a considerable share in producing the winds which are generally so violent on their tops.—This will appear the more probable, when we consider that frequently storms of wind, and those of the most violent kind, seem to be brought along with clouds; as, for instance, that mentioned under the article MALTA, in which a dreadful tempest, brought along with a cloud, almost destroyed the whole town.

Uses of meteors.

Thus we have endeavoured to give a general sketch of the doctrine of METEOROLOGY: a more particular detail of the causes by which meteors are produced is given under the names of each of them as they occur in the order of the alphabet. With regard to their uses, those of the more magnificent and tremendous kind seem to be destined to preserve the balance of the electric fluid in the atmosphere, the want of which would be productive of the most fatal effects to the world in general. The effects of the inferior ones are more confined, and are of use only to particular districts, scarcely ever extending their influence over a whole country. Thus the clouds, which produce rain for the purposes of vegetation, do not extend themselves over a whole country at once, but transitorily fly over different parts of it; so that when it is rain, for instance, in one place, it may be sunshine in another, thunder in a third, &c. It is, however, surprising to observe how equally these act over the whole of a very large tract of land; so that though there is never precisely the same weather in two places twenty miles distant from one another, yet vegetation goes on without any perceptible difference in the one as well as the other; neither, unless there be some very remarkable difference in the weather of one year from that of another, will there be any perceptible difference in the crop. For a more particular investigation of this point, however, see the articles VEGETATION and WEATHER.

For the application of meteorology to the foreknowledge of the weather, see the article WEATHER.

METEOROMANCY, a species of divination by meteors, principally by lightning and thunder. This method of divination passed from the Tuscans to the Romans, with whom, as Seneca informs us, it was held in high esteem.

METESSIB, an officer of the eastern nations, who has the care and oversight of all the public weights and measures, and sees that things are made justly according to them.

METHEGLIN, a species of mead; one of the most

Metheglin, Methodists.

most pleasant and general drinks the northern parts of Europe afford, and much used among the ancient inhabitants: (See Mead). The word is Welsh, *meddyglin*, where it signifies the same.—There are divers ways of making it; one of the best whereof follows: Put as much new honey, naturally running from the comb, into spring-water, as that when the honey is thoroughly dissolved an egg will not sink to the bottom, but be just suspended in it; boil this liquor for an hour or more, till such time as the egg swim above the liquor about the breadth of a groat; when very cool, next morning it may be barrelled up; adding to each 15 gallons an ounce of ginger, as much of mace and cloves, and half as much cinnamon, all grossly pounded; a spoonful of yeast may be also added at the bung-hole to promote the fermentation. When it has done working, it may be closely stopped up; and after it has stood a month, it should be drawn off into bottles.

METHOD, the arrangement of our ideas in such a regular order, that their mutual connection and dependence may be readily comprehended. See Logic, Part IV.

METHODISTS, in ecclesiastical history, is a denomination applied to different sects, both Papists and Protestants.

I. The *Popish Methodists* were those polemical doctors, of whom the most eminent arose in France towards the middle of the 17th century, in opposition to the Huguenots or Protestants. Those Methodists, from their different manner of treating the controversy with their opponents, may be divided into two classes. The one may comprehend those doctors, whose method of disputing with the Protestants was disingenuous and unreasonable, and who followed the examples of those military chiefs, who shut up their troops in intrenchments and strong holds, in order to cover them from the attacks of the enemy. Of this number were the Jesuit Veron, who required the Protestants to prove the tenets of their church by plain passages of scripture, without being allowed the liberty of illustrating those passages, reasoning upon them, or drawing any conclusions from them; Nihusius, an apostate from the Protestant religion; the two Walenburgs, and others, who confined themselves to the business of answering objections and repelling attacks; and cardinal Richelieu, who confined the whole controversy to the single article of the divine institution and authority of the church. The Methodists of the second class were of opinion, that the most expedient manner of reducing the Protestants to silence, was not to attack them by piecemeal, but to overwhelm them at once, by the weight of some general principle or presumption, some universal argument, which comprehended or might be applied to all the points contested between the two churches: thus imitating the conduct of those military leaders who, instead of spending their time and strength in sieges and skirmishes, endeavoured to put an end to the war by a general and decisive action. These polemics rested the defence of Popery upon prescription; the wicked lives of Protestant princes who had left the church of Rome; the crime of religious schism; the variety of opinions among Protestants with regard to doctrine and discipline; and the uniformity of the tenets and worship of the church of Rome. To this class belong Nicolle the Jansenist doctor, the famous Bossuet, &c.

Methodists.

II. The *Protestant Methodists* form a very considerable body in this country. The sect was founded in the year 1729 by one Mr Morgan and Mr John Wesley. In the month of November that year, the latter being then fellow of Lincoln college, began to spend some evenings in reading the Greek New Testament, along with Charles Wesley student, Mr Morgan commoner of Christ-church, and Mr Kirkham of Merton-college. Next year two or three of the pupils of Mr John Wesley and one pupil of Mr Charles Wesley obtained leave to attend these meetings. Two years after they were joined by Mr Ingham of Queen's-college, Mr Broughton of Exeter, and Mr James Hervey; and in 1735 they were joined by the celebrated Mr Whitefield, then in his 18th year.

At this time it is said that the whole kingdom of England was tending fast to infidelity. "It is come (says Bishop Butler), I know not how, to be taken for granted by many persons, that Christianity is not so much as a subject of inquiry, but that it is now at length discovered to be fictitious; and accordingly they treat it as if in the present age this were an agreement among all people of discernment, and nothing remained but to set it up as a principal subject of mirth and ridicule, as it were by way of reprisals, for its having so long interrupted the pleasures of the world." The Methodists are said, with great probability, to have been very instrumental in stemming this torrent. They obtained their name from the exact regularity of their lives; which gave occasion to a young gentleman of Christ-church to say, "Here is a new set of *Methodists* sprung up;" alluding to a sect of ancient physicians which went by that name. This extreme regularity, however, soon brought a charge against them, perhaps not altogether without foundation, of being too scrupulous, and carrying their sanctity to too great an height. In particular it was urged, that they laid too much stress upon the rubrics and canons of the church, insisted too much on observing the rules of the university, and took the scriptures in too literal a sense; and to the name of *Methodists* two others were quickly added, *viz.* those of *Sacramentarians* and the *Godly club*.

The principal person in this club while in its infancy appears to have been Mr Morgan, and next to him Mr John Wesley. They visited the sick, and instituted a fund for the relief of the poor; and the better to accomplish their benevolent designs, Mr Wesley abridged himself of all his superfluities, and even of some of the necessaries of life; and by proposing the scheme to some gentlemen, they quickly increased their funds to 80 l. *per annum*. This, which one should have thought would have been attended with praise instead of censure, quickly drew upon them a kind of persecution; some of the seniors of the university began to interfere, and it was reported "that the college censors were going to blow up the Godly club *." They found themselves, however, patronised and encouraged by some men eminent for their learning and virtue; so that the society still continued, though they had suffered a severe loss in 1730 in the death of Mr Morgan, who had indeed been the founder of it. In the month of October 1735, John and Charles Wesley,

* See Hervey's Life, p. 105.

Methodists. ley, Mr Ingham, and Mr Delamotte son to a merchant in London, embarked for Georgia along with Mr Oglethorpe, afterwards General Oglethorpe. The design of this voyage was to preach the gospel to the Indians. By this time, however, it appears, that Mr Wesley had embraced such notions as may without the least breach of charity be accounted fanatical. Thus in a letter to his brother Samuel, he conjures him to banish from his school "the classics with their poison, and to introduce instead of them such Christian authors as would work together with him in 'building up his flock in the knowledge and love of God."

During the voyage such a profusion of worship was observed, as we cannot help thinking savoured more of a Pharisaical than Christian behaviour; an account of which, as a similar strictness would certainly be inculcated upon the disciples, and consequently must give a just idea of the principles of the early Methodists, we shall here transcribe from Mr Wesley's Life. "From four in the morning till five each of us used private prayer; from five to seven we read the Bible together, carefully comparing it (that we might not lean to our own understandings) with the writings of the earliest ages; at seven we breakfasted: at eight were the public prayers; from nine to twelve learned the languages and instructed the children; at twelve we met to give an account to one another what we had done since our last meeting, and what we designed to do before our next; at one we dined; the time from dinner to four we spent in reading to those of whom each of us had taken charge, or in speaking to them separately as need required; at four were the evening prayers, when either the second lesson was explained (as it always was in the morning), or the children were catechised and instructed before the congregation; from five to six we again used private prayer; from six to seven I read in our cabin to two or three of the passengers, of whom there were about 80 English on board, and each of my brethren to a few more in theirs; at seven I joined with the Germans in their public service, while Mr Ingham was reading between decks to as many as desired to hear; at eight we met again, to instruct and exhort one another; between nine and ten we went to bed, when neither the roaring of the sea nor the motion of the ship could take away the refreshing sleep which God gave us."

As they proceeded in their passage, this austerity instead of being diminished was increased. Mr Wesley discontinued the use of wine and flesh; confining himself to vegetables, chiefly rice and bisket. He eat no supper; and his bed having been made wet by the sea, he lay upon the floor, and slept soundly till morning. In his Journal he says, "I believe I shall not find it needful to go to bed, *as it is called*, any more;" but whether this was really done or not, we cannot say.

The missionaries, after their arrival, were at first very favourably received, but in a short time lost the affections of the people entirely. This was owing to the behaviour of Mr Wesley himself, who appeared not only capricious but frequently despotic. He particularly gave offence by insisting upon the baptism of children by immersion; and his excessive austerity with regard to himself did not tend to give his hearers any favourable opinion either of the superior sanctity or wisdom of their teacher. At last, on account of a difference with Mr Causton the store-keeper and chief magistrate of Savannah, which ended in a law-suit, he was obliged to return to England.

Thus the cause of Methodism seemed to be entirely lost in Georgia. But Mr Wesley was soon succeeded by a more popular and successful champion, *viz.* Mr George Whitefield; who having spent his time during the voyage in converting the soldiers with whom he sailed, arrived at Savannah in Georgia on the 7th of May 1738. Here he was received by Mr Delamotte, was joined by several of Mr Wesley's hearers, and became intimate with some other ministers. Mr Ingham had made some progress in converting a few runaway Creek Indians, who had a settlement about four miles from Savannah; but being obliged to return to England in a few months, this design was frustrated, and the Indians in a few years separated. During the short time that Mr Whitefield resided at Savannah, he became extremely popular: and indeed the instances of his success in the way of making converts are very surprising. However, he was obliged to return to England in the autumn of that year, that he might receive priests orders. On his return to America in October 1739, he landed at Philadelphia, and instantly began his spiritual labours as in other places; being attended with astonishing success not only there but wherever he went. Passing through the colonies of Virginia, Maryland, North and South Carolina, the number of converts continually increased; but on his arrival at Savannah, he found the colony almost deserted. He now resumed the scheme he had formerly projected of building an orphan-house; and for this he made the first collection at Charlestown in South Carolina, amounting to about 70 l. sterling. His zeal in the cause of religion, or of the colony, were not, however, sufficient to procure him the favour of those in power. On his return to Philadelphia, after a short stay at Savannah, the churches were denied him; but he was made ample amends by the success which attended his field preachings and private efforts. Religious societies were every where set up, and many were converted with symptoms of enthusiasm, different according to their various tempers and constitutions. During this excursion, he was so successful in his collection for the orphan-house, that on his return to Savannah he brought along with him money and provisions to the value of 500l. sterling.

The success in Georgia was now greater than ever; but the many charities which it was necessary to supply, rendered it necessary in a short time for him to undertake another journey to Charlestown. Here his principles met with the greatest opposition. He had lost the favour of the commissary by his field-preaching, and was denied the sacrament. The opposition, however, was altogether fruitless; the number of converts increased wherever he went, and he now undertook a voyage to New England. In this place also the established clergy were his enemies; but the usual success attended his other endeavours, and procured 500 l. more for the use of the orphans in Georgia.

From the year 1741 to 1742 America was deprived of Mr Whitefield's preachings, he having spent that interval in England; but in 1744 he again set out for the

Methodists. the western continent. The remarkable success which had hitherto attended his labours now stirred up many opponents; and these had met with the greater success, as none of the Methodist preachers whom he had left were possessed of such abilities either to gain the favour of those who heard them, or to defend their doctrines against objections. Mr Whitefield's success, however, was the same as before: he even found means to inspire the military class with such sentiments of devotion, that Colonel Pepperell could not undertake his expedition against Louisbourg without first consulting Mr Whitefield; and great numbers of New-Englanders went volunteers, confident of victory, in consequence of the discourses of their teacher.

From the continent of America Mr Whitefield took a voyage to the Bermudas islands; and here, as every where else, he met with the most surprising success. Here also collections were made for the Orphan-house in Savannah, which were transmitted to that place.

Supposing it to be better for his cause to visit different countries, than to take up a permanent residence in one, Mr Whitefield left Bermudas in a few months, and did not return to America till 1751, when the Orphan-house was found to be in a very flourishing situation. After a short stay, he set sail again for Britain. Here he remained two years, and then set out on another visit to America, landing at Charlestown on the 27th of May 1754. His presence constantly revived the spirits and cause of his party, and added to their numbers wherever he went. Next year he returned to England; but after labouring in the usual manner, and meeting with the usual success there till the year 1763, he set sail again for America, and arrived at Virginia in the latter end of August. He now visited all the colonies, and found that great progress had been made in converting the Indians. On his arrival at Georgia, matters were found in a very flourishing situation, and he received the thanks of the governor and principal people for the great benefit he had been to the colony; which shows, that the stories which had been so industriously propagated, concerning the avarice of him and other Methodist preachers, were, partly at least, unfounded. In 1765 he returned to England; and in 1769 made his seventh and last voyage to America, landing at Charlestown on the 30th of November the same year. He was still attended with the same success; and indeed it is impossible to read, without admiration, an account of the efforts made by himself and Mr Wesley, to propagate their tenets in the different parts of the world.

For a very considerable time Mr Whitefield was the only Methodist who paid any attention to America; and in that country he was more popular than even in Europe. Towards the end of his life several Methodists having emigrated from Britain, formed distinct societies in New York and Philadelphia. These quickly increased in number; and, about the time that the war with Britain began, their numbers amounted to about 3000 in Virginia, Maryland, New York, and Pennsylvania. They would probably have increased much more, had it not been for the imprudence of some of their preachers, who introduced politics into their discourses, and thus rendered themselves obnoxious to the people among whom they lived. Among those who hurt the cause in this manner was Mr Wesley himself, who, by writing a piece intitled *A Calm Address to the American Colonies*, would in all probability have ruined it, had not a gentleman, with whom he was connected, destroyed or sent back to England the whole impression as soon as it arrived in America, so that its existence was scarce known in that continent. At the conclusion of the war, Dr Coke, who in 1776 had left a curacy in England in order to join Mr Wesley, paid a visit to his friends in America; though it had been imagined that a total separation had taken place between the American and European Methodists. This breach was, however, made up by a manœuvre of Mr Wesley; for no sooner had the Americans obtained their independence, than he, who had hitherto branded them with the name of *rebels*, sent a congratulatory letter on their freedom from the "State and the Hierarchy," and exhorting them to "stand fast in that liberty with which God had so strangely made them free." To show his zeal in their service still farther, he gave ordination, by laying on of hands, to several preachers who were to embark for America, and consecrated Dr Coke one of the bishops of the Methodist Episcopal church in that country. He extracted also from the liturgy of the English church one for the American Methodists, taking particular care to expunge every expression that had a particular respect to the regal authority.

Such proceedings in one who had formerly professed such extraordinary attachment to the English church, could not but require an apology; and this was accordingly made in a pastoral letter transmitted to the American societies, and addressed "to Dr Coke, Mr Astbury, and our brethren in North America." In this letter he makes the following defence of his conduct. "Lord King's account of the primitive church convinced me, many years ago, that bishops and presbyters are the same order, and consequently have the same right to ordain. For many years I have been importuned, from time to time, to exercise this right, by ordaining part of our travelling preachers. But I have still refused, not only for the sake of peace, but because I was determined, as little as possible, to violate the established order of the national church to which I belonged. But the case is widely different between England and North America. Here there are bishops who have a legal jurisdiction; in America there are none, neither any parish-ministers: so that for some hundred miles together, there is none either to baptize, or to administer the Lord's supper. Here, therefore, my scruples are at an end; and I conceive myself at full liberty, as I violate no order, and invade no man's right, by appointing and sending labourers into the harvest. It has indeed been proposed to desire the English bishops to ordain part of our preachers for America; but to this I object. 1. I desired the bishop of London to ordain only one, but could not prevail. 2. If they consented, we know the slowness of their proceedings; but the matter admits of no delay. 3. If they would ordain them now, they would likewise expect to govern them; and how grievously would that entangle us. 4. As our American brethren are now totally disentangled, both from the state and the English

Methodiſts. gliſh hierarchy, we dare not entangle them again either with the one or the other. They are now at full liberty ſimply to follow the ſcripture and the primitive church; and we judge it beſt, that they ſhould ſtand faſt in that liberty wherewith God has ſo ſtrangely made them free."

Dr Coke, on the conſecration of Mr Aſtbury to the office of a biſhop, made another apology. "The church of England (ſays he), of which the ſociety of Methodiſts in general have till lately profeſſed themſelves a part, did for many years groan in America under grievances of the heavieſt kind. Subjected to a hierarchy which weighed every thing in the ſcale of politics, its moſt important intereſts were repeatedly ſacrificed to the ſuppoſed advantages of England. The churches were in general filled with the paraſites and bottle-companions of the rich and great. The humble and moſt importunate intreaties of the oppreſſed flocks, yea the repreſentations of a general aſſembly itſelf, were contemned and deſpiſed. Every thing ſacred muſt bow down at the feet of a party; the holineſs and happineſs of mankind be ſacrificed to their views; and the drunkard, the fornicator, and the extortioner, triumphed over bleeding Zion, becauſe they were faithful abettors of the ruling powers. The memorable revolution has ſtruck off theſe intolerable fetters, and broken the antichriſtian union which before ſubſiſted between church and ſtate. And had there been no other advantage ariſing from that glorious epoch, this itſelf, I believe, would have made ample compenſation for all the calamities of the war; one happy conſequence of which was the expulſion of moſt of thoſe hirelings, who "eat the fat, and clothed themſelves with the wool, but ſtrengthened not the diſeaſed," &c. The parochial churches in general being hereby vacant, our people were deprived of the ſacraments through the greateſt part of theſe ſtates, and continue ſo ſtill. What method can we take in ſo critical a juncture? God has given us ſufficient reſources in ourſelves; and, after mature deliberation, we believe that we are called to draw them forth.

"But what right have you to ordain?" The ſame right as moſt of the churches in Chriſtendom; our ordination, in its loweſt view, being equal to any of the preſbyterian, as originating with three preſbyters of the church of England. "But what right have you to exerciſe the Epiſcopal office?" To me the moſt manifeſt and clear. God has been pleaſed to raiſe up, by Mr Weſley, in America and Europe, a numerous ſociety well known by the name of *Methodiſts*. The whole body have invariably eſteemed this man as their chief paſtor under Chriſt. He has conſtantly appointed all their religious officers from the higheſt to the loweſt, by himſelf or his delegate. And we are fully perſuaded there is no church office which he judges expedient for the welfare of the people entruſted to his charge, but, as eſſential to his ſtation, he has power to ordain. "But, do not you break the ſucceſſion?" The uninterrupted ſucceſſion of biſhops is a point that has long been given up by the moſt able Proteſtant defenders of epiſcopacy. Biſhop Hoadley himſelf, in his celebrated controverſy with Dr Calamy, allows it to be unneceſſary. His words are, 'To the 13th queſtion I anſwer, that I think not an uninterrupted line of ſucceſſion of regularly ordained biſhops neceſſary.' He alſo grants the authenticity of the anecdote given us by St Jerom, which informs us, that the church of Alexandria had no regular ſucceſſion from the time of St Mark the evangeliſt, the firſt biſhop of that church, to the time of Dionyſius, a ſpace of 200 years; but the college of preſbyters, on the death of a biſhop, elected another in his ſtead. We are alſo informed, from the epiſtle of St Clement to the Corinthians, written ſoon after the death of St Paul, a writer whoſe works are next in precedence to the canon of ſcripture, and probably written by immediate inſpiration, that the church of Corinth was then governed only by a college of Preſbyters. And from the epiſtle of Polycarp to the church of Philippi, written in 116, we alſo find that the Chriſtian Philippians were then governed only by a college of Preſbyters. So that the primitive Chriſtians were ſo far from eſteeming the regular ſucceſſion as eſſential to the conſtitution of a Chriſtian church, that, in ſome inſtances, epiſcopacy itſelf was wholly omitted."

Such was the defence urged by Mr Weſley for this extraordinary aſſumption of epiſcopal powers: a conduct, however, of which he afterwards repented, as tending to make a final ſeparation betwixt his followers and the church of England. Yet it does not appear that this had any bad effect on the minds of his American brethren; for Dr Coke, on his arrival on the weſtern continent, found the ſocieties numerous and flouriſhing. His firſt efforts were directed againſt the ſlave-trade; and not only the abolition of that traffic, but the releaſe of all thoſe who were actually ſlaves at the time, ſeem to have been his favourite objects. By interfering in this matter, however, perhaps with too much zeal, he involved himſelf in danger. Some riots took place, and a lady offered the mob 50 guineas if they would give the Doctor 100 laſhes. This piece of diſcipline would have been inflicted, had it not been for the interpoſition of a ſturdy colonel; and the Doctor had not only the ſatisfaction of eſcaping the intended puniſhment, but of ſeeing his doctrine ſo far attended to, that ſome ſlaves were emancipated.

Mr Hanſon, in his Memoirs of Mr Weſley, obſerves, that "the coloniſts, in the infancy of Methodiſm, conducted themſelves with more propriety than the Engliſh. There was little or no perſecution, nor any thing like a riot, except in one or two inſtances which have been mentioned as the conſequence of the animadverſions on ſlavery; and even theſe were productive of no miſchief. Not a creature was materially injured; no bones were broken, nor any lives loſt; which was not the caſe in this country. Here many thouſands of innocent people were ſubjected to the groſſeſt indignities, and ſeveral were eventually ſacrificed to the fury of their perſecutors.

"While we commend the Americans for their behaviour in oppoſition to the brutality of Engliſh mobs, it may be proper to inquire into the ſources of this diſtinction. Something of this may have ariſen from ſimilarity of ſentiment. The Americans, from the firſt beginnings of colonization, had been accuſtomed to the doctrines of the old puritans and nonconformiſts, which in many reſpects have a near affinity to the Methodiſtic tenets. The origin of Methodiſm in America

Methodists. rica was seldom, if ever, attended, either under the discourses of Mr Whitefield's or Mr Wesley's preachers, with those ridiculous effects with which it was accompanied in these kingdoms. Most of the preachers, who went over to the continent, having laboured for some years in Europe previous to their having crossed the water, had exhausted their wild-fire; so that their discourses were more scriptural and rational than those of the primitive Methodists. Another reason may be found in the education of the Americans. As a people, they are better cultivated than the body of the English; they are chiefly composed of merchants and a respectable yeomanry: and there is but a small proportion of that class so superabundant here which we distinguish by the name of *mob*.

"The only exception we have heard, to their exemption from the extravagancies which in this country marked the infancy of Methodism, is a custom they have introduced in Maryland and Virginia. Frequently, at the conclusion of a sermon, the whole congregation begin to pray and to praise God aloud. The uproar which this must create may easily be conceived. Some, we are told, are great admirers of this species of enthusiasm, in which every man is his own minister, and one sings and another prays, with the most discordant devotion. But we will not dignify such indecency with such a name. Its proper appellation is *fanaticism*. We hope, that, for the future, religion will never appear in this country under so odious a form; and greatly is it to be lamented, that, among the friends of Christianity, any such absurdities should arise, to furnish infidels with occasions of triumph."

Our author informs us, that the occupation of the Methodist preachers in America was very laborious. In the course of the day they frequently rode 20 or 30 miles, preaching twice or thrice, and sometimes to considerable congregations. Notwithstanding this labour, however, few or none of them ever thought of returning to Britain. Several reasons may be assigned for the pleasure they took in this laborious exercise. "Their excursions (says Mr Hanson) thro' immense forests abounding in trees of all sorts and sizes, were often highly romantic. Innumerable rivers and falls of water; vistas opening to the view, in contrast with the uncultivated wild; deer now shooting across the road, and now scouring through the woods, while the eye was frequently relieved by the appearance of orchards and plantations, and the houses of gentlemen and farmers peeping through the trees; formed a scenery so various and picturesque, as to produce a variety of reflection, and present, we will not say to a philosophic eye, but to the mind of every reasonable creature, the most sublime and agreeable images.

"Their worship partook of the general simplicity. It was frequently conducted in the open air. The woods resounded to the voice of the preacher, or to the singing of his numerous congregations; while their horses, fastened to the trees, formed a singular addition to the solemnity. It was indeed a striking picture; and might naturally impress the mind with a retrospect of the antediluvian days, when the hills and valleys re-echoed the patriarchal devotions, and a Seth or an Enoch, in the shadow of a projecting rock, or beneath the foliage of some venerable oak, delivered his primeval lectures, and was a "preacher of righteousness to the people." Methodists.

The American hospitality is supposed by Mr Hanson to have been another reason for the assiduity of the Methodist teachers, as well as the consciousness of being well employed, and the satisfaction resulting from considerations of public utility. As many of the preachers were men of fervent piety, this reflection would have its full weight; and the instruction of the ignorant and the reformation of the profligate would be considered as the best recompence of their labours. Spreading themselves through the continent, they took in Nova Scotia, Georgia, with the principal places in both Carolinas, Virginia, Maryland, Delaware, Pennsylvania, New Jersey, and New York; numbering upwards of 43,000 members of their society, exclusive of about 80 itinerants, and a considerable number of local preachers, who took no circuits, but assisted occasionally in the neighbourhood of their respective residence.

The large and expensive buildings which the colonists have erected for public worship, almost exceed credibility; and several colleges are founded for the instruction of youth. How far the proposed plan of uniting genuine religion and extensive learning will be carried into execution, time only can discover. It must materially depend on the character of the presidents and tutors, and the provision that shall be made for their support. Men of real erudition will never be procured at low salaries; and it is in vain to attempt establishments of this sort without a liberal provision for the professors in every branch of science. Two of these places are called *Cokesbury* and *Wesley Colleges*. How they are endowed, or whether they propose to obtain authority to confer degrees, we are not informed. But perhaps they are rather schools than colleges; which indeed is a circumstance to be wished, as good grammar-schools are of the utmost service to the progress of literature.

The great success which attended the Methodist preachers in America naturally determined Mr Wesley to try the West India islands. The Moravians had already attempted to establish their principles in some of these islands; and in 1786 some preachers were sent from the Methodists in England to the West Indies. In many of these they met with success. Societies were formed in Barbadoes, St Vincent's, Dominica, St Christopher's, Nevis, Antigua, St Eustatius, Tortola, and St Croix, amounting in all to near 5000 persons. At this time the whole number of Methodists in America and the West Indies amounted to about 48,302. These societies consist both of whites and blacks: on the continent they were mostly whites, but in the islands negroes. "But it is to be observed (says Mr Hanson) that the subjection of the negroes, and the obedience in which they are trained, must inculcate a docility peculiarly favourable to the purposes of a mission." Some of the missionaries went also to St Vincent's, where they met with some success, and have established some schools, in which their children are carefully instructed in the principles of religion.

"In January 1789 (says our author), Dr Coke paid a visit to Jamaica, and gave them several ser-

Methodists. mons. As he made but a short stay, it could hardly be considered as a fair trial. Should a mission be established here, as well as in the other islands, which will probably be the case, it is hoped, it will be the means of correcting one vice at least, and that is duelling; a savage relict of Gothic barbarity, by which all the islands have for many years been distinguished. Perhaps too it will give some check to the spirit of luxury and dissipation; and teach the planters, if it be found impracticable to emancipate their slaves, at least to treat them with humanity."

It has been debated among the leading men of the Methodistical profession, whether the cause might not be served by sending missionaries to the East Indies and to Africa; but these projects were dropped, as there was no invitation, nor any prospect of success if it had been adopted. A mission has been formed to the new settlement called *Kentucky*, on the confines of the Indian territories, near the Mississippi. The danger of the missionaries at the time they undertook this service was certainly very great; yet such was their zeal for the cause, that they voluntarily offered themselves: but we are not yet informed what success they have met with.

While Methodism was thus making rapid progress in America, its teachers were equally indefatigable in Britain. A most remarkable particular, however, occurs with regard to Mr Wesley himself; for though he had gone to Georgia, as has been already related, to convert the Indians to Christianity, yet on his return to England in 1738, he took it into his head that he, their teacher, was not yet converted: the reason was, that he had not the faith of assurance. This, however, was not long wanting. He arrived in England on the first day of February, and was blest with the assurance on the sixth of March following. This was immediately announced to the public; and the consequence, if we may believe him, was, that God then began to work by his ministry, which he had not done before. Being joined by one Kinchin, a fellow of Corpus, they travelled to Manchester, Holms-Chapel, Newcastle in Staffordshire, and other places, where they preached, exhorted, and conversed on religious subjects, in public-houses, stables, &c. sometimes meeting with success and sometimes not. During this peregrination Mr Wesley certainly displayed a great deal of superstition, which we must undoubtedly suppose to have been communicated to his hearers, and to have caused them act on many occasions in a very ridiculous manner. An instance follows:—"The next day (says he), March 11th, we dined at Birmingham, and, soon after we left it, were reproved for our negligence there (in letting those who attended us go without either exhortation or instruction) by a severe shower of hail!" About the latter end of March or beginning of April he and his companion began to pray *extempore*, leaving off entirely the forms of the church of England, to which he had formerly been so devoted. The doctrine of instantaneous conversion, which his imagination had suggested to him as a work performed on himself, was greatly received by some of his hearers, and all the converts to the new doctrine confirmed themselves, and contributed greatly to persuade others by declarations of their *experiences*, as they called them: however, though a knowledge of the saving assurance had been given on March 6th, he does not date his conversion sooner than May 24th of the same year.

This new doctrine of an instantaneous, and in fact miraculous impulse, though greatly relished by the enthusiastical part of the society, was very much disliked by others, particularly Mr Charles Wesley his brother, who warned him of the mischief he was doing; though he himself was soon converted, and, what is very astonishing, two days before John Wesley himself. The particulars related of these miraculous conversions are truly disgraceful, and could not but bring into contempt the society which consisted of such enthusiasts. "Many (says Mr Hanson) are represented as falling suddenly to the ground, in horror and agony not to be conceived, and rising again with equal expressions of peace and consolation."—Their conversions were usually attended with these violent symptoms; and, for several years, few meetings occurred where Mr Wesley presided, without one or more instances of the same kind. It was not possible that such transactions should pass without notice. The confusion that too often prevailed, the emotions of the persons affected, and the exultations of the rest, which were severally animadverted upon, gave great and general offence. Many insisted, that it must either be occasioned by the heat of the rooms, and the agitation of the animal spirits under discourses of the most alarming nature; or that it was mere artifice and hypocrisy.

In the mean time, two of the sons of a Mrs Hutton in London, happening to become converts to the new doctrine, this lady was so much offended, that she wrote to Mr Samuel Wesley, informing him, that she was of opinion his brother John had lost his senses; and requesting, that the next time he came to his house, he, Mr Samuel, would either confine or convert him. All that could be done, however, to prevent the progress of the new doctrine was insufficient; and the first Methodist society was formed in London, on the first of May 1738, when about 50 agreed to meet together once a-week for free conversation, begun and ended with singing and prayer.

All this time, however, it seems that the conversion of Mr Wesley was far from being so complete as that of many of his hearers. He had preached and converted others, while he himself was absolutely unconverted. The knowledge of the true saving faith was only revealed to him on the 6th of March, and he did not experience its power till the 24th of May; and even after this, his doubts and fears were still so great, that on the 13th of June he undertook a voyage to Germany, where, in the company of Count Zinzendorff, his faith seems to have been thoroughly confirmed.

On Mr Wesley's return, September 16th, 1738, he applied himself with the greatest assiduity and success to the propagation of his doctrine. Multitudes of converts were made in various parts of the kingdom; and the reproaches poured upon him by his opponents, seemed to have rendered his zeal more fervent if possible than before. It is remarkable, however, that some of his old friends were now so much offended with his conduct or his principles, that they absolutely refused to keep company with him. His original

Methodiſts. original plan ſeems to have been, to make an union of clergymen, and diſſeminate his principles by their means. But in this he ſucceeded ſo ill, that in a letter written in 1742, he wiſhed for a clerical aſſiſtant, were he only in deacons orders: but adds, "I know of none ſuch, who is willing to caſt in his lot with us; and I ſcarce expect I ſhall, becauſe I know how faſt they are rivetted in the ſervice of the devil and the world before they leave the univerſity."—Finding at laſt that nothing could be done with them, he was obliged to have recourſe to lay preachers; and eaſily ſelected thoſe who appeared to have the greateſt talents for prayer and exhortation in the private meetings appointed for that purpoſe. Thus he at once raiſed himſelf to be the head of a ſect; as the lay-preachers willingly yielded obedience to him who had the advantages of ſuperior learning and abilities, and was beſides in orders as a clergyman; and this obedience he did not fail on every occaſion to exact.

If his doctrine had formerly given offence to the eſtabliſhed clergy, the appointment of lay preachers was reckoned much worſe; and their being appointed without any form of ordination whatever, which almoſt all of them were, ſubjected them to contempt and reproach, which their want of learning, and very often of natural abilities, did not contribute to remove. Thus finding the churches ſhut againſt him and his followers, he was obliged to preach in the fields, and made his firſt eſſay in this way on the ſecond of April 1739, in the neighbourhood of Briſtol; Mr Whitefield having ſet him an example the day before.

The ſucceſs of thoſe ignorant and itinerant preachers, with their abſurd and uncharitable diſcourſes and behaviour, ſo provoked their adverſaries, that a perſecution was ſoon commenced againſt them. Mr Weſley himſelf was calumniated in the harſheſt manner, being ſometimes ſaid to be a Jeſuit, ſometimes an illiterate enthuſiaſt, as the people took it into their heads. Many pretended to anſwer him in writing, without being able to do ſo: the conſequence was, that their deficiency of argument was ſupplied by invective, and the moſt ſcandalous performances made their appearance. Some of the Engliſh clergy ſo far forgot themſelves as to inſtigate the mob againſt them, and the moſt cruel outrages were committed upon them in various places. For ſome time the perſecuted party adhered to the doctrines of paſſive obedience and non-reſiſtance, which their inhuman adverſaries did not fail to take the advantage of.—The leſs they were oppoſed, the more inſolent they became. The Methodiſts were frequently in danger of their lives. Men, women with child, and even children, were knocked down and abuſed with the ſame undiſtinguiſhing fury. Houſes were ſtripped of their furniture, vaſt quantities of furniture carried off, feather-beds cut in pieces and ſtrewed over the ſtreets, ſeveral reputable people were forced into the army, &c. To the diſgrace of magiſtracy alſo it was found, that when application was made to the juſtices of the peace, redreſs was commonly denied; nor was a ſtop put to theſe ſhameful proceedings without a royal mandate for the purpoſe.

From the year 1738 to 1747 Mr Weſley and his itinerants were employed in various parts of England. In 1747 he went over to Dublin, where a ſociety had been formed by one Mr Williams a clergyman.—Here they proved ſo ſucceſsful, notwithſtanding the number of Papiſts, and the violence of their other opponents, that in 1750 they had erected meeting-houſes in every part of the kingdom, and had formed 29 circuits, which employed 67 itinerants, beſides a conſiderable number of local preachers. An invitation was given to Mr Weſley, in 1751, to viſit Scotland, by an officer in quarters at Muſſelburgh. He accordingly took a journey thither the ſame year; but left the place, after preaching in it once or twice. In 1753 he returned to Scotland, and viſited Glaſgow. Societies were at length formed in that city, as well as at Edinburgh, Dundee, Aberdeen, Inverneſs, and a few other places: but his ſucceſs was by no means equal to what it had been in other parts; for in 1790 the number of circuits in Scotland was no more than eight, which were ſupplied by 20 itinerants.

Mr Whitefield, the other great labourer in the vineyard, was equally indefatigable, and probably more ſucceſsful than Mr Weſley. Before entering into orders, he had formed a ſociety of religious perſons at Glouceſter: here he preached his firſt ſermon on the Neceſſity and Benefit of Religious Society; here he became extremely popular, as well as at Briſtol and London, while preparing to ſet ſail for Georgia for the firſt time; and in all places to which he came, large collections were made for the poor. He maintained the ſame doctrine with Mr Weſley as to the new birth; which likewiſe gave offence to the clergy when delivered by him, as it had done with Mr Weſley. In the various intervals of his voyages to America, he employed himſelf with the very ſame aſſiduity in Britain and in Ireland, which we have already taken notice of in the weſtern continent. His ſucceſs was every where prodigious. In 1741 he was invited to Scotland, and preached his firſt ſermon there at Dunfermline. From thence he went to Edinburgh, and preached in ſeveral of the eſtabliſhed churches, but differed with Meſſrs Ralph and Ebenezer Erſkines; ſo that he, as well as Mr Weſley, proved unſucceſsful in forming a coalition with any other religious party. In the private way, however, his ſucceſs was very conſiderable, at Edinburgh, Glaſgow, Aberdeen, Dundee, and other places. In 1742 he paid a ſecond viſit to Scotland, and a third one in 1748. In 1751 he viſited Ireland for the firſt time; and preached to great multitudes without being moleſted, even in places where others had been mobbed. From thence he returned to Scotland the ſame year, and ſpeaks in very favourable terms of the attention the people there paid to their bibles. In 1752 and 1753 he again viſited the ſame kingdom, and the laſt time diſtinguiſhed himſelf by preaching againſt the playhouſe in Glaſgow. In 1756 he returned; and by his animated diſcourſes at Edinburgh againſt Popery and arbitrary power, was owned to have contributed very much to the increaſe of courage and loyalty in this country. Next year he again viſited the Scottiſh capital during the time that the General Aſſembly ſat, and his ſermons were attended by ſeveral of the members. At Glaſgow he made a large collection for the poor of that city, and from thence took a

Methodists. a voyage to Ireland. He was received with the usual affection by the lower classes of Protestants; but the Popish rabble, exasperated at his success, almost murdered him with stones. After passing through a great part of Ireland, visiting England and Wales, he paid another visit to Scotland, where four clergymen now lent him their pulpits. His last visit was in the summer of 1758, where his congregations were as large as ever; and it is to his endeavours principally that we are to ascribe the great number of Methodist societies now existing in Scotland.

With regard to the religious principles of the Methodists, we cannot enter into any particular detail; neither indeed are there any doctrines peculiar to all included under that name, except the single one of salvation by faith without works. In March 1741, Mr Whitefield being returned to England, entirely separated from Mr Wesley and his friends, "because he did not hold the decrees."—Here was the first breach, which warm men persuaded Mr Whitefield to make, merely for a difference of opinion. Those indeed who believed universal redemption, had no desire at all to separate: but those who held particular redemption, would not hear of any accommodation, being determined to have no fellowship with men that "were in such dangerous errors." So there were now two sorts of Methodists so called; those for particular, and those for general, redemption.

History of Methodism, &c.

Not many years passed, before William Cudworth and James Relly separated from Mr Whitefield.—These were properly Antinomians, absolute avowed enemies to the law of God, which they never preached or professed to preach, but termed all *Legalists* who did. With them, preaching the law was an abomination. They had nothing to do with the law. They would preach Christ, as they called it; but without one word either of holiness or good works. Yet these were still denominated *Methodists*, although differing from Mr Whitefield both in judgment and practice, abundantly more than Mr Whitefield did from Mr Wesley.

In the mean time, Mr Venn and Mr Romaine began to be spoken of: and not long after Mr Madan and Mr Berridge, with a few other clergymen, who, although they had no connection with each other, yet preaching salvation by faith, and endeavouring to live accordingly, to be Bible-Christians, were soon included in the general name of *Methodists*. And so indeed were all others who preached salvation by faith, and appeared more serious than their neighbours. Some of these were quite regular in their manner of preaching: some were quite irregular, (though not by choice; but necessity was laid upon them, they must preach irregularly, or not at all): and others were between both; regular in most, tho' not in all particulars.

In 1762, George Bell and a few other persons began to speak great words. In the latter end of the year they foretold that the world would be at an end on the 28th of February. Mr Wesley, with whom they were then connected, withstood them both in public and private. This they would not endure: so, in January and February 1763, they separated from him, under the care of Mr Maxfield, one of Mr Wesley's preachers. But still Mr Maxfield and his adherents, even the wildest enthusiasts among them, go under the general name of *Methodists*, and so bring a scandal upon those with whom they have no connection.

At present, those who remain with Mr Wesley are mostly Church-of-England men. They love her articles, her homilies, her liturgy, her discipline, and unwillingly vary from it in any instance. Meantime, all who preach among them declare, *we are all by nature children of wrath*, but *by grace we are saved through faith*; saved from both the guilt and from the power of sin. They endeavour to live according to what they preach, to be plain Bible-Christians; and they meet together at convenient times, to encourage one another therein. They tenderly love many that are Calvinists, though they do not love their opinions. Yea, they love the Antinomians themselves; but it is with a love of compassion only, for they hate their doctrines with a perfect hatred; they abhor them as they do hell-fire: being convinced nothing can so effectually destroy all faith, all holiness, and all good works.

We shall conclude this article with the words of Mr Hanson, which must certainly be accounted just, whatever objections may be made to some parts of the principles or behaviour of the Methodists. "If they possess not much knowledge, which, however, we do not know to be the case, it is at least certain, they are not deficient in zeal: and without any passionate desire to imitate their example, we may at least commend their endeavours for the general good. Every good man will contemplate with pleasure the operation of the spirit of reformation, whether foreign or domestic; and will rejoice in every attempt to propagate Christianity in the barbarous parts of the world: An attempt which, if in any tolerable degree successful, will do infinitely more for their civilization and happiness, than all the united energies of those boasted benefactors of mankind, the philosophic infidels."

Methodists (*Methodici*), in the history of medicine, a sect of ancient physicians, who reduced the whole art of healing to a few common principles or appearances. The Methodists were the followers of Thessalus; whence they were also called *Thessalici*. They were strenuously opposed by Galen in several of his writings; who scrupled not to assert, that the methodical heresy ruined every thing that was good in the art.

Quincy mistakenly uses *Methodists (Methodici)* for those physicians who adhere to the doctrine of Galen, and the schools; and who cure with bleeding, purges, &c. duly applied according to the symptoms, circumstances, &c. in opposition to empirics and chemists, who use violent medicines, and pretended secrets or nostrums.

METHODIUS, a father of the church, bishop of Olympus or Patara in Lycia, and afterward of Tyre in Palestine, suffered martyrdom at Chalcis in Greece towards the end of Dioclesian's persecution in the year 302. He composed many works in a clear and elaborate style, which were extant in Jerome's time. Father Combesis collected several considerable fragments of this writer, cited by Epiphanius, Photius, and others;

others; and printed them with notes of his own, together with the works of Amphilochius, and Andreas Cretenfis, in folio, Paris 1644.

METHUSELAH, the fon of Enoch and father of Lamech, was born in the year of the world 687, begat Lamech in 874, and died in 1656, being the very year of the deluge, at the age of 969, which is the greateft age that has been attained to by any mortal man upon earth (Gen. v. 21, 22, &c.) According to the text of the feptuagint, Methufelah muft have lived 14 years after the deluge; and according to other copies, he died fix years before it: but it is generally agreed on, that thefe copies, as well as the feptuagint, are corrupted in this place.

METHYMNA (anc. geog.), a town of the ifland of Lefbos. It was the fecond city of the ifland in greatnefs, population, and opulence. Its territory was fruitful, and the wines it produced excellent. It was the native place of Theophraftus, and of Arion the mufician. When the whole ifland of Lefbos revolted from the power of the Athenians, Methymna alone remained firm to its ancient allies.

METIUS (James), of Alcmaer, in Holland, the inventor of telefcopes with glaffes, one of which he prefented to the States-General in 1609. Tubes, extended, by uniting them, to a great length, were known to the ancients; but Metius was the firft who added glaffes, and he was indebted to chance for the difcovery: he had frequently obferved fome fchoolboys playing upon the ice, who made ufe of their copy books rolled up in the fhape of tubes, to look at each other, to which they fometimes added pieces of ice at each end, to view diftant objects: this led him to the invention of optic glaffes.

METO, a famous mathematician of Athens, 432 B. C. publifhed his *Ennea decaterides*, that is, his "Cycle of Ninteen Years," by which he endeavoured to adjuft the courfe of the fun to that of the moon, and to make the folar and lunar years begin at the fame point of time.

METŒCI, a name given by the Athenians to fuch as had their fixed habitations in Attica, though foreigners by birth. The *metœci* were admitted by the council of Areopagus, and entered in the public regifter. They differed both from the πολιται and ξενοι; becaufe the *politæ* or "citizens" were freemen of Athens, and the *xeni* or "ftrangers" had lodgings only for a fhort time; whereas the *metœci*, though not freemen of Athens, conftantly refided upon the fpot whether they had removed.

METONYMY, in rhetoric, is a trope in which one name is put for another, on account of the near relation there is between them. See ORATORY, n° 51.

METOPE, in architecture, is the interval or fquare fpace between the triglyphs of the Doric freeze, which among the ancients ufed to be painted or adorned with carved work, reprefenting the heads of oxen or utenfils ufed in facrifices.

METOPOSCOPY, the pretended art of knowing a perfon's difpofitions and manners by viewing the traces and lines in the face. Ciro Spontoni, who has written exprefsly on metopofcopy, fays, that feven lines are examined in the forehead, and that each line is confidered as having its particular planet: the firft is the line of Saturn, the fecond of Jupiter, the third of Mars, &c. Metopofcopy is only a branch of phyfiognomy, which founds its conjectures on all the parts of the body.

METRE, μετρον, in poetry, a fyftem of feet of a juft length.

The different metres in poetry, are the different manners of ordering and combining the quantities, or the long and fhort fyllables: thus hexameter, pentameter, iambic, fapphic verfes, &c. confift of different metres or meafures. See HEXAMETER.

The Englifh verfes, the metres are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleafes. The moft ufual are the heroic, generally confifting of five long and five fhort fyllables, and verfes of four feet, and of three feet, and a cæfura or fingle fyllable.

The ancients, by varioufly combining and tranfpofing their quantities, made a vaft variety of different meafures, by forming fpondees, &c. of different feet. See POETRY.

METRETES, a Grecian meafure, containing fomething more than nine Englifh gallons. See MEASURE.

METRICAL VERSES, are thofe confifting of a determinate number of long and fhort fyllables; as thofe of the Greek and Latin poets.—Capellus obferves, that the genius of the Hebrew language is incompatible with metrical poetry.

METRODORUS, a Greek phyfician, born at Chios, was the difciple of Democritus the philofopher, and the mafter of Hippocrates the phyfician and Anaxarchus the philofopher. He maintained that the univerfe is infinite and eternal: but his works are loft. He lived about 444 B. C.

METROCOMIA (from μητηρ *mother*, and κωμη *town* or *village*), a term in the ancient church-hiftory, fignifying "a borough or village that had other villages under its jurifdiction."—What a metropolis was among cities, a *metrocomia* was among country towns. The ancient *metrocomiæ* had each its choriepifcopus or rural dean, and here was his fee or refidence. See METROPOLIS and CHORIEPISCOPUS.

METRONOMI, the name given by the Athenians to five officers in the city and ten in the *piræus*, whofe duty it was to infpect all forts of meafures except thofe of corn. The *piræus* was the greateft mart in Attica.

METROPOLIS (from μητηρ *mother*, and πολις *city*), the capital of a country or province; or the principal city, and as it were mother of all the reft.

The term METROPOLIS is alfo applied to archiepifcopal churches, and fometimes to the principal or mother-church of a city. The Roman empire having been divided into 13 diocefes and 120 provinces, each diocefe and each province had its metropolis or capital city, where the proconful had his refidence. To this civil divifion the ecclefiaftical was afterwards adapted, and the bifhop of the capital city had the direction of affairs, and the pre-eminence over all the bifhops of the province. His refidence in the metropolis gave him the title of *metropolitan*. This erection of metropolitans is referred to the end of the third century, and was confirmed by the council of Nice.

Metulum || Meulen.

A metropolitan has the privilege of ordaining his suffragans; and appeals from sentences passed by the suffragans are preferred to the metropolitan.

METROPOLIS (anc. geog.), a town of Acarnania, a little to the south of Stratos.—Another, of Lydia; situated between Colophon and Priene, near the Cayster.—A third of Phrygia; sacred to the mother of the gods, who was here worshipped.—A fourth Metropolis of Estiotis, a district in Thessaly, to the east of Gomphi, and the last town of that district. *Metropolitæ*, the people.

METULUM (anc. geog.), a considerable city of Liburnia, at the siege of which Octavius Cæsar was wounded. Said to be the metropolis, and situated on two eminences, intersected by a valley (Appian.) Now generally thought to be *Metling* in Carniola. E. Long. 16. N. Lat. 46. 5.

METZ, an ancient, large, and strong town of France, and capital of the territory of Messin, with a citadel, a parliament, and a bishop's see, whose bishop assumes the title of a prince of the empire. The cathedral church is one of the finest in Europe, and the square called *Coslin* and the house of the governor are worth seeing. The Jews live in a part of the town by themselves, where they have a synagogue. The sweetmeats they make here are in high esteem. It is seated at the confluence of the rivers Moselle and Seille. E. Long. 6. 16. N. Lat. 49. 7.

METZU (Gabriel), an eminent painter, was born at Leyden in 1615. His subjects were usually taken from low life; but they were all designed after nature, and surprisingly well represented; such as women selling fish, fowls, or hares; sick persons attended by the doctor; chemists in their laboratories; dead game, painters rooms, shops, and drawing schools hung with prints and pictures; all which subjects he composed well, and finished them with extreme neatness, as he likewise did his portraits. He spent a great deal of time on his pictures, which has occasioned their scarcity and dearness at this time; and besides, it is confidently said, the Dutch prevent their being carried out of their own country, as much as possible. So that those paintings of Metzu, which are sometimes seen in the collections of our kingdoms, are either obtained by chance, or purchased at large prices. Though it ought also to be remembered, that the value set upon the works of this master throughout Holland and Flanders, has induced several painters to endeavour at imitating and copying his works, which having gradually circulated abroad and being a little mellowed by time, are now called originals. He died in 1658.

MEVANIA (anc. geog.), a town of the Cisappenine Umbria; seated at the confluence of the Tina and Clitumnus, on the Via Flaminia, famous for its herds of white cattle brought up there for sacrifice; the white colour said to be owing to the waters of the Clitumnus (Virgil). Mevania was the country of Propertius. *Mevenates* the people. Now said to be *Bevagna*, in the territory of the Pope.

MEULEN (Anthony Francis Vander), painter of battles, &c. was born at Brussels in 1634; and was a disciple of Peter Sneyers, a battle-painter of considerable note. Some of his compositions happening to be carried to Paris, were shown to M. Colbert; who soon discerned the abilities of Vander Meulen, and by his generous offers induced him to leave his native city and settle at Paris. Here he was employed by Louis XIV. and had an appointment of 2000 livres pension, beside being paid for his work. He attended that monarch in most of his expeditions in the field, and designed on the spot the sieges, attacks, encampments, and marches, of the king's armies, also the views of those cities and towns memorable by any degree of success; and from those sketches he composed the paintings, which were intended to perpetuate the remembrance of those military exploits. He died in 1690. The principal works of this master are at Versailles and Marli; but many of his easel pictures are dispersed through England, France, and Flanders.

MEURSIUS (John), a learned and laborious writer, born at Losdun, near the Hague, in 1579. He early discovered a fondness for polite literature and the sciences; and went to study the law at Orleans with the son of Barneveldt, whom he accompanied in his travels. In 1610 he was made professor of history at Leyden, and afterwards Greek professor. In the following year, the magistrates of the United Provinces proved how high their opinion was of his abilities, by fixing on him to write the history of his country. Meursius married in the year 1612. His wife, Anna Catherina Bilberbeccia, descended from a very ancient and noble family in Angermond a city of Pomerania, possessed many amiable qualities, and rendered his domestic life remarkably happy, while he discharged the duties of his professorship with an assiduity equal to his abilities. At the same time the republic of letters did not lose the advantages to be derived from his labours; for during the fourteen years of his residence at Leyden, the works which he published were more numerous than those which had been presented to the world by the whole body of professors from the original foundation of the university in 1575.

Meursius's writings had now disseminated his reputation in every part of Europe; nor had the fame of his diligence and talents as a professor spread with less rapidity. In so high a rank, indeed, did he stand among his literary contemporaries, that Christian IV. king of Denmark conferred on him the place of historiographer royal, and invited him to undertake the professorship of history and politics in the academy of Sora, which was founded by King Frederick II. although the revival of its honours and dignities may be dated from this period, when it seemed to be again founded under the auspices of Christian IV. Meursius and his family left Leyden in the year 1635. On his arrival at Sora, he was received with the most friendly tokens of regard by his Majesty and the Danish nobility, and more particularly by Chancellor Rosenkrantz, on whom he has bestowed very ample praises in one of his letters. Here he resided, equally beloved and admired, for above twelve years. His pupils were not very numerous, but his exertions never relaxed. Those hours likewise which were not devoted to the duties of his professorship, he employed in revising the works of the ancients, and in philological disquisitions.

His health was not much impaired by the intenseness of application; but in the year 1638 he had a violent attack of the stone, from which disorder he had

had suffered severely before. In a letter to Vossius he thus describes his melancholy condition: "The state of my health during the whole of the last winter has been truly deplorable. My sufferings from the stone have been really dreadful. I have voided so many, that the repeated discharges brought on a wound which emitted blood for above four months. I was next attacked by a tertian fever, which increased constantly, and produced an universal lassitude of body, a dejection of spirits, and a total loss of appetite. But, thank heaven, I have now in some measure recovered my strength, and gotten the better of these complaints." He recovered from this attack; but in the following year the disorder returned with redoubled violence, and brought on a consumption which terminated his existence on the 20th day of September 1639. He left behind him a son who was named after him, and one daughter.

So mild were the dispositions of Meursius, that in all his writings he constantly avoided literary disputes. He was sometimes unavoidably drawn into them; but constantly endeavoured to promote a reconciliation, rather than widen any breach, by his replies to the attacks of his adversaries. In his friendships he was firm and affectionate. Of his domestic life, whatever is known has been gathered from his letters. The same easy tranquillity seems to have attended him in every situation. In his family he was particularly fortunate. In his son, to whom he gave his own name, he seemed to behold his own youth renewed. The same application, the same eagerness in the pursuit of knowledge, marked the conduct of this promising young man; who did not long survive his father, but died soon after he had recommended himself to the notice of the learned world by his publications. They were only three in number; but displayed so much solid learning, that they have been assigned to the father, John Meursius, by Labbe Beughem and others. This mistake was occasioned as much by the similitude of their names, as by the nature of their works, and their manner of treating philological subjects.

His works may be divided into four classes, of which each might form a separate volume if they were ever to be republished. Meursius himself indeed, in one of his letters to Vossius, proposes such a division. From that epistle, and from another which the younger Meursius sent to G. I. Vossius, who strongly advised him to republish the whole of his father's writings, and from the collections of his posthumous works which have appeared from Struvius, Groschupsius, Moller, and some others, a catalogue of his works might be formed. Some assistance will also be derived from the indexes published in their respective works, by Hankins, Dessclius, Wettenius, and Bartholinus. The plan which Meursius recommends for publishing his works, is to insert in the first volume all that he has written relative to Athens; in the second, his historical pieces; in the third, his miscellaneous dissertations; and in the fourth, the various authors which he published, with his notes and corrections.

Before we conclude, one mistake with respect to this great scholar, which prevails very generally, must be corrected. A scandalous and indecent work, which is intitled *Meursii elegantiæ Latini sermonis*, and has *Aloisiæ Sigeæ Satyræ Sotadicæ* annexed to it, is very falsely attributed to Meursius; nor indeed are the *Satires* with more reason assigned to Aloisia Sigea, who was a Spanish lady eminent for her piety and virtue. The real author of these infamous productions was Westrenius, an advocate at Copenhagen, who probably assumed the name of Meursius, in order to shield himself from the disgrace which would naturally have attended the writer of such a performance. To insure the sale of his book, however, might have been the principal view of Westrenius. At any rate, such a conclusion may be fairly deduced from the disguised title, and from his desire that the world should affix it to a character so distinguished and respectable in almost every branch of various literature.

MEW, Sea-mew, or *Sea-mall*. See Larus.

Winter-Mew, or *Coddy-moddy*, in ornithology. See Larus.

MEWING, the falling off or change of hair, feathers, skin, horns, or other parts of animals, which happens in some annually, in others only at certain stages of their lives: but the generality of beasts mew in the spring. An old hart casts his horns sooner than a young one, which is commonly in the months of February and March, after which they begin to button in March or April: and as the sun grows strong, and the season of the year puts forth the fruits of the earth, so their heads grow, and are summed full by the middle of June. It is to be observed, that if a hart be gelt before he has a head, he will never have any; and if he be gelt after he has a head, he will never cast his horns; again, if he be gelt when he has a velvet-head, it will always be so, without fraying or burnishing.

Mew || Mexico.

MEXICO, a province of the Spanish empire in America, once a celebrated kingdom, the most powerful and civilized in the New World.

1 Kingdoms into which Mexico was anciently divided.

In former times the country now distinguished by the name of the *Vale of Mexico*, was called *Anahuac*, the rest of it being divided into the kingdoms of *Mexico*, *Acolhuacan*, *Tlacopan*, and *Michuacan*; the republics of *Tlaxcallan*, *Chololan*, *Huexotzinco*, and some other states. Of these the most westerly was Michuacan, which to the east and south had Mexico; on the north the country of the Chichemecas, and some other barbarous nations; on the west the lake of Chapallan, and some independent tribes. It had four considerable cities; the capital being seated on the eastern shore of a beautiful lake named *Pazcuaro*. The kingdom of Tlacopan lay betwixt Mexico and Michuacan, and was of very small extent; its capital was seated on the western border of a lake called *Tezcuco*, four miles westward of that of Mexico. Acolhuacan was the most extensive as well as the most ancient. It was bounded on the east by the republic of Tlaxcallan; on the south by a province of Mexico named Chalco; on the north by the country of the Huaxtecas; and on the west by other states of Mexico, terminating at the lake Tezcuco. Its length from south to north was somewhat more than 200 miles, and its breadth about 60; it was very populous, and had a great many cities. On the eastern bank of the lake of Tezcuco was situated the capital of that territory, 15 miles to the eastward of that of Mexico; and no less celebrated for its antiquity than the politeness and civilization of its inhabitants. Tlaxcallan, or Tlascala, a celebrated republic, had Acolhuacan to the west;

the

the republics of Chollolan and Huexotzinco to the ſouth; and ſome of the Mexican ſtates on the north and eaſt. It was but of ſmall extent; not reaching more than 50 miles in length and 30 in breadth. Its capital ſtood on the ſide of a great mountain, about 70 miles to the eaſtward of Mexico. The kingdom of Mexico, though the moſt modern, came at laſt to be the moſt extenſive of the whole. On the ſouth and ſouth-weſt it extended as far as the Pacific Ocean; on the eaſt it was bounded by the republics of Tlacopan and Michuacan; on the north by the country of the Huextacas; and on the north-weſt by the country of the Chichemecas; the whole being comprehended between the 14th and 21ſt degrees of north latitude, and between 271 and 283 of longitude, computed from the meridian of Ferro.

2 Uncertainty of the origin of the Mexicans.

If the origin of the nations on the eaſtern continent is obſcure, that of the inhabitants of the weſtern continent is much more ſo; and indeed, till very lately, the hiſtory of every one of the American nations, till the arrival of the Spaniards, has been either treated as entirely fabulous, or very ſlightly touched upon by hiſtorians. By the induſtry of the Abbé Franceſco Clavigero, however, we are now furniſhed with an account of the ancient kingdoms juſt enumerated; more full and authentic than could have been expected, conſidering the difficulty there muſt have been of procuring materials.

3 They came from the north.

According to this gentleman, it is undeniable that Mexico was firſt peopled from the more northerly parts of the continent, which for many ages had been filled with inhabitants. Some have ſuppoſed, from the traditions of the natives, and the diſcovery of very large human ſkeletons in many parts of New Spain, that this country was firſt inhabited by giants: but though ſimilar conjectures and diſcoveries have been made in other countries, we are by no means warranted from thence to conclude that the whole human race were formerly of an immenſe ſize; it being moſt probable, as our author obſerves, that the gigantic race were but a few individuals who lived at different times and in different nations.

4 Toltecans the firſt inhabitants.

The Toltecans are the moſt ancient Mexican nation of which we know any thing. They were expelled, as we are told, from their own country (ſuppoſed by Clavigero to have been *Tollan*, to the northward of Mexico) in the year 472; and for ſome time led a migratory and wandering life. In whatever place they determined to reſide for any conſiderable time, they erected houſes and cultivated the ground. Thus their migrations were extremely ſlow, and it was not till 104 years after they ſet out that they reached a place about 50 miles to the eaſtward of the city of Mexico, where they ſettled for 20 years, giving to their new place of reſidence the name of *Tollantzinco*. From thence they proceeded about 40 miles farther to the weſt, where they built a city called, from the name of their country, *Tollan*, or *Tula*.

5 Their hiſtory.

The Toltecans, during their journeys, were conducted by a number of chiefs; who, by the time they arrived at Tollantzinco, were reduced to ſeven, and, after their final ſettlement, the government was changed into a monarchy; but by what means, or on what account, we are not told. Their firſt king began his reign in 667, and their monarchy laſted 384 years, during which time they reckon juſt eight princes. We are not, however, to imagine that each of their kings lived long enough to make up this ſpace. It was a cuſtom among them that the name of the king ſhould be continued for 52 years, and no longer, from the time he aſcended the throne. If he died within that period, the government was carried on in his name by a regency; if he ſurvived, he was obliged to reſign his authority. During the four centuries that the Toltecan monarchy continued, they had increaſed very conſiderably in number, and had built many cities; but when in the height of proſperity, almoſt the whole nation was deſtroyed by a famine occaſioned by drought; and a peſtilence, probably the conſequence of the former. "According to Torquemada (ſays our author), at a certain feſtival-ball made by the *Toltecas*, the *ſad looking* devil appeared to them of a gigantic ſize, with immenſe arms, and in the midſt of the entertainment he embraced and ſuffocated them; that then he appeared in the form of a child with a putrid head, and brought the plague; and, finally, at the perſuaſion of the ſame devil, they abandoned the country of Tula."

Theſe ſtories, according to Clavigero, are taken from the ſymbolical repreſentations or hieroglyphics, by which this piece of hiſtory was repreſented, and which the Spaniſh author has taken literally. Be the cauſe what it will, however, it is certain that the ſurviving Toltecans abandoned their country, and diſperſed themſelves among the ſurrounding nations, where they were well received, on account of their ſuperior knowledge and civilization. They were ſucceeded by the Chichemecas, a much more barbarous people, who came from an unknown country called *Amaquemecan*, where they had for a long time reſided; but of which no traces or remembrance can be found among any of the American nations known to Europeans; ſo that Clavigero ſuppoſes it muſt have been very far to the northward.

6 Succeeded by the Chichemecas.

The motive which the Chichemecas had for leaving their own country is not known. They were eighteen months on their journey, and took poſſeſſion of the deſolate country of the Toltecas about an hundred years after the former had left it. They were much more uncivilized than the Toltecans; but, however, had a regular form of monarchical government, and in other reſpects were leſs diſguſting in their manners than ſome of the neighbouring nations. The laſt king who reigned in Amaquemecan before the departure of the Chichemecas, had left his dominions between his two ſons Auchcauhtli and Xolotl, and the latter conducted the new colony. Having proceeded from the ruins of Tula towards Chempoalla and Tepepolio, Xolotl ſent his ſon to ſurvey the country. The prince croſſed the borders of the lakes and the mountains which ſurround the vale of Mexico; then aſcending to the top of a very high one, he viewed the whole country, and took poſſeſſion of it in the name of his father, by ſhooting four arrows to the four winds.

7 Xolotl firſt king.

Xolotl being informed by his ſon of the nature of the country, choſe for the capital of his kingdom Tenayuca, about ſix miles to the northward of the city of Mexico, and diſtributed his people in the neighbouring territory; but as moſt of them went to the northward, that part obtained the name of the country.

try of the Chichemecas, in diſtinction from the reſt. Here a review of the people was taken, and their number, according to Torquemada, was more than a million. In confirmation of this the hiſtorian adds, that in his time there were ſtill remaining twelve piles of the ſtones they threw to aſcertain their numbers; but Clavigero thinks it improbable that ſo large an army ſhould ſet out on ſo long an expedition, or that ſo ſmall a diſtrict could maintain ſo many hunters.

Xolotl finding himſelf peacefully ſettled in his new dominion, ſent one of his officers to explore the ſources of ſome of the rivers of the country. While performing this taſk he came to the habitations of ſome Toltecans, who it ſeems had ſtill kept together, and were likely once more to become a nation. As theſe people were not inclined to war, and greatly eſteemed for their knowledge and ſkill in the arts, the Chichemecas entered into a ſtrict alliance with them, and Prince Nopaltzin, who had firſt ſurveyed the country, married a Toltecan princeſs. The conſequence of this alliance was the introduction of the arts and knowledge of the Toltecans among the Chichemecas. Till now the latter had ſubſiſted entirely by hunting, and ſuch fruits and roots as the earth ſpontaneouſly produced. They were clad in the ſkins of wild beaſts, and, like theſe beaſts, they are ſaid to have ſucked the blood of the animals they caught; but after their connection with the Toltecans they began to ſow corn, to learn the art of digging and working metals, to cut ſtones, manufacture cotton, and, in every reſpect, to make great improvements.

When Xolotl had reigned about eight years in his new territories, an embaſſy of ſix perſons arrived from a diſtant country not far from *Amaquemecan*, expreſſing a deſire of coming with their people to reſide in the country of the Chichemecas. The king gave them a gracious reception, and aſſigned them a diſtrict; and, in a few years after, three other princes, with a great army of Acolhuans, who were likewiſe neighbours of Amaquemecan, made their appearance. The king was at that time at Tezcuco, to which place he had removed his court: and here he was accoſted by the princes, who, in a ſubmiſſive and flattering manner, requeſted him to allow them a place in his happy country, where the people enjoyed ſuch an excellent government. Xolotl not only gave them a favourable reception, but offered them his two daughters in marriage, expreſſing his concern that he had no more, that none might have been excluded from the royal alliance. On the third prince, however, he beſtowed a noble virgin of Chalco, in whom the Toltecan and Chichemecan blood were united. The nuptials were celebrated with extraordinary pomp; and the two nations, after the example of the ſovereigns, continued to intermarry. As the Acolhuans were the more civilized nation of the two, the name of Chichemecas began to be appropriated to the more rude and barbarous part, who preferred hunting to agriculture, or who choſe a life of ſavage liberty in the mountains to the reſtraints of ſocial laws. Theſe barbarians aſſociated with the Otomies, another ſavage nation who lived to the northward, occupying a tract of more than three hundred miles in extent; and by their deſcendants the Spaniards were haraſſed for many years after the conqueſt of Mexico.

As ſoon as the nuptial rejoicings were over, Xolotl divided his territories into three parts, aſſigning one to each of the princes. Acolhuatzin, who had married his eldeſt daughter, had Azcopazalco, 18 miles to the weſtward of Tezcuco; Chiconquauhtli, who married the other, had a territory named Xaltocan; and Tzontecomatl, who married the lady of inferior rank, had one named Coatlichan. The country continued for ſome time to flouriſh, population increaſed greatly, and with it the civilization of the people; but as theſe advanced, the vices of luxury and ambition increaſed in proportion. Xolotl found himſelf obliged to treat his ſubjects with more ſeverity than formerly, and even to put ſome of them to death.—This produced a conſpiracy againſt him, which, however, he had the good fortune to eſcape; but while he meditated a ſevere revenge on the conſpirators, he was ſeized with the diſtemper of which he died, in the fortieth year of his reign, and in a very advanced age. His corpſe was adorned with various figures of gold and ſilver, and placed in a chair made of gum copal and other precious ſubſtances, where it remained five days, until the lords ſummoned to the funeral attended. The body was then burnt, and the aſhes depoſited in an urn of the hardeſt ſtone. This urn was kept expoſed in the palace for forty days, during which time the nobility attended with lamentations; after which it was carried to a cave in the neighbourhood, with ſimilar demonſtrations of grief.

11 Nopaltzin the ſecond king.

Xolotl was ſucceeded by his ſon Nopaltzin, who at the time of his acceſſion is ſuppoſed to have been about fifty years of age. In his time, the tranquillity of the kingdom, which had begun to ſuffer diſturbance under his father, underwent much more violent ſhocks, and civil wars took place. Alcohuatzin, the only one of the three princes who remained alive, thinking the territory he poſſeſſed too narrow, made war upon the lord of a neighbouring province named Tapotzotlan, and deprived him of his territory. Huetzin, ſon to the late prince Tzontecomatl, lord of Coatlichan, fell in love with the grand-daughter of the queen, a celebrated beauty, but was rivalled by a neighbouring lord, who determined to ſupport his pretenſions by force of arms. Huetzin, however, got the better, defeated and killed his adverſary, and then poſſeſſed himſelf of the lady and his eſtate. This was followed by a rebellion of the whole province of Tollantzinco, ſo that the king himſelf was obliged to take the field. As the rebels were very numerous, the royal army was at firſt defeated: but having at laſt received a ſtrong reinforcement, the rebels were overcome, and their ringleaders ſeverely puniſhed. The king did not long ſurvive the reſtoration of tranquillity to his dominions. He died in the thirty-ſecond year of his reign, and ninety-ſecond of his age, leaving the throne to his eldeſt ſon Tlotzin.

12 Civil wars.

13 Tlotzin.

We are not informed of any particulars relating to this prince farther that he was of an excellent diſpoſition, greatly beloved by his ſubjects, and, though addicted to peace, yet aſſiduous in exerciſing his people in the art of war. He reigned thirty-ſix years, and died of a very painful diſeaſe.

14 Quinatzin a luxurious prince.

Quinatzin, the ſon and ſucceſſor of Tlotzin, proved a vain and luxurious prince. His acceſſion to the throne was celebrated with much greater pomp than any

any of his predeceſſors. Xolotl had removed his court from Tenayuca to Tezcuco; but being diſguſted with this laſt place, on account of the conſpiracy formed againſt him there, he had returned to Tenayuca.—There the court continued till the reign of Quinatzin, who removed it back to Tezcuco. In his paſſage thither, he cauſed himſelf be tranſported in an open chair or litter, carried on the ſhoulders of four of his principal lords, while four others held an umbrella over his head. Before his time the kings had been accuſtomed to walk upon their feet like other people; but this example, once ſet, was quickly followed by all the lords and great people in the kingdom, who now ſtrove to out-do one another in expenſive and oſtentatious grandeur.

15 Diſturbances in various parts.

The reign of Quinatzin, though tranquil at firſt, was ſoon diſturbed by dangerous revolts and rebellions. Theſe firſt broke out in two ſtates, named Maztillen and Totopec, ſituated among the northern mountains. The king, having collected a great army, marched without delay againſt the rebels, and challenged their leaders to come down and fight him in the plain—This challenge being accepted, a furious engagement enſued, in which, though great numbers fell on both ſides, no deciſive advantage was gained by either party. Frequent engagements took place for the ſpace of forty days, until at laſt the rebels, perceiving that their own numbers were daily diminiſhing, without any poſſibility of being recruited like the royal army, made a final ſurrender to the king, who puniſhed the ringleaders with great ſeverity. Tranquillity, however, was not yet reſtored: the rebellion ſpread to ſuch a degree, that the king was obliged not only to take the field in perſon, but to employ ſix other armies, under the command of faithful and experienced generals, to reduce the rebels. Thoſe proved ſo ſucceſsful in their enterprizes, that in a ſhort time the rebellious cities were reduced to obedience, and the kingdom enjoyed the bleſſings of peace during the long reign of Quinatzin, who is ſaid to have ſat on the throne for no leſs than ſixty years. He was ſucceeded by his ſon Techotlatla; but as the affairs of the Acolhuans now began to be connected with thoſe of the Mexicans, it will be proper to give ſome account of that people.

16 Migrations of the Mexicans.

The Mexicans, called alſo the Aztecas, dwelt till the year 1160 in a country called *Aztlan*, ſituated to the north of the gulf of California, as appears by the route they purſued in their journey; but how far to the northward we are not certainly informed. Betancourt makes it no leſs than 2700 miles, and Boturini ſays it was a province of Aſia. The cauſe of their migration is ſaid to have been as follows:

Among the Aztecas was a perſon of great authority, named *Huiztilin*, to whoſe opinion every one paid the utmoſt deference. He had conceived a deſign, for what reaſon we know not, to perſuade his countrymen to change their reſidence; and to effect this he fell upon the following ſtratagem. Having heard, while meditating on his ſcheme, a little bird ſinging on the branches of a tree, the notes of which reſembled the word *Tihui*, which in the Azteca language ſignified "let us go," he took that opportunity to work upon the ſuperſtition of the people. With this view, he took along with him a reſpectable perſon, and made him attend to the note of the bird. "What can it mean (ſays he), but that we muſt leave this country, and find ourſelves another? Without doubt it is the warning of ſome ſecret divinity who watches over our welfare: let us obey, therefore, his voice, and not draw his anger upon us by a refuſal." Tecpaltzin, for that was the name of his friend, readily agreed to the interpretation; and both of them being perſons of great influence, their united perſuaſions ſoon gained over to their project the bulk of the nation; and they accordingly ſet out.

This account, though it has ſomewhat the air of fable, is what the Mexicans themſelves give; and is certainly more worthy of credit than that of the Spaniards, who maintain that the Aztecas ſet out by the expreſs command of the devil. But whatever was their motive, it is certain that they began their migration about the year above-mentioned. Torquemada ſays, that in all the hieroglyphic paintings which record this migration, there is delineated an arm of the ſea, or a great river, which, however, Clavigero takes to be a repreſentation of the univerſal deluge. Boturini ſuppoſes it to have been the gulf of California, over which, he thinks, they tranſported themſelves; but our author controverts this opinion, becauſe there are no remains of the buildings they conſtructed, during their migration, in California as there are in other places. If there really was any river of conſequence which they croſſed, he ſays it muſt have been the *Colorado*, or Red River, which diſcharges itſelf into the gulf of California, in lat. 32°. 3′. Having croſſed this beyond the lat. of 35°, they proceeded towards the ſouth-eaſt, as far as the river *Gila*, where they ſtopped for ſome time; and on the banks of that river there are remains of the great edifices they conſtructed. From thence having reſumed their courſe towards the S.S.E. they proceeedd to lat. 29°. and ſtopped again at a place upwards of 250 miles diſtant from the city of Chihuahua, towards the N. N. W. This place is now known by the name of *Caſe grandi*, on account of a very large building ſtill extant, and univerſally attributed to them by the traditions of the country. It is conſtructed on the plan of thoſe of New Mexico, that is, conſiſting of three floors with a terrace above them, and without any entrance to the under floor. The door for entrance opens to the ſecond floor; ſo that a ſcaling ladder is neceſſary: and the inhabitants of New Mexico build in this manner, in order to be leſs expoſed to the attack of their enemies; putting out the ſcaling ladder only for thoſe to whom they give admiſſion into their houſes. No doubt the Aztecas had the ſame motive for raiſing their edifice on this plan, as every mark of a fortreſs is to be obſerved in it, being defended on one ſide by a lofty mountain, and the reſt ſurrounded by a wall about ſeven feet thick, the foundations of which are ſtill exiſting. In this there are ſtones as big as mill-ſtones; the beams of the roof are of pine, and well finiſhed. In the centre is a little artificial mount, apparently conſtructed with a deſign to keep guard on, and obſerve the enemy. Some ditches have been formed in this place, and ſeveral kitchen utenſils found, as earthen pots, diſhes, and jars, with ſome looking-glaſſes made of a ſtone called *itztli*.

The Atzecas having ſtaid here as long as they thought

Mexico.

thought proper, croſſed the mountains of Tarahumara, directed their courſe ſouthward, and ſtopped again for three years at Culiacan, a place ſituated on the gulf of California, in 24 degrees north latitude. Here they formed a wooden image of a god called *Huitzilopochtli*, whom they imagined to be their tutelar deity, and made a chair of reeds and ruſhes to tranſport it, calling this vehicle *the chair of God.* Four prieſts were choſen, to carry the image on their ſhoulders, whom they called *the ſervants of God;* and the act of carrying it they name *teomama*, which ſignifies "to carry *God* on one's *back*."

The Aztecas, when they left their original habitations, were divided into ſix tribes; but here the Mexicans were left with their god by five of them, viz. the Xochimilcas, Tepanecas, Chalceſe, Tlahuicas, and Tlaſcalans. The cauſe of this ſeparation is not known. The tribes juſt mentioned pretend that it was done at the expreſs command of God; but there can be little doubt that it was occaſioned by ſome diſagreement among themſelves. This is rendered farther probable, when we conſider that on their journey towards Tula, the remaining tribe was divided into two violent factions, which alternately perſecuted one another: neither did they afterwards conſtruct any more edifices. However, they always travelled together, in order to enjoy the company of their imaginary God. At every place where they ſtopped an altar was erected to him; and at their departure they left behind them all their ſick, and probably alſo ſome others to take care of them, or ſuch as were not willing to endure the fatigue of farther journeys. They ſtopped in Tula nine years, and eleven more in the neighbouring parts. At laſt, in 1216, they arrived at Zumpanco, a conſiderable city in the vale of Mexico, where they were received in a very hoſpitable manner by the lord of that diſtrict. He not only aſſigned them proper habitations, but became very much attached to them; and even demanded from among them a wife for his ſon Ilhuicatl. This requeſt was complied with; and from this marriage all the Mexican kings deſcended.

The Mexicans continued to migrate from one place to another along the lake of Tezcuco. Xoltotl, who was then on the throne of the Acolhuans or Chichemechas, allowed them to ſettle in whatever places of his dominions they thought proper; but ſome of them finding themſelves haraſſed by a neighbouring lord, were obliged, in 1245, to retire to Chapoltepec, a mountain on the weſtern borders of the lake, ſcarce two miles diſtant from the ſite of Mexico. This took place in the reign of Nopaltzin; when, as has already been obſerved, diſturbances began to take place in the Acolhuan dominions. The Mexicans, however, did not find themſelves any more ſecure in their new place of reſidence than formerly: they were perſecuted by the neighbouring lords, and obliged to take refuge in a number of ſmall iſlands, named *Acolco*, at the ſouthern extremity of the lake of Mexico. Here for 52 years they lived in the moſt miſerable manner that can be imagined; ſubſiſting on fiſh, inſects, roots, &c. and clothing themſelves with the leaves of the amoxtli, which abounds in that lake.

In this miſerable plight the Mexicans continued till the year 1314, when they were all reduced to a ſtate of the moſt abſolute ſlavery. This was done by the king of a petty ſtate named Colhuacan: but there are different accounts of the manner in which it was effected. Some ſay that this prince, unwilling to allow the Mexicans to maintain themſelves in his territories without paying tribute, made war upon them, ſubdued and enſlaved them. Others affirm, that, pretending compaſſion for their miſerable ſituation, he offered them a more commodious place of reſidence. The Mexicans accepted the offer with great pleaſure; but had ſcarcely ſet out to take poſſeſſion of their new place of reſidence when they were attacked by the Colhuans, made priſoners, and carried off for ſlaves.

20
They regain their liberty in conſequence of a monſtrous piece of cruelty.

After ſome years a war broke out betwixt the Colhuans and Xochimilcas; in which the latter gained ſuch advantages, that they were obliged to employ their ſlaves to aſſiſt them. They accordingly ordered them to prepare for war, but without furniſhing them with arms neceſſary for a military enterpriſe; ſo that the Mexicans were obliged to content themſelves with long ſtaves, having their points hardened in the fire: they alſo made knives of the ſtone itztli, and ſhields of reeds woven together. They agreed among themſelves not to waſte their time, as was uſual, in making priſoners, but to content themſelves with cutting off one ear of their enemies, and then leaving them without farther injury. They adhered punctually to this reſolution; and ruſhing furiouſly upon the Xochimilcas, cut off an ear from as many as they could, killing thoſe who ſtruggled to ſuch a degree that they could not effect their purpoſe. In ſhort, ſo well did the Mexicans acquit themſelves in this engagement, that the Xochimilcas not only abandoned the field, but were obliged to take refuge among the mountains. After the battle, the Colhuan ſoldiers preſented themſelves before their general with the priſoners they had taken; for it was by the number of theſe, not of the enemy left dead on the field, that they judged of their valour. The Mexicans had taken only four, and theſe they kept concealed for the abominable purpoſe of ſacrificing them. The Colhuans, therefore, ſeeing no trophies of their valour, began to reproach them with cowardice; but the Mexicans, producing their baſkets of ears, deſired them to judge from theſe how many priſoners they might have taken, had they not been unwilling to retard their victory by taking up time in binding them.

Notwithſtanding the valour diſplayed by the Mexicans in this engagement, it doth not appear that their haughty maſters were in the leaſt mollified or inclined to afford them eaſier terms than before. Having erected an altar to their god, they demanded of their lord ſomething precious to offer in ſacrifice to him; but he in diſdain ſent them a dirty cloth, incloſing the filthy carcaſe of a vile bird. This was carried by Colhuan prieſts; and without any ceremony laid upon the altar. The Mexicans, with apparent unconcern, removed this filthy offering, and put in its place a knife made of itztli, and an odoriferous herb. On the day of conſecration, the Colhuan prince failed not to attend with his nobility; not with a view to do honour to the feſtival, but to make a mockery of the Mexicans. Their deriſion, however, was ſoon changed into horror, when the Mexicans, after a ſolemn dance, brought forth the four Xochimilcan priſoners they had taken; and, after having made them dance a little, cut open their

21
The firſt human ſacrifice in Mexico.

Mexico.

their breafts with the knife which lay on the altar, and plucking out their hearts, offered them, while yet warm and palpitating with life, to their diabolical idol. This horrible facrifice had fuch an effect upon the fpectators, that both king and fubjects defired the Mexicans immediately to quit their territories and go where they pleafed. This order was inftantly obeyed: the whole nation took their rout towards the north, until they came to a place named *Acatzitzintlan*, fituated betwixt two lakes, and afterwards named *Mexicaltzinco*; but for fome reafon or other, being difcontented with this fituation, as indeed they feem very often to have been, they proceeded to *Iztacalco*, ftill nearer to the fite of Mexico. Here they formed the image of a little mountain of paper, and danced round it a whole night, finging their victory over the Xochimilcas, and returning thanks to their god for having freed them from the yoke of the Colhuas. Clavigero is of opinion, that by this mountain they reprefented Colhuacan, as in their pictures it was always reprefented by a hunch-backed mountain; and this is the literal fignification of the name.

22
They fettle at laft on the iflands on which Mexico was built.

Having ftaid two years in Iztacalco, they came to a place on the lake where they found a nopal or opuntia growing in a ftone, and over it the foot of an eagle. All the Mexican hiftorians fay that this was the mark given them by their oracle of the place where they were finally to fettle. Here, then, they put an end to their wanderings; and, as foon as they had taken poffeffion of the fpot, an altar was erected to the god, or rather devil, whom they worfhipped. The altar was confecrated in a manner conformable to the cruel religion which thefe people had adopted. Having at that time no prifoners among them, one of their number went out in queft of fome animal for a victim; but happening to meet with a Colhuan, a quarrel enfued; and the Mexican proving victorious, bound his enemy, brought him home, and prefented his heart to the idol. Around this altar they now began to build their habitations; which, like the celebrated city of Rome, confifted at firft of a parcel of miferable rufh huts; as they were then furnifhed with no better materials. Their city, if fuch it might be called, was named *Tenochtitlan*, and afterwards *Mexico*, which name afterwards prevailed; and, according to Clavigero, fignifies the place of *Mexitli* or *Huitzilopochtli*, their god of war: and in this refpect alfo the founding of Mexico was fimilar to that of Rome, the latter being protected by *Mars* their god of war, as the Mexicans were by *Mexitli*.

23
Their miferable fituation at firft.

The city of Mexico was founded in the year 1325, in the moft incommodious fituation we can imagine, viz on a fmall ifland named Tenochtitlan, in the middle of a great lake, without ground to cultivate for their fubfiftence, or even room fufficient to build their habitations. Their life was therefore as miferable here for fome time as it had been when they were on the iflands at the end of the lake, and they were reduced to the fame fhifts to maintain themfelves. To enlarge the boundaries of their ifland, they drove palifades into thofe parts of the water which were moft fhallow, terracing them with ftones and turf, and uniting to their principal ifland feveral other fmaller ones which lay in the neighbourhood. To procure to themfelves afterwards ftones, wood, &c. for conftructing their habitations, as well as clothing and other neceffaries, they inftituted a commerce with the people who dwelt on the borders of the lake, fupplying them with fifh, water-fowl, and other more minute inhabitants of the lake and marfhes, which they contrived to render eatable; and in return for all this they received the neceffaries above-mentioned. The greateft effort of their induftry, however, was the conftruction of floating gardens, by means of bufhes and mud of the lake; and thefe they brought to fuch perfection that they produced maize, pepper, chia, French beans, and gourds.

For thirteen years that the Mexicans had to ftruggle with extreme difficulty, they remained at peace; but no fooner did they begin to profper and live comfortably, than the inveterate enmity betwixt the two factions formerly mentioned broke out in all its fury. This produced a feparation; and one of the parties took up their refidence on a fmall ifland at a little diftance to the northward, which, from an heap of fand found there, they at firft named *Xaltilolco*, but afterwards *Tlatelolco*, from a terrace conftructed by themfelves. This ifland was afterwards united to that of Tenochtitlan.

24
The factions feparate.

About this time the Mexicans divided their city into four parts, a divifion which ftill fubfifts; each quarter having now its tutelar faint, as it had formerly its tutelar god. In the midft of their city was the fanctuary of their great god *Mexitli*, whom they conftantly preferred to all the reft. To him they daily performed acts of adoration: but inftead of making any progrefs in humanity, they feem to have daily improved in the moft horrible barbarities, at leaft in their religion. The dreadful facrifices made of their prifoners already mentioned, could only be exceeded by that which we are now about to relate. Being now on a more refpectable footing than formerly, they fent an embaffy to the petty king of Colhuacan, requefting him to fend them one of his daughters, that fhe might be confecrated the mother of their protecting god. The unfufpecting prince, intoxicated with the thoughts of having his daughter made a goddefs, readily complied with their defire.—The unfortunate princefs was conducted in great triumph to Mexico; but no fooner was fhe arrived, than fhe was facrificed in the fhocking manner above related; and, to add to the horror of the deed, the body was flayed, and one of the braveft young men of the nation dreffed in her fkin. Her father, ignorant of this dreadful tranfaction, was invited by the Mexicans to be prefent at the apotheofis of his daughter, and went to fee the folemnity, and to worfhip the new divinity. He was led into the fanctuary, where the young man ftood clothed in the bloody fkin of his daughter; but the darknefs of the place prevented him from feeing what was before him. They gave him a cenfer in his hand, and fome copal to begin his worfhip: but having difcovered by the flame of the copal the horrible fpectacle, he ran out in a diftracted manner, calling upon his people to revenge the injury; but this they were not able to do at that time nor ever after. Hiftorians are unanimous, that this facrifice was performed at the exprefs command of the devil; and indeed in this inftance, their credulity feems pardonable; though Clavigero, with more reafon, afcribes it to his priefts.

25
Monftrous barbarity of their religion.

In

In the year 1352 the Mexican government was changed from an ariſtocracy to a monarchy. At firſt they were governed by 20 lords, of whom one had an authority ſuperior to the reſt. This naturally ſuggeſted the idea of monarchy; and to this change they were alſo induced by the contemptible ſtate in which their nation ſtill continued, thinking that the royal dignity would confer upon it a degree of ſplendor which otherwiſe it could not enjoy; and that by having one leader, they would be better able to oppoſe their enemies. Proceeding, therefore, to elect a king, the choice fell upon Acamapitzin, a man of great eſtimation among them, and deſcended from Opochtli a noble Atzecan, and a princeſs of the royal family of Colhuacan. As he was yet a bachelor, they attempted to negociate a marriage, firſt with the daughter of the lord of Tacuba, and then of the king of Azcapozalco: but theſe propoſals being rejected with diſdain, they applied to Acolmiztli lord of Coatlichan, and a deſcendant of one of the three Acolhuan princes; who complied with their requeſt, and the nuptials were celebrated with great rejoicings.

In the meantime, the Tlatelolcos, the natural rivals of the Mexicans, reſolved not to be behind them in any thing which had the leaſt appearance of augmenting the glory of their ſtate. They likewiſe, therefore, choſe a king; but not thinking proper to chooſe him from among themſelves, they applied to the king of the Tepanecas, who readily ſent them his ſon; and he was crowned firſt king of Tlatelolco in 1353. In this the Tlatelolcos ſeem to have had a deſign of humbling their rivals, as well as rendering themſelves more reſpectable; and therefore it is probable, that they had repreſented the Mexicans as wanting in that reſpect due to the Tepanecan monarch, as having elected a king without his leave, though at the ſame time they were tributaries to him. The conſequence of this was, that he took a reſolution to double their tribute. Hitherto they had paid only a certain number of fiſh and water-fowl; but now they were ordered to bring alſo ſeveral thouſands of fir and willow plants to be ſet in the roads and gardens of Azcapozalco, and to tranſport to the court a great floating garden, which produced vegetables of every kind known in Anahuac. This being accompliſhed with great difficulty, the king commanded them next year to bring him another garden, with a duck and ſwan in it both ſitting upon eggs; but ſo, that on their arrival at Azcapozalco the brood might be ready to hatch. This was alſo done; and the prince had the ſatisfaction of ſeeing the young birds come out of the eggs. The third year they were ordered to bring a live ſtag along with a garden. This was more difficult than any of the former taſks; becauſe they were obliged, in order to hunt the ſtag, to go to the mountains of the continent, where they were in danger of falling into the hands of their enemies; however, this alſo was accompliſhed, and the deſire of the king gratified.

In this manner the Mexicans were oppreſſed for no leſs than 50 years. They freed themſelves, however, from all their difficulties by vigorous exertions, abſurdly aſcribing to the protection of that malevolent being whom they worſhipped the glory of every deliverance. Acamapitzin governed this city, which at that time comprehended the whole of his dominions, for 37 years in peace. His queen being barren, he married another wife, but without abandoning the firſt; and theſe two, inſtead of being rivals to one another, lived together in the utmoſt harmony; the firſt wife taking upon herſelf the charge of educating *Huitzilihuitl*, the ſon of the ſecond. He had, beſides, ſeveral children by other women, and one named *Itzcoatl*, who afterwards proved one of the beſt and moſt renowned kings who ſat on the throne of Mexico. He is ſaid alſo to have conquered four conſiderable cities; but Clavigero thinks he muſt in this only have been an auxiliary, it being very improbable, that while he could ſcarce maintain his own territories, he ſhould think of foreign conqueſts.

Acamapitzin died in 1389, greatly lamented by the Mexicans, and his death was followed by an interregnum of four months. As the deceaſed monarch had formally reſigned his authority into the hands of his nobles, it was neceſſary that a new election ſhould take place; and when this was done, the choice fell upon Huitzilihuitl, the ſon of Acamapitzin. As he was ſtill unmarried, it was reſolved, if poſſible, to procure him an honourable and advantageous match. With this view, a deputation of nobility was ſent to the king of Azcapozalco, requeſting, in very humble terms, an alliance with one of his daughters. The expreſſions made uſe of by theſe ambaſſadors are ſaid by our author to have been particularly elegant in the Mexican language: but it is difficult to underſtand how a ſpeech made among a people ignorant of the art of writing could be particularly recorded at the interval of ſome hundreds of years after. They are as follow: "We beſeech you, with the moſt profound reſpect, to take compaſſion on our maſter and your ſervant Huitzilihuitl, confined among the thick ruſhes of the lake.—He is without a wife, and we without a queen.—Vouchſafe, Sir, to part with one of your jewels or moſt precious feathers. Give us one of your daughters, who may come to reign over us in a country which belongs to you."

29 Huitzilihuitl the ſecond king.

This piece of oratory had ſuch an effect upon the king, that he granted their requeſt, and a Tepanecan princeſs was conducted in great triumph to Mexico, where the marriage was ſolemnized with the utmoſt joy. Though this princeſs brought him a ſon the firſt year of their marriage, the king, in order to ſtrengthen himſelf by freſh alliances, married alſo the daughter of another prince, by whom he had Montezuma *Ilhuicamina*, the moſt celebrated of all the Mexican kings.

30 Marries a daughter of the king of the Tepanecans.

We muſt now return to the hiſtory of the Acolhuans, who at this time were governed by Techotlala the ſon of Quinatzin. For 30 years this prince enjoyed an uninterrupted tranquillity. This was interrupted by the revolt of Tzompan, prince of Xaltocan, and the laſt of the family of Chiconquauhtli, one of the three original Acolhuan princes, who had drawn into his conſpiracy the ſovereigns of ſix other ſtates. The king, out of reſpect to the quality of the rebel, offered to pardon him if he would lay down his arms; but Tzompan, confident of his ſtrength, rejected the offer with contempt. The king was therefore obliged to ſend an army againſt him,

31 Reign of Techotlala king of Acolhuan.

Mexico.

in which the Tepanecans and Mexicans served as auxiliaries. The war lasted only two months; Tzompan was defeated and put to death, along with several others of the principal rebels. The Mexicans, who had behaved with great valour, returned in triumph to their city, while Techotlala took several very prudent measures to strengthen his government, prevent rebellions in future, and to augment the splendor of his throne.

In consequence of the renown acquired in this war by the Mexicans, and the advantages resulting from the alliance with the king of Azcapozalco, that people now began to be held in much higher estimation by their neighbours than before. They extended their commerce, and in consequence of that, came to wear cotton instead of the threads of the wild-palm, which had formerly constituted their whole dress: but this gleam of prosperity was soon overcast, and they had to encounter a more inveterate and formidable enemy than any that they had yet met with. This was Maxtlaton prince of Coyoacan, and son to the king of Azcapozalco. Being of a cruel and revengeful temper, for which he was dreaded even by his father, he resolved to resent the indignity which he pretended to have been done to him by the marriage of his sister to the king of Mexico. The true cause of his displeasure, however, was his fear that the Tepanecan crown might devolve on his sister's son by Huitzilihuitl; and to prevent this, he took the barbarous method of sending assassins to murder his nephew. The king of Mexico was not then able to resent the injury; for though, by his marriage with the Tepanecan princess, the oppressive tribute was taken off, and the Mexicans had only to pay a couple of ducks annually, by way of acknowledging the Tepanecan superiority, yet the one nation was far from being in a condition to cope with the other.—The barbarity of Maxtlaton was not unknown to his father; but it is certain that he did not resent it; and indeed there is great reason to suppose that he took part with his son in most of his wicked enterprises.

32
Maxtlaton an inveterate enemy to the Mexicans.

As the Mexicans advanced in wealth and power, so did their rivals the inhabitants of Tlatlelolco.—Their first king died in 1390, leaving his subjects greatly improved in civilization, and the city much enlarged and beautified. The rivalship which subsisted between the two cities had indeed greatly contributed to the aggrandizement of both. The Mexicans had formed so many alliances by marriage with the neighbouring nations, had so much improved their agriculture, and floating gardens on the lake, and had built so many more vessels to supply their extended commerce and fishing, that they were enabled to celebrate their secular year, answering to A. D. 1402, with greater magnificence than they had ever done since they left their original country of Atztlan.

33
Unfortunate reign of Techotlala's son.

All this time Techotlala continued to reign in Acolhuacan; but being now very far advanced in years, and finding his end approach, he called to him his son Ixtlilxochitl, and recommended to him to beware of the ambitious disposition of the king of Azcapozalco, as he was apprehensive that he might attempt something against the peace of the empire. His suspicions were verified; for on the death of Techotlala, which happened in 1406, the king of Azcapozalco, without making the usual submissions to the new king, to whom he was a feudatory, set out for his own territories, with a view to stir up the other feudatory princes to rebellion. Having called to him the kings of Mexico and Tlatleloco, he told them, that Techotlala, who had long tyrannized over that country, being dead, he designed to procure freedom to the princes, so that each might rule his own territory entirely independent of the king of Acolhuacan; but for this purpose he needed their assistance, and trusted to their well known spirit to take part with him in the enterprise. He informed them likewise, that in order to ensure success, he would find means to unite other princes in the confederacy.

The new king of Acolhuacan, in the mean time, was employed in settling the affairs of his kingdom, and endeavouring to gain the good will of his subjects. The combination against him was soon discovered: but though Ixtlilxochitl was desirous of heading his army in person, he was dissuaded from so doing by his courtiers; so that the conduct of the war was committed to his generals. To weaken the enemy, they ravaged the territories of six revolted states; but notwithstanding this, and the superior discipline of the royal army, the war was carried on by the rebels with great obstinacy, their armies being constantly recruited by fresh troops in proportion to their losses. At last, after three years of a ruinous war, the king of Azcapozalco, finding that his resources would at last fail him, sued for peace; but with a design of accomplishing by treachery what he had not yet been able to do by force. His adversary, equally reduced with himself, consented to a peace, though he knew very well that the Tepanecan prince intended to observe it no longer than suited his purpose.

3[4]
Chimalpopoca the king of Mexico.

In the year 1409 died Huitzilihuitl king of Mexico, who likewise left the right of electing a successor to the nobility. They made choice of his brother Chimalpopoca; and from thence it became an established law to choose one of the brothers of the deceased king, or if he had no brothers to elect one of his grandsons. While the new prince was endeavouring to secure himself on the throne, the treacherous Tezozomoc used all means in his power to strengthen the party he had formed against the king of Acolhuacan. In this he was attended with such success, that the unfortunate prince found himself reduced to the necessity of wandering among the neighbouring mountains, at the head of a small army, accompanied by the lords of Huexolta and Coatlichan, who remained always faithful to him. The Tepanecans distressed him to such a degree, by intercepting his provisions, that he was forced to beg them of his enemies. One of his grandsons was sent to Otompan, a rebel state, to request them to supply their king with the provisions he stood in need of, and to exhort them to abandon the cause of the rebels, which they had espoused. No task could be more dangerous; yet such was the magnanimity of the young prince's disposition, that he readily set out on the journey; nor was he deterred by the information he got that there were in the place certain Tepanecans who had come on purpose to publish a proclamation from Tezozomoc. He went boldly to the most public place of the town, and in presence of those who

3[5]
Distress and death of the king of Acolhuacan.

xico.

who publiſhed the proclamation made known his requeſt. This heroiſm, however, did not meet with the ſucceſs it deſerved. His propoſitions were derided from the moment they were made; but the people did not offer any farther inſult, until one of the meaner ſort threw a ſtone at him, exciting others of the ſame ſtamp to put him to death. The Tepanecans, who had hitherto continued ſilent, perceiving their opportunity, joined in the general cry to kill the prince, and began alſo to throw ſtones. The prince attempted firſt to defend himſelf, and afterwards to eſcape by flight; but, both being equally impoſſible, he fell under a ſhower of ſtones. The Tepanecans exulted in this act of treachery, and ſoon after cut off Ixtlixochitl himſelf, after having treacherouſly perſuaded him to a conference with two of their captains. This perfidious act was committed in ſight of the royal army, who were too weak to revenge it: the royal corpſe was ſaved with difficulty; and *Nezahualcojotl*, heir apparent to the crown, was obliged to ſhelter himſelf among the buſhes from the fury of his enemies.

5
ua-
d by
o-

Tezozomoc having now in a great meaſure gained his point, proceeded to pour down his troops upon thoſe cities and diſtricts which had remained faithful to the late unfortunate monarch. The people made a moſt deſperate defence, and killed vaſt numbers of their enemies; but at laſt being themſelves reduced by the calamities of war, and in danger of total extermination, they were obliged to quit their habitations and fly to other countries. The tyrant, then, finding himſelf ſuperior to all his adverſaries, gave Tezcuco in fief to Chimalpopoca king of Mexico, Huexotla to Tlacacotl king of Tlatelolco; placing faithful governors in other places, and appointing Azcapozalco, the capital of his own territory, the royal reſidence and capital of Acolhuacan.

Prince Nezahualcajotl was preſent in diſguiſe at this diſpoſal of his dominions, along with ſeveral other perſons of diſtinction who were enemies of the tyrant; and ſo much was he tranſported with paſſion, that it was with difficulty he could be reſtrained from killing Tezozomoc on the ſpot, though this would certainly have been done at the expence of his own life. All the reſt of the Acolhuacan empire ſubmitted; and Nezahualcojotl ſaw himſelf for the preſent deprived of all hopes of obtaining the crown.

7
ran-
d

Tezozomoc had now attained the ſummit of his ambition: but inſtead of conciliating the minds of his new ſubjects, oppreſſed them with new taxes; and being conſcious of the precarious ſituation in which he ſtood, and tormented with remorſe on account of his crimes, fell into melancholy, and was haunted with frightful dreams. In one, he imagined that Nezahualcojotl, transformed into an eagle, had eat out his heart; and in another, that, in the ſhape of a lion, he licked his body and ſucked his blood. Terrified by theſe viſions, he called his three ſons, Tajatzin, Teuctzintli, and Maxtlaton, enjoining them to put to death Nezahualcojotl as ſoon as they could get it done without being publicly known. He himſelf ſurvived his dreams only about a year. He was now become ſo old, that his body no longer retained its natural heat. He was therefore obliged to be covered up with cotton in a great cradle, not being able to ſit erect in a chair. In this miſerable condition, however, he never forgot his tyranny nor cruelty. From his cradle he iſſued oppreſſive laws relating to the Acolhuacans; and almoſt with his laſt breath renewed his commands with regard to Nezahualcojotl. At laſt he expired in the year 1422, leaving the crown to his ſon Tajatzin.

Mexico.

38
The throne uſurped by Maxtlaton.

Tezozomoc was no ſooner dead than Maxtlaton, without paying the leaſt regard to his father's will, began to exerciſe the functions of a ſovereign. Though it was the right of Tajatzin to invite to his father's funeral whom he pleaſed, Maxtlaton took that upon himſelf. Nezahualcajotl, though not invited, came among the reſt; but though Teuctzintli, brother to Maxtlaton, inſiſted upon his being put to death, the latter oppoſed it, as it could not then be done privately, and he hoped to find another opportunity. No ſooner were the funeral ceremonies over, however, than Maxtlaton behaved in ſuch a manner to his brother Tajatzin, that the prince thought proper to retire to Chimilpopoca king of Mexico, to whom he had been particularly recommended by his father, in order to have his advice. This monarch, agreeable to the character of that age and people, adviſed him to invite his brother to an entertainment, and then murder him. Unluckily for them both, this diſcourſe was overheard by a ſervant, who in expectation of a reward informed the tyrant of what he had heard: but inſtead of this, Maxtlaton, pretending to diſbelieve his ſtory, drove the informer from his preſence with ignominy. Notwithſtanding this pretence, the tyrant had not the leaſt doubt of the truth of what was told him; and therefore determined to rid himſelf of his brother without delay. This he ſoon accompliſhed in the very ſame way that had been projected againſt himſelf. Tajatzin, along with the king of Mexico, Tlatelolco, and ſome other feudatory princes, were invited by Maxtlaton to an entertainment. The king of Mexico prudently excuſed himſelf, but the unſuſpecting Tajatzin fell into the ſnare. He came to the place of entertainment, and was inſtantly put to death. The company were greatly alarmed; but Maxtlaton, having explained to them his reaſons for ſo doing, they not only excuſed him, but proclaimed him king; to which it is not to be doubted that their fears greatly contributed.

39
Tajatzin murdered.

Though the king of Mexico eſcaped a ſudden death by his abſence at this time, it was only to periſh in a more ſlow and ignominious manner. The vengeance of Maxtlaton firſt appeared by ſending him a woman's dreſs in return to the preſent he ſent him as a feudatory; which being a reflection upon his courage, was the higheſt affront that could be offered him. This inſult, however, was quickly followed by one of a much higher nature. Having heard that one of the Mexican princes's wives was an extraordinary beauty, he enjoined ſome Tepanecan ladies, who were accuſtomed to viſit that princeſs, to invite her to ſpend ſome days with them at Azcapozalco. This being complied with, the tyrant eaſily got an opportunity of raviſhing her, and then ſent her back to her huſband. Chimilpopoca was ſo much affected by this misfortune, that he reſolved to offer himſelf up a ſacrifice to his god. Maxtlaton, however, was reſolved that

40
Miſerable fate of the king of Mexico.

Mexico.

that he ſhould not have even this ſatisfaction. At the very time of the ceremony therefore he ſent a body of troops; who entering Mexico without reſiſtance, carried off the king alive, to the aſtoniſhment of the multitude; and who probably were ſo much confounded by this unexpected adventure, that they did not think of making any reſiſtance.

Chimilpopoca being carried priſoner to Azcapozalco, was confined in a ſtrong wooden cage, the common priſon for criminals. Maxtlaton ſtill was not ſatisfied: he wiſhed to get into his hands Nezahualcajotl; and with this view ſent a meſſage to him, pretending that he was willing to come to an agreement with him reſpecting the kingdom of Acolhuacan. Though the prince was well aſſured of the tyrant's treacherous intentions, he went boldly to his palace, preſented himſelf before him, and told him that he had heard of the impriſonment of the king of Mexico; he had heard alſo that he wiſhed to take away his own life; he deſired him to do ſo, and to gratify his malice. Maxtlaton was ſo ſtruck with this ſpeech, that he aſſured the prince he had not formed any deſign againſt his life; and that he neither had put to death the king of Mexico, nor would do ſo. He then gave orders for his being properly entertained, and even allowed him to pay a viſit to the king of Mexico in priſon. The unfortunate Chimilpopoca, after reciting his misfortunes, requeſted the prince not to return to court, where they would certainly fall upon ſome project for taking away his life; and having pathetically recommended to him the care of his ſubjects, made him a preſent of a gold pendant and ſome other jewels he wore; after which they took a laſt farewell.

41
He is viſited in priſon by Nazahualcajotl.

Chimilpopoca languiſhed in priſon for ſome little time after the departure of Nezahualcojotl; but life became at laſt ſo intolerable to him, that he hanged himſelf in his girdle. His voluntary death, in ſpite of all that the tyrant had done to prevent it, ſo exaſperated the latter, that he reſolved upon the death of the prince at all events, whether in the way recommended by his father or not; to which it is not improbable that he was likewiſe inſtigated to this by certain predictions of the prieſts. He ſent out four captains, therefore, with a ſmall party of troops, in queſt of the fugitive prince, with orders to kill him as ſoon as they overtook him. Theſe meſſengers of death ſet out directly for Tezcuco, where the prince happened to be at that time playing at foot-ball; for he ſpent great part of his time in ſuch diverſions, that he might remove all ſuſpicions of his aſpiring to the throne; and thus he had an opportunity of carrying on his negociations without moleſtation. As he knew the errand on which the Tepanecan captains came, he left off his play on their appearance, and retired to his inner apartment. On being informed that they inquired for him, he ſent for anſwer that he would wait upon them after they had repoſed and refreſhed themſelves. The prince made uſe of this opportunity to quit the houſe, and retire by a ſecret door; or, according to Torquemada, by a kind of labyrinth which he had conſtructed, and through which none but himſelf knew the way. He then fled to Coatlichan, a ſmall ſettlement of weavers, who were all exceedingly attached to him. He was purſued thither by the aſſaſſins, who had been informed by a countryman of the road he had taken; but ſuch was the inviolable fidelity of the inhabitants, that ſeveral of them ſuffered themſelves to be put to death rather than diſcover the place of his concealment. Leaving this place, therefore, they went thro' the country in queſt of him; and no ſooner were they gone, than the prince ſet out in a way directly contrary to that which they had taken. Being purſued in all directions, however, he was in the utmoſt danger, and would once have been made priſoner if ſome countrymen had not concealed him under an heap of chia. Having eſcaped this danger, he went to a pleaſant villa at Tezcotzinco, belonging to his anceſtors; where he was met by ſix lords who had left their ſtates. Having conſulted with them, it was determined to apply to the Chalceſe, although they knew that they were an unfaithful and treacherous people, and had been concerned in the death of the late king. He was then met by ambaſſadors from the Cholulans, who offered him their aſſiſtance againſt the uſurper. In a ſhort time he was joined by numbers of others; ſo that he was not only no longer in danger of his life, but began to be formidable to his enemies.

42
Adventures of that prince.

In the mean time, the Mexicans, who had ſuffered many injuries ſince the death of Chimilpopoca, raiſed to the throne Itzcoatl, the ſon of Acamapitzin by a ſlave, and who was accounted the moſt prudent, juſt, and brave, of all the Mexican nation. His election was no leſs pleaſing to Nezahualcajotl and his party, than it was offenſive to Maxtlaton. An alliance was quickly concluded between the exiled prince and the king of Mexico; and this was ſoon followed by the commencement of hoſtilities on the part of the former. His firſt enterpriſe was againſt the city of Tezcuco, which he determined to take by aſſault, but was prevented by the ſubmiſſion of the inhabitants. He put to death, however, all the officers eſtabliſhed by the tyrant; and all the Tepanecans he found there. The very ſame day another large city named Acolman was furiouſly attacked by a detachment of his army; great numbers put to the ſword, and among the reſt the governor, who was brother to Maxtlaton; and the ſame day alſo Coatlichan was taken by the Chalceſe.

43
Itzcoatl raiſed to the throne of Mexico who aſſiſts Nezahualcajotl.

The Mexican monarch, hearing of the ſucceſſes of his ally, ſent an embaſſy to congratulate him upon them. His ambaſſador was a ſon of king Huitzilihuitl, named *Montezuma*, who for his invincible courage and great qualities was ſurnamed the *man of great heart and the archer of heaven*. The journey was extremely dangerous; but Montezuma undertook it without any fear, accompanied by another nobleman. They got in ſafety to the place where the prince was; but had the misfortune to be taken priſoners, and were carried to Chalco; the lord of which city, named Toteotzin, was an inveterate enemy to the Mexicans. By him he was immediately put in cloſe confinement, under the care of one Quateozin, who was inviolably attached to the Mexican intereſt. Orders were given to the latter to provide no ſuſtenance for the priſoners but what was preſcribed by his lord, until the mode of death which they were to ſuffer ſhould be determined. Toteotzin then, with a view to flatter the Huexotzincas, ſent his priſoners to them, that they might be ſacrificed there if they thought proper. Theſe people, however, rejected the propoſal with diſdain; on which Toteotzin,

44
Dangerous embaſſy undertaken by Montezuma.

Mexico.

zin, thinking to regain the favour of Maxtlaton, notwithſtanding his treachery in abandoning his cauſe, informed him of the priſoners he had in his poſſeſſion. But Maxtlaton (whoſe character ſeems not to deſerve all the reproaches with which it is loaded) called him a double-minded traitor, and commanded him inſtantly to ſet the priſoners at liberty. Before this anſwer arrived, however, Quateozin had inſtructed the priſoners how to make their eſcape, and directed them alſo not to return by land leſt they ſhould again be intercepted, but to embark at a certain place, and proceed by water to Mexico. They followed his advice exactly; and having got to the place to which they were directed, arrived ſafely at their city, to the great ſurpriſe and joy of the inhabitants.

Maxtlaton ... ces againſt Mexico.

Toteotzin, enraged at the loſs of his priſoners, put Quateozin to a cruel death, deſtroying alſo all his family excepting one ſon and a daughter; of whom the latter fled to Mexico, where ſhe was highly honoured on her father's account. Maxtlaton, too, notwithſtanding his generoſity to the priſoners (which Clavigero derives from mere oppoſition to Toteotzin), prepared to wage a formidable war with the Mexicans, who had agreed to unite their troops with thoſe of the prince. The Mexican populace, terrified at engaging ſo powerful an enemy, demanded that their king ſhould ſubmit and beg for peace. So great was the tumult, that the king himſelf was obliged to conſent; and it required the utmoſt exertions of Montezuma's eloquence to perſuade the people to agree to a commencement of hoſtilities. This being done at laſt, the king next called together the chief nobility, and aſked which of them would have the courage to carry an embaſſy to the king of the Tepanecans? This adventure appeared ſo hazardous, that all of them kept a deep ſilence until Montezuma declared himſelf willing to undertake the arduous enterpriſe. He was ordered to propoſe peace to Maxtlaton, but to accept of no diſhonourable conditions; to which he punctually adhered. Maxtlaton refuſed to give any immediate anſwer, but promiſed to give one next day, after he had conſulted his nobility. Montezuma, dreading ſome treachery if he ſtaid all night, promiſed to return next day; which he did, and was told that Maxtlaton had determined upon war. Montezuma then performed the ceremony of challenging him, by preſenting him with certain defenſive weapons, anointing his head, and fixing feathers upon it, as was cuſtomary to do with dead perſons. Laſtly, he proteſted, in the name of his maſter, that as Maxtlaton would not accept of the offered peace, he and all the Tepanecans would infallibly be ruined. Maxtlaton ſhowed not the leaſt ſign of diſpleaſure, but gave Montezuma arms in like manner to preſent to the king of Mexico; and directed him, for his perſonal ſecurity, to return in diſguiſe through a ſmall outlet from the palace. Montezuma followed his advice; but as ſoon as he found himſelf out of danger, began to inſult the Tepanecan guards; and though they ruſhed violently upon him, he not only eſcaped from their attacks, but killed one or two of them.

On his return to Mexico, the populace were again thrown into the utmoſt conſternation by the news that war was inevitable, as the chiefs of the two nations had challenged one another. They now requeſted the king to allow them to retire from their city, of which they ſuppoſed the ruin to be certain. The king encouraged them with the hopes of victory. "But if we are conquered (replied they), what will become of us?" "If that happens (anſwered the king), we are that moment bound to deliver ourſelves into your hands, to be made ſacrifices at your pleaſure." "Be it ſo (replied they), if we are conquered; but if we obtain the victory, we and our deſcendants are bound to be tributary to you; to cultivate your lands and thoſe of your nobles; to build your houſes; and to carry for you, when you go to war, your arms and baggage."

46 He is defeated and killed.

Matters being thus ſettled, intelligence was ſent to prince Nezahualcajotl to repair with his army to Mexico, which he did without delay; and the day after his arrival a furious engagement took place. The Tepanecan army was commanded by a general named *Mazatl*; Maxtlaton himſelf not judging it proper to quit his capital. The ſoldiers on both ſides fought with the utmoſt bravery; but towards night the Mexicans, diſheartened by ſeeing the army of their enemies continually increaſing in number, began once more to loſe their courage and talk of ſurrendering. The king, greatly concerned, aſked Montezuma what ſhould be done to diſſipate the fears of the people? That brave prince replied, that they muſt fight till death; that if they died with their arms in their hands, it would be honourable; but to ſurvive their defeat, would be eternal ignominy. Nothing could be more ſalutary than this advice at ſo critical a juncture: for the Mexicans were already begun to implore the mercy of their enemies, and to promiſe to ſacrifice their chiefs, whoſe ambition had brought the whole nation into ſuch a dilemma. On hearing this, the whole body of nobility, with the king and Montezuma at their head, aſſaulted the enemy ſo furiouſly, that they repulſed them from a ditch of which they had taken poſſeſſion; after which, Montezuma, happening to encounter Mazatl the Tepanecan general, ſtruck him ſuch a blow on the head that he fell down lifeleſs. Thus the Mexicans were inſpired with freſh courage, and their enemies proportionally diſpirited: however, they retired for that night to the city, in ſome hopes of being able to retrieve their fortune next day. Maxtlaton encouraged them by every method in his power; but fortune proved ſtill more unfavourable than the day before. The Tepanecans were now entirely defeated, and the city of Azcapozalco taken. Maxtlaton, who ſeems not to have had the courage to fight, had not now the preſence of mind to fly. He attempted indeed to hide himſelf; but being quickly diſcovered, he was beaten to death with ſticks and ſtones. The city was plundered, the inhabitants butchered, and the houſes deſtroyed by the victors.

47 The Tepanecans entirely reduced.

This victory proved deciſive in favour of the confederates. Every other place of ſtrength in the country was quickly reduced, until the Tepanecans, finding themſelves on the verge of deſtruction, ſent an humble embaſſy to the king of Mexico, requeſting to be taken under his protection, and to become tributaries to him. Itzcoatl received them graciouſly; but threatened them with total extirpation if they violated the fidelity they had ſworn to him. Thus the whole Tepanecan nation was ſubjected to the Mexicans, excepting

Mexico.

cepting only the ſtate and city of Cojohuacan, which continued refractory for a conſiderable time.

Itzcoatl, after this extraordinary ſucceſs, took care to have the above mentioned contract ratified between the nobility and common people, by which the latter were bound to perpetual ſervices. Thoſe who had diſcouraged the ſoldiers in time of battle were baniſhed for ever from the ſtate of Mexico; while Montezuma and others who had diſtinguiſhed themſelves by their bravery, were rewarded with lands, as was uſual with other conquerors.

48 Nezahualcajotl made king of Acolhuacan.

Itzcoatl, now finding himſelf firmly ſeated on the throne of Mexico, ſet about performing his engagements to the Acolhuacan prince, by ſeating him on the throne of his anceſtors. Having again joined their armies, they marched againſt Huaxotla, a city which refuſed to ſubmit even though terms of pardon were offered them. Inſtead of this, they raſhly ventured a battle, in which they were entirely defeated; and were then fain to ſend a deputation of their old men, pregnant women, &c. as was cuſtomary in caſes of diſtreſs, to move the enemy to compaſſion. At laſt all obſtacles being removed, Nezahualcajotl was ſeated on the throne of Acolhuacan, the auxiliary troops were diſmiſſed, and Itzcoatl left at liberty to purſue his conqueſts, in which he was ſtill aſſiſted by the king of Acolhuacan. The firſt expedition was againſt Cojohuacan and other two Tepanecan cities, who had not only refuſed ſubmiſſion themſelves, but excited others to ſhake off the yoke alſo. The war againſt them proved bloody. Three battles were fought, in

49 Conqueſts of the Mexicans.

which Itzcoatl gained no other advantage than making the enemy retreat a little; but in the fourth, while the two armies were hotly engaged, Montezuma, with a body of choſen troops, which he had placed in ambuſcade, attacked the rear-guard of the rebels with ſuch vigour, that they were ſoon diſordered, and obliged to fly to the city. The conquerors purſued them thither; and Montezuma perceiving that they intended to fortify themſelves in the greater temple, fruſtrated their deſign by getting poſſeſſion of it and burning the turret. By this diſaſter they were ſo much terrified, that they fled to the mountains ſouth of Cojohuacan; but even there the royal army overtook and purſued them more than 30 miles, till they came to another mountain, where, quite exhauſted with fatigue, and ſeeing no means of eſcape, they were obliged to ſurrender at diſcretion.

Having thus happily accompliſhed the conqueſt of Cojohuacan and the other rebellious cities, the two kings returned to Mexico. Itzcoatl gave great part of the Tepanecan country to *Totoquihuatzin*, with the title of king of *Tacuba*, a grandſon of Tezozomoc, but who does not appear to have been any way con-

50 Alliance between the kings of Mexico, Acolhuacan, and Tepaneca.

cerned in his projects againſt the Mexicans. An alliance was then formed among the three kings on the following terms: The king of Tacuba held his crown on condition of ſerving the king of Mexico with all his troops, at any time when required; for which he was to have a fifth part of the ſpoils taken from the enemy. The king of Acolhuacan was likewiſe to aſſiſt the king of Mexico in war; and for this he was to have a third part of the plunder, after deducting the ſhare of the king of Tacuba; and the remainder was to belong to the king of Mexico. The kings of Tacuba and Acolhuacan were both declared honorary electors of the kings of Mexico; the real electors being four nobles: and the king of Mexico was likewiſe bound to aſſiſt in the wars of his allies whenever it was demanded.

After having thus ſettled matters among themſelves, and rewarding their ſoldiers, Itzcoatl ſet out with Nezahualcajotl for Tezcuco, where the Acolhuacan king was crowned with all poſſible ceremony. Here the new king took every method which prudence could ſuggeſt to eſtabliſh his authority on a permanent baſis; but while he was thus employed, the Xochimilcas, fearing leſt the Mexicans might conquer their country as they had done that of the Tepanecans, held a council on what was to be done to prevent ſuch a diſgrace. In this council it was determined to commence hoſtilities againſt that riſing ſtate, before it ſhould become more formidable by new conqueſts.

51 Other conqueſts.

Itzcoatl was no ſooner informed of this determination, than he ſent Montezuma with a great army againſt them. The Xochimilcas met him with one ſtill more numerous; but being worſe diſciplined, they were quickly defeated, and their city taken in a very ſhort time after. This conqueſt was followed by the reduction of Cuitlahuac, ſituated on a ſmall iſland on the lake of Chalco. Their inſular ſituation gave them confidence to attack the formidable power of the Mexicans. The king was ſo ſenſible of the difficulty of this enterpriſe, that he propoſed to attack them with the whole force of the alliance: Montezuma, however, with only a ſmall number of men of his own training, whom he furniſhed with proper veſſels, reduced them in ſeven days.

Theſe conqueſts were followed by the reduction of the cities of Quauhnahuac, Quantitlan, and Toltitlan; the firſt of which was ſo ſtrong, that Itzcoatl was obliged to call in his allies to his aſſiſtance. In ſhort, in the ſpace of twelve years, Mexico, from being a contemptible and tributary ſtate, became able to command thoſe whom it had formerly ſerved, and who thought themſelves very much ſuperior in every reſpect.

52 Montezuma I. king of Mexico.

Itzcoatl died in the year 1436, at a very advanced age, in the height of proſperity, and was ſucceeded by Montezuma I. the greateſt monarch that ever ſat on the Mexican throne. Before his coronation, in order to comply with the barbarous rites of his religion, he made war upon the Chalceſe in order to procure the priſoners who were to be ſacrificed at his coronation; and ſcarce was this ceremony over, than a new war commenced, which terminated in the deſtruction of that city. This quarrel happened between the Chalceſe and the Tezcucans. Two of the royal princes of Tezcuco having gone a-hunting on the mountains which overlook the plains of Chalco, while employed in the chace, and ſeparated from their retinue, with only three Mexican lords, fell in with a troop of Chalceſe ſoldiers; who, to gratify the cruelty of their maſter, carried them all priſoners to Chalco. The cruel and inconſiderate tyrant who commanded there inſtantly put them all to death; after which he cauſed their bodies to be ſalted, dried, and placed in an hall of his palace, where they ſerved as ſupporters to the pine torches burned there for light every evening. The king of Tezcuco, overwhelmed with

with grief, and to the laſt degree exaſperated at ſuch an inhuman act, called for the aſſiſtance of the allied kings. The city was attacked at once by land and water. The inhabitants, knowing that they had no mercy to expect, fought like men in deſpair. Even the old tyrant who commanded them, though unable to walk, cauſed himſelf to be carried in a litter among the combatants; notwithſtanding which they were totally defeated, and the moſt ſevere vengeance executed upon them.

Montezuma, on his return, found himſelf obliged to encounter an enemy more formidable on account of his vicinity, than more powerful ones at a diſtance. This was the king of Tlateloleo, who had formerly conſpired againſt the life of Itzcoatl; and finding himſelf diſappointed in this, had tried to reduce his power by entering into a confederacy with ſome of the neighbouring lords. At that time his deſigns proved abortive, but he reſumed them in the time of Montezuma; the conſequence of which was, that he was defeated and killed. One *Moquihuix* was choſen in his room; in whoſe election it is probable that Montezuma had a conſiderable ſhare. This was followed by conqueſts of a much more important nature. The province of *Cuihixcas*, lying to the ſouthward, was added to his dominions, comprehending a tract of country more than 150 miles in breadth; then, turning to the weſtward, he conquered another named *Tzompahacuan*. This ſucceſs, however, was for a ſhort time interrupted by a war with Atonaltzin, lord of a territory in the country of the Mixtecas. This prince, puffed up on account of the great wealth he poſſeſſed, took it into his head that he would allow no Mexican to travel through his country. Montezuma ſent ambaſſadors to know the reaſon of ſuch ſtrange conduct; but Atonaltzin gave them no other anſwer than ſhowing them ſome part of his wealth, making a preſent to the king, and deſiring him from thence to obſerve how much the ſubjects of Atonaltzin loved him; and that he willingly accepted of war, which was to determine whether he ſhould pay tribute to the Mexicans or the Mexicans to him. Montezuma having informed his allies of this inſolent anſwer, ſent a conſiderable army againſt Atonaltzin, but had the mortification to be informed of its defeat; in conſequence of which the pride of Atonaltzin was increaſed to a great degree. Montezuma, greatly chagrined at this firſt check, determined to head his next army in perſon; but before he could call together another, Atonaltzin had drawn into a confederacy with him the Huexotzineas and Tlaſcalans, who were glad of the opportunity, as they ſuppoſed, of reducing the power of the Mexicans. Their numbers, however, availed but little; Montezuma in the very firſt engagement totally defeated the confederate army. The allies of Atonaltzin were particularly unfortunate; for ſuch of them as were not killed in the field of battle, were deſtroyed by their own party out of revenge for the unfortunate event of the battle.

By this victory the Mexican monarch became maſter not only of the dominions of Atonaltzin, but of many other neighbouring princes, againſt whom he made war on account of their having put to death ſome Mexican merchants or couriers without any juſt cauſe. The conqueſt of *Cuetlachtlan* or *Cotaſta*, however, which he attempted in 1457, proved a much more difficult taſk. This province lies on the coaſt of the Mexican gulph, and had been formerly inhabited by the Olmecans, whom the Tlaſcalans had driven out. The inhabitants were very numerous; but dreading the power of Montezuma, called in thoſe of Tlaſcala, together with the Huexotzineas, to their aſſiſtance. Along with theſe the allies drew the Cholulans alſo into the confederacy; ſo that this appears to have been the moſt formidable combination that had yet been formed againſt the Mexican power. Montezuma collected an excellently equipped army; which, however, he did not on this occaſion command in perſon. It contained a great number of perſons of very high rank, among whom were three princes of royal blood, and *Moquihuix* king of Tlateloleo already mentioned. The combination of the three republics againſt Mexico was not known at court when the army ſet out; but Montezuma, being informed of it ſoon after, ſent an order to his generals to return. This accorded ſo ill with the romantic notions of valour entertained by the Mexicans, that a conſultation of the generals was held whether they ſhould obey it or not. At laſt it was determined that the king's order ſhould be obeyed; but no ſooner was this agreed to than Moquihuix accuſed them all of cowardice, and threatened, with his own troops, unaſſiſted, to go and conquer the enemy. His ſpeech had ſuch an effect upon them all, that they went to meet the confederates. The Cotaſteſe fought with great valour, but were unable to reſiſt the royal forces; and their allies were almoſt totally deſtroyed. Six thouſand two hundred of them were taken priſoners, and ſoon after ſacrificed to the Mexican god of war in the barbarous manner already deſcribed. The victory was ſaid to have been owing principally to the valour and good conduct of Moquihuix, inſomuch that to this day a ſong made in his praiſe on that occaſion is known in Mexico. Montezuma was ſo well pleaſed with the victory, that he not only forgave the diſobedience of his orders, but beſtowed upon Moquihuix a princeſs, one of his own couſins, to wife.

56
Chalceſe rebel, and are deſtroyed.

The next exploit of this great warrior was the entire deſtruction of the Chalceſe, whoſe reſtleſs diſpoſition continually brought miſchief upon themſelves. They had, it ſeems, formed a deſign of making their city a rival to Mexico; and with this view had taken priſoner one of the brothers of Montezuma himſelf, whom they attempted to make their ſovereign abſolutely againſt his own inclination. The prince, finding it impoſſible to reſiſt, pretended to comply with their wiſhes; but that the act of exalting him to this dignity might be more conſpicuous, he deſired them to plant in the market-place one of the higheſt trees, and place a ſcaffold upon it, from whence every body might ſee him. This being done, the Mexicans who had been taken along with him aſſembled round the tree; and the prince having aſcended the ſcaffold with a bunch of flowers in his hand, addreſſed them to the following purpoſe: "Ye know well, my brave Mexicans, that the Chalceſe wiſh to make me their king; but it is not agreeable to our god that I ſhould betray our native country; I chooſe rather to teach you, by my example, to place higher value on fidelity to it.

Mexico.

it than on life itſelf." With theſe words he threw himſelf from the ſcaffold, and was killed. The Chalceſe were ſo enraged at this, that they inſtantly fell upon the Mexicans and killed them with their darts. Next evening they were terrified by a ſcreech owl; the diſmal voice of which animal they interpreted into an omen of their approaching ruin. They were not deceived in their predictions, which indeed they might have made without any ſcreech-owl. They were quickly attacked by Montezuma; who on this occaſion was ſo much exaſperated, that he cauſed fires to be lighted on the tops of the adjacent mountains, as ſymbols of the puniſhment to which he condemned the rebels. The havock he made among them was ſuch, that the province was almoſt depopulated. Vaſt numbers were ſlaughtered, while thoſe who eſcaped with life fled into the caves of the neighbouring mountains. Some fled into diſtant countries, leaving their city to be deſtroyed by the enemy. At laſt Montezuma, ſatiated with revenge, proclaimed a general pardon, and invited the fugitives to return; but many of them, not putting any confidence in his ſincerity, choſe to remain in their ſtate of exile. The remainder of this emperor's reign was taken up in making new conqueſts; ſo that by the time of his death, which happened in 1464, he had extended his dominions as far as the gulf of Mexico on the eaſt; to the middle of the country of the Mixtecas on the ſouth-eaſt; ſomething farther than Chilapan on the ſouth; to the valley of Toluca on the weſt; the centre of the country of the Otomies on the north-weſt; and, on the north, to the extremity of the vale of Mexico.

3
Inundation and famine at Mexico

During the reign of this great monarch a violent inundation happened in Mexico. The lake, ſwelled by the exceſſive rains which fell in the year 1446, poured its waters into the city with ſo much violence that many houſes were deſtroyed, and the ſtreets inundated to ſuch a degree that boats were every where made uſe of. To prevent accidents of this kind for the future, Montezuma, by advice of the king of Tezcuco, conſtructed a great dyke nine miles in length, eleven cubits in breadth, and conſiſting of two parallel lines of paliſades, the interval betwixt which was filled up with ſtones and ſand. The greateſt difficulty in the conſtruction lay in being obliged occaſionally to work in the lake itſelf, which in ſome places was of conſiderable depth; but this was ſurmounted by the ſkill and perſeverance of the workmen. The dyke, when conſtructed, proved of great ſervice in keeping out the waters, though it did not entirely remedy the evil; nor indeed have the Spaniards been able to ſecure this city effectually from inundations, after being in poſſeſſion of it for more than two centuries.

The inundation was ſoon followed by a famine. This was occaſioned by the ſtinting of the crop of maize in 1448; the ears while young and tender being deſtroyed by froſt. In 1450 the crop was totally loſt for want of water; and in 1451, beſides the unfavourable ſeaſons, there was a ſcarcity of ſeed. Hence, in 1452, the neceſſities of the people became ſo great, that they were obliged to ſell themſelves for ſlaves in order to procure ſubſiſtence. Montezuma permitted them to go to other countries for ſupport; but being informed that many ſold themſelves for a few days proviſion, he ordered by proclamation, that no woman ſhould ſell herſelf for leſs than 400 ears of wheat, nor any man for leſs than 500. He opened alſo the public granaries for the relief of the lower claſſes; but nothing was able to ſtop the progreſs of the famine. Many who went for relief to other countries periſhed with hunger on their journey; and great numbers who ſold themſelves for ſlaves never returned to their native country. Moſt of the populace ſupported themſelves, like their anceſtors, on the produce of the lake, until all their diſtreſſes were relieved by a moſt plentiful harveſt in the year 1454.

4
Axayacatl ſucceeds Montezuma.

Montezuma was ſucceeded by Axayacatl, who like his predeceſſor inſtantly commenced a war, for no other reaſon than that he might have priſoners to ſacrifice at his coronation. The people whom he now attacked inhabited the province of *Tecuantepec* on the coaſt of the Pacific Ocean, and ſituated at 400 miles diſtance from the city of Mexico. A very deſperate battle enſued on this occaſion, in which, however, the Mexicans at laſt prevailed; and, beſides the poor wretches doomed to deſtruction whom they carried off, acquired a conſiderable ſpoil, as well as a tract of territory extending to Coatulco, a maritime place much frequented in the next century by the Spaniards.

5
His conqueſts.

Axayacatl purſued Montezuma's plan of conqueſt; in which, however, he was leſs ſucceſsful, many of the provinces reduced by that monarch having revolted after his death, ſo that it was neceſſary to reconquer them. On his returning ſucceſsful from one of theſe expeditions, he built a new temple, to which he gave the name of *Coatlon;* but the Tlatelolcos, whoſe ancient rivalſhip ſeems to have revived on the death of Montezuma, built another in oppoſition, which they called *Coaxolotl.* Thus the former hatred between the two nations was renewed, and a diſcord took place which ended in the ruin of the Tlatelolcos.

6
Death of the kings of Acolhuacan and Tacuba.

The Mexicans ſuſtained an irreparable loſs in 1469 and 1470 by the death of their allies the kings of Tacuba and Acolhuacan; for though the league which had been concluded between the three nations continued without any violation till the arrival of the Spaniards, we cannot ſuppoſe that any of the ſucceſſors of the Tacuban and Acolhuacan princes would have the ſame cordial affection for thoſe of Mexico which was entertained by thoſe who lay under ſuch great obligations to Montezuma. The king of Tacuba was ſucceeded by his ſon Chimalpopoca, and the Acolhuan monarch by his ſon Nezahualpilli. A ſhort time after the acceſſion of the latter, the war broke out between the Tlatelolcos and Mexicans, which ended in the deſtruction of the former. King Moquihuix had been married by Montezuma to a ſiſter of Axayacatl, now on the throne of Mexico; but it appears that this princeſs never was greatly the object of his affection. On the contrary, he took all methods of expreſſing his diſlike, either out of enmity to herſelf, or envy of the ſuperior greatneſs of her brother. Not content with this, he entered into an alliance with a great number of the neighbouring ſtates, in order to reduce the Mexican greatneſs. His wife, however, being informed of this ſcheme, communicated the particulars to her brother; and ſoon after, being impatient of the ill uſage ſhe received, came to Mexico with her four ſons to claim the protection of her brother. This uncommon accident exaſperated the Mexicans and Tlatelolcans againſt each other to ſuch a degree, that wherever they met, they fought, abuſed, and murdered each other. The king of Tlatelolco prepared for war with many horrid ceremonies, of which the drinking of human blood was one. A day was appointed for attacking Mexico. Xiloman, lord of Colhuacan, was to begin the attack, afterwards to pretend flight, in order to induce the Mexicans to follow him; after which the Tlateloleos were to fall upon their rear. For ſome reaſon, however, with which we are not acquainted, the Tlateloleos began the attack without waiting for Xiloman; the conſequence of which was, that he retired in diſguſt, leaving them to finiſh their battle the beſt way they could. The engagement laſted till night, when the Tlateloleos were obliged to retire. Axayacatl, during the night, diſpoſed of his troops in all the roads which led to Tlatelolco, appointing them to meet in the market-place. The Tlatelolcos, finding themſelves attacked on all ſides, retired gradually before the Mexicans, until at laſt they were forced into the market-place, where they found themſelves worſe than ever on account of its narrowneſs, which did not allow them room to act. The king ſtood on the top of the great temple, encouraging his men to exert themſelves againſt the enemy. His words, however, had now loſt their uſual influence. He not only was not obeyed, but was reproached with cowardice becauſe he did not come down and fight among the reſt. At laſt the Mexicans arrived at the temple, and aſcended to the balcony where the king was. He made a deſperate defence for a little; but by a violent puſh in the breaſt was thrown backward upon the ſteps of the temple, and ſtunned or perhaps killed by the fall. The ſoldiers took him up and carried him to Axayacatl; who with his own hand cut open his breaſt and tore out his heart. His people then attempted to fly acroſs the market-place; but a great number of them were killed, among whom were many officers of diſtinction. The city of Tlatelolco was then united with Mexico, as a part or kind of ſuburb, which it ſtill continues to be.

The Tlatelolcos being thus reduced, Axayacatl next ſet out on an expedition againſt the Matlatzincas, a tribe in the vale of Toluca, who ſtill refuſed to ſubmit to the Mexican yoke. Having proved ſucceſsful in this expedition, he undertook to ſubdue alſo the northern part of the valley, now called *Valle d' Ixtlahuacan*, particularly *Xiquipilco*, a conſiderable city and ſtate of the Otomies, whoſe chief was much renowned for ſtrength and bravery. Axayacatl, who likewiſe valued himſelf on theſe qualities, encountered him in ſingle combat. In this, however, he was over-matched, and received a violent wound on the thigh; after which he would have been taken priſoner, had not ſome young Mexicans made a deſperate effort for his reſcue. Notwithſtanding this diſaſter, Axayacatl's army gained a complete victory, carrying off 11060 priſoners, among whom was the chief of the Otomies himſelf, and two of his officers who had attacked the king. Theſe chiefs were put to death at an entertainment of the allied kings, the ſight of their agonies not interrupting in the leaſt the mirth of the feaſt; ſo much were they familiarized to the ſhedding of human blood. Mexico.

Axayacatl continued to extend his territories to the eaſt and weſt, till his progreſs was ſtopped by death in 1477. He was ſucceeded by his elder brother Tizoc; of whoſe reign we know little, but that he conquered fourteen cities, ſome of which had been in rebellion. He intended to have built a larger temple than any that had yet been ſeen in Mexico, though that originally built had been greatly enlarged by ſome of his predeceſſors. For this purpoſe he collected a great quantity of materials; but before he could bring his projects to bear, he was taken off by a conſpiracy of his ſubjects. We are not informed in what manner he died; moſt probably it was by poiſon, as the conſpirators wiſhed his death to paſs for natural. It being diſcovered to be otherwiſe, however, diligent ſearch was made for the criminals, who were puniſhed according to their deſerts. During the reign of Tizoc, the Acolhuacans made war upon the Huexotzincas, ruined their city, and conquered their territory. Nezahualpilli alſo, the Acolhuacan monarch, though he had already ſeveral wives, had not made any of them queen, having wiſhed to confer that honour upon one of the royal family of Mexico. Tizoc readily gave him one of his grand-daughters, who had a ſiſter of ſingular beauty named *Xocotzin*. The friendſhip betwixt theſe two ladies was ſuch, that the one could not think of being ſeparated from the other; for which reaſon the new queen ſought and obtained permiſſion to take her ſiſter along with her to Tezcuco. Xocotzin had not been long there before the king fell in love with her, and married her with the title of queen likewiſe. Soon after this ſecond marriage, the firſt queen brought forth a ſon named *Cacamatzin*, who ſucceeded him in the throne, and was afterwards taken priſoner by the Spaniards.

63 Is ſucceeded by Tizoc.

Ahuitzotl, the brother of Tizoc, ſucceeded him in the kingdom of Mexico. His firſt object was to finiſh the great temple begun by his predeceſſor; and ſuch was the number of workmen, that it was completed in four years. During the time that it was building, the king employed himſelf in making war with different nations, reſerving all the priſoners he took for victims at the dedication of the temple. The number of priſoners ſacrificed at this dedication is ſaid by Torquemada to have been 72,224; by other hiſtorians 64,060. The miſerable victims were ranged in two files, each a mile and an half in length, terminating at the temple. The ſame year another temple was built by a feudatory lord, in imitation of the great one built by the king; at the dedication of which a vaſt number of priſoners were alſo ſacrificed. Theſe temples were dedicated in 1486. In 1487 happened a violent earthquake; and Chimalpopoca king of Acolhuacan died, who was ſucceeded by Totoquihuatzin II.

64 Ahuitzotl dedicates a temple with a multitude of human victims.

The remainder of the life of Ahuitzotl was a continued ſeries of wars, in all of which he proved ultimately ſucceſsful, extending the Mexican dominions as far as Guatimala, 900 miles to the ſouth-eaſt of Mexico. In only one expedition the Mexicans were defeated with diſgrace. This happened in 1495, when they ſuddenly, and as appears without any provocation, entered the vale of Atlixco in an hoſtile

65 His conqueſts.

manner.

Mexico. manner. So unexpected was the invasion, that the inhabitants of Atlixco knew only of the intention of their enemies by seeing them in arms in their country. Finding it impossible to raise in an instant a sufficient force among themselves, they applied to their neighbours, the Huexotzincas. On their arrival at the city, which it seems had already been rebuilt since its destruction by the Acolhuacans, they found a most celebrated captain, named Toltecatl, amusing himself at foot-ball. Being informed of the arrival of the Mexican army, he instantly quitted his diversion to repair to Atlixco; where, to show his contempt for the enemy, he entered the battle unarmed.—He supplied himself with armour by knocking down the first Mexican he met with his fist, and seizing his armour. He then attacked the enemy with such fury, and was so well seconded by his troops, that the Mexicans were totally defeated; and, in consideration of his signal bravery, the Huexotzincas made him the chief of their republic. He had not continued in his new office more than a year, however, when, finding himself unqualified for being legislator to such turbulent subjects as he had to deal with, he quitted his dignity and his country at once; and crossing the mountains with some other nobles, came to Tlalmanalco, where he was put to death, with all his companions, by order of Ahuizotl.

66 His death. Ahuizotl died in 1502, of a disorder produced by a contusion in his head. Of the cause of which we have the following account: In 1498, the king, thinking that the navigation of the lake of Mexico was become difficult on account of the scarcity of water, formed a project of supplying the deficiency from a fountain which supplied the Cojoacanese, and called upon the lord of the district to give orders for that purpose. This nobleman represented that the spring was not constant; that sometimes it was dry, and at others ran so abundantly that it might occasion some disaster in his court. Ahuizotl, however, supposing this to be a pretence, renewed his order, and put the nobleman to death for insisting upon his objection. He then caused a spacious aqueduct to be constructed from Cojoacan to Mexico; and the water was brought in with a great many superstitious ceremonies. That very year, however, there fell such quantities of rain, that the waters of the lake, augmented also by those of the spring, overflowed the city, so that the streets were filled with sailing vessels, and some houses were destroyed. The king happening to be one day in a lower apartment of his palace, the waters entered with such rapidity and violence that he was obliged to fly; and the door being low, he struck his head with such force against the top, that he never recovered the effects of the contusion. This inundation was followed by a famine, all the maize being rotted by the water.

67 Montezuma II. At the time of Ahuizotl's death, the Mexican empire was brought to its utmost extent. His successor, Montezuma *Xocojotzin*, or Montezuma *Junior*, was a person of great bravery, besides which he was likewise a priest, and held in great estimation on account of his gravity and the dignity of his deportment. His election was unanimous; and the nobles congratulated themselves on the happiness the country was to enjoy under him, little thinking how short the duration of their happiness or of their empire was to be.

The first care of the new monarch, as usual, was to procure victims for the barbarous sacrifices to be made at his coronation. The people of Atlixco, who had again shaken off the Mexican yoke, were the sufferers on this occasion, being once more reduced, though not without great loss on the part of the Mexicans, some of whose bravest officers perished in the war. The ceremony of coronation was performed with such pomp as had never been seen before in Mexico; but no sooner was this ceremony over than Montezuma began to discover a pride which nobody had suspected before. All his predecessors had been accustomed to confer offices upon persons of merit, and those who appeared the most able to discharge them, without any partiality as to birth or wealth. Montezuma, however, disapproved of the conduct of his predecessors, under pretence that the plebeians should be employed according to their rank; for that in all their actions the baseness of their birth and the meanness of their education appeared: and in consequence of this maxim he deprived all the commoners of the offices they held about the court, declaring them incapable of holding any for the future. All the royal servants now were people of rank. Besides those who lived in the palace, 600 feudatory lords and nobles came to pay court to him. They passed the whole day in the antichamber, where none of their servants were permitted to enter; conversing in a low voice, and waiting the orders of their sovereign.—The servants of these lords were so numerous that they occupied three small courts of the palace, and many waited in the streets. The women were not less numerous. All these last were confined in one vast seraglio, under the care of some noble duennas, who kept a strict watch over their conduct. From this collection the emperor selected such as he liked best for himself, giving away the rest; and so well did he acquit himself in his matrimonial capacity, that *an hundred and fifty* of his wives are said to have been pregnant at once.

The pride of Montezuma was no less conspicuous in the ceremonials than in the magnificence of his court. None durst enter the palace without pulling off his shoes and stockings at the gate; neither durst they appear pompously dressed in the imperial presence; this being deemed a want of respect to majesty.—All who entered the hall of audience, before speaking to the king, made three bows; at the first, saying *Lord!* at the second, *My Lord!* and at the third, *Great Lord!* They spoke low, and with the head inclined, receiving the answer which the king gave them by secretaries, with as great humility as if it had been the voice of a deity; and no person in taking leave ever turned his back on the throne. When this mighty emperor went abroad, he was carried on the shoulders of the nobility, in a litter covered with a rich canopy, and attended by a numerous retinue of courtiers; and wherever he passed, every person shut their eyes, as fearing to be dazzled with the splendor of Majesty. When he alighted from the litter to walk on foot, carpets were spread on the ground, that the emperor might not be permitted to touch the earth with his feet.

In

In every reſpect Montezuma kept up, as far as was poſſible, this extravagant appearance of dignity. His kitchen-utenſils were of the fineſt earthen ware, and his table-cloths and napkins of the fineſt cotton; but none of theſe ever ſerved the emperor more than once, being immediately made a preſent of to ſome nobleman. The veſſels in which his chocolate and other drinks from cocoa were prepared, were all of gold, or ſome beautiful ſea-ſhell, or naturally-formed veſſels, curiouſly varniſhed. He had alſo gold-plate, but it was uſed only on particular occaſions in the temple. The number and variety of his diſhes aſtoniſhed the Spaniards. Cortes ſays, that they covered the floor of a great hall; and that there were diſhes of every kind of game, fiſh, fruit, or herbs, in the country. This dinner was carried in ſtate by three or four hundred of the young nobility, who retired as ſoon as the king ſat down to table: and that the meat might not grow cold, each plate was furniſhed with a chafing diſh. The king marked with a rod the diſhes he choſe for himſelf, and the reſt were diſtributed among the nobility in the antichamber. Before he ſat down, four of the moſt beautiful women of his ſeraglio ſupplied him with water to waſh his hands, and continued ſtanding all the time of his dinner, along with ſix of his principal miniſters and his carvers.

Montezuma took great delight in the cleanlineſs of his own perſon, and of every thing about him. He bathed regularly every day, and had baths in all his palaces. Every day he wore four dreſſes, never uſing again thoſe which he had put off, but reſerving them as largeſſes for the nobility, or thoſe who had diſtinguiſhed themſelves in war.

The expence of all this, and many other inſtances of magnificence, rendered the emperor very diſagreeable to a great number of his ſubjects; though others were pleaſed with the readineſs he ſhowed to relieve the neceſſities of individuals, and his generoſity in rewarding his generals and miniſters who deſerved it. Among other actions worthy of imitation, he appointed the city of Colhuacan as an hoſpital for all invalids, who after having faithfully ſerved the crown either in the civil or military line, required a proviſion on account of their age and infirmities. In this place they were maintained and attended at the expence of the king.

The reign of Montezuma, even before the arrival of the Spaniards, was far from being ſo glorious with regard to his ſucceſſes in war as thoſe of his predeceſſors had been. He reduced indeed one rebellious province, and conquered another which had never before been ſubjugated; but in his war with Tlaſcala he was by no means ſucceſsful. This was but a ſmall republic at no great diſtance from the capital, but the inhabitants were remarkable for their bravery and independent ſpirit. The neighbouring ſtates, however, who had been reduced by the Mexicans, envious of their liberty and proſperity, exaſperated the Mexicans againſt them, by repreſenting that the Tlaſcalans were deſirous of making themſelves maſters of the maritime provinces on the Mexican gulf, and that by their commerce with theſe provinces they were encreaſing their wealth and power, and gaining the hearts of the people with whom they were to traffic. In conſequence of this repreſentation, ſtrong garriſons were placed on the frontiers of Tlaſcala, to obſtruct the commerce of the inhabitants, and thus to deprive them of the means of obtaining ſome of the neceſſaries of life. The Tlaſcalans complained; but received no other anſwer than that the king of Mexico was lord of all the world, and that the Tlaſcalans muſt ſubmit and pay tribute to him. The Tlaſcalans returned a ſpirited anſwer to this inſolent ſpeech, and began to fortify their frontier. They had already incloſed all the lands of the republic with intrenchments; and to theſe they now added a wall of ſix miles in length on the weſt ſide, where an invaſion was moſt to be apprehended; and ſo well did they defend themſelves, that though they were frequently attacked by the neighbouring ſtates in alliance with Mexico, or ſubject to it, not one of them was able to wreſt a foot of ground from them. Thus a continual ſeries of wars and engagements took place between the ſtates of Mexico and this republic, which continued till the arrival of the Spaniards. The moſt remarkable occurrences in theſe wars are the exploits of a Tlaſcalan general named Tlahuicol. His courage and ſtrength were ſo great, that his enemies fled whereever he appeared. The ſword with which he fought was ſo weighty, that no man of ordinary ſtrength could lift it from the ground. At laſt, however, having in the heat of an engagement got into a marſh, his great ſtrength was of no uſe to him, ſo that he was taken priſoner, put into a ſtrong cage, and carried to Mexico. The emperor, in conſideration of his extraordinary qualities, gave him liberty to return to his own country: but this he abſolutely refuſed, ſaying, that he wiſhed to die, like other priſoners, in honour of their god. In this he perſiſted obſtinately for ſeveral years; until at laſt Montezuma reſolved to comply with his barbarous deſire; and he was permitted to die by the gladiatorian ſacrifice, to be afterwards deſcribed, in which the priſoner was allowed, though under great diſadvantages, to fight for his life. He was oppoſed by ſeveral brave men, one at a time, of whom he killed eight, and wounded twenty more; until, falling almoſt dead by a violent blow he received on the head, he was carried to the temple and there ſacrificed.

71 Exploits and death of Tlahuicol.

72 Apprehenſion entertained by the Mexicans of the arrival of a new people.

During the remainder of Montezuma's reign the empire was diſturbed by various rebellions, of which the accounts are not ſufficiently intereſting to merit a particular detail; but in the year 1508, Montezuma began to entertain apprehenſions of that fatal event which at length overtook him. An expedition having been undertaken againſt a very diſtant region named Amatla, the army in marching over a lofty mountain were attacked by a furious north-wind, accompanied with ſnow; which made great havock in the army, many of them periſhing with cold, and others being killed by the trees rooted up by the wind. The remains of the army continued their march to Amatla, where they were almoſt all killed in battle. By this and other calamities, together with the appearance of a comet, the Mexicans were thrown into the utmoſt conſternation. Montezuma was ſo terrified by theſe omens, that having in vain conſulted his aſtrologers, he applied to the king of Acolhuacan, who was reported to be very ſkilful in divination. Nezahualpilli having conferred with him at length upon the ſubject, told Montezuma that the comet preſaged ſome calamity which was about to befal their kingdoms by the arrival

Mexico.

arrival of a new people: but this being unſatisfactory to the emperor, the king of Acolhuacan challenged him to a game at foot-ball, ſtaking the truth of his prediction on the iſſue of the game. Montezuma loſt the game, but did not yet acquieſce in the truth of his prediction. He therefore applied to a celebrated aſtrologer, whom it ſeems he had not yet conſulted; but he confirmed the interpretation of Nezahualpilli: for which the emperor cauſed his houſe to be pulled down, and himſelf buried in the ruins.

73 Story of the reſurrection of a princeſs.

Many other preſages of the arrival of the Spaniards are related. The following, though apparently the moſt incredible of them all, ſeems to be believed by Clavigero. "A ſiſter of Montezuma named Papantzin, who had been married to the governor of Tlatelolco, lived in his palace after he was dead to the year 1509, when ſhe died of old age. The day after her burial a child of five or ſix years old happened to paſs from her mother's apartment to that of the major domo of the deceaſed princeſs. In paſſing by, the child ſaw the princeſs ſitting upon the ſteps of the fountain where ſhe had been accuſtomed to bathe, and heard herſelf called by the name of *cocoton*, a Mexican expreſſion of endearment, ſignifying "little girl." The child, incapable from its age of reflecting on the death of the princeſs, approached without fear, and was deſired to call the wife of her major-domo. The woman careſſed the child, and told her that the princeſs was dead; but being importuned and pulled by the gown, ſhe at laſt went; but no ſooner ſaw the princeſs than ſhe fainted. The child then ran to call her mother, who with two other women came to the aſſiſtance of the wife of the major-domo; but they alſo would have fainted, had not the princeſs called to them, and aſſured them that ſhe was really alive. Having cauſed them call the major-domo, ſhe deſired him to go and tell Montezuma what he had ſeen: but he, dreading the ſeverity of the emperor, durſt not undertake the taſk. She then deſired him to go to Tezeuco, and tell Nezahualpilli that ſhe wiſhed to ſee him. He came accordingly, and at her deſire brought Montezuma; whom ſhe informed, that during the time ſhe lay entranced ſhe had ſeen a viſion. The main purport of this viſion was to announce to her, that all her forefathers were damned; that another race of men ſhould arrive, who ſhould conquer the kingdom, and introduce the true religion; and "as ſoon as the bath ſhould be publiſhed and made known, which would waſh away ſin, ſhe ſhould be the firſt to accept of it."

74 The expectation of the Mexicans accounted for.

There can be very little doubt that this ſtory is a fiction of the Spaniſh prieſts, though it cannot be doubted that the Mexicans had ſome expectations of the arrival of the Spaniards among them at the time they actually came. This, however, we may account for without having recourſe to any thing the leaſt ſupernatural, or out of the ordinary courſe of things. The Weſt India iſlands had been diſcovered by Columbus in 1492: he had made frequent voyages, and had even diſcovered the continent. Settlements had been made; the Spaniards had ſhown their proweſs and their cruelty; and we are not to doubt, that many of the iſlanders would quit their habitations to eſcape the fury of the invaders. It would naturally occur to theſe fugitives, that the arms of theſe new comers could not be reſiſted by thoſe of the weſtern nations, while their relentleſs cruelty might eaſily ſuggeſt that they would deſtroy all before them. From the year 1492, therefore, to 1508, there was time enough for this report to have reached Mexico: and we can only attribute it to the barbarous ſtate in which the Americans were, that the Spaniards were not perfectly known and deſcribed before their arrival.

75 Vaſt numbers of human ſacrifices.

But whatever were the omens by which the arrival of the Spaniards was announced, they appear to have had no effect in working any reformation upon Montezuma or his Mexicans. Inſtead of relaxing any thing from the barbarity of their religion, they ſeem to have augmented it. Wars were carried on every where, and priſoners ſacrificed by thouſands; inſomuch, that Montezuma finding the ſtone on which the priſoners were ſacrificed too ſmall, he cauſed one of monſtrous ſize to be put in its place. It was dragged along by an immenſe number of people: but, in paſſing a wooden bridge over a canal, in the entry to the city, the bridge broke down by its enormous weight, and dragged ſeveral people into the water, among whom was the high-prieſt, who had accompanied it on the road, ſcattering incenſe as he went along. This misfortune diſconcerted them conſiderably: nevertheleſs the ſtone, by dint of exceſſive labour, was got up again, and conſecrated by the murder of 12,200 priſoners. The time, however, was now at hand when this horrible and never-ceaſing butchery was to be ended, and a moſt ſevere vengeance to overtake the perpetrators. The Spaniards having eſtabliſhed themſelves pretty well in the iſland of Cuba and Hiſpaniola, now prepared to explore the continent alſo, with a view to extend the dominions of their ſovereign, and to ſatiate, if poſſible, their own appetites for wealth.

76 Conqueſt of Mexico undertaken by Cortes.

Mexico itſelf was firſt diſcovered, though imperfectly, by a Spaniard named *Nunez de Balboa*; but in 1518 the conqueſt of it was undertaken by a celebrated adventurer named *Ferdinando Cortes*. It was not, however, without great difficulty that he got his expedition ſet on foot; being perſecuted by the Spaniſh governors in the Weſt Indies, ſo that he was at laſt obliged to throw off his allegiance to them, and proceed without any commiſſion. However, on the 10th of February 1519, he ſet ſail from the Havannah in Cuba; and ſoon landed on the iſland of Cozumel, on the coaſt of Yucatan, diſcovered the preceding year. Here he joined one of his officers named *Pedro d'Alvaredo*, who had arrived ſome days before, and collected ſome booty and taken a few priſoners. But the general ſeverely cenſured his conduct; and the priſoners were diſmiſſed, after they had been informed by an Indian interpreter named *Melchior*, that ſuch injuries were entirely diſagreeable to the intentions and wiſhes of Cortes. Here he muſtered his army, and found that it amounted to 508 ſoldiers, 16 horſemen, and 109 mechanics, pilots, and mariners. Having encouraged his men by a proper ſpeech, and releaſed, by means of ſome Indian ambaſſadors, a Spaniard named *Jerom de Aguilar*, who had been detained a priſoner for eight years, he proceeded to the river Tabaſco, where he hoped to be received in a friendly manner, as one Grijalva had been a ſhort time before; but, from ſome unknown cauſe, he was violently attacked by them: however, the ſuperiority of the Spaniſh arms ſoon decided the victory, and the inhabitants were

were obliged to own the king of Caſtile as their ſovereign.

The Spaniards then continued their courſe weſtward, to the harbour of St Juan de Ulloa; where they were met by two Mexican canoes, who carried two ambaſſadors from the emperor of that country, and ſhowed the greateſt ſigns of peace and amity. Their language was unknown to Aguilar; but one of the female priſoners above-mentioned underſtood it, and tranſlated it into the Yucatan tongue; after which Aguilar interpreted the meaning in Spaniſh. This ſlave was afterwards named *Donna Marina*, and proved very uſeful in their conferences with the natives.

At this time the Mexican empire, according to Dr Robertſon, was arrived at a pitch of grandeur to which no ſociety had ever attained in ſo ſhort a period. Though it had ſubſiſted only for 130 years, its dominion extended from the north to the ſouth ſea; over territories ſtretching about 500 leagues from eaſt to weſt, and more than 200 from north to ſouth; comprehending provinces not inferior in fertility, population, and opulence, to any in the torrid zone.—Though by nature Montezuma poſſeſſed a good deal of courage and reſolution; yet from the firſt moment that the Spaniards appeared on his coaſt, he diſcovered ſymptoms of timidity and embarraſſment, and all his ſubjects were embarraſſed as well as himſelf. The general diſmay which took place on this occaſion was partly owing to the ſtrange figure the Spaniards made, and the prodigious power of their arms; but partly alſo to the following circumſtance: An opinion prevailed almoſt univerſally among the Americans, that ſome dreadful calamity impended over their heads, from a race of formidable invaders who ſhould come from regions towards the riſing ſun, to over-run and deſolate their country. The origin of this we have already attempted to explain; but as the Mexicans were more prone to ſuperſtition than any people in the new world, they were more deeply affected with the appearance of the Spaniards, whom they inſtantly ſuppoſed to be the inſtruments deſtined to bring about that fatal revolution which they dreaded: and this produced the embaſſy above-mentioned.

By means of his two interpreters, Donna Marina and Aguilar, Cortes learned that the chiefs of the Mexican embaſſy were deputies from Pilpatoe and Teutile; the one governor of a province under the emperor, and the other the commander of all his forces in that province: the purport of their embaſſy was, to inquire what his intentions were in viſiting their coaſts, and to offer him what aſſiſtance he might need in order to continue his voyage. Cortes, in his turn, alſo profeſſed the greateſt friendſhip; and informed the ambaſſadors, that he came to propoſe matters of the utmoſt conſequence to the welfare of the prince and his kingdom; which he would more fully unfold in perſon to the governor and the general. Next morning, without waiting for any anſwer, he landed his troops, his horſes, and his artillery; began to erect huts for his men, and to fortify his camp.—The natives, inſtead of oppoſing the entrance of theſe fatal gueſts into their country, aſſiſted them in all their operations with an alacrity which they had ere long reaſon to repent.

Mexico.

The next day the ambaſſadors had a formal audience; at which Cortes acquainted them, that he came from Don Carlos of Auſtria, king of Caſtile, the greateſt monarch of the eaſt, and was intruſted with propoſitions of ſuch moment, that he would impart them to none but the emperor himſelf, and therefore required to be conducted immediately to the capital. This demand produced the greateſt uneaſineſs; and the ambaſſadors did all in their power to diſſuade Cortes from his deſign, endeavouring to conciliate his good-will by the preſents ſent him by Montezuma. Theſe they introduced with great parade, and conſiſted of fine cotton-cloth, of plumes of various colours, and of ornaments of gold and ſilver to a conſiderable value, the workmanſhip of which appeared to be as curious as the materials were rich. But theſe preſents ſerved only to excite the avidity of the Spaniards, and to increaſe their deſire for becoming maſters of a country which abounded with ſo many precious commodities. Cortes indeed could ſcarcely reſtrain himſelf ſo far as to hear the arguments made uſe of by the ambaſſadors to diſſuade him from going to the capital; and, in a haughty, determined tone, inſiſted on his former demand of being admitted to a perſonal interview with their ſovereign.

80 The Indians endeavour to diſſuade him from going to the capital, but in vain.

During this converſation, ſome painters in the retinue of the Mexican chiefs had been diligently employed in delineating, upon white cotton cloths, figures of the ſhips, horſes, artillery, ſoldiers, and whatever elſe attracted their eyes as ſingular. When Cortes obſerved this, and was informed that theſe pictures were to be ſent to Montezuma, he reſolved to render the repreſentation ſtill more ſtriking and intereſting. The trumpets, by his orders, ſounded an alarm; the troops formed in order of battle, and ſhowed their agility and ſtrength in the beſt manner they could; while the artillery was pointed againſt the neighbouring trees, among which it made dreadful havock. The Indians for ſome time looked on with ſilent aſtoniſhment; but at the exploſion of the cannon, ſome fled, others fell to the ground, and all were ſo confounded, that Cortes found it difficult to quiet and compoſe their minds.

81 Montezuma made acquainted with his deſign.

When the painters had exerted their utmoſt efforts in repreſenting all theſe wonderful things, meſſengers were immediately diſpatched to Montezuma with the pictures, and a full account of every thing that had paſſed ſince the arrival of the Spaniards, together with ſome European curioſities to Montezuma; which, though of no great value, Cortes believed would be acceptable on account of their novelty. The Mexican monarchs, in order to obtain the earlieſt information of every occurrence in all parts of their empire, had couriers poſted at proper ſtations along the principal roads; and as theſe were trained to agility by a regular education, they conveyed intelligence with ſurpriſing rapidity. Though the city in which Montezuma reſided was above 180 miles from St Juan de Ulloa, Cortes's preſents were carried thither, and an anſwer returned to his demands, in a few days. As the anſwer was unfavourable, Montezuma had endeavoured to mollify the Spaniſh general by the richneſs of his preſents. Theſe conſiſted of the manufactures of the country; cotton-ſtuffs ſo fine, and of ſuch delicate

Mexico.

82 Sends an unfavourable answer, but accompanied with rich presents.

delicate texture, as to resemble silk; pictures of animals, trees, and other natural objects, formed with feathers of different colours, disposed and mingled with such skill and elegance as to rival the works of the pencil in truth and beauty of imitation. But what chiefly attracted their attention, were two large plates of a circular form; one of massive gold representing the sun, the other of silver representing the moon. These were accompanied with bracelets, collars, rings, and other trinkets of gold; and that nothing might be wanting which could give the Spaniards a complete idea of what the country afforded, some boxes filled with pearls, precious stones, and grains of gold unwrought, as they had been found in the mines or rivers, were sent along with the rest. Cortes received all with an appearance of the most profound respect for Montezuma; but when the Mexicans, presuming upon this, informed him, that their master, though he desired him to accept of what he had sent as a token of his regard for the prince whom he represented, would not give his consent that foreign troops should approach nearer to his capital, or even allow them to continue longer in his dominions, Cortes declared, in a manner more resolute and peremptory than formerly, that he must insist on his first demand; as he could not, without dishonour, return to his own sovereign until he was admitted into the presence of the prince whom he was appointed to visit in his name. The Mexicans were astonished at the sight of a man who dared to oppose the will of their emperor; but not being willing to come to an open rupture with such formidable enemies, with much ado they prevailed upon Cortes to promise that he would not move from his present camp until the return of a messenger whom they sent to Montezuma for further instructions.

83 Cortes still insists on his demands.

The pusillanimity of the Indian monarch afforded time to the Spaniards to take measures which would have been out of their power had they been vigorously attacked on their first refusal to obey his orders. Cortes used every method of securing the affections of the soldiers; which indeed was very necessary, as many of them began to exclaim against the rashness of his attempt in leading them against the whole force of the Mexican empire. In a short time Teutile arrived with another present from Montezuma, and together with it delivered the ultimate orders of that monarch to depart instantly out of his dominions; and when Cortes, instead of complying with his demands, renewed his request of audience, the Mexican immediately left the camp with strong marks of surprise and resentment. Next morning, none of the natives appeared; all friendly correspondence seemed to be at an end, and hostilities were expected to commence every moment. A sudden consternation ensued among the Spaniards, and a party was formed against him by the adherents of Velasques; who took advantage of the occasion, and deputed one of their number, a principal officer, to remonstrate, as if in name of the whole army, against his rashness, and to urge the necessity of his returning to Cuba. Cortes received the message without any appearance of emotion; and as he well knew the temper and wishes of his soldiery, and foresaw how they would receive a proposition so fatal to all the splendid hopes and schemes which they had been forming

84 Montezuma peremptorily commands him to leave his dominions.

with such complacency, he pretended to comply with the request now made him, and issued orders that the army should be in readiness next day to embark for Cuba. Upon hearing this, the troops, as Cortes had expected, were quite outrageous: they positively refused to comply with these orders, and threatened immediately to choose another general if Cortes continued to insist on their departure.

Our adventurer was highly pleased with the disposition which now appeared among his troops: nevertheless, dissembling his sentiments, he declared, that his orders for embarking had proceeded from a persuasion that it was agreeable to his fellow-soldiers, to whose opinion he had sacrificed his own; but now he acknowledged his error, and was ready to resume his original plan of operation. This speech was highly applauded; and Cortes, without allowing his men time to cool, set about carrying his designs into execution. In order to give a beginning to a colony, he assembled the principal persons in his army, and by their suffrages elected a council and magistrates, in whom the government was to be vested. The persons chosen were most firmly attached to Cortes; and the new settlement had the name of *Villa Rica de la Vera Cruz*; that is, the rich town of the true cross.

Villa ca[...] foun[...]

Before this court of his own making, Cortes did not hesitate at resigning all his authority, and was immediately re-elected chief-justice of the colony, and captain-general of his army, with an ample commission, in the king's name, to continue in force till the royal pleasure should be farther known. The soldiers eagerly ratified their choice by loud acclamations; and Cortes, now considering himself as no longer accountable to any subject, began to assume a much greater degree of dignity, and to exercise more extensive powers than he had done before. Some of the soldiers began to exclaim against the proceedings of the council as illegal; but the ringleaders were instantly sent on board the fleet loaded with irons. By this timely severity the rest were overawed; and Cortes, knowing of how great importance unanimity was to his future success, soon found means to reconcile those who were most disaffected; to which purpose a liberal distribution of the Mexican gold, both among friends and foes, contributed not a little.

The [...]vernm[...] of the [...] colon[...] ted i[...] Corte[...]

Cortes having thus strengthened himself as well as he could, resolved to advance into the country; and to this he was encouraged by the behaviour of the cacique or petty prince of Zempoalla, a considerable town at no great distance. This prince, though subject to Montezuma, was exceedingly impatient of the yoke; and so filled with dread and hatred of the emperor, that nothing could be more acceptable to him than an appearance of being delivered from that subjection; and a deliverance of this kind he now hoped from the Spaniards. For this reason, he sent ambassadors to Cortes, with offers of friendship, which were gladly accepted by him; and in consequence of the alliance, he very soon visited Zempoalla. Here he was received in the most friendly manner imaginable, and had a respect paid towards him almost equivalent to adoration. The cacique informed him of many particulars relating to the character of Montezuma.—He told him that he was a tyrant, haughty, cruel, and

and ſuſpicious; who treated his own ſubjects with arrogance, ruined the conquered provinces by his extortions, and often tore their ſons and daughters from them by violence; the former to be offered as victims to his gods, the latter to be reſerved as concubines for himſelf and favourites. Cortes, in reply, artfully inſinuated, that one great object of the Spaniards in viſiting a country ſo remote from their own was, to redreſs grievances, and to relieve the oppreſſed; and having encouraged him to hope for this interpoſition in due time, continued his march to Quiabiſlan, the territory of another cacique, and where, by the friendly aid of the Indians, a Spaniſh colony was ſoon formed.

During the reſidence of Cortes in theſe parts, he ſo far wrought on the minds of the caciques of Zempoalla and Quiabiſlan, that they ventured to inſult the Mexican power, at the very name of which they had been formerly accuſtomed to tremble. Some of Montezuma's officers having appeared to levy the uſual tribute, and to demand a certain number of human victims, as an expiation of their guilt in preſuming to hold intercourſe with thoſe ſtrangers whom the emperor had commanded to leave his dominions; inſtead of obeying his orders, they made them priſoners, treated them with great indignity, and, as their ſuperſtition was no leſs barbarous than Montezuma's, they threatened to ſacrifice them to their gods. From this laſt danger, however, they were delivered by the interpoſition of Cortes, who manifeſted the utmoſt horror at the mention of ſuch a deed. This act of rebellion firmly attached the two caciques to the intereſt of Cortes; and without heſitation they acknowledged themſelves vaſſals of the king of Spain. Their example was followed by the Totonaques, a fierce people who inhabited the mountainous parts of the country. They willingly ſubjected themſelves to the crown of Caſtile; and offered to accompany Cortes with all their forces in his march towards Mexico.

Though Cortes had now taken ſuch meaſures as in a manner enſured his ſucceſs; yet as he had thrown off all dependence on the governor of Cuba, who was his lawful ſuperior, and apprehended his intereſt at court, he thought proper, before he ſet out on his intended expedition, to take the moſt effectual meaſures againſt the impending danger. With this view, he perſuaded the magiſtrates of his colony to addreſs a letter to the king, containing a pompous account of their own ſervices, of the country they had diſcovered, &c. and of the motives which had induced them to throw off their allegiance to the governor of Cuba, and to ſettle a colony dependent on the crown alone, in which the ſupreme power civil as well as military had been veſted in Cortes; humbly requeſting their ſovereign to ratify what had been done by his royal authority. Cortes himſelf wrote in a ſimilar ſtrain; but as he knew that the Spaniſh court, accuſtomed to the repeated exaggerations of American adventurers, would give little credit to the ſplendid accounts of New-Spain, if they were not accompanied with ſuch a ſpecimen of what it contained as would excite an high idea of its opulence, he ſolicited his ſoldiers to relinquiſh what they might claim as their part of the treaſures which had hitherto been collected, in order that the whole might be ſent to the king. Portocarrero and Montejo, the chief magiſtrates of the colony, were appointed to carry this preſent to Caſtile, with expreſs orders not to touch at Cuba in their paſſage thither. But while a veſſel was preparing for their departure, an unexpected event produced a general alarm. Some ſoldiers and ſailors, ſecretly diſaffected to Cortes, formed a deſign of ſeizing one of the brigantines, and making their eſcape to Cuba, in order to give ſuch intelligence to the governor as might enable him to intercept the veſſel which was to carry the treaſure and diſpatches to Spain. This conſpiracy was conducted with profound ſecrecy; but at the moment when every thing was ready for execution, the ſecret was diſcovered by one of the aſſociates. The latent ſpirit of diſaffection which Cortes was now too well convinced had not been extinguiſhed amongſt his troops, gave him very great uneaſineſs. The only method which he could think of to prevent ſuch conſpiracies for the future was, to deſtroy his fleet; and thus deprive his ſoldiers of every reſource except that of conqueſt: and with this propoſal he perſuaded his men to comply. With univerſal conſent therefore the ſhips were drawn aſhore, and, after being ſtripped of their ſails, rigging, iron-work, and whatever elſe might be of uſe, they were broke in pieces.

91 Cortes burns his fleet.

Cortes having thus rendered it neceſſary for his troops to follow wherever he choſe to lead, began his march to Zempoalla with 500 infantry, 15 horſe, and ſix field-pieces. The reſt of his troops, conſiſting chiefly of ſuch as from age or infirmity were leſs fit for active ſervice, he left as a garriſon in Villa Rica, under the command of Eſcalante, an officer of merit, and warmly attached to his intereſt. The cacique of Zempoalla ſupplied him with proviſions; and with 200 of thoſe Indians called *Tamames*, whoſe office, in a country where tame animals were unknown, was to carry burdens, and perform all manner of ſervile labour. He offered likewiſe a conſiderable body of troops; but Cortes was ſatisfied with 400; taking care, however, to chooſe perſons of ſuch note, that they might ſerve as hoſtages for the fidelity of their maſter.

Nothing memorable happened till the Spaniards arrived on the confines of the republic of Tlaſcala. The inhabitants of that province were warlike, fierce, and revengeful, and had made conſiderable progeſs in agriculture and ſome other arts. They were implacable enemies to Montezuma; and therefore Cortes hoped that it would be an eaſy matter for him to procure their friendſhip. With this view, four Zempoallans of high rank were ſent ambaſſadors to Tlaſcala, dreſſed with all the badges of that office uſual among the Indians. The ſenate were divided in their opinions with regard to the propoſals of Cortes: but at laſt Magiſcatzin, one of the oldeſt ſenators, and a perſon of great authority, mentioned the tradition of their anceſtors, and the revelations of their prieſts; that a race of invincible men, of divine origin, who had power over the elements, ſhould come from the eaſt to ſubdue their country. He compared the reſemblance which the ſtrangers bore to the perſons figured in the tradition of Mexico, their dominion over the elements of fire, air, and water; he reminded the

92 Sends ambaſſadors to the republic of Tlaſcala.

the ſenate of their prodigies, omens, and ſignals, which had lately terrified the Mexicans, and indicated ſome very important event; and then declared his opinion, that it would be raſhneſs to oppoſe a force apparently aſſiſted by heaven, and men who had already proved, to the ſad experience of thoſe who oppoſed them, that they were invincible. This orator was oppoſed by Xicotencal, who endeavoured to prove that the Spaniards were at beſt but powerful magicians: that they had rendered themſelves obnoxious to the gods by pulling down their images and altars, (which indeed Cortes had very imprudently done at Zempoalla); and of conſequence, that they might eaſily be overcome, as the gods would not fail to reſent ſuch an outrage. He therefore voted for war, and adviſed the cruſhing of theſe invaders at one blow.

93 The Tlaſcalans reſolve on war.

The advice of Xicotencal prevailed; and in conſequence of it, the ambaſſadors were detained; which giving Cortes the alarm, he drew nearer the city of Tlaſcala. In this tranſaction we may eaſily ſee how little the Tlaſcalans, notwithſtanding all their ferocity, were ſkilled in military affairs. They ſuffered Cortes, with his army drawn up in good order, to paſs a ſtrong wall between two mountains, which might have been very advantageouſly defended againſt him. He had not advanced far beyond this paſs, however, before a party of Tlaſcalans with plumes were diſcovered, which denoted that an army was in the field. Theſe he drove before him by a detachment of ſix horſe, obliged them to join another party, and then reinforcing the advanced detachment, charged the enemy with ſuch vigour that they began to retire. Five thouſand Tlaſcalans, whom Xicotencal had placed in ambuſh, then ruſhed out of their hiding places, juſt as the infantry came up to aſſiſt their ſlender body of cavalry. The enemy attacked with the utmoſt fury; but were ſo much diſconcerted by the firſt diſcharge of the fire-arms, that they retreated in confuſion, furniſhing the Spaniards with an opportunity of purſuing them with great ſlaughter. Cortes, however, ſuppoſing that this could not be their whole force, advanced with the utmoſt caution, in order of battle, to an eminence, from whence he had a view of the main body of the Tlaſcalan army commanded by Xicotencal, conſiſting of no fewer than 40,000 men. By theſe the ſmall army of Cortes was entirely ſurrounded; which Xicotencal no ſooner perceived, than he contracted the circle with incredible diligence, while the Spaniards were almoſt overwhelmed with ſhowers of arrows, darts, and ſtones. It is impoſſible but in this caſe many of the Spaniards muſt have periſhed, had it not been for the inſufficiency of the Indian weapons. Their arrows and ſpears were headed only with flint, or the bones of fiſhes; their ſtakes hardened in the fire, and wooden ſwords, though deſtructive weapons among naked Indians, were eaſily turned aſide by the Spaniſh bucklers, and could hardly penetrate the quilted jackets which the ſoldiers wore. Theſe circumſtances gave the Spaniards a prodigious advantage over them; and therefore the Tlaſcalans, notwithſtanding their valour and ſuperiority in number, could accompliſh no more in the preſent inſtance, than to kill one horſe and ſlightly wound nine ſoldiers.

The Tlaſcalans being taught by this, and ſome ſubſequent encounters, how much they were inferior to the Spaniards, began to conceive them to be really what Magiſcatzin had ſaid: a ſuperior order of beings, againſt whom human power could not prevail. In this extremity they had recourſe to their prieſts, requiring them to reveal the cauſes of ſuch extraordinary events, and to declare what means they ſhould take to repel ſuch formidable invaders. The prieſts, after many ſacrifices and incantations, delivered their reſponſe, That theſe ſtrangers were the offspring of the ſun, procreated by his animating energy in the regions of the eaſt: that, by day, while cheriſhed with the influence of his parental beams, they were invincible; but by night, when his reviving heat was withdrawn, their vigour declined and faded like herbs in the field, and they dwindled down into mortal men. In conſequence of this, the Tlaſcalans acted in contradiction to one of their moſt eſtabliſhed maxims in war, and ventured to attack the enemy in the night-time, hoping to deſtroy them when enfeebled and ſurpriſed. But the Spaniſh centinels having obſerved ſome extraordinary movements among the Tlaſcalans, gave the alarm. Immediately the troops were under arms, and ſallying out, defeated their antagoniſts with great ſlaughter, without allowing them to approach the camp. By this diſaſter the Tlaſcalans were heartily diſpoſed to peace; but they were at a loſs to form an adequate idea of the enemies they had to deal with. They could not aſcertain the nature of theſe ſurpriſing beings, or whether they were really of a benevolent or malignant diſpoſition. There were circumſtances in their behaviour which ſeemed to favour each opinion. On the one hand, as the Spaniards conſtantly diſmiſſed the priſoners whom they took, not only without injury, but often with preſents of European toys, and renewed their offers of peace after every victory; this lenity amazed people accuſtomed to the exterminating ſyſtem of war known in America, and who ſacrificed and devoured without mercy all the captives taken in battle; and diſpoſed them to entertain ſentiments favourable to their humanity. But, on the other hand, as Cortes had ſeized 50 of their countrymen who brought proviſions to their camp, and cut off their heads; this bloody ſpectacle, added to the terror occaſioned by the fire-arms and horſes, filled them with dreadful ideas of their ferocity. Accordingly they addreſſed them in the following manner: "If (ſaid they) you are divinities of a cruel and ſavage nature, we preſent to you five ſlaves, that you may drink their blood and eat their fleſh. If you are mild deities, accept an offering of incenſe and variegated plumes. If you are men, here is meat, bread, and fruit, to nouriſh you." After this addreſs, the peace was ſoon concluded, to the great ſatisfaction of both parties. The Tlaſcalans yielded themſelves as vaſſals to the crown of Caſtile, and engaged to aſſiſt Cortes in all his operations; while he took the republic under his protection, and promiſed to defend their perſons and poſſeſſions from injury and violence.

94 But are defeated and ſue for peace.

95 Which is granted.

96 Great diſtreſſes of the Spaniards.

This reconciliation took place at a very ſeaſonable juncture for the Spaniards. They were not only worn out with inceſſant toil, but ſo deſtitute of neceſſaries, that they had no other ſalve to dreſs their wounds but what

what was compoſed of the fat of Indians whom they had ſlain. Their diſtreſſes, in ſhort, were ariſen to ſuch an height, that they had begun to murmur, and even to deſpair, inſomuch that Cortes had much difficulty in reſtraining them within any kind of bounds; but the ſubmiſſion of the Tlaſcalans, and their own triumphant entry into the city, where they were received with the reverence due to a ſuperior order of beings, baniſhed at once all memory of paſt ſufferings, diſpelled every anxious thought, and fully convinced them that they could not be reſiſted by any power in America.

Cortes left no method untried to gain the favour and confidence of the Tlaſcalans; which, however, he had almoſt entirely loſt, by his untimely zeal in deſtroying their idols as he had done thoſe of Zempoalla. But he was deterred from this raſh action by his chaplain, father Bartholomew de Olmedo; and left the Tlaſcalans in the undiſturbed exercife of their ſuperſtition, requiring only that they ſhould deſiſt from their horrid practice of offering human victims. As ſoon as his troops were fit for ſervice, he reſolved to continue his march towards Mexico, notwithſtanding the remonſtrances of the Tlaſcalans, who looked upon his deſtruction as unavoidable if he put himſelf into the power of ſuch a faithleſs prince as Montezuma. But the emperor, probably intimidated with the fame of his exploits, had reſolved to admit his viſit; and informed Cortes that he had given orders for his friendly reception at Cholula, the next place of any conſequence on the road to Mexico. In this, however, he was by no means ſincere. Cholula was looked upon by all the inhabitants of the empire as a very holy place; the ſanctuary and chief ſeat of their gods, to which pilgrims reſorted from every province, and a greater number of human victims were offered in its principal temple than even in that of Mexico. Montezuma therefore invited the Spaniards thither, either from ſome ſuperſtitious hope that the gods would not ſuffer this ſacred manſion to be defiled; or from a belief, that he himſelf might there find an opportunity of cutting them off with more certainty of ſucceſs, when under the immediate protection of his gods. Cortes, however, was received with much ſeeming cordiality; but 6000 Tlaſcalan troops who accompanied him were obliged to remain without the town, as the Cholulans refuſed to admit their ancient enemies within their precincts. Yet two of theſe, by diſguiſing themſelves, got into the city, and acquainted Cortes that they obſerved the women and children belonging to the principal citizens retiring every night in a great hurry, and that ſix children had been ſacrificed in the great temple; a ſign that ſome warlike enterpriſe was at hand. At the ſame time Donna Marina, the interpreter, received information from an Indian woman of diſtinction, whoſe confidence ſhe had gained, that the deſtruction of the Spaniards was concerted; that a body of Mexican troops lay concealed near the town; that ſome of the ſtreets were barricaded, in others deep pits or trenches were dug, and ſlightly covered over, as traps into which the horſe might fall; that ſtones and miſſive weapons were collected on the tops of the temples, with which to overwhelm the infantry; that the fatal hour was already at hand, and their ruin unavoidable. Cortes, alarmed at this news, ſecretly arreſted three of the chief prieſts, from whom he extorted a confeſſion that confirmed the intelligence he had already received. As not a moment was to be loſt, he inſtantly reſolved to prevent his enemies, and to inflict on them ſuch dreadful vengeance as might ſtrike Montezuma and his ſubjects with terror. For this purpoſe the Spaniards and Zempoallans were drawn up in a large court, which had been allotted for their quarters, near the centre of the town; the Tlaſcalans had orders to advance; the magiſtrates and chief citizens were ſent for under various pretexts, and ſeized. On a ſignal given, the troops ruſhed out, and fell upon the multitude, deſtitute of leaders, and ſo much aſtoniſhed, that the weapons dropped from their hands, and they ſtood motionleſs, and incapable of defence. While the Spaniards attacked them in front, the Tlaſcalans did the ſame in the rear; the ſtreets were filled with ſlaughter; the temples, which afforded a retreat to the prieſts and ſome leading men, were ſet on fire, and they periſhed in the flames. This ſcene of horror continued two days, during which the wretched inhabitants ſuffered all that the deſtructive rage of the Spaniards, or the implacable revenge of their Indian allies, could inflict. At length the carnage ceaſed, after the ſlaughter of 6000 Cholulans, without the loſs of a ſingle Spaniard. Cortes then releaſed the magiſtrates; and reproaching them bitterly for their intended treachery, declared, that as juſtice was now appeaſed, he forgave the offence; but required them to recal the inhabitants who had fled, and re-eſtabliſh order in the town. Such was the aſcendant that the Spaniards had now obtained over this ſuperſtitious race, that this order was inſtantly complied with; and the city was in a few days again filled with people, who paid the moſt reſpectful ſervice to thoſe men whoſe hands were ſtained with the blood of their relations and fellow-citizens.

Mexico. 99 Severe puniſhment of the Cholulans.

From Cholula, Cortes advanced directly towards Mexico; and throughout the whole of his journey was entertained with accounts of the oppreſſions and cruelty of Montezuma. This gave him the greateſt hope of accompliſhing his deſign; as he now perceived that the empire was entirely divided, and no ſort of unanimity prevailed among them. No enemy appeared to check his progreſs. Montezuma was quite irreſolute; and Cortes was almoſt at the gates of the capital before the emperor had determined whether to receive him as a friend or oppoſe him as an enemy. But as no ſign of open hoſtility appeared, the Spaniards, without regarding the fluctuations of Montezuma's ſentiments, continued their march to Mexico, with great circumſpection and the ſtricteſt diſcipline, though without ſeeming to ſuſpect the prince whom they were about to viſit.

100 Diſaffection of Montezuma's ſubjects.

When they drew near the city, about 1000 perſons, who appeared to be of diſtinction, came forth to meet them, adorned with plumes, and clad in mantles of fine cotton. Each of theſe, in his order, paſſed by Cortes, and ſaluted him according to the mode deemed moſt reſpectful and ſubmiſſive in their country. They announced the approach of Montezuma himſelf, and ſoon after his harbingers came in ſight. There appeared firſt 200 perſons in an uniform dreſs, with large plumes of feathers, alike in faſhion, marching two and two, in deep ſilence, barefooted, with their eyes fixed on the ground. Theſe were followed by a company of higher

101 Meeting of Cortes and Montezuma.

rank,

Mexico. rank, in their moſt ſhowy apparel; in the midſt of whom was Montezuma, in a chair or litter richly ornamented with gold, and feathers of various colours. Four of his principal favourites carried him on their ſhoulders, others ſupported a canopy of curious workmanſhip over his head. Before him marched three officers with rods of gold in their hands, which they lifted up on high at certain intervals; and at that ſignal all the people bowed their heads, and hid their faces, as unworthy to look on ſo great a monarch. When he drew near, Cortes diſmounted, advancing towards him with officious haſte, and in a reſpectful poſture. At the ſame time Montezuma alighted from his chair, and leaning on the arms of two of his near relations, approached with a ſlow and ſtately pace, his attendants covering the ſtreet with cotton cloths, that he might not touch the ground. Cortes accoſted him with profound reverence, after the European faſhion. He returned the ſalutation, according to the mode of his country, by touching the earth with his hand, and then kiſſing it. This ceremony, the cuſtomary expreſſion of reverence from inferiors towards thoſe who are above them in rank, appeared ſuch amazing condeſcenſion in a proud monarch, who ſcarcely deigned to conſider the reſt of mankind as of the ſame ſpecies with himſelf, that all his ſubjects firmly believed thoſe perſons, before whom he humbled himſelf in this manner, to be ſomething more than human. Accordingly, as they marched through the crowd, the Spaniards frequently, and with much ſatisfaction, heard themſelves denominated *teules*, or *divinities*. Nothing material paſſed in this firſt interview. Montezuma conducted Cortes to the quarters which he had prepared for his reception; and immediately took leave of him, with a politeneſs not unworthy of a court more refined. "You are now (ſays he), with your brothers, in your own houſe; refreſh yourſelves after your fatigue, and be happy until I return." The place allotted to the Spaniards for their lodging was a houſe built by the father of Montezuma. It was ſurrounded by a ſtone-wall, with towers at proper diſtances, which ſerved for defence as well as for ornament; and its apartments and courts were ſo large as to accommodate both the Spaniards and their Indian allies. The firſt care of Cortes was to take precautions for his ſecurity, by planting the artillery ſo as to command the different avenues which led to it, by appointing a large diviſion of his troops to be always on guard, and by poſting centinels at proper ſtations, with injunctions to obſerve the ſame vigilant diſcipline as if they were within ſight of an enemy's camp.

In the evening Montezuma returned to viſit his gueſts with the ſame pomp as in their firſt interview; and brought preſents of ſuch value, not only to Cortes and to his officers, but even to the private men, as proved the liberality of the monarch to be ſuitable to the opulence of his kingdom. A long conference enſued, in which Cortes learned what was the opinion of Montezuma with reſpect to the Spaniards It was an eſtabliſhed tradition, he told him, among the Mexicans, that their anceſtors came originally from a remote region, and conquered the provinces now ſubject to his dominion; that after they were ſettled there, the great captain who conducted this colony returned to his own country, promiſing, that at ſome future period his deſcendants ſhould viſit them, aſſume the government, and reform their conſtitutions and laws; that, from what he had heard and ſeen of Cortes and his followers, he was convinced that they were the very perſons whoſe appearance and prophecies taught them to expect; that accordingly he had received them, not as ſtrangers, but as relations of the ſame blood and parentage, and deſired that they might conſider themſelves as maſters in his dominions; for both himſelf and his ſubjects ſhould be ready to comply with their will, and even to prevent their wiſhes. Cortes made a reply in his uſual ſtyle with reſpect to the dignity and power of his ſovereign, and his intention in ſending him into that country; artfully endeavouring ſo to frame his diſcourſe, that it might coincide as much as poſſible with the idea which Montezuma had formed concerning the origin of the Spaniards. Next morning, Cortes and ſome of his principal attendants were admitted to a public audience of the emperor. The three ſubſequent days were employed in viewing the city; the appearance of which, ſo far ſuperior in the order of its buildings and the number of its inhabitants to any place the Spaniards had beheld in America, and yet ſo little reſembling the ſtructure of an European city, filled them with ſurpriſe and admiration.

Deſcription of the city of Mexico. Mexico, *Tenuchtitlan*, as it was anciently called by the natives, is ſituated in a large plain, environed by mountains of ſuch height, that though within the torrid zone, the temperature of its climate is mild and healthful. All the moiſture which deſcends from the high grounds is collected in ſeveral lakes, the two largeſt of which, of about 90 miles in circuit, communicate with each other. The waters of the one are freſh, thoſe of the others brackiſh. On the banks of the latter, and on ſome ſmall iſlands adjoining to them, the capital of Montezuma's empire was built. The acceſs to the city was by artificial cauſeways or ſtreets, formed of ſtones and earth, about 30 feet in breadth. As the waters of the lake, during the rainy ſeaſon, overflowed the flat country, theſe cauſeways were of conſiderable length. That of Tacuba on the weſt a mile and a half; that of Tezenco on the north-weſt three miles; that of Cuoyacan towards the ſouth ſix miles. On the eaſt there was no cauſeway, and the city could be approached only by canoes. In each of theſe cauſeways were openings, at proper intervals, through which the waters flowed; and over theſe beams of timber were laid, which being covered with earth, the cauſeway or ſtreet had every where an uniform appearance. As the approaches to the city were ſingular, its conſtruction was remarkable. Not only the temple of their gods, but the houſes belonging to the monarch and to perſons of diſtinction, were of ſuch dimenſions, that, in compariſon with any other buildings which had been diſcovered in America, they might be termed *magnificent*. The habitations of the common people were mean, reſembling the huts of other Indians. But they were all placed in a regular manner, on the banks of the canals which paſſed thro' the city, in ſome of its diſtricts, or on the ſides of the ſtreets which interſected it in other quarters In ſeveral places were large openings or ſquares, one of which, allotted for the great market, is ſaid to have been ſo ſpacious, that 40,000 or 50,000 perſons carried on traffic

traffic there. In this city, the pride of the New World, and the nobleft monument of the induftry and art of man, while unacquainted with the ufe of iron, and deftitute of aid from any domeftic animal, the Spaniards, who are moft moderate in their computations, reckon that there were at leaft 60,000 inhabitants.

But how much foever the novelty of thofe objects might amufe or aftonifh the Spaniards, they felt the utmoft folicitude with refpect to their own fituation. From a concurrence of circumftances, no lefs unexpected than favourable to their progrefs, they had been allowed to penetrate into the heart of a powerful kingdom, and were now lodged in its capital, without having once met with open oppofition from its monarch. The Tlafcalans, however, had earneftly diffuaded them from placing fuch confidence in Montezuma as to enter a city of fuch a peculiar fituation as Mexico, where that prince would have them at mercy, fhut up as it were in a fnare, from which it was impoffible to efcape. They affured them that the Mexican priefts had, in the name of the gods, counfelled their fovereign to admit the ftrangers into the capital, that he might cut them off there at one blow with perfect fecurity. The Spaniards now perceived, too plainly, that the apprehenfions of their allies were not deftitute of foundation; that, by breaking the bridges placed at certain intervals on the caufeways, or by deftroying part of the caufeways themfelves, their retreat would be rendered impracticable, and they muft remain cooped up in the centre of a hoftile city, furrounded by multitudes fufficient to overwhelm them, and without a poffibility of receiving aid from their allies. Montezuma had, indeed, received them with diftinguifhed refpect. But ought they to reckon upon this as real, or to confider it as feigned? Even if it were fincere, could they promife on its continuance? Their fafety depended upon the will of a monarch in whofe attachment they had no reafon to confide; and an order flowing from his caprice, or a word uttered by him in paffion, might decide irrevocably concerning their fate.

Thefe reflections, fo obvious as to occur to the meaneft foldier, did not efcape the vigilant fagacity of their general. Before he fet out from Cholula, Cortes had received advice from Villa Rica, that Qualpopoca, one of the Mexican generals on the frontiers, having affembled an army in order to attack fome of the people whom the Spaniards had encouraged to throw off the Mexican yoke, Efcalante had marched out with part of the garrifon to fupport his allies; that an engagement had enfued, in which, though the Spaniards were victorious, Efcalante, with feven of his men, had been mortally wounded, his horfe killed, and one Spaniard had been furrounded by the enemy and taken alive; that the head of this unfortunate captive, after being carried in triumph to different cities, in order to convince the people that their invaders were not immortal, had been fent to Mexico. Cortes, though alarmed with this intelligence, as an indication of Montezuma's hoftile intentions, had continued his march. But as foon as he entered Mexico, he became fenfible, that, from an excefs of confidence in the fuperior valour and difcipline of his troops, as well as from the difadvantage of having nothing to guide him in an unknown country but the defective intelligence which he received from people with whom his mode of communication was very imperfect, he had pufhed forward into a fituation, where it was difficult to continue, and from which it was dangerous to retire. Difgrace, and perhaps ruin, was the certain confequence of attempting the latter. The fuccefs of his enterprife depended upon fupporting the high opinion which the people of New Spain had formed with refpect to the irrefiftible power of his arms. Upon the firft fymptom of timidity on his part, their veneration would ceafe, and Montezuma, whom fear alone reftrained at prefent, would let loofe upon him the whole force of his empire. At the fame time, he knew that the countenance of his own fovereign was to be obtained only by a feries of victories; and that nothing but the merit of extraordinary fuccefs could fcreen his conduct from the cenfure of irregularity. From all thefe confiderations, it was neceffary to maintain his ftation, and to extricate himfelf out of the difficulties in which one bold ftep had involved him, by venturing upon another ftill bolder. The fituation was trying, but his mind was equal to it; and after revolving the matter with deep attention, he fixed upon a plan no lefs extraordinary than daring. He determined to feize Montezuma in his palace, and carry him a prifoner to the Spanifh quarters. From the fuperftitious veneration of the Mexicans for the perfon of their monarch, as well as their implicit fubmiffion to his will, he hoped, by having Montezuma in his power, to acquire the fupreme direction of their affairs; or at leaft, with fuch a facred pledge in his hands, he made no doubt of being fecure from any effort of their violence.

Mexico.

105 Cortes refolves to feize Montezuma in his palace.

This he immediately propofed to his officers. The timid ftartled at a meafure fo audacious, and raifed objections. The more intelligent and refolute, confcious that it was the only refource in which there appeared any profpect of fafety, warmly approved of it, and brought over their companions fo cordially to the fame opinion, that it was agreed inftantly to make the attempt. At his ufual hour of vifiting Montezuma, Cortes went to the palace, accompanied by Alvarado, Sandoval, Lugo, Velafquez de Leon, and Davila, five of his principal officers, and as many trufty foldiers. Thirty chofen men followed, not in regular order, but fauntering at fome diftance, as if they had no object but curiofity; fmall parties were pofted at proper intervals, in all the ftreets leading from the Spanifh quarters to the court; and the remainder of his troops, with the Tlafcalan allies, were under arms, ready to fally out on the firft alarm. Cortes and his attendants were admitted without fufpicion; the Mexicans retiring, as ufual, out of refpect. He addreffed the monarch in a tone very different from that which he had employed in former conferences; reproaching him bitterly as the author of the violent affault made upon the Spaniards by one of his officers, and demanding public reparation for the lofs which he had fuftained by the death of fome of his companions, as well as for the infult offered to the great prince whofe fervants they were. Montezuma, confounded at this unexpected accufation, and changing colour either from the confcioufnefs of guilt, or from feeling the indignity with which he was treated, afferted his own innocence with great earneftnefs; and, as a proof of it, gave orders inftantly to bring Qualpopoca and his accomplices prifoners to Mexico. Cortes replied, with feeming complaifance, that a declaration fo refpectable left no doubt remaining

Mexico. remaining in his own mind; but that something more was requisite to satisfy his followers, who would never be convinced that Montezuma did not harbour hostile intentions against them, unless, as an evidence of his confidence and attachment, he removed from his own palace and took up his residence in the Spanish quarters, where he should be served and honoured as became a great monarch. The first mention of so strange a proposal bereaved Montezuma of speech, and almost of motion. At length he haughtily answered, "That persons of his rank were not accustomed voluntarily to give up themselves as prisoners; and were he mean enough to do so, his subjects would not permit such an affront to be offered to their sovereign." Cortes, unwilling to employ force, endeavoured alternately to soothe and intimidate him. The altercation became warm; and having continued above three hours, Velasquez de Leon, an impetuous and gallant young man, exclaimed with impatience, "Why waste more time in vain? Let us either seize him instantly, or stab him to the heart." The threatening voice and fierce gestures with which these words were uttered, struck Montezuma. The Spaniards, he was sensible, had now proceeded so far, as left him no hope that they would recede. His own danger was imminent, the necessity unavoidable. He saw both; and abandoning himself to his fate, complied with their request.

106 The emperor carried to the Spanish quarters.

His officers were called. He communicated to them his resolution. Though astonished and afflicted, they presumed not to question the will of their master, but carried him in silent pomp, all bathed in tears, to the Spanish quarters. When it was known that the strangers were conveying away the emperor, the people broke out into the wildest transports of grief and rage, threatening the Spaniards with immediate destruction, as the punishment justly due to their impious audacity. But as soon as Montezuma appeared with a seeming gaiety of countenance, and waved his hand, the tumult was hushed; and upon his declaring it to be of his own choice that he went to reside for some time among his new friends, the multitude, taught to revere every intimation of their sovereign's pleasure, quietly dispersed.

The Spaniards at first pretended to treat Montezuma with great respect; but soon took care to let him know that he was entirely in their power. Cortes wished that the shedding the blood of a Spaniard should appear the most heinous crime that could be committed; and therefore not only took a most exemplary vengeance on those who had been concerned in the affair of Villa Rica, but even put the emperor himself in chains till the execution of the Mexican general was over. By these, and other insults, he at last gained entirely the ascendant over this unhappy monarch; and he took care to improve his opportunity to the utmost. He sent his emissaries into different parts of the kingdom, accompanied with Mexicans of distinction, who might serve both to guide and to protect them. They visited most of the provinces, viewed their soil and productions, surveyed with particular care the districts which yielded gold or silver, pitched upon several places as proper for future colonies, and endeavoured to prepare the minds of the people for submitting to the Spanish yoke: and while they were thus employed, Cortes, in the name and by the authority of Montezuma, degraded some of the principal officers in the empire, whose abilities or independent

107 Cortes rules the empire.

spirit excited his jealousy; and substituted in their place persons who he imagined would be more obsequious. One thing, however, was still wanting to complete his security. He wished to have such a command of the lake as might ensure a retreat, if, either from levity or disgust, the Mexicans should take arms against him, and break down the bridges or causeways, in order to inclose him in the city. In order to obtain this without giving disgust to the emperor or his court, Cortes artfully inflamed the curiosity of the Indians with accounts of the Spanish shipping, and those floating palaces that moved with such velocity on the water, without the assistance of oars; and when he found that the monarch himself was extremely desirous of seeing such a novelty, he gave him to understand, that nothing was wanting to his gratification besides a few necessaries from Vera Cruz, for that he had workmen in his army capable of building such vessels. The bait took with Montezuma; and he gave immediate orders that all his people should assist Cortes in whatever he should direct concerning the shipping. By this means, in a few days, two brigantines were got ready, full-rigged and equipped; and Montezuma was invited on board, to make the first trial of their sailing, of which he could form no idea. Accordingly he embarked for this purpose, and gave orders for a great hunting upon the water, in order that all his people might be diverted with the novelty presented by the Spaniards. On the day appointed, the royal equipage was ready early in the morning; and the lake was covered with a multitude of boats and canoes loaded with people. The Mexicans had augmented the number of their rowers on board the royal barges, with an intention to disgrace the Spanish vessels, which they regarded as clumsy, unwieldy, and heavy. But they were soon undeceived; a fresh gale started up, the brigantines hoisted sail, to the utter astonishment of all the spectators, and soon left all the canoes behind; while the monarch exulted in the victory of the Spaniards, without once considering that now he had effectually rivetted his own chains.

108 By a pretence obtains leave to build brigantines on the lake.

109 Montezuma owns himself vassal to the king of Spain.

Cortes having obtained this important point, resolved to put the condescension of the emperor to a trial still more severe. He urged Montezuma to acknowledge himself a vassal to the crown of Castile; to hold his crown of him as superior, and to subject his dominions to the payment of an annual tribute. With this requisition, humiliating as it was, Montezuma complied. He called together the chief men of his empire, and, in a solemn harangue, reminded them of the traditions and prophecies which led them to expect the arrival of a people sprung from the same stock with themselves, in order to take possession of the supreme power; he declared his belief that the Spaniards were this promised race; and that therefore he recognised the right of their monarch to govern the Mexican empire, would lay his crown at his feet, and obey him as a tributary. While uttering these words, Montezuma discovered how deeply he was affected in making such a sacrifice. Tears and groans frequently interrupted his discourse. The first mention of such a resolution struck the assembly dumb with astonishment. This was followed by a sullen murmur of sorrow mingled with indignation; which indicated some violent eruption of rage to be near at hand. This Cortes foresaw, and seasonably interposed to prevent it, by declaring that

that his maſter had no intention to deprive Montezuma of the royal dignity, or to make any innovation upon the conſtitution and laws of the Mexican empire. This aſſurance, added to their dread of the Spaniſh arms, and the authority of their monarch's example, extorted the conſent of the aſſembly; and the act of ſubmiſſion and homage was executed with all the formalities which the Spaniards pleaſed to preſcribe.

Montezuma, at the requeſt of Cortes, accompanied this profeſſion of fealty and homage with a magnificent preſent to his new ſovereign; and, after his example, his ſubjects brought in very liberal contributions. The Spaniards then collected all the treaſure which had been either voluntarily beſtowed upon them at different times by Montezuma, or had been extorted from his people under various pretences; and having melted the gold and ſilver, the value of theſe, without including jewels and ornaments of various kinds, which were preſerved on account of their curious workmanſhip, amounted to 600,000 peſos. The ſoldiers were impatient to have it divided; and Cortes complied with their deſire. A fifth of the whole was ſet apart as the tax due to the king. Another fifth was allowed to Cortes as commander. The ſums advanced by the governor of Cuba, who had originally fitted out the expedition, were then deducted. The remainder was then divided among the army, including the garriſon of Vera Cruz, in proportion to their different ranks; and after ſo many deductions, the ſhare of a private man did not exceed 100 peſos. This ſum fell ſo far below their ſanguine expectations, that it required all the addreſs, and no ſmall exertions of the liberality of Cortes, to prevent an open mutiny. However, he at laſt reſtored tranquillity; but had no ſooner eſcaped this danger, than he involved himſelf, by his imprudent zeal for religion, in one much worſe. Montezuma, though often importuned, had obſtinately refuſed to change his religion, or aboliſh the ſuperſtitious rites which had been for ſuch a long time practiſed throughout his dominions. This at laſt tranſported the Spaniard with ſuch rage, that, in a ſally of zeal, he led out his ſoldiers in order to throw down the idols in the great temple by force. But the prieſts taking arms in defence of their altars, and the people crowding with great ardour to ſupport them, Cortes's prudence over-ruled his zeal, and induced him to deſiſt from his raſh attempt, after diſlodging the idols from one of the ſhrines, and placing in their ſtead an image of the Virgin Mary.

From this moment the Mexicans began to meditate the expulſion or the deſtruction of the Spaniards. The prieſts and leading men held frequent meetings with Montezuma for this purpoſe. But as any violent attempt might have proved fatal to the captive monarch, it was thought proper firſt to try more gentle means. Having called Cortes into his preſence, he obſerved, that now, as all the purpoſes of his embaſſy were fully accompliſhed, the gods had declared their will, and the people ſignified their deſire, that he and his followers ſhould inſtantly depart out of the empire. With this he required them to comply, or unavoidable deſtruction would fall ſuddenly on their heads. This unexpected requiſition, as well as the manner in which it was delivered, alarmed Cortes. However, he ſuppoſed that more might be gained by a feigned compliance than by open reſiſtance; and therefore replied with great compoſure, that he had already begun to prepare for his return; but as he had deſtroyed the veſſels in which he arrived, ſome time was requiſite for building other ſhips. This appeared reaſonable; and a number of Mexicans were ſent to Vera Cruz to cut down timber, and ſome Spaniſh carpenters were appointed to ſuperintend the work.

114 An armament ſent from Cuba againſt Cortes.

Cortes flattered himſelf, that, during this interval, he might either find means to avert the threatened danger, or receive ſuch reinforcements as would enable him to defend himſelf. Nine months had now elapſed ſince Portocarrero and Montejo had ſailed with his diſpatches to Spain; and he daily expected a return with a confirmation of his authority from the king, without which all that he had done ſerved only to mark him out as an object of puniſhment. While he remained in great anxiety on this account, news were brought that ſome ſhips had appeared on the coaſt. Theſe were imagined by Cortes to be a reinforcement ſent him from Spain: but his joy was of ſhort continuance, for a courier very ſoon arrived from Vera Cruz, with certain information that the armament was fitted out by Velaſquez, the governor of Cuba; and inſtead of bringing ſuccours, threatened them with immediate deſtruction.

Velaſquez had been excited to this hoſtile meaſure chiefly through the indiſcretion, or rather treachery, of the meſſengers of Cortes; who, contrary to his expreſs injunctions, had landed on the iſland of Cuba, and given intelligence of all that had paſſed: and Velaſquez, tranſported with rage at hearing of the proceedings of Cortes, had now ſent againſt him this armament; conſiſting of 18 ſhips, which carried 80 horſemen, 800 infantry, of which 80 were muſketeers, and 120 croſs-bowmen, commanded by a brave officer named *Pamphilo de Narvaez*; whoſe inſtructions were, to ſeize Cortes and his principal officers, to ſend them priſoners to him, and then to complete the diſcovery and conqueſt of the country in his name. This proved a moſt afflicting piece of news to Cortes. However, thinking it imprudent to attempt any thing againſt his countrymen at firſt by force, he ſent his chaplain Olmedo with propoſals of accommodation. Narvaez rejected his propoſals with ſcorn; but his followers were leſs violent in their reſentments. Olmedo delivered many letters to them, either from Cortes himſelf, or from his officers their ancient friends and companions. Theſe Cortes had artfully accompanied with preſents of rings, chains of gold, and other trinkets of value; which inſpired thoſe needy adventurers with high ideas of the wealth he had acquired, and with envy of the good fortune of thoſe who were engaged in his ſervice. Some, from hopes of becoming ſharers in theſe rich ſpoils, declared for an immediate accommodation; while others were for the ſame pacific meaſure, through fear of ſubverting the Spaniſh power entirely in a country where it was ſo imperfectly eſtabliſhed. Narvaez diſregarded both; and, by a proclamation, denounced Cortes and his adherents rebels and enemies to their country.

115 Which is defeated by that general.

Cortes having now no reſource but in war, left 150 men under the command of Pedro de Alvarado, an officer of great bravery, and much reſpected by

Mexico.

by the Mexicans, to guard the capital and the captive emperor; while he himfelf marched with the remainder, to meet his formidable opponent, who had taken poffeffion of Zempoalla. Even after being reinforced by Sandoval his governor of Vera Cruz, the force of Cortes did not exceed 250 men. He hoped for fuccefs chiefly from the rapidity of his motions and the poffibility of furprifing his enemies; and as he chiefly dreaded their cavalry, he armed his foldiers with long fpears, accuftoming them to that deep and compact arrangement which the ufe of this formidable weapon enabled them to affume. As he advanced, however, he repeated his propofals of accommodation: but thefe being conftantly rejected, and a price fet upon his head, he at laft attacked Narvaez in the night-time, entirely defeated and took him prifoner, obliging all his troops to own allegiance to himfelf.

Nothing could be more feafonable than this victory, by which Cortes found his army very confiderably increafed; for moft of the foldiers of Narvaez chofe rather to follow Cortes than to return to Cuba, whither the conqueror had offered to fend them if they chofe. His affairs at Mexico, in the mean time, were in the utmoft danger of being totally ruined; and had this decifive victory been delayed but a few days longer, he muft have come too late to fave his companions. A fhort time after the defeat of Narvaez, a courier arrived from Mexico with the difagreeable intelligence that the Mexicans had taken arms; and having feized and deftroyed the two brigantines which he had built in order to fecure the command of the lake, had attacked the Spaniards in their quarters, killed fome, and wounded many more, burnt their magazine of provifions, and, in fhort, carried on hoftilities with fuch fury, that though Alvarado and his men defended themfelves with undaunted refolution, they muft either be cut off by famine, or fink under the multitude of their enemies. This revolt was excited by motives which rendered it ftill more alarming. On the departure of Cortes for Zempoalla, the Mexicans flattered themfelves, that the long-expected opportunity of reftoring their fovereign to liberty, and driving out the Spaniards, was arrived; and confultations were accordingly held for bringing about both thefe events. The Spaniards in Mexico, confcious of their own weaknefs, fufpected and dreaded thefe machinations; but Alvarado, who had neither the prudence nor the addrefs of Cortes, took the worft method imaginable to overcome them. Inftead of attempting to foothe or cajole the Mexicans, he waited the return of one of their folemn feftivals, when the principal perfons in the empire were dancing, according to cuftom, in the court of the great temple; he feized all the avenues which led to it; and, allured partly by the rich ornaments which they wore in honour of their gods, and partly by the facility of cutting off at once the authors of that confpiracy which he dreaded, he fell upon them, unarmed and unfufpicious of danger, and maffacred a great number; none efcaping but fuch as made their way over the battlements of the temple. An action fo cruel and treacherous filled not only the city, but the whole empire, with indignation and rage; and the Mexicans immediately proceeded in the manner abovementioned.

116
Danger us fituation of the Spaniards left at Mexico.

Mex.

Cortes advanced with the utmoft celerity to the relief of his diftreffed companions; but as he paffed along, had the mortification to find that the Spaniards were generally held in abhorrence. The principal inhabitants had deferted the towns through which he paffed; no perfon of note appeared to meet him with the ufual refpect; nor were provifions brought to his camp as ufual. Notwithftanding thefe figns of averfion and horror, however, the Mexicans were fo ignorant of the military art, that they again permitted him to enter the capital without oppofition; though it was in their power to have eafily prevented him, by breaking down the bridges and caufeways which led to it.

11[7]
Corte[s] lowe[d] retur[n to] Mexi[co]

Cortes was received by his companions with the utmoft joy; and this extraordinary fuccefs fo far intoxicated the general himfelf, that he not only neglected to vifit Montezuma, but expreffed himfelf very contemptuoufly concerning him. Thefe expreffions being reported among the Mexicans, they all at once flew to arms, and made fuch a violent and fudden attack, that all the valour and fkill of Cortes were fcarce fufficient to repel them. This produced great uneafinefs among the foldiers of Narvaez, who had imagined there was nothing to do but to gather the fpoils of a conquered country. Difcontent and murmurings, however, were now of no avail; they were inclofed in an hoftile city, and, without fome extraordinary exertions, were inevitably undone. Cortes therefore, made a defperate fally; but, after exerting his utmoft efforts for a whole day, was obliged to retire with the lofs of 12 killed, and upwards of 60 wounded. Another fally was attempted with the like bad fuccefs, and in it Cortes himfelf was wounded in the hand.

11[8]
But i[s] to[...] tacked [by] the na tives.

The Spanifh general was now thoroughly convinced of his error; and therefore betook himfelf to the only refource which was left; namely, to try what effect the interpofition of Montezuma would have to foothe or overawe his fubjects. When the Mexicans approached the next morning to renew the affault, that unfortunate prince, at the mercy of the Spaniards, and reduced to the fad neceffity of becoming the inftrument of his own difgrace, and of the flavery of his people, advanced to the battlements in his royal robes, and with all the pomp in which he ufed to appear on folemn occafions. At the fight of their fovereign, whom they had been long accuftomed to reverence almoft as a god, the Mexicans inftantly forebore their hoftilities, and many proftrated themfelves on the ground: but when he addreffed them in favour of the Spaniards, and made ufe of all the arguments he could think of to mitigate their rage, they teftified their refentment with loud murmurings; and at length broke forth with fuch fury, that before the foldiers, appointed to guard Montezuma, had time to cover him with their fhields, he was wounded with two arrows, and a blow on his temple with a ftone ftruck him to the ground. On feeing him fall, the Mexicans inftantly fled with the utmoft precipitation: but the unhappy monarch, now convinced that he was become an object of contempt even to his own fubjects, obftinately refufed

119
Montez[u]ma kill[ed]

refuſed all nouriſhment; and thus in a ſhort time ended his days.

On the death of Montezuma, Cortes having loſt all hope of bringing the Mexicans to any terms of peace, prepared for retreat. But his antagoniſts, having taken poſſeſſion of a high tower in the great temple, which overlooked the Spaniſh quarters, and placing there a garriſon of their principal warriors, the Spaniards were ſo much expoſed to their miſſile weapons, that none could ſtir without danger of being killed or wounded. From this poſt, therefore, it was neceſſary to diſlodge them at any rate; and Juan de Eſcobar, with a large detachment of choſen ſoldiers, was ordered to make the attack. But Eſcobar, though a valiant officer, and though he exerted his utmoſt efforts, was thrice repulſed. Cortes, however, ſenſible that not only his reputation, but the ſafety of his army, depended on the ſucceſs of this aſſault, cauſed a buckler to be tied to his arm, as he could not manage it with his wounded hand, and ruſhed with his drawn ſword among the thickeſt of the combatants. Encouraged by the preſence of their general, the Spaniards returned to the charge with ſuch vigour, that they gradually forced their way up the ſteps, and drove the Mexicans to the platform at the top of the tower. There a dreadful carnage began; when two young Mexicans of high rank, obſerving Cortes, as he animated his ſoldiers, reſolved to ſacrifice their own lives in order to cut off the author of ſo many calamities which deſolated their country. They approached him in a ſuppliant poſture, as if they intended to lay down their arms; and ſeizing him in a moment, hurried him towards the battlements, over which they threw themſelves headlong, in hopes of dragging him along with them. But Cortes, by his ſtrength and agility, diſengaged himſelf from their graſp; ſo that the two Mexicans periſhed alone.

As ſoon as the Spaniards became maſters of the tower, they ſet fire to it, and without further moleſtation continued the preparations for their retreat. This became the more neceſſary, as their enemies, aſtoniſhed at this laſt effort of their valour, had now entirely changed their ſyſtem of hoſtility; and, inſtead of inceſſant attacks, endeavoured, by barricading the ſtreets, and breaking down the cauſeways, to cut off the communication of the Spaniards with the continent, and thus to ſtarve an enemy whom they could not ſubdue. The firſt point to be determined was, whether they ſhould march out openly in the face of day, when they could diſcern every danger, or whether they ſhould endeavour to retire ſecretly in the night. The latter was preferred, partly from hopes that the ſuperſtition of the Mexicans would prevent them from attacking them in the night, and partly from their own ſuperſtition in giving credit to the predictions of a private ſoldier, who pretended to aſtrology, and aſſured them of ſucceſs if they retreated in this manner. Towards midnight, therefore, they began their march, in three diviſions. Sandoval led the van; Pedro Alvarado and Velaſquez de Leon had the conduct of the rear; and Cortes commanded in the centre, where he placed the priſoners, among whom were a ſon and two daughters of Montezuma, together with ſeveral Mexicans of diſtinction; the artillery, baggage, and a portable bridge of timber intended to be laid over the breaches in the cauſeway. They marched in profound ſilence along the cauſeway which led to Tacuba, becauſe it was ſhorter than any of the reſt, and, lying moſt remote from the road towards Tlaſcala and the ſea coaſt, had been left moſt entire by the Mexicans.

121
Cortes retreats with great loſs.

They reached the firſt breach in the cauſeway without moleſtation, hoping that their retreat was undiſcovered. But the Mexicans had not only watched all their motions, but made preparations for a moſt formidable attack. While the Spaniards were intent upon placing their bridges in the breach, and occupied in conducting their horſes and artillery along it, they were ſuddenly alarmed with the ſound of warlike inſtruments, and found themſelves aſſaulted on all ſides by an innumerable multitude of enemies. Unfortunately the wooden bridge was wedged ſo faſt in the mud by the weight of the artillery, that it was impoſſible to remove it. Diſmayed at this accident, the Spaniards advanced with precipitation to the ſecond breach. The Mexicans hemmed them in on every ſide; and though they defended themſelves with their uſual courage, yet, crowded as they were in a narrow cauſeway, their diſcipline and military ſkill were of little avail; nor did the obſcurity of the night allow them to derive much advantage from their fire-arms or the ſuperiority of their other weapons. At laſt the Spaniards, overborne with the numbers of their enemies, began to give way, and in a moment the confuſion was univerſal. Cortes, with about 100 foot-ſoldiers, and a few horſe, forced his way over the two remaining breaches in the cauſeway, the bodies of the dead ſerving to fill up the chaſms, and reached the main land. Having formed them as ſoon as they arrived, he returned with ſuch as were yet capable of ſervice, to aſſiſt his friends in their retreat. He met with part of his ſoldiers who had forced their way through the enemy, but found many more overwhelmed by the multitude of their aggreſſors, or periſhing in the lake; and heard the grievous lamentations of others whom the Mexicans were carrying off in triumph to be ſacrificed to the god of war.

In this fatal retreat more than one half of Cortes's army periſhed, together with many officers of diſtinction. All the artillery, ammunition, and baggage, were loſt; the greater part of the horſes and above 2000 Tlaſcalans were killed, and only a very ſmall part of their treaſure ſaved. The firſt care of the Spaniſh general was to find ſome ſhelter for his wearied troops; for, as the Mexicans infeſted them on every ſide, and the people of Tacuba began to take arms, he could not continue in his preſent ſtation. At laſt he diſcovered a temple ſeated on an eminence, in which he found not only the ſhelter he wanted, but ſome proviſions; and though the enemy did not intermit their attacks throughout the day, they were without much difficulty prevented from making any impreſſion. For ſix days after, they continued their march through a barren, ill cultivated, and thinly peopled country, where they were often obliged to feed on berries, roots, and the ſtalks of green maize; at the ſame time they were haraſſed without intermiſſion by large parties of Mexicans, who attacked them on all ſides. On the ſixth day they reached Otumba, not far from the road between Mexico and Tlaſcala. Early next morning they

Mexico.

they began to advance towards it, flying parties of the enemy ſtill hanging on their rear; and amidſt the inſults with which they accompanied their hoſtilities, Donna Marina remarked, that they often exclaimed with exultation, "Go on, robbers; go to the place where you ſhall quickly meet the vengeance due to your crimes." The meaning of this threat the Spaniards did not comprehend, until they reached the ſummit of an eminence before them. There a ſpacious valley opened to their view, covered with a vaſt army as far as the eye could reach. The Mexicans, while with one body of their troops they haraſſed the Spaniards in their retreat, had aſſembled their principal force on the other ſide of the lake; and marching along the road which led directly to Tlaſcala, poſted it in the plain of Otumba, through which they knew Cortes muſt paſs. At the ſight of this incredible multitude, which they could ſurvey at once from the riſing ground, the Spaniards were aſtoniſhed, and even the boldeſt began to deſpair. But Cortes, without allowing their fears time to operate, after warning them briefly that no alternative remained but to conquer or die, led them inſtantly to the charge. The Mexicans waited their approach with unuſual fortitude: yet ſuch was the ſuperiority of the Spaniſh diſcipline and arms, that the impreſſion of this ſmall body was irreſiſtible; and which ever way its force was directed, it penetrated and diſperſed the moſt numerous battalions. But while theſe gave way in one quarter, new combatants advanced from another; and the Spaniards, though ſucceſsful in every attack, were ready to ſink under theſe repeated efforts, without ſeeing any end to their toil, or any hope of victory. At that time Cortes obſerved the great ſtandard of the empire, which was carried before the Mexican general, advancing; and fortunately recollecting to have heard, that on the fate of it depended the event of every battle, he aſſembled a few of his braveſt officers, whoſe horſes were ſtill capable of ſervice, and, placing himſelf at their head, puſhed towards the ſtandard with ſuch impetuoſity that he bore down every thing before him. A choſen body of nobles, who guarded the ſtandard, made ſome reſiſtance, but were ſoon broken. Cortes, with a ſtroke of his lance, wounded the Mexican general, and threw him to the ground. One of his followers alighting, put an end to his life, and laid hold of the imperial ſtandard. The moment that their leader fell, and the ſtandard, towards which all directed their eyes, diſappeared, an univerſal panic ſtruck the Mexicans; and, as if the bond which held them together had been diſſolved, every enſign was lowered, each ſoldier threw away his weapons, and fled with precipitation to the mountains. The Spaniards, unable to purſue them far, returned to collect the ſpoils of the field; and theſe were ſo valuable as to be ſome compenſation for the wealth which they had loſt in Mexico; for in the enemy's army were moſt of their principal warriors dreſſed out in their richeſt ornaments, as if they had been marching to aſſured victory.

122 The battle of Otumba.

123 Mexicans defeated.

The day after this important action (being July 8th 1520), the Spaniards entered the Tlaſcalan territories, where they were received with the moſt cordial friendſhip. Cortes endeavoured to avail himſelf of this diſpoſition as much as poſſible; for which purpoſe he diſtributed among them the rich ſpoils taken at Otumba with ſuch a liberal hand, that he made himſelf ſure of obtaining from the republic whatever he ſhould deſire. He drew a ſmall ſupply of ammunition, and two or three field-pieces, from his ſtores at Vera Cruz. He diſpatched an officer of confidence with four ſhips of Narvaez's fleet to Hiſpaniola and Jamaica, to engage adventurers, and to purchaſe horſes, gunpowder, and other military ſtores. And as he knew that it would be in vain to attempt the reduction of Mexico, unleſs he could ſecure the command of the lake, he gave orders to prepare, in the mountains of Tlaſcala, materials for building 12 brigantines, ſo that they might be carried thither in pieces, ready to be put together, and launched when he ſtood in need of their ſervice. But, in the mean time, his ſoldiers, alarmed at the thoughts of being expoſed to ſuch calamities a ſecond time, preſented a remonſtrance to their general, in which they repreſented the imprudence of attacking a powerful empire with his ſhattered forces, and formally required him to return back to Cuba. All the eloquence of Cortes could now only prevail with them to delay their departure for ſome time, when he promiſed to diſmiſs ſuch as ſhould deſire it. However, this was only a pretence; for Cortes, in fact, had the conqueſt of Mexico as much at heart as ever. Without giving his ſoldiers an opportunity of caballing, therefore, he daily employed them againſt the people of the neighbouring provinces, who had cut off ſome detachments of Spaniards during his misfortunes at Mexico; and by which, as he was conſtantly attended with ſucceſs, his men ſoon reſumed their wonted ſenſe of ſuperiority.

124 Cortes receives an unexpected reinforcement.

But all the efforts of Cortes could have been of little avail, had he not unexpectedly obtained a reinforcement of Spaniſh ſoldiers. The governor of Cuba, to whom the ſucceſs of Narvaez appeared an event of infallible certainty, having ſent two ſmall ſhips after him with new inſtructions, and a ſupply of men and military ſtores, the officer whom Cortes had appointed to command on the coaſt artfully decoyed them into the harbour of Vera Cruz, ſeized the veſſels, and eaſily perſuaded the ſoldiers to follow the ſtandard of a more able leader than him whom they were deſtined to join. Soon after, three ſhips of more conſiderable force came into the harbour ſeparately. Theſe belonged to an armament fitted out by Franciſco de Garay, governor of Jamaica, who had long aimed at dividing with Cortes the glory and gain of annexing the empire of Mexico to the crown of Caſtile. They had, however, unadviſedly made their atempt on the northern provinces, where the country was poor, and the inhabitants fierce and warlike; ſo that, after a ſucceſſion of diſaſters, they were now obliged to venture into Vera Cruz, and caſt themſelves upon the mercy of their countrymen; and here they alſo were ſoon perſuaded to throw off their allegiance to their maſter, and to enliſt with Cortes. About the ſame time a ſhip arrived from Spain, freighted by ſome private adventurers, with military ſtores; and the cargo was eagerly purchaſed by Cortes, while the crew, following the example of the reſt joined him at Tlaſcala.

From theſe various quarters, the army of Cortes was

was augmented with 180 men and 20 horfes; by which means he was enabled to difmifs fuch of the foldiers of Narvaez as were moft troublefome and difcontented; after the departure of whom he ftill muftered 550 infantry, of whom 80 were armed with mufkets or crofs-bows, 40 horfemen, and nine pieces of artillery. At the head of thefe, with 10,000 Tlafcalans and other friendly Indians, he began his march towards Mexico, on the 28th of December, fix months after his fatal retreat from that city.

The Mexicans, in the mean time, had made the beft preparations they could for oppofing fuch a formidable enemy. On the death of Montezuma, his brother Quetlavaca was raifed to the throne; and he had an immediate opportunity of fhowing that he was worthy of their choice, by conducting in perfon thofe fierce attacks which obliged the Spaniards to retire from his capital. His prudence in guarding againft the return of the invaders was equal to the fpirit he had fhown in driving them out. He repaired what the Spaniards had ruined in the city, ftrengthened it with fuch fortifications as his people could erect; and befides filling his magazines with the ufual implements of war, gave directions to make long fpears, headed with the fwords and daggers which they had taken from the Spaniards, in order to annoy the cavalry. But in the midft of thefe preparations he was taken off by the fmall-pox; and Guatimozin, his nephew and fon-in-law, raifed to the throne.

As foon as Cortes entered the enemy's territories, he difcovered various preparations to obftruct his progrefs. But his troops forced their way with little difficulty; and took poffeffion of Tezeuco, the fecond city of the empire, fituated on the banks of the lake, about 20 miles from Mexico. Here he determined to eftablifh his head-quarters, as the moft proper ftation for launching his brigantines, as well as for making his approaches to the capital. In order to render his refidence there more fecure, he depofed the cazique or chief, who was at the head of that community, under pretence of fome defect in his title, and fubftituted in his place a perfon whom a faction of the nobles pointed out as the right heir of that dignity. Attached to him by this benefit, the new cazique and his adherents ferved the Spaniards with inviolable fidelity.

As the conftruction of the brigantines advanced flowly under the unfkilful hands of foldiers and Indians, whom Cortes was obliged to employ in affifting three or four carpenters who happened fortunately to be in his fervice, and as he had not yet received the reinforcement which he expected from Hifpaniola, he was not in a condition to turn his arms directly againft the capital. To have attacked a city fo populous, fo well prepared for defence, and in a fituation of fuch peculiar ftrength, muft have expofed his troops to inevitable deftruction. Three months elapfed before the materials for conftructing the brigantines were finifhed, and before he heard any thing with refpect to the fuccefs of his negociation in Hifpaniola. This, however, was not a feafon of inaction to Cortes. He attacked fucceffively feveral of the towns fituated around the lake; and though all the Mexican power was exerted to obftruct his operations, he either compelled them to fubmit to the Spanifh crown, or reduced them to ruins. Other towns he endeavoured to conciliate by more gentle means; and though he could not hold any intercourfe with the inhabitants but by the intervention of interpreters, yet, under all the difadvantage of that tedious and imperfect mode of communication, he had acquired fuch thorough knowledge of the ftate of the country, as well as of the difpofitions of the people, that he conducted his negociations and intrigues with aftonifhing dexterity and fuccefs. Moft of the cities adjacent to Mexico were originally the capitals of fmall independent ftates; and fome of them having been but lately annexed to the Mexican empire, ftill retained the remembrance of their ancient liberty, and bore with impatience the rigorous yoke of their new mafters. Cortes having early obferved fymptoms of their difaffection, availed himfelf of this knowledge to gain their confidence and friendfhip. By offering with confidence to deliver them from the odious dominion of the Mexicans, and by liberal promifes of more indulgent treatment if they would unite with him againft their oppreffors, he prevailed on the people of feveral confiderable diftricts, not only to acknowledge the king of Caftile as their fovereign, but to fupply the Spanifh camp with provifions, and to ftrengthen his army with auxiliary troops. Guatimozin, on the firft appearance of defection among his fubjects, exerted himfelf with vigour to prevent or to punifh their revolt; but, in fpite of his efforts, the fpirit continued to fpread. The Spaniards gradually acquired new allies; and with deep concern he beheld Cortes arming againft his empire thofe very hands which ought to have been active in his defence, and ready to advance againft the capital at the head of a numerous body of his own fubjects.

While, by thefe various methods, Cortes was gradually circumfcribing the Mexican power within fuch narrow limits that his profpect of overturning it feemed neither to be uncertain nor remote, all his fchemes were well nigh defeated by a confpiracy againft his own perfon, and which was difcovered only a fhort time before it was to have been executed. Though many were concerned, Cortes did not think proper to punifh any more than the principal ringleader, whom he caufed immediately to be hanged; and then, without allowing them leifure to ruminate on what had happened, and as the moft effectual means of preventing the return of a mutinous fpirit, he determined to call forth his troops immediately to action. Fortunately a proper occafion for this occurred, without his feeming to court it. He received intelligence, that the materials for building the brigantines were at length completely finifhed, and waited only for a body of Spaniards to conduct them to Tezeuco. The command of this convoy, confifting of 200 foot-foldiers, 15 horfemen, and 2 field-pieces, he gave to Sandoval, who by the vigilance, activity, and courage, which he manifefted on every occafion, was growing daily in his confidence, and in the eftimation of his fellow-foldiers. The fervice was no lefs fingular than important; the beams, the planks, the mafts, the cordage, the fails, the iron work, and all the infinite variety of articles requifite for the conftruction of 13 brigantines were to be carried 60 miles over land, thro' a mountainous country, by people who were unacquainted with the miniftry of domeftic animals, or the aid of machines to facilitate any work of labour. The

Tlaf-

Mexico Tlascalans furnished 8000 *Tamenes*, an inferior order of men destined for servile tasks, to carry the materials on their shoulders, and appointed 15,000 warriors to accompany and defend them. Sandoval made the disposition for their progress with great propriety, placing the Tamenes in the centre, one body of warriors in the front, another in the rear, with considerable parties to cover the flanks. To each of these he joined some Spaniards, not only to assist them in danger, but to accustom them to regularity and subordination. Parties of Mexicans frequently appeared hovering around them on the high grounds: but perceiving no prospect of success in attacking an enemy continually on his guard, and prepared to receive them, they did not venture to molest him; and Sandoval had the glory of conducting safely to Tezeuco a convoy on which all the future operations of his countrymen depended.

128
The Spaniards receive another reinforcement.

This was followed by another event of no less moment. Four ships arrived at Vera Cruz from Hispaniola, with 200 soldiers, 80 horses, two battering cannon, and a considerable supply of ammunition and arms. Elevated with observing that all his preparatory schemes, either for recruiting his own army or impairing the force of the enemy, had now produced their full effect, Cortes, impatient to begin the siege in form, hastened the launching of the brigantines. To facilitate this, he had employed a vast number of Indians, for two months, in deepening the small rivulet which runs by Tezeuco into the lake, and in forming it into a canal near two miles in length; and though the Mexicans, aware of his intentions, as well as of the danger which threatened them, endeavoured frequently to interrupt the labourers, or to burn the brigantines, the work was at last completed. On the 28th of April, all the Spanish troops, together with auxiliary Indians, were drawn up on the banks of the canal; and with extraordinary military pomp, heightened and rendered more solemn by the celebration of the most sacred rites of religion, the brigantines were launched. As they fell down the canal in order, Father Olmedo blessed them, and gave each its name. Every eye followed them with wonder and hope, until they entered the lake, when they hoisted their sails, and bore away before the wind. A general shout of joy was raised; all admiring that bold inventive genius, which, by means so extraordinary, that their success almost exceeded belief, had acquired the command of a fleet, without the aid of which Mexico would have continued to set the Spanish power and arms at defiance.

129
The city besieged.

Cortes determined to attack the city from three different quarters; from Tezeuco on the east side of the lake, from Tacuba on the west, and from Cuyocan towards the south. Those towns were situated on the principal causeways which led to the capital, and intended for their defence. He appointed Sandoval to command in the first, Pedro de Alvarado in the second, and Christoval de Olid in the third; allotting to each a numerous body of Indian auxiliaries, together with an equal division of Spaniards, who, by the junction of the troops from Hispaniola, amounted now to 86 horsemen, and 818 foot-soldiers; of whom 118 were armed with muskets or cross-bows. Their train of artillery consisted of three battering cannon, and 15 field-pieces. He reserved for himself, as the station of greatest importance and danger, the conduct of the brigantines, each armed with one of his small cannon, and manned with 25 Spaniards.

As Alvarado and Olid proceeded towards the posts assigned them, they broke down the aqueducts which the ingenuity of the Mexicans had erected for conveying water into the capital, and, by the distress to which this reduced the inhabitants, gave a beginning to the calamities which they were destined to suffer. Alvarado and Olid found the towns, of which they were ordered to take possession, deserted by their inhabitants, who had fled for safety to the capital, where Guatimozin had collected the chief force of his empire, as there alone he could hope to make a successful stand against the formidable enemies who were approaching to assault him.

130
The Spaniards defeat the Mexicans and become masters of the lake.

The first effort of the Mexicans was to destroy the fleet of brigantines, the fatal effects of whose operations they foresaw and dreaded. Though the brigantines, after all the labour and merit of Cortes in forming them, were of inconsiderable bulk, rudely constructed, and manned chiefly with landmen, hardly possessed of skill enough to conduct them, they must have been ojects of terror to a people unacquainted with any navigation but that of their lake, and possessed of no vessel larger than a canoe. Necessity, however, urged Guatimozin to hazard the attack; and hoping to supply by numbers what he wanted in force, he assembled such a multitude of canoes as covered the face of the lake. They rowed on boldly to the charge, while the brigantines, retarded by a dead calm, could scarcely advance to meet them. But as the enemy drew near, a breeze suddenly sprung up; in a moment the sails were spread, and the brigantines with irresistible impetuosity broke their feeble opponents, overset many canoes, and dissipated the whole armament with such slaughter, as convinced the Mexicans, that the progress of the Europeans in knowledge and arts rendered their superiority greater on this new element than they had hitherto found it by land.

From that time Cortes remained master of the lake; and the brigantines not only preserved a communication between the Spaniards in their different stations, though at considerable distance from each other, but were employed to cover the causeways on each side, and keep off the canoes, when they attempted to annoy the troops as they advanced towards the city. He formed the brigantines in three divisions, allotting one to each station, with orders to second the operations of the officer who commanded there. From all the three stations he pushed on the attack against the city with equal vigour; but in a manner so very different from that whereby sieges are conducted in regular war, as might appear no less improper than singular to persons unacquainted with his situation. Each morning his troops assaulted the barricades which the enemy had erected on the causeways, forced their way over the trenches which they had dug, and through the canals where the bridges were broken down, and endeavoured to penetrate into the heart of the city, in hopes of obtaining some decisive advantage, which might force the enemy to surrender, and terminate the war at once; but when the obstinate valour of the Mexicans rendered the efforts of the day ineffectual, the Spaniards retired in in the evening to their former quarters. Thus their toil and danger were, in some measure, continually renewed, the Mexicans repairing in the night what the Spaniards had destroyed through the day, and recovering the posts from which they had driven them. But necessity prescribed this slow and untoward mode of operation. The number of his troops was so small, that Cortes durst not, with a handful of men, attempt to make a lodgment in a city where he might be surrounded and annoyed by such a multitude of enemies. The remembrance of what he had already suffered by the ill-judged confidence with which he had ventured into such a dangerous situation, was still fresh in his mind. The Spaniards, exhausted with fatigue, were unable to guard the various posts which they daily gained; and though their camp was filled with Indian auxiliaries, they durst not devolve this charge upon them, because they were so little accustomed to discipline, that no confidence could be placed in their vigilance. Besides this, Cortes was extremely solicitous to preserve the city as much as possible from being destroyed, both as he destined it to be the capital of his conquests, and wished that it might remain as a monument of his glory. From all these considerations, he adhered obstinately, for a month after the siege was opened, to the system which he had adopted. The Mexicans, in their own defence, displayed valour which was hardly inferior to that with which the Spaniards attacked them. On land, on water, by night and by day, one furious conflict succeeded to another. Several Spaniards were killed, more wounded, and all were ready to sink under the toils of unintermitting service, which were rendered more intolerable by the injuries of the season, the periodical rains being now set in with their usual violence.

Astonished and disconcerted with the length and difficulties of the siege, Cortes determined to make one great effort to get possession of the city before he relinquished the plan which he had hitherto followed, and had recourse to any other mode of attack. With this view, he sent instructions to Alvarado and Sandoval to advance with their divisions to a general assault, and took the command in person of that posted on the causeway of Cuyocan. Animated by his presence, and the expectation of some decisive event, the Spaniards pushed forward with irresistible impetuosity. They broke through one barricade after another, forced their way over the ditches and canals, and having entered the city, gained ground incessantly, in spite of the multitude and ferocity of their opponents. Cortes, though delighted with the rapidity of his progress, did not forget that he might still find it necessary to retreat; and in order to secure it, appointed Julian de Alderete, a captain of chief note in the troops which he had received from Hispaniola, to fill up the canals and gaps in the causeway as the main body advanced. That officer deeming it inglorious to be thus employed, while his companions were in the heat of action and the career of victory, neglected the important charge committed to him, and hurried on inconsiderately to mingle with the combatants. The Mexicans, whose military attention and skill were daily improving, no sooner observed this, than they carried an account of it to their monarch.

Guatimozin instantly discerned the consequences of the error which the Spaniards had committed, and, with admirable presence of mind, prepared to take advantage of it. He commanded the troops posted in the front to slacken their efforts, in order to allure the Spaniards to push forward, while he dispatched a large body of chosen warriors through different streets, some by land, and others by water, towards the great breach in the causeway, which had been left open. On a signal which he gave, the priests in the great temple struck the great drum consecrated to the god of war. No sooner did the Mexicans hear its doleful solemn sound, calculated to inspire them with contempt of death and with enthusiastic ardour, than they rushed upon the enemy with frantic rage. The Spaniards, unable to resist men urged on no less by religious fury than hope of success, began to retire, at first leisurely, and with a good countenance; but as the enemy pressed on, and their own impatience to escape increased, the terror and confusion became so general, that when they arrived at the gap in the causeway, Spaniards and Tlascalans, horsemen and infantry, plunged in promiscuously, while the Mexicans rushed upon them fiercely from every side, their light canoes carrying them through shoals which the brigantines could not approach. In vain did Cortes attempt to stop and rally his flying troops; fear rendered them regardless of his intreaties or commands. 131 Cortes repulsed in an attack.
Finding all his endeavours to renew the combat fruitless, his next care was to save some of those who had thrown themselves into the water; but while thus employed, with more attention to their situation than to his own, six Mexican captains suddenly laid hold of him, and were hurrying him off in triumph; and tho' two of his officers rescued him at the expence of their own lives, he received several dangerous wounds before he could break loose. Above 60 Spaniards perished in the rout; and what rendered the disaster more afflicting, 40 of these fell alive into the hands of an enemy never known to shew mercy to a captive.

The approach of night, though it delivered the dejected Spaniards from the attacks of the enemy, ushered in, what was hardly less grievous, the noise of their barbarous triumph, and of the horrid festival with which they celebrated their victory. Every quarter of the city was illuminated; the great temple shone with such peculiar splendor, that the Spaniards could plainly see the people in motion, and the priests busy in hastening the preparations for the death of the prisoners. Through the gloom they fancied that they discerned their companions by the whiteness of their skins, as they were stripped naked and compelled to dance before the image of the god to whom they were to be offered. They heard the shrieks of those who were sacrificed, and thought they could distinguish each unhappy victim by the well-known sound of his voice. Imagination added to what they really saw or heard, and augmented its horror. The most unfeeling melted into tears of compassion, and the stoutest heart trembled at the dreadful spectacle which they beheld.

Cortes, who, besides all that he felt in common with his soldiers, was oppressed with the additional load of anxious reflections natural to a general on such an unexpected calamity, could not like them relieve his mind by giving vent to its anguish. He was obliged to assume an air of tranquillity in order to revive the spirits and

and hopes of his followers. The juncture, indeed, required an extraordinary exertion of fortitude. The Mexicans, elated with their victory, ſallied out next morning to attack him in his quarters. But they did not rely on the efforts of their own arms alone: they ſent the heads of the Spaniards whom they had ſacrificed to the leading men in the adjacent provinces, and aſſured them that the god of war, appeaſed by the blood of their invaders, which had been ſhed ſo plentifully on his altars, had declared with an audible voice, that in eight days time thoſe hated enemies ſhould be finally deſtroyed, and peace and proſperity re-eſtabliſhed in the empire.

132 The Mexicans renew the attack with great fury.

A prediction, uttered with ſuch confidence, and in terms ſo void of ambiguity, gained univerſal credit among a people prone to ſuperſtition. The zeal of the provinces which had already declared againſt the Spaniards augmented, and ſeveral which had hitherto remained inactive took arms with enthuſiaſtic ardour to execute the decrees of the gods. The Indian auxiliaries who had joined Cortes, accuſtomed to venerate the ſame deities with the Mexicans, and to receive the reſponſes of their prieſts with the ſame implicit faith, abandoned the Spaniards as a race of men devoted to certain deſtruction. Even the fidelity of the Tlaſcalans was ſhaken, and the Spaniſh troops were left almoſt alone in their ſtations. Cortes, finding that he attempted in vain to diſpel the ſuperſtitious fears of his confederates by argument, took advantage, from the imprudence of thoſe who had framed the prophecy in fixing its accompliſhment ſo near at hand, to give them a ſtriking demonſtration of its falſity. He ſuſpended all military operations during the period marked out by the oracle. Under cover of the brigantines, which kept the army at a diſtance, his troops lay in ſafety, and the fatal term expired without any diſaſter.

His allies, aſhamed of their own credulity, returned to their ſtation. Other tribes, judging that the gods, who had now deceived the Mexicans, had decreed finally to withdraw their protection from them, joined his ſtandard; and ſuch was the levity of a ſimple people, moved by every ſlight impreſſion, that, in a ſhort time after ſuch a general defection of his confederates, Cortes ſaw himſelf, if we may believe his own account, at the head of 150,000 Indians. Even with ſuch a numerous army, he found it neceſſary to adopt a new and more wary ſyſtem of operation. Inſtead of renewing his attempts to become maſter of the city at once, by ſuch bold but dangerous efforts of valour as he had already tried, he made his advances gradually, and with every poſſible precaution againſt expoſing his men to any calamity ſimilar to that which they ſtill bewailed. As the Spaniards puſhed forward, the Indians regularly repaired the cauſeways behind them. As ſoon as they got poſſeſſion of any part of the town, the houſes were inſtantly levelled with the ground. Day by day, the Mexicans, forced to retire as their enemies gained ground, were hemmed in within more narrow limits. Guatimozin, though unable to ſtop the career of the enemy, continued to defend his capital with obſtinate reſolution, and diſputed every inch of ground. But the Spaniards, having not only varied their mode of attack, but, by order of Cortes, having changed the weapons with which they fought, were again armed with the long Chinantlan ſpears, which they had employed with ſuch ſucceſs againſt Narvaez; and, by the firm array in which this enabled them to range themſelves, they repelled, with little danger, the looſe aſſault of the Mexicans: incredible numbers of them fell in the conflicts, which they renewed every day. While war waſted without, famine began to conſume them within the city. The Spaniſh brigantines, having the entire command of the lake, rendered it impoſſible to receive any ſupply of proviſions by water. The vaſt number of his Indian auxiliaries enabled Cortes to ſhut up the avenues to the city by land. The ſtores which Guatimozin had laid up were exhauſted by the multitudes which crowded into the capital to defend their ſovereign and the temples of their gods. Not only the people, but perſons of the higheſt rank, felt the utmoſt diſtreſſes of want. What they ſuffered brought on infectious and mortal diſtempers, the laſt calamity that viſits beſieged cities, and which filled up the meaſure of their woes.

133 Cortes adopts a more cautious method of proceeding.

But, under the preſſure of ſo many and ſuch various evils, the ſpirit of Guatimozin remained firm and unſubdued. He rejected with ſcorn every overture of peace from Cortes; and, diſdaining the idea of ſubmitting to the oppreſſors of his country, determined not to ſurvive its ruin. The Spaniards continued their progreſs. At length all the three diviſions penetrated into the great ſquare in the centre of the city, and made a ſecure lodgment there. Three-fourths of the city were now reduced, and laid in ruins. The remaining quarter was ſo cloſely preſſed, that it could not long withſtand aſſailants who attacked it from their new ſtation with ſuperior advantage, and more aſſured expectation of ſucceſs. The Mexican nobles, ſolicitous to ſave the life of a monarch whom they revered, prevailed on Guatimozin to retire from a place where reſiſtance was now vain, that he might rouſe the more diſtant provinces of the empire to arms, and maintain there a more ſucceſsful ſtruggle with the public enemy. In order to facilitate the execution of this meaſure, they endeavoured to amuſe Cortes with overtures of ſubmiſſion, that, while his attention was employed in adjuſting the articles of pacification, Guatimozin might eſcape unperceived. But they made this attempt upon a leader of greater ſagacity and diſcernment than to be deceived by their arts. Cortes ſuſpecting their intention, and aware of what moment it was to defeat it, appointed Sandoval, the officer on whoſe vigilance he could moſt perfectly rely, to take the command of the brigantines, with ſtrict injunctions to watch every motion of the enemy. Sandoval, attentive to the charge, obſerving ſome large canoes crowded with people rowing along the lake with extraordinary rapidity, inſtantly gave the ſignal to chace. Gracia Holguin, who commanded the fleeteſt brigantine, ſoon overtook them, and was preparing to fire on the foremoſt canoe, which ſeemed to carry ſome perſon whom all the reſt followed and obeyed. At once the rowers dropt their oars, and all on board, throwing down their arms, conjured him with cries and tears to forbear, as the emperor was there. Holguin eagerly ſeized his prize; and Guatimozin, with a dignified compoſure, gave himſelf up into his hands, requeſting only that no inſult might be offered to the empreſs or his children. When conducted to Cortes, he

Mexico.

he appeared neither with the ſullen fierceneſs of a barbarian, nor with the dejection of a ſuppliant. "I have done," ſaid he, addreſſing himſelf to the Spaniſh general, "what became a monarch. I have defended my people to the laſt extremity. Nothing now remains but to die. Take this dagger," laying his hand on one which Cortes wore, "plant it in my breaſt, and put an end to a life which can no longer be of uſe."

As ſoon as the fate of their ſovereign was known, the reſiſtance of the Mexicans ceaſed; and Cortes took poſſeſſion of that ſmall part of the capital which yet remained undeſtroyed. Thus terminated the ſiege of Mexico, the moſt memorable event in the conqueſt of America. It continued 75 days, hardly one of which paſſed without ſome extraordinary effort of one party in the attack, or of the other in the defence of a city, on the fate of which both knew that the fortune of the empire depended. As the ſtruggle here was more obſtinate, it was likewiſe more equal, than any between the inhabitants of the Old and New Worlds. The great abilities of Guatimozin, the number of his troops, the peculiar ſituation of his capital, ſo far counterbalanced the ſuperiority of the Spaniards in arms and diſcipline, that they muſt have relinquiſhed the enterpriſe, if they had truſted for ſucceſs to themſelves alone. But Mexico was overturned by the jealouſy of neighbours who dreaded its power, and by the revolt of ſubjects impatient to ſhake off its yoke. By their effectual aid, Cortes was enabled to accompliſh what, without ſuch ſupport, he would hardly have ventured to attempt. How much ſoever this account of the reduction of Mexico may detract, on the one hand, from the marvellous relations of ſome Spaniſh writers, by aſcribing that to ſimple and obvious cauſes which they attribute to the romantic valour of their countrymen, it adds, on the other, to the merit and abilities of Cortes, who, under every diſadvantage, acquired ſuch an aſcendant over unknown nations, as to render them inſtruments towards carrying his ſcheme into execution.

The exultation of the Spaniards, on accompliſhing this arduous enterpriſe, was at firſt exceſſive. But this was quickly damped by the cruel diſappointment of thoſe ſanguine hopes which had animated them amidſt ſo many hardſhips and dangers. Inſtead of the inexhauſtible wealth which they expected from becoming maſters of Montezuma's treaſures, and the ornaments of ſo many temples, their rapaciouſneſs could collect only an inconſiderable booty amidſt ruins and deſolation (A). Guatimozin, aware of his impending fate, had ordered what remained of the riches amaſſed by his anceſtors to be thrown into the lake. The Indian auxiliaries, while the Spaniards were engaged in conflict with the enemy, had carried off the moſt valuable part of the ſpoil. The ſum to be divided among the conquerors was ſo ſmall, that many of them diſdained to accept of the pittance which fell to their ſhare, and all murmured and exclaimed; ſome againſt Cortes and his confidents, whom they ſuſpected of having ſecretly appropriated to their own uſe a large portion of the riches which ſhould have been brought into the common ſtock; others againſt Guatimozin, whom they accuſed of obſtinacy, in refuſing to diſcover the place where he had hidden his treaſure.

Arguments, intreaties, and promiſes, were employed in order to ſoothe them; but with ſo little effect, that Cortes, from ſolicitude to check this growing ſpirit of diſcontent, gave way to a deed which ſtained the glory of all his great actions. Without regarding the former dignity of Guatimozin, or feeling any reverence for thoſe virtues which he had diſplayed, he ſubjected the unhappy monarch, together with his chief favourite, to torture, in order to force from them a diſcovery of the royal treaſures, which it was ſuppoſed they had concealed. Guatimozin bore whatever the refined cruelty of his tormentors could inflict, with the invincible fortitude of an American warrior. His fellow-ſufferer, overcome by the violence of the anguiſh, turned a dejected eye towards his maſter, which ſeemed to implore his permiſſion to reveal all that he knew. But the high-ſpirited prince, darting on him a look of authority mingled with ſcorn, checked his weakneſs, by aſking, "Am I now repoſing on a bed of flowers?" Overawed by the reproach, he perſevered in his dutiful ſilence, and expired. Cortes, aſhamed of a ſcene ſo horrid, reſcued the royal victim from the hands of his torturers, and prolonged a life reſerved for new indignities and ſufferings.

137 Guatimozin tortured.

138 The Spaniards become maſters of the whole Mexican empire.

The fate of the capital, as both parties had foreſeen, decided that of the empire. The provinces ſubmitted one after another to the conquerors. Small detachments of Spaniards marching through them without interruption, penetrated, in different quarters, to the great Southern Ocean, which, according to the ideas of Columbus, they imagined would open a ſhort as well as eaſy paſſage to the Eaſt Indies, and ſecure to the crown of Caſtile all the envied wealth of thoſe fertile regions; and the active mind of Cortes began already to form ſchemes for attempting this important diſcovery. In his after ſchemes, however, he was diſappointed; but Mexico hath ever ſince remained in the hands of the Spaniards.

139 Ancient diviſions of Mexico.

The *ancient* kingdom of Mexico, properly ſo called, was divided into ſeveral provinces, of which the vale of Mexico itſelf was the fineſt in every reſpect. It is ſurrounded by verdant mountains, meaſuring upwards of 120 miles in circumference at their baſe. A great part of this vale is occupied by two lakes, the upper one of freſh water, but the lower one brackiſh, communicating with the former by means of a canal. All the water running from the mountains is collected in this lower lake, on account of its being in the bottom of the valley; hence it was ready, when ſwelled by extraordinary rains, to overflow the city of Mexico, as has already been obſerved. This delightful region contained the three imperial cities of Mexico, Acolhuacan, and Tlacopan; beſides 40 others, with innumerable villages and hamlets; but the moſt conſiderable of theſe, according to Clavigero, now ſcarcely retain one-twentieth part of their former magnificence. The principal inland provinces to the northward were

(A) The gold and ſilver, according to Cortes, amounted only to 120,000 peſos, Relat. 281, A. a ſum far inferior to that which the Spaniards had formerly divided in Mexico.

Mexico.

the Otomies; to the south-west the Malatzincas and Cuitlatecas; to the south the Tlahuicas and Cohuixcas; to the south-east, after the states of Itzocan, Jauhtepac, Quauhquecollon, Atlixco, Tehuacan, and others, were the great provinces of the Mixtecas, the Zapotecas, and the Chiapanecas; towards the east were the provinces of Tepayacac, the Popolocas, and Totonacas. The maritime provinces on the Mexican Gulf were Coatzacualco and Cuetlachtlan, called by the Spaniards *Cotasta*. On the Pacific Ocean were those of Coliman, Zacatollan, Tototepec, Tecuantepec, and Zoconochco.

The province of the Otomies began in the northern part of the vale of Mexico, extending through the mountains to the north to the distance of 90 miles from the city of Mexico; the principal cities being Tollan or Tula, and Xilotepec: the latter made the capital of the country by the Spaniards. Beyond the settlements of the Otomies, the country for more than a thousand miles in extent was inhabited only by barbarous and wandering savages.

The Malatzinca province contained the valley of Tolocan, and all the country from *Taximaroa* to the frontier of the kingdom of Michuacan. The valley of Tolocan is upwards of 40 miles long from south-east to north-west, and 30 in breadth where broadest. Its principal city, named also *Tolocan*, is situated at the foot of a high mountain covered with snow, 30 miles distant from Mexico.

The country of the Cuitlatecas extended from north-east to south-west, upwards of 200 miles, extending as far as the Pacific Ocean. Their capital was named Mexcaltepec, once a great and populous city, situated upon the sea-coast; but of which the ruins are now scarcely visible. That of the Tlahuicas was named Quauhnahuac, and situated about 40 miles to the southward of Mexico. The province extended almost 60 miles southward, commencing from the southern mountains of the vale of Mexico.

The country of the Cohuixcas extended on the southward as far as the Pacific Ocean, through that part where at present the port and city of Acapulco lie. It was divided into the states of Tzompanco, Chilapan, Tlapan, and Tistla; the latter a very hot and unwholesome country. To this province belonged a place named *Tlachco*, celebrated for its silver-mines.

The province of the Mixtecas extended from *Acatlan*, a place distant about 120 miles from Mexico, as far as the Pacific Ocean towards the south east. The inhabitants carried on a considerable commerce, and had several well inhabited cities and villages. To the east of the Mixtecas were the Zapotecas, so called from their capital Teotzapotlan. In their district was the valley of Huaxyacac, now Oaxaca or Guaxaca.

The province of Mazatlan lay to the northward of the Mixtecas; and to the northward and eastward of the Zapotecas was *Chimantla*, having their capitals of the same name with their provinces. The Chiapanecas, Zoqui, and Queleni, were the last of the Mexican provinces towards the south-east. On the side of the mountain Popocatepec and around it lay several states, of which the most considerable were Cholallan and Huexotzinco. These two having, with the assistance of the Tlascalans, shaken off the Mexican yoke, re-established their former aristocratical government. The Cholulans possessed a small hamlet called Cuitlaxcoapan, in the place where the Spaniards afterwards founded the city of Angelopoli, which is the second of New Spain.

To the eastward of Cholula lay a considerable state named Tepeyacac; and beyond that the Popolocas, whose principal cities were Tecamachalco and Quechollac. To the southward of the Popolocas was the state of Tehuacan, bordering upon the country of the Mixtecas; to the east, the maritime province of Cuetlachtlan; and to the north the Totonacas. The extent of this province was 150 miles, beginning from the frontier of Zacatlan, a state distant about 80 miles from the court, and terminating in the Gulf of Mexico. Besides the capital, named *Mizquihuacan*, this country had the beautiful city of Chempoallan, situated on the coast of the Gulf; remarkable for being that by which the Spaniards entered the Mexican empire.

Coliman was the most northerly of the provinces on the Pacific Ocean; the capital, named also Coliman, being in lat. 19. long. 272 Towards the south-east was the province of Zacotlan, with its capital of the same name; then came the coast of the Cuitlatecas; after it that of the Cohuixcans, in which was the celebrated port of Acapulco. The *Jopi* bordered on the Cohuixca coast; and adjoining to that the Mixteca country, now called *Misteca*; next to that was the large province of Tecuantepec; and lastly, that of Xochonochco.

This province, the most southerly of the Mexican empire, was bounded on the east and south-east by the country of Xochitepec, which did not belong to Mexico; on the west by Tecuantepec; and on the south by the ocean. The capital, called also *Xoconochco*, was situated between two rivers, in 14 degrees of latitude and 283 of longitude. On the Mexican Gulf there were, besides the country of the Totonecas, the provinces of Cuetlachtlan and Coatzacualco; the latter bounded on the east by the states of Tabasco and the peninsula of Yucatan. The province of Cuetlachtlan comprehended all the coast between the rivers Alvarado and Antigua, where the province of the Totonecas began.

14 Climate.

The climate of this vast country varies very much according to the situation of its different parts. The maritime places are hot, unhealthy, and moist; the heat being so great as to cause people sweat even in the month of January. This heat is supposed to be owing to the flatness of the coasts, and the accumulation of sand upon them. The moisture arises from the vast evaporation from the sea, as well as from the great torrents of water descending from the mountains. The lands which lie in the neighbourhood of high mountains, the tops of which are always covered with snow, must of necessity be cold; and Clavigero informs us, that he has been on a mountain not more than 25 miles distant from the city of Mexico, where there was white frost and ice even in the dog-days. "All the other inland countries (says our author), where the greatest population prevailed, enjoy a climate so mild and benign, that they neither feel the rigour of winter nor the heats of summer. It is true, in many of these countries, there is frequently white frost in in the three months of December, January, and February, and sometimes even it snows; but the small inconvenience which such cold occasions continues only till the rising sun: no other fire than his rays is necessary to give warmth in winter; no other relief is wanted in the season of heat but the shade: the same clothing which covers men in the dog-days defends them in January, and the animals sleep all the year under the open sky.

"This mildness and agreeableness of climate under the torrid zone is the effect of several natural causes entirely unknown to the ancients, who did not believe it to be inhabited; and not well understood by some moderns, by whom it is believed unfavourable to those who live in it. The purity of the atmosphere, the smaller obliquity of the solar rays, and the longer stay of this luminary above the horizon in winter, in comparison of other regions farther removed from the equator, concur to lessen the cold, and to prevent all that horror which disfigures the face of nature in other climes. During that season a serene sky and the natural delights of the country are enjoyed; whereas, under the frigid, and even for the most part under the temperate zones, the clouds rob man of the prospect of heaven, and the snow buries the beautiful productions of the earth. No less causes combine to temper the heat of summer. The plentiful showers which frequently water the earth after mid-day from April or May to September or October; the high mountains, continually loaded with snow, scattered here and there through the country of Anahuac; the cool winds which breathe from them in that season; and the shorter stay of the sun above the horizon, compared with the circumstances of the temperate zone, transform the climes of those happy countries into a cool and cheerful spring. But the agreeableness of the climate is counterbalanced by thunder-storms, which are frequent in summer, particularly in the neighbourhood of the mountain of Tlascala; and by earthquakes, which are at all times felt, though with less danger than terror. Storms of hail are neither more frequent nor more severe than in Europe."

One undoubted inconvenience which Mexico has is that of volcanoes, of which our author enumerates five. One named by the Spaniards *Volcan d'Orizaba* is higher than the peak of Teneriffe, according to the account of the Jesuit Tallandier, who measured them both. It began to send forth smoke in the year 1545, and continued burning for 20 years, but has not discovered any symptoms of eruption since that time. It is of a conical figure; and, by reason of its great height, may be seen at 50 leagues distance. The top is always covered with snow, but the lower part with woods of pine and other valuable timber. It is about 90 miles to the eastward of the capital.

Two other mountains, named *Popocatepec* and *Iztaccihuatl*, which lie near each other, at the distance of 33 miles to the south-east of Mexico, are likewise surprisingly high. Clavigero supposes the former to be higher than the highest of the Alps, considering the elevated ground on which the base of it stands. It has a crater more than half a mile wide; from which, in the time of the Mexican kings, great quantities of smoke and flame issued. In the last century it frequently threw out great showers of ashes upon the adjacent places; but in this century hardly any smoke has been observed. This mountain is named by the Spaniards *Volcan*, and the other *Sierra Nevada*. The latter has also sometimes emitted flames. Both of them have their tops always covered with snow in such quantities, that the masses which fall down upon the neighbouring rocks supply the cities of Mexico, Gelopoli, Cholula, and all the adjacent country to the distance of 40 miles, with that commodity; of which the consumpt is so great, that in 1746 the impost upon what was consumed in the city of Mexico amounted to 15,212 Mexican crowns; some years after it amounted to 20,000; and is now in all probability a great deal more. Besides these, there are the two mountains of Coliman and Tochtlan, both of which have occasionally emitted flames. Our author does not include in the list of Mexican volcanoes either those of Nicaragua or Guatimala; because these countries were not subject to the Mexican sovereigns. Those of Guatimala sometimes break forth in a most furious manner, and in the year 1773 entirely destroyed that beautiful city. The Nicaraguan volcano called *Juruyo* was only a small hill before the year 1760. In that year, however, on the 29th of September, it began to burn with furious explosions, ruining entirely the sugar-work and the neighbouring village of *Guacana*; and from that time continued to emit fire and burning rocks in such quantities, that the erupted matters in six years had formed themselves into three high mountains nearly six miles in circumference. During the time of the first eruption, the ashes were carried as far as the city of Queretaro, 150 miles distant from the volcano; and at Valladolid, distant 60 miles from it, the shower was so abundant, that the people were obliged to sweep the house-yards two or three times a-day.

Besides these volcanoes, there are others in Mexico of a very remarkable height. The great chain of mountains called the *Andes* are continued through the isthmus of Panama and through all Mexico, until they are lost in the unknown mountains of the north. The most considerable of that chain is known in Mexico by the name of *Sierra Madre*, particularly in Cinaloa and Tarahumara, provinces no less than 1200 miles distant from the capital.

143 Rivers and lakes.

Mexico is well watered by very considerable rivers, though none of them are comparable to those of South America. Some of these run into the gulf of Mexico, and others into the Pacific Ocean. The Alvarado has its principal source among the mountains of the Zapotecas, and discharges itself by three navigable mouths into the Mexican gulf, at the distance of 30 miles from Vera Cruz. The Coatzocualco rises among the mountains of the Mixtecas, and empties itself into the gulf near the country of Onohualco. The river Chiapan, which likewise runs into this gulf, rises among the mountains which separate the district of Chiapan from that of Guatimala. The Spaniards call this river *Tabasco*; by which name they also called that tract of land which unites Yucatan to the Mexican continent. It was also called the *Grijalva*, from the name of the commander of the first Spanish fleet who discovered it.

The most celebrated of the rivers which run into the Pacific Ocean is that called by the Spaniards

Gua-

Mexico. *Guadalaxara* or *Great River.* It riſes in the mountains of Toloccan; and after running a courſe of more than 600 miles, diſcharges itſelf into the ocean in 22° latitude.

There are likewiſe in this country ſeveral lakes of very conſiderable magnitude; but thoſe of Nicaragua, Chapallan, and Pazquaro, which are of the greateſt extent, did not belong to the ancient Mexican empire. The moſt remarkable were thoſe in the vale of Mexico, upon which the capital of the empire was founded. Of theſe, the freſh water one called the *lake of Chalco*, extended in length from eaſt to weſt 12 miles, as far as the city of Xochimilco; from thence, taking a northerly direction, it incorporated itſelf by means of a canal with the lake of Tezcuco; but its breadth did not exceed ſix miles. The other, named the *lake of Tezcuco*, extended 15, or rather 17, miles from eaſt to weſt, and ſomething more from ſouth to north; but its extent is now much leſs, by reaſon of the Spaniards having diverted the courſe of many of the ſtreams which run into it. This lake is ſalt, which Clavigero ſuppoſes to ariſe from the nature of the ſoil which forms its bed.

Beſides theſe, there are a number of ſmaller lakes, ſome of which are very delightful. There is a vaſt variety of mineral waters, of the nitrous, ſulphureous, and aluminous kinds, ſome of them ſo hot that meat might be boiled in them. At Tecuhuacan is a kind of petreſying water, as well as in ſeveral other parts of the empire. One of them forms a kind of ſmooth white ſtones, not diſpleaſing to the taſte; the ſcrapings of which taken in broth are celebrated as a diaphoretic, probably without any good reaſon. The doſe for a perſon not difficult to be ſweated is one drachm of the ſcrapings. Many of the rivers of Mexico afford ſurpriſing and beautiful caſcades; particularly the great river Guadalaxara, at a place called *Tempizque*, 15 miles to the ſouthward of that city. Along a deep river called *Atoyaque* is a natural bridge, conſiſting of a vaſt mound of earth, along which carriages paſs conveniently. Clavigero ſuppoſes it to have been the fragment of a mountain thrown down by an earthquake, and then penetrated by the river.

144 Metals and minerals. The mineral productions of Mexico are very valuable. The natives found gold in ſeveral provinces of the empire. They gathered it principally from among the ſands of their rivers in grains; and the people in whoſe country it was found, were obliged to pay a certain quantity by way of tribute to the emperor. They dug ſilver out of mines in Tlochco, and ſome other countries, but it was leſs prized by them than by other nations. Since the conqueſt, however, ſo many ſilver mines have been diſcovered in that country, eſpecially in the provinces to the northweſt of the capital, that it is in vain to attempt any enumeration of them. They had two ſorts of copper: one hard, which ſerved them inſtead of iron, to make axes and other inſtruments for war and agriculture; the other kind, which was ſoft and flexible, ſerved for domeſtic utenſils as with us. They had alſo tin from the mines of Tlachco, and dug lead out of mines in the country of the Otomies; but we are not informed what uſes they put this laſt metal to. They had likewiſe mines of iron in Tlaſcala, Tlachco, and ſome other places; but theſe were either unknown to the Mexicans, or they did not know how to benefit themſelves by them. In Chilapan were mines of quickſilver; and in many places they had ſulphur, alum, vitriol, cinnabar, ochre, and an earth greatly reſembling white lead. Theſe minerals were employed in painting and dyeing; but we know not to what uſe they put their quickſilver. There was great abundance of amber and aſphaltum upon their coaſts; both of which were paid in tribute to the king of Mexico from many parts of the empire. The former was wont to be ſet in gold by way of ornament, and aſphaltum was employed in their ſacrifices.

145 Precious ſtones. Mexico produces ſome diamonds, though but few in number; but they had in greater plenty ſome other precious ſtones, ſuch as amethyſts, cats-eyes, turquoiſes, cornelians, and ſome green ſtones reſembling emeralds, and very little inferior to them; of all which a tribute was paid to the emperor by the people in whoſe territories they were found. They were likewiſe furniſhed with cryſtal in plenty from the mountains which lay on the coaſt of the Mexican gulph, between the port of Vera Cruz and the river Coatzacualco. In the mountains of Celpolalpan, to the eaſtward of Mexico, were quarries of jaſper and marble of different colours: they had likewiſe alabaſter at a place called *Tecalco*, now *Tecale*, in the neighbourhood of the province of Tapeyacac and many other parts of the empire. The ſtone tetzontli is generally of a dark red colour, pretty hard, porous, and light, and unites moſt firmly with lime and ſand; on which account it is of great requeſt for buildings in the capital, where the foundation is bad. There are entire mountains of loadſtone, a very conſiderable one of which lies between Teoitztlan and Chilapan, in the country of the Cohuixcas. They formed curious figures of nephritic ſtone, ſome of which are ſtill preſerved in European muſeums. They had a kind of fine white talc which burnt into an excellent plaſter, and with which they uſed to whiten their paintings. But the moſt uſeful ſtone they had was that called *itztli*, of which there is great abundance in many parts of Mexico. It has a gloſſy appearance, is generally of a black colour, and ſemitranſparent; though ſometimes alſo of a blue or white colour. In South America this ſtone is called *pietra del galinazzo*: and Count Caylus endeavours to ſhow, in a manuſcript diſſertation quoted by Bomare, that the *obſidiana*, of which the ancients made their *vaſes murini*, were entirely ſimilar to this ſtone. The Mexicans made of it looking-glaſſes, knives, lancets, razors, and ſpears. Sacred vaſes alſo were made of it after the introduction of Chriſtianity.

146 Vegetable production. The ſoil of Mexico, though various, produced every where the neceſſaries and even the luxuries of life. "The celebrated Dr Hernandez, the Pliny of New Spain (ſays Clavigero), has deſcribed in his Natural Hiſtory about 1200 plants natives of the country; but his deſcription, though large, being confined to medicinal plants, has only compriſed one part of what provident nature has produced there for the benefit of mortals. With regard to the other claſſes of vegetables, ſome are eſteemed for their flowers, ſome for their fruit, ſome for their leaves, ſome for their root, ſome for their trunk or their wood; and others for their gum, reſin, oil, or juice."

Mexico.

Mexico abounds with a great variety of flowers, many of which are peculiar to the country, while multitudes of others imported from Europe and Aſia rival in luxuriance the natives of the country itſelf. The fruits are partly natives of the Canary iſlands, partly of Spain, beſides thoſe which grow naturally in the country. The exotics are water-melons, apples, pears, peaches, quinces, apricots, pomegranates, figs, black cherries, walnuts, almonds, olives, cheſnuts, and grapes; though theſe laſt are likewiſe natives. There are two kinds of wild vine found in the country of the Mixtecas; the one reſembling the common vine in the ſhoots and figure of its leaves. It produces large red grapes covered with an hard ſkin, but of ſweet and grateful taſte, which would undoubtedly improve greatly by culture. The grape of the other kind is hard, large, and of a very harſh taſte, but they make an excellent conſerve of it. Our author is of opinion that the cocoa tree, plantain, citron, orange, and lemon, came from the Philippine iſlands and Canaries; but it is certain that theſe, as well as other trees, thrive in this country as well as in their native ſoil. All the maritime countries abound with cocoa-nut trees; they have ſeven kinds of oranges and four of lemons, and there are likewiſe four kinds of plantains. The largeſt, called the *zapalot*, is from 15 to 20 inches long, and about three in diameter; it is hard, little eſteemed, and only eat when roaſted or boiled. The *platano largo*, or "long plantain," is about eight inches long and one and a half in diameter; the ſkin is at firſt green, and blackiſh when perfectly ripe. The *guineo* is a ſmaller fruit, but richer, ſofter, and more delicious, though not ſo wholeſome. A ſpecies of plantain, called the *dominico*, is ſmaller and more delicate than the others. There are whole woods of plantain trees, oranges, and lemons; and the people of Michuacan carry on a conſiderable commerce with the dried plantains, which are preferable either to raiſins or figs. Clavigero enumerates 28 different ſorts of fruit natives of Mexico, beſides many others, the names of which are not mentioned. Hernandez mentions four kinds of cocoa nuts; of which the ſmalleſt of the whole was in moſt uſe for chocolate and other drinks daily made uſe of; the other kinds ſerved rather for money in commerce than for aliment. The cocoa was one of the plants moſt cultivated in the warm countries of the empire; and many provinces paid it in tribute to the emperor, particularly that of Xoconocho, the cocoa nut of which is preferable to the others. Cotton was one of the moſt valuable productions of the country, as it ſerved inſtead of flax; though this laſt alſo was produced in the country. It is of two kinds, white and tawny-coloured. They made uſe of *rocou* or Braſil-wood in their dying, as the Europeans alſo do. They made cordage of the bark, and the wood was made uſe of to produce fire by friction.

The principal grain of Mexico, before the introduction of thoſe from Europe, was maize, in the Mexican language called *tlaolli*; of which there were ſeveral kinds, differing in ſize, weight, colour, and taſte. This kind of grain was brought from America to Spain, and from Spain to the other countries of Europe. The French bean was the principal kind of pulſe in uſe among them, of which there were more ſpecies than of the maize. The largeſt was called *ayacotli*, of the ſize of a common bean, with a beautiful red flower; but the moſt eſteemed was the ſmall, black, heavy, French bean. This kind of pulſe, which is not good in Italy, is in Mexico ſo excellent, that it not only ſerves for ſuſtenance to the poorer claſs of people, but is eſteemed a luxury even by the Spaniſh nobility.

149 Eſculent roots.

Of the eſculent roots of Mexico, the following were the moſt remarkable. 1. The *xicama*, called by the Mexicans *catzotl*, was of the figure and ſize of an onion; ſolid, freſh, juicy, and of a white colour; it was always eat raw. 2. The *camote*, is another very common in the country, of which there are three ſorts, white, yellow, and purple: they eat beſt when boiled. 3. The *cacomite*, is the root of a plant which has a beautiful flower called the *tyger-flower*, with three red pointed petals, the middle part mixed with white and yellow, ſomewhat reſembling the ſpots of the creature whence it takes its name. 4. The *huacamote*, is the root of a kind of Caſſava plant, and is likewiſe boiled. 5. The *papa*, a root tranſplanted into Europe, and greatly valued in Ireland, was brought from South America into Mexico. Beſides all which they have a number of kitchen vegetables imported from the Canaries, Spain, and other countries of Europe. The American aloe is very ſimilar to the real one, and is a plant of which the Mexicans formerly, and the Spaniards ſtill, make great uſe.

150 Trees.

They have a variety of palm trees. From the fibres of the leaves of one ſpecies they make thread. The bark of another kind, to the depth of three fingers, is a maſs of membranes, of which the poor people make mats. The leaves of another kind are uſed for ornaments in their feſtivals. They are round, groſs, white, and ſhining; having the appearance of ſhells heaped upon one another. A fourth kind bears nuts called *cocoas*, or nuts of oil. Theſe nuts are of the ſize of a nutmeg, having in the inſide a white, oily, eatable kernel, covered by a thin, purple, pellicle. The oil has a ſweet ſcent, but is eaſily condenſed, when it becomes a ſoft maſs, as white as ſnow.

Of timber trees there are great variety, of a quality not inferior to any in the world; and as there are a variety of climates in the country, every one produces a kind of wood peculiar to itſelf. There are whole woods of cedars and ebonies, vaſt quantities of agallochum or wood of aloes; beſides others valuable on account of their weight, durability, and hardneſs; or for their being eaſily cut, pliable, of a fine colour, or an agreeable flavour. There are alſo in Mexico innumerable trees remarkable for their ſize. Acoſta mentions a cedar, the trunk of which was 16 fathoms in circumference; and Clavigero mentions one of the length of 107 Paris feet. In the city of Mexico he mentions very large tables of cedar made out of ſingle planks. In the valley of Atlixco is a very ancient fir tree, hollowed by lightning; the cavity of which could conveniently hold fourteen horſemen; nay, we are informed by the archbiſhop of Toledo, that, in 1770, he went to view it along with the archbiſhop of Guatimala, at which time he cauſed an hundred young lads enter its cavity. Our author mentions ſome other trees, of the ſpecies called *cedars*, which for magnitude may be compared with this ce-

lebrated

Mexico. lebrated fir. "The largeneſs of theſe trees (ſays he) is proportioned to their prodigious elevation; and they afford a moſt delightful proſpect at the time they are adorned with new leaves and loaded with fruit, in which there is incloſed a particular ſpecies of fine, white, and moſt delicate cotton. This might be, and actually has been, made into webs as ſoft, delicate, and perhaps more ſo than ſilk; but it is toilſome to ſpin, on account of the ſmallneſs of the threads, and the profit does not requite the labour, the web not being laſting. Some uſe it for pillows and matraſſes, which have the ſingular property of expanding enormouſly when expoſed to the heat of the ſun. De Bomare ſays, that the Africans make of the thread of the ceiba that vegetable taffety which is ſo ſcarce, and ſo much eſteemed in Europe. The ſcarcity of ſuch cloth is not to be wondered at conſidering the difficulty of making it. The ceiba, according to this author, is higher than all other trees yet known."

Clavigero mentions a Mexican tree, the wood of which is very valuable, but poiſonous, and if incautiouſly handled, when freſh cut, produces a ſwelling in the ſcrotum. Our author has forgot the name given to it by the Mexicans; nor has he ever ſeen the tree itſelf, nor been witneſs to the effect.

151 Medicinal and aromatic gums.

This country abounds alſo with aromatic and medicinal trees, producing gums, reſins, &c. From one of theſe a balſam is produced not in the leaſt inferior to the celebrated balſam of Mecca. It is of a reddiſh black or yellowiſh white, of a ſharp bitter taſte, and of a ſtrong but moſt grateful odour. It is common in the provinces of Panuco and Chiapan, and other warm countries. The kings of Mexico cauſed it to be tranſplanted into their celebrated garden of Huaxtepec, where it flouriſhed, and was afterwards multiplied in all the neighbouring mountains. The Indians, in order to procure a greater quantity of this balſam, burn the branches, which affords more than mere diſtillation, though undoubtedly of an inferior quality; nor do they regard the loſs of the trees, which are very abundant. The ancient Mexicans were wont to extract it alſo by decoction. The firſt parcel of this balſam brought from Mexico to Rome was ſold at one hundred ducats per ounce; and was, by the apoſtolic ſee, declared to be matter fit for chriſm; though different from that of Mecca, as Acoſta and all other writers on this ſubject obſerve. An oil is likewiſe drawn from the fruit of this tree, ſimilar in taſte and ſmell to that of the bitter almond, but more acrimonious. From two other trees named the *huaconex* and *maripenda*, an oil was extracted equivalent to the balſam. The former is a tree of a moderate height; the wood of which is aromatic, and ſo hard, that it will keep freſh for ſeveral years, though buried under the earth. The leaves are ſmall and yellow; the flowers likewiſe ſmall and white, and the fruit ſimilar to that of the laurel. The oil was diſtilled from the bark of the tree, after breaking it, and keeping it three days in ſpring-water, and then drying it in the ſun. The leaves likewiſe afforded an agreeable oil by diſtillation. The Maripenda is a ſhrub with lanceolated leaves, the fruit of a red colour when ripe, and reſembling the grape. The oil is extracted by boiling the branches with a mixture of ſome of the fruit.

The tree producing liquid amber, the liquid ſtorax of the Mexicans, is of a large ſize, the leaves ſimilar to thoſe of the maple, indented, white in one part and dark in the other, diſpoſed of in threes; the fruit is thorny and round, but polygonous, with the ſurface and the angles yellow; the bark of the tree partly green and partly tawny. By inciſions in the trunk they extract that valuable ſubſtance named *liquid amber*, and the oil of the ſame name, which is ſtill more valuable. Liquid amber is likewiſe obtained from a decoction of the branches, but it is inferior to that obtained from the trunk.

The name *copalli* in Mexico is generic, and common to all the reſins; but eſpecially ſignifies thoſe made uſe of for incenſe. There are ten ſpecies of theſe trees yielding reſins of this kind; the principal of which is that from which the COPAL is got, ſo well known in medicine and varniſhes. A great quantity of this was made uſe of by the ancient Mexicans, and is ſtill uſed for ſimilar purpoſes by the Spaniards. The *tecopalli* or *tepecopalli* is a reſin ſimilar to the incenſe of Arabia; which diſtils from a tree of moderate ſize that grows in the mountains, having a fruit like an acorn, and containing the nut inveloped in a mucilage, within which there is a ſmall kernel uſeful in medicine.

The *mizquitl*, or mezquite, is a ſpecies of true acacia, and the gum diſtilling from it is ſaid to be the true gum arabic. It is a thorny ſhrub, with branches irregularly diſpoſed, the leaves ſmall, thin, and pinnated; the flowers being like thoſe of the birch-tree.—The fruits are ſweet and eatable, containing a ſeed, of which the barbarous Chichemecas were wont to make a kind of paſte that ſerved them for bread. The wood is exceedingly hard and heavy, and the trees are as common in Mexico as oaks are in Europe, particularly on hills in the temperate countries.

Of the elaſtic gum, which is found in plenty in Mexico, the natives were in uſe to make foot-balls, which, though heavy, have a better ſpring than thoſe filled with air. At preſent they varniſh with it their hats, cloaks, boots, and great coats, in a manner ſimilar to what is done in Europe with wax; and by which means they are rendered all water-proof.

152 Mexican animals.

Our author laments that the natural hiſtory of vegetables in Mexico is very little known, and that of animals no better. The firſt Spaniards (ſays he) who gave them names, were more ſkilful in the art of war than in the ſtudy of nature. Inſtead of retaining the terms which would have been moſt proper, they denominated many animals tygers, wolves, bears, dogs, ſquirrels, &c. although they were very different in kind, merely from ſome reſemblance in the colour of their ſkin, their figure, or ſome ſimilarity in habits and diſpoſition. The quadrupeds found in Mexico at the arrival of the Spaniards, were lions, tygers, wild cats, bears, wolves, foxes, the common ſtags, white ſtags, bucks, wild goats, badgers, pole-cats, weaſles, martins, ſquirrels, polatucas, rabbits, hares, otters, and rats. All theſe animals are ſuppoſed by our author to be common to both continents. The white ſtag, whether it be the ſame ſpecies of the other or not, is undoubtedly common to both, and was known to the Greeks and Romans. The Mexicans call it the *king of the ſtags*. M. Buffon imagines the white

Mexico. white colour of this creature to be the effect of captivity; but Clavigero says, that it is found wild, and of the same white colour, on the mountains of New Spain. In many other points, he also controverts the opinions of this celebrated naturalist, who will not allow the lion, tyger, or rabbit, to be natives of America. "The *miztli* of the Mexicans (says he) is no other than the lion without hair mentioned by Pliny, and totally distinct from the African lion; and the *ocelotl* is no way different from the African tyger, according to the testimony of Hernandez, who knew both the one and the other. The *tochtli* of Mexico is exactly the rabbit of the old continent; and at least as ancient as the Mexican calendar, in which the figure of the rabbit was the first symbolical character of their years. The wild cats, in size much larger than the domestic cats, are fierce and dangerous; the bears are all black, and more corpulent than those which are brought from the Alps into Italy. The hares are distinguished from those of Europe by their longer ears, and the wolves by a grosser head. According to M. Buffon, the Mexicans give the name of *polutaca* to the quimicpaltan, or flying rat of the Mexicans. We call it rat, because it resembles a rat in the head, though it is much larger, and flying; because in its natural state, the skin of its sides is loose and wrinkled, which it distends and expands together with its feet like wings, when it makes any considerable leap from one tree to another. This is confounded with the common squirrel on account of their likeness, but they are undoubtedly different. Mice were brought to Mexico in European ships; the rats were not so, but known in the country by the name of *quimichin*, a word metaphorically applied to spies."

Our author now proceeds to enumerate the quadrupeds common to New Spain with the rest of the continent of America. Among these he will not allow a place to the Peruvian sheep, the *huanaco*, and sloth; all of which are peculiar to South America Hernandez indeed makes mention of the Peruvian sheep, and gives a drawing of it; but this was only on account of a few individuals brought thence from Peru, which the Mexicans called by that name, in the same manner as he describes several animals of the Philippine isles; not that they had ever been bred in Mexico, or found in any country of North America, unless it was some individual carried there, as they are carried as a curiosity from Europe. The animals which he allows to be common to both countries are, the Mexican hog, the moufete, the opossum, the armadillo, the *techichi*, a small animal resembling a dog; which being perfectly dumb, gave occasion to a report that the Mexican dogs could not bark. The flesh of this animal was eat by them, and was esteemed agreeable and nourishing food. After the conquest of Mexico, the Spaniards having neither large cattle nor sheep, provided their markets with this quadruped; by which means, the species soon came to be extinct, though it had been very numerous. The land-squirrel is very numerous in the kingdom of Michuacan, has great elegance of form, and is extremely graceful in its movement; but it cannot be tamed, and bites most furiously every person who approaches it.

Besides these, there are sea-lions, rattoons, and that voracious animal named the *tapir*. Oviedo informs us, that he has seen it at one bite tear off two or three hand-breadths of skin from a hound, and at another a whole leg and thigh. The flesh is eatable, and its skin is valued on account of its being sufficiently strong to resist musket-balls. There are likewise great numbers of monkeys of many different kinds; some of which have heads resembling those of dogs. Some of them are strong and fierce, equalling a man in stature when they stand upright.

153 Description of some animals peculiar to Mexico.

Among the animals peculiar to Mexico, is one named by our author *coyoto*, which appears to have been inaccurately described by other natural historians; some making it one species and some another. He says it has the voracity of a wolf, the cunning of a fox, the form of a dog, and in some properties resembles the *adive* and *chacal*. It is about the size of a mastiff, but more slender. The eyes are yellow and sparkling, ears small, pointed, and erect; the snout blackish, strong limbs, and the feet armed with large crooked nails. The tail is thick and hairy, the skin a mixture of black, brown, and white; and the voice is compounded of the howl of the wolf and the bark of the dog. It is one of the most common quadrupeds in Mexico, and most destructive to the flocks. When it invades a sheep-fold, if it cannot find a lamb to carry off, it seizes a sheep by the neck with its teeth, and coupling with it, and beating it on the rump with its tail, conducts it whether it pleases. It pursues the deer, and will sometimes even attack men. Its usual pace is a trot, but so quick that a horse at the gallop can scarce overtake it. The *tlalcojotl* or *tlalcoyoto* is about the size of a middling dog, and in our author's opinion is the largest animal that lives under the earth. Its head has some resemblance to that of a cat; but in colour and length of hair it resembles the lion.—It has a long thick tail, and feeds upon poultry and small animals, which it catches in the night-time. The *tepeizuintli*, or mountain-dog, though it is but of the size of a small dog, is so bold that it attacks deer, and sometimes kills them. Its hair and tail are long, the body black, but the head, neck, and breast, white. Mr Buffon reckons this animal the same with the glutton, but Clavigero denies it. Another animal, larger than the two foregoing, is called the *xoloitzcuintli*. Some of these are no less than four feet in length. It has a face like the dog, but tusks like the wolf, with erect ears, the neck gross, and the tail long.—It is entirely destitute of hair, excepting only the snout, where there are some thick crooked bristles. The whole body is covered with a smooth, soft, ash-coloured skin, spotted partly with black and tawney. This species of animals, as well as the two former, are almost totally extinct. A Lyncean academician named *Giovanni Fabri*, has endeavoured to prove that the xoloitzcuintli is the same with the wolf of Mexico; but this is denied by our author.

An animal called *ocotochtli*, a kind of wild cat, is remarkable more for the fabulous account of it than for any singular property with which it is really endowed. According to Dr Hernandez, when this creature takes any prey, it covers it with leaves, and afterwards mounting on some neighbouring tree, it begins howling to invite other animals to eat its prey; being itself always the last to eat; because the poison of

Mexico.

of its tongue is ſo ſtrong, that if it eat firſt, the prey would be infected, and other animals which eat of it would die.

(153) Curious kind of mole.

A curious animal of the mole kind is called *tozan* or *tuza*. It is about the ſize of an European mole, but very different otherwiſe. The body is about ſeven or eight inches long, and well made; the ſnout like that of a mouſe, the ears ſmall and round, with the tail ſhort. The mouth is armed with very ſtrong teeth, and its paws are furniſhed with ſtrong crooked nails, with which it digs its habitation in the earth. It is extremely deſtructive to the corn fields by the quantity of grain it ſteals, and to the highways by the number of holes it makes in them; for when, on account of the dimneſs of its ſight, it cannot find its firſt hole, it makes another, and ſo on. It digs the earth with its claws and two canine teeth which it has in the upper jaw. In digging, it puts the earth into two membranes like purſes, which are under its ear, and which are furniſhed with muſcles neceſſary for contraction and diſtenſion. When the membranes are full, it empties them by ſtriking the bottom with its paws, and then digs again as before. Theſe creatures are very numerous; but our author does not remember to have ſeen them in the place where land-ſquirrels inhabit.

154 Mexican birds.

The birds are ſo numerous, and of ſuch various appearances and qualities, that Mexico has been called the country of birds as Africa is of quadrupeds. Though Hernandez paſſes over a great number of ſpecies, he yet deſcribes above 200 peculiar to the country. He allows to the eagles and hawks of Mexico a ſuperiority over thoſe of Europe; and the falcons of this country were formerly eſteemed ſo excellent, that, by the deſire of Philip II. an hundred of them were ſent every year over to Spain. The largeſt, the moſt beautiful, and the moſt valuable kind of eagles, is called by the Mexicans *itzquauhtli*, and will purſue not only the larger kind of birds, but quadrupeds, and even men.

The ravens of Mexico do not, like thoſe of other countries, feed upon carrion, but ſubſiſt entirely by ſtealing corn. The carrion is devoured by the birds called in South America *gallinazzi*, in Mexico *zopilots* and *oure*. By Hernandez they are ſaid to be a ſpecies of ravens; but, according to Clavigero, they are very different, not only in their ſize, but in the ſhape of their head, their flight, and their voice.—They fly ſo high, that though pretty large, they are loſt to the ſight: before a hail-ſtorm they may be ſeen wheeling in great numbers in the air, until they entirely diſappear. They diſcover carrion by the acuteneſs of their ſight and ſmell at a great height in the air, and deſcend upon it in a ſpiral flight. They are extremely numerous, and are very uſeful to the country, becauſe they not only clear the fields of carrion, but attend the crocodiles, and deſtroy the eggs of theſe terrible animals. There is another bird, called by the Mexicans the *king of the zopilots*, on account, as it is ſaid, that the true zopilot will not touch a bit of carrion till the other has firſt taſted it.

The aquatic birds are very numerous, and of great variety.—There are at leaſt 20 ſpecies of ducks, a vaſt number of geeſe, with ſeveral kinds of herons, great numbers of ſwans, quails, water-rails, divers, king's fiſhers, pelicans, &c. The multitude of ducks is ſometimes ſo great, that they cover the fields, and appear at a diſtance like flocks of ſheep. Some of the herons and egrets are perfectly white, ſome aſh-coloured; others have the plumage of the body white, while the neck, with the tops and upper part of the wings, and part of the tail, are enlivened with a bright ſcarlet, or beautiful blue. Clavigero mentions a ſingular quality of the pelican, in which it differs from all other birds hitherto known, viz. that it aſſiſts ſuch of its own ſpecies as are hurt or ſick. Of this diſpoſition the Americans ſometimes take the advantage to procure fiſh without any trouble. They take a live pelican and break its wing, and, after tying it to a tree, conceal themſelves in the neighbourhood: there they watch the coming of the other pelicans with their proviſions; and as ſoon as they ſee them throw up the fiſh from the pouch they have below their bill, they run in, and leaving a little for the captive bird carry off all the reſt. The *yoalquachilli* is a ſmall aquatic bird, with a long narrow neck, ſmall head, long yellow bill, long legs, feet, and claws, and a ſhort tail. It is remarkable for the weapons with which it is naturally provided. On the head is a little circle or coronet, of a horny ſubſtance, which is divided into three very ſharp points, and there are two others on the fore-part of the wings.

15[5] Singu[lar] prope[rty] o[f] the pe[lican].

Numbers of the other claſſes of birds are valuable for their fleſh, plumage, or ſong, while ſome are remarkable for their extraordinary inſtinct or other properties. Our author enumerates more than 70 ſpecies of thoſe which afford an agreeable and wholeſome food. Beſides the common fowls which were brought from the Canaries to the Antilles, and from theſe to Mexico, there were, and ſtill are, fowls peculiar to the country itſelf. Theſe partly reſemble the common fowl and partly the peacock, whence they had the name of *gallipavos* from the Spaniards. From Mexico they were imported into Europe, where they have multiplied very faſt, eſpecially in Italy, though the common fowls have multiplied much more in Mexico. There are three kinds of pheaſants; one of which is as large as a gooſe, and very docile. It will become ſo tame as to pick food from its maſter's hand, and run to meet him with ſigns of joy when he comes home, ſhut the door with its bill, &c. By keeping in a yard along with other poultry, it learns to fight like a cock, raiſing the feathers of its creſt, as cocks do thoſe of their neck.

There are great numbers of birds valuable on account of their plumage, which was made uſe of by the Mexicans in their excellent moſaic works; an art which ſeems now to be totally loſt. Peacocks have been carried from the old continent to Mexico; but, not being attended to, have propagated very ſlowly. The birds remarkable for their ſong are likewiſe very numerous; among which that called the *centzontl*, by Europeans the *mocking-bird*, is the moſt remarkable, on account of its counterfeiting naturally the notes of all others it hears. It has been attempted to bring it to Europe, but without ſucceſs. The cardinals are very remarkable, not only on account of their fine colours, but likewiſe of their notes; and even the ſparrows have a moſt delightful and various ſong.

There are great numbers of beautiful parrots; and there is a bird which counterfeits the human voice, but in a kind of burleſque tone, and will follow travellers a great way. The *tzacua* is remarkable for its inſtinct. Birds of this kind live in ſociety, every tree being a village or city to them, having great numbers of neſts in the neighbourhood of each other, all hanging from the boughs. One of them, whoſe office it is to be the head or guard of the village, reſides in the middle of the tree; from which it flies about from one neſt to another, viſiting them all, and after ſinging a little, returns to its place, while the reſt continue perfectly ſilent. If any bird of a different ſpecies approaches the tree, he flies to it, and with his bill and wings endeavours to drive it off; but if a man or any large animal comes near, he flies ſcreaming to another tree; and if at that time any of his fellows happen to be returning to their neſts, he meets them, and, changing his note, obliges them to retire again: as ſoon as he perceives the danger over, he returns to his wonted round of viſiting the neſts.

Mexico, like all other American countries, abounds with reptiles, many of them of an enormous ſize. The crocodiles are not leſs to be dreaded than thoſe of Africa or Aſia; and there are likewiſe ſome of thoſe monſtrous ſerpents met with in the Eaſt Indies and in South America; though happily the ſpecies of thoſe terrible creatures ſeems to be nearly extinct, as they are ſeldom to be found but in ſome ſolitary wood, or other remote place. There are great numbers of lizards, ſome of which the people ſuppoſe to be poiſonous; but our author thinks this opinion ill founded. There are ſeveral kinds of poiſonous ſerpents, of which the rattle-ſnake is one. The *cenocoatl* is another poiſonous ſerpent, and remarkable for having a luminous appearance in the dark; by which, as by the rattle in the tail of the former, travellers are warned to avoid it. Among the harmleſs ſnakes is a very beautiful one about a foot in length, and of the thickneſs of the little finger. It appears to take great pleaſure in the ſociety of ants, inſomuch that it will accompany theſe inſects upon their expeditions, and return with them to their uſual neſt.—It is called both by the Mexicans and Spaniards the *mother of the ants;* but our author ſuppoſes that all the attachment which the ſnake ſhows to the ant-hills proceeds from its living on the ants themſelves. The ancient Mexicans were wont to take delight in keeping an harmleſs green ſnake which they catched in the fields, and which, when well fed, would grow to the length of five or ſix feet. It was generally kept in a tub, which it never left but to receive food from the hand of its maſter; and this it would take either mounted on his ſhoulder or coiled about his legs.

The aquatic animals are innumerable. Clavigero mentions a ſpecies of frogs ſo large that a ſingle one will weigh a pound, and which are excellent food.—Of fiſh proper for food, our author ſays that he has counted upwards of 100 ſpecies, without taking in the turtle, crab, lobſter, or any other cruſtaceous animal. The ſharks are well known for their voracity. A whole ſheep's ſkin, and even a large butcher's knife, has been found in the belly of one of them. They are accuſtomed to follow veſſels, to devour any filth that is thrown overboard; and, according to Oviedo, they have been known to keep up with ſhips ſailing before a fair wind for no leſs than 500 miles. The bottetto is a fiſh about eight inches in length, but exceſſively thick. While this fiſh lies alive upon the beach, it ſwells whenever it is touched to an enormous ſize, and boys often take pleaſure in making it burſt with a kick. The liver is ſo poiſonous as to kill with ſtrong convulſions in half an hour after it is eaten. The oechione is a round flat fiſh, of eight or ten inches in diameter; the under part of the body being perfectly flat, but the upper part convex; and in the centre, which is the higheſt part, it has a ſingle eye as large as that of an ox, furniſhed with eye-lids like the eyes of land animals. This eye remains open even after the fiſh is dead, and has an hideous appearance, ſo as ſometimes to ſtrike the ſpectators with horror. Campoi endeavours to prove, that this is the fiſh named by Pliny *uranoſcopos*. The Roman hiſtorian does not deſcribe this fiſh; but Clavigero obſerves, that the name of *uranoſcopos* might be equally applicable to all fiſh which have eyes upon the head that look up to the ſky, as ſkates and other flat fiſh. The axolotl is a great ugly water-lizard, remarkable for having a periodical evacuation of blood from the uterus, like the human ſpecies. It is eatable, taſtes like an eel, and the fleſh is looked upon to be good in conſumptions There are likewiſe a vaſt variety of ſhells, ſponges, and lithophyts. Hernandez gives the figure of a ſponge ſent to him from the Pacific Ocean, which was of the ſhape of a man's hand, but with ten or more fingers; of a clay colour, with black backs and red ſtreaks, harder than the common ſponges.

158 Inſects.

Of flying and other minute inſects, the number is prodigiouſly great. There are a variety of beetles: ſome of a green colour make a great noiſe in flying; on which account children are fond of them. There are great numbers of ſhining beetles, which make a delightful appearance at night, as well as the luminous flies which abound in the country. There are ſix kinds of bees and four kinds of waſps; of which laſt, one collects wax and honey of a very ſweet taſte: another is called the *wandering waſp* from its frequent change of abode; and in conſequence of theſe changes, it is conſtantly employed in collecting materials for its habitations. There is alſo a black hornet with a red tail, the ſting of which is ſo large and ſtrong, that it will not only penetrate a ſugar-cane but even the trunk of a tree. The lake of Mexico abounds with a kind of fly, the eggs of which are depoſited upon the flags and ruſhes in ſuch quantities as to form large maſſes. Theſe are collected by the fiſhermen, and carried to market for ſale. They are eaten by both Mexicans and Spaniards, and have much the ſame taſte as the caviare of fiſh. The Mexicans eat alſo the flies themſelves ground and made up with ſalt-petre. There are abundance of gnats in the moiſt places and lakes; but the capital, though ſituated upon a lake, is entirely free from them. There are other flies which make no noiſe in their flight, but cauſe a violent itching by their bite; and if the part be ſcratched, an open wound is apt to enſue. The butterflies are in vaſt numbers, and their

Mexico. their wings glow with colours far superior to those of Europe; the figures of some of them are given by Hernandez. But notwithstanding its beauties and advantages, Mexico is subject to the dreadful devastations of locusts, which sometimes occasion the most destructive famines.

There are some of the worms of Mexico made use of by the inhabitants as food; others are poisonous. There are great numbers of scolopendræ and scorpions, some of the former growing to an immense size. Hernandez says, that he has seen some of them two feet long and two inches thick. The scorpions are very numerous; and in the hot parts of the country their poison is so strong as to kill children, and give terrible pain to adults. Their sting is most dangerous during those hours of the day in which the sun is hottest. In the province of Michuacan is a singular species of ant, larger than the common one, with a greyish body and black head. On its hinder part is a little bag full of a sweet substance, of which children are very fond. The Mexicans suppose this to be a kind of honey collected by the insect; but Clavigero thinks it rather is its eggs. There is a mischievous kind of tick, which in the hot countries abounds among the grass. From thence it easily gets upon the cloaths, and from them upon the skin. There it fixes with such force, from the particular figure of its feet, that it can scarcely be got off. At first it seems nothing but a small black speck, but in a short time enlarges to such a degree, from the blood which it sucks, that it equals the size of a bean, and then assumes a leaden colour. Oviedo says, that the best and safest method of getting speedily rid of it is by anointing the part with oil, and then scraping it with a knife.—If it is not speedily removed, a wound is made similar to that which the nigera or chegoe makes. The following insects were eaten by the ancient Mexicans: 1. The *atelepitz*, a marsh beetle, resembling in shape and size the flying beetles, having four feet, and covered with an hard shell. 2. The *atopinan*, a marsh-grasshopper of a dark colour, and great size, being not less than six inches long and two broad. 3. The *ahuihuitla*, a worm which inhabits the Mexican lake, four inches long, and of the thickness of a goose-quill, of a tawney colour on the upper part of the body, and white upon the under part. It stings with its tail, which is hard and poisonous. 4. The *ocuiliztac*, a black marsh-worm, which becomes white on being roasted.

159
Curious zoophytes.

Among the curious productions of the animal kind to be met with in this country, Clavigero mentions a kind of zoophytes which he saw in the year 1751, in a house in the country, about ten miles from Angelopoli, towards the south-east. They were three or four inches long, and had four very slender feet, with two antennæ; but their body was nothing more than the fibres of the leaves, of the same shape, size, and colour with those of the other leaves of the trees upon which these creatures were found. Gemelli describes another kind of these zoophytes which are found in Manilla.

160
Silk and cochineal.

Mexico produces also silk-worms: and the manufacture of silk might be carried on to great advantage, were it not prohibited for some political reasons. Besides the common silk, there is another found in the woods, very white, soft, and strong. It grows on the trees in several maritime places, particularly in dry seasons. Unless by poor people, however, this silk is not turned to any use, partly from inattention to their interests, but "chiefly (says our author) to the obstructions which would be thrown in the way of any one who should attempt a trade of that kind. We know from Cortes's letters to Charles V. that silk used to be sold in the Mexican markets; and some pictures are still preserved, done by the ancient Mexicans upon a paper made of silk."

Cochineal is one of the most valuable products of Mexico, and great care is taken to rear the insect in different parts; but the best is that which comes from the province of Mizteca. Some have reckoned that more than 2500 bags of cochineal are sent every year from Mizteca to Spain; and the trade in that article carried on by the city of Oaxaca is computed at 200,000 crowns value.

161
General descript of the inhabitants.

Though Mexico, as we have seen, was originally inhabited by a number of different nations, yet all of them resembled each other pretty much, not only in character, but in external appearance. "They generally rather exceed (says our author) than fall under the middle size, and are well proportioned in all their limbs. They have good complexions, narrow foreheads, black eyes, clean, firm, white, and regular teeth; thick, black, coarse, glossy hair; thin beards, and generally no hair upon their legs, thighs, and arms, their skin being of an olive colour. There is scarcely a nation on earth in which there are fewer persons deformed; and it would be more difficult to find a single hump backed, lame, or squint-eyed man among a thousand Mexicans, than among an hundred of any other nation. The unpleasantness of their colour, the smallness of their foreheads, the thinness of their beards, and the coarseness of their hair, are so far compensated by the regularity and fine proportion of their limbs, that they can neither be called very beautiful nor the contrary, but seem to hold a middle place between the extremes. Their appearance neither engages nor disgusts; but among the young women of Mexico, there are many very beautiful and fair, whose beauty is at the same time rendered more winning by the natural sweetness of their manner of speaking, and by the pleasantness and natural modesty of their whole behaviour. Their senses are very acute, especially that of sight, which they enjoy unimpaired to the latest age. Their constitutions are sound, and their health robust. They are entirely free of many disorders which are common among the Spaniards; but of the epidemical diseases to which their country is occasionally subject, they are generally the victims: with them these diseases begin, and with them they end. One never perceives in a Mexican that stinking breath which is occasioned in other people by the corruption of the humours or indigestion. Their constitutions are phlegmatic; but the pituitous evacuations from their heads are very scanty, and they seldom spit. They become grey-headed and bald earlier than the Spaniards; and although most of them die of acute diseases, it is not very uncommon among them to attain the age of an hundred. They are now, and ever have been, moderate in eating, but their passion for strong liquors is carried to the greatest excess. Formerly they were kept within bounds by the severity of the laws; but now

now that thefe liquors are become fo common, and drunkennefs is unpunifhed, one half of the people feem to have loft their fenfes; and this, together with the poor manner in which they live, expofed to all the baneful impreffions of difeafe, and deftitute of the means of correcting them, is undoubtedly the principal caufe of the havoc which is made among them by epidemical diforders.

"Many perfons allow the Mexicans to poffefs a great talent of imitation, but deny them that of invention; a vulgar error, which is contradicted by the ancient hiftory of that people. Their minds are affected by the fame variety of paffions with thofe of other nations, but not to an equal degree. The Mexicans feldom exhibit thefe tranfports of anger, or frenzies of love, which are fo common in other countries. They are flow in their motions; and fhow a wonderful tenacity and fteadinefs in thofe works which require time and long continued attention. They are moft patient of injury and hardfhip; and where they fufpect no evil intention, are moft grateful for any kindnefs fhown: but fome Spaniards, who cannot diftinguifh patience from infenfibility, nor diftruft from ingratitude, fay proverbially, that the Indians are alike infenfible to injuries or benefits. That habitual diftruft which they entertain of all who are not of their nation, prompts them often to lie and betray; fo that good faith certainly has not been refpected among them fo much as it deferves. They are by nature taciturn, ferious, and auftere; and fhow more anxiety to punifh crimes than to reward virtues.

"Generofity and perfect difintereftednefs are the principal features of their character. Gold with the Mexicans has not that value which it enjoys elfewhere. They feem to give without reluctance what has coft them the utmoft labour to acquire. The neglect of felfifh interefts, with the diflike which they bear to their rulers, and confequently their averfion to perform the tafks impofed by them, feem to have been the only grounds of that much exaggerated indolence with which the Americans have been charged; and, after all, there is no fet of people in that country who labour more, or whofe labour is more neceffary. The refpect paid by the young people to the old, and by children to their parents, feem to be feelings that are born with them. Parents are very fond of their children; but the affection which hufbands bear to their wives is certainly lefs than that which wives bear to their hufbands; and it is very common for the men to love their neighbours wives better than their own.

Courage and cowardice feem alternately fo to affect their minds, that it is often difficult to determine whether the one or the other predominates. They meet dangers with intrepidity, when they proceed from natural caufes, but are eafily terrified by the ftern look of a Spaniard. That ftupid indifference about death and eternity, which many authors have thought inherent in the character of every American, is peculiar only to thofe who are yet fo rude and uninformed as to have no idea of a future ftate."

Thus much with refpect to the general character of the Mexicans: but our author obferves, that "the modern Mexicans are not in all refpects fimilar to the ancient, as the Greeks of thefe days have little refemblance to thofe who lived in the times of Plato and Pericles. The ancient Mexicans fhowed more fire, and were more fenfible to the impreffions of honour. They were more intrepid, more nimble, more active, more induftrious; but they were at the fame time more fuperftitious and cruel." Mexico.

162 Of the Toltecas and Chichemecas.

The Toltecas, who firft inhabited Mexico, were accounted much more polifhed than thofe who came after them, infomuch that in after ages it was cuftomary to diftinguifh people of ingenuity and learning by the name of Toltecas. They always lived in fociety, collected into cities, under the government of kings, and had regular laws. They were more addicted to the arts of peace than of war; and it was to them that the fucceeding nations owned themfelves indebted for their knowledge of the culture of grain, cotton, pepper, &c. They underftood the art of cafting gold and filver, and melting them in whatever forms they pleafed, acquiring alfo great reputation from their fkill in cutting gems of all kinds; and they were befides well verfed in the fciences of aftronomy and chronology.

According to the ancient hiftories of thefe people, they obferved, about an hundred years before the Chriftian era, how far the folar year exceeded the civil one; fupplying the defect, as we do, by the addition of a day once in four years. In the year 660, while their monarchy continued in Tula, a celebrated aftronomer, named Huematzin, affembled with the king's confent all the wife men of the nation; and, with their affiftance, painted a famous book named *Teoamoxtli*, or "divine book," in which were reprefented, in very plain figures, the origin of the Indians, their difperfion after the confufion of tongues of Babel, their journey in Afia, their firft fettlements in America, the founding of the kingdom of Tula, and their progrefs till that time: but thefe, and other accounts of their great knowledge and accuracy, favour too much of exaggeration, or perhaps invention, from both which it is impoffible to clear the Spaniards when fpeaking of American affairs.

163 Their progrefs in agriculture.

The Chichemecas derived their knowledge of agriculture from the Toltecas, and of confequence the Mexicans alfo. Being deftitute of ploughs or animals of fufficient ftrength to affift them in their labour, they made ufe of an inftrument of hard copper, which they called *coatl* or *coa*, but differing in fhape either from a fpade or mattock. They ufed copper axes to cut trees, the figure of which was the fame with ours; only that they put the ax into the eye of the handle, inftead of putting the handle into the eye of the ax as we do. They had feveral other inftruments of agriculture, but the forms of them are not mentioned by hiftorians. They watered their fields by means of the rivers and fmall torrents which came from the mountains; raifing dams to collect them, and forming canals to conduct them properly to the places which required moifture. They ufed inclofures of ftone, as well as hedges for the fields, ufing for their hedges the aloe plant, which is well calculated for the purpofe; and what reparations were neceffary they gave in December. They dibbled their maize: a method of fowing more flow indeed than the ordinary one, but which certainly repays the trouble by a vaftly larger crop, as well as by faving a very confiderable quantity of feed. Clofe to the newly-fown fields they com-

monly

Mexico. monly erected a small tower of wood, where a man kept watch, in order to drive away the birds that came to feed upon the grain; a custom still preserved among the Spaniards.

164 Magnificent gardens. In the cultivation of their gardens, the Mexicans were extremely skilful and magnificent; planting in them not only kitchen herbs, but fruit trees, medicinal herbs, and flowers, with great taste and regularity. Some of the royal gardens excited the admiration of the Spaniards so much, that Cortes, in a letter to Charles V. informed him that the garden at Huaxtepec was the most extensive, the most beautiful, and most delightful, that had ever been beheld. It was six miles in circumference, and watered by a beautiful river which crossed it; and there were pleasure-houses erected at proper distances from one another. It was for many years preserved by the Spaniards.——The plants most cultivated, next to maize, were cotton, cacao, and aloe; which last served a great many useful purposes. See Aloe.

165 Tame animals. Though they had not the advantage of the larger quadrupeds, as horses, oxen, or sheep, they bred up an immense number of quadrupeds unknown in Europe. Private persons brought up the small quadrupeds already mentioned, resembling little dogs; as well as turkeys, quails, geese, ducks, and other kinds of fowl. In the houses of the great men were bred fish, deer, rabbits, and a variety of birds; and in the royal palaces, almost all the species of quadrupeds and winged animals to be found in these kingdoms were kept, as well as a great number of aquatic animals and reptiles. According to Clavigero, Montezuma II. surpassed all the kings in the world in this kind of magnificence; and there never was a nation equal to the Mexicans in the care they took in taming animals.

166 Paintings. Painting was an art in great request among the Mexicans, and one of very great use; as it was only by means of paintings that they recorded their histories. This art they derived, like others, from the Toltecas. Some of these paintings were mere images of their gods, kings, heroes, or of terrestrial objects. Others were historical, containing an account of particular events; others mythological, of which a volume is preserved in the great library of the order of Bologna: others were codes of laws, civil and religious; while some were chronological, astronomical, or astrological; in which was represented their calendar, the position of the stars, changes of the moon, eclipses, and prognostications and variations of the weather. Great numbers of these were burned by the superstitious Spaniards, who imagined that they contained some emblems of heathen worship. They had likewise geographical paintings, which served not only to show the extent and boundaries of their possessions, but likewise the situation of places, the direction of the coasts, and the course of the rivers. In his first letter to Cha. V. Cortes says, that having made inquiries if there was any secure harbour for vessels on the Mexican coast, Montezuma presented him with a painting of the whole coast, from the port of Vera Cruz, at that time called *Chalchiuhuecan*, to the river Coatzacualco. Another author informs us also, that Cortes, in a long and difficult voyage which he made to the bay of Honduras, made use of a chart presented to him by the lords of Coatzacualco, in which all the places and rivers were marked from the coast of Coatzacualco to Huejacallan.

As every thing relating to the Mexican empire was thus delineated in painting, the artists were innumerable: and had the numerous paintings been preserved, we might by means of them have had a complete history of Mexico; but vast numbers were destroyed by the superstitious zeal of the Spaniards. The chief school of painting was in Tezcuco: and of the paintings made there they collected such a mass, that it resembled a little mountain; and to all these they set fire at once, to the inexpressible grief of the Indians, and even of themselves, when they came to know their error: for they were compelled afterwards to attempt to remedy the evil, by collecting all the paintings that could be found throughout the empire, and to obtain what information they could from the mouths of the Indians. But though they recovered many, these were still not sufficient; for, from that time forward, the possessors of paintings became so jealous, that they concealed them from the Spaniards with the utmost care; and it was in a manner impossible to make them part with a single piece.

The cloth on which these paintings were done was made of the thread of the aloe or a kind of palm; or they painted on sheeps skins or upon paper. This last was made of the leaves of a certain kind of aloe, steeped like hemp, and afterwards washed, stretched, and smoothed. They used also the bark of other trees, prepared with gum; but we are ignorant of the method they used in the manufacture. This paper is similar in thickness to the European pasteboard, but softer, smoother, and more easy for writing. In general it was made up in very long sheets, which they preserved in rolls, or folded like bed-skreens. The volume of Mexican paintings, preserved in the library of Bologna, is a thick skin, ill-dressed, composed of different pieces painted all over, and folded up in that manner. The beautiful colours which they employed both in their paintings and in their dyes, were obtained from wood, leaves, and the flowers of different plants, as well as from various animal substances. Their white was made from a kind of stone which burns into a fine plaster; or from a mineral, which after being made into a paste worked like clay, and formed into small balls, turns white in the fire like Spanish white. Their *black* was got from another mineral, which has a disagreeable smell, or from the soot of a kind of pine collected in small earthen vessels. They obtained *blue* and *azure* colours from indigo; but their mode of obtaining these was very different from that used by the moderns. They put the branches of the plant into hot, or rather lukewarm, water: and after having stirred them about for a sufficient time with a stick or laddle, they passed the water, when impregnated with the dye, into certain pots or cups in which they let it remain until the solid part of the dye was deposited; after which they poured off the water. This sediment was first dried in the sun, and afterwards put between two plates before a fire until it grew hard. They had another plant which likewise afforded a blue colour, but inferior to the indigo. *Red* was obtained from the seeds of the achiot or rocou,

rocou, and *purple* from cochineal. Their *yellows* were ochre, and a colour extracted from the beautiful flower of a plant refembling artemifia. With nitre thefe flowers afforded a fine orange colour; and by means of alum they extracted other colours.

The Mexican painters were by no means arrived at much perfection in the knowledge of light and fhade, or of defign; neverthelefs, in fome of the ancient paintings, particularly in the portraits of the kings, the proportions were exactly obferved. But this was by no means the cafe in their common paintings: though this is afcribed by Clavigero, not to the want of fkill in thefe painters, but to the hafte with which the figures were executed, and of which the Spaniards were witneffes. Befides paintings, however, the Mexicans are faid to have employed hieroglyphics and characters: but this is abfolutely denied by our author; who tells us, that "they reprefented material things by their proper figures; but, in order to fave labour, paper, and colours, they contented themfelves with reprefenting part of an object, which was fufficient to make it underftood. But as we cannot underftand the writings of others till we have learned to read them, in like manner thofe American authors, who fay that the Mexicans made ufe of characters, required to have been firft inftructed in the Mexican manner of reprefenting objects, in order to have been able to underftand the paintings which ferved them in place of writing. When they would reprefent any perfon, they painted a man, or a human head, and over it a figure expreffing the meaning of his name, as appears in the figures of the Mexican kings. To exprefs a city or village, they painted in like manner a figure which fignified the fame thing, with its name. To form their hiftories or annals, they painted on the margin of the cloth or paper the figures of the years in fo many fquares, and at the fide of each fquare the event or events which happened that year: and if, on account of the number of years, the hiftory of which they meant to relate, they could not all be contained in one canvas, they were continued on another. With refpect to the order of reprefenting the years and events, it was at the liberty of the hiftorian to begin at whichever angle of the piece he pleafed; but at the fame time conftantly obferving, that if the painting began at the upper angle of the right-hand, he proceeded towards the left; but if it began, as it moft commonly did, at the upper angle of the left hand, he proceeded ftraight downwards. If he painted the firft year at the lower angle of the left, he continued towards the right; but if he began at the lower angle of the right, he painted ftraight upwards: fo that on the upper part of his canvas he never painted from left to right, nor ever on the lower part from right to left; never advanced upwards from the left, nor downwards from the right. When this method of the Mexicans is underftood, it is eafy to difcover at firft fight which is the beginning and which the ending of any hiftorical painting. Their paintings, however, ought not to be confidered as a regular full hiftory, but only as monuments and aids of tradition. We cannot exprefs too ftrongly the care which parents and mafters took to inftruct their children and pupils in the hiftory of the nation. They made them learn fpeeches and difcourfes which they could not exprefs by the pencil; they put the events of their anceftors into verfe, and taught them to fing them. This tradition difpelled the doubts and undid the ambiguity which paintings alone might have occafioned; and, by the affiftance of thofe monuments, perpetuated the memory of their heroes and of virtuous examples; their mythology, rites, laws, and cuftoms. 169

Preferved the memory of events by knotted threads.

"Nor did that people only make ufe of tradition, paintings, and fongs, to preferve the memory of events, but alfo of threads of different colours and differently knotted. This curious method of the reprefentation of things, however much ufed in Peru, does not appear to have been employed in the province of Anahuac, if not in the moft early ages; for no traces of fuch monuments are now to be found. Boturini fays, that after the moft diligent fearch, he with difficulty found one in a place in Tlafcala, the threads of which were already wafted and confumed by time. If thofe who peopled South America ever paffed the country of Anahuac, they poffibly might have left there this art, which was afterwards abandoned for that of painting, introduced by the Toltecans or fome other nation ftill more ancient." 170

Their knowledge in fculpture.

The Mexicans arrived at greater perfection in fculpture, cafting of metals, and mofaic works, than in painting. Sculpture was likewife one of the arts exercifed by the ancient Toltecans; but the Mexicans had fculptors among them when they left their native country of Atztlan. Several of the Toltecan ftatues, however, were preferved till the time of the conqueft, particularly that of the idol Tlaloc, placed upon the mountain of the fame name, and fome gigantic ftatues in one of their temples. Stone and wood were the ufual materials of their ftatues: the former was worked with a chiffel made of flint; and, in fpite of the unfitnefs of the inftrument, fuch was the phlegmatic nature of the people, that they furmounted every difficulty arifing from the tedioufnefs of the work. In their ftatues they learned to exprefs all the attitudes and poftures of which the human body is capable. They obferved the proportions exactly, and could when neceffary execute the moft delicate ftrokes with the chiffel. They not only made entire ftatues, but cut out in wood and in ftone figures in baffo relievo; of which kind are thofe of Montezuma II. and one of his fons, recorded with praifes by Acofta. They alfo made ftatues of clay and wood, employing for thefe a chiffel of copper. The number of their ftatues was in proportion to that of their idols; but fo active were the Spanifh priefts in deftroying thefe, that there is now fcarce any veftige of them remaining. The foundation of the firft church in Mexico was laid with idols; on which occafion many thoufand ftatues of their gods were neceffarily broke in pieces. In cafting of metals, 171

Excelled in the art of cafting metals.

however, the Mexicans greatly excelled their works either of painting or fculpture. "The miracles they produced of this kind (fays Clavigero), would not be credible, if, befides the teftimony of thofe who faw them, a great number of curiofities of this kind had not been fent from Mexico to Europe. The works of gold and filver fent in prefents from the conqueror Cortes to Charles V. filled the goldfmiths of Europe with aftonifhment; who, as feveral authors of the period atteft, declared that they were altogether inimitable. The Mexican founders made both of gold and filver

Mexico.

ſilver the moſt perfect images of natural bodies. They made a fiſh in this manner, which had its ſcales alternately one of ſilver and the other of gold; a parrot with a moveable head, tongue, and wings; and an ape with a moveable head and feet, having a ſpindle in its hand in the attitude of ſpinning. They ſet gems in gold and ſilver, and made moſt curious jewellery of great value. In ſhort, theſe ſort of works were ſo admirably finiſhed, that even the Spaniſh ſoldiers, all ſtung with the ſame wretched thirſt for gold, valued the workmanſhip above the materials. This wonderful art, formerly practiſed by the Tolteca, the invention of which they aſcribed to one of their gods, has been entirely loſt by the debaſement of the Indians, and the indolent neglect of the Spaniards. We are doubtful if there are any remains of thoſe curious works; at leaſt we apprehend that it would be more eaſy to find them in ſome of the cabinets of Europe than in all New Spain. Covetouſneſs to profit by the materials muſt unqueſtionably have conquered all deſire to preſerve them as curioſities." The works of the Mexicans in gold and ſilver, executed with the hammer, were much inferior to thoſe of the Europeans.

172 Beautiful moſaic.

But of all the works executed by the ancient Mexicans, thoſe of moſaic were the moſt curious, as well as moſt highly valued by themſelves. Theſe were made of the feathers of birds; and for procuring them they reared a great number of thoſe birds of fine plumage, with which the country abounded, not only in the royal palaces, but alſo in private houſes; and at certain ſeaſons they carried off the feathers for theſe purpoſes, or to ſell them at market. They valued particularly the feathers of the humming birds, on account of their ſmallneſs, fineneſs, and various colours; and in theſe, as well as other birds of fine plumage, nature ſupplied them not only with all the colours producible by art, but likewiſe with many which art cannot imitate. Their moſaic works, as well as indeed all others of the Mexicans, required infinite patience. At the undertaking of every work of this kind ſeveral artiſts aſſembled; and having agreed upon a deſign, and fixed their meaſures and proportions, each artiſt charged himſelf with the execution of a certain part of the image, and exerted himſelf ſo diligently in it, that he frequently ſpent a whole day in adjuſting a feather; firſt trying one and then another, viewing it ſometimes one way, then another, until he found one which gave his part that ideal perfection propoſed to be attained. When the part which each artiſt undertook was done, they aſſembled again to form the entire image from them. If any part happened to be in the leaſt deranged, it was wrought again until it was perfectly finiſhed. They laid hold of the feathers with ſmall pincers, that they might not do them the leaſt injury, and paſted them on the cloth with ſome glutinous matter: then they united all the parts upon a little table or a plate of copper, and flattened them ſoftly until they left the ſurface of the image ſo equal and ſmooth, that it appeared to be the work of a pencil. Theſe works were prodigiouſly admired by the Spaniards. "It is wonderful (ſays Acoſta) how it was poſſible with the feathers of birds to execute works ſo fine and ſo equal, that they appear the performance of the pencil; and what neither the pencil nor the colours in painting can effect, they have, when viewed from a ſide, an appearance ſo beautiful, ſo lively, and ſo animated, that they give delight to the ſight. Some Indians, who are able artiſts, copy whatever is painted with a pencil ſo exactly with plumage, that they rival the beſt painters of Spain." The laſt artiſt in this admirable kind of work lived lately in Pazcuaro, the capital of Michuacan; but it is moſt probable that the art either has already died or will die with him. A beautiful kind of moſaic was likewiſe done with broken ſhells; and this is ſtill carried on in Guatimala. There were many other artiſts who formed figures in imitation of the moſaic works, with flowers and leaves upon mats, which were made uſe of at feſtivals; and theſe were eagerly ſought after by the Spaniſh nobility, on account of their ſingular beauty. Others imitated with ſilk the figures done with feathers; but theſe laſt were always greatly ſuperior.

The Mexicans were ſkilled in architecture even before they left their native country; and many edifices ſtill remain which were conſtructed by them during their frequent journeys from one place to another. At their firſt arrival on the lake, they had no other materials to build their houſes with but reeds and mud, until the ſucceſs of their commerce allowed them to purchaſe better materials. When the city came to its perfection, the houſes of the principal people were conſtructed of ſtone and lime: they conſiſted of two floors, having halls, large court-yards, and chambers fitly diſpoſed: the roofs were flat and terraced; the walls ſo well whitened, poliſhed, and ſhining, that they appeared to the Spaniards when at a diſtance to have been conſtructed of ſilver. The floor was paved with plaſter, perfectly level, plain, and ſmooth. Many of their houſes were crowned with battlements and turrets; and their gardens had fiſh-ponds, and the walks of them ſymmetrically laid out. The large houſes had in general two entrances, the principal one to the ſtreet, the other to the canal: they had no wooden doors to their houſes, but covered the entrance with ſmall reeds, from whence they ſuſpended a ſtring of cocoa ſhells, or ſome other materials which would make a noiſe, ſo as to awake the attention of the family when any perſon lifted up the reeds to enter the houſe. —The houſes of the poorer ſort were conſtructed of reeds, unburnt bricks, ſtone, or mud; and the roofs made of a kind of long hay which grows plentifully in the fields, particularly in the warm parts of the country. For this purpoſe they uſed alſo the leaves of the aloe placed in the manner of tiles, to which they bear ſome reſemblance both in thickneſs and ſhape. One of the columns or ſupports of theſe houſes was generally a tree in the vigour of its growth; by which means, beſides the pleaſure derived from its foliage and ſhade, they ſaved themſelves ſome labour and expence. Theſe houſes had one or more apartments according to the circumſtances of the family.

Our author is of opinion, that the ancient Mexicans underſtood the method of conſtructing arches or vaults, as appears, he ſays, from ſome remains of their buildings as well as from their paintings. They had likewiſe cornices and other ornaments of architecture. They had alſo ſquare or cylindrical columns; but it is not known whether theſe had any capitals or not. They frequently adorned them with figures in *baſſo relievo*;

relievo; but their great ambition was to have them all made out of one ſtone. The foundations of the large houſes in the capital were laid upon beams of cedar driven into the ground, on account of its want of ſolidity; and the ſame method is ſtill practiſed by the Spaniards. The roofs of theſe were made of cedar, fir, cypreſs, pine, &c. In the royal palaces the columns were of marble or even of alabaſter, which the Spaniards miſtook for jaſper. In the reign of Ahuizotl a new kind of ſtone, named *tetzontli*, was diſcovered in the Mexican lake, which was ever afterwards made uſe of for building. It is hard, light, and porous like a ſponge; by which means the lime adheres very firmly to it. It is valued likewiſe on account of its colour, which is a blood red. Some of the pavements were chequered with marble and other valuable ſtones.

The moſt remarkable pieces of Mexican architecture, however, were their aqueducts. There were two which conveyed the water to the capital from the diſtance of two miles. Theſe were conſtructed of ſtone and cement five feet high, and two paces broad, upon a road for that purpoſe upon the lake; by which the water was brought to the entrance of the city, from whence it was ſent forth in ſmaller channels to ſupply the different fountains. The famous aqueduct of Chempoallan, which was done in the 16th century, is worthy of being ranked among the greateſt in Europe. The conductor of this work was a Franciſcan miſſionary named *Tembleque*; and it was executed with great ſkill by the Chempoalleſe. The water was brought from a great diſtance, and the country through which it muſt paſs was mountainous and rocky; but every difficulty was overcome by the induſtry of the Mexicans. The aqueduct, including all the turnings and windings, exceeded 30 miles in length. The principal difficulty conſiſted in croſſing three great precipices, over which they were obliged to conſtruct three bridges, the firſt of 47, the ſecond of 13, and the third of 67 arches. The largeſt arch was 100 feet high, and 61 broad; ſo that a large veſſel could have paſſed under it. It muſt, however, be obſerved, that, in executing this undertaking, the Mexicans were undoubtedly aſſiſted by European tools, and the directions of European workmen; ſo that we cannot with ſtrict propriety call it one of their works.

Though the ancient Mexicans never uſed any inſtruments of iron in their works, they nevertheleſs executed beautiful engravings by means of tools made of flint ſtone. They wrought alſo marble, jaſper, alabaſter, itztli, and other valuable ſtones. Of itztli they made their looking-glaſſes, which were ſometimes ſet in gold, the ſharp pieces which were ſet in their ſwords, and razors to ſhave with. Theſe laſt were made with ſuch expedition, that an artiſt could finiſh upwards of *an hundred* in an hour.

They were, as has already been obſerved, expert jewellers, and underſtood the art of cutting and poliſhing the ſtones, as well as of ſetting them. The gems moſt common in their country were the emeralds, amethyſts, cornelians, turquoiſes, and others unknown in Europe. Emeralds were ſo common, that no lord or noble wanted them; and none of them died without having one fixed to his lip, that it might ſerve him, as they imagined, in the other world, inſtead of a heart. When Cortes returned the firſt time to Spain, he brought with him five emeralds valued, by the jewellers there, at 100,000 ducats. The firſt was in the form of a roſe; the ſecond of an horn; the third of a little fiſh with eyes of gold; the fourth in the form of a bell, with a fine pearl for a clapper. The fifth was a ſmall cup with a foot of gold, and four little golden chains which united in a pearl in the form of a button. For this alone the Genoeſe merchants offered 40,000 ducats, in order to ſell it again to the grand ſignior. Beſides theſe, he had two emerald vaſes valued at 300,000 ducats; but theſe laſt were loſt by ſhipwreck in the unfortunate expedition of Charles V. againſt Algiers. There are no ſuch gems wrought at preſent, nor is it even known where the emerald mines are ſituated; though there are ſtill extant ſome enormous maſſes of this precious ſtone, particularly two in as many churches; but the prieſts take care to ſecure them with iron chains, leſt any body ſhould carry them off.

176 Manufactures of different kinds.

In other more common manufactures the Mexicans were by no means deficient. The earthen ware of Cholula was much praiſed by the Spaniards; and they had the art of ornamenting this kind of ware with various colours, though they did not underſtand the making of glaſs. Their carpenters wrought with inſtruments of copper; and there are ſtill remains of their labours which diſplay a tolerable ſkill. Almoſt every one was acquainted with the method of making cloth. Being deſtitute of wool, common ſilk, lint, or hemp, they were obliged to ſupply the deficiency by other materials. For wool they ſubſtituted cotton, for ſilk they uſed feathers, the wool of the hare or rabbit; and inſtead of lint and hemp, they uſed the fibrous part of the leaves of the aloe. From theſe laſt they obtained a thread as fine as from lint; and from ſome ſpecies they had a coarſer ſort reſembling hemp. To obtain this thread they ſoaked the leaves in water, cleaned them, expoſed them to the ſun, and then beat them till they were fit to be ſpun. Sometimes they interwove with their cotton the fineſt down on the belly of the rabbits or hares, after having ſpun it into thread; and of theſe they made moſt beautiful cloths, which were particularly uſed for winter waiſtcoats for the lords. Their cotton manufactures were equal to any produced in Europe; they wove them with different figures and colours, repreſenting different animals and flowers. Of feathers interwoven with cotton they made mantles and bed-curtains, carpets, gowns, &c. Theſe were exceedingly beautiful; but this kind of manufactory is now loſt, though there are ſtill ſome of theſe garments in the poſſeſſion of the principal lords, who wear them upon ſolemn occaſions.

177 Their horrible religion.

All theſe advances towards civilization, however, in the ancient Mexicans, were much more than counterbalanced by the horrible barbarities they committed in their religious ceremonies, and in which they exceeded every nation on earth. Human ſacrifices were indeed in uſe among all the ancient heathens; but ſuch prodigious maſſacres as have been already related at the dedication of their temples, are unheard of in hiſtory. Whether they uſed theſe barbarous ſacrifices in their own country, or whether the practice began with that of the four Xochimilca priſoners, of whom we have already given an account, is not known;

Mexico.

known; but as they only uſed their priſoners or ſlaves whom they bought in this way, it is impoſſible that, during the infancy of their ſtate, the number of human victims could have been very great. Moſt of thoſe unhappy creatures periſhed by having their breaſts opened, and their hearts pulled out; ſome were drowned, others ſtarved to death with hunger; and ſometimes they were burnt. Priſoners of high rank were allowed to die by what Clavigero calls the *gladiatorian* ſacrifice, which was performed in the following manner. Near to the greater temple of large cities, in an open ſpace of ground ſufficient to contain an immenſe number of people, was a round terrace eight feet high, upon which was placed a large round ſtone reſembling a milſtone in ſhape, but much larger, almoſt three feet high, well poliſhed, and having figures cut upon it. On this ſtone, which was called *temalcatl*, the priſoner was placed, armed with a ſhield and ſhort ſword, and tied by one foot. Here he was encountered by a Mexican officer or ſoldier better armed than himſelf. If the priſoner was vanquiſhed, he was carried, dead or alive, to the temple, where his heart was taken out and offered in the uſual manner; but if he conquered ſix combatants, he gained his life and liberty. An inſtance, however, is given in which this cuſtom was infringed; for the Huetzotzincas having taken the principal lord of Cholula, a man of ſingular bravery, he overcame ſeven combatants; notwithſtanding which he was put to death; but on this account the Huetzotzincas were rendered forever infamous among theſe nations.

178 Gladiatorian ſacrifice.

179 Number of human victims annually ſacrificed.

Hiſtorians differ concerning the number of victims who periſhed annually in theſe ſacrifices: Clavigero inclines to think it was 20,000, but others make it much more. Zumarraga, the firſt biſhop of Mexico, ſays in a letter of the 12th of June 1531, addreſſed to the general chapter of his order, that in that capital alone there were above 20,000 victims annually ſacrificed. Some authors, quoted by Gomara, ſay that 50,000 were annually ſacrificed in the various parts of the empire. Acoſta ſays, that there was a certain day of the year on which they ſacrificed 5000 victims, and another on which 20,000 were ſacrificed. According to others they ſacrificed, on the mountain Tepeyacac only, 20,000 annually to one of their female deities. On the other hand, Bartholomew de las Caſas reduces the number of human victims to 50 or at moſt to 100. "We are ſtrongly of opinion (ſays Clavigero), that all theſe authors have erred in the number; Las Caſas by diminution, and the reſt by exaggerating the truth."

180 Their monſtrous auſterities.

Beſides theſe cruelties which they practiſed upon others, the Mexicans were accuſtomed to treat themſelves with the moſt inhuman auſterities, thinking that the diabolical rage of their deities would be appeaſed by human blood. "It makes one ſhudder (ſays Clavigero), to read the auſterities which they practiſed upon themſelves, either in atonement for their tranſgreſſions, or in preparation for their feſtivals. They mangled their fleſh as if it had been inſenſible, and let their blood run in ſuch profuſion as if it had been a ſuperfluous fluid in the body. The effuſion of blood was frequent and daily with ſome of their prieſts. They pierced themſelves with the ſharpeſt ſpines of the aloe, and bored ſeveral parts of their bodies, particularly their ears, lips, tongue, and the fat of their arms and legs. Through the holes which they made with theſe ſpines they introduced pieces of cane, the firſt of which were ſmall; but every time this penitential ſuffering was renewed a thicker piece was made uſe of. The blood which flowed from them was carefully collected in the leaves of the plant *acxojatl*. They fixed the bloody ſpines in little balls of hay, which they expoſed upon the battlements of the walls of the temple, to teſtify the penance which they did for the people. Thoſe who exerciſed ſuch ſeverities upon themſelves within the incloſure of the greater temple of Mexico, bathed in a pond that was formed there, and which, from being always tinged with blood, was called *ezapan*."

Dreſs.

The dreſs of the Mexicans was very ſimple; that of the men conſiſted only of a large belt or girdle, the two ends of which hung down before and behind; the women wore a ſquare mantle, about four feet long; the two ends were tied upon the breaſt or upon one ſhoulder. The Mexican gown was alſo a piece of ſquare cloth, in which the women wrapped themſelves from the waiſt down to the middle of the leg. They wore alſo a ſmall under-veſt or waiſtcoat without ſleeves, named *huepilli*.

The dreſs of the poorer ſort was made of the thread of the mountain palm, or of coarſe cotton; but thoſe of better ſtation wore the fineſt cotton embelliſhed with various colours, and figures of animals or flowers; or woven with feathers, or the fine hair of the rabbit, &c. The men wore two or three mantles, and the women three or four veſts, and as many gowns, putting the longeſt undermoſt, ſo that a part of each of them might be ſeen. Their ſhoes were only ſoles of leather, or coarſe cloth of the mountain palm tied with ſtrings; but thoſe of the great people were adorned with ribbands of gold and jewels. They all wore long hair, and thought themſelves diſhonoured by being ſhaved, or having their hair clipped, except the conſecrated virgins in the temple. The women wore it looſe; but the men tied it up in different forms, and adorned their heads with fine feathers, both when they danced and went to war. With this ſimplicity, however, they mixed no ſmall quantity of extravagance. Beſides feathers and jewels, with which they uſed to adorn their heads, they wore ear-rings, pendants at their upper lip, as well as many at their noſes, necklaces, bracelets for the hands and arms, as well as certain rings like collars which they wore about their legs. The ear-rings of the poor were ſhells, pieces of cryſtal, amber, &c.; but the rich wore pearls, emeralds, amethyſts, or other gems, ſet in gold.

Inſtead of ſoap the Mexicans uſed a kind of fruit called *copalxocotl;* the pulp of which is white, viſcous, and very bitter, makes water white, raiſes a froth, and will clean linen like ſoap. They uſed alſo a kind of root named *amolli*, which is not unlike the *ſaponaria* of the old continent. It is now more uſed for waſhing the body, eſpecially the head, than for clothes. Clavigero ſays that there is a kind of this root which dyes the hair of a golden colour, and that he has been witneſs to this effect on the hair of an old man.

181 Modern inhabitants, &c.

The principal inhabitants of Mexico, in modern times, are Spaniards ſent hither by the court, to fill the

the posts of government. They are obliged, like those in the mother-country who aspire to any ecclesiastical, civil, or military employments, to prove that there have been neither heretics, Jews, Mohammedans, nor any person in their family who have been called before the inquisition for four generations. Merchants who are desirous of going to Mexico, as well as to other parts of America, without becoming colonists, are compelled to observe the same forms. They are also obliged to swear that they have 300 palms of merchandise, their own property, in the fleet in which they embark, and that they will not carry their wives with them. On these absurd conditions they become the principal agents of the European commerce with the Indies. Though their charter is only to continue three years, and a little longer for countries more remote, it is of great importance. To them alone belongs the right of selling, as commissioners, the major part of the cargo. If these laws were observed, the merchants stationed in the new world would be confined to dispose of what they have received on their own account.

The predilection which administration has for Spaniards born in Europe, has reduced the Spanish Creoles to acquiesce in subordinate stations. The descendants of the companions of Cortes, and of those who came after them, being constantly excluded from all places of honour or of trust that were any way considerable, have seen the gradual decay of the power that supported their fathers. The habit of being obliged to bear that unjust contempt with which they have been treated, has at last made them become really contemptible. They have totally lost, in the vices which originate from indolence, from the heat of the climate, and from a superfluous enjoyment of all things, that firmness and that sort of pride which have ever characterised their nation. A barbarous luxury, shameful pleasures, and romantic intrigues, have enervated all the vigour of their minds, and superstition hath completed the ruin of their virtues. Blindly devoted to priests too ignorant to enlighten them by their instructions, too depraved to edify them by their example, and too mercenary to attend to both these duties of their function, they have no attachment to any part of their religion but that which enfeebles the mind, and have neglected what might have contributed to rectify their morals.

The Mestees, who constitute the third order of citizens, are held in still greater contempt. It is well known that the court of Madrid, in order to replenish a part of that dreadful vacancy which the avarice and cruelty of the conquerors had occasioned, and to regain the confidence of those who had escaped their fury, encouraged as much as possible the marriage of Spaniards with Indian women. These alliances, which became pretty common throughout all America, were particularly frequent in Mexico, where the women had more understanding and were more agreeable than in other places. The Creoles transferred to this mixed progeny the contemptuous slight they received from the Europeans. Their condition, equivocal at first, in process of time was fixed between the whites and the blacks.

These blacks are not very numerous in Mexico. As the natives are more intelligent, more robust, and more industrious, than those of the other colonies, they have hardly introduced any Africans except such as were required either to indulge the caprice, or perform the domestic service, of rich people. These slaves, who are much beloved by their masters, on whom they absolutely depend, who purchased them at an extravagant price, and who make them the ministers of their pleasures, take advantage of the high favour they enjoy, to oppress the Mexicans. They assume over these men, who are called *free*, an ascendant which keeps up an implacable hatred between the two nations. The law has studied to encourage this aversion, by taking effectual measures to prevent all connection between them. Negroes are prohibited from having any amorous correspondence with the Indians; the men, on pain of being mutilated; the women, of being severely punished. On all these accounts, the Africans, who in other settlements are enemies to Europeans, are in the Spanish Indies their warm friends.

Authority has no need of this support, at least in Mexico, where population is no longer what it was formerly. The first historians, and those who copied them, have recorded, that the Spaniards found there 10,000,000 of souls. This is supposed to have been the exaggerated account of conquerors, to exalt the magnificence of their triumph; and it was adopted, without examination, with so much the more readiness, as it rendered them the more odious. We need only trace with attention the progress of those ruffians who at first desolated these fine countries, in order to be convinced that they had not succeeded in multiplying men at Mexico and the adjacent parts, but by depopulating the centre of the empire; and that the provinces which are remote from the capital, differed in nothing from the other deserts of South and North-America. It is making a great concession, to allow that the population of Mexico has only been exaggerated one-half: for it does not now much exceed 2,000,000.

183 Mexicans cruelly treated by the Spaniards.

It is generally believed, that the first conquerors massacred the Indians out of wantonness, and that even the priests incited them to these acts of ferocity. Undoubtedly these inhuman soldiers frequently shed blood without even an apparent motive; and certainly their fanatic missionaries did not oppose these barbarities as they ought to have done. This was not, however, the real cause, the principal source of the depopulation of Mexico; it was the work of a slow tyranny, and of that avarice which exacted from its wretched inhabitants more rigorous toil than was compatible with their constitution and the climate.

This oppression was coeval with the conquest of the country. All the lands were divided between the crown, the companions of Cortes, and the grandees or ministers who were most in favour at the court of Spain. The Mexicans, appointed to the royal domains, were destined to public labours, which originally were considerable. The lot of those who were employed on the estates of individuals was still more wretched. All groaned under a dreadful yoke: they were ill-fed; they had no wages given them; and services were required of them, under which the most robust men would have sunk. Their misfortunes excited the compassion of Bartholomew de las Casas.

184 Bartholomew de las Casas takes their part.

This

Mexico. This man, so famous in the annals of the new world, had accompanied his father in the first voyage made by Columbus. The mildness and simplicity of the Indians affected him so strongly, that he made himself an ecclesiastic, in order to devote his labours to their conversion. But this soon became the least of his attention. As he was more a *man* than a *priest*, he felt more for the cruelties exercised against them than for their superstitions. He was continually hurrying from one hemisphere to the other, in order to comfort the people for whom he had conceived an attachment, or to soften their tyrants. This conduct, which made him be idolized by the one and dreaded by the other, had not the success he expected. The hope of striking awe, by a character revered among the Spaniards, determined him to accept the bishoprick of Chiapa in Mexico. When he was convinced that this dignity was an insufficient barrier against that avarice and cruelty which he endeavoured to check, he abdicated it. It was then that this courageous, firm, disinterested man, accused his country before the tribunal of the whole universe. In his account of the tyranny of the Spaniards in America, he accuses them of having destroyed 15,000,000 of Indians. They ventured to find fault with the acrimony of his style; but no one convicted him of exaggeration. His writings, which indicate the amiable turn of his disposition, and the sublimity of his sentiments, have stamped a disgrace upon his barbarous countrymen, which time hath not, and never will, efface.

185 In consequence of which their condition is rendered somewhat easier.

The court of Madrid, awakened by the representations of the virtuous Las Casas, and by the indignation of the whole world, became sensible at last, that the tyranny it permitted was repugnant to religion, to humanity, and to policy, and resolved to break the chains of the Mexicans. Their liberty was now only constrained by the sole condition, that they should not quit the territory where they were settled. This precaution owed its origin to the fear that was entertained of their going to join the wandering savages to the north and south of the empire.

With their liberty their lands ought also to have been restored to them; but this was not done. This injustice compelled them to work solely for their oppressors. It was only decreed, that the Spaniards, in whose service they laboured, should stipulate to keep them well, and pay them to the amount of 5 l. 5 s. a year.

From these profits the tribute imposed by government was subtracted, together with 4 s. 4½ d. for an institution which it is astonishing the conquerors should have thought of establishing. This was a fund set apart in each community, and appropriated to the relief of such Indians as were decayed or indisposed, and to their support under private or public calamities.

The distribution of this fund was committed to their caciques. These were not the descendants of those whom they found in the country at the time of the conquest. The Spaniards chose them from among those Indians who appeared the most attached to their interests; and were under no apprehensions at making these dignities hereditary. Their authority was limited to the supporting the police in their district, which in general extended eight or ten leagues; to the collecting the tribute of those Indians who laboured on their own account, that of the others being stopt by the masters whom they served; and to the preventing their flight by keeping them always under their inspection, and the not suffering them to contract any engagement without their consent. As a reward of their services, these magistrates obtained from government a property. They were permitted to take out of the common stock 2¼ d. annually for every Indian under their jurisdiction. At last they were empowered to get their fields cultivated by such young men as were not yet subject to the poll tax; and to employ girls, till the time of their marriage, in such occupations as were adapted to their sex, without allowing them any salary except their maintenance.

These institutions, which totally changed the condition of the Indians of Mexico, irritated the Spaniards to a degree not to be conceived. Their pride would not suffer them to consider the Americans as free men; nor would their avarice permit them to pay for labour which hitherto had cost them nothing. They employed themselves successively, or in combination, craft, remonstrances, and violence, to effect the subversion of an arrangement which so strongly contradicted their warmest passions; but their efforts were ineffectual. Las Casas had raised up for his beloved Indians protectors who seconded his design with zeal and warmth. The Mexicans themselves, finding a support, impeached their oppressors before the tribunals; and even the tribunals that were either weak or in the interest of the court. They carried their resolution so far, as even unanimously to refuse to work for those who had treated any of their countrymen with injustice. This mutual agreement, more than any other circumstance, gave solidity to the regulations which had been decreed. The other, prescribed by the laws, was gradually established. There was no longer any regular system of oppression; but merely several of those particular vexations which a vanquished people, who have lost their government, can hardly avoid from those who have subdued it.

These clandestine acts of injustice did not prevent the Mexicans from recovering, from time to time, certain detached portions of that immense territory of which their fathers had been despoiled. They purchased them of the royal domain, or of the great proprietors. It was not their labour which enabled them to make these acquisitions: for this they were indebted to the happiness of having discovered some of them mines, others treasures, which had been concealed at the time of the conquest. The greatest number derived their resources from the priests and monks, to whom they owed their existence.

Even those who experienced a fortune less propitious, procured for themselves, by the sole profits of their pay, more conveniences than they had enjoyed before they underwent a foreign yoke. We should be very much deceived if we should judge of the ancient prosperity of the inhabitants of Mexico by what has been said of its emperor, its court, its capital, and the governors of its provinces. Despotism had there produced those fatal effects which it produces every-where. The whole state was sacrificed to the

caprices,

caprices, pleafures, and magnificence, of a fmall number of perfons.

The government drew confiderable advantages from the mines which it caufed to be worked, and ftill greater from thofe which were in the hands of individuals. The falt-works greatly added to its revenue. Thofe who followed agriculture, at the time of harveft paid in a kind of a third of all the produce of the lands, whether they belonged to them as their own property, or whether they were only the farmers of them. Men who lived by the chace, fifhermen, potters, and all mechanics, paid the fame proportion of their induftry every month. Even the poor were taxed at certain fixed contributions, which their labour or their alms might put them in a condition to pay.

The Mexicans are now lefs unhappy. Our fruits, our corn, and our cattle, have rendered their food more wholfefome, agreeable, and abundant. Their houfes are better built, better difpofed, and better furnifhed. Shoes, drawers, fhirts, a garment of wool or cotton, a ruff, and a hat, conftitute their drefs. The dignity which it has been agreed to annex to thefe enjoyments has made them better economifts, and more laborious. This cafe, however, is far from being univerfal; it is even very uncommon in the vicinity of the mines, towns, and great roads, where tyranny feldom fleeps: but we often find it with fatisfaction in remote parts, where the Spaniards are not numerous, and where they have in fome meafure become Mexicans.

The employments of this people are very various. The moft intelligent, and thofe who are in eafy circumftances, devote themfelves to the moft neceffary and moft ufeful manufactures, which are difperfed through the whole empire. The moft beautiful manufactures are eftablifhed among the people of Tlafcala. Their old capital, and the new one, which is called *Angelos*, are the centre of this induftry. Here they manufacture cloth that is pretty fine, callicoes that have an agreeable appearance, certain flight filks, good hats, gold lace, embroidery, lace, glaffes, and a great deal of hard-ware.

The care of flocks affords a maintenance to fome Mexicans, whom fortune or nature have not called to more diftinguifhed employments. America, at the time it was difcovered, had neither hogs, fheep, oxen, horfes, nor even any domeftic animal. Columbus carried fome of thefe ufeful animals to St Domingo, from whence they were generally difperfed, and at Mexico more than in any other place. Thefe have multiplied prodigioufly. They count their horned cattle by thoufands, whofe fkins are become an object of confiderable exportation. The horfes are degenerated, but the quality is compenfated by the number. Hog's lard is here fubftituted for butter. Sheep's wool is dry, coarfe, and bad, as it is every where between the tropics.

The vine and olive-tree have experienced the fame degeneracy. The cultivation of them was at firft prohibited, with a view of leaving a free market for the commodities of the mother-country. In 1706, permiffion was given to the Jefuits, and a little afterwards to the marquis Del Valle, a defcendant from Cortes, to cultivate them. The attempts have not proved fuccefsful. The trials, indeed, that have been made, have not been abandoned; but no perfon has folicited the liberty of following an example which did not promife any great emoluments. Other cultures have been more fuccefsful. Cotton, fugar, filk, cocoa, tobacco, and European corn, have all thriven in fome degree. The Spaniards are encouraged to profecute the labours which thefe cultures require, from the happy circumftance of their having difcovered iron mines, which were entirely unknown to the Mexicans, as well as fome mines of a kind of copper that is hard enough to ferve for implements of hufbandry. All thefe articles, however, for want of men and induftry, are merely confumed within the country.—There is only the vanilla, indigo, and cochineal, which make part of the trade of Mexico with other nations.

New-Mexico, fo called becaufe of its being difcovered later than Old-Mexico, a country of America, is bounded on the north by high mountains, beyond which is a country altogether unknown; by Louifiana on the eaft; by New-Spain on the fouth; and on the weft by the gulph of California, and the Rio Colorado; extending, it is faid, above 100 miles from eaft to weft, and about 900 from fouth to north; but the twentieth part of the country within thefe limits is neither cultivated nor inhabited either by Spaniards or Indians. As it lies in the midft of the temperate zone, the climate, in general, is very pleafant; the fummers, though very warm, are neither fultry nor unwholefome; and the winters, though pretty fharp, are far from being infupportable, and, for the moft part, clear and healthy.

The greateft encomiums are lavifhed on the fertility of the foil, the richnefs of the mines, and the variety of valuable commodities produced in this country. It is faid to be beautifully diverfified with fields, meadows, rifing grounds, and rivers; abounding with fruit and timber-trees, turquoifes, emeralds, and other precious ftones, mines of gold and filver, a great variety of wild and tame cattle, fifh and fowls. Upon the whole, we may fafely affirm, that New-Mexico is among the pleafanteft, richeft, and moft plentiful countries in America, or any other part of the world. There are few great or navigable rivers in it: the moft confiderable are, the Rio Solado and Rio del Norte, which, with feveral fmaller ftreams, fall into the gulph of Mexico. On the coaft of the gulph are divers bays, ports, and creeks, which might be eafily converted into excellent harbours if the Spaniards were poffeffed of any portion of that commercial fpirit which animates the other maritime nations of Europe.

The Spanifh writers tell us, that New-Mexico is inhabited by a great variety of Indian nations or tribes, totally unconnected with each other: but the principal are the Apaches, a brave, warlike, refolute people; fond of liberty, and the inveterate enemies of tyranny and oppreffion. About the clofe of the laft century, thinking themfelves aggrieved by the Spanifh government, they made a general infurrection, and did a great deal of mifchief; but were at laft obliged to fubmit, and have fince been curbed by ftronger garrifons. Moft of the natives are now Chriftians. When the

the Spaniards first entered this country, they found the natives well clothed, their lands cultivated, their villages neat, and their houses built with stone. Their flocks also were numerous, and they lived more comfortably than most of the other savages of America. As to religion, they were idolaters, and worshipped the sun and moon; but whether they offered human sacrifices, we are not sufficiently informed.

As to the number of the provinces of this country, we can advance nothing certain: some writers making them only five, others 10, 15, 20, and 25; but adding no description, either of them or the towns contained in them, excepting the capital, Santa Fé, which we are told stands near the source of the Rio del Norte, in 36° of north latitude, and about 130 leagues from the gulph: that it is a well-built, handsome, rich town; and the seat of the bishop, suffragan of Mexico, as well as the governor of the province, who is subordinate to the viceroy of Mexico, or New-Spain.

MEYER (Felix), an eminent landscape painter, was born at Winterthur in 1653, and received his earliest instruction from a painter at Nuremburg: but he was afterwards a disciple of Ermels, a good landscape painter, whose manner he entirely followed.—In search of still greater improvement, however, he travelled to Italy: but the climate not agreeing with his constitution, he retired to Switzerland; where, as he was indefatigable in surveying all the beauty, the wildness, and magnificence of nature in those romantic scenes, he made a multitude of noble designs, which procured him very high reputation. As he was not expert at painting figures, those which he inserted in his own pictures being very indifferent, such of his landscapes as were supplied with figures by Roos or Rugendas, are accounted most estimable. He died in 1713.

MEYSENS (John), a painter of considerable eminence, was born at Brussels in 1612; and at first was taught the principles of painting by Anthony van Opstal, but afterwards he became a disciple of Nicholas vander Horst When he commenced painter, he undertook both history and portrait: but the latter seems to have been his principal employment; and his reputation for that style of painting became very great throughout the Low Countries. His remarkable excellence consisted in his producing a very striking resemblance, in his finishing his pictures with a great deal of care, and in giving them a lively and good expression.

MEZERAY (Francis Eudes de), an eminent French historian, the son of Isaac Eudes a surgeon, was born at Rye, in Lower Normandy, in 1610; and took the surname of *Mezeray*, from a hamlet near Rye. Having performed his studies at Caen, he discovered a strong inclination to poetry; but going to Paris, he, by the advice of one of his friends, applied himself to the study of politics and history, and procured the place of commissary at war, which he held for two campaigns. He then shut himself up in the college of St Barbe, in the midst of books and manuscripts; and, in 1643, published the first volume of the History of France, in folio; and some years after, the other two volumes. Mezeray in that work surpassed all who had written the history of France before him, and was rewarded by the king with a pension of 4000 livres. In 1668, he published an Abridgement of his History of France, in three volumes 4to, which was well received by the public: but as he inserted in that work the origin of most of the taxes with very free reflections, Mr Colbert complained of it, when Mezeray promised to correct what he had done in a second edition: but those corrections being only palliations, the minister caused half of his pension to be suppressed. Mezeray complained of this in very severe terms; when he obtained no other answer than the suppression of the other half. Vexed at this treatment, he resolved to write on subjects that could not expose him to such disappointments; and composed his treatise on the origin of the French, which did him much honour. He was elected perpetual secretary to the French academy; and died in 1683. He is said to have been a man extremely negligent in his person; and so careless in his dress, that he might have passed for a beggar rather than for what he was. He was actually seized one morning by the *archers des pauvres*, or parish-officers; which mistake was so far from provoking him, that he was highly diverted with it, and told them, that "he was not able to walk on foot, but that as soon as a new wheel was put to his chariot, he would attend them wherever they thought proper." He used to study and write by candle-light, even at noon day in summer; and, as if there had been no sun in the world, always waited upon his company to the door with a candle in his hand. With regard to religion, he affected Pyrrhonism; which however was not, it seems, so much in his heart as in his mouth. This appeared from his last sickness: for having sent for those friends who had been the most usual witnesses of his licentious talk about religion, he made a sort of recantation, which he concluded with desiring them "to forget what he might formerly have said upon the subject of religion, and to remember, that Mezeray dying was a better believer than Mezeray in health." Besides his history, he also wrote, 1. A continuation of the history of the Turks. 2. A French translation of John de Sarisbury's Latin treatise on the vanities of the court. 3. There are attributed to him several satires against the government; and in particular, those that bear the name of *Sandricourt*.

MEZIERS, a strong town of France in Champagne, with a citadel. It was besieged with a powerful army by Charles V. who was obliged to raise the siege in 1521. It is seated on the river Mease, partly upon a hill, and partly in a valley, in E. Long. 3. 48. N. Lat. 49. 46.

MEZIRIAC (Claude Gaspar Backet Sieur de), one of the most ingenious men of the 17th century, was born at Bresse, of an ancient and noble family. He was a good poet in French, Italian, and Latin; an excellent grammarian, a great Greek scholar, and an admirable critic. He was well versed in the controversies, both in philosophy and religion; and was deeply skilled in algebra and geometry, of which last he gave proof by publishing the six books of Diophantes, enriched with a very able Commentary and Notes. In his youth he spent a considerable time at Paris and at Rome: at which last place he wrote a small collection of Italian poems, in competition with Vaugelas, who was there at the same time; among which there are imitations

imitations of the most beautiful similies contained in the eight first books of the Æneid. He also translated Ovid's Epistles; a great part of which he illustrated with very curious Commentaries of his own. While he was at Paris, they talked of making him preceptor of Louis XIII.: upon which he left the court in great haste, and afterwards declared that he had never felt so much pain upon any occasion of his life; for he seemed to have already upon his shoulders the important weight of the whole kingdom. He undertook the translation of all Plutarch's works, with notes; which he had brought nearly to a conclusion, when he died at Bourg, in Bresse, anno 1638, at 45 years of age. He left behind him several finished works, that were not printed

MEZUZOTH, in the Jewish customs, certain pieces of parchment which the Jews fix to the door-posts of their houses, taking that literally which Moses commands them, saying, "Thou shalt never forget the laws of thy God, but thou shalt write them upon the posts of thy house, and on thy gates." This expression means nothing else, but that thou shalt always remember them, whether thou comest into thy house or goest out. But the Hebrew doctors imagined, that the lawgiver meant something more than this. They pretended, that, to avoid making themselves ridiculous, by writing the commandments of God without their doors, or rather to avoid exposing themselves to the profanation of the wicked, they ought at least to write them on a parchment, and to enclose it in something. Therefore they wrote these words upon a square piece of parchment prepared on purpose, with a particular ink, and a square kind of character. Deut. vi. 4, 5, 6, 7, 8, 9. "Hear, O Israel, the Lord our God is one Lord, &c."—Then they left a little space, and afterwards went on, Deut. xi. 13. "And it shall come to pass, if thou shalt hearken diligently to my commandments, &c." as far as, "Thou shalt write them upon the door-posts of thy house, &c." After this they rolled up the parchment, and put it into a case of reeds or other matter; they wrote on the end of the case the word *Shadai*, which is one of the names of God; and they put it at the doors of their houses, chambers, and all places most frequented; they fixed it to the knockers of the door, on the right side; and as often as they entered in or went out they touched it in this place, with the end of their finger, which they afterwards kissed out of devotion. The Hebrew word *mezuza* properly signifies the door-posts of a house; but it is also given to this roll of parchment now mentioned.

MEZZOTINTO, a particular manner of representing figures on copper, so as to form prints in imitation of painting in Indian ink. See ENGRAVING.

The invention of this art has been usually attributed to prince Rupert. But Baron Heinikin, a very judicious and accurate writer upon the subject of engraving, asserts, with great appearance of truth, that it was a lieutenant-colonel de Siegan, an officer in the service of the landgrave of Hesse, who first engraved in this manner; and that the print which he produced was a portrait of the princess Amelia Elizabeth of Hesse, engraved in the year 1643. Prince Rupert learned the secret from this gentleman, and brought it into England when he came over the second time with Charles II. Prince Rupert's print of An Executioner holding a Sword in one Hand and a Head in the other, a half length, from Spagnoletto, is dated 1658. This art has never been cultivated with success in any country but England

Mezzotinto.

The prince laid his grounds on the plate with a channelled roller; but one Sherwin, about the same time, laid his grounds with a half-round file, which was pressed down with a heavy piece of lead. Both these grounding tools have been laid aside for many years; and a hand tool, resembling a shoemaker's cutting-board-knife, with a fine crenelling on the edge, was introduced by one Edial, a smith by trade, who afterwards became a mezzotinto painter.

It is very different from the common way of engraving. To perform it, they rake, hatch, or punch, the surface of the plate all over with a knife, or instrument made for the purpose, first one way, then the other, across, &c. till the surface of the plate be thus entirely furrowed with lines or furrows, close and as it were contiguous to each other; so that, if an impression was then taken from it, it would be one uniform blot or smut. This done, the design is drawn or marked on the same face; after which, they proceed with burnishers, scrapers, &c. to expunge and take out the dents or furrows, in all the parts where the lights of the piece are to be; and that more or less as the lights are to be stronger or fainter; leaving those parts black which are to represent the shadows or deepenings of the draught.

As it is much easier to scrape or burnish away parts of a dark ground corresponding with the outline of any design sketched upon it, than to form shades upon a light ground by an infinite number of hatches, strokes, and points, which must all terminate with exactness on the outline, as well as differ in their force and manner; the method of scraping, as it is called, in mezzotinto, consequently becomes much more easy and expeditious than any other method of engraving. The instruments used in this kind of engraving are cradles, scrapers, and burnishers.

In this engraving, the plate must be prepared and polished in the same manner as for other engraving; and afterwards divided equally by lines parallel to each other, and traced out with very soft chalk.—The distance of these lines should be about one-third of the length of the face of the cradle which is to be used, and these lines should be marked with capital letters, or strokes of the chalk. The cradle is then to be placed exactly betwixt the two first lines, and passed forwards in the same direction; being kept as steady as possible, and pressed upon with a moderate force. The same operation must be repeated with respect to all the other lines; till the instrument has thus passed over the whole surface of the plate.—Other lines must be then drawn from the extremities of the other two sides, in the same manner; which, intersecting the first at right angles, will with them form squares; and the same operation must be repeated with the cradle as in the case of the first. New lines must then be drawn diagonally, and the cradle passed betwixt them as before; and when the first diagonal operation is performed, the lines must be crossed at right angles as the former, and the

 cradles

Mezzotinto.

cradles paſſed betwixt them in the ſame manner.—The plate having undergone the action of the cradle, according to the diſpoſition of the firſt order of lines, a ſecond ſet muſt be formed, having the ſame diſtances from each other as the firſt. But they muſt be ſo placed as to divide thoſe already made into ſpaces one-third leſs than their whole extent; *i. e.* every one after the firſt on each ſide will take in one-third of that before it, *e. g.* beginning at A, of which the firſt third muſt be left out; a third of B will conſequently be taken in, and ſo of the reſt. Theſe lines of the ſecond order muſt be marked with ſmall letters, or leſſer ſtrokes to diſtinguiſh them from the firſt: and the ſame treatment of the plate muſt be purſued with reſpect to them as was practiſed for the others. When this ſecond operation is finiſhed, a third order of lines muſt be made; the firſt of which, *e. g.* in A, muſt omit two-thirds of it, and conſequently take in two-thirds of B, &c. By theſe means, the original ſpaces will be exactly divided into equal thirds; and the cradle muſt be again employed betwixt theſe lines as before.—When the whole of this operation is finiſhed, it is called *one turn*; but in order to produce a very dark and uniform ground, the plate muſt undergo the repetition of all theſe ſeveral operations for above twenty times; beginning to paſs the cradle again betwixt the firſt lines, and proceeding in the ſame manner through all the reſt. When the plate is prepared with a proper ground, the ſketch muſt be chalked on it, by rubbing the paper on the backſide with chalk. It is alſo proper to overtrace it afterwards with black lead or Indian ink. The ſcraping is then performed, by pairing or cutting away the grain of the ground in various degrees; ſo that none of it is left in the original ſtate except in the touches of the ſtrongeſt ſhade. The general manner of proceeding is the ſame as drawing with white upon black paper. The maſſes of light are firſt begun with; and thoſe parts which go off into light in their upper part but are brown below: the reflections are then entered upon; after which the plate is blackened with a printer's blacking-ball made of felt, in order to diſcover the effect: and then the work is proceeded with; obſerving always to begin every part in the places where the ſtrongeſt lights are to be.

The art of ſcraping mezzotintoes has been applied to the printing with a variety of colours, in order to produce the reſemblance of paintings. The inventor of the method of doing this was J. C. Le Blon, a native of Frankfort, and pupil of Carlo Marata, between the years 1720 and 1730. It was eſtabliſhed by the inventor on this principle, that there are three primitive colours, of which all the reſt may be compoſed by mixing them in various proportions; that any two of theſe colours being mixed together, preſerve their original power, and only produce a third colour ſuch as their compound muſt neceſſarily give; but if tranſparent colours be mixed, and three primitive kinds compounded together, they deſtroy each other, and produce black, or a tendency to it, in proportion to the equality or inequality of the mixture; and that if, therefore, theſe three colours be laid, either ſeparately or upon each other, by three plates, engraved correſpondently on theſe principles to the colouring of the deſign, the whole variety of teints neceſſary may be produced. The requiſites, therefore, to the execution of any deſign in this method of printing are as follow: 1. To ſettle a plan of the colouring to be imitated; ſhowing where the preſence of each of the three ſimple colours is neceſſary, either in its pure ſtate or combined with ſome other, to produce the effect required; and to reduce this plan to a painted ſketch of each, in which not only the proper outlines, but the degree of ſtrength, ſhould be expreſſed. 2. To engrave three plates according to this plan, which may print each of the colours exactly in the places where, and proportion in which, they are wanted. 3. To find three tranſparent ſubſtances proper for printing with theſe three primitive colours. The manner in which Mr Le Blon prepared the plates was as follows: The three plates of copper were firſt well fitted with reſpect to ſize and figure to each other, and grounded in the ſame manner as thoſe deſigned for mezzotinto prints: and the exact place and boundary of each of the three primitive colours, conformably to the deſign, were ſketched out on three papers, anſwering in dimenſions to the plate. Theſe ſketches were then chalked on the plates; and all the parts of each plate that were not to convey the colour to which it was appropriated to the print, were entirely ſcraped away, as in forming the light of mezzotinto prints. The parts that were to convey the colours were then worked upon; and where the moſt light or diluted teints of the colour were to be, the grain in the ground was proportionably taken off; but where the full colour was required, it was left entire. In this regard was had, not only to the effects of the colour in its ſimple ſtate, but to its combined operation, either in producing orange-colour, green, or purple, by its admixture with one alone; and likewiſe to its forming brown, grey, and ſhades of different degrees, by its co-operation with both the others. But though the greateſt part of the engraving was performed in the mezzotinto manner, yet the graver was employed occaſionally for ſtrengthening the ſhades, and for correcting the outline where it required great accuracy and ſteadineſs. It was found neceſſary ſometimes to have two ſeparate plates for printing the ſame colour, in order to produce a ſtronger effect: but the ſecond plate, which was uſed to print upon the firſt, was intended only to glaze and ſoften the colours in particular parts that might require it. With reſpect to the black and brown teints, which could not be ſo conveniently produced in a due degree by the mixture of the colours, umber and black were likewiſe uſed.

Mezzotinto.

With reſpect to the order in which the plates are to be applied, it may be proper to obſerve, that the colour which is leaſt apparent in the picture ſhould be laid on firſt; that which is betwixt the moſt and leaſt apparent next; and that which predominates laſt; except where there may be occaſion for two plates for the ſame colour, as was before-mentioned; or where there is any required for adding browns and ſhades.

Mr Le Blon applied this art to portraits, and ſhowed, by the ſpecimens he produced, the poſſibility of its being brought, by farther improvements, to afford imitations of painting which might have ſome value. It is nevertheleſs much better adapted to the ſimpler ſubjects,

subjects, where there are fewer intermixtures of colours; and where the accuracy of the reflections, and demi-teints, are not so effentially neceffary to the truth of the defign, from the greater latitude of form, and difpofition of the colour, as in plants, anatomical figures, and fome fubjects of architecture. But perhaps plates engraved or rather finifhed with the tool, particularly with refpect to the outline, would be better accommodated in fome of thefe cafes than thofe prepared only by fcraping.

Mr Cochin remarks, at the end of an account he has given of Mr Le Blon's manner, that though this ingenious artift confined his method principally to the ufe of three colours; yet, fhould this invention be again taken up and cultivated, there would be more probability of fuccefs in ufing a greater variety: and that feveral different kinds might be printed by one plate; provided they were laid on in their refpectively proper places by printing-balls, which fhould be ufed for that colour only. His hint might however be very greatly improved, by the further affiftance of pencils, accommodated to the plates, for laying on the colours in the proper parts.—For the method of taking off mezzotinto prints on glafs, fee *Back-painting*.

MIASMA, among phyficians, a particular kind of effluvia, by which certain fevers, particularly intermittents, are produced.

MICA, Daze, *Talc*, *Mufcovy-glafs*, *Glimmer*, or *Glift*; a genus of magnefian earths, known by the following characters: 1. They confift of thin flexible particles, divifible into plates or leaves, having a fhining furface. 2. Thefe leaves or fcales, expofed to the fire, lofe their flexibility and become brittle, feparating afterwards into thinner leaves: but in a quick and ftrong fire they curl or crumple, which is a ftep towards fufion; though it is very difficult to reduce them into pure glafs without addition. 3. They melt eafily with borax, the microcofmic falt, and alkaline falt; and, by means of the two former falts, may be brought to a clear glafs before the blow-pipe. That which contains iron, however, is more fufible than the uncoloured earths of this kind. No loofe or friable mica has yet been difcovered, but all of an indurated kind. Its fpecific gravity, according to Fabroni, is about 3000. Kirwan tells us, that the fpecific gravity of this fubftance, when it contains much iron, is from 2535 to 3000. An hundred parts of the colourlefs kind contain 38 of filex, 28 of argill, 20 of magnefia, and 14 of the moft dephlogifticated calx of iron. Martial mica contains alfo 10 or 12 *per cent.* of a more phlogifticated calx of iron; whence its various colours are derived, and a proportionably fmaller quantity of the other ingredients. The fpecies are,

I. Mica alba, colourlefs or pure mica; of which there are the following varieties. 1. Mufcovy glafs, confifting of large parallel plates, and as tranfparent as glafs, found in Siberia and Sweden. This differs externally from the common talc, in being more foapy to the touch. An hundred parts of it contain 50 of filex, 45 of mild magnefia, and 5 of argill or clay. Venetian talc is white, grey, yellowifh, or greenifh, and femitranfparent. It is much more tender and brittle than mica, and fo foft that it may be fcratched with the nail. Its fpecific gravity is 2729. 2. Mica fquamofa, compofed of fmall plates, found in Sweden and other countries of Europe. 3. Compofed of fine particles like chaff. 4. Talcum officinale, crumpled mica, compofed of crumpled plates. Mica.

II. Mica colorata martialis, coloured and martial glimmer. Of this there are many varieties. 1. Brown and femitranfparent, found in Lapland. 2. Confifting of fine and minute fcales, of a brown, deep-green, light-green, or black colour, found in different parts of Sweden. 3. Twifted or crumpled glimmer, of a light green colour, found alfo in Sweden. 4. Chaffy glimmer, of a black colour, found in the ftone called *hornberg*, occurring in moft of the Swedifh copper mines, as at Norberg, Flodberg, &c. 5. Cryftallized glimmer, with erect fcales, or with hexagonal horizontal plates, found alfo in Sweden.

Moft of thefe ftones are fuppofed abfolutely to refift the fire; but this is to be underftood only of certain degrees of heat, and when they are mixed with certain bodies. Cronftedt obferves, however, that they may with equal propriety be called *vitrefcent*; becaufe they melt with that degree of heat in which neither quartz nor limeftone are in the fmalleft degree altered. They are ftill more readily melted when either naturally or artificially combined with a martial earth. Hence fome ores, though much mixed with mica, may be very readily melted; while others, in which the fame fubftance is mixed with quartz, it may be impoffible to melt; becaufe the mica renders the quartz fo compact as to prevent it from cracking. It does the fame with an apyrous clay, which is the reafon why the lapis ollaris refifts the fire fo ftrongly.

M. Margraaf afferts, that he has obtained Epfom falt from talc; and Mr Fabroni informs us, that in decompofing nitre by means of a micaceous fubftance, as foon as the acid is diftilled there rifes fome other fubftance hitherto unknown at the end of the operation: he adds, that on employing aqua regia or marine acid to diffolve this fubftance, the yellow colour which refults from the folution fhows that it contains fome iron. This laft affertion is confirmed by M. Monnet, who found that phlogifticated alkali and folution of galls produce a bluifh colour with that of mica. He adds, that its component parts are the fame with thofe of afbeftos, excepting only that the latter contains more iron.

Cronftedt informs us, that the martial mica acquires a fhining yellow colour in a calcining heat, which has induced many to examine it in hopes of finding gold; though no metal can be obtained from it except iron, which may be diffolved by means of aqua regia. A late German author indeed has pretended, that he produced from mica an unknown femimetal which refembled iron mixed with zinc. He owned, however, that he made ufe of a flux compofed of feveral metals, fome of which probably united with the talc, and thus deceived him. The talc cubes, which are micaceous bodies of the figure of aluminous cryftals, are much valued and fought after by fome mineralogifts. They are met with in fome parts of Sweden; and when broken are found to confift of an iron ore frequently mixed with a marcafitical copper ore, and are only covered with a very thin coat of mica. The broad and tranfparent talc named *Mufcovy-glafs* is ufed inftead of glafs for windows; and has this advantage above common glafs, that it refifts the explofion of cannon. Cronftedt thinks that it might be advantageoufly ufed for covering houfes. The twifted or crumpled mica, found in fome places of Sweden, is manufactured into kettles and other veffels, likewife into hearths for chimneys; "and the powder which falls in the working (fays our author) may be mixed with the common falt for the diftillation of the muriatic acid."

According to M. Magellan, many mineral fubftances may have the glittering appearance of talc without really belonging to that genus. An artificial production of this kind he happened to obferve in Mr Wedgewood's work It was an unexpected refult from vitriol calcined to rednefs, then mixed without being wafhed with common falt. It now underwent a fecond calcination under a muffle, with a heat fomewhat ftronger; about the tenth degree of his thermometer. The colour was of a dark purple, and the fhining particles fo bright as to fhow their glaffy form, very different from true mica.

MICAH, or *The Book of Micah*, a canonical book of the Old Teftament, written by the prophet Micah, who is the feventh of the twelve leffer prophets. He is cited by Jeremiah, and prophefied in the days of Jotham, Ahaz, and Hezekiah. He cenfures the reigning vices of Jerufalem and Samaria, and denounces the judgments of God againft both kingdoms. He likewife foretels the confufion of the enemies of the Jews, the coming of the Meffiah, and the glorious fuccefs of his church.

MICHAEL, or Michel, (i. e. *who is like to God?*) The fcripture account of Michael is, that he was an archangel, who prefided over the Jewifh nation, as other angels did over the Gentile world, as is evident of the kingdoms of Perfia and Greece, (Dan. x. 13.); that he had an army of angels under his command (Rev. xii. 7.); that he fought with the Dragon, or Satan and his angels; and that, contending with the Devil, he difputed about the body of Mofes, (Jude 9.) As to the combat between Michael and the Dragon, fome authors underftand it literally, and think it means the expulfion of certain rebellious angels, with their head or leader, from the prefence of God. Others take it in a figurative fenfe; and refer it, either to the conteft that happened at Rome between St Peter and Simon Magus, in which the apoftle prevailed over the magician, or to thofe violent perfecutions under which the church laboured for three hundred years, and which happily ceafed when the powers of the world became Chriftians. Among the commentators who maintain the former opinion is Grotius; and among thofe who take it in a figurative fenfe are Hammond and Mede.

The conteft about the body of Mofes is likewife taken both literally and figuratively. Thofe who underftand it literally are of opinion, that Michael by the order of God hid the body of Mofes after his death; and that the Devil endeavoured to difcover it, as a fit means to entice the people to idolatry, by a fuperftitious worfhip of his relics. But this difpute is figuratively underftood to be a controverfy about rebuilding the temple, and reftoring the fervice of God among the Jews at Jerufalem; the Jewifh church being fitly enough ftyled the body of Mofes. It is thought by fome, that this ftory of the conteft between Michael and the Devil was taken by St Jude out of an apocryphal book called, *The Affumption of Mofes*.

The Romifh church celebrates three appearances of Michael, of which no mention is made in fcripture, and which have happened, they fay, a long time after the age of the apoftles. The firft appearance of this archangel was at Coloffæ in Phrygia, but at what time is uncertain. The fecond is that of mount Garganus, in the kingdom of Naples, about the end of the fifth century. The third is his appearance to Aubert bifhop of Avranches, upon a rock called the *Tomb*, where at this day is the abbey of St Michael. This was about the year 706. The firft of thefe feftivals is obferved on the 6th of September, the fecond on the 8th of May, and the laft on the 16th of October. It has been fuppofed, that it was Michael the archangel who conducted the Ifraelites in their journey through the wildernefs, (fee Ex. xxxii. 20, 23, and xxxiii. 2.); that it was he who appeared to Mofes in the burning bufh; who appeared to Jofhua in the fields of Jericho, and to Gideon and Manoah the father of Samfon; and, in a word, to him have been imputed the greateft part of the moft remarkable appearances either in the Old or New Teftament.

Michael Angelo. See Angelo.

Mount Michael, one of the moft celebrated ftate-prifons of France, lies about 20 miles from Granville. It is a rock fituated in the middle of the bay of Avranches; and is only acceffible at low water. Nature has completely fortified one fide, by its craggy and almoft perpendicular defcent, which renders it impracticable to mount it by any addrefs or courage, however confummate. The other parts are furrounded by walls fenced with femilunar towers after the Gothic manner; but fufficiently ftrong, together with the advantage of its fituation, to render it impregnable to any attack. At the foot of the mountain begins a ftreet or town, which winds round its bafe to a confiderable height. Above are chambers where ftate-prifoners are kept, and where there are other buildings intended for refidence. On the fummit is erected the abbey itfelf, occupying a prodigious fpace of ground, and of a ftrength and folidity equal to its enormous fize; fince it has for many centuries withftood all the injuries of the weather, to which it is fo much expofed. In an apartment, called the *Sale de Chavalerie*, the knights of St Michael ufed to meet in folemn convocation on important occafions. They were the defenders and guardians of this mountain and abbey, as thofe of the temple, and of St John of Jerufalem, were of the holy fepulchre. The hall in which they met is very fpacious, but rude and barbarous. At one end is a painting of the archangel, the patron of their order; and in this hall Louis XI. firft inftituted and invefted with the infignia of knighthood the chevaliers of the crofs of St Michael. There is a miferable dark apartment, or rather dungeon, in which many eminent perfons were formerly confined. In the middle of it is a cage, compofed of prodigious bars of wood; and the wicket which gives entrance into it is 10 or 12 inches in thicknefs. The infide of it comprifes about 12 or 14 feet fquare, and it is nearly 20 in height. Towards the latter end of the laft century, a certain newfwriter in Holland, who had prefumed to print fome very severe and sarcastic reflections on Madame de Maintenon, was confined in this place. Some months after his publication, he was induced, by a person sent expressly for that purpose, to make a tour into French Flanders. The moment he had quitted the Dutch territories, he was put under arrest; and immediately, by his majesty's express command, conducted to Mount Michael, where he was shut up in this cage. Here he lived upwards of 23 years; and here he at length expired. During the long nights of winter, no candle or fire was allowed him. He was not permitted to have any book. He saw no human face, except the gaoler, who came once every day to present him, through a hole in the wicket, with his little portion of bread and wine. No instrument was given him with which he could destroy himself: but he found means at length to draw out a nail from the wood, with which he engraved, or cut on the bars of his cage, certain fleurs de lis and armorial bearings, which formed his only employment and recreation. They are very curiously performed considering the rudeness of his tool.

The subterraneous chambers in this mountain are said to be so numerous, that the gaolers themselves do not know them. There are certain dungeons called *oublieттes*, into which they were accustomed anciently to let down malefactors guilty of very heinous crimes: they provided them with a loaf of bread and a bottle of wine, and then they were totally forgotten, and left to perish by hunger in the dark vaults of the rock. This punishment, however, has not been inflicted by any king in the last or present century.

Here also is a remarkable chamber, in one corner of which is a kind of window: between this and the wall of the building is a very deep space, of near 100 feet perpendicular, at the bottom of which is another window opening to the sea. It is called the *Hole of Montgomeri;* and the history of it is as follows: In the year 1559, Henry II. king of France was unfortunately killed at a tournament by the count de Montgomeri †. He was a Huguenot; and having escaped the massacre of Paris, made head against the royal forces in Normandy, supported by queen Elizabeth with arms and money. Being driven from his fortresses in these parts, he retired to a rock called the *Tombelaine.* This is another similar to Mount Michael; only three quarters of a league from it, and of nearly equal dimensions. At that time there was a castle upon it, which has since been demolished, and of which scarce any vestiges now remain. From this fortress, accessible only at low-water, he continually made excursions, and annoyed the enemy, who never dared to attack him. He coined money, laid all the adjacent country under contribution, and rendered himself universally dreaded. Desirous, however, to surprise Mount Michael, he found means to engage one of the monks resident in the abbey; who promised to give him the signal for his enterprise by displaying a handkerchief. The monk having made the signal, betrayed him, and armed all his associates, who waited Montgomeri's arrival. The chieftain came, attended by 50 chosen soldiers, all desperate, and capable of any attempt. They crossed the sand; and having placed their scaling-ladders, mounted one by one. As they came to the top, they were dispatched, each in turn, without noise. Montgomeri, who followed last, discovered the perfidy, and escaped with only two of his men, with whom he regained the Tombelaine. They preserve with great care the ladders and grappling irons used on this occasion. The count was at last besieged and taken prisoner by the mareshal de Matignon, in 1574, at Domfront, in Normandy; and Catharine de Medicis, who hated him for having been, though innocently, the cause of her husband's death, caused him to be immediately executed.

Michael, St Michael's.

The church of Mount Michael is a great curiosity. It stands on nine pillars of most enormous dimensions, built on the solid rock. Each of them appears to be about 25 feet in circumference: besides these, there are two others much inferior in size, on which the centre of the church rests, and over which is the tower. The following is the legendary account of the origin of this church: In the reign of Childebert II. there was a bishop of Avranches named *St Aubert.* To this holy man the archangel Michael was pleased to appear one night, and ordered him to go to this rock to build a church. St Aubert treated this as a dream; upon which the angel appeared a second time; and being still disobeyed, he returned a third time, when, by way of imprinting his command upon the saint's memory, he made a hole in his skull, by touching it with his thumb. The skull is still preserved in the treasury of the church. It is inclosed in a little shrine of gold, and a crystal, which opens over the orifice, admits the gratification of curiosity by the minutest examination of it. The hole is of a size and shape proportionable to the thumb said to have produced it; but it is impossible to determine whether it has been really made by a knife or any other way. It is not to be supposed that the saint would forget such a sensible mark of the angel's displeasure; he therefore immediately repaired to the rock, and constructed a small church, as he had been commanded. Here, however, true history supplies the place of fable; and informs us, that it was in 96› when Richard the second duke of Normandy began to build the abbey. It was completed about the year 1070, under William the Conqueror, though many other additions were made by succeeding abbots.

In the treasury of the church are innumerable other relics; among which some few have a real and intrinsic value. There is a fine head of Charles VI. of France, cut in a crystal, and the representation of a cockle-shell in gold, weighing many pounds, given by Richard II. duke of Normandy, when he founded the abbey. There is an arm said to belong to *St Richard* king of England; but who this saint was it must be very difficult to determine.

St MICHAEL'S, a borough town of Cornwal, between St Columb and Truro, 247 miles from London. Though one of the oldest boroughs in the county by prescription, and of great note in the Saxons time, it is a mean hamlet in the parishes of Newland and St Enidore; yet it is governed by a portreeve, yearly chosen by a jury of the chief inhabitants, out of the six chief tenants, called deputy lords of the manor, because they hold lands in the borough. Here is no market, but two fairs. A court-leet is held here twice a year. This place was formerly called Modishole, and afterwards Michel. Its list of members begins in the 6th of Edward VI.

St Michael's Mount, in the county of Cornwal, in the corner of Mount's-Bay, is a very high rock, Michaelis.

only divided by the tide from the main-land, so that it is land and island twice a-day. The town here was burnt by the French in the reign of king Henry VIII. At the bottom of this mount, in digging for tin, there have been found spear-heads, battle axes, and swords, of brass, all wrapt up in linen. The county is contracted here into a sort of isthmus, so that it is scarce four miles between the Channel and the Severn sea.—There have been large trees driven in by the sea between this mount and Penzance.

MICHAELIS (John David), a celebrated biblical critic, and author of many esteemed works, was the eldest son of Dr Christian Benedict Michaelis, professor in the university of Halle in Lower Saxony, and was born at that place Feb. 27. 1717. His father devoted him at an early age to an academical life; and with that view he received the first part of his education in a celebrated Prussian seminary, called the *Orphan-house*, at Glanche, in the neighbourhood of his native place. He commenced his academical career at Halle in 1733, and took his master's degree in the faculty of philosophy in 1739. In 1741 he made an excursion to this country, where his superior knowledge of the oriental languages, which was considerably increased by his indefatigable researches in the Bodleian library at Oxford, introduced him to the acquaintance, and gained him the esteem, of our first literary characters; with several of whom, and particularly bishop Lowth, he was in correspondence for many years. On his return to Halle, after an absence of fifteen months, he began to read lectures on the historical books of the Old Testament, which he continued after his removal to Gottingen in 1745. In 1746 he was appointed professor extraordinary, and soon after professor of philosophy, in that university. The next year he obtained a place of secretary to the royal society there, of which he was director in 1761, and was soon afterwards made Aulic counsellor by the court of Hanover. In 1764 his distinguished talents, but chiefly a publication relative to a journey to Arabia, which was undertaken by several literary men, at the expence of the king of Denmark, in consequence of his application by means of Count Bernsdorff, procured him the honour of being chosen a correspondent, and afterwards foreign member, of the academy of inscriptions at Paris, of whom the institution admitted only eight; and in the same year he became a member of the society of Haarlem. In 1775, Count Hopkin, who eighteen years before had prohibited the use of his writings at Upsal, when he was chancellor of that university, prevailed upon the king of Sweden to confer on him the order of the polar star, as a national compensation. In 1786 he was raised to the distinguished rank of privy counsellor of justice by the court of Hanover; and in 1788 received his last literary honour, by being unanimously elected a fellow of the royal society of London.—His great critical knowledge of the Hebrew language, which he displayed in a new translation of the Bible, and in other works, raised him to a degree of eminence almost unknown before in Germany; and his indefatigable labours were only equalled by his desire of communicating the knowledge he acquired to the numerous students of all countries who frequented his admirable lectures, which he continued to deliver on various parts of the sacred writings in half-yearly courses, and on the Hebrew, Arabic, and Syriac languages, to the last year of his life. He was professor in the university of Gottingen forty-five years, and, during that long period, he filled the chair with dignity, credit, and usefulness. He died October 22. 1791, aged 74. He is said to have left behind him several valuable MSS. Of the works that were published during his life time, and which are very numerous, a catalogue, in the order of their publication, is given in the *Gentleman's Magazine* for March 1792.

Michaelmas, Mickle.

MICHAELMAS, or *Feast of St* MICHAEL *and all Angels*, a festival of the Christian church, observed on the 29th of September. See MICHAEL.

MICKLE (William Julius), the celebrated translator of the Lusiad, was the son of the reverend Alexander Mickle a Scottish clergyman, who had formerly been a dissenting minister in London, an assistant to the reverend Dr Watts, and one of the translators of Bayle's Dictionary. This gentleman having resided a few years in London, was presented to the church of Langholm near Kelso in Scotland, where he married; and our author was one of the younger sons. He was born about the year 1735, and was educated by his father. In his early years his passion for poetry frequently discovered itself; though till the age of 13 he did not show any particular attachment to books. At that time having accidentally met with Spencer's Fairy Queen, he became enamoured of his manner of writing, and instantly began to imitate him. After the death of his father, he came to Edinburgh to reside with an uncle who was a brewer there, and who admitted him into a share of his business; but not being qualified to succeed in this line, he went to London about the time of the conclusion of the war which began in 1755, with a view to procure a commission in the marine service. Here he was disappointed; but introduced himself to the first Lord Lyttelton, to whom he sent one of his poems. From his lordship, however, he received no other favour than being admitted to several interviews, and encouraged to persevere in his poetical plans.

So closely did our author cultivate the study of the muses, that before he was 18 years of age he had written two tragedies and half an epic poem; but all these were committed to the flames. The first of his poems which appeared in print was published in one of the Edinburgh magazines, and intitled, "On passing thro' the Parliament Close of Edinburgh at Midnight." This was afterwards inserted in A Collection of Original Poems by a Scotch gentleman, Vol. II. p. 137.

From the time of Mr Mickle's arrival at London till the year 1765, it is not known how he employed his time, though it is probable that he was employed in some branch of the printing business; and in 1765 he engaged himself as corrector to the Clarendon press. This year he published the poem which first brought him into notice, intitled, "Pollio, an Elegiac Ode, written in the Wood near R—— (Roslin) Castle," 4to. This was an elegy written on the death of his brother; which, previous to its publication, had been shown to Lord Lyttelton, and received some corrections from him. The latter, in an epistle to the author, spoke of it as equal to any thing of the kind in our language. In 1767 he published a poem called "The Concubine, in two Cantos, after the manner of Spencer,"

Spencer," 4to; and in 1769 he published, "A Letter to Mr Harwood, wherein some of his evasive Glosses, false Translations, and blundering Criticisms, in support of the Arian Heresy, contained in his Literal Translation of the New Testament, are pointed out and confuted," 8vo: and next year he published "Mary Queen of Scots, an Elegy;" "Hengist and Mary, a Ballad;" and "Knowledge, an Ode;" in Pearch's Collection of Poems. In 1770 he published "Voltaire in the Shades, or Dialogues on the Deistical Controversy," 8vo. The Elegy on Mary had been submitted to the judgment of Lord Lyttelton, who declined to criticise it, not for its deficiency in poetical merit, but from thinking differently from the author concerning that unfortunate princess.

About this time Mr Mickle was a frequent writer in the Whitehall Evening Post; but a more important work now engaged his attention. When no more than 17 years of age he had read Castara's translation of the Lusiad of Camoens into French, and then projected the design of giving an English translation of it. From this, however, he was prevented by various avocations till the year 1771, when he published the first book as a specimen: and having prepared himself by acquiring some knowledge of the Portuguese language, he determined to apply himself entirely to this work. With this view he quitted his residence at Oxford, and went to a farm-house at Forest-hill, where he pursued his design with unremitting assiduity till the year 1775, when the work was entirely finished.

During the time that Mr Mickle was engaged in this work, he subsisted entirely by his employment as corrector of the press; and on his quitting that employment he had only the subscriptions he received for his translation to support him. Notwithstanding these difficulties, he adhered steadily to the plan he had laid down, and completed it in about five years.

When his work was finished, Mr Mickle applied to a person of great rank, with whom his family had been connected, for permission to dedicate it to him. Permission was granted, and his patron honoured him with a very polite letter; but after receiving a copy, for which an extraordinary price was paid for the binding, he did not think proper to take any notice of the author. At last a gentleman of high rank in the political world, a firm friend to the author, and who afterwards took him under his protection, waited on the patron, and heard him declare that he had not read the work, but that it had been represented not to have the merit it was at first said to possess. The applause with which the work was received, however, soon banished from the author's mind those disagreeable sensations which had been occasioned by the contemptuous neglect of his patron, as well as some severe criticisms which had been circulated concerning it. A second edition was prepared in 1778, with a plate prefixed to it, executed by the celebrated artist Mortimer; on whom Mr Mickle wrote an epitaph in 1779. This year also he published a pamplet, intitled, "A Candid Examination of the Reasons for depriving the East India Company of its Charter, contained in The History and Management of the East India Company from its Commencement to the Present Time; together with some Strictures on the Self-Contradictions and Historical Errors of Dr Adam Smith, in his Reasons for the Abolition of the said Company," 4to. About this time some of his friends thought of recommending him to the king as deserving of a pension; but this scheme was never put in execution. Dr Lowth, bishop of London, would have put him into orders, and provided for him in the church; but this was not agreeable to our author's disposition. While he was meditating a publication of all his poems, in which he would most probably have found his account, he was appointed secretary to Commodore Johnstone, who had lately obtained the command of the Romney man of war. In November 1779 he arrived at Lisbon, and was named by his patron joint agent for the prizes which were taken. In this capital and its neighbourhood he resided more than six months, being every where received with every mark of politeness and attention; and during this period he composed his poem called "Almada Hill," which in 1781 was published in quarto. He collected also many particulars concerning the manners of the Portuguese, which he intended also to have published. During his stay at Lisbon the royal academy was opened; and Mr Mickle, who was present at the ceremony of its commencement, had the honour to be admitted a member under the presidency of Don John of Braganza duke of Lafoens. His presence being thought necessary in England to attend to the proceedings of the courts of law respecting the condemnation of some of the prizes, he did not accompany the commodore in his last expedition, nor did he go any more to sea. In 1782 he published "The Prophecy of Queen Emma, an ancient Ballad lately discovered, written by Johannes Turgottus, prior of Durham, in the reign of William Rufus; to which is added by the Editor, an Account of the Discovery, and Hints towards a Vindication of the Authenticity, of the Poems of Ossian and Rowley," 8vo.

In June this year Mr Mickle married Miss Tomkins, daughter of the person with whom he resided at Forest-hill, while engaged in translating the Lusiad. Having received some fortune with this lady, as well as made some money himself when in the service of Commodore Johnstone, he now enjoyed a comfortable independence. Having fixed his residence at Wheatley in Oxfordshire, he devoted his time to the revision of his poetical works, which he proposed to publish by subscription; but the plan has not yet been carried into execution. The last seven years of his life were employed in writing for the European Magazine. The Fragments of Leo, and some of the most approved reviews of books, in that performance, were of his production. He died after a short illness on the 25th of October 1788 at Wheatley, leaving one son behind him. His poetry possesses much beauty, variety, harmony of numbers, and vigour of imagination: his life was without reproach; his foibles were few and inoffensive; his virtues many; and his genius very considerable.

MICROCOSM, a Greek term signifying the *little world;* used by some for *man*, as being supposed an epitome of the universe or great world.

MICROCOSMIC ACID. See PHOSPHORUS (*Acid of*).

Micrography, Micrometer.

MICROGRAPHY, the defcription of objects too minute to be viewed without the affiftance of a microfcope. See *Microscopic Objects*.

MICROMETER, an inftrument, by the help of which the apparent magnitudes of objects viewed thro' telefcopes or microfcopes are meafured with great exactnefs.

I. The firft TELESCOPIC micrometers were only mechanical contrivances for meafuring the image of an object in the focus of the object-glafs. Before thefe contrivances were thought of, aftronomers were accuftomed to meafure the field of view in each of their telefcopes, by obferving how much of the moon they could fee through it, the femidiameter being reckoned at 15 or 16 minutes; and other diftances were eftimated by the eye, comparing them with the field of view. Mr Gafcoigne, an Englifh gentleman, however, fell upon a much more exact method, and had a Treatife on Optics prepared for the prefs; but he was killed during the civil wars in the fervice of Charles I. and his manufcript was never found. His inftrument, however, fell into the hands of Mr R Townly, who fays, that by the help of it he could mark above 40,000 divifions in a foot.

Mr Gafcoigne's inftrument being fhown to Dr Hooke, he gave a drawing and defcription of it, and propofed feveral improvements in it, which may be feen in Phil. Tranf. abr. Vol. I. p 217. Mr Gafcoigne divided the image of an object, in the focus of the object-glafs, by the approach of two pieces of metal ground to a very fine edge, in the place of which Dr Hooke would fubftitute two fine hairs ftretched parallel to one another. Two other methods of Dr Hooke's, different from this, are defcribed in his Pofthumous Works, p. 497, 498. An account of feveral curious obfervations that Mr Gafcoigne made by the help of his micrometer, particularly in the menfuration of the diameters of the moon and other planets, may be feen in the Phil. Tranf. Vol. XLVIII. p. 190.

Mr Huygens, as appears by his Syftem of Saturn, publifhed in 1659, ufed to meafure the apparent diameters of the planets, or any fmall angles, by firft meafuring the quantity of the field of view in his telefcope; which, he fays, is beft done by obferving the time which a ftar takes up in paffing over it, and then preparing two or three long and flender brafs plates, of various breadths, the fides of which were very ftraight, and converging to a fmall angle. In making ufe of thefe pieces of brafs, he made them flide in two flits, that were made in the fides of the tube, oppofite to the place of the image, and obferved in what place it juft covered the diameter of any planet, or any fmall diftance that he wanted to meafure. It was obferved, however, by Sir Ifaac Newton, that the diameters of planets, meafured in this manner, will be larger than they fhould be, as all lucid objects appear to be when they are viewed upon dark ones.

In the Ephemerides of the Marquis of Malvafia, publifhed in 1662, it appears that he had a method of meafuring fmall diftances between fixed ftars and the diameters of the planets, and alfo of taking accurate draughts of the fpots of the moon; and this was by a net of filver wire, fixed in the common focus of the object and eye-glafs. He alfo contrived to make one of two ftars to pafs along the threads of this net, by turning it, or the telefcope, as much as was neceffary for that purpofe; and he counted, by a pendulum-clock, beating feconds, the time that elapfed in its paffage from one wire to another, which gave him the number of the minutes and feconds of a degree contained between the intervals of the wires of his net, with refpect to the focal length of his telefcope.

In 1666, Meffrs Azout and Picard publifhed a defcription of a micrometer, which was nearly the fame with that of the Marquis of Malvafia, excepting the method of dividing it, which they performed with more exactnefs by a fcrew. In fome cafes they ufed threads of filk, as being finer than filver wires. Dechales alfo recommends a micrometer confifting of fine wires, or filken threads, the diftances of which were exactly known, difpofed in the form of a net, as peculiarly convenient for taking a map of the moon.

M. de la Hire fays, that there is no method more fimple or commodious for obferving the digits of an eclipfe than a net in the focus of the telefcope. Thefe, he fays, were generally made of filken threads; and that for this particular purpofe fix concentric circles had alfo been made ufe of, drawn upon oiled paper; but he advifes to draw the circles on very thin pieces of glafs with the point of a diamond. He alfo gives feveral particular directions to affift perfons in the ufe of them. In another memoir he fhows a method of making ufe of the fame net for all eclipfes, by ufing a telefcope with two object-glaffes, and placing them at different diftances from one another.

Plate CCXC fig 1.

Different Conftructions of Micrometers. The firft we fhall defcribe is that by Mr Huygens. Let ABCD be a fection of the telefcope at the principal focus of the object-glafs, or where the wires are fituated, which are placed in a fhort tube containing the eye-glafs, and may be turned into any pofition by turning that tube; mn is a fine wire extended over its centre; vw, xy, are two ftraight plates whofe edges are parallel and well defined, and perpendicular to mn; vw is fixed, and xy moves parallel to it by means of a fcrew, which carries two indexes over a graduated plate, to fhow the number of revolutions and parts of a revolution which it makes. Now to meafure any angle, we muft firft afcertain the number of revolutions and parts of a revolution correfponding to fome known angle, which may be thus done: 1ft, Bring the inner edges of the plates exactly to coincide, and fet each index to 0; turn the fcrew, and feparate the plates to any diftance; and obferve the time a ftar m is in paffing along the wire mn from one plate to the other: for that time, turned into minutes and feconds of a degree, will be the angle anfwering to the number of revolutions, or the angle correfponding to the diftance. Thus, if d = cof. of the ftar's declination, we have $15' dm$, the angle correfponding to this diftance; and hence, by proportion, we find the angle anfwering to any other. 2dly, Set up an object of a known diameter, or two objects at a given diftance, and turn the fcrew till the edges of the plates become tangents to the object, or till their opening juft takes in the diftance of the two objects upon the wire mn: then from the diameter, or diftance of the two objects from each other, and their diftance from the glafs, calculate the angle, and obferve the number of revolutions and parts correfponding. 3dly, Take the diameter of the fun on any day, by making the edges of the plates tangents to the oppofite limbs, and find, from

from the nautical almanac, what is his diameter on that day. Here it will be best to take the upper and lower limbs of the sun when on the meridian, as he has then no motion perpendicular to the horizon. If the edges do not coincide when the indexes stand at 0, we must allow for the error. Instead of making a proportion, it is better to have a table calculated to show the angle corresponding to every revolution and parts of a revolution. But the observer must remember, that when the micrometer is fixed to telescopes of different focal lengths, a new table must be made. The whole system of wires is turned about in its own plane, by turning the eye-tube round with a hand, and by that means the wire *mn* can be thrown into any position, and consequently angles in any position may be measured. Dr Bradley added a small motion by a rack and pinion to set the wires more accurately in any position.

Instead of two plates, two wires were afterwards put; and Sir Isaac Newton observed that the diameters of the planets measured by the plates were somewhat bigger than they ought, as appeared by comparing Mr Huygens's measures with others taken with the wires; and also by comparing the diameter of mercury observed in and out of the sun's disk, the latter being the greatest. Dark objects on bright ones appear less, and light objects on dark ones appear greater, than if they were equally bright; owing, perhaps, to the brighter image on the retina diffusing itself into the darker: and the bright image of the planet being intercepted by the plates, the faint diffused light becomes more sensible, and is mistaken for the edge of the planet.

But the micrometer, as now contrived, is of use, not only to find the angular distance of bodies in the field of view at the same time, but also of those which, when the telescope is fixed, pass through the field of view successively; by which means we can find the difference of their right ascensions and declinations. Let A *a*, B *b*, C *c*, be three parallel and equidistant wires, the middle one bisecting the field of view; H O R a fixed wire perpendicular to them passing through the centre of the field; and F *f*, G *g*, two wires parallel to it, each moveable by a micrometer screw, as before, so that they can be brought up to H O R, or a little beyond. Then to find the angular distance of two objects, bring them very near to B*b*, and in a line parallel to it, by turning about the wires, and bring one upon HOR, and by the micrometer screw make F *f* or *Gg* pass through the other; then turn the screw till that wire coincides with H O R, and the arc which the index has passed over shows their angular distance. If the objects be further remote than you can carry the distance of one of the wires F *f*, G *g*, from H O R, then bring one object to F *f* and the other to G *g*; and turn each micrometer screw till they meet, and the sum of the arcs passed over by each index gives their angular distance. If the objects be two stars, and one of them be made to run along H O R, or either of the moveable wires as occasion may require, the motion of the other will be parallel to these wires, and their difference of declinations may be observed with great exactness; but in taking any other distances, the motion of the stars being oblique to them, it is not quite so easy to get them parallel to B *b*; because if one star be brought near, and the eye be applied to the other to adjust the wires to it, the former star will have gotten a little away from the wire. Dr Bradley, in his account of the use of this micrometer, published by Dr Maskeleyne in the Philosophical Transactions for 1772, thinks the best way is to move the eye backwards and forwards as quick as possible; but it seems to me to be best to fix the eye at some point between, by which means it takes in both at once sufficiently well defined to compare them with B *b*. In finding the difference of declinations, if both bodies do not come into the field of view at the same time, make one run along the wire H O R, as before, and fix the telescope and wait till the other comes in, and then adjust one of the moveable wires to it, and bring it up to H O R, and the index gives the difference of their declinations. The difference of time between the passage of the star at either of the cross moveable wires, and the transit of the other star over the cross fixed wire (which represents a meridian), turned into degrees and minutes, will give the difference of right ascension. The star has been here supposed to be bisected by the wire; but if the wire be a tangent to it, allowance must be made for the breadth of the wire, provided the adjustment be made for the coincidence of the wires. In observing the diameters of the sun, moon, or planets, it may perhaps be most convenient to make use of the outer edges of the wires, because they appear most distinct when quite within the limb: but if there should be any sensible inflection of the rays of light in passing by the wires, it will be best avoided by using the inner edge of one wire and the outward edge of the other; for by that means the inflection at both limbs will be the same way, and therefore there will be no alteration of the relative position of the rays passing by each wire. And it will be convenient in the micrometer to note at what division the index stands when the moveable wire coincides with H O R; for then you need not bring the wire when a star is upon it up to H O R, only reckon from the division at which the index then stands to the above division.

With a micrometer therefore thus adapted to a telescope, Mr Servington Savery of Exeter proposed a new way of measuring the difference between the greatest and least apparent diameters of the sun, although the whole of the sun was not visible in the field of view at once. The method we shall briefly describe. Place two object-glasses instead of one, so as to form two images whose limbs shall be at a small distance from each other; or instead of two perfect lenses, he proposed to cut a single lens into four parts of equal breadths by parallel lines, and to place the two segments with their straight sides against each other, or the two middle frustrums with their opposite edges together; in either case, the two parts which before had a common centre and axis, have now their centres and axes separated, and consequently two images will be formed as before by two perfect lenses. Another method in reflectors was to cut the large concave reflector through the centre, and by a contrivance to turn up the outer edges whilst the straight ones remained

mained fixed; by which means the axis of the two parts became inclined, and formed two images. Two images being formed in this manner, he proposed to measure the distance between the limbs when the diameters of the sun were the greatest and least, the difference of which would be the difference of the diameters required. Thus far we are indebted to Mr Savery for the idea of forming two images; and the admirable uses to which it was afterwards applied, we shall next proceed to describe.

The divided object-glass micrometer, as now made, was contrived by the late Mr John Dollond, and by him adapted to the object-end of a reflecting telescope, and has been since by the present Mr P. Dollond his son applied with equal advantage to the end of an achromatic telescope. The principle is this: The object glass is divided into two segments in a line drawn through the centre; each segment is fixed in a separate frame of brass, which is moveable, so that the centres of the two segments may be brought together by a handle for that purpose, and thereby form one image of an object; but when separated they will form two images, lying in a line passing through the centre of each segment; and consequently the motion of each image will be parallel to that line, which can be thrown into any position by the contrivance of another handle to turn the glass about in its own plane. The brass-work carries a vernier to measure the distance of the centres of the two segments. Now let E and H be the centres of the two segments, F their principal focus, and P Q two distant objects in FE, FH, produced, or the opposite limbs of the same object PBQD; then the images of P and Q, formed by each segment, or the images of the opposite limbs of the object PBQD, coincide at F: hence two images mzF, nxF of that object are formed, whose limbs are in contact; therefore the angular distance of the points P and Q is the same as the angle which the distance EH subtends at F, which, as the angles supposed to be measured are very small, will vary as EH extremely nearly; and consequently if the angle corresponding to one interval of the centres of the segments be known, the angle corresponding to any other will be found by proportion. Now to find the interval for some one angle, take the horizontal diameter of the sun on any day, by separating the images till the contrary limbs coincide, and read off by the vernier the interval of their centres, and look into the nautical almanac for the diameter of the sun on that day, and you have the corresponding angle. Or if greater exactness be required than from taking the angle in proportion to the distances of their centres, we may proceed thus:—Draw FG perpendicular to EH, which therefore bisects it; then one half EH, or EG, is the tangent of half the angle EFH; hence, half the distance of their centres : tangent of half the angle corresponding to that distance : : half any other distance of the centres : tangent of half the corresponding angle (A).

Fig 3.

Hence the method of measuring small angles is manifest; for we consider P, Q, either as two objects whose images are brought together by separating the two segments, or as the opposite limbs of one object PBQA, whose images, formed by the two segments E, H, touch at F: in the former case, EFH gives the angular distance of the two objects; and in the latter, it gives the angle under which the diameter of the object appears. Hence, to find the angular distance of two objects, separate the segments till the two images which approach (B) each other coincide; and to find the diameter of an object, separate the segments till the contrary limbs of the images touch each other, and read off the distance of the centres of the segment from the vernier (C), and find the angle as directed in the last article. From hence appears one great superiority in this above the wire micrometer; as, with this, any diameter of an object may be measured with the same ease and accuracy; whereas with that we cannot with accuracy measure any diameter, except that which is at right angles to its apparent motion.

But, besides these two uses to which the instrument seems so well adapted, Dr Maskelyne has shown, in the Philosophical Transactions for the year 1771, how it may be applied to find the difference of right ascensions and declinations. For this purpose, two wires at right angles to each other, bisecting the field of view, must be placed in the principal focus of the eye-glass, and moveable about in their own plane.— Let

(A) If the object be not a distant one, let f be the principal focus; then Ff : FG : : FG : FK (FG being produced to meet a line joining the apparent places of the two objects P, Q), ∴ dividendo, fG : FG : : GK : FK, and alternando, fG : GK : : FG : FK : : (by similar triangles) EH : PQ, hence $\frac{EH}{fG}=\frac{PQ}{GK}$, therefore the angle subtended by EH at f = the angle subtended by PQ at G; and consequently, as fG is constant, the angle measured at G is, in this case also, in proportion to EH. The instrument is not adapted to measure the angular distance of bodies, one of which is near and the other at a distance, because their images would not be formed together.

(B) Besides these two images, there will be two others receding from each other, for each segment gives an image of each object.

(C) To determine whether there be any error of adjustment of the micrometer scale, measure the diameter of any small well defined object, as Jupiter's equatorial diameter, or the longest axis of Saturn's ring, both ways, that is, with 0 on the vernier to the right and left of 0 on the scale, and half the difference is the error required; which must be added to or subtracted from all observations, according as the diameter measured with 0 on the vernier, when advanced on the scale, is less or greater than the diameter measured the other way. And it is also evident, that half the sum of the diameters thus measured gives the true diameter of the object.

Let HCRc be the field of view, HR and Cc the two wires; turn the wires till the westernmost star (which is the best, having further to move) run along ROH; then separate the two segments and turn about the micrometer till the two images of the same star lie in the wire Cc; and then, partly by separating the segments, and partly by raising or depressing the telescope, bring the two innermost images of the two stars to appear and run along ROH, as a, b, and the vernier will give the difference of their declinations; because, as the two images of one of the stars coincided with Cc, the image of each star was brought perpendicularly upon HR, or to HR in their proper meridian. And, for the same reason, the difference of their times of passing the wire CO. will give their difference of right ascensions. These operations will be facilitated, if the telescope be mounted on a polar axis. If two other wires KL, MN, parallel to Cc, be placed near H and R, the observation may be made on two stars whose difference of meridians is nearly equal to HR the diameter of the field of view, by bringing the two images of one of the stars to coincide with one of these wires. If two stars be observed whose difference of declinations is well settled, the scale of the micrometer will be known.

It has hitherto been supposed, that the images of the two stars can be both brought into the field of view at once upon the wire HOR; but if they cannot, set the micrometer to the difference of their declinations as nearly as you can, and make the image which comes first run along the wire HOR, by elevating or depressing the telescope; and when the other star comes in, if it do not also run along HOR, alter the micrometer till it does, and half the sum of the numbers shown by the micrometer at the two separate observations of the two stars on the wire HOR will be the difference of their declinations. That this should be true, it is manifestly necessary that the two segments should recede equally in opposite directions; and this is effected by Mr Dollond in his new improvement of the object-glass micrometer.

The difference of right ascensions and declinations of Venus or Mercury in the sun's disk and the sun's limb may be thus found. Turn the wires so that the north limb n of the sun's image AB, or the north limb of the image V of the planet, may run along the wire RH, which therefore will then be parallel to the equator, and consequently Cc a secondary to it; then separate the segments, and turn about the micrometer till the two images Vv of the planet pass Cc at the same time, and then by separating the segments, bring the north limb of the northernmost image V of the planet to touch HR, at the time the northernmost limb n of the southernmost image AB of the sun touches it, and the micrometer shows the difference of declinations of the northernmost limbs of the planet and sun, for the reason formerly given †, we having brought the northernmost limbs of the two innermost images V and AB to HR, these two being manifestly interior to v and the northernmost limb N of the image PQ. In the same manner we take the difference of declinations of their southernmost limbs; and half the difference of the two measures, (taking immediately one after another) is equal to the difference of the declinations of their centres, without any regard to the sun's or planet's diameters, or error of adjustment of the micrometer; for as it affects both equally, the difference is the same as if there were no error: and the difference of the times of the transits of the eastern or western limbs of the sun and planet over Cc gives the difference of their right ascensions.

Instead of the difference of right ascensions, the distance of the planet from the sun's limb, in lines parallel to the equator, may be more accurately observed thus: Separate the segments, and turn about the wires and micrometer, so as to make both images V, v, run along HR, or so that the two intersections I, T, of the sun's image may pass Cc at the same time. Then bring the planet's and sun's limbs into contact, as at V, and do the same for the other limb of the sun, and half the difference gives the distance of the centre of the planet from the middle of the chord on the sun's disk parallel to the equator, or the difference of the right ascensions of their centres, allowing for the motion of the planet in the interval of the observations, without any regard to the error of adjustment, for the same reason as before. For if you take any point in the chord of a circle, half the difference of the two segments is manifestly the distance of the point from the middle of the chord; and as the planet runs along HR, the chord is parallel to the equator. Fig. 6.

In like manner, the distances of their limbs may be measured in lines perpendicular to the equator, by bringing the micrometer into the position already described*, and instead of bringing V to HR, separate the segments till the northernmost limbs coincide as at V; and in the same manner make their southernmost images to coincide, and half the difference of the two measures, allowing for the planet's motion, gives the difference of the declinations of their centres. Fig. 7.

* See the preceding column, par. 3.

Hence the true place of a planet in the sun's disk may at any time of its transit be found; and consequently the nearest approach to the centre and the time of ecliptic conjunction may be deduced, although the middle should not be observed.

But however valuable the object-glass micrometer undoubtedly is, difficulties sometimes have been found in its use, owing to the alteration of the focus of the eye, which will cause it to give different measures of the same angle at different times. For instance, in measuring the sun's diameter, the axis of the pencil coming through the two segments from the contrary limbs of the sun, as PF, QF, fig. 3. crossing one another in the focus F under an angle equal to the sun's semidiameter, the union of the limbs cannot appear perfect, unless the eye be disposed to see objects distinctly at the place where the images are formed; for if the eye be disposed to see objects nearer to or further off than that place, in the latter case the limbs will appear separated, and in the former they will appear to lap over (D). This imperfection led Dr Maskelyne

(D) For if the eye can see distinctly an image at F, the pencils of rays, of which PF, QF are the two axes, diverging from F, are each brought to a focus on the retina at the same point; and therefore the two limbs appear

Micrometer.

ſkelyne to inquire, whether ſome method might not be found of producing two diſtinct images of the ſun, or any other object, by bringing the axis of each pencil to coincide, or very nearly ſo, before the formation of the images, by which means the limbs when brought together would not be liable to appear ſeparated from any alteration of the eye; and this he found would be effected by the refraction of two priſms, placed either without or within the teleſcope; and on this principle, placing the priſms within, he conſtructed a new micrometer, and had one executed by Mr Dollond, which upon trial anſwered as he expected. The conſtruction is as follows.

Fig. 8, 9. Let AB be the object-glaſs; *ab* the image, ſuppoſe of the ſun, which would have been formed in the principal focus Q; but let the priſms PR, SR be placed to intercept the rays, and let EF, WG, be two rays proceeding from the eaſtern and weſtern limbs of the ſun, converging, after refraction at the lens, to *a* and *b*; and ſuppoſe the refraction of the priſms to be ſuch, that in fig. 8. the ray EFR, after refraction at R by the priſm PR, may proceed in the direction RQ; and as all the rays which were proceeding to *a* ſuffer the ſame refraction at the priſm, they will all be refracted to Q; and therefore, inſtead of an image *ab*, which would have been formed by the lens alone, an image Q*c* is formed by thoſe rays which fall on the priſm PR; and for the ſame reaſon, the rays falling on the priſm SR will form an image Q*d*: and in fig. 9. the image of the point *b* is brought to Q, by the priſm PR, and conſequently an image Q*d* is formed by thoſe rays which fall on PR: and for the ſame reaſon, an image Q*c* is formed by the rays falling on SR. Now in both caſes, as the rays EFR, WGR, coming from the two oppoſite limbs of the ſun, and forming the point of contact of the two limbs, proceed in the ſame direction RQ, they muſt thus accompany each other through the eye-glaſs and alſo through the eye, whatever refractive power it has, and therefore to every eye the images muſt appear to touch. Now the angle *a*R*b* is twice the refraction of the priſm, and the angle *a*C*b* is the diameter of the ſun; and as theſe angles are very ſmall, and have the ſame ſubtenſe *ab*, we have the angle *a*R*b* : angle *a*C*b* : : CQ : RQ.— Now as CQ is conſtant, and alſo the angle *a*R*b*, being twice the refraction of the priſm, the angle *a*C*b* varies as RQ. Hence the extent of the ſcale for meaſuring angles becomes the focal length of the object glaſs, and the angle meaſured is in proportion to the diſtance of the priſms from the principal focus of the object glaſs; and the micrometer can meaſure all angles (very ſmall ones excepted, for the reaſon afterwards given*) which do not exceed the ſum of the refractions of the priſms; for the angle *a*C*b*, the diameter of the object to be meaſured, is always *leſs* than the angle *a*R*b*, the ſum of the refractions of the priſms, except when the priſms touch the object glaſs, and then they become *equal*. The ſcale can never be out of adjuſtment, as the point o, where the meaſurement begins, anſwers to the focus of the object glaſs, which is a fixed point for all diſtant objects, and we have only to find the value of the ſcale anſwering to ſome known angle: for inſtance, bring the two limbs of the ſun's images into contact, and meaſure the diſtance of the priſms from the focus, and look in the nautical almanac for the ſun's diameter, and you get the value of the ſcale.

* Next col. Par. laſt.

In fig. 8. the limb Q, of the image Q*c*, is illuminated by the rays falling on the object glaſs between A and F, and of the image Q*d* by thoſe falling between B and G; but in fig. 9. the ſame limbs are illuminated by the rays falling between B and F, A and G reſpectively, and therefore will be more illuminated than in the other caſe; but the difference is not conſiderable in achromatic teleſcopes, on account of the great aperture of the object-glaſs compared with the diſtance FG.

It might be convenient to have two ſets of priſms, one for meaſuring angles not exceeding 36′, and therefore fit for meaſuring the diameters of the ſun and moon, and the lucid parts and diſtances of the cuſps in their eclipſes; and another for meaſuring angles not much greater than 1′, for the conveniency of meaſuring the diameters of the planets. For as QC : QR : : ſum of the refractions of the priſms : angle *a*C*b*, the apparent diameter of the object, it is evident that if you diminiſh the third term, you muſt increaſe the ſecond in the ſame ratio, in order to meaſure the ſame angle; and thus by diminiſhing the refractive angle of the priſms, you throw them further from Q, and conſequently avoid the inconvenience of bringing them near to Q, for the reaſon in the next paragraph; and at the ſame time you will increaſe the illumination in a ſmall degree. The priſms muſt be achromatic, each compoſed of two priſms of flint and crown glaſs, placed with their refracting angles contrariways, otherwiſe the images will be coloured.

In the conſtruction here deſcribed, the angle meaſured becomes evaneſcent when the priſms come to the principal focus of the object glaſs, and therefore o on the ſcale then begins: but if the priſms be placed in the principal focus they can have no effect, becauſe the pencil of rays at the junction of the priſms would then vaniſh, and therefore it is not practicable to bring the two images together to get o on the ſcale. Dr Maſkelyne, therefore, thought of placing another pair of priſms within, to refract the rays *before* they came to the other priſms, by which means the two images would be formed into one before they came to the principal focus, and therefore o on the ſcale could be determined. But to avoid the error ariſing from the multiplication of mediums, he, inſtead of adding another pair of priſms, divided the object glaſs through its centre, and ſliding the ſegments a little it ſeparated the images, and then by the priſms he could form one image very diſtinctly, and conſequently could determine o on the ſcale; for by ſeparating the two ſegments you form two images, and you will ſeparate the two pencils ſo that you may move up the two priſms, and the two pencils will fall on each reſpectively, and the two images may be formed into one. In the inſtrument which Dr Maſkelyne had made, o on the ſcale was choſen to be about $\frac{2}{7}$ of the focal length of the object-glaſs,

appear to coincide: but if we increaſe the refractive power of the eye, then each pencil is brought to a focus, and they croſs each other before the rays come to the retina, conſequently the two limbs on the retina will lap over; and if we diminiſh the refractive power of the eye, then each pencil being brought to a focus beyond the retina, and not croſſing till after they have paſſed it, the two limbs on the retina muſt be ſeparated.

glafs, and each prifm refracted 27′. By this means all angles are meafured down to 0.

In the Philofophical Tranfactions for 1779, Mr Ramfden has defcribed two new micrometers, which he contrived with a view of remedying the defects of the object-glafs micrometer.

1. One of thefe is a *catoptric* micrometer, which, befide the advantage it derives from the principle of reflection, of not being difturbed by the heterogeneity of light, avoids every defect of other micrometers, and can have no aberration, nor any defect arifing from the imperfection of materials or of execution; as the extreme fimplicity of its conftruction requires no additional mirrors or glaffes to thofe required for the telefcope; and the feparation of the image being effected by the inclination of the two fpecula, and not depending on the focus of any lens or mirror, any alteration in the eye of an obferver cannot affect the angle meafured. It has peculiar to itfelf the advantages of an adjuftment, to make the images coincide in a direction perpendicular to that of their motion; and alfo of meafuring the diameter of a planet on both fides of the zero, which will appear no inconfiderable advantage to obfervers who know how much eafier it is to afcertain the contact of the external edges of two images than their perfect coincidence.

A reprefents the fmall fpeculum divided into two equal parts; one of which is fixed on the end of the arm B; the other end of the arm is fixed on a fteel axis X, which croffes the end of the telefcope C. The other half of the mirror A is fixed on the arm D, which arm at the other end terminates in a focket *y*, that turns on the axis X; both arms are prevented from bending by the braces *a a*. G reprefents a double fcrew, having one part *e* cut into double the number of threads in an inch to that of the part *g*: the part *e* having 100 threads in one inch, and the part *g* 50 only. The fcrew *e* works in a nut F in the fide of the telefcope, while the part *g* turns in a nut H, which is attached to the arm B; the ends of the arms B and D, to which the mirrors are fixed, are feparated from each other by the point of the double fcrew preffing againft the ftud *b*, fixed to the arm D, and turning in the nut H on the arm B. The two arms B and D are preffed againft the direction of the double fcrew *eg* by a fpiral fpring within the part *n*, by which means all fhake or play in the nut H, on which the meafure depends, is entirely prevented.

From the difference of the threads on the fcrew at *e* and *g*, it is evident, that the progreffive motion of the fcrew through the nut will be half the diftance of the feparation of the two halves of the mirror; and confequently the half mirrors will be moved equally in contrary directions from the axis of the telefcope C.

The wheel V fixed on the end of the double fcrew has its circumference divided into 100 equal parts, and numbered at every fifth divifion with 5, 10, &c. to 100, and the index I fhows the motion of the fcrew with the wheel round its axis, while the number of revolutions of the fcrew is fhown by the divifions on the fame index. The fteel fcrew at R may be turned by the key S, and ferves to incline the fmall mirror at right angles to the direction of its motion. By turning the finger-head T (fig. 11.), the eye-tube P is brought nearer or farther from the fmall mirror, to adjuft the telefcope to diftinct vifion; and the telefcope itfelf hath a motion round it axis for the conveniency of meafuring the diameter of a planet in any direction. The inclination of the diameter meafured with the horizon is fhown in degrees and minutes by a level and vernier on a graduated circle, at the breech of the telefcope. Micrometer.

"It is neceffary to obferve (fays Mr Ramfden), that, befides the table for reducing the revolutions and parts of the fcrew to minutes, feconds, &c. it may require a table for correcting a very fmall error which arifes from the excentric motion of the half-mirrors. By this motion their centres of curvature will (when the angle to be meafured is large) approach a little towards the large mirror: the equation for this purpofe in fmall angles is infenfible; but when angles to be meafured exceed ten minutes, it fhould not be neglected. Or, the angle meafured may be corrected by diminifhing it in the proportion the verfed fine of the angle meafured, fuppofing the eccentricity radius, bears to the focal length of the fmall mirror."

Mr Ramfden preferred Caffegrain's conftruction of the reflecting telefcope to either the Gregorian or Newtonian; becaufe in the former, errors caufed by one fpeculum are diminifhed by thofe in the other. From a property of the reflecting telefcope (which, he obferves, has not been attended to), that the apertures of the two fpecula are to each other very nearly in the proportion of their focal lengths, it follows, that their aberrations will be to each other in the fame proportion; and thefe aberrations are in the fame direction, if the two fpecula are both concave; or in contrary directions, if one fpeculum is concave and the other convex. In the Gregorian conftruction, both fpecula being concave, the aberration at the fecond image will be the fum of the aberrations of the two mirrors; but in the Caffegrain conftruction, one mirror being concave and the other convex, the aberration at the fecond image will be the difference between their aberrations. By affuming fuch proportions for the *foci* of the fpecula as are generally ufed in the reflecting telefcope, which is about as 1 to 4, the aberration in the Caffegrain conftruction will be to that in the Gregorian as 3 to 5.

2. The other is a *dioptric* micrometer, or one fuited to the principle of refraction. This micrometer is applied to the erect eye-tube of a refracting telefcope, and is placed in the conjugate focus of the firft eye-glafs: in which pofition, the image being confiderably magnified before it comes to the micrometer, any imperfection in its glafs will be magnified only by the remaining eye-glaffes, which in any telefcope feldom exceeds five or fix times. By this pofition alfo the fize of the micrometer glafs will not be the [illegible] part of the area which would be required if it was placed in the object-glafs; and, notwithftanding this great difproportion of fize, which is of great moment to the practical optician, the fame extent of fcale is preferved, and the images are uniformly bright in every part of the field of the telefcope.

Fig. 12. reprefents the glaffes of a refracting telefcope; *xy*, the principal pencil of rays from the object-glafs O; *t t* and *u u*, the axis of two oblique pencils; *a*, the firft eye-glafs; *m*, its conjugate focus, or the place Plate CCXCVI.

Micrometer.

place of the micrometer; *b* the second eye-glass; *c* the third; and *d* the fourth, or that which is nearest the eye. Let *p* be the diameter of the object-glass, *e* the diameter of a pencil at *m*, and *f* the diameter of the pencil at the eye; it is evident, that the axis of the pencils from every part of the image will cross each other at the point *m*; and *e*, the width of the micrometer-glass, is to *p* the diameter of the object-glass as *m o* is to *g o*, which is the proportion of the magnifying power at the point *m*; and the error caused by an imperfection in the micrometer glass placed at *m* will be to the error, had the micrometer been at O, as *m* is to *p*.

Fig. 13. represents the micrometer; A, a convex or concave lens divided into two equal parts by a plane across its centre; one of these semi-lenses is fixed in a frame B, and the other in the frame E; which two frames slide on a plate H, and are pressed against it by thin plates *a a*: the frames B and E are moved in contrary directions by turning the button D; L is a scale of equal parts on the frame B; it is numbered from each end towards the middle with 10, 20, &c. There are two verniers on the frame E, one at M and the other at N, for the convenience of measuring the diameter of a planet, &c. on both sides the zero. The first division on both these verniers coincides at the same time with the two zeros on the scale L; and, if the frame is moved towards the right, the relative motion of the two frames is shown on the scale L by the vernier M; but if the frame B be moved towards the left, the relative motion is shown by the vernier N.—This micrometer has a motion round the axis of vision, for the convenience of measuring the diameter of a planet, &c. in any direction, by turning an endless screw F; and the inclination of the diameter measured with the horizon is shown on the circle *g* by a vernier on the plate V. The telescope may be adjusted to distinct vision by means of an adjusting screw, which moves the whole eye-tube with the micrometer nearer or farther from the object-glass, as telescopes are generally made: or the same effect may be produced in a better manner, without moving the micrometer, by sliding the part of the eye tube *m* on the part *n*, by help of a screw or pinion. The micrometer is made to take off occasionally from the eye tube, that the telescope may be used without it.

Still, however, micrometers remained in several respects imperfect. In particular, the imperfections of the parallel-wire micrometer in taking the distance of very close double stars, are the following.

When two stars are taken between the parallels, the diameters must be included. Mr Herschel informs us, he has in vain attempted to find lines sufficiently thin to extend them across the centres of the stars so that their thickness might be neglected. The single threads of the silk-worm, with such lenses as he uses, are so much magnified that their diameter is more than that of many of the stars. Besides, if they were much less than they are, the power of deflection of light would make the attempt to measure the distance of the centres this way fruitless: for he has always found the light of the stars to play upon those lines and separate their apparent diameters into two parts. Now since the spurious diameters of the stars thus included, as Mr. Herschel assures us, are continually changing according to the state of the air, and the length of time we look at them, we are, in some respect, left at an uncertainty, and our measures taken at different times and with different degrees of attention, will vary on that account. Nor can we come at the true distance of the centres of any two stars, one from another, unless we could tell what to allow for the semidiameters of the stars themselves; for different stars have different apparent diameters, which, with a power of 227, may differ from each other as far as two seconds.

The next imperfection is that which arises from a deflection of light upon the wires when they approach very near to each other; for if this be owing to a power of repulsion lodged at the surface, it is easy to understand, that such powers must interfere with each other, and give the measures larger in proportion than they would have been if the repulsive power of one wire had not been opposed by a contrary power of the other wire.

Another very considerable imperfection of these micrometers is a continual uncertainty of the real zero. Mr Herschel has found, that the least alteration in the situation and quantity of light will affect the zero, and that a change in the position of the wires, when the light and other circumstances remain unaltered, will also produce a difference. To obviate this difficulty, whenever he took a measure that required the utmost accuracy, his zero was always taken immediately after, while the apparatus remained in the same situation it was in when the measure was taken; but this enhances the difficulty, because it introduces an additional observation.

The next imperfection, which is none of the smallest, is that every micrometer that has hitherto been in use requires either a screw or a divided bar and pinion, to measure the distance of the wires or divided image. Those who are acquainted with works of this kind are but too sensible how difficult it is to have screws that shall be perfectly equal in every thread or revolution of each thread; or pinions and bars that shall be so evenly divided as perfectly to be depended upon in every leaf and tooth to perhaps the two, three, or four thousandth part of an inch: and yet, on account of the small scale of those micrometers, these quantities are of the greatest consequence; an error of a single thousandth part inducing in most instruments a mistake of several seconds.

The last and greatest imperfection of all is, that these wire micrometers require a pretty strong light in the field of view; and when Mr Herschel had double stars to measure, one of which was very obscure, he was obliged to be content with less light than is necessary to make the wires perfectly distinct; and several stars on this account could not be measured at all, though otherwise not too close for the micrometer.

Mr Herschel, therefore, having long had much occasion for micrometers that would measure exceeding small distances exactly, was led to bend his attention to the improvement of these instruments; and the result of his endeavours has been a very ingenious instrument called a *lamp-micrometer*, which is not only free from the imperfections above specified, but also possesses the advantages of a very large scale. This instrument is described in the Philosophical Transactions for 1782; and the construction of it is as follows:

ABGCFE

ABGCFE (fig. 14.) is a ftand nine feet high, upon which a femicircular board *qhogp* is moveable upwards or downwards, in the manner of fome fire-fcreens, as occafion may require, and is held in its fituation by a peg *p* put into any one of the holes of the upright piece AB. This board is a fegment of a circle of fourteen inches radius, and is about three inches broader than a femicircle, to give room for the handles *r*D, *e*P, to work. The ufe of this board is to carry an arm L, thirty inches long, which is made to move upon a pivot at the centre of the circle, by means of a ftring, which paffes in a groove upon the edge of the femicircle *pgohq*; the ftring is faftened to a hook at *o* (not expreffed in the figure, being at the back of the arm L), and paffing along the groove from *oh* to *q* is turned over a pulley at *q*, and goes down to a fmall barrel *e*, within the plane of the circular board, where a double-jointed handle *e*P commands its motion. By this contrivance, we fee, the arm L may be lifted up to any altitude from the horizontal pofition to the perpendicular, or be fuffered to defcend by its own weight below the horizontal to the reverfe perpendicular fituation. The weight of the handle P is fufficient to keep the arm in any given pofition; but if the motion fhould be too eafy, a friction fpring applied to the barrel will moderate it at pleafure.

In front of the arm L a fmall flider, about three inches long, is moveable in a rabbet from the end L towards the centre backwards and forwards. A ftring is faftened to the left fide of the little flider, and goes towards L, where it paffes round a pulley at *m*, and returns under the arm from *m*, *n*, towards the centre, where it is led in a groove on the edge of the arm, which is of a circular form, upwards to a barrel (raifed above the plane of the circular board) at *r*, to which the handle *r*D is faftened. A fecond ftring is faftened to the flider, at the right fide, and goes towards the centre, where it paffes over a pulley *n*; and the weight *w*, which is fufpended by the end of this ftring, returns the flider towards the centre, when a contrary turn of the handle permits it to act.

By *a* and *b* are reprefented two fmall lamps, two inches high, $1\frac{1}{2}$ in breadth by $1\frac{1}{4}$ in depth. The fides, back, and top, are made fo as to permit no light to be feen, and the front confifts of a thin brafs fliding door. The flame in the lamp *a* is placed three-tenths of an inch from the left fide, three-tenths from the front, and half an inch from the bottom. In the lamp *b* it is placed at the fame height and diftance, meafuring from the right fide. The wick of the flame confifts only of a fingle very thin lamp cotton-thread; for the fmalleft flame being fufficient, it is eafier to keep it burning in fo confined a place. In the top of each lamp muft be a little flit lengthways, and alfo a fmall opening in one fide near the upper part, to permit air enough to circulate to feed the flame. To prevent every reflection of light, the fide opening of the lamp *a* fhould be to the right, and that of the lamp *b* to the left. In the fliding door of each lamp is made a fmall hole with the point of a very fine needle juft oppofite the place where the wicks are burning, fo that when the fliders are fhut down, and every thing dark, nothing fhall be feen but two fine lucid points of the fize of two ftars of the third or fourth magnitude. The lamp *a* is placed fo that its lucid point may be in the centre of the circular board where it remains fixed. The lamp *b* is hung to the little flider which moves in the rabbet of the arm, fo that its lucid point, in an horizontal pofition of the arm, may be on a level with the lucid point in the centre. The moveable lamp is fufpended upon a piece of brafs faftened to the flider by a pin exactly behind the flame, upon which it moves as a pivot. The lamp is balanced at the bottom by a leaden weight, fo as always to remain upright, when the arm is either lifted above or depreffed below the horizontal pofition. The double-jointed handles *r*D, *e*P, confift of light deal rods, ten feet long, and the loweft of them may have divifions, marked upon it near the end P, expreffing exactly the diftance from the central lucid point in feet, inches, and tenths.

From this conftruction we fee, that a perfon at a diftance of ten feet may govern the two lucid points, fo as to bring them into any required pofition fouth or north preceding or following from 0 to 90° by ufing the handle P, and alfo to any diftance from fix-tenths of an inch to five or fix and twenty inches by means of the handle D. If any reflection or appearance of light fhould be left from the top or fides of the lamps, a temporary fcreen, confifting of a long piece of pafteboard, or a wire frame covered with black cloth, of the length of the whole arm, and of any required breadth, with a flit of half an inch broad in the middle, may be affixed to the arm by four bent wires projecting an inch or two before the lamps, fituated fo that the moveable lucid point may pafs along the opening left for that purpofe.

Fig. 15. reprefents part of the arm L, half the real fize; S the flider; *m* the pulley, over which the cord *xtyz* is returned towards the centre; *v* the other cord going to the pulley *n* of fig. 14. R the brafs piece moveable upon the pin *c*, to keep the lamp upright. At R is a wire rivetted to the brafs piece, upon which is held the lamp by a nut and fcrew. Fig. 16. 17. reprefent the lamps *a*, *b*, with the fliding doors open, to fhow the fituation of the wicks. W is the leaden weight with a hole *d* in it, through which the wire R of fig. 15. is to be paffed when the lamp is to be faftened to the flider S. Fig. 18. reprefents the lamp *a* with the fliding door fhut; *l* the lucid point; and *ik* the openings at the top, and *s* at the fides, for the admiffion of air.

"Every ingenious artift (fays Mr Herfchel) will foon perceive, that the motions of this micrometer are capable of great improvement by the application of wheels and pinions, and other well known mechanical refources; but as the principal object is only to be able to adjuft the two lucid points to the required pofition and diftance, and to keep them there for a few minutes, while the obferver goes to meafure their diftance, it will not be neceffary to fay more upon the fubject.

"I am now to fhow the application of this inftrument. It is well known to opticians and others who have been in the habit of ufing optical inftruments, that we can with one eye look into a microfcope or telefcope, and fee an object much magnified, while the naked eye may fee a fcale upon which the magnified picture is thrown. In this manner I have generally determined the power of my telefcopes; and any one who has acquired a facility of taking fuch obfervations will

will very feldom miftake fo much as one in fifty in determining the power of an inftrument, and that degree of exactnefs is fully fufficient for the purpofe.

"The Newtonian form is admirably adapted to the ufe of this micrometer; for the obferver ftands always erect, and looks in a horizontal direction, notwithftanding the telefcope fhould be elevated to the zenith. Befides, his face being turned away from the object to which his telefcope is directed, this micrometer may be placed very conveniently without caufing the leaft obftruction to the view: therefore, when I ufe this inftrument, I put it at ten feet diftance from the left eye, in a line perpendicular to the tube of the telefcope, and raife the moveable board to fuch a height that the lucid point of the central lamp may be upon a level with the eye. The handles, lifted up, are paffed through two loops faftened to the tube, juft by the obferver, fo as to be ready for his ufe. I fhould obferve, that the end of the tube is cut away, fo as to leave the left eye entirely free to fee the whole micrometer.

"Having now directed the telefcope to a double ftar, I view it with the right eye, and at the fame time with the left fee it projected upon the micrometer: then, by the handle P, which commands the pofition of the arm, I raife or deprefs it fo as to bring the two lucid points to a fimilar fituation with the two ftars; and, by the handle D, I approach or remove the moveable lucid point to the fame diftance of the two ftars, fo that the two lucid points may be exactly covered by or coincide with the ftars. A little practice in this bufinefs foon makes it eafy, efpecially to one who has already been ufed to look with both eyes open.

"What remains to be done is very fimple. With a proper rule, divided into inches and fortieth parts, I take the diftance of the lucid points, which may be done to the greateft nicety, becaufe, as I obferved before, the little holes are made with the point of a very fine needle. The meafure thus obtained is the tangent of the magnified angle under which the ftars are feen to a radius of ten feet; therefore, the angle being found and divided by the power of the telefcope gives the real angular diftance of the centres of a double ftar.

"For inftance, September 25, 1781, I meafured ϵ Herculis with this inftrument. Having caufed the two lucid points to coincide exactly with the ftars centre upon centre, I found the radius or diftance of the central lamp from the eye 10 feet 4.15 inches; the tangent or diftance of the two lucid points 50.6 fortieth parts of an inch; this gives the magnified angle 35', and dividing by the power 460, which I ufed, we obtain 4'' 34''' for the diftance of the centres of the two ftars. The fcale of the micrometer at this very convenient diftance, with the power of 460 (which my telefcope bears fo well upon the fixed ftars that for near a twelvemonth paft I have hardly ufed any other), is above a quarter of an inch to a fecond; and by putting on my power of 932, which in very fine evenings is extremely diftinct, I obtain a fcale of more than half an inch to a fecond, without increafing the diftance of the micrometer; whereas the moft perfect of my former micrometers, with the fame inftrument, had a fcale of lefs than the two thoufandth part of an inch to a fecond.

"The meafures of this micrometer are not confined to double ftars only, but may be applied to any other objects that require the utmoft accuracy, fuch as the diameters of the planets or their fatellites, the mountains of the moon, the diameters of the fixed ftars, &c.

"For inftance, October 22. 1781, I meafured the apparent diameter of α Lyræ; and judging it of the greateft importance to increafe my fcale as much as convenient, I placed the micrometer at the greateft convenient diftance, and (with fome trouble, for want of longer handles, which might eafily be added) took the diameter of this ftar by removing the two lucid points to fuch a diftance as juft to enclofe the apparent diameter. When I meafured my radius, it was found to be twenty-two feet fix inches. The diftance of the two lucid points was *about* three inches, for I will not pretend to *extreme* nicety in this obfervation, on account of the very great power I ufed, which was 6450. From thefe meafures we have the magnified angle 38 10'': this divided by the power gives 0''.355 for the apparent diameter of α Lyræ. The fcale of the micrometer, on this occafion, was no lefs than 8.443 inches to a fecond, as will be found by multiplying the natural tangent of a fecond with the power and radius in inches.

"November 28. 1781, I meafured the diameter of the new ftar; but the air was not very favourable, for this fingular ftar was not fo diftinct with 227 that evening as it generally is with 460: therefore, without laying much ftrefs upon the exactnefs of the obfervation, I fhall only report it to exemplify the ufe of the micrometer. My radius was 35 feet 11 inches. The diameter of the ftar, by the diftance of the lucid points, was 2.4 inches, and the power I ufed 227: hence the magnified angle is found 19', and the real diameter of the ftar 5''.022. The fcale of this meafure .474 millefimals of an inch, or almoft half an inch to a fecond."

In the Philofophical Tranfactions for 1791, a very fimple micrometer for meafuring fmall angles with the telefcope is defcribed by Mr Cavallo; who introduces his defcription with the following obfervations upon the different forts of telefcopical micrometers in ufe. "Thefe inftruments may be divided into two claffes; namely, thofe which have not, and thofe which have, fome movement amongft their parts. The micrometers of the former fort confift moftly of fine wires or hairs, varioufly difpofed, and fituated within the telefcope, juft where the image of the object is formed. In order to determine an angle with thofe micrometers, a good deal of calculation is generally required. The micrometers of the other fort, of which there is a great variety, fome being made with moveable parallel wires, others with prifms, others again with a combination of lenfes, and fo on, are more or lefs fubject to feveral inconveniencies, the principal of which are the following. 1. Their motions generally depend upon the action of a fcrew; and of courfe the imperfections of its threads, and the greater or lefs quantity of loft motion, which is obfervable in moving a fcrew, efpecially when fmall, occafion a confiderable error in the menfuration of angles. 2. Their complication and bulk renders them difficultly applicable to a variety of telefcopes, efpecially to the pocket ones. 3. They do not meafure the angle without fome lofs of time, which is neceffary to turn the

 fcrew,

fcrew, or to move fome other mechanifm. 4. and laftly, They are confiderably expenfive, fo that fome of them coft even more than a tolerably good telefcope."

After having had long in view (our author informs us) the conftruction of a micrometer which might be in part at leaft, if not entirely, free from all thofe objections; he, after various attempts, at laft fucceeded with a fimple contrivance, which, after repeated trials, has been found to anfwer the defired end, not only from his own experience, but from that alfo of feveral friends, to whom it has been communicated.

This micrometer, in fhort, confifts of a thin and narrow flip of mother-of-pearl finely divided, and fituated in the focus of the eye-glafs of a telefcope, juft where the image of the object is formed. It is immaterial whether the telefcope be a refractor or a reflector, provided the eye-glafs be a convex lens, and not a concave one as in the Galilean conftruction.

The fimpleft way of fixing it is to ftick it upon the diaphragm which generally ftands within the tube and in the focus of the eye-glafs. When thus fixed, if you look through the eye-glafs, the divifions of the micrometrical fcale will appear very diftinct, unlefs the diaphragm is not exactly in the focus; in which cafe, the micrometrical fcale muft be placed exactly in the focus of the eye-glafs, either by pufhing the diaphragm backwards or forwards, when that is practicable; or elfe the fcale may be eafily removed from one or the other furface of the diaphragm by the interpofition of a circular piece of paper or card, or by a bit of wax. This conftruction is fully fufficient, when the telefcope is always to be ufed by the fame perfon; but when different perfons are to ufe it, then the diaphragm which fupports the micrometer muft be conftructed fo as to be eafily moved backwards or forwards, though that motion needs not be greater than about a tenth or an eighth of an inch. This is neceffary, becaufe the diftance of the focus of the fame lens appears different to the eyes of different perfons; and, therefore, whoever is going to ufe the telefcope for the menfuration of any angle, muft firft of all unfcrew the tube which contains the eye-glafs and micrometer from the reft of the telefcope, and, looking through the eye-glafs, muft place the micrometer where the divifions of it may appear quite diftinct to his eye.

In cafe that any perfon fhould not like to fee always the micrometer in the field of the telefcope, then the micrometrical fcale, inftead of being fixed to the diaphragm, may be fitted to a circular perforated plate of brafs, wood, or even paper, which may be occafionally placed upon the faid diaphragm.

Mr Cavallo has made feveral experiments to determine the moft ufeful fubftance for this micrometer.—Glafs, which he had fuccefsfully applied for a fimilar purpofe to the compound microfcope, feemed at firft to be the moft promifing; but it was at laft rejected after feveral trials: for the divifions upon it generally are either too fine to be perceived, or too rough; and though with proper care and attention the divifions may be proportioned to the fight, yet the thicknefs of the glafs itfelf obftructs in fome meafure the diftinct view of the object. Ivory, horn, and wood, were found ufelefs for the conftruction of this micrometer, on account of their bending, fwelling, and contracting very eafily; whereas mother-of-pearl is a very fteady fubftance, the divifions upon it may be marked very eafily, and when it is made as thin as common writing paper it has a very ufeful degree of tranfparency.

Micrometer.

Fig. 19. exhibits this micrometer fcale, but fhows it four times larger than the real fize of one, which he has adapted to a three-feet achromatic telefcope that magnifies about 84 times. It is fomething lefs than the 24th part of an inch broad; its thicknefs is equal to that of common writing paper; and the length of it is determined by the aperture of the diaphragm, which limits the field of the telefcope. The divifions upon it are the 200ths of an inch, which reach from one edge of the fcale to about the middle of it, excepting every fifth and tenth divifion, which are longer. The divided edge of it paffes through the centre of the field of view, though this is not a neceffary precaution in the conftruction of this micrometer. Two divifions of the above defcribed fcale in my telefcope are very nearly equal to one minute; and as a quarter of one of thofe divifions may be very well diftinguifhed by eftimation, therefore an angle of one eighth part of a minute, or of $7''\frac{1}{2}$, may be meafured with it.

When a telefcope magnifies more, the divifions of the micrometer muft be more minute; and Mr Cavallo finds, that when the focus of the eye-glafs of the telefcope is fhorter than half an inch, the micrometer may be divided with the 500ths of an inch; by means of which, and the telefcope magnifying about 200 times, one may eafily and accurately meafure an angle fmaller than half a fecond. On the other hand, when the telefcope does not magnify above 30 times, the divifions need not be fo minute: for inftance, in one of Dollond's pocket telefcopes, which when drawn out for ufe is about 14 inches long, a micrometer with the hundredths of an inch is quite fufficient, and one of its divifions is equal to little lefs than three minutes, fo that an angle of a minute may be meafured by it.

"In looking through a telefcope furnifhed with fuch a micrometer (fays our author), the field of view appears divided by the micrometer fcale, the breadth of which occupies about one-feventh part of the aperture; and as the fcale is femitranfparent, that part of the object which happens to be behind it may be difcerned fufficiently well to afcertain the divifion, and even the quarter of a divifion, with which its borders coincide. Fig. 20. fhows the appearance of the field of my telefcope with the micrometer, when directed to the title page of the Philofophical Tranfactions, wherein one may obferve that the thicknefs of the letter C is equal to three-fourths of a divifion, the diameter of the O is equal to three divifions, and fo on.

"At firft view, one is apt to imagine, that it is difficult to count the divifions which may happen to cover or to meafure an object; but upon trial it will be found, that this is readily performed; and even people who have never been ufed to obferve with the telefcope,

Micrometer.

ſcope, ſoon learn to meaſure very quickly and accurately with this micrometer; for ſince every fifth and tenth diviſion is longer than the reſt, one ſoon acquires the habit of ſaying, five, ten, fifteen; and then, by adding the other diviſions leſs than five, completes the reckoning. Even with a teleſcope which has no ſtand, if the object end of it be reſted againſt a ſteady place, and the other end be held by the hand near the eye of the obſerver, an object may be meaſured with accuracy ſufficient for ſeveral purpoſes, as for the eſtimation of ſmall diſtances, for determining the height of a houſe, &c.

"After having conſtructed and adapted this micrometer to the teleſcope, it is then neceſſary to aſcertain the value of the diviſions. It is hardly neceſſary to mention in this place, that though thoſe diviſions meaſure the chords of the angles, and not the angles or arches themſelves, and the chords are not as the arches, yet it has been ſhown by all the trigonometrical writers, that in ſmall angles the chords, arches, ſines, and tangents, follow the ſame proportion ſo very nearly, that the very minute difference may be ſafely neglected: ſo that if one diviſion of this micrometer is equal to one minute, we may ſafely conclude, that two diviſions are equal to two minutes, three diviſions to three minutes, and ſo on. There are various methods of aſcertaining the value of the diviſions of ſuch a micrometer, they being the very ſame that are uſed for aſcertaining the value of the diviſions in other micrometers. Such are, the paſſage of an equatorial ſtar over a certain number of diviſions in a certain time; or the meaſuring of the diameter of the ſun, by computation from the focal diſtance of the object and other lenſes of the teleſcope; the laſt of which, however, is ſubject to ſeveral inaccuracies; but as they are well known to aſtronomical perſons, and have been deſcribed in many books, they need not be farther noticed here. However, for the ſake of workmen and other perſons not converſant in aſtronomy, I ſhall deſcribe an eaſy and accurate method of aſcertaining the value of the diviſions of the micrometer.

"Mark upon a wall or other place the length of ſix inches, which may be done by making two dots or lines ſix inches aſunder, or by fixing a ſix-inch ruler upon a ſtand; then place the teleſcope before it ſo that the ruler or ſix-inch length may be at right angles with the direction of the teleſcope, and juſt 57 feet $3\frac{1}{2}$ inches diſtant from the object glaſs of the teleſcope: this done, look through the teleſcope at the ruler or other extenſion of ſix inches, and obſerve how many diviſions of the micrometer are equal to it, and that ſame number of diviſions is equal to half a degree, or 30′; and this is all that needs be done for the required determination; the reaſon of which is, becauſe an extenſion of ſix inches ſubtends an angle of 30 at the diſtance of 57 feet $3\frac{1}{2}$ inches, as may be eaſily calculated by the rules of plane trigonometry

"In one of Dollond's 14-inch pocket teleſcopes, if the diviſions of the micrometer be the hundredths of an inch, $11\frac{1}{2}$ of thoſe diviſions will be found equal to 30′, or 23 to a degree. When this value has been once aſcertained, any other angle meaſured by any other number of diviſions is determined by the rule of three. Thus, ſuppoſe that the diameter of the ſun ſeen through the ſame teleſcope, be found equal to 12 diviſions, ſay as $11\frac{1}{2}$ diviſions are to 30 minutes, ſo are 12 diviſions to $\left(\frac{12 \times 30'}{11.5}\right)$ 31′.3, which is the required diameter of the ſun.

"Notwithſtanding the facility of this calculation, a ſcale may be made anſwering to the diviſions of a micrometer, which will ſhow the angle correſponding to any number of diviſions to mere inſpection. Thus, for the above-mentioned ſmall teleſcope, the ſcale is repreſented in fig. 21. AB is a line drawn at pleaſure; it is then divided into 23 equal parts, and thoſe diviſions which repreſent the diviſions of the micrometer that are equal to one degree, are marked on one ſide of it. The line then is divided again into 60 equal parts, which are marked on the other ſide of it; and theſe diviſions repreſent the minutes which correſpond to the diviſions of the micrometer: thus the figure ſhows, that ſix diviſions of the micrometer are equal to $15\frac{1}{2}$ minutes, $11\frac{1}{2}$ diviſions are nearly equal to 29 minutes, &c. What has been ſaid of minutes may be ſaid of ſeconds alſo, when the ſcale is to be applied to a large teleſcope.

"Thus far this micrometer and its general uſe have been ſufficiently deſcribed; and mathematical perſons may eaſily apply it to the various purpoſes to which micrometers have been found ſubſervient. But as the ſimplicity, cheapneſs, and at the ſame time the accuracy of this contrivance, may render the uſe of it much more general than that of any other micrometer; and I may venture to ſay, that it will be found very uſeful in the army, and amongſt ſea-faring people, for the determination of diſtances, heights, &c.; I ſhall therefore join ſome practical rules to render this micrometer uſeful to perſons unacquainted with trigonometry and the uſe of logarithms.

"Problem I. The angle, not exceeding one degree, which is ſubtended by an extenſion of one foot, being given, to find its diſtance from the place of obſervation. *N. B.* This extenſion of one foot, or any other which may be mentioned hereafter, muſt be perpendicular to the direction of the teleſcope through which it is obſerved. The diſtances are reckoned from the object-glaſs of the teleſcope; and the anſwers obtained by the rules of this problem, though not exactly true, are however ſo little different from the truth, that the difference ſeldom amounts to more than two or three inches, which may be ſafely neglected.

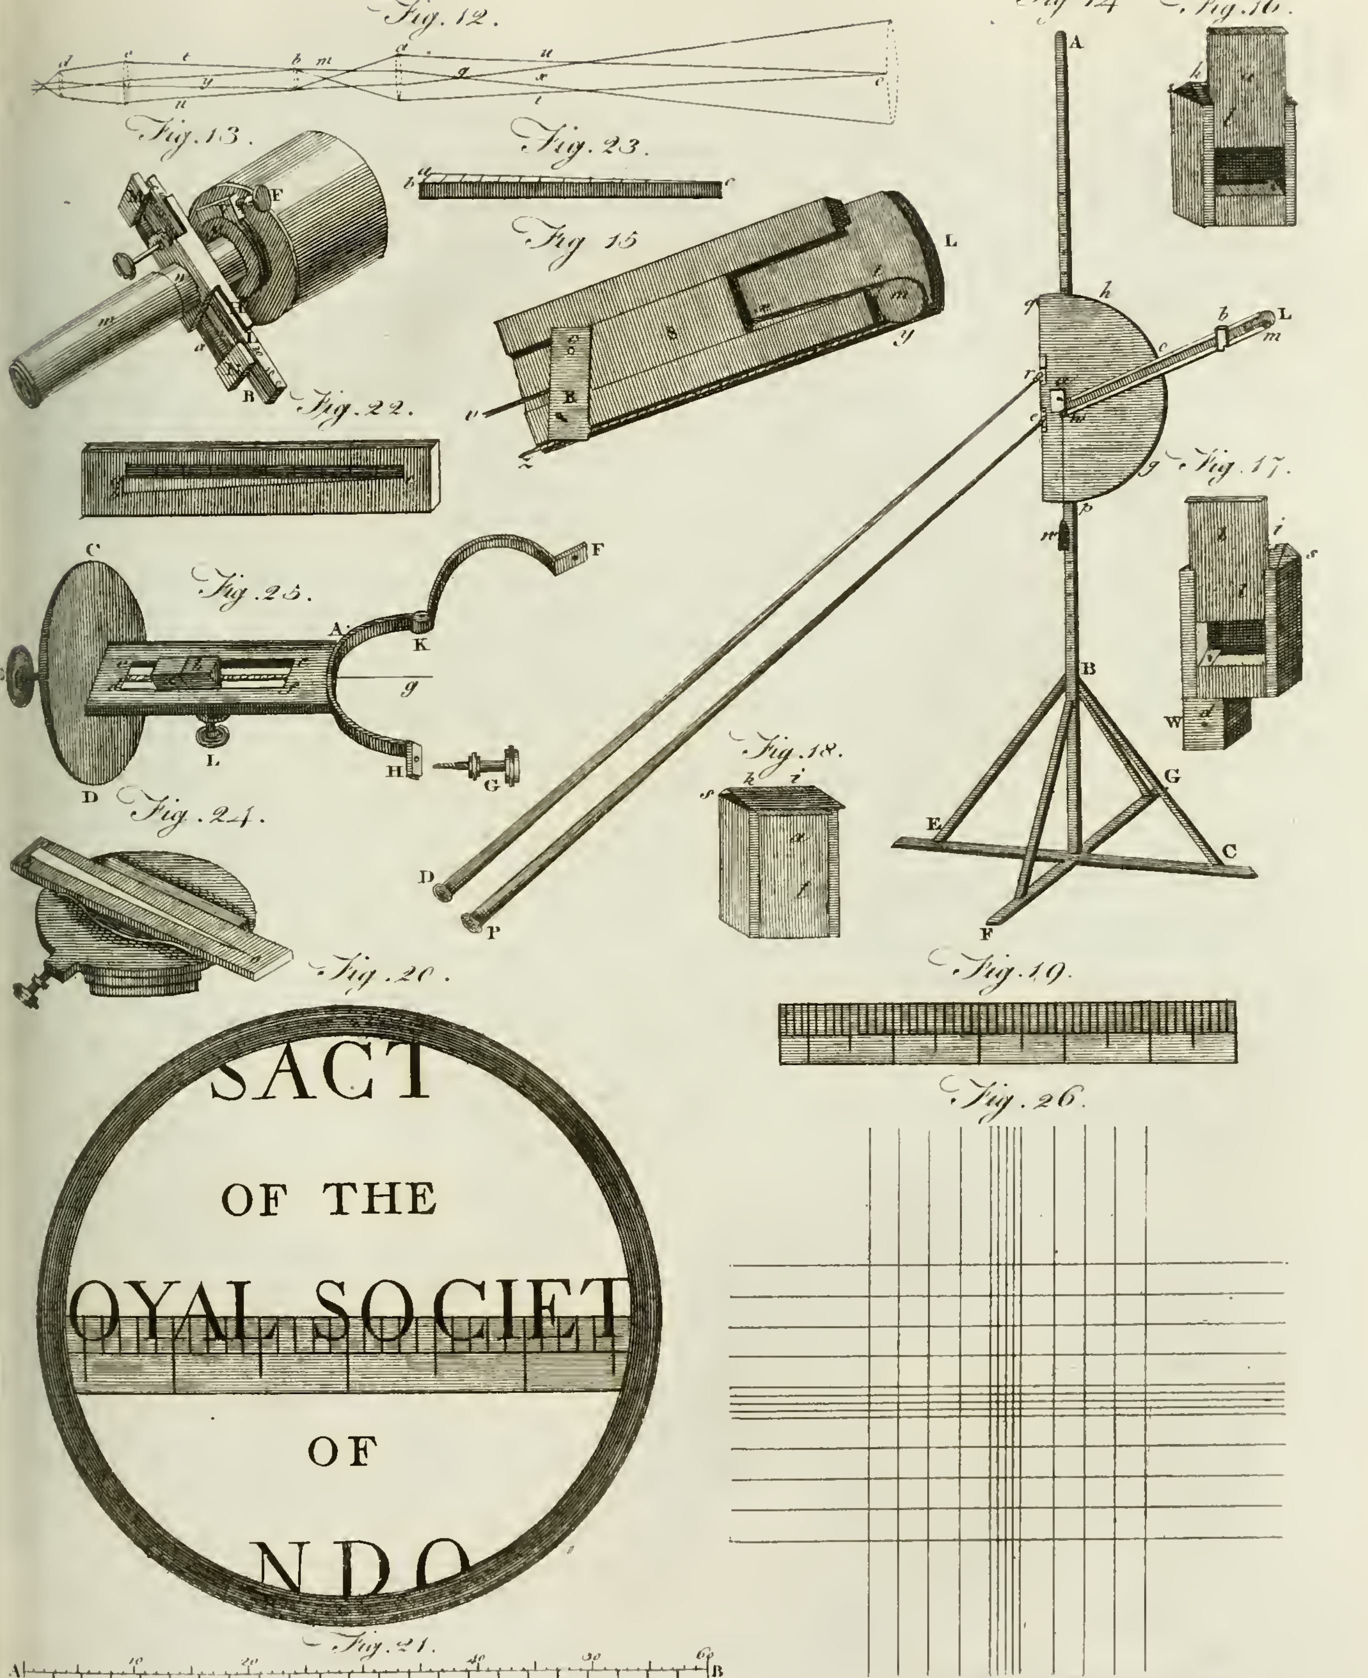
"Rule 1. If the angle be expreſſed in minutes, ſay, as the given angle is to 60, ſo is 687.55 to a fourth proportional, which gives the anſwer in inches.—2. If the angle be expreſſed in ſeconds, ſay, as the given angle is to 3600, ſo is 687.55 to a fourth proportional, which expreſſes the anſwer in inches.—3. If the angle be expreſſed in minutes and ſeconds, turn it all into ſeconds, and proceed as above.

"Example. At what diſtance is a globe of one foot in diameter when it ſubtends an angle of two ſeconds?

$$2 : 3600 :: 687{,}55 : \frac{3600 \times 687.55}{2} = 123759$$

inches, or $10313\frac{1}{4}$ feet, which is the anſwer required.

This



A. Bell Prin. Wal. Sculptor fecit.

"This calculation may be shortened; for since two of the three proportionals are fixed, their product in the first case is 41253, and in the other two cases is 2475180; so that in the first case, viz. when the angle is expressed in minutes, you need only divide 41253 by the given angle; and in the other two cases, viz. when the angle is expressed in seconds, divide 2475180 by the given angle, and the quotient in either case is the answer in inches.

"Problem II. The angle, not exceeding one degree, which is subtended by any known extension, being given, to find its distance from the place of observation.

"Rule. Proceed as if the extension were of one foot by Problem I. and call the answer B; then, if the extension in question be expressed in inches, say, as 12 inches are to that extension, so is B to a fourth proportional, which is the answer in inches; but if the extension in question be expressed in feet, then you need only multiply it by B, and the product is the answer in inches.

"Example. At what distance is a man six feet high, when he appears to subtend an angle of 30″.

"By problem I. if the man were one foot high, the distance would be 82506 inches; but as he is six feet high, therefore multiply 82506 by 6, and the product gives the required distance, which is 495036 inches, or 41253 feet.

"For greater conveniency, especially in travelling, or in such circumstances in which one has not the opportunity of making even the easy calculations required in those problems, I have calculated the following two tables; the first of which shows the distance answering to any angle from one minute to one degree, which is subtended by an extension of one foot; and the second table shows the distance answering to any angle from one minute to one degree, which is subtended by a man, the height of which has been called an extension of six feet; because, at a mean, such is the height of a man when dressed with hat and shoes on. These tables may be transcribed on a card, and may be had always ready with a pocket telescope furnished with a micrometer. Their use is evidently to ascertain distances without any calculation; and they are calculated only to minutes, because with a pocket telescope and micrometer it is not possible to measure an angle more accurately than to a minute.

"Thus, if one wants to measure the extension of a street, let a foot ruler be placed at the end of the street; measure the angular appearance of it, which suppose to be 36′, and in the table you will have the required distance against 36′, which is $95\frac{1}{2}$ feet. Thus also a man who appears to be 49′ high, is at the distance of 421 feet.

II. The Micrometer has not only been applied to telescopes, and employed for astronomical purposes; but there have also been various contrivances for adapting it to MICROSCOPICAL observations. Mr Leeuwenhoek's method of estimating the size of small objects was by comparing them with grains of sand, of which 100 in a line took up an inch. These grains he laid upon the same plate with his objects, and viewed them at the same time. Dr Jurin's method was similar to this; for he found the diameter of a piece of fine silver wire, by wrapping it as close as he could about a pin, and observing how many rings made an inch; and he used this wire in the same manner as Leeuwenhoek used his sand. Dr Hooke used to look upon the magnified object with one eye, while at the same time he viewed other objects placed at the same distance with the other eye. In this manner he was able, by the help of a ruler, divided into inches and small parts, and laid on the pedestal of the microscope, to cast as it were the magnified appearance of the object upon the ruler, and thus exactly to measure the diameter which it appeared to have through the glass; which being compared with the diameter as it appeared to the naked eye, easily showed the degree in which it was magnified. A little practice, says Mr Baker, will render this method exceedingly easy and pleasant.

Mr Martin in his Optics recommended such a micrometer for a microscope as had been applied to telescopes: for he advises to draw a number of parallel lines on a piece of glass, with the fine point of a diamond, at the distance of one-fortieth of an inch from one another, and to place it in the focus of the eye-glass. By this method, Dr Smith contrived to take the exact draught of objects viewed by a double microscope; for he advises to get a lattice, made with small silver wires or squares, drawn upon a plain glass by the strokes of a diamond, and to put it into the place of the image, formed by the object-glass: then by transferring the parts of the object, seen in the squares of the glass or lattice upon similar corresponding squares drawn on paper, the picture may be exactly taken. Mr Martin also introduced into compound microscopes another micrometer, consisting of a screw. See both these methods described in his *Optics*, p. 277.

The mode of actual admeasurement (Mr Adams observes *) is without doubt the most simple that can be used; as by it we comprehend, in a manner, at one glance, the different effects of combined glasses; and as it saves the trouble, and avoids the obscurity, of the usual modes of calculation: but many persons find it exceedingly difficult to adopt this method, because they have not been accustomed to observe with both eyes at once. To obviate this inconvenience, the late Mr Adams contrived an instrument called the *Needle-Micrometer*, which was first described in his *Micrographia Illustrata;* and of which, as now constructed, we have the following description by his son Mr George Adams in the ingenious Essays above quoted.

* *Microscopical Essays*, p. 59.

This micrometer consists of a screw, which has 50 threads to an inch; this screw carries an index, which points to the divisions on a circular plate, which is fixed at right angles to the axis of the screw. The revolutions of the screw are counted on a scale, which is an inch divided into 50 parts; the index to these divisions is a flower-de-luce marked upon the slider, which carries the needle point across the field of the microscope. Every revolution of the micrometer screw measures $\frac{1}{50}$th part of an inch, which is again subdivided by means of the divisions on the circular plate, as this is divided into 20 equal parts, over which the index passes at every revolution of the screw; by which means we obtain with ease the measure of 1000th part of an inch: for 50, the number of threads on the screw in one inch, being multiplied by 20, the divisions on the circular plate are equal to 1000; so that each division on the circular plate shows that the needle has either advanced or receded 1000th part of an inch.

To place this micrometer on the body of the microscope, open the circular part FKH, fig. 25. by taking out the screw G, throw back the semicircle FK, which moves upon a joint at K; then turn the sliding tube of the body of the microscope, so that the small holes which are in both tubes may exactly coincide, and let the needle *g* of the micrometer have a free passage through them; after this, screw it fast upon the body by the screw G. The needle will now traverse the field of the microscope, and measure the length and breadth of the image of any object that is applied to it. But further assistance must be had, in order to measure the object itself, which is a subject of real importance; for though we have ascertained the power of the microscope, and know that it is so many thousand times, yet this will be of little assistance towards ascertaining an accurate idea of its real size; for our ideas of bulk being formed by the comparison of one object with another, we can only judge of that of any particular body, by comparing it with another whose size is known: the same thing is necessary, in order to form an estimate by the microscope; therefore, to ascertain the real measure of the object, we must make the point of the needle pass over the image of a known part of an inch placed on the stage, and write down the revolutions made by the screw, while the needle passed over the image of this known measure; by which means we ascertain the number of revolutions on the screw, which are adequate to a real and known measure on the stage. As it requires an attentive eye to watch the motion of the needle point as it passes over the image of a known part of an inch on the stage, we ought not to trust to one single measurement of the image, but ought to repeat it at least six times; then add the six measures thus obtained together, and divide their sum by six, or the number of trials; the quotient will be the mean of all the trials. This result is to be placed in a column of a table next to that which contains the number of the magnifiers.

Pl. CCX.

By the assistance of the sectoral scale, we obtain with ease a small part of an inch. This scale is shown at fig. 22, 23, 24, in which the two lines *ca*, *cb*, with the side *ab*, form an isosceles triangle; each of the sides is two inches long, and the base still only of one-tenth of an inch. The longer sides may be of any given length, and the base still only of one-tenth of an inch. The longer lines may be considered as the line of lines upon a sector opened to one-tenth of an inch. Hence whatever number of equal parts *ca*, *cb* are divided into, their transverse measure will be such a part of one-tenth as is expressed by their divisions. Thus if it be divided into ten equal parts, this will divide the

the inch into 100 equal parts; the first division next *c* will be equal to 100th part of an inch, because it is the tenth part of one-tenth of an inch. If these lines are divided into twenty equal parts, the inch will be by that means divided into 200 equal parts. Lastly, if *ab*, *ca*, are made three inches long, and divided into 100 equal parts, we obtain with ease the 1000th part. The scale is represented as solid at fig. 23. but as perforated at fig. 22. and 24. so that the light passes thro' the aperture, when the sectoral part is placed on the stage.

To use this scale, first fix the micrometer, fig. 25. to the body of the microscope; then fit the sectoral scale, fig. 24. in the stage, and adjust the microscope to its proper focus or distance from the scale, which is to be moved till the base appears in the middle of the field of view; then bring the needle point *g*, fig. 25. (by turning the screw L) to touch one of the lines *ca*, exactly at the point answering to 20 on the sectoral scale. The index *a* of the micrometer is to be set to the first division, and that on the dial plate to 20, which is both the beginning and end of its divisions; we are then prepared to find the magnifying power of every magnifier in the compound microscope which we are using.

Example. Every thing being prepared agreeable to the foregoing directions, suppose you are desirous of ascertaining the magnifying power of the lens marked N° 4. turn the micrometer screw until the point of the needle has passed over the magnified image of the tenth part of one inch; then the division, where the two indices remain, will show how many revolutions, and parts of a revolution, the screw has made, while the needle point traversed the magnified image of the one-tenth of an inch; suppose the result to be 26 revolutions of the screw, and 14 parts of another revolution, this is equal to 26 multiplied by 20, added to 14; that is, 534,000 parts of an inch.—The 26 divisions found on the straight scale of the micrometer, while the point of the needle passed over the magnified image of one-tenth part of an inch, were multiplied by 20, because the circular plate CD, fig. 25. is divided into 20 equal parts; this produced 520; then adding the 14 parts of the next revolution, we obtain the 534,000 parts of an inch, or five-tenths and 3400 parts of another tenth, which is the measure of the magnified image of one-tenth of an inch, at the aperture of the eye-glasses or at their foci. Now if we suppose the focus of the two eye-glasses to be one inch, the double thereof is two inches; or if we reckon in the 1000th part of an inch, we have 2000 parts for the distance of the eye from the needle point of the micrometer. Again, if we take the distance of the image from the object at the stage at 6 inches, or 6000, and add thereto 2000, double the distance of the focus of the eye-glass, we shall have 8000 parts of an inch for the distance of the eye from the object; and as the glasses double the image, we must double the number 534 found upon the micrometer, which then makes 1068: then, by the following analogy, we shall obtain the number of times the microscope magnifies the diameter of the object; say, as 240, the distance of the eye from the image of the object, is to 800, the distance of the eye from the object; so is 1068, double the measure found on the micrometer, to 3563, or the number of times the microscope magnifies the diameter of the object. By working in this manner, the magnifying power of each lens used with the compound microscope may be easily found, though the result will be different in different compound microscopes, varying according to the combination of the lenses, their distance from the object and one another, &c.

Having discovered the magnifying power of the microscope, with the different object-lenses that are used therewith, our next subject is to find out the real size of the objects themselves, and their different parts: this is easily effected, by finding how many revolutions of the micrometer-screw answer to a known measure on the sectoral scale or other object placed on the stage; from the number thus found, a table should be constructed, expressing the value of the different revolutions of the micrometer with that object lens, by which the primary number was obtained. Similar tables must be constructed for each object lens. By a set of tables of this kind, the observer may readily find the measure of any object he is examining; for he has only to make the needle point traverse over this object, and observe the number of revolutions the screw has made in its passage, and then look into his table for the real measure which corresponds to this number of revolutions, which is the measure required.

Mr Coventry of Southwark has favoured us with the description of a micrometer of his own invention; the scale of which, for minuteness, surpasses every instrument of the kind of which we have any knowledge, and of which, indeed, we could scarcely have formed a conception, had he not indulged us with several of these instruments, graduated as underneath.

The micrometer is composed of glass, ivory, silver, &c. on which are drawn parallel lines from the 10th to the 10,000th part of an inch. But an instrument thus divided, he observes, is more for curiosity than use: but one of those which Mr Coventry has sent us is divided into squares, so small that sixteen million of them are contained on the surface of one square inch, each square appearing under the microscope true and distinct; and though so small, it is a fact, that animalcula are found which may be contained in one of these squares.

The use of micrometers, when applied to microscopes, is to measure the natural size of the object, and how much that object is magnified. To ascertain the real size of an object in the single microscope, nothing more is required than to lay it on the micrometer, and adjust it to the focus of the magnifier, noticing how many divisions of the micrometer it covers. Suppose the parallel lines of the micrometer to be the 1000th of an inch, and the object covers two divisions; its real size is 500ths of an inch; if five, 200ths, and so on.

But to find how much the object is magnified, is not mathematically determined so easy by the single as by the compound microscope: but the following simple method (says Mr Coventry) I have generally adopted, and think it tolerably accurate. Adjust a micrometer under the microscope *o*, say the 100th of an inch of divisions, with a small object on it; if square, the better: notice how many divisions one side of the object covers, suppose 10: then cut a piece

of

Micrometer.

of white paper something larger than the magnified appearance of the object: then fix one eye on the object through the microscope, and the other at the same time on the paper, lowering it down till the object and the paper appear level and distinct: then cut the paper till it appear exactly the size of the magnified object; the paper being then measured, suppose an inch square: Now, as the object under the magnifier, which appeared to be one inch square, was in reality only ten hundredths, or the tenth of an inch, the experiment proves that it is magnified ten times in length, one hundred times in superfices, and one thousand times in cube, which is the magnifying power of the glass; and, in the same manner, a table may be made of the power of all the other glasses.

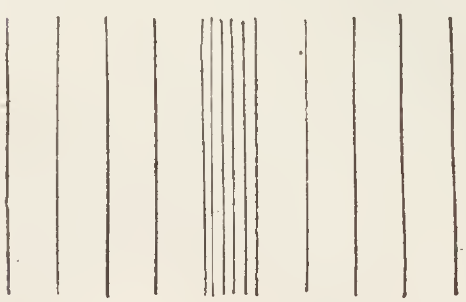
In using the compound microscope, the real size of the object is found by the same method as in the single: but to demonstrate the magnifying power of each glass to greater certainty, adopt the following method.—Lay a two-feet rule on the stage, and a micrometer level with its surface (an inch suppose, divided into 100 parts): with one eye see how many of those parts are contained in the field of the microscope, (suppose 50); and with the other, at the same time, look for the circle of light in the field of the microscope, which with a little practice will soon appear distinct; mark how much of the rule is intersected by the circle of light, which will be half the diameter of the field. Suppose eight inches; consequently the whole diameter will be sixteen. Now, as the real size of the field, by the micrometers, appeared to be only 50 hundredths, or half an inch, and as half an inch is only one 32d part of 16 inches, it shows the magnifying power of the glass to be 32 times in length, 1024 superfices, and 32,768 cube (E).

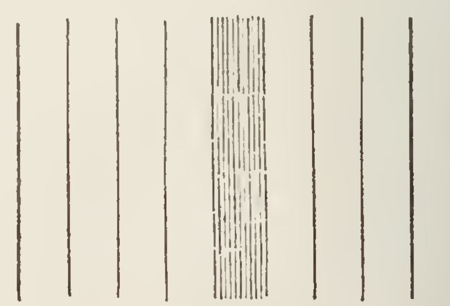
Another way of finding the magnifying power of compound microscopes, is by using two micrometers of the same divisions; one adjusted under the magnifier, the other fixed in the body of the microscope in the focus of the eye-glass. Notice how many divisions of the micrometer in the body are seen in one division of the micrometer under the magnifier, which again must be multiplied by the power of the eye-glass. Example: Ten divisions of the micrometer in the body are contained in one division under the magnifier; so far the power is increased ten times: now, if the eye-glass be one inch focus, such glass will of itself magnify about eight times in length, which, with the ten times magnified before, will be eight times ten, or 80 times in length, 6400 superficies, and 512,000 cube.

"If (says Mr Coventry) these micrometers are employed in the solar microscope, they divide the object into squares on the screen in such a manner as to render it extremely easy to make a drawing of it. And (says he) I apprehend they may be employed to great advantage with such a microscope as Mr Adams's Lucernal; because this instrument may be used either by day or night, or in any place, and gives the actual magnifying power without calculation."

The case with which we have been favoured by Mr Coventry contains six micrometers, two on ivory and four on glass. One of those on ivory is an inch divided into one hundred parts, every fifth line longer than the intermediate one, and every tenth longer still, for the greater ease in counting the divisions under the microscope, and is generally used in measuring the magnifying power of microscopes. The other ivory one is divided into squares of the 50th and 100th of an inch, and is commonly employed in measuring opaque objects.

Those made of glass are for transparent objects, which, when laid on them, show their natural size.—That marked on the brass 100, are squares divided to the 100th of an inch: that marked 5000 are parallel lines forming nine divisions, each division the 1000th of an inch; the middle division is again divided into 5, making divisions to the 5000th of an inch. That marked 10,000 is divided in the same manner, with the middle division divided into 10, making the 10,000th of an inch. Example:





The glass micrometer without any mark is also divided, the outside lines into 100th, the next into 1000th, and the inside lines into the 4000th of an inch: these are again crossed with an equal number of lines in the same manner, making squares of the 100th, 1000th, and 4000th of an inch, thus demonstrating each other's size. The middle square of the 100th of an inch (see fig. 26.) is divided into sixteen squares; now

(E) It will be necessary, for great accuracy, as well as for comparative observations, that the two-feet rule should always be placed at a certain distance from the eye: eight inches would, in general, be a proper distance.

A. Bell Prin. Wal. Sculptor fecit.

now as 1000 fquares in the length of an inch, multiplied by 1000, gives one million in an inch furface; by the fame rule, one of thofe fquares divided into 16 muft be the fixteen millionth part of an inch furface. See fig. 26. which is a diminifhed view of the apparent furface exhibited under the magnifier n° 1 of Wilfon's microfcope. In viewing the fmalleft lines, Mr Coventry ufes n° 2. or 3.; and they are all better feen, he fays, by candle than by day-light.

MICROPUS, BASTARD CUDWEED: A genus of the polygamia neceffaria order, belonging to the fyngenefia clafs of plants; and in the natural method ranking under the 49th order, *Compofitæ*. The receptacle is paleaceous; there is no pappus; the calyx is calyculated; there is no radius of the corolla. The female florets are wrapped in the fcales of the calyx. There are two fpecies, the fupinus and erectus; but only the former is ever cultivated in gardens. It is an annual plant, growing naturally in Portugal, in places near the fea. The root fends out feveral trailing ftalks, about fix or eight inches long, which are garnifhed with fmall, oval, filvery leaves, whofe bafes embrace the ftalks. The flowers come out in clufters from the wings of the ftalks, and are very fmall, and of a white colour. It flowers in June and July; and is frequently preferved in gardens on account of the beauty of its filvery leaves. It is eafily propagated by feed fown in autumn, and requires no other culture but to be kept free from weeds.

MICROSCOPE, an optical inftrument, confifting of lenfes, or mirrors, by means of which fmall objects appear larger than they do to the naked eye. *Single* microfcopes confift of a fingle lens or mirror; or if more lenfes or mirrors be made ufe of, they only ferve to throw light upon the object, but do not contribute to enlarge the image of it. *Double* or *compound* microfcopes are thofe in which the image of an object is compofed by means of more lenfes or mirrors than one.

For the principles on which the conftruction of microfcopes depends, fee OPTICS. In the prefent article, it is intended to defcribe the finifhed inftrument, with all its varied apparatus, according to the lateft improvements; and to illuftrate by proper details its ufes and importance.

I. *Of* SINGLE *Microfcopes.*

THE famous microfcopes made ufe of by Mr Leewenhoeck, were all, as Mr Baker affures us, of the fingle kind, and the conftruction of them was the moft fimple poffible; each confifting only of a fingle lens fet between two plates of filver, perforated with a fmall hole, with a moveable pin before it to place the object on and adjuft it to the eye of the beholder. He informs us alfo, that *lenfes* only, and not *globules*, were ufed in every one of thefe microfcopes.

Plate CXCVII. f. 1. 1. The fingle microfcope now moft generally known and ufed is that called *Wilfon's Pocket Microfcope.* The body is made of brafs, ivory, or filver, and is reprefented by AA, BB. CC is a long fine-threaded male fcrew that turns into the body of the microfcope; D a convex glafs at the end of the fcrew. Two concave round pieces of thin brafs, with holes of different diameters in the middle of them, are placed to cover the abovementioned glafs, and thereby diminifh the aperture when the greateft magnifiers are employed. EE, three thin plates of brafs within the body of the microfcope; one of which is bent femicircularly in the middle, fo as to form an arched cavity for the reception of a tube of glafs, the ufe of the other two being to receive and hold the fliders between them. F, a piece of wood or ivory, arched in the manner of the femicircular plate, and cemented to it. G, the other end of the body of the microfcope, where a hollow female fcrew is adapted to receive the different magnifiers. H, is a fpiral fpring of fteel, between the end G and the plates of brafs, intended to keep the plates in a right pofition and counteract the long fcrew CC. I, is a fmall turned handle, for the better holding of the inftrument, to fcrew on or off at pleafure.

To this microfcope belong fix or feven magnifying glaffes: fix of them are fet in filver, brafs, or ivory, as in the figure K; and marked 1, 2, 3, 4, 5, 6, the loweft numbers being the greateft magnifiers. L is the feventh magnifier, fet in the manner of a little barrel, to be held in the hand for the viewing of any larger object. M, is a flat flip of ivory, called a *flider*, with four round holes through it, wherein to place objects between two pieces of glafs or Mufcovy talc, as they appear at *dddd*. Six fuch fliders, and one of brafs, are ufually fold with this microfcope, fome with objects placed in them, and others empty for viewing any thing that may offer: but whoever pleafes to make a collection, may have as many as he defires. The brafs flider is to confine any fmall object, that it may be viewed without crufhing or deftroying it. N, is a tube of glafs contrived to confine living objects, fuch as frogs, fifhes, &c. in order to difcover the circulation of the blood. All thefe are contained in a little neat box of fifh-fkin or mahogany, very convenient for carrying in the pocket.

When an object is to be viewed, thruft the ivory flider, in which the faid object is placed, between the two flat brafs plates EE: obferving always to put that fide of the flider where the brafs rings are fartheft from the eye. Then fcrew on the magnifying glafs you intend to ufe, at the end of the inftrument G; and looking through it againft the light, turn the long fcrew CC, till your object be brought to fuit your eye; which will be known by its appearing perfectly diftinct and clear. It is moft proper to look at it firft through a magnifier that can fhow the whole at once, and afterwards to infpect the feveral parts more particularly with one of the greateft magnifiers; for thus you will gain a true idea of the whole, and of all its parts. And though the greateft magnifiers can fhow but a minute portion of any object at once, fuch as the claw of a flea, the horn of a loufe, or the like; yet by gently moving the flider which contains the object, the eye will gradually examine it all over.

As objects muft be brought very near the glaffes when the greateft magnifiers are made ufe of, be careful not to fcratch them by rubbing the flider againft them as you move it in or out. A few turns of the fcrew CC will eafily prevent this mifchief, by giving them room enough. You may change the objects in your fliders for any others you think proper, by taking out the brafs rings with the point of a penknife; the talcs will then fall out, if you but turn the fliders; and

and after putting what you please between them, by replacing the brass rings you will fasten them as they were before. It is proper to have some sliders furnished with talcs, but without any object between them, to be always in readiness for the examination of fluids, salts, sands, powders, the farina of flowers, or any other casual objects of such sort as need only be applied to the outside of the talc.

The circulation of the blood may be easiest seen in the tails or fins of fishes, in the fine membranes between a frog's toes, or best of all in the tail of a water-newt. If your object be a small fish, place it within the tube N, and spread its tail or fin along the side thereof: if a frog, choose such an one as can but just be got into your tube; and, with a pen, or small stick, expand the transparent membrane between the toes of the frog's hind foot as much as you can. When your object is so adjusted that no part of it can intercept the light from the place you intend to view, unscrew the long screw CC, and thrust your tube into the arched cavity, quite through the body of the microscope; then screw it to the true focal distance, and you will see the blood passing along its vessels with a rapid motion, and in a most surprising manner.

The third or fourth magnifiers may be used for frogs or fishes: but for the tails of water-newts, the fifth or sixth will do; because the globules of their blood are twice as large as those of frogs or fish. The first or second magnifier cannot well be employed for this purpose; because the thickness of the tube in which the object lies, will scarce admit its being brought so near as the focal distance of the magnifier.

An apparatus for the purpose of viewing opaque objects generally accompanies this microscope; and which consists of the following parts. A brass arm QR, which is screwed at Q, upon the body of the microscope at G. Into the round hole R, any of the magnifiers suitable to the object to be viewed are to be screwed; and under it, in the same ring, the concave polished silver speculum S. Through a small aperture in the body of the microscope under the brass plates EE, is to slide the long wire with the forceps T: This wire is pointed at one of its ends; and so, that either the points or forceps may be used for the objects as may be necessary. It is easy to conceive, therefore, that the arm at R, which turns by a twofold joint at *a* and *b*, may be brought with its magnifier over the object, the light reflected upon it by the application of the speculum, and the true focus obtained by turning of the male screw CC as before directed.—As objects are sometimes not well fixed for view, either by the forceps or point, the small piece shown at N is added, and in such cases answers better: it screws over the point of T; it contains a small round piece of ivory, blackened on one side, and left white upon the other as a contrast to coloured objects, and by a small piece of watch-spring fastens down the objects upon the ivory.

2. *Single Microscope by reflection.* In fig. 2. A is a scroll of brass fixed upright upon a round wooden base B, or mahogany drawer or case, so as to stand perfectly firm and steady. C is a brass screw, that passes through a hole in the upper limb of the scroll into the side of the microscope D, and screws it fast to the said scroll. E is a concave speculum set in a box of brass, which hangs in the arch G by two small screws *ff*, that screw into the opposite sides thereof. At the bottom of this arch is a pin of the same metal, exactly fitted to a hole *h* in the wooden pedestal, made for the reception of the pin. As the arch turns on this pin, and the speculum turns on the end of the arch, it may, by this twofold motion, be easily adjusted in such a manner as to reflect the light of the sun, of the sky, or of a candle, directly upwards through the microscope that is fixed perpendicularly over it; and by so doing may be made to answer many purposes of the large double reflecting microscope. The body of the microscope may also be fixed horizontally, and objects viewed in that position by any light you choose; which is an advantage the common double reflecting microscope has not. It may also be rendered further useful by means of a slip of glass; one end of which being thrust through between the plates where the sliders go, and the other extending to some distance, such objects may be placed thereon as cannot be applied in the sliders: and then, having a limb of brass that may fasten to the body of the microscope, and extend over the projecting glass a hollow ring wherein to screw the magnifiers, all sorts of subjects may be examined with great convenience, if a hole be made in the pedestal, to place the speculum exactly underneath, and thereby throw up the rays of light. The pocket-microscope, thus mounted, says Mr Baker, "is as easy and pleasant in its use; as fit for the most curious examination of the animalcules and salts in fluids, of the farinæ in vegetables, and of the circulation in small animals; in short, is as likely to make considerable discoveries in objects that have some degree of transparency, as any microscope I have ever seen or heard of."

The brass scroll A is now generally made to unscrew into three parts, and pack with the microscope and apparatus into the drawer of a mahogany pocket-case, upon the lid of which the scroll is made to fix when in use.

The opaque apparatus also, as above described, is applicable this way by reflection. It only consists in turning the arm R (fig. 1.), with the magnifier over the concave speculum below (fig. 2), or to receive the light as reflected obliquely from it: the silver speculum screwed into R will then reflect the light, which it receives from the glass speculum, strongly upon the object that is applied upon the wire T underneath.

This microscope, however, is not upon the most convenient construction, in comparison with others now made: it has been esteemed for many years past from its popular name, and recommendation by its makers. Its portability is certainly a great advantage in its favour; but in most respects it is superseded by the microscopes hereafter described.

Fig. 3.

3. *Microscope for Opaque Objects, called the Single Opaque Microscope.* This microscope remedies the inconvenience of having the dark side of an object next the eye, which formerly was an unsurmountable objection to the making observations on opaque objects with any considerable degree of exactness or satisfaction: for, in all other contrivances commonly known, the nearness of the instrument to the object (when glasses that magnify much are used) unavoidably overshadows it so much, that its appearance is rendered obscure and indistinct. And, notwithstanding ways have

Microscope have been tried to point light upon an object, from the sun or a candle, by a convex glass placed on the side thereof, the rays from either can be thrown upon it in such an acute angle only, that they serve to give a confused glare, but are insufficient to afford a clear and perfect view of the object. But this microscope, by means of a concave speculum of silver highly polished, in whose centre a magnifying lens is placed, such a strong and direct light is reflected upon the object, that it may be examined with all imaginable ease and pleasure. The several parts of this instrument, made either of brass or silver, are as follow.

Through the first side A, passes a fine screw B, the other end of which is fastened to the moveable side C. D is a nut applied to this screw, by the turning of which the two sides A and C are gradually brought together. E is a spring of steel that separates the two sides when the nut is unscrewed. F is a piece of brass, turning round in a socket, whence proceeds a small spring tube moving upon a rivet; through which tube there runs a steel wire, one end whereof terminates in a sharp point G, and the other with a pair of pliers H fastened to it. The point and plyers are to thrust into, or take up and hold, any insect or object; and either of them may be turned upwards, as best suits the purpose. I is a ring of brass, with a female screw within it, mounted on an upright piece of the same metal; which turns round on a rivet, that it may be set at a due distance when the least magnifiers are employed. This ring receives the screws of all the magnifiers. K is a concave speculum of silver, polished as bright as possible; in the centre of which is placed a double convex lens, with a proper aperture to look through it. On the back of this speculum a male screw L is made to fit the brass ring I, to screw into it at pleasure. There are four of these concave specula of different depths, adapted to four glasses of different magnifying powers, to be used as the objects to be examined may require. The greatest magnifiers have the least apertures. M, is a round object-plate, one side of which is white and the other black: The intention of this is to render objects the more visible, by placing them, if black, on the white side, or, if white, on the black side. A steel spring N turns down on each side to make any object fast; and issuing from the object-plate is a hollow pipe to screw it on the needle's point G. O, is a small box of brass, with a glass on each side, contrived to confine any living object, in order to examine it: this also has a pipe to screw upon the end of the needle G. P, is a turned handle of wood, to screw into the instrument when it is made use of. Q, a pair of brass pliers to take up any object, or manage it with conveniency. R, is a soft hair-brush for cleaning the glasses, &c. S, is a small ivory box for tales, to be placed, when wanted, in the small brass-box O.

When you would view any object with this microscope, screw the speculum, with the magnifier you think proper to use, into the brass ring I. Place your object, either on the needle G in the pliers H, on the object-plate M, or in the hollow brass box O, as may be most convenient: then holding up your instrument by the handle P, look against the light through the magnifying lens; and by means of the nut D, together with the motion of the needle, by managing its lower end, the object may be turned about, raised, or depressed, brought nearer the glass, or removed farther from it, till you find the true focal distance, and the light be seen strongly reflected from the speculum upon the object, by which means it will be shown in a manner surprisingly distinct and clear; and for this purpose the light of the sky or of a candle will answer very well. Transparent objects may also be viewed by this microscope; only observing, that when such come under examination, it will not always be proper to throw on them the light reflected from the speculum; for the light transmitted through them, meeting the reflected light, may together produce too great a glare. A little practice, however, will show how to regulate both lights in a proper manner.

4. *Ellis's single and Aquatic Microscope.* Fig. 4. represents a very convenient and useful microscope, contrived by Mr John Ellis, author of An Essay upon Corallines, &c. To practical botanists, observers of animalcula, &c. it possesses many advantages above those just described. It is portable, simple in its construction, expeditious, and commodious in use. K, represents the box containing the whole apparatus: it is generally made of fish-skin; and on the top there is a female screw, for receiving the screw that is at the bottom of the pillar A: this is a pillar of brass, and is screwed on the top of the box. D, is a brass pin which fits into the pillar; on the top of this pin is a hollow socket to receive the arm which carries the magnifiers; the pin is to be moved up and down, in order to adjust the lenses to their focal or proper distance from the object. [N. B. In the representations of this microscope, the pin D is delineated as passing through a socket at one side of the pillar A; whereas it is usual at present to make it pass down a hole bored through the middle of the pillar.] E, the bar which carries the magnifying lens; it fits into the socket X, which is at the top of the pin or pillar D. This arm may be moved backwards and forwards in the socket X, and sideways by the pin D; so that the magnifier, which is screwed into the ring at the end E of this bar, may be easily made to traverse over any part of the object that lies on the stage or plate B. FF is a polished silver speculum, with a magnifying lens placed at the centre thereof, which is perforated for this purpose. The silver speculum screws into the arm E, as at F. G, another speculum, with its lens, which is of a different magnifying power from the former. H, the semicircle which supports the mirror I; the pin R, affixed to the semicircle H, passes thro' the hole which is towards the bottom of the pillar A. B, the stage, or the plane, on which the objects are to be placed; it fits into the small dove-tailed arm which is at the upper end of the pillar DA. C, a plane glass, with a small piece of black silk stuck on it; this glass is to lay in a groove made in the stage B. M, a hollow glass to be laid occasionally on the stage instead of the plane glass C. L, a pair of nippers. These are fixed to the stage by the pin at bottom; the steel wire of these nippers slides backwards and forwards in the socket, and this socket is moveable upwards and downwards by means of the joint, so that the position of the object may be varied at pleasure. The object may be fixed in the nippers, stuck on the point, or affixed, by a little gum-water, &c. to the

ivory

ivory cylinder N, which occaſionally ſcrews to the point of the nippers.

To *uſe* this microſcope: Take all the parts of the apparatus out of the box; then begin by ſcrewing the pillar A to the cover thereof; paſs the pin R of the ſemicircle which carries the mirror thro' the hole that is near the bottom of the pillar A; puſh the ſtage into the dove-tail at B, ſlide the pin into the pillar (ſee the N. B. above); then paſs the bar E through the ſocket which is at the top of the pin D, and ſcrew one of the magnifying lenſes into the ring at F. The microſcope is now ready for uſe; and though the enumeration of the articles may lead the reader to imagine the inſtrument to be of a complex nature, we can ſafely affirm that he will find it otherwiſe. The inſtrument has this peculiar advantage, that it is difficult to put any of the pieces in a place which is appropriated to another. Let the object be now placed either on the ſtage or in the nippers L, and in ſuch manner that it may be as nearly as poſſible over the centre of the ſtage: bring the ſpeculum F over the part you mean to obſerve; then throw as much light on the ſpeculum as you can, by means of the mirror I, and the double motion of which it is capable; the light received on the ſpeculum is reflected by it on the object. The diſtance of the lens F from the object is regulated by moving the pin D up and down, until a diſtinct view of it is obtained. The beſt rule is, to place the lens beyond its focal diſtance from the object, and then gradually to ſlide it down till the object appears ſharp and well defined. The adjuſtment of the lenſes to their focus, and the diſtribution of the light on the object, are what require the moſt attention: on the firſt the diſtinctneſs of the viſion depends; the pleaſure ariſing from a clear view of the parts under obſervation is due to the modification of the light. No preciſe rule can be given for attaining accurately theſe points; it is from practice alone that ready habits of obtaining theſe neceſſary properties can be acquired, and with the aſſiſtance of this no difficulty will be found.

5. A very ſimple and convenient microſcope for botanical and other purpoſes, though inferior in many reſpects to that of Mr Ellis, was contrived by the late ingenious Mr Benjamin Martin, and is repreſented at fig. 5. where AB repreſents a ſmall arm ſupporting two or more magnifiers, one fixed to the upper part as at B, the other to the lower part of the arm at C; theſe may be uſed ſeparately or combined together. The arm AB is ſupported by the ſquare pillar IK, the lower end of which fits into the ſocket E of the foot FG; the ſtage DL is made to ſlide up and down the ſquare pillar; H, a concave mirror for reflecting light on the object.—To *uſe* this microſcope, place the object on the ſtage, reflect the light on it from the concave mirror, and regulate it to the focus, by moving the ſtage nearer to or farther from the lens at B. The ivory ſliders paſs through the ſtage; other objects may be fixed in the nippers MN, and then brought under the eye-glaſſes; or they may be laid on one of the glaſſes which fit the ſtage. The apparatus to this inſtrument conſiſts of three ivory ſliders; a pair of nippers; a pair of forceps; a flat glaſs and a concave ditto, both fitted to the ſtage.

The two laſt microſcopes are frequently fitted up with a toothed rack and pinion, for the more ready adjuſtment of the glaſſes to their proper focus.

6. *Withering's portable Botanic Microſcope.* Fig. 6. repreſents a ſmall botanical microſcope contrived by Dr Withering, and deſcribed by him in his *Botanical Arrangements.* It conſiſts of three braſs plates, A, B, C, which are parallel to each other; the wires D and E are rivetted into the upper and lower plates, which are by this means united to each other; the middle plate or ſtage is moveable on the aforeſaid wires by two little ſockets which are fixed to it. The two upper plates each contain a magnifying lens, but of different powers; one of theſe confines and keeps in their places the fine point F, the forceps G, and the ſmall knife H.—To *uſe* this inſtrument, unſcrew the upper lens, and take out the point, the knife, and the forceps; then ſcrew the lens on again, place the object on the ſtage, and then move it up or down till you have gained a diſtinct view of the object, as one lens is made of a ſhorter focus than the other; and ſpare lenſes of a ſtill deeper focus may be had if required. This little microſcope is the moſt portable of any. Its principal merit is its ſimplicity.

7. *Botanical Lenſes or Magnifiers.* The haſte with which botaniſts, &c. have frequently occaſion to view objects, renders an extempore pocket-glaſs indiſpenſably neceſſary. The moſt convenient of any yet conſtructed, appears to be that contrived, in regard to the form of the mounting, by the late Mr Benjamin Martin; and is what he called a *Hand Megalaſcope*, becauſe it is well adapted for viewing all the larger ſort of ſmall objects univerſally, and by only three lenſes it has ſeven different magnifying powers.

Fig. 7. repreſents the caſe with the three frames and lenſes, which are uſually of 1, $1\frac{1}{2}$, and 2 inches focus; they all turn over each other, and ſhut into the caſe, and are turned out at pleaſure.

The three lenſes ſingly, afford three magnifying powers; and by combining two and two, we make three more: for *d* with *e* makes one, *d* with *f* another, and *e* with *f* a third; which, with the three ſingly, make ſix; and laſtly, all three combined together make another; ſo that upon the whole, there are ſeven powers of magnifying with theſe glaſſes only.

When the three lenſes are combined, it is better to turn them in, and look through them by the ſmall apertures in the ſides of the caſe. The eye in this caſe is excluded from extra light; the aberration of the ſuperfluous rays through the glaſſes is cut off; and the eye coincides more exactly with the common axes of the lenſes.

A very uſeful and eaſy kind of microſcope (deſcribed by Joblot, and which has been long in uſe), adapted chiefly for viewing, and confining at the ſame time, any living inſects, ſmall animals, &c. is ſhown at fig. 8. where A repreſents a glaſs tube, about $1\frac{1}{2}$ inches diameter, and 2 inches high. B, a caſe of braſs or wood, containing a ſliding tube, with two or three magnifying glaſſes that may be uſed either ſeparately or combined. In the inſide, at the bottom, is a piece of ivory, black and white on oppoſite ſides, that is occaſionally removed, and admits a point to be ſcrewed into the centre. The cap unſcrews at D, to admit the placing of the object; the proper diſtance of the glaſſes from

Plate CCXCVIII.

from the object is regulated by pulling up or down the brass tube E at top containing the eye-glasses.

This microscope is particularly useful for exhibiting the well-known curious *curculio imperialis*, vulgarly called the *diamond beetle*, to the greatest advantage; for which, as well as for other objects, a glass bottom, and a polished reflector at the top, are often applied, to condense the light upon the object. In this case, the stand and brass-bottom F, as shown in the figure, are taken away by unscrewing.

9. *Mr Lyonet's Single Anatomical Dissecting Microscope.* Fig. 9. represents a curious and extremely useful microscope, invented by that gentleman for the purpose of minute dissections, and microscopic preparations. This instrument must be truly useful to amateurs of the minutiæ of insects, &c. being the best adapted of any for the purposes of dissection. With this instrument Mr Lyonet made his very curious microscopical dissection of the *chenille de saule*, as related in his *Traitè Anatomique de la chenille qui ronge le bois de saule*, 4to.

AB is the anatomical table, which is supported by a pillar NO; this is screwed on the foot CD. The table AB is prevented from turning round by means of two steady pins. In this table or board there is a hole G, which is exactly over the centre of the mirror EF, that is to reflect the light on the object; the hole G is designed to receive a flat or concave glass, on which the objects for examination are to be placed.

RXZ is an arm formed of several balls and sockets, by which means it may be moved in every possible situation; it is fixed to the board by means of the screw H. The last arm IZ has a female screw, into which a magnifier may be screwed as at Z By means of the screw H, a small motion may be occasionally given to the arm IZ, for adjusting the lens with accuracy to its focal distance from the object.

Another chain of balls is sometimes used, carrying a lens to throw light upon the object; the mirror is likewise so mounted, as to be taken from its place at K, and fitted on a clamp, by which it may be fixed to any part of the table AB.

To use the Dissecting Table:—Let the operator sit with his left side near a light window; the instrument being placed on a firm table, the side DH towards the stomach, the observations should be made with the left eye. In dissecting, the two elbows are to be supported by the table on which the instrument rests, the hands resting against the board AB; and in order to give it greater stability (as a small shake, though imperceptible to the naked eye, is very visible in the microscope), the dissecting instruments are to be held one in each hand, between the thumb and two fore-fingers.

II. *Of* Double *Microscopes, commonly called* Compound *Microscopes.*

Double microscopes are so called, from being a combination of two or more lenses.

The particular and chief advantages which the compound microscopes have over the single, are, that the objects are represented under a larger field of view, and with a greater amplification of reflected light.

1. *Culpeper's Microscope.* The compound microscope, originally contrived by Mr Culpeper, is represented at fig. 10. It consists of a large external brass body A, B, C, D, supported upon three scrolls, which are fixed to the stage EF; the stage is supported by three larger scrolls, that are screwed to the mahogany pedestal GH. There is a drawer in the pedestal, which holds the apparatus. The concave mirror *I* is fitted to a socket in the centre of the pedestal. The lower part LMCD of the body forms an exterior tube, into which the upper part of the body ABLM slides, and may be moved up or down, so as to bring the magnifiers, which are screwed on at N, nearer to or farther from the object.

To *use* this microscope: Screw one of the buttons, which contains a magnifying lens, to the end N of the body; place the slider, with the objects, between the plates of the slider-holder. Then, to attain distinct vision, and a pleasing view of the object, adjust the body to the focus of the lens you are using, by moving the upper part gently up and down, and regulate the light by the concave mirror.

For opaque objects, two additional pieces must be used. The first is a cylindrical tube of brass (represented at L, fig. 11.), which fits on the cylindrical part at N of the body. The second piece is the concave speculum *b*; this is to be screwed to the lower end of the aforesaid tube: the upper edge of this tube should be made to coincide with the line which has the same number affixed to it as to the magnifier you are using; *ex. gr.* if you are making use of the magnifier marked 5, slide the tube to the circular line on the tube N that is marked also with N°5. The slider-holder should be removed when you are going to view opaque objects, and a plane glass should be placed on the stage in its stead to receive the object; or it may be placed in the nippers, the pin of which fits into the hole in the stage.

The apparatus belonging to this microscope consists of the following particulars; *viz.* Five magnifiers, each fitted in a brass button; one of these is seen at N, fig. 10. Six ivory sliders, five of them with objects. A brass tube, to hold the concave speculum. The concave speculum in a brass box. A fish pan. A set of glass tubes. A flat glass fitted to the stage. A concave glass fitted to the stage. A pair of forceps. A steel wire, with a pair of nippers at one end and a point at the other. A small ivory cylinder, to fit on the pointed end of the aforesaid nippers. A convex lens, moveable in a brass semicircle; this is affixed to a long brass pin, which fits into a hole on the stage.

The construction of the foregoing microscope is very simple, and it is easy in use; but the advantages of the stage and mirror are too much confined for an extensive application and management of all kinds of objects. Its greatest recommendation is its cheapness; and to those who are desirous of having a compound microscope at a low price, it may be acceptable.

2. *Cuff's Microscope.* The improved microscope next in order is that of Mr Cuff. Besides remedying the disadvantages above mentioned, it contains the addition of an adjusting screw, which is a considerable improvement, and highly necessary to the examination of objects under the best defined appearance from the glasses. It is represented at fig. 11. with the apparatus that usually accompanies it. A, B, C, shows the body of this microscope; which contains an eye-glass at A, a broad lens at B, and

Microscope a magnifier which is screwed on at C. The body is supported by the arm D E, from which it may be removed at pleasure. The arm D E is fixed on the sliding-bar F, and may be raised or depressed to any height within its limits. The main pillar *a b* is fixed in the box *b e;* and by means of the brass foot *d* is screwed to the mahogany pedestal X Y, in which is a drawer containing all the apparatus. O, is a milled-headed screw, to tighten the bar F when the adjusting screw *c g* is used. *p q* Is the stage, or plate, which carries the objects; it has a hole at the centre *n*. G a concave mirror, that may be turned in any direction, to reflect the light of a candle, or the sky, upon the object.

To *use* this microscope: Screw the magnifier you intend to use to the end C of the body, place the slider-holder P in the hole *n*, and the slider with the object between the plates of the slider-holder; set the upper edge of the bar D E to coincide with the divisions which correspond to the magnifier you have in use, and pinch it by the milled nut; now reflect a proper quantity of light upon the object, by means of the concave mirror G, and regulate the body exactly to the eye and the focus of the glasses by the adjusting screw *c g*.

To view *opaque* objects, take away the slider-holder P, and place the object on a flat glass under the centre of the body, or on one end of the jointed nippers *o p*. Then screw the silver concave speculum *h* to the end of the cylinder L, and slide this cylinder on the lower part of the body, so that the upper edge thereof may coincide with the line which has the same mark with the magnifier that is then used; reflect the light from the concave mirror G to the silver speculum, from which it will again be reflected on the object. The glasses are to be adjusted to their focal distance as before directed.

The *apparatus* consists of a convex lens H, to collect the rays of light from the sun or a candle, and condense them on the object. L a cylindrical tube, open at each side, with a concave speculum screwed to the lower end *h*. P the slider-holder: this consists of a cylindrical tube, in which an inner tube is forced upwards by a spiral spring; it is used to receive an ivory slider K, which is to be slid between the plates *h* and *i*. The cylinder P fits the hole *n* in the stage; and the hollow part at *k* is designed to receive a glass tube. R is a brass cone, to be put under the bottom of the cylinder P, to intercept occasionally some of the rays of light. S a box containing a concave and a flat glass, between which a small living insect may be confined: it is to be placed over the hole *n*. T a flat glass, to lay any occasional object upon; there is also a concave one for fluids. O is a long steel wire, with a small pair of pliers at one end, and a point at the other, designed to stick or hold objects; it slips backwards and forwards in the short tube *o;* the pin *p* fits into the hole of the stage. W a little round ivory box, to hold a supply of talc and rings for the sliders. V a small ivory cylinder, that fits on the pointed end of the steel wire: it is designed for opaque objects. Light-coloured ones are to be stuck upon the dark side, and *vice versa*. M a fish-pan, whereon to fasten a small fish, to view the circulation of the blood: the tail is to be spread across the oblong hole *k* at the small end, and tied fast, by means of a riband fixed thereto; the knob *l* is to be shoved through the slit made in the stage, that the tail may be brought under the magnifier.

3. This microscope has received several material improvements from Mr Martin, Mr Adams, &c. By an alteration, or rather an enlargement, of the body of the tube which contains the eye-glasses, and also of the eye-glasses themselves, the field of view is made much larger, the mirror below for reflecting light is made to move upon the same bar with the stage; by which means the distance of it from the stage may be very easily and suitably varied. A condensing glass is applied under the stage in the slider-holder, in order to modify and increase the light that is reflected by the mirrors below from the light of a candle or lamp. It is furnished also with two mirrors in one frame, one concave and the other plane, of glass silvered; and by simply unscrewing the body, the instrument, when desired, may be converted into a single microscope. Fig. 12. is a representation of the instrument thus improved; and the following is the description of it, as given by Mr Adams in his Essays.

A B represents the body of the microscope, containing a double eye-glass and a body-glass: it is here shown as screwed to the arm C D, from whence it may be occasionally removed, either for the convenience of packing, or when the instrument is to be used as a single microscope.

The eye glasses and the body glasses are contained in a tube which fits into the exterior tube A B; by pulling out a little this tube when the microscope is in use, the magnifying power of each lens is increased.

The body A B of the microscope is supported by the arm C D; this arm is fixed to the main pillar C F, which is screwed firmly to the mahogany pedestal G H; there is a drawer to this pedestal, which holds the apparatus.

N I S, The plate or stage which carries the slider-holder K L: this stage is moved up or down the pillar CF, by turning the milled nut M; this nut is fixed to a pinion, that works in a toothed rack cut on one side of the pillar. By means of this pinion, the stage may be gradually raised or depressed, and the object adjusted to the focus of the different lenses.

K L is a slider-holder, which fits into a hole that is in the middle of the stage N I S; it is used to confine and guide either the motion of the sliders which contain the objects, or the glass tubes that are designed to confine small fishes for viewing the circulation of the blood. The sliders are to be passed between the two upper plates, the tubes through the bent plates.

L is a brass tube, to the upper part of which is fixed the condensing lens before spoken of; it fits into the under part of the slider-holder K L, and may be set at different distances from the object, according to its distance from the mirror or the candle.

O is the frame which holds the two reflecting mirrors, one of which is plane, the other concave. These mirrors may be moved in various directions, in order to reflect the light properly, by means of the pivots on which they move, in the semicircle Q S R, and the motion of the semicircle itself on the pin S: the concave mirror generally answers best in the day-time; the plane mirror combines better with the condensing

 lens,

Microscope lens, and a lamp or candle. At D there is a socket for receiving the pin of the arm Q (fig. 31.), to which the concave speculum, for reflecting light on opaque objects, is fixed. At S is a hole and slit for receiving either the nippers L (fig. 31. Pl. ccci.) or the fish-pan I; when these are used, the slider-holder must be removed. T, a hole to receive the pin of the convex lens M, fig. 31.

To *use* this microscope: Take it out of the box. Screw the body into the round end of the upper part of the arm C D. Place the brass sliders, which contain the magnifiers, into the dove-tailed slit which is on the under side of the aforesaid arm, as seen at E, and slide it forwards until the magnifier you mean to use is under the centre of the body: opposite to each magnifier in this slit there is a notch, and in the dove-tailed part of the arm C D there is a spring, which falls into the above-mentioned notch, and thus makes each magnifier coincide with the centre of the body. Pass the ivory slider you intend to use between the upper plates of the slider-holder KL, and then reflect as strong a light as you can on the object by means of one of the mirrors; after this, adjust the object to the focus of the magnifier and your eye, by turning the milled screw M, the motion of which raises and depresses the stage N I S. The degree of light necessary for each object, and the accuracy required in the adjustment of the lenses to their proper focal distance from the object will be easily attained by a little practice.

When *opaque* objects are to be examined, remove the slider-holder, and place the object on a flat glass, or fix it to the nippers L, the pin of these fit into the hole on the stage; screw the concave speculum R into the arm Q (fig. 31.), and then pass the pin of this arm through the socket D, fig. 12. the light is now to be reflected from the concave mirror to the silver speculum, and from this down on the object. No exact rule can be given for reflecting the light on the object; we must therefore refer the reader to the mother of all aptness, practice. The speculum must be moved lower or higher, to suit the focus of the different magnifiers and the nature of the object.

The foregoing directions apply equally to the using of this instrument as a *single microscope;* with this difference only, that the body AB is then removed, and the eye is applied to the upper surface of the arm CD, exactly over the magnifiers.

This microscope is sometimes made with the following *alterations*, which are supposed to make it still more convenient and useful. The arm CD that carries the body and magnifiers is made both to turn on a pin, and to slide backwards and forwards in a socket at C; so that, instead of moving the objects below on the stage, and disturbing them, the magnifiers are more conveniently brought over any part of the objects as desired. The condensing glass is made larger, and slides upon the square bar CF quite distinct from the stage, like the mirrors below; and it is thereby made useful for any other objects that may be applied on glasses fitted to the stage, as well as those put into the slider-holder K. It is thereby not confined to this stage alone, as in the preceding. When the body AB is taken away, the arm CD may be slipt away from its bar, with the magnifiers, and the forceps, wire, and joint, applied to it; and it thereby serves the purpose of a small hand single or opaque microscope, for any object occasionally applied to this wire. The magnifiers in the slider E are mounted in a wheel case, which perhaps prevents its being in the way so much as the long slider E before described.—This contrivance is represented at X, fig. 12.

4. *Martin's New Universal Compound Microscope.*—This instrument was originally constructed by the late Mr B. Martin, and intended to comprise all the uses and advantages of the single, compound, opaque, and aquatic microscopes. The following is a description of it as now made, with a few alterations, chiefly suggested (we are told) by Mr Jones of Holborn.

Fig. 13. is a representation of the instrument placed up for use. A, B, C, D, is the body of the microscope: which consists of four parts, viz. AB the eye-piece, or that containing the eye-glasses, and is screwed into C, which is a moveable or sliding tube on the top; this inner tube contains the body-glass screwed into its lower part. D is the exterior tube or case, in which the other slides up and down in an easy and steady manner. This motion of the tube C is useful to increase or decrease the magnifying power of the body-glass when thought necessary, as before mentioned. E is a pipe or snout screwed on to the body of the microscope D, and at its lower part, over the several magnifying lenses hereafter described. FGHI is the square stem of the microscope, upon which the stage R moves in an horizontal position, upwards or downward, by means of the fine rackwork of teeth and pinion. KL is a strong solid joint and pillar, by which the position of the instrument is readily altered from a vertical one to an oblique or to a perfectly horizontal one, as may be required: it is thus well adapted to the ease of the observer either sitting or standing; and as it is very often convenient to view objects by direct unreflected light, when the square stem FI is placed in an horizontal position for this purpose, the mirror T is then to be taken off in order to prevent the obstruction of the rays. M is a circular piece of brass, serving as a base to the pillar. NOP, the tripod or foot by which the whole body of the microscope is steadily supported; it folds up when packed into the case. W is a brass frame, that contains the condensing lens, and acts in conjunction with the large concave and plane mirrors below at T; the reflected rays from which, either of the common light or of that of a candle or lamp, it agreeably modifies, and makes steady in the field of view. Plate CCXCIX.

The particulars of the apparatus to this microscope are as follow: Q is a circular brass box, containing six magnifiers or object lenses, numbered 1, 2, 3, 4, 5, 6; the digits of which appear severally through a small round hole in the upper plate of it. To the upper side is fixed a small circle of brass, by which it is connected with, and screwed into, the round end of the arm *abcd;* which is a long piece of brass, and moves through either by teeth or pinion, or not, as may be desired, in *ef;* which is a socket on the upper part of the pillar, and admits, with a motion both easy and steady, the brass arm. R is a fixed stage, upon which the objects to be viewed are to be placed: it is firmly fastened to the square pillar, which is moved by the rackwork. In the middle is a large circular hole, for

 receiving

receiving concave glasses, with fluids, &c. it has also a sliding spring-frame to fasten down slips of glass or other things: at *a b c* are three small sockets or holes, intended to receive several parts of the apparatus. S is the refractor, or illuminating lens, for converging the sun's rays upon opaque objects laid upon the stage R. To this purpose it moves on a semicircle upon a long shank *g*, in a spring socket *h*, in the arm *i*; this arm moving every way by a stout pin *k* in the socket *a* of the stage. In this manner it is easily adjusted to any position of the sun, candle, &c.—T, the reflecting-glass frame, containing a concave and plane speculum, which is moved upon the square pillar by the hand. The use of it is to illuminate all transparent objects that are applied to the stage above.

Fig. 14. n° 1. is an auxiliary moveable stage: which by means of a pin *b* is placed in the hole *a* of the stage R, and can be moved in an horizontal direction over the whole field of the stage. In this stage, there are three circular holes with shouldered bottoms; a large one in the middle, and on each side a small one, for the reception of the three following necessary articles: n° 2. a watch glass to be placed in the large hole, to hold fluids containing animalcules, &c.; a circular piece of ivory, n° 3 one side of which is black, the other white, to support opaque objects of different contrasted colours; and circular plane and concave glasses, n° 4. for extemporaneous transparent objects.—The same use is made of the other small hole as of the large one, only in a lesser degree, to receive small concave glasses, plates, &c.

N° 5.* is the silvered speculum, called a *Liberkhun*, which makes the single opaque microscope, by being screwed to the slider *abcd* (fig. 13.) in room of the box of lenses Q, and the body AE above it. The chief use of this is to view very small objects strongly illuminated near the compounded focus of the mirror T (fig. 13.) N° 6. is the forceps or pliers, for holding such kind of objects, and by which they can be applied very readily to the focus of the lens in the liberkhun. They have a motion all ways by means of the spring socket *a*, the joint *b*, and the shank *c*: they are placed in the socket *c* of the fixed stage R (fig. 13.) N° 7. is a small piece of ivory, to be placed upon the pointed end of the pliers: it is black upon one side, and white upon the other, to receive opaque objects.

* Or that adjoining to n° 8. (the n° having been omitted by the engraver).

N° 8. is a liberkhun of a larger size than that first mentioned, with a hole in its centre: this is screwed into n° 9. the hole *a* of a brass ring, fastened to a long wire *b*; which moves up and down in the spring socket *b* of the stage R, in which it also moves sideways; and thus, with the body AE above, forms an *aquatic compound microscope* for showing all sorts of objects in water and other fluids placed under it in the watch-glass n° 2. on the stage.

N° 11. is a cone, with a proper aperture *a* to exclude superfluous light, that would disturb a critical observation of a curious object; it is placed on the under side of the fixed stage R.

N° 12. is what is usually called a bug-box, consisting of a concave glass with a plane one screwed over it; by means of which a bug, louse, flea, &c. may be secured and viewed alive. It is to be placed on either of the stages R (fig. 13.), or n° 1 (fig. 14.)

N° 13. is the fish-pan. In the long concave body *ab*, a fish may be so confined by the ribband *c*, that the transparent tail may be in part over the slit or hole at *a*. In this state, it is placed on the stage R, with the pin *d* in the hole *c* of the stage, and moves freely and horizontally for viewing the circulation of the blood, &c.

N° 14. is the slider-holder that is placed on the stage R: it receives the sliders and tubes when filled with transparent objects, to be viewed either by the compound or single microscope.

N° 15. represents the ivory slider, to hold the objects between the talcs as usual.

N° 16. is a useful auxiliary slider framed in brass. In this slider small concave glasses are cemented; and a slip of plane glass slides over them; by which any small living object, as mites, &c. may be confined without injury, and deliberately viewed.

N° 17. represents a set of glass tubes, three in number, one within another; they are useful for small tadpoles, water-newts, eels, &c. when the circulation of the blood is to be viewed. There is a small hole at one end of each tube, that serves to admit the air; for when they are filled with water, the other end is stopped with a cork.

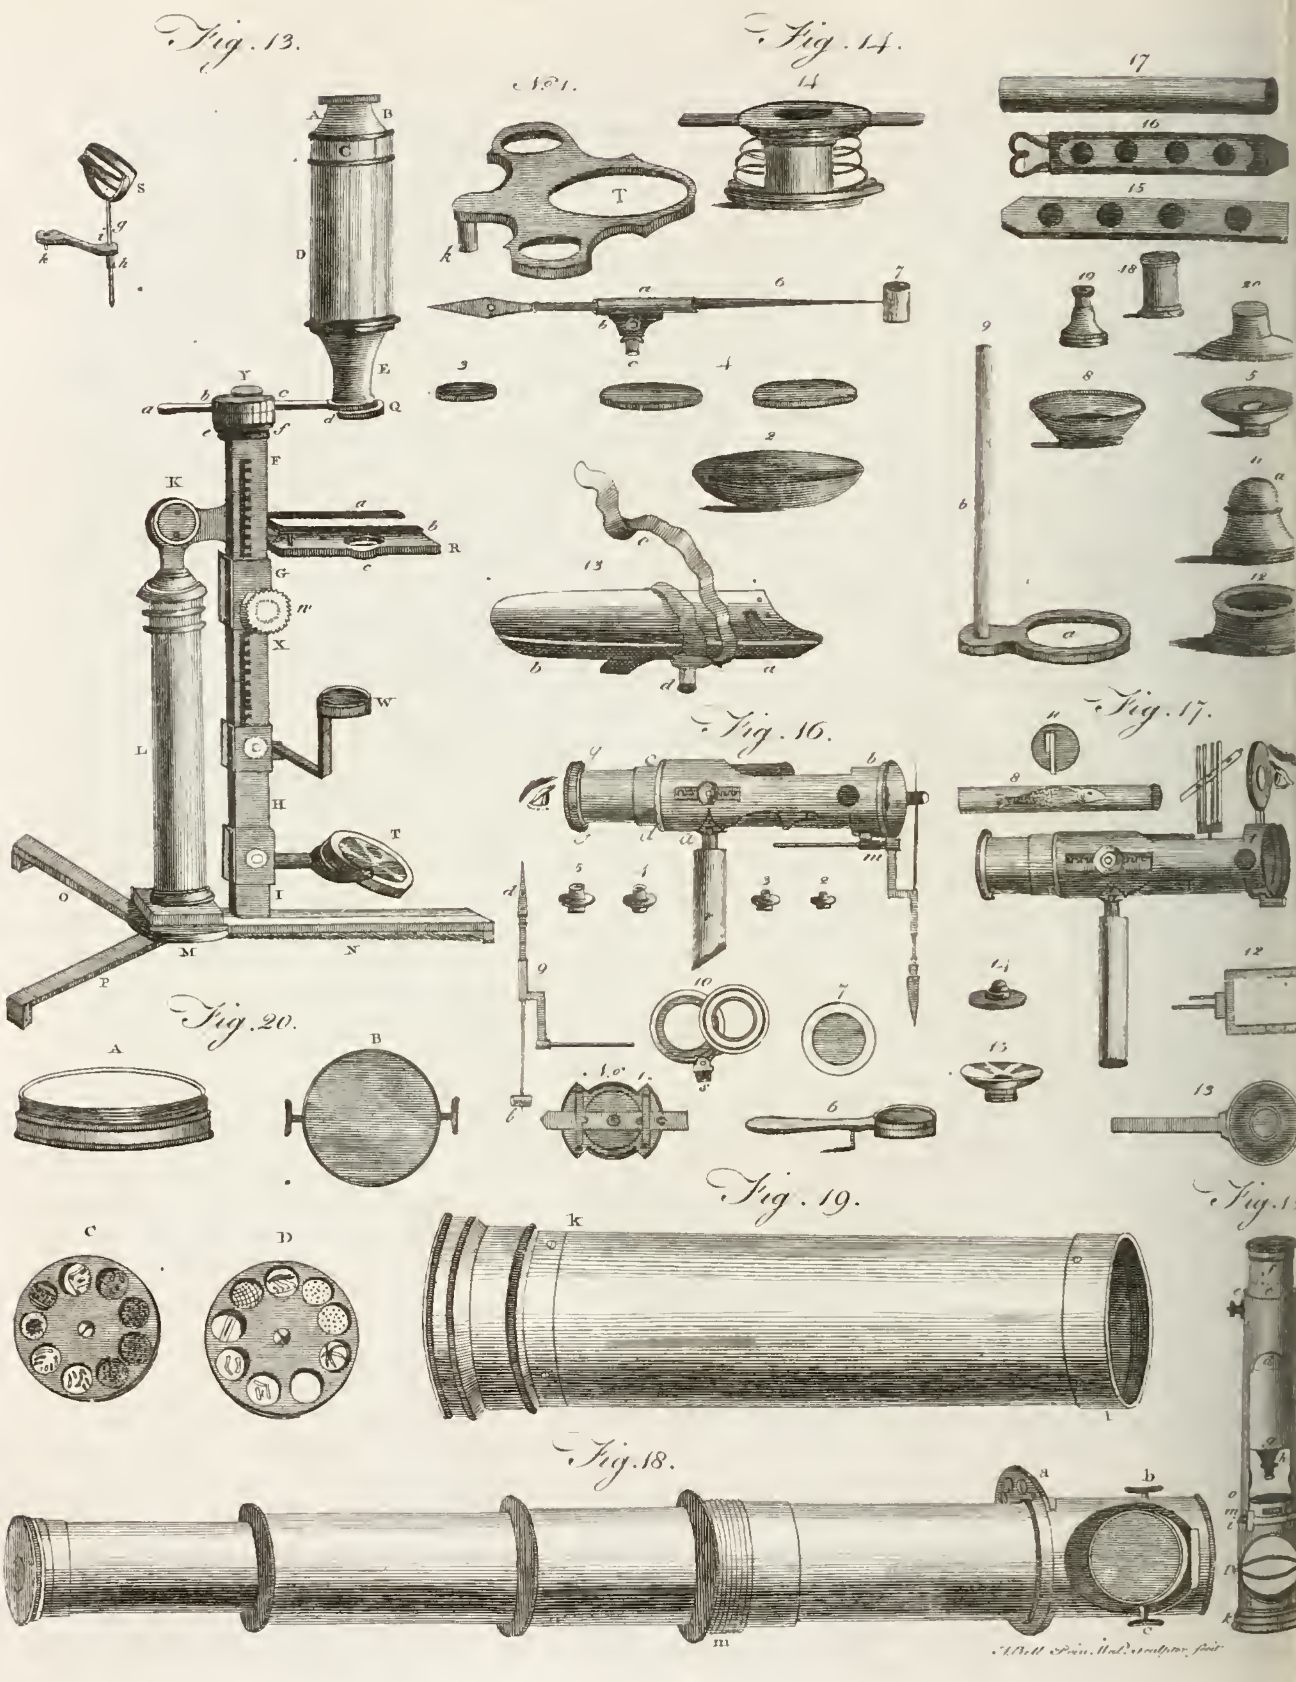
N° 18. is a small ivory box, containing spare talcs and wires, to supply the sliders with occasionally.

N° 19. a brass cell or button, containing a very small lens, properly set between two small plates of brass, that it may be brought very near to the object when viewed therewith as a single microscope. This magnifier is screwed into the same hole as the wheel of six magnifiers Q are (fig. 13).

N° 20. is a lens, adapted to view and examine objects, by magnifying them sufficiently, so as to be able to apply them to the microscope for inspection: on this account it is called the *explorator*.

The preceding are the chief articles of the apparatus; which, on account of their being somewhat different from what is applied to other microscopes, we have been thus particular in describing. In using the microscope, and while viewing objects by either the single or compound instrument, the focal distances of the magnifiers are made perfectly exact by turning of the pinion at the nut *w*, in one way or the other, very gently in the teeth of the rack-work at X (fig. 13).

It is necessary that the centres of the object lenses or magnifiers, the stage, and the mirrors at bottom, should all be in a right line in the axis of the microscope, when opaque objects are to be viewed, that are placed upon the ivory piece n° 7, or the forceps n° 6. and all other such sort of objects which are placed in the centre of the stage R, or slider-holder n° 14: But when aquatic or living objects, which require a great space to move in, are to be viewed, then the horizontal motion at *ef* (fig. 13.) is made use of, and the view may be extended laterally over the whole of the diameter of the object or field of view; and by putting the arm *abcd* forward or backward in its socket *ef*, the view is extended in the contrary direction equally well; and in this manner the whole of



A. Bell Prin. Wal. Sculptor fecit

of the objects may be viewed without the leaft difturbance.

As the brafs arm *abcd* may be brought to the height of three or four inches above the ftage R; fo, by means of the rack-work motion of the ftage, a lens of a greater focal diftance than the greateft in the wheel Q may be occafionally applied in place of the wheel, and thereby the larger kind of objects be viewed; the inftrument becoming, in this cafe, what is called a *megalafcope*.

In viewing moving living objects, or even fixed ones, when nice motions are requifite, a rack-work and pinion is often applied to the arm *abcd:* the arm is cut out with teeth; and the pinion, as fhown at Y, is applied to work it. This acts but in one direction; and, in order to produce an equally neceffary motion perpendicular to this, rack-work and pinion is applied tangent-wife to the ftage, which is then jointed.

What has been related above refpects the conftruction of thofe denominated *parlour* microfcopes, in contradiftinction to thofe which are portable: their dimenfions, however, have been confiderably reduced by opticians, in order to render them fit for the pocket; and as they are for the moft part conftructed on nearly the fame principles as thofe which have been already defcribed, what has been faid will fufficiently inftruct our readers in ufing any pocket microfcope whatever. Only it may be obferved, that in thofe reduced inftruments, both the field of view and the magnifying power are proportionably diminifhed.

We fhall conclude the account of this fort of microfcope with defcriptions of a very portable pocket apparatus of microfcopic inftruments, and of a new microfcopic pocket-telefcope, both invented by the late Mr B. Martin, and fince made by moft inftrument-makers in London.

The former is reprefented at fig. 15. It confifts of two parts, viz. the body *ab*, and the pedeftal *ik*, which is joined by a fcrew at the part between *b* and *i*. It confifts of three cylindric tubes, viz. (1.) the exterior tube, or cafe *ab;* (2.) a middle tube *cb;* and (3.) the interior tube *fg*.—The middle tube *cd* is the adjufter; and is connected with the outer tube by the rack-work of teeth and pinion, as fhown at *e:* by which means it is moved up and down at pleafure through the fmalleft fpace, and carries with it the internal tube *fg*. The interior tube *fg* receives on its lower part at *b* the feveral capfules or boxes 2, 3, 4, 5, (fig. 16.) which contain the object lenfes or magnifiers.

The method of *ufing* this compound microfcope in the perpendicular pofition, is as follows. The ftage n° 1. is put within the exterior tube at *b*. Under the fprings are applied the four ivory fliders, which contain a variety of tranfparent objects; then move the interior tube *fg* up and down with the hand, till you difcern the object in the flider, and there let it reft. After this, turn the pinion at *e* very tenderly one way or the other, till you obtain a perfect view of the tranfparent objects properly illuminated, from a mirror contained in the pedeftal or ftand *ik*, fufpended upon, and moveable about, the points of two fcrews *(ll)*. N° 6. (fig. 16.) reprefents a moveable ftage, which is placed in the fpring focket *m*. It contains a concave glafs, for the reception of animalcules in fluids; and has the advantage of bringing any part into view by moving the handle at *n*. If living and moving objects are required to be fhown, they muft be confined in the concave, by putting a glafs cover, n° 7. upon the ftage; and then a fmall fpider, a loufe, flea, bug, &c. may be feen, and the motion or circulation of the blood, &c. obferved with furprifing diftinctnefs.

To view the circulation of the blood in the moft eminent degree, it muft be done by placing fmall frogs, tadpoles, water-newts, fifhes, &c. in a tube as reprefented n° 8. (fig. 17.); which tube is placed in the holes *o* in the oppofite fides of the cafe *al*, fig. 15. in the lower part.—N° 9. (fig. 16.) is a pair of pincers or pliers *a*, for holding any object; the other end of the fteel wire is pointed to receive a piece of ivory *b*, with one end black, and the other white, on which you flick objects of different hue: this alfo, when ufed, is placed in the fpring focket *m*.

To ufe this inftrument as a compound opaque, you fcrew off the body part *ab*, and fcrew to it the handle *r* (fig. 16.); by this means you may hold the microfcope in a horizontal pofition, as fhown in the figure. The filver difh or fpeculum (which is contained in the bottom or bafe *k*, fig. 15), is then fcrewed on at *b*. N° 9. is placed in the fpring-focket *m*, and adjufted backward and forward in *m*, till the reflected light from the fpeculum falls in a proper manner on the opaque object. Either of the 4 magnifiers, 2, 3, 4, 5, may be ufed, and brought to a proper focus, as before defcribed, by the tooth and pinion *e* (fig. 15.) If you take off the opaque apparatus, and apply the ftage n° 1. (fig. 16.) with an ivory flider, and at the end *b* fcrew in either of the two lenfes, n° 10. (which are diftinguifhed by the name of illuminators), the microfcope being held up to the light (and properly adjufted), the whole field of view will be ftrongly illuminated, and prefent a moft pleafing appearance of any tranfparent object. Thefe two convex lenfes are of different focufes, and are to be ufed fingly or together; n° 2. being the greateft magnifier, will require the object to be ftrongly illuminated, and of courfe both the lenfes muft be ufed together. By candle-light, this method of viewing tranfparent objects will prove very entertaining; by fcrewing the handle *r* into the part *s* of n° 10. it becomes a delightful hand megalafcope for viewing flowers, foffils, fhells, &c.; and each lens, as before mentioned, having a different focus, produces two magnifying powers ufed fingly, and when combined a third.

The manner of ufing this inftrument as a fingle microfcope (like Wilfon's) is reprefented in fig. 17. where the button or magnifier at each is to be fcrewed off, and the circular piece n° 11. is fcrewed in its place. This piece has a fpring focket made to receive the flider holder n° 12. N° 13. is a circular piece of brafs, with a long fhank and fpring, and is introduced through the outfide tube *ab* at *t*. N° 2, 3, 4, 5, are fcrewed occafionally in the centre of this piece, and ufed as fingle lenfes with ivory fliders, &c. N° 14. contains a lens of a great magnifying power, for viewing very minute objects: to render this inftrument the moft complete fingle opaque microfcope, you have only to fcrew into n° 13. the filver fpeculum n° 15, which has a small lens set in its centre. The slider-holder n° 12 is taken out of n° 11, and the pincers or nippers *d b*, being detached from the other part of n° 9. are passed through the long spring socket n° 11. and ready to receive any opaque body in the pincers or on the black and white piece of ivory. To the large screw of n° 13. are applied the two lenses n° 10. which make it the completest megalascope that can be desired.

The handle *r* contains the four ivory sliders with objects.

The shagreeen case which contains this universal microscope and its apparatus, is six inches long, three inches wide, two inches deep, and weighs together 16 ounces. "Thus (says Mr Martin) so small, so light, so portable, and yet so universally complete, is this pocket microscopic apparatus, that you find nothing material in the large three-pillared microscope, the opaque microscope, Wilson's single microscope, and the aquatic microscope, all together, which you have not in this; beside some very considerable advantages in regard to the field of view, &c. which they have not (A)."

This inventive artist having contrived a construction of the compound microscope so small as to admit of being packed in a common walking cane, thought next of introducing the same instrument into the inside of what he called his *Pocket Three-brass drawer Achromatic Telescope*. The same eye-glasses that serve the purpose of a telescope, answer as the compound magnifier, for viewing transparent and opaque objects in a microscope.

Fig. 18, 19, 20. represent the telescope separated by unscrewing it at *m*, in order that the whole of the necessary parts in use may be exhibited. Fig. 19. represents the exterior tube, which is of mahogany, and its rims of brass. It is detached from the rest of the telescope, as not making any part of the microscope. The brass cover *k l*, that shuts up the object-glass of the telescope, is also the box which contains the two-wheel object frames, and a small plain reflecting mirror.

In fig. 20. A is the cover taken off, by unscrewing the top part: The mirror B is taken out; and also, by unscrewing the bottom part, the two circular wheels, with the objects shown in C and D.

Fig. 18. is a representation of the three internal brass sliding tubes of the telescope, which form the microscopic part. The tubes are to be drawn out as shown in this figure; then, at the lower end of the large tube in the inside, is to be pulled out a short tube *bc*, that serves as a kind of stage to hold the wheels with objects, and support the reflecting mirror. This tube is to be partly drawn out, and turned so that the circular hole that is pierced in it may coincide with a similar hole that is cut in the exterior tube. This tube is represented as drawn out in the figure; and the mirror B placed therein, and the wheel with transparent objects. C (fig. 20.) represents the wheel with transparent objects, and D the wheel with opaque objects. They are both made of ivory; and turn round upon a centre brass pin slit upon the top, which sits upon the edge of the tube; which tube is then to be pushed up into the telescope tube, so that its lower end may rest upon the upper edge of the wheel according to its view at *a* fig. 18.

In viewing the objects, the second brass tube of the telescope must be pushed down, till its milled edge at top falls upon that of the exterior tube; taking care that the circular hole is duly placed to the exterior one. These circular holes are not seen in fig. 18. being supposed in the opposite side, where the wheel is fixed. The adjustment for the focus is now only necessary; which is obtained by pushing downwards or upwards the proper tube, till the object appear quite distinct. In viewing transparent objects, the instrument may be used in two positions; one vertical, when the light is to be reflected upon the object by the mirror; the other, by looking up directly against the light of a candle, common light, &c.; in which case the mirror must be taken away. In viewing opaque objects, the mirror is not used: but as much common light as possible must be admitted through the circular holes in the sides of the tubes.

There is a spare hole in the transparent wheel, and also one in the opaque, to receive any occasional object that is to be viewed. Any sort of object whatsoever may be viewed, by only pushing up the microscope tube into its exterior, and bringing the first eye-tube to its focal distance from the object.

The brass tubes are so contrived, that they stop when drawn out to the full length: so that by applying one hand to the outside tube, and the other to the end of the smallest tube, the telescope at one pull may be drawn out; then any of the tubes (that next to the eye is best) may be pushed in gradually, till the most distinct view of the object be obtained.

The tubes all slide through short brass spring tubes, any of which may be unscrewed from the ends of the sliding tubes by means of the milled edges which project above the tubes, taken from each other, and the springs set clear if required.

III. *Of Solar Microscopes.*

Plate CCC.

This instrument, in its principle, is composed of a tube, a looking-glass or mirror, a convex lens, and Wilson's single microscope before described. The sun's rays being reflected through the tube by means of the mirror upon the object, the image or picture of the object is thrown distinctly and beautifully upon a screen of white paper or a white linen sheet, placed at

(A) Notwithstanding the properties that have been ascribed to the above instrument, and the praises bestowed upon it by some, which induced us to admit so minute a description; we must apprise our readers, that it has been omitted in Mr Adams's enumeration: and upon inquiry we learn, that it has fallen into neglect among the most judicious opticians, being found too imperfect to serve the purposes of science, and too complicated for the use of persons who seek only entertainment.

Microſcope at a proper diſtance to receive the ſame; and may be magnified to a ſize not to be conceived by thoſe who have not ſeen it: for the farther the ſcreen is removed, the larger will the object appear; inſomuch, that a louſe may thus be magnified to the length of five or ſix feet, or even a great deal more; though it is more diſtinct when not enlarged to above half that ſize.

The different forms in which the Solar Microſcope is conſtructed, are as follow.

I. The old conſtruction is repreſented in fig. 21. A is a ſquare wodden frame, through which paſs two long ſcrews aſſiſted by a couple of nuts 1, 1. By theſe it is faſtened firmly to a window ſhutter, wherein a hole is made for its reception; the two nuts being let into the ſhutter, and made faſt thereto. A circular hole is made in the middle of this frame to receive the piece of wood B, of a circular figure; whoſe edge, that projects a little beyond the frame, compoſes a ſhallow groove 2, wherein runs a catgut 3; which, by twiſting round, and then croſſing over a braſs pulley 4, (the handle whereof 5, paſſes through the frame), affords an eaſy motion for turning round the circular piece of wood B, with all the parts affixed to it. C is a braſs tube, which, ſcrewing into the middle of the circular piece of wood, becomes a caſe for the uncovered braſs tube D to be drawn backwards or forwards in. E is a ſmaller tube, of about one inch in length, cemented to the end of the larger tube D. F is another braſs tube, made to ſlide over the above deſcribed tube E; and to the end of this the microſcope muſt be ſcrewed, when we come to uſe it. 5. a convex lens, whoſe focus is about 12 inches, deſigned to collect the ſun's rays, and throw them more ſtrongly upon the object. G is a looking-glaſs of an oblong figure, ſet in a wooden frame, faſtened by hinges in the circular piece of wood B, and turning about therewith by means of the abovementioned cat-gut. H is a jointed wire, partly braſs and partly iron; the braſs part whereof 6, which is flat, being faſtened to the mirror, and the iron part 7, which is round, paſſing through the wooden frame, enable the obſerver, by putting it backwards or forwards, to elevate or depreſs the mirror according to the ſun's altitude. There is a braſs ring at the end of the jointed wire 8, whereby to manage it with the greater eaſe. The extremities of the cat-gut are faſtened to a braſs pin, by turning of which it may be braced up, if at any time it becomes too ſlack.

When this microſcope is employed, the room muſt be rendered as dark as poſſible; for on the darkneſs of the room, and the brightneſs of the ſunſhine, depend the ſharpneſs and perfection of your image. Then putting the looking-glaſs G through the hole in your window-ſhutter, faſten the ſquare frame A to the ſhutter by its two ſcrews and nuts 1, 1. This done, adjuſt your looking-glaſs to the elevation and ſituation of the ſun, by means of the jointed wire H, together with the cat-gut and pulley, 3, 4. For the firſt of theſe raiſing or lowering the glaſs, and the other inclining it to either ſide, there reſults a twofold motion, which may eaſily be ſo managed as to bring the glaſs to a right poſition, that is, to make it reflect the ſun's rays directly through the lens 5, upon the paper ſcreen, and form thereon a ſpot of light exactly round. But though the obtaining a perfect circular ſpot of light upon the ſcreen before you apply the microſcope, is a certain proof that your mirror is adjuſted right, that proof muſt not always be expected: for the ſun is ſo low in winter, that if it ſhine in a direct line againſt the window, it cannot then afford a ſpot of light exactly round; but if it be on either ſide, a round ſpot may be obtained, even in December. As ſoon as this appears, ſcrew the tube C into the braſs collar provided for it in the middle of your wood-work, taking care not to alter your looking-glaſs: then ſcrewing the magnifier you chooſe to employ to the end of your microſcope in the uſual manner, take away the lens at the other end thereof, and place a ſlider, containing the objects to be examined, between the thin braſs plates, as in the other ways of uſing the microſcope.

Things being thus prepared, ſcrew the body of the microſcope over the ſmall end E of the braſs tube F; which ſlip over the ſmall end E of the tube D, and pull out the ſaid tube D leſs or more as your object is capable of enduring the ſun's heat. Dead objects may be brought within about an inch of the focus of the convex lens 5; but the diſtance muſt be ſhortened for living creatures, or they will ſoon be killed.

If the light fall not exactly right, you may eaſily, by a gentle motion of the jointed wire and pulley, direct it through the axis of the microſcopic lens. The ſhort tube F, to which the microſcope is ſcrewed, renders it eaſy, by ſliding it backwards or forwards on the other tube E, to bring the objects to their focal diſtance; which will be known by the ſharpneſs and clearneſs of their appearance: they may alſo be turned round by the ſame means without being in the leaſt diſordered.

The magnifiers moſt uſeful in the ſolar microſcope are in general, the fourth, fifth, or ſixth. The ſcreen on which the repreſentations of the objects are thrown, is uſually compoſed of a ſheet of the largeſt elephant paper, ſtrained on a frame which ſlides up or down, or turns about at pleaſure on a round wooden pillar, after the manner of ſome fire-ſcreens. Larger ſcreens may alſo be made of ſeveral ſheets of the ſame paper paſted together on cloth, and let down from the ceiling with a roller like a large map.

"This microſcope (ſays Mr Baker) is the moſt entertaining of any; and perhaps the moſt capable of making diſcoveries in objects that are not too opaque: as it ſhows them much larger than can be done any other way. There are alſo ſeveral conveniences attending it, which no other microſcope can have: for the weakeſt eyes may uſe it without the leaſt ſtraining or fatigue: numbers of people together may view any object at the ſame time; and by pointing to the particular parts thereof, and diſcourſing on what lies before them, may be able better to underſtand one another, and more likely to find out the truth, than in other microſcopes, where they muſt peep one after another, and perhaps ſee the object neither in the ſame light nor in the ſame poſition. Thoſe alſo, who have no ſkill in drawing, may, by this contrivance, eaſily ſketch out the exact figure of any object they have a mind to preſerve a picture of; ſince they need only faſten a paper on the ſcreen, and trace it

Microfcope it out thereon either with a pen or pencil, as it appears before them. It is worth the while of thofe who are defirous of taking many draughts in this way, to get a frame, wherein a fheet of paper may be put in or taken out at pleafure; for if the paper be fingle, the image of an object will be feen almoft as plainly on the back as on the fore-fide; and, by ftanding behind the fcreen, the fhade of the hand will not obftruct the light in drawing, as it muft in fome degree when one ftands before it." This conftruction, however, has now become rather obfolete, and is fuperfeded by the following.

II. *The improved Solar Microfcope, as ufed with the improved fingle Microfcope, with teeth and pinion.* Fig. 22. reprefents the whole form of the *fingle microfcope*; the parts of which are as follows: ABCD the external tube; GHIK the internal moveable one; QM part of another tube within the laft, at one end of which is fixed a plate of brafs hollowed in the middle, for receiving the glafs tubes: there is alfo a moveable flat plate, between which, and the fixed end of the fecond tube, the ivory fliders are to be placed. L, a part of the microfcope, containing a wire fpiral fpring, keeping the tube QM with its plates firm againft the fixed part IK of the fecond tube.

EF is the fmall rack-work of teeth and pinion, by which the tube IG is moved gradually to or from the end AB, for adjufting the objects exactly to the focus of different lengths. NO is a brafs flider, with fix magnifiers; any one of which may eafily be placed before the object. It is known when either of the glaffes is in the centre of the eye-hole, by a fmall fpring-falling into a notch in the fide of the flider, made againft each of the glaffes. Thofe parts of the apparatus, fig. 14. (Pl.cccxix.) marked n° 15, 16, 17, 18, 19, 20, 21. and 22. are made ufe of here to this microfcope. GH is a brafs cell, which holds an illuminating glafs for converging the fun's beams or the light of a candle ftrongly upon the objects. The aperture of the glafs is made greater or lefs, by two circular pieces of brafs, with holes of different fizes, that are fcrewed feparately over the faid lens. But at times, objects appear beft when the microfcope is held up to the common light only, without this glafs. It is alfo taken away when the microfcope is applied to the apparatus now to be defcribed.

Fig. 23. reprefents the apparatus, with the fingle microfcope fcrewed to it, which conftitutes the *Solar Microfcope*. AB is the inner moveable tube, to which the fingle microfcope is fcrewed. CD, is the external tube, containing a condenfing convex glafs at the end D, and is fcrewed into the plate EF, which is cut with teeth at its circumference, and moved by the pinion I, that is fixed with the plate GH. This plate is fcrewed faft againft the window-fhutter, or board fitted to a convenient window of a darkened room, when the inftrument is ufed. KL is a long frame, fixed to the circular plate EF; containing a looking-glafs or mirror for reflecting the folar rays through the lens in the body of the tube D. O is a brafs milled head, faftened to a worm or endlefs fcrew; which on the outfide turns a fmall wheel, by which the reflecting mirror M is moved upwards or downwards.

In *ufing* this microfcope, the fquare frame GH is firft to be fcrewed to the window-fhutter, and the room well darkened: which is beft done by cutting a round hole of the fize of the moveable plate EF, that carries the reflector, in the window-fhutter or board; and, by means of two brafs nuts *a a*, let into the fhutter to receive the fcrews PP, when placed through the holes in the fquare frame GH, at the two holes QQ; which will firmly faften the microfcope to the fhutter, and is eafily taken away by only unfcrewing the fcrews PP.

The white paper fcreen, or white cloth, to receive the images, is to be placed feveral feet diftant from the window: which will make the reprefentations the larger in proportion to the diftance. The ufual diftances are from 6 to 16 feet.

The frame KL, with its mirror M, is to be moved by turning the pinion I, one way or the other, till the beams of the fun's light come through the hole into the room: then, by turning of the worm at O, the mirror muft be raifed or depreffed till the rays become perfectly horizontal, and go ftraight acrofs the room to the fcreen. The tube CD, with its lens at D, is now to be fcrewed into the hole of the circular plate EF: by this glafs the rays will be converged to a focus; and from thence proceed diverging to the fcreen, and there make a large circle of light. The fingle microfcope, fig. 22. is to be fcrewed on to the end AB (fig. 23.) of the inner tube; and the flider NO, with either of the lenfes marked 1, 2, 3, 4, 5, or 6, in the centre of the hole at the end AB. This will occafion a circle of light upon the fcreen much larger than before. The flider or glafs-tube, with the objects to be viewed, is to be placed between the plates at IK againft the fmall magnifier, and moved at pleafure. By fhifting the tube AB in or out, you may place the object in fuch a part of the condenfed rays as fhall be fufficient to illuminate it, and not fcorch or burn it; which will generally require the glafs to be about one inch diftant from the focus. It now remains only to adjuft the object, or to bring it fo near to the magnifier that its image formed upon the fcreen fhall be the moft diftinct or perfect: and it is effected by gently turning the pinion F, fig. 22, a fmall matter one way or the other. If the object be rather large in fize, the leaft magnifiers are generally ufed, and *vice verfa*.

N° 1. is the greateft magnifier, and n° 6. the leaft, in the brafs flider NO. But, if defired, fingle lenfes of greater magnifying powers are made: and they are applied, by being fcrewed to the end A B, fig. 12. and the brafs flider N O is then taken away.

The fame object may be varioufly magnified, by the lenfes feverally applied to it; and the degree of magnifying power is eafily known by this rule: *As the diftance of the object is to that of its image from the magnifier; fo is the length or breadth of the object to that of the image.*

Inftead of the brafs fliders with the lenfes NO, there is fometimes fcrewed a lens of a large fize, and longer focal diftance: the inftrument is then converted into a *megalafcope*; and is adapted for viewing the larger kind of objects contained in large fliders, fuch as is reprefented at R. And, in the fame manner, fmall objects of entertainment, painted upon glafs like the fliders of a magic lanthorn, are much magnified, and reprefented upon the fame fcreen.

The folar microfcopes juft defcribed are capable only

Microscope. ly of magnifying transparent objects; for which purpose the last instrument is extremely well adapted. But as opaque objects form the most considerable part of the curious collections in the works of art as well as nature, a solar microscope for this purpose was a long time wanted.—For several years previous to 1774, the late Mr Martin made several essays towards the construction of such an instrument; and at last completed one about the time just mentioned, which he named,

III. *The Opaque Solar Microscope.* With this instrument (to use his own words) all *opaque* objects, whether of the animal, vegetable, or mineral kingdom, may be exhibited in great perfection, in all their native beauty; the lights and shades, the prominences and cavities, and all the varieties of different hues, tints, and colours; heightened by reflection of the solar rays condensed upon them."—*Transparent objects* are also shown with greater perfection than by the common solar microscope.

Fig. 24. represents the solar opaque microscope, mounted for exhibiting opaque objects.

Fig. 25. is the single tooth-and-pinion microscope, as before, which is used for showing transparent objects; the cylindrical tube Y thereof being made to fit into the tube FE of the solar microscope.

ABCDEF, (fig. 24.) represents the body of the solar microscope; one part thereof, ABCD, is conical; the other, CDEF, is cylindrical. The cylindrical part receives the tube G of the opaque box, or the tube Y of the single microscope. At the large end AB of the conical part, there is a lens to receive the rays from the mirror, and refract them towards the box HIKL. NOP is a brass frame; which is fixed to the moveable circular plate *abc*: in this frame there is a plane mirror, to reflect the solar rays on the aforementioned lens. This mirror may be moved into the most convenient position for reflecting the light, by means of the nuts Q and R. By the nut Q it may be moved from east to west; and it may be elevated or depressed by the nut R. *de*, Two screws to fasten the microscope to a window-shutter. The box for opaque objects is represented at HIKL: it contains a plane mirror M, for reflecting the light which it receives from the large lens to the object. and thereby illuminating it; S is a screw to adjust this mirror, or place it at a proper angle for reflecting the light. VX, two tubes of brass, one sliding within the other, the exterior one in the box HIKL; these carry the magnifying lenses: the interior tube is sometimes taken out, and the exterior one is then used by itself. Part of this tube may be seen in the plate within the box HIKL. At H there is a brass plate, the back part of which is fixed to the hollow tube *h*, in which there is a spiral wire, which keeps the plate always bearing against the side H of the brass box HIKL. The sliders, with the opaque objects, pass between this plate and the side of the box; to put them there, the plate is to be drawn back by means of the nut *g*: *ik* is a door to one side of the opaque box. The foregoing pieces constitute the several parts necessary for viewing opaque objects. We shall now proceed to describe the single microscope, which is used for transparent objects: but in order to examine these, the box HIKL must be first removed, and in its place we must insert the tube Y of the single microscope that we are now going to describe.

Fig. 25. represents a large tooth-and-pinion microscope: at *m*, within the body of this microscope, are two thin plates, that are to be separated, in order to let the ivory sliders pass between them; they are pressed together by a spiral spring, which bears up the under plate, and forces it against the upper one.

The slider S (under fig. 24.), which contains the magnifiers, fits into the hole *n*; and any of the magnifiers may be placed before the object, by moving the aforesaid slider: when the magnifier is at the centre of the hole P, a small spring falls into one of the notches which is on the side of the slider.

Under the plate *m* are placed two lenses, for enlarging the field of view on the screen: the smaller of the two is fixed in a piece of brass, and is nearest the plate *m*; this is to be taken out when the magnifiers, N° 4, 5, or 6, are used, or when the megalascope lens T (fig. 24.) is used; but is to be replaced for N° 1, 2, 3.

This microscope is adjusted to the focus by turning the milled nut O.

To *use* the solar microscope:—Make a round hole in the window-shutter, a little larger than the circle *abc*; pass the mirror ONP through this hole, and apply the square plate to the shutter; then mark with a pencil the places which correspond to the two holes through which the screw is to pass; take away the microscope, and bore two holes at the marked places, sufficiently large to let the milled screws *de* pass through them.

The screws are to pass from the outside of the shutter, to go through it; and being then screwed into their respective holes in the square plate, they will, when screwed home, hold it fast against the inside of the shutter, and thus support the microscope.

Screw the conical tube ABCD to the circle *abc*, and then slide the tube G of the opaque box into the cylindrical part CD EF of the body, if opaque objects are to be examined; but if they be transparent objects you mean to show, then place the tube Y within the tube CDEF.

The room is to be darkened as much as possible, that no light may enter but what passes through the body of the microscope; for, on this circumstance, together with the brightness of the sun shine, the perfection and distinctness of the image in a great measure depend.

When the microscope is to be used for opaque objects, 1. Adjust the mirror NOP, so as to receive the solar rays, by means of the two finger screws or nuts, Q R; the first, Q, turns the mirror to the right or left; the second, R, raises or depresses it: this you are to do till you have reflected the sun's light through the lens at AB strongly upon a screen of white paper placed at some distance from the window, and formed thereon a round spot of light. An unexperienced observer will find it more convenient to obtain the light by forming this spot before he puts on either the opaque box or the tooth-and-pinion microscope.

Now put in the *opaque* box, and place the object between the plates at H; open the door *ik*, and adjust the mirror M till you have illuminated the object strongly. If you cannot effect this by the screw S, you

you must move the screws Q, R, in order to get the light reflected strongly from the mirror NOP, or the mirror M, without which the latter cannot illuminate the object.

The object being strongly illuminated, shut the door *ik*, and a distinct view of the object will soon be obtained on your screen, by adjusting the tubes VX, which is effected by moving them backwards or forwards.

A round spot of light cannot always be procured in northern latitudes, the altitude of the sun being often too low; neither can it be obtained when the sun is directly perpendicular to the front of the room.

As the sun is continually changing its place, it will be necessary, in order to keep his rays full upon the object, to keep them continually directed thro' the axis of the instrument, by the two screws Q and R.

To view *transparent* objects, remove the opaque box, and insert the tube Y, fig. 25. in its place; put the slider S into its place at *n*, and the slider with the objects between the plates at *m*; then adjust the mirror NOP, as before directed by the screws Q, R, so that the light may pass through the object; regulate the focus of the magnifier by the screw O. The most pleasing magnifiers in use are the fourth and fifth.

The size of the object may be increased or diminished, by altering the distance of the screen from the microscope: five or six feet is a convenient distance.

To examine transparent objects of a larger size, or to render the instrument what is usually called a *megalascope*, take out the slider S from its place at *n*, and screw the button T (fig. 24.) into the hole at P, fig. 25. and remove the glass which is under the plate at *m*, and regulate the light and focus agreeable to the foregoing directions.

N. B. At the end of the tube G there is a lens for increasing the density of the rays, for the purpose of burning or melting any combustible or fusible substance: this lens must be removed in most cases, lest the objects should be burnt. The intensity of the light is also varied by moving this tube backwards or forwards.

Apparatus of the Opaque Solar Microscope.—The large square plate and mirror; the body of the microscope; the opaque box and its tube; the tooth-and-pinion microscope; the slider with the magnifiers; the megalascope magnifier; the two screws *d* and *e*; some ivory sliders; some sliders with opaque objects; a brass frame, with a bottom of soft deal to stick any object on; a brass cylinder K (fig. 31.), for confining opaque objects.

IV. *The* CAMERA OBSCURA, *or* LUCERNAL, *Microscope.*—The great facility with which objects can be represented on paper or a rough glass in the camera obscura, and copies drawn from them by any person though unskilled in drawing, evidently suggested the application of the microscope to this instrument. The greatest number of experiments that appear to have been made with this view, were by the late Mr Martin and Mr Adams; the former of whom frequently applied the microscope to the portable camera, and with much effect and entertainment. But these instruments being found to answer only with the assistance of the sun, Mr Adams directed his experiments to the construction of an instrument of more extended utility, which could be equally employed in the day-time and by night. He accordingly succeeded so far as to produce, by *candle-light*, the images of objects refracted from a single magnifier upon one or two large convex lenses (of about five inches or upwards in diameter), at the end of a pyramidal shaped box, in a very pleasing and magnified appearance, so as to give opaque objects as well as transparent ones the utmost distinctness of representation: but still the light of a candle or lamp was found generally insufficient to throw the requisite degree of illumination upon the objects. The invention of what is called *Argand's lamp*, within these few years offered a complete remedy for this defect, by the intensity and steadiness of its light. This did not escape the present Mr Adams (son of the former), who immediately applied it; and who had likewise so altered and improved his father's instrument, both in construction and form, as to render it altogether a different one, and far more perfect and useful.

The advantages and properties of this excellently conceived instrument are numerous and important. "As the far greater part of the objects which surround us are opaque (says our author), and very few are sufficiently transparent to be examined by the common microscopes, an instrument that could be readily applied to the examination of opaque objects has always been a desideratum. Even in the examination of transparent objects, many of the fine and more curious portions are lost, and drowned, as it were, in the light which must be transmitted through them; while different parts of the same object appear only as dark lines or spots, because they are so opaque as not to permit any light to pass through them. These difficulties, as well as many more, are obviated in the lucernal microscope; by which opaque objects of various sizes may be seen with ease and distinctness: the beautiful colours with which most of them are adorned, are rendered more brilliant, without changing in the least the real tint of the colour; and the concave and convex parts retain also their proper form.—The facility with which all opaque objects are applied to this instrument, is another considerable advantage, and almost peculiar to itself; as the texture and configuration of the more tender parts are often hurt by previous preparation, every object may be examined by this instrument, first as opaque, and afterwards (if the texture will admit of it) as transparent.—The lucernal microscope does not in the least fatigue that eye; the object appears like nature itself, giving ease to the sight and pleasure to the mind: there is also, in the use of this instrument, no occasion to shut the eye which is not directed to the object. A further advantage peculiar to this microscope is, that by it the outlines of every object may be taken, even by those who are not accustomed to draw; while those who can draw well will receive great assistance, and execute their work with more accuracy and in less time than they would otherwise have been able to have performed it. Transparent objects as well as opaque may be copied in the same manner. The instrument may be used at any time of the day, but the best effect is by night; in which respect it has a superiority over the solar microscope, as that instrument can only be used when the sun shines.

Microscope

Transparent objects may be examined with the lucernal microscope in three or four different modes, from a blaze of light almost too great for the eye to bear, to that which is perfectly easy to it: And by the addition of a tin lanthorn to the apparatus, may be thrown on a screen, and exhibited at one view to a large company, as by the solar mircoscope.

We shall now proceed to the description of the instrument and apparatus as given by Mr Adams.

Fig. 26. represents the improved *Lucernal Microscope*, mounted to view opaque objects. ABCD is a large mahogany pyramidal box, which forms the body of the microscope; it is supported firmly on the brass pillar FG, by means of the socket H and the curved piece IK.

LMN is a guide for the eye, in order to direct it in the axis of the lenses; it consists of two brass tubes, one sliding within the other, and a vertical flat piece, at the top of which is the hole for the eye. The outer tube is seen at MN, the vertical piece is represented at LM. The inner tube may be pulled out, or pushed in, to adjust it to the focus of the glasses. The vertical piece may be raised or depressed, that the hole, through which the object is to be viewed, may coincide with the centre of the field of view; it is fixed by a milled screw at M, which could not be shown in this figure.

At N is a dove-tailed piece of brass, made to receive the dove-tail at the end of the tubes MN, by which it is affixed to the wooden box ABCDE. The tubes MN may be removed from this box occasionally, for the convenience of packing it up in a less compass.

OP, a small tube which carries the magnifiers.

O, one of the magnifiers; it is screwed into the end of a tube, which slides within the tube P; the tube P may be unscrewed occasionally from the wooden body.

QRSTVX, a long squarebar, which passes through the sockets YZ, and carrries the stage or frame that holds the objects; this bar may be moved backward or forward, in order to adjust it to the focus by means of the pinion which is at *a*.

b, A handle furnished with an universal joint, for more conveniently turning the pinion. When the handle is removed, the nut (fig. 27.) may be used in its stead.

de, A brass bar, to support the curved piece KI, and keep the body AB firm and steady.

fghi, The stage for opaque objects: it fits upon the bar QRST by means of the socket *hi*, and is brought nearer to or removed farther from the magnifying lens by turning the pinion *a*: the objects are placed in the front side of the stage (which cannot be seen in this figure) between four small brass plates; the edges of two of these are seen at *kl*. The two upper pieces of brass are moveable; they are fixed to a plate, which is acted on by a spiral spring, that presses them down, and confines the slider with the objects: this plate, and the two upper pieces of brass, are lifted up by the small nut *m*.

At the lower part of the stage, there is a semicircular lump of glass *n*, which is designed to receive the light from the lamp, fig. 29. and to collect and throw it on the concave mirror *o*, whence it is to be reflected on the object.

The upper part *fgrs* (fig. 26.) of the opaque stage takes out, that the stage for transparent objects may be inserted in its place.

Fig. 28. represents the stage for transparent objects; the two legs 5 and 6 fit into the top of the under part *rshi* of the stage for opaque objects; 7 is the part which confines or holds the sliders, and through which they are to be moved; 9 and 10 a brass tube, which contains the lenses for condensing the light, and throwing it upon the object; there is a second tube within that, marked 9 and 10, which may be placed at different distances from the object by the pin 11.

When this stage is used as a single microscope, without any reference to the lucernal, the magnifiers, or object lenses, are to be screwed into the hole 12, and to be adjusted to a proper focus by the nut 13.

N. B. At the end AB (fig 26.) of the wooden body there is a slider, which is represented as partly drawn out at A: when quite taken out, three grooves will be perceived; one of which contains a board that forms the end of the box; the next contains a frame with a greyed glass; and the third, or that farthest from the end AB, two large convex lenses.

Fig. 29. represents one of Argand's lamps, which are the most suitable for microscopic purposes, on account of the clearness, the intensity, and the steadiness of the light. The following account of the method of managing them, with other observations, is copied from an account given by Mr Parker with those he sells.

The principle on which the lamp acts, consists in disposing the wick in thin parts, so that the air may come into contact with all the burning fuel; by which means, together with an increase of the current of air occasioned by rarefaction in the glass tube, the whole of the fuel is converted into flame.

The wicks are circular; and, the more readily to regulate the quantity of light, are fixed on a brass collar, with a wire handle, by means of which they are raised or depressed at pleasure.

To fix the wick on, a wooden mandril is contrived, which is tapered at one end, and has a groove turned at the other.

The wick has a selvage at one end, which is to be put foremost on the mandril, and moved up to the groove; then putting the groove into the collar of the wick-holder, the wick is easily pushed forward upon it.

The wick-holder and wick being put quite down in their place, the spare part of the wick should, while dry, be set a-light, and suffered to burn to the edge of the tubes; this will leave it more even than by cutting, and, being black by burning, will be much easier lighted: for this reason, the black should never be quite cut off.

The lamp should be filled an hour or two before it is wanted, that the cotton may imbibe the oil and draw the better.

The lamps which have a reservoir and valve, need no other direction for filling than to do it with a proper trimming pot, carefully observing when they are full; then pulling up the valve by the point, the reservoir, being turned with the other hand, may be replaced without spilling a drop.

Those lamps which fill in the front like a bird fountain, must be reclined on the back to fill; and this

Microscope. should be done gently, that the oil in the burner may return into the body when so placed and filled: if, by being too full, any oil appears above the guard, only move the lamp a little, and the oil will disappear; the lamp may then be placed erect, and the oil will flow to its proper level.

The oil must be of the spermaceti kind, commonly called chamber-oil, which may generally be distinguished by its paleness, transparency, and inoffensive scent: all those oils which are of a red and brown colour, and of an offensive scent, should be carefully avoided, as their glutinous parts clog the lamp, and the impurities in such oil, not being inflammable, will accumulate and remain in the form of a crust on the wick. Seal oil is nearly as pale and sweet as chamber oil; but being of a heavy sluggish quality, is not proper for lamps with fine wicks.

Whenever bad oil has been used, on changing it, the wick must also be changed; because, after having imbibed the coarse particles in its capillary tubes, it will not draw up the fine oil.

To obtain the greatest degree of light, the wick should be trimmed exactly even, the flame will then be completely equal.

There will be a great advantage in keeping the lamp clean, especially the burner and air-tubes; the neglect of cleanliness in lamps is too common: a candlestick is generally cleaned every time it is used, so should a lamp; and if a candlestick is not to be objected to because it does not give light after the candle is exhausted, so a lamp should not be thought ill of, if it does not give light when it wants oil or cotton; but this last has often happened, because the deficiency is less visible.

The glass tubes are best cleaned with a piece of wash leather.

If a fountain-lamp is left partly filled with oil, it may be liable to overflow; this happens by the contraction of the air when cold, and its expansion by the warmth of a room, the rays of the sun, or the heat of the lamp when re-lighted: this accident may be effectually prevented by keeping the reservoir filled, the oil not being subject to expansion like air. On this account, those with a common reservoir are best adapted for microscopic purposes.

To examine Opaque Objects with the Lucernal Microscope. To render the use of this instrument easy, it is usually packed with as many of the parts together as possible: it occupies on this account rather more room, but is much less embarrassing to the observer, who has only three parts to put on after it is taken out of its box, namely, the guide for the eye, the stage, and the tube with its magnifier.

But to be more particular: Take out the wooden slider A (fig. 26.), then lift out the cover and the grey glass from their respective grooves under the slider A.

Put the end N of the guide for the eye LMM into its place, so that it may stand in the position which is represented in this figure.

Place the socket which is at the bottom of the opaque stage, on the bar Q X T, so that the concave mirror *o* may be next the end DE of the wooden body.

Screw the tubes PO into the end DE. The magnifier you intend to use is to be screwed on the end O of these tubes. Microscope.

The handle G*b*, or the milled nut fig. 27. must be placed on the square end of the pinion *a*.

Place the lamp lighted before the glass lump *n*, and the object you intend to examine between the spring-plates of the stage; and the instrument is ready for use.

In all microscopes there are two circumstances which must be particularly attended to: first, the modification of the light, or the proper quantity to illuminate the object; secondly, the adjustment of the instrument to the focus of the glasses and eye of the observer. In the use of the lucernal microscope there is a third circumstance, which is, the regulation of the guide for the eye.

1. To throw the light upon the object. The flame of the lamp is to be placed rather below the centre of the glass lump *n*, and as near it as possible; the concave mirror *o* must be so inclined and turned as to receive the light from the glass lump, and reflect it thence upon the object; the best situation of the concave mirror and the flame of the lamp depends on a combination of circumstances, which a little practice will discover.

2. To regulate the guide for the eye, or to place the centre of the eye-piece L so that it may coincide with the focal point of the lenses and the axis of vision: Lengthen and shorten the tubes MN, by drawing out or pushing in the inner tube, and raising or depressing the eye-piece ML, till you find the large lens (which is placed at the end AB of the wooden body) filled by an uniform field of light, without any prismatic colours round the edge; for till this piece is properly fixed, the circle of light will be very small, and only occupy a part of the lens: the eye must be kept at the centre of the eye-piece L, during the whole of the operation; which may be rendered somewhat easier to the observer, on the first use of the instrument, if he hold a piece of white paper parallel to the large lens, removing it from or bringing it nearer to them till he find the place where a lucid circle, which he will perceive on the paper, is brightest and most distinct; then he is to fix the centre of the eye-piece to coincide with that spot; after which a very small adjustment will set it perfectly right.

3. To adjust the lenses to their focal distance. This is effected by turning the pinion *a*, the eye being at the same time at the eye-piece L. The grey glass is often placed before the large lenses, while regulating the guide for the eye, and adjusting for the focal distance.

If the observer, in the process of his examination of an object, advance rapidly from a shallow to a deep magnifier, he will save himself some labour by pulling out the internal tube at O.

The upper part *f g r s* of the stage is to be raised or lowered occasionally, in order to make the centre of the object coincide with the centre of the lens at O.

To delineate objects, the grey glass must be placed before the large lenses; the picture of the object will be formed on this glass, and the outline may be accurately taken by going over the picture with a pencil.

The

Fig. 29.
Fig. 30.
Fig. 31.

The opaque part may be uſed in the day-time without a lamp, provided the large lenſes at AB are ſcreened from the light.

To uſe the Lucernal Microſcope in the examination of Tranſparent Objects. The inſtrument is to remain as before: the upper part *fgs* of the opaque ſtage muſt be removed, and the ſtage for tranſparent objects, repreſented at fig. 28. put in its place; the end 9 10 to be next the lamp.

Place the greyed glaſs in its groove at the end AB, and the objects in the ſlider-holder at the front of the ſtage; then tranſmit as ſtrong a light as you are able on the object, which you will eaſily do by raiſing or lowering the lamp.

The object will be beautifully depicted on the grey glaſs: it muſt be regulated to the focus of the magnifier, by turning the pinion *a*.

The object may be viewed either with or without the guide for the eye. A ſingle obſerver will ſee an object to the greateſt advantage by uſing this guide, which is to be adjuſted as we have deſcribed above. If two or three wiſh to examine the object at the ſame time, the guide for the eye muſt be laid aſide.

Take the large lens out of the groove, and receive the image on the grey glaſs; in this caſe, the guide for the eye is of no uſe: if the grey glaſs be taken away, the image of the object may be received on a paper ſcreen.

Take out the grey glaſs, replace the large lenſes, and uſe the guide for the eye; attend to the foregoing directions, and adjuſt the object to its proper focus. You will then ſee the object in a blaze of light almoſt too great for the eye, a circumſtance that will be found very uſeful in the examination of particular objects. The edges of the object in this mode will be ſomewhat coloured: but as it is only uſed in this full light for occaſional purpoſes, it has been thought better to leave this ſmall imperfection, than, by remedying it, to ſacrifice greater advantages; the more ſo, as this fault is eaſily corrected, and a new and intereſting view of the object is obtained, by turning the inſtrument out of the direct rays of light, and permitting them to paſs through only in an oblique direction, by which the upper ſurface is in ſome degree illuminated, and the object is ſeen partly as opaque, partly as tranſparent. It has been already obſerved, that the tranſparent objects might be placed between the ſlider-holders of the ſtage for opaque objects, and then be examined as if opaque.

Some tranſparent objects appear to the greateſt advantage when the lens at 9 10 is taken away; as, by giving too great a quantity of light, it renders the edges leſs ſharp.

The variety of views which may be taken of every object by means of the improved lucernal microſcope, will be found to be of great uſe to an accurate obſerver: it will give him an opportunity of correcting or confirming his diſcoveries, and inveſtigating thoſe parts in one mode which are inviſible in another.

To throw the image of tranſparent objects on a ſcreen, as in the ſolar microſcope. It has been long a microſcopical deſideratum, to have an inſtrument by which the image of tranſparent objects might be thrown on a ſcreen, as in the common ſolar microſcope: and this not only becauſe the ſun is ſo uncertain in this climate, and the uſe of the ſolar microſcope requires confinement in the fineſt part of the day, when time ſeldom hangs heavy on the mind; but as it alſo affords an increaſe of pleaſure, by diſplaying its wonders to ſeveral perſons at the ſame inſtant, without the leaſt fatigue to the eye.

This purpoſe is now effectually anſwered, by affixing the tranſparent ſtage of the lucernal to a lanthorn, with one of Argand's lamps.—The lamp is placed within the lanthorn, and the end 9 10 of the tranſparent ſtage is ſcrewed into a female ſcrew, which is rivetted in the ſliding part of the front of the lanthorn: the magnifying lenſes are to be ſcrewed into the hole repreſented at 12, and they are adjuſted by turning the milled nut. The quantity of light is to be regulated by raiſing and lowering the ſliding-plate or the lamp.

Apparatus which uſually accompanies the improved Lucernal Microſcope. The ſtage for opaque objects, with its ſemicircular lump of glaſs, and concave mirror. The ſtage for tranſparent objects, which fits on the upper part of the foregoing ſtage. The ſliding tube, to which the magnifiers are to be affixed: one end of theſe is to be ſcrewed on the end D of the wooden body; the magnifier in uſe is to be ſcrewed to the other end of the inner tube. Eight magnifying lenſes: theſe are ſo conſtructed, that they may be combined together, and thus produce a very great variety of magnifying powers. A fiſh-pan, ſuch as is repreſented at I. A ſteel wire L, with a pair of nippers at one end, and a ſmall cylinder of ivory *l* at the other. A ſlider of braſs N, containing a flat glaſs ſlider, and a braſs ſlider into which are fitted ſome ſmall concave glaſſes. A pair of forceps. Six large and ſix ſmall ivory ſliders, with tranſparent objects. Fourteen wooden ſliders, with four opaque objects in each ſlider; and two ſpare ſliders. Some capillary tubes for viewing ſmall animalcula.

Ingenious men ſeldom content themſelves with an inſtrument under one form; hence ſuch a variety of microſcopes, hence many alterations in the Lucernal Microſcope. Mr Adams himſelf, we underſtand, has fitted up this laſt in a great many different ways; and it is reaſonable to think that no perſon is more likely to give it every improvement of which is is ſuſceptible. Of the alterations by other hands we ſhall only particulariſe one, made by Mr Jones of Holborn (B), whoſe deſcription is as follows:

A, repreſents a portion of the top of the mahogany box

(B) We truſt the reader will never conſider any paragraph wherein the name of an inſtrument-maker or other artiſt is inſerted, as a recommendation of thoſe artiſts by the editors of this work. In the courſe of a pretty extenſive correſpondence, they have been favoured with very liberal communications from various artiſts, for which they are greatly indebted to them: the inſerting their names in this work is therefore to be conſidered as a grateful acknowledgment from the editors for favours conferred on them,—not as a teſtimonial box in which it packs, to preserve it steady; it slides in a dove-tail groove withinside, a similar groove to which is cut in the top of the box A; so that when the instrument is to be used, it is slipt out of the box withinside, and then slipt into the groove at top ready for use, almost instantly, as shown in the figure. The adjustment of the objects is at the stage E; for the right focal distance is readily and conveniently made by turning the long screw-rod BB, which goes thro' the two pillars supporting the box, and works in the base of the brass stage E; which base is also dove-tailed, so as to have a regular and steady motion in another brass basis that supports it. In this instrument, therefore, the pyramidical box does not move; but the stage part only, which, from its small weight, moves in the most agreeable and steady manner. While observing the image of the object upon the glass through the sight-hole at G, the object may be moved or changed by only turning the rack-work and pinion applied to the stage, by means of the handle D, for that purpose. By this contrivance you have no occasion to change your position during the view of the objects upon one of the sliders. This motion changes the objects horizontally only; and as they are generally placed exactly in one line, it answers all the purposes for which this motion is intended very well. But it may sometimes happen that the observer would wish to alter the vertical position of the object; to perform which there is another plane rod at F, that acts simply as a lever for this purpose, and moves the sliding part of the stage E vertically either upwards or downwards.

Thus, without altering his position, the observer may investigate all parts of the objects in the most satisfactory manner. Rack-work and pinion might be applied to the stage for the vertical motion also; but as it would materially enhance the expence, it is seldom applied. The brass work at the handle of D contains a Hooke's universal joint.

The brilliancy of the images of the objects shown upon the large lenses at the end of the box, being very frequently so great as to dazzle the eyes. Mr Jones applies a slight tinge of blue, green, and other coloured glass, to the sight-hole at G, which softens this glare, and casts an agreeable hue upon the objects.

Description of those Parts of a Microscopical Apparatus, common to most Instruments, which are delineated at fig. 31.

A and B represent the brass cells which contain the magnifiers belonging to the different kinds of compound microscopes. The magnifiers are sometimes contained in a slider like that which is delineated at S (fig. 24). The lenses of A and B are confined by a small cap; on unscrewing this, the small lens may be taken out and cleaned. The magnifiers A of the lucernal microscope are so contrived, that any two of them may be screwed together, by which means a considerable variety of magnifying power is obtained.

To get at the lenses in the slider S (fig. 24.), take out the two screws which hold on the cover.

C, represents the general form of the slider-holder. It consists of a cylindrical tube, in which an inner tube is forced up by a spring It is used to receive the ivory or any other slider, in which the transparent objects are placed; these are to be slid between the two upper plates: the hollow part in one of the plates is designed for the glass tubes.

D, the condensing lens and its tube, which fits into the slider-holder C, and may be moved up and down in it. When this piece is pushed up as far as it will go, it condenses the light of a candle, which is reflected on it by the plain mirror of the compound microscope, and spreads it uniformly over the object; in this case it is best adapted to the shallowest magnifiers. If the deeper lenses are used, it should be drawn down, or rather removed further from the object, that it may concentrate the light in a small compass, and thus render it more dense. The condensing lens is sometimes fitted up differently; but the principle being the same, it will be easy to apply it to use notwithstanding some variations in the mechanism.

E, a brass cone. It fixes under the slider-holder, and is used to lessen occasionally the quantity of light which comes from the mirror to any object.

F, a box with two flat glasses, which may be placed at different distances from each other in order to confine a small living insect.

G, a small brass box to hold the silver speculum H.

H, a small silver concave speculum, designed to reflect the light from the mirror on opaque objects; it should only be used with the shallow magnifiers. It is applied in different ways to the compound microscope; sometimes to a tube similar to that represented at X, which slides on the lower part of the body; sometimes it is screwed into the ring of the piece Q; the pin of this generally fits into one of the holes in the stage. When this speculum is used, the slider-holder should be removed.

I, a fish-pan, whereon a small fish may be fastened, in order to view the circulation of the blood: its tail is to be spread across the oblong hole at the smallest end, and tied fast by means of the ribbon fixed thereto, by shoving the knob which is on the back of it through the slit made in the stage; the tail of the fish may be brought under the lens which is in use.

K, a cylindrical piece, intended for the solar opaque microscope: by pulling back the spiral spring, smaller or larger objects may be confined in it.

k, A pair of triangular nippers for taking hold of and confining a large object.

L, a long steel wire, with a small pair of pliers at one end and a steel point at the other: the wire slips backwards or forwards in a spring tube, which is affixed to a joint, at the bottom of which is a pin to fit one of the holes in the stage; this piece is used to confine small objects.

l, A small ivory cylinder that fits on the pointed end of the steel wire L; it is designed to receive opaque objects. Light-coloured ones are to be stuck on the dark side, and *vice versa*.

M, a convex lens, which fits to the stage by means of

nial of their opinion of the abilities of an individual, or as designed to insinuate any preference over others in the same line, where such preference has not been already bestowed by the public.

of the long pin adhering to it. This piece is defigned to collect the light from the fun or a candle, and to throw them on any object placed on the ftage; but it is very little ufed at prefent.

N, a brafs flider, into which is fitted a flat piece of glafs, and a brafs flider containing four fmall glaffes, one or two of them concave, the others flat; it is defigned to confine fmall living objects, and when ufed is to be placed between the two upper plates of the flider-holder.

O, a glafs tube to receive a fmall fifh, &c.

P, reprefents one of the ivory fliders, wherein objects are placed between two pieces of talc, and confined by a brafs ring.

Q, a piece to hold the fpeculum H: this piece is generally fitted to the microfcope reprefented at fig. 12.

R, a pair of forceps, to take up any occafional object.

S, a camel's hair pencil to brufh the duft off the glaffes; the upper part of the quill is fcooped out, to take up a drop of any fluid, and place it on either of the glaffes for examination.

T, an inftrument for cutting thin tranfverfe fections of wood. It confifts of a wooden bafe, which fupports four brafs pillars; on the top of the pillars is placed a flat piece of brafs, near the middle of which there is a triangular hole.

A fharp knife, which moves in a diagonal direction, is fixed on the upper fide of the afore-mentioned plate, and in fuch a manner that the edge always coincides with the furface thereof.

The knife is moved backwards and forwards by means of the handle *a*. The piece of wood is placed in the triangular trough which is under the brafs plate, and is to be kept fteady therein by a milled fcrew which is fitted to the trough; the wood is to be preffed forward for cutting by the micrometer fcrew *b*.

The pieces of wood fhould be applied to this inftrument immediately on being taken out of the ground, or elfe they fhould be foaked for fome time in water, to foften them fo that they may not hurt the edge of the knife.

When the edge of the knife is brought in contact with the piece of wood, a fmall quantity of fpirits of wine fhould be poured on the furface of the wood, to prevent its curling up; it will alfo make it adhere to the knife, from which it may be removed by preffing a piece of blotting paper on it.

y, An appendage to the cutting engine, which is to be ufed inftead of the micrometer fcrew, being preferred to it by fome. It is placed over the triangular hole, and kept flat down upon the furface of the brafs plate, while the piece of wood is preffed againft a circular piece of brafs which is on the under fide of it. This circular piece of brafs is fixed to a fcrew, by which its diftance from the flat plate on which the knife moves may be regulated.

z, An ivory box, containing at one end fpare talc for the ivory fliders, and at the other fpare rings for preffing the talcs together and confining them to the flider.

After what has been related of Microfcopes, they cannot be faid to be complete without the valuable addition of a *micrometer*; for the ufe and advantages of which, fee the article Micrometer.

Having prefented our readers with defcriptions of the various mifcrofcopes generally ufed, we think it our duty to point out to them thofe which we conceive to be beft calculated to anfwer the purpofes of fcience. The firft which prefents itfelf to our mind is that of *Ellis*: It is better adapted, than any other portable microfcope, to the purpofe of general obfervation; fimple in its conftruction, and general in its application. To thofe who prefer a double microfcope, we fhould recommend that figured in Plate CCXCVIII. (12.) If opaque objects, as infects, &c. be fubjects of inveftigation, the *Lucernal Microfcope* claims the preference: but if amufement alone guides the choice, the *Solar Microfcope* muft be fixed upon.

We fhall now proceed to explain fome neceffary particulars refpecting the method of ufing microfcopes; after which, we fhall fubjoin an enumeration of the principal objects difcovered or elucidated by their means. On this fubject Mr Adams, in his *Effay on the Microfcope*, has been very copious; with a view, as he informs us, to remove the common complaint made by Mr Baker, "that many of thofe who purchafe microfcopes are fo little acquainted with their general and extenfive ufefulnefs, and fo much at a lofs for objects to examine by them, that after diverting their friends fome few times with what they find in the fliders which generally accompany the inftrument, or perhaps with two or three common objects, the microfcope is laid afide as of little further value; whereas no inftrument has yet appeared in the world capable of affording fo conftant, various, and fatisfactory an entertainment to the mind."

I. In ufing the microfcope, there are three things neceffary to be confidered. (1.) The preparation and adjuftment of the inftrument itfelf. (2.) The proper quantity of light, and the beft method of adapting it to the object. (3.) The method of preparing the objects, fo that their texture may be properly underftood.

1. With regard to the microfcope itfelf, the firft thing neceffary to be examined is, whether the glaffes be clean or not: if they are not fo, they muft be wiped with a piece of foft leather, taking care not to foil them afterwards with the fingers; and, in replacing them, care muft be taken not to place them in an oblique fituation. We muft likewife be careful not to let the breath fall upon the glaffes, nor to hold that part of the body of the inftrument where the glaffes are placed with a warm hand; becaufe thus the moifture expelled by the heat from the metal will condenfe upon the glafs, and prevent the object from being diftinctly feen. The object fhould be brought as near the centre of the field of view as poffible; for there only it will be exhibited in the greateft perfection. The eye fhould be moved up and down from the eye-glafs of a compound microfcope, till the fituation is found where the largeft field and moft diftinct view of the object are to be had: but every perfon ought to adjuft the microfcope to his own eye, and not to depend upon the fituation it was placed in by another. A fmall magnifying power fhould

always be begun with; by which means the obſerver will beſt obtain an exact idea of the ſituation and connection of the whole; and will of conſequence be leſs liable to form any erroneous opinion when the parts are viewed ſeparately by a lens of greater power. Objects ſhould alſo be examined firſt in their moſt natural poſition: for if this be not attended to, we ſhall be apt to form very inadequate ideas of the ſtructure of the whole, as well as of the connection and uſe of the parts. A living animal ought to be as little hurt or diſcompoſed as poſſible.

From viewing an object properly, we may acquire a knowledge of its nature: but this cannot be done without an extenſive knowledge of the ſubject, much patience, and many experiments; as in a great number of caſes the images will reſemble each other, though derived from very different ſubſtances. Mr Baker therefore adviſes us not to form an opinion too ſuddenly after viewing a microſcopical object; nor to draw our inferences till after repeated experiments and examinations of the object in many different lights and poſitions; to paſs no judgment upon things extended by force, or contracted by dryneſs, or in any manner out of a natural ſtate, without making ſuitable allowances. The true colour of objects cannot be properly determined by very great magnifiers; for as the pores and interſtices of an object are enlarged according to the magnifying power of the glaſſes made uſe of, the component particles of its ſubſtance will appear ſeparated many thouſand times farther aſunder than they do to the naked eye: hence the reflection of the light from theſe particles will be very different, and exhibit different colours. It is likewiſe ſomewhat difficult to obſerve opaque objects; and as the apertures of the larger magnifiers are but ſmall, they are not proper for the purpoſe. If an object be ſo very opaque, that no light will paſs through it, as much as poſſible muſt be thrown upon the upper ſurface of it. Some conſideration is likewiſe neceſſary in forming a judgment of the motion of living creatures, or even of fluids, when ſeen through the microſcope; for as the moving body, and the ſpace wherein it moves, are magnified, the motion will alſo be increaſed.

2. On the management of the light depends in a great meaſure the diſtinctneſs of the viſion: and as, in order to have this in the greateſt perfection, we muſt adapt the quantity of light to the nature of the object and the focus of the magnifier, it is therefore neceſſary to view it in various degrees of light. In ſome objects, it is difficult to diſtinguiſh between a prominence and a depreſſion, a ſhadow or a black ſtain; or between a reflection of light and whiteneſs, which is particularly obſervable in the eye of the libella and other flies: all of theſe appearing very different in one poſition from what they do in another. The brightneſs of an object likewiſe depends on the quantity of light, the diſtinctneſs of viſion, and on regulating the quantity to the object; for ſome will be in a manner loſt in a quantity of light ſcarce ſufficient to render another viſible.

There are various ways in which a ſtrong light may be thrown upon objects; as by means of the ſun and a convex lens. For this purpoſe, the microſcope is to be placed about three feet from a ſouthern window; then take a deep convex lens, mounted on a ſemicircle and ſtand, ſo that its poſition may eaſily be varied: place this lens between the object and the window, ſo that it may collect a conſiderable number of ſolar rays, and refract them on the object or the mirror of the microſcope. If the light thus collected from the ſun be too powerful, it may be leſſened by placing a piece of oiled paper, or a piece of glaſs lightly greyed, between the object and lens. Thus a proper degree of light may be obtained, and diffuſed equally all over the ſurface of an object: a circumſtance which ought to be particularly attended to; for if the light be thrown irregularly upon it, no diſtinct view can be obtained. If we mean to make uſe of the ſolar light, it will be found convenient to darken the room, and to reflect the rays of the ſun on the abovementioned lens by means of the mirror of a ſolar microſcope fixed to the window-ſhutter; for thus the obſerver will be enabled to preſerve the light on his object, notwithſtanding the motion of the ſun. But by reaſon of this motion, and the variable ſtate of the atmoſphere, ſolar obſervations are rendered both tedious and inconvenient: whence it will be proper for the obſerver to be furniſhed with a large tin lanthorn, formed ſomething like the common magic lanthorn, capable of containing one of Argand's lamps. This, however, ought not to be of the fountain kind, leſt the rarefaction of the air in the lanthorn ſhould force the oil over. There ought to be an aperture in the front of the lanthorn, which may be moved up and down, and be capable of holding a lens; by which means a pleaſant and uniform as well as ſtrong light may eaſily be procured. The lamp ſhould likewiſe move on a rod, ſo that it may be eaſily raiſed or depreſſed. This lanthorn may likewiſe be uſed for many other purpoſes; as viewing of pictures, exhibiting microſcopic objects on a ſcreen, &c. A weak light, however, is beſt for viewing many tranſparent objects: among which we may reckon the prepared eyes of flies, as well as the animalcules in fluids. The quantity of light from a lamp or candle may be leſſened by removing the microſcope to a greater diſtance from them, or by diminiſhing the ſtrength of the light which falls upon the objects. This may very conveniently be done by pieces of black paper with circular apertures of different ſizes, and placing a larger or ſmaller one upon the reflecting mirror, as occaſion may require. There is an oblique ſituation of the mirrors, which makes likewiſe an oblique reflection of the light eaſily diſcovered by practice, (but for which no general rule can be given in theory); and which will exhibit an object more diſtinctly than any other poſition, ſhowing the ſurface, as well as thoſe parts through which the light is tranſmitted. The light of a lamp or candle is generally better for viewing microſcopic objects than day-light; it being more eaſy to modify the former than the latter, and to throw it upon the objects with different degrees of denſity.

3. With regard to the preparation of objects, Swammerdam has, in that particular, excelled almoſt all other inveſtigators who either preceded or have ſucceeded him. He was ſo aſſiduous and indefatigable, that neither difficulty nor diſappointment could make the leaſt impreſſion upon him; and he never abandoned the purſuit of any object until he had obtained

Microscope tained a satisfactory idea of it. Unhappily, however, the methods he made use of in preparing his objects for the microscope are now enerely unknown. Dr Boerhaave examined with the strictest attention all the letters and manuscripts of Swammerdam which he could find; but his researches were far from being successful. The following particulars, however, have thus come to the knowledge of the public.

For dissecting of *small insects*, Swammerdam had a brass table made by S. Muschenbrock, to which were affixed two brass arms moveable at pleasure to any part of it. The upper part of these vertical arms was constructed in such a manner as to have a slow vertical motion; by which means the operator could readily alter their height as he saw convenient. One of these arms was to hold the minute objects, and the other to apply the microscope.

The lenses of Swammerdam's microscopes were of various sizes as well as foci; but all of them the best that could be procured, both for the transparency of the glass and the fineness of the workmanship. His observations were always begun with the smallest magnifiers, from which he proceeded to the greatest; but in the use of them, he was so exceedingly dexterous, that he made every observation subservient to that which succeeded it, and all of them to the confirmation of each other, and to the completing of the description. His chief art seems to have been in constructing scissars of an exquisite fineness, and making them very sharp. Thus he was enabled to cut very minute objects to much more advantage than could be done by knives and lancets; for these, though ever so sharp and fine, are apt to disorder delicate substances by displacing some of the filaments, and drawing them after them as they pass through the bodies; but the sciffars cut them all equally. The knives, lancets, and styles he made use of in his dissections, were so fine that he could not see to sharpen them without the assistance of a magnifying glass; but with these he could dissect the intestines of bees with the same accuracy that the best anatomists can do those of large animals. He made use also of very small glass tubes no thicker than a bristle, and drawn to a very fine point at one end, but thicker at the other. These were for the purpose of blowing up, and thus rendering visible the smallest vessels which could be discovered by the microscope; to trace their courses and communications, or sometimes to inject them with coloured liquors.

Swammerdam sometimes made use of spirit of wine, water, or oil of turpentine, for suffocating the insects he wished to examine; and would preserve them for a time in these liquids. Thus he kept the parts from putrefying, and gave them besides such additional strength and firmness, as rendered the dissections much more easy than they would otherwise have been. Having then divided the body transversely with the sciffars, and made what observations he could without farther dissection, he proceeded to extract the intestines carefully with very fine instruments, to wash away the fat in the like careful manner; and thus to put the parts into such a state as would best expose them to view; but these operations are best performed while the insects are in their nympha state.

Sometimes the delicate viscera of the insects, after having been suffocated as abovementioned, were put into water; after which, having shaken them gently, he procured an opportunity of examining them, especially the air vessels, which last he could thus separate entire from all the other parts, to the admiration of all who beheld them; as these vessels cannot be distinctly seen in any other manner, or indeed in any way whatever, without injuring them. Frequently also he injected water with a syringe to cleanse the parts thoroughly, after which he blew them up with air and dried them; thus rendering them durable, and fit for examination at a proper opportunity. Sometimes he made very important discoveries, by examining insects which he had preserved for several years in balsam. Other insects he punctured with a very fine needle; and after squeezing out all their moisture through the holes made in this manner, he filled them with air, by means of very slender glass tubes; then dried them in the shade; and lastly anointed them with oil of spike in which a little rosin had been dissolved; and by which means they, for a long time, retained their proper forms. He was likewise in possession of a singular secret, by which he could preserve the limbs of insects as limber and perspicuous as ever they had been. He used to make a small puncture or incision in the tails of worms; and after having with great caution squeezed out all the humours, as well as great part of the viscera, he injected them with wax in such a manner as to give them the appearance of living creatures in perfect health. He found that the fat of all insects was entirely dissolvable in oil of turpentine; by which means he was enabled plainly to discern the viscera; though, after this dissolution, it was necessary to cleanse and wash them frequently in clean water. In this manner he would frequently have spent whole days in the preparation of a single caterpillar, and cleansing it from its fat, in order to discover the true situation of the insect's heart. He had a singular dexterity in stripping off the skins of caterpillars that were on the point of spinning their cones. This was done by letting them drop by their threads into scalding water, and then suddenly withdrawing them. Thus the epidermis peeled off very easily; and, when this was done, he put them into distilled vinegar and spirit of wine mixed together in equal proportions; which, by giving a due degree of firmness to the parts, gave him an opportunity of separating them with very little trouble from the exuviæ, without any danger to the internal parts. Thus the nymph could be shown to be wrapped up in the caterpillar and the butterfly in the nymph; and there is little doubt that those who look into the works of Swammerdam, will be amply recompensed, whether they consider the unexampled labour or the piety of the author.

M. Lyonet, a late eminent naturalist, usually drowned the insects he designed to examine; by which means he was enabled to preserve both the softness and transparency of the parts. According to him, the insect, if very small, *viz.* one tenth of an inch, or little more, in length, should be dissected on a glass somewhat concave. If it should be suspected that the insect will putrefy by keeping for a few days, spirit of wine diluted with water must be substituted instead of pure water. The insect must be suffered to dry; after which it may be

Microscope be fastened by a piece of soft wax, and again covered with water.—Larger objects should be placed in a trough of thin wood; and for this purpose the bottom of a common chip box will answer very well; only surrounding the edge of it with soft wax, to keep in the water or other fluid employed in preserving the insect. The body is then to be opened; and if the parts are soft like those of a caterpillar, they should be turned back, and fixed to the trough by small pins, which ought to be set by a small pair of nippers. At the same time, the skin being stretched by another pair of finer forceps, the insect must be put into water, and dissected therein, occasionally covering it with spirit of wine. Thus the subject will be preserved in perfection, so that its parts may be gradually unfolded, no other change being perceived than that the soft elastic parts become stiff and opaque, while some others lose their colour.

The following instruments were made use of by M. Lyonet in his dissection of the *Chenille de Saul.* A pair of scissars as small as could be made, with long and fine arms: A pair of forceps, with their ends so nicely adjusted, that they could easily lay hold of a spider's thread, or a grain of sand: Two fine steel needles fixed in wooden handles, about two inches and three quarters in length; which were the most generally useful instruments he employed.

Dr Hooke, who likewise made many microscopic observations, takes notice, that the common ant or pismire is much more troublesome to draw than other insects, as it is extremely difficult to get the body in a quiet natural posture. If its feet be fettered with wax or glue, while the animal remains alive, it so twists its body, that there is no possibility of gaining a proper view of it; and if it be killed before any observation is made, the shape is often spoiled before it can be examined. The bodies of many minute insects, when their life is destroyed, instantly shrivel up; and this is observable even in plants as well as insects, the surface of these small bodies being affected by the least change of air; which is particularly the case with the ant. If this creature, however, be dropped into rectified spirit of wine, it will instantly be killed; and when it is taken out, the spirit of wine evaporates, leaving the animal dry, and in its natural posture, or at least in such a state that it may easily be placed in whatever posture we please.

Parts of Insects. The *wings*, in many insects, are so transparent, that they require no previous preparation: but some of those that are folded up under *elytra* or cases, require a considerable share of dexterity to unfold them; for these wings are naturally endowed with such a spring, that they immediately fold themselves again, unless care be taken to prevent them. The wing of the earwig, when expanded, is of a tolerable size, yet is folded up under a case not one eighth part of its bulk; and the texture of this wing renders it difficult to be unfolded. This is done with the least trouble immediately after the insect is killed. Holding then the creature by the thorax, between the finger and thumb, with a blunt-pointed pin endeavour gently to open it, by spreading it over the fore-finger, and at the same time gradually sliding the thumb over it. When the wing is sufficiently expanded, separate it from the insect by a sharp knife or a pair of scissars. The wing should be pressed for some time between the thumb and finger before it be removed; it should then be placed between two pieces of paper, and again pressed for at least an hour; after which time, as there will be no danger of its folding up any more, it may be put between the talcs, and applied to the microscope. Similar care is requisite in displaying the wings of the notonecta and other water-insects, as well as most kinds of grylli.

The minute *scales* or *feathers*, which cover the wings of moths or butterflies, afford very beautiful objects for the microscope. Those from one part of the wing frequently differ in shape from such as are taken from other parts; and near the thorax, shoulder, and on the fringes of the wings, we generally meet with hair instead of scales. The whole may be brushed off the wing, upon a piece of paper, by means of a camel's-hair pencil; after which the hairs can be separated with the assistance of a common magnifying glass.

It is likewise a matter of considerable difficulty to dissect properly the *proboscis* of insects, such as the gnat, tabanus, &c. and the experiment must be repeated a great number of times before the structure and situation of the parts can be thoroughly investigated, as the observer will frequently discover in one what he could not in another. The *collector of the bee*, which forms a very curious object, ought to be first carefully washed in spirit of turpentine; by which means it will be freed from the unctuous matter adhering to it: when dry, it is again to be washed with a camel's-hair pencil to disengage and bring forward the small hairs which form part of this microscopic beauty. The best method of managing the *stings* of insects, which are in danger of being broken by reason of their hardness, is to soak the case and the rest of the apparatus for some time in spirit of wine or turpentine; then lay them on a piece of paper, and with a blunt knife draw out the sting, holding the sheath with the nail of the finger or any blunt instrument; but great care is necessary to preserve the *feelers*, which when cleaned add much to the beauty of the object. The *beard* of the lepas antifera is to be soaked in clean soft water, frequently brushing it while wet with a camel's-hair pencil: after it is dried, the brushing must be repeated with a dry pencil to disengage and separate the hairs, which are apt to adhere together.

To view to advantage the *fat*, *brains*, and other similar substances, Dr Hooke advises to render the surface smooth, by pressing it between two plates of thin glass, by which means the matter will be rendered much thinner and more transparent: without this precaution, it appears confused, by reason of the parts lying too thick upon one another. For *muscular fibres*, take a piece of the flesh, thin and dry; moisten it with warm water, and after this is evaporated the vessels will appear more plain and distinct; and by repeated macerations they appear still more so. The *exuviæ* of insects afford a pleasing object, and require but little preparation. If bent or curled up, they will become so relaxed by being kept a few hours in a moist atmosphere, that you may easily extend them to their natural positions; or the steam of warm water will answer the purpose very well.

The *eyes* of insects in general form very curious and

and beautiful objects. Those of the libellula and other flies, as well as of the lobster, &c. must first be cleaned from the blood, &c. after which they should be soaked in water for some days: one or two skins are then to be separated from the eye, which would be otherwise too opaque and confused; but some care is requisite in this operation; for if the skin be rendered too thin, it is impossible to form a proper idea of the organization of the part. In some substances, however, the organization is such, that by altering the texture of the part, we destroy the objects which we wish to observe. Of this sort are the nerves, tendons, muscular fibres, many of which are viewed to most advantage when floating in some transparent fluid. Thus very few of the muscular fibres can be discovered when we attempt to view them in the open air, though great numbers may be seen if they be placed in water or oil. By viewing the thread of a ligament in this manner, we find it composed of a vast number of smooth round threads lying close together. Elastic objects should be pulled or stretched out while they are under the microscope, that the texture and nature of those parts, the figure of which is altered by being thus pulled out, may be more fully discovered.

Other objects. To examine *bones* by the microscope, they should first be viewed as opaque objects; but afterwards, by procuring thin slices of them, they may be viewed as transparent. The sections should be cut in all directions, and be well washed and cleaned; and in some cases maceration will be useful, or the bones may be heated red hot in a clear fire, and then taken out; by which means the bony cells will appear more conspicuous. The *pores of the skin* may be examined by cutting off a thin slice off the upper skin with a razor, and then a second from the same place; applying the latter to the microscope. The lizard, guana, &c. have two skins, one very transparent, the other thicker and more opaque; and, separating these two, you obtain very beautiful objects.

To view the *scales of fish* to advantage, they ought to be soaked in water for a few days, and then carefully rubbed to clean them from the skin and dirt which may adhere to them. The scales of the eel are a great curiosity; and the more so, as this creature was not known to have any scales till they were discovered by the microscope. The method of discovering them is this. Take a piece of the skin of an eel from off its side, and spread it while moist on a piece of glass, that it may dry very smooth: when thus dried, the surface will appear all over dimpled or pitted by the scales, which lie under a sort of cuticle or thin skin; which may be raised with the sharp point of a penknife, together with the scales, which will then easily slip out; and thus we may procure as many as we please.

The *leaves* of many *trees*, as well as of some plants, when dissected, form a very agreeable object. In order to dissect them, take a few of the most perfect leaves you can find, and place them in a pan with clean water. Let them remain there three weeks, or a month, without changing the water; then take them up; and if they feel very soft, and almost rotten, they are sufficiently soaked. They must then be laid on a flat board, and holding them by the stalk, draw the edge of a knife over the upper side of the leaf, which will take off most of the skin. Then turn the leaf, and do the same with the under side; and when the skin is taken off on both sides, wash out the pulpy matter, and the fibres will be exhibited in a very beautiful manner. The leaf may be slit into two parts, by splitting the stalk; and the skins peeled from the fibres will also make a good object. This operation is best performed in the autumn: the fibres of the leaves are much stronger at that season, and less liable to be broken.—The internal structure of shells may be observed by grinding them down on a hone: and all ores and minerals should be carefully washed and brushed with a small brush to remove any sordes that may adhere to them.

To view the *circulation of the blood*, we must observe living animals of the most transparent kind.—A small eel is sometimes used for this purpose; in which case it must be cleansed from the slime naturally adhering to it; after which it may be put into a tube filled with water, where it can be viewed in a satisfactory manner. The tail of any other small fish may be viewed in the same manner, or put upon a slip of flat glass, and thus laid before the microscope. By filling the tube with water when an eel is made use of, we prevent in a great measure the sliminess of the animal from soiling the glass.

The particles of the blood form a very curious object, and have been carefully viewed by different philosophers; who, nevertheless, differ from one another very much in their accounts of them. The best method of viewing these is to take a small drop of blood when warm, and spread it as thin as possible upon a flat piece of glass. By diluting it a little with warm water, some of the large globules will be separated from the smaller, and many of them subdivided; or a small drop of blood may be put into a capillary glass-tube, and then placed before the microscope. Mr Baker advises warm milk as proper to be mixed with the blood; but Mr Hewson, who is accounted the most accurate observer, diluted the blood with that fluid which undoubtedly is more natural to it, *viz.* its own serum: by this method he could preserve the small particles entire, and view them distinctly; and thus he found that they were not globular, as had been imagined by other anatomists, but flat. Having shaken a piece of the crassamentum of the blood in serum till the latter became a little coloured, he spread it with a soft hair pencil on a piece of thin glass, which he placed under the microscope, in such a manner as not to be quite horizontal, but rather higher at one end than the other. Thus the serum flows from the higher to the lower part; and, as it flows, some of the particles will be found to swim on their flat sides, and will appear to have a dark spot in the middle; while others will turn over from one side to the other as they roll down the glass. Many cruel experiments have been tried in order to observe the circulation of the blood in living creatures, and an apparatus has been invented for viewing the circulation in the mesentery of a frog; but as this can answer no useful purpose, and will never be put in practice by persons of humanity, we forbear to mention it.

 II. Besides

II. Besides the objects for the microscope already mentioned, there are innumerable others, some hardly visible, and others totally invisible, to the naked eye; and which therefore, in a more peculiar sense, are denominated,

Microscopic animals. They are the animalcules or moving bodies in water, in which certain substances have been infused; and of which there are a great many different kinds. These animalcula are sometimes found in water which we would call *pure*, did not the microscopes discover its minute inhabitants; but not equally in all kinds of water, or even in all parts of the same kind of it. The surfaces of infusions are generally covered with a scum which is easily broken, but acquires thickness by standing. In this scum the greatest number of animalcules are usually found. Sometimes it is necessary to dilute the infusions; but this ought always to be done with water, not only distilled, but viewed through a microscope, lest it should also have animalcules in it, and thus prove a source of deception. It is, however, most proper to observe those minute objects after the water is a little evaporated; the attention being less diverted by a few objects than when they appear in great numbers. One or two of the animalcules may be separated from the rest by placing a small drop of water on the glass near that of the infusion; join them together by making a small connection between them with a pin; and as soon as you perceive that an animalcule has entered the clear drop, cut off the connection again.

Eels in paste are obtained by boiling a little flour and water into the consistence of book-binders paste; then exposing it to the air in an open vessel, and beating it frequently together to keep the surface from growing mouldy or hard. In a few days it will be found peopled with myriads of little animals visible to the naked eye, which are the eels in question. They may be preserved for a whole year by keeping the paste moistened with water; and while this is done, the motion of the animals will keep the surface from growing mouldy. Mr Baker directs a drop or two of vinegar to be put into the paste now and then. When they are applied to the microscope, the paste must be diluted in a piece of water for them to swim in.

Numberless animalcules are observed by the microscope in infusions of pepper. To make an infusion for this purpose, bruise as much common black pepper as will cover the bottom of an open jar, and lay it thereon about half an inch thick: pour as much soft water into the vessel as will rise about an inch above the pepper. Shake the whole well together: after which they must not be stirred, but be left exposed to the air for a few days; in which time a thin pellicle will be formed on the surface, in which innumerable animals are to be observed by the microscope.

The microscopic animals are so different from those of the larger kinds, that scarce any sort of analogy seems to exist between them; and one would almost be tempted to think that they lived in consequence of laws directly opposite to those which preserve ourselves and other visible animals in existence. They have been systematically arranged by O. F. Muller; though it is by no means probable that all the different classes have yet been discovered. Such as have been observed, however, are by this author divided in the following manner.

I. *Such as have no external organs.*

1. Monas: Punctiforma. A mere point.
2. Proteus: Mutabilis. Mutable.
3. Volvox: Sphæricum. Spherical.
4. Enchelis: Cylindracea. Cylindrical.
5. Vibrio: Elongatum. Long.
   * Membranaceous.
6. Cyclidium: Ovale. Oval.
7. Paramecium: Oblongum. Oblong.
8. Kolpoda: Sinuatum. Sinuous.
9. Gonium: Angulatum. With angles.
10. Bursaria. Hollow like a purse.

II. *Those that have external organs.*

* Naked, or not inclosed in a shell.

1. Cercaria: Caudatum. With a tail.
2. Trichoda: Crinitum. Hairy.
3. Kerona: Corniculatum. With horns.
4. Himantopus: Cirratum. Cirrated.
5. Leucophra: Ciliatum undique. Every part ciliated.
6. Vorticella: Ciliatum apice. The apex ciliated.
   * Covered with a shell.
7. Brachionus: Ciliatum apice. The apex ciliated.

I. *Monas.*

This is by our author defined to be "an invisible (to the naked eye), pellucid, simple, punctiform worm;" but of which, small as it is, there are several species.

1. The *monas termo* or *gelatinosa*, is a small jelly-like point, which can be but imperfectly seen by the single microscope, and not at all by the compound one. In a full light they totally disappear, by reason of their transparency. Some infusions are so full of them that scarce the least empty space can be perceived; the water itself appearing composed of innumerable globular points, in which a motion may be perceived somewhat similar to that which is observed when the sun's rays shine on the water; the whole multitude of animals appearing in commotion like a hive of bees. This animal is very common in ditch-water, and in almost all infusions either of animal or vegetable substances.

2. *Monas atomus* or *albida*; white monas with a variable point. This appears like a white point, which thro' a high magnifier apppears somewhat egg-shaped. The smaller end is generally marked with a black point, the situation of which is variable; sometimes it appears on the large end, and sometimes there are two black spots in the middle. This species was found in sea-water, which had been kept through the whole winter, but was not very fetid. No other kind of animalcule was found in it.

3. *Monas punctum* or *nigra*, black monas. This was found in a fetid infusion of pears, and appears in form of a very minute, opaque, and black point, moving with a slow and wavering motion.

4. *Monas ocellus*, transparent like talc, with a point in the middle. This is found in ditches covered with conferva,

ferva, and fometimes with the cyclidium milium; the margin of it is black, with a black point in the middle.

5. *Monas lens* or *hyalina;* of a talcy appearance. This is found in all kinds of water; fometimes even in that which is pure, but always in the fummer-time in ditch-water. It is found alfo in all infufions of animal or vegetable fubftances, whether in frefh or falt water; myriads being contained in a fingle drop. It is found likewife in the filth of the teeth. It is nearly of a round figure; and fo tranfparent, that it is impoffible to difcover the leaft veftige of inteftines. They generally appear in clufters, but fometimes fingly. Contrary to what happens to other animalcules, they appear to cover the edges of the drop when evaporating, and where they inftantly die. A few dark fhades, probably occafioned by the wrinkling of the body, are perceived when the water is nearly evaporated. The motions of this animalcule are generally very quick; and two united together, may fometimes be feen fwimming among the reft; which is thought to be a fingle one generating another by divifion, as is related under the article Animalcule. Thefe and the animalcules of the firft fpecies are fo numerous, that they exceed all calculation even in a very fmall fpace.

6. *Monas mica,* marked with a circle. This is found in the pureft waters, and may be difcovered with the third lens of the fingle microfcope when the magnifying power is increafed. It appears like a fmall lucid point; but can affume an oval or fpherical fhape at pleafure: fometimes the appearance of two kidneys may be perceived in its body, and there is commonly the figure of an ellipfe in it; the fituation of which is moveable, fometimes appearing in the middle and fometimes approaching to either extremity. It feems encompaffed with a beautiful halo, which is thought to be occafioned by the vibration of fine invifible hairs. It has a variety of motions, and often turns round for a long time in the fame place.

7. The *tranquilla,* or egg-fhaped tranfparent monas with a black margin, is found in urine which has been kept for fome time. Urine in this ftate acquires a fcum in which the animalcules refide; but though kept for feveral months, no other fpecies was found in it. A drop of urine is ufually fatal to other animalcules, though this fpecies is to be met with in no other fubftance. It is generally fixed to one point, but has a kind of vacillatory motion. Frequently thefe creatures are furrounded with a halo. Sometimes they are quadrangular, and at other times fpherical; the black margin is not always to be found; and fometimes there is even an appearance of a tail.

8. The *lamellula,* or flat tranfparent monas, is moft ufually found in falt-water; is of a whitifh colour and tranfparent, more than twice as long as it is broad, with a dark margin, having a vacillatory motion, and frequently appearing as double.

9. The *pulvifculus* or *monas* with a green margin. Thefe are generally found in marfhy grounds in the month of March. They appear like fmall fpherical grains of a green colour on the circumference, having fometimes a green bent line paffing through the middle. They appear fometimes in clufters, from three to feven or more in number, having a wavering kind of motion.

10. The *uva,* or tranfparent gregarious mona, is found in a variety of infufions, and is of that kind which multiplies by dividing itfelf. They appear in clufters of four, five, or fometimes many more; the corpufcles being of various fizes, according to the number collected into one group. The fmaller particles, when feparated from the larger, move about with incredible fwiftnefs. A fingle corpufcle feparated from the heap, and put by itfelf into a glafs, foon increafed in fize till it nearly attained the bulk of the parent group. The furface then affumed a wrinkled appearance, and gradually became like the former, feparating again into fmall particles, which likewife increafed in bulk as before.

II. *The Proteus.*

An invifible, very fimple, pellucid worm, of a variable form.

1. The *diffluens,* branching itfelf out in a variety of directions. It is very rare, and only met with in fens; appearing like a grey mucous mafs, filled with a number of black globules, and continually changing its figure, pufhing out branches of different lengths and breadths. The internal globules divide immediately, and pafs into the new formed parts; always following the various changes of the animalcule; which changes feem to proceed entirely from the internal mechanifm of its body, without the aid of any external power.

2. The *tenax,* running out into a fine point. This is a pellucid gelatinous body, ftored with black molecules, and likewife changing its figure, but in a more regular order than the former. It firft extends itfelf in a ftraight line, the lower part terminating in a bright acute point. It appears to have no inteftines; and when the globules are all collected in the upper part, it next draws the pointed end up toward the middle of the body, which affumes a round form. It goes through a number of different fhapes, part of which are defcribed under the article Animalcule. It is found in fome kinds of river-water, and appears confined almoft entirely to one place, only bending fidewife.

III. *Volvox.*

An invifible, very fimple, pellucid, fpherical worm.

1. The *punctum;* of a black colour, with a lucid point. This is a fmall globule, with one hemifphere opaque and black, the other having a cryftalline appearance; and a vehement motion is obferved in the black part. It moves as on an axis, frequently paffing thro' the drop in this manner. Many are often feen joined together in their paffage through the water; fometimes moving as in a little whirlpool, and then feparating. They are found in great numbers on the furface of fetid fea-water.

2. The *granulum* is of a fpherical figure and green colour, the circumference being bright and tranfparent. It is found in marfhy places about the month of June, and moves but flowly. It feems to have a green opaque nucleus.

3. The *globulus,* with the hinder part fomewhat obfcure, fometimes verges a little towards the oval in its fhape, having a flow fluttering kind of motion, but more

more quick when difturbed. The inteftines are but juft vifible. It is found in moft vegetable infufions, and is ten times larger than the mona lens.

4. The *pilula*, fmall and round, with green inteftines. This is found in water where the lemna minor grows, in the month of December, and has a kind of rotatory motion, fometimes flow and at others quick. The inteftines are placed near the middle, apparently edged with yellow. There is a fmall incifion on one of the edges of the fphere, which may poffibly be the mouth of the creature. The whole animal appears encompaffed with an halo.

5. The *grandinella*, with immoveable inteftines, is much fmaller than the laft, and marked with feveral circular lines. The inteftines are immoveable, and no motion is perceived among the interior molecules. Sometimes it moves about in a ftraight line, at others irregularly, and fometimes keeps in the fame fpot, with a tremulous motion.

6. The *focialis*, with cryftalline molecules placed at equal diftances from one another. This is found in water where the chara vulgaris has been kept; and has its molecules difpofed in a fphere, filling up the whole body of the animalcule; but whether they be covered by a common membrane or united by a ftalk (as in the *vorticella focialis* to be afterwards defcribed) is not known. When very much magnified, fome black points may be feen in the cryftalline molecules. Its motion is fometimes rotatory and fometimes not.

7. The *fphericula*, with round molecules, appears to confift of pellucid homogeneous points of different fizes. It moves flowly from right to left and back again, about a quarter of a circle each time.

8. The *lunula*, with lunular molecules, is a fmall roundifh tranfparent body, confifting of an innumerable multitude of homogeneous molecules of the fhape of a crefcent, without any common margin. It moves continually in a twofold manner, *viz.* of the molecules among one another, and the whole mafs turning flowly round. It is found in marfhy places in the beginning of fpring.

9. The *globator*, or fpherical membranaceous volvox, is found in great numbers in the infufions of hemp and tremella, and in ftagnant waters in fpring and fummer; it was firft obferved and depicted by Leewenhoeck, but the defcriptions of it given by authors differ confiderably from each other. The following is that of Mr Baker. "There is no appearance of either head, tail, or fins. It moves in every direction, backwards, forwards, up or down, rolling over and over like a bowl, fpinning horizontally like a top, or gliding along fmoothly without turning itfelf at all; fometimes its motions are very flow, at other times very fwift; and when it pleafes it can turn round as upon an axis very nimble, without moving out of its place. The body is tranfparent, except where the circular fpots are placed, which are probably its young. The furface of the body in fome is as if all dotted over with little points, and in others as if granulated like fhagreen. In general it appears as if fet round with fhort moveable hairs." Another author informs us, that "they are at firft very fmall, but grow fo large that they can be difcerned with the naked eye: they are of a yellowifh green colour, globular figure, and in fubftance membranaceous and tranfparent; and in the midft of this fubftance feveral fmall globes may be perceived. Each of thefe are fmaller animalcula, which have alfo the diaphanous membrane, and contain within themfelves ftill fmaller generations, which may be diftinguifhed by means of very powerful glaffes. The larger globules may be feen to efcape from the parent, and then increafe in fize."

This little animal appears like a tranfparent globule of a greenifh colour, the fœtus being compofed of fmaller greenifh globules. In proportion to its age it becomes whiter and brighter, and moves flowly round its axis; but to the microfcope its furface appears as if granulated, the roundeft molecules fixed in the centre being largeft in thofe that are young. The exterior molecules may be wiped off, leaving the membrane naked. When the young ones are of a proper fize, the membrane opens, and they pafs through the fiffure; after which the mother melts away. Sometimes they change their fpherical figure, and become flat in feveral places. They contain from 8 to between 30 and 40 globules within the membrane.

10. The *morum*, with fpherical green globules in the centre. This is found amongft the lemna in the months of October and December, and has a flow rotatory motion. The globules feldom move, though a flow quivering motion may fometimes be perceived among them in the centre.

11. The *alva*, compofed of green globules not inclofed in any membrane, is found in the month of Auguft in water where the lemma polyrrhiza grows. —It confifts of a congeries of greenifh-coloured globules, apparently of an equal fize, with a bright fpot in the middle; the whole mafs is fometimes of a fpherical form, fometimes oval, without any common membrane: a kind of halo may be perceived round it, and the mafs generally moves from right to left, but fcarce any motion can be perceived among the globules themfelves. Thefe maffes contain from four to fifty globules, of which a folitary one may fometimes be feen. Sometimes alfo two maffes of globules have been perceived joined together.

12. The *vegetans*, terminating in a little bunch of globules. This is found in river-water in the month of November. It confifts of a number of floccofe opaque branches invifible to the naked eye; and at the apex of thefe is a fmall congeries of very minute oval pellucid corpufcles. Muller, who difcovered this, fuppofed it at firft to be a fpecies of microfcopic and river fertularia: but he afterwards found the bunches quitting the branches, and fwimming about in the water with a proper fpontaneous motion; many of the old branches being deferted, and the younger ones furnifhed with them.

IV. *Enchelis*:

A fimple, invifible, cylindric worm.

1. The *viridis*, or green enchelis, has an obtufe tail, the forepart terminating in an acute truncated angle; the inteftines are obfcure and indiftinct. It continually varies its motion, turning from right to left.

2. The *punctifera*, having the fore part obtufe, the hinder part pointed. It is opaque, and of a green colour, with a fmall pellucid fpot in the fore part, in which two black points may be feen; and a kind of double

 double band crosses the middle of the body. The hinder part is pellucid and pointed, with an incision, supposed to be the mouth, at the apex of the fore-part. It is found in marshes.

3. The *deses*, or gelatinous enchelis, is found, though rarely, in an infusion of lemnæ, and moves very slowly. The body is round, of a very dark-green, the fore-part bluntly rounded off, and the hinder part somewhat tapering, but finished with a round end: near the extremities there is a degree of transparency.

4. The *similis*, with moveable intestines, is found in water that has been kept for several months: it is of an egg-shape, and generally moves very quick, either to the right or left. It is supposed to be furnished with hairs, because when moving quickly the margin appears striated. The body is opaque with a pellucid margin, and filled with moveable spherules.

5. The *serotina*, with immoveable intestines, is of an oval figure, partly cylindrical, the fore-part smaller than the hind, with a black margin, full of gray vesicular molecules: it moves very slowly.

6. The *nebulosa*, with visible moveable intestines, is found in the same water with the cyclidium glaucoma, but is much more scarce. The body is egg-shaped, the fore-part narrow, and frequently filled with opaque confused intestines: when moving, it elevates the fore-part of the body. It is about three times as large as the cyclidium glaucoma.

7. The *feminulum* is found in water that has been kept for some days, and moves by ascending and descending altenately. It is of a cylindrical figure, twice as long as broad, the intestines in the fore-part transparent, but opaque in the hinder part. Sometimes it is observed swimming about with the extremities joined together.

8. The *intermedia*, with a blackish margin, is one of the smallest animalcules: it has a transparent body, without any visible intestines. The fore and hind parts are of an equal size, and the edge is of a deeper colour than the rest. Some have a point in the middle, others a line passing through it.

9. The *ovulum*, is transparent, round, and egg-shaped. A very strong magnifier discovers some long foldings on the surface, with a few bright molecules here and there.

10. The *pirum*, with the hinder part transparent, has the fore-part protuberant and filled with molecules. The hinder part is smaller and empty, with moveable molecular intestines. Its motion is rapid, passing backwards and forwards through the diameter of the drop. When at rest, it appears to have a little swelling on the middle of the body.

11. The *tremula* was found in an infusion with the paramæcia aurelia, and many other animalcules. It is among the least of these minute creatures, and is of a cylindrical figure and gelatinous texture. Its extremity appears pointed, and has a tremulous motion, so as to induce a suspicion that the creature has a tail. Two of these creatures may at times be seen to adhere together.

12. The *constricta*, with a stricture in the middle, is found in salt-water, and is of a very small size, having the middle drawn in as if tied with a string. It is of an oval shape.

13. The *elliptica*, with a congeries of green intestines, is found among the green matter on the sides of vessels in which water has been kept for some time. It is of a roundish shape, and transparent; the fore-part obtuse, the hinder part rather sharp, and marked with green spots. They are generated in such numbers, that myriads may sometimes be found in one drop.

14. The *fusus*, with both ends truncated, was found in water called pure, and had a languid motion. The body is round and transparent, with the fore and hind parts somewhat smaller then the rest. In the inside is a long and somewhat winding intestine, with a bright sky-coloured fluid, and some black molecules transversely situated.

15. The *fritillus*, with the fore-part truncated, is found in an infusion of grass and hay, and runs backward and forward through the drop with a wavering motion. It is one of the most transparent animalcules, and has the fore-part obtusely convex.

16. The *caudata*, with a kind of tail, is but seldom met with. The body is grey and transparent, with globular molecules divided from each other, and dispersed thro' the whole; the fore-part is thick and obtuse, the hind part crystalline and small, the end truncated.

17. The *epistomium*, with the fore-part slender and roundish, is among the smaller animalcula; the body cylindrical and bright, the hind part obtuse, the fore-part smaller, and terminating in a globule, with now and then a black line down the middle.

18. The *gemmata* is found in ditch-water where the lemna thrives. It has a cylindrical body, the upper part running out into a transparent neck, with a double series of globules running down the body. It moves slowly, and generally in a straight line.

19. The *retrograda* moves commonly sideways, and sometimes in a retrograde manner. It has a gelatinous transparent body, thicker in the middle than at the ends, without any thing that can be called intestines, except a pellucid globule discoverable near the hinder part.

20. The *festinans*, with obtuse ends, is found in sea-water, and has a quick vacillatory motion from one side to the other. The body is round, with the fore-part transparent. More than half the length of it is without any visible intestines; but the lower end is filled with minute vesicular and transparent globules; a large globular vesicle is also observed in the fore-part.

21. The *farcimen* was found by Joblot in an infusion of blue bottles, moving very slowly in an undulatory manner. The body is cylindrical, about four times as long as broad, truncated at both ends, the intestines opaque, and not to be distinguished from one another. It forms itself into the shape of the letter *S*, by turning the two extremities contrariwise.

22. The *index* is found in water with the lemna minor; the body opaque, of a grey colour, and long conical shape: the lower end is obtuse, one side projecting like a finger from the edge, with two very small projections from the lower end. It has the power of retracting these projections, and making both ends appear obtuse.

23. The *truncus*, with a kind of head, is the largest of this kind of animalcules. The body is grey, long, and mucous; the fore-part globular, the hinder part obtuse; but it can alter its shape considerably. Sometimes there is an appearance of three teeth proceeding from

Microscope from one of the fides. Globules of different fizes may be obferved within the body. The creature rolls flowly about from right to left.

24. The *larva* is long, round, and filled with molecules. The fore-part is obtufe and tranfparent, with a kind of neck or fmall contraction formed near this end: the lower part is pointed; and about the middle of the body are two fmall pointed projections like nipples, one on each fide.

25. The *fpatula*, with the fore-part tranfparent, and of the fhape of a fpatula. It is perfectly cylindrical, cryftalline, and marked with fine longitudinal furrows; having generally two tranfparent globules, one below the middle, the other near the extremity. It moves in a wavering kind of manner, retaining its general form, but moving the fpatula in various ways. Muller informs us, that he faw it once draw the fpatula within the body, and keep it there for two hours.

26. The *pupula*, with the fore-part papillary, is found in dunghill water in November and December: it has a rotatory motion on a longitudinal axis, and moves in an oblique direction through the water. Both ends are obtufe; and the hinder part is marked with a tranfparent circle, or circular aperture.

27. The *pupa*, with a fmall nipple proceeding from the apex, has a very flow motion, and refembles the former, only that it wants the tranfparent circle, and is much larger. It is all opaque but the fore-end, and filled with obfcure points.

V. *Vibrio:*

A very fimple, invifible, round, and rather long worm.

1. The *lineola* is found in moft vegetable infufions in fuch numbers, that it feems to fill up almoft the whole of their fubftance. It is fo fmall, that with the beft magnifiers we can difcern little more than an obfcure tremulous motion among them. It is more flender than the monas terma.

2. The *rugula* is like a bent line; and fometimes draws itfelf up in an undulated fhape, at others moves without bending the body at all.

3. The *bacillus*, equally truncated at both ends, is found in an infufion of hay; but Muller mentions the following remarkable fact, *viz.* that having made two infufions of hay in the fame water, he put the hay whole in the one, but cut it in pieces in the other: he found in the former none of the vibrio bacillus, but many of the monas lens and kolpoda cucullus; in the latter were many of the vibrio, but few of the other.—This is from fix to ten times longer than the monas lens, but much more flender.

4. The *undula*, is a round, gelatinous, little, undulating line. This is the animal which Leewenhoeck fays is lefs than the tail of one of the feminal animalcules. It never appears ftraight; but when at reft it refembles the letter V, and when in motion the letter M. It commonly refts on the top of the water: fometimes it fixes itfelf by one extremity, and whirls round.

5. The *ferpens*, with obtufe windings or flexures, is found in river-water, but feldom. It is flender, and gelatinous, refembling a ferpentine line, with an inteftine down the middle.

6. The *fpirillum* is exceedingly minute, and twifted in the form of a fpiral, which feems to be its natural fhape, as it never untwifts itfelf, but moves forward in a ftraight line, vibrating the hind and fore parts. It was found in 1782 in an infufion of the fonchus arvenfis.

7. The *vermiculus* has a milky appearance, with an obtufe apex, and a languid undulatory motion, like that of the common worm. It is found in marfhy water in November, but feldom. It is thought to be the animal mentioned by Leewenhoeck as found in the dung of the frog and fpawn of the male libellula.

8. The *inteftinum* is found in marfhy waters, and has a flow progreffive motion. It is milk-coloured, with two obtufe ends, and four or five fpherical eggs are perceivable at the hinder extremity.

9. The *bipunctatus* is found in fetid falt-water, and moves flowly; for the moft part in a ftraight line. The body is pellucid, and of a talc-like appearance; both ends are truncated, and in the middle one or two pellucid globules placed lengthwife.

10. The *tripunctatus* is alfo tranfparent and talcy, with both ends tapering. It has three pellucid globules, the middle one of which is largeft, the fpace between them being generally filled with a green matter. It moves in a ftraight line, backwards and forwards.

11. The *paxillifer*, or ftraw-like vibrio, confifts of a tranfparent membrane, with yellow inteftines, and two or three vifible points. They are found in parcels together from feven to forty in number, and ranged in a variety of forms. When at reft, they generally affume a quadrangular figure; and are thought to have fome affinity to the *hair-like animal* defcribed by Mr Baker, and of which an account is given under the article ANIMALCULE, n° 3.

12. The *lunula*, or bow-fhaped vibrio, refembles the moon at its firft quarter; it is of a green colour, and has from feven to ten globules difpofed in a longitudinal direction.

13. The *verminus* is found in great plenty in falt-water kept for fome days till it becomes fetid. It moves quickly, and with an undulatory motion, backwards and forwards. It is a long tranfparent membrane, with the hind part broader than the fore one. Thefe animalcula feem to be joined together in a very fingular manner.

14. The *malleus* is found in great plenty in fpring-water, and is alternately at reft and in motion every moment; in the former cafe refembling the letter T, and in the latter V. It is a white pellucid animalcule, with a globule affixed to the bafe.

15. The *acus* is in the fhape of a fewing needle; the neck round and partly tranfparent, and marked in the middle with a red point; the tail refembling a fine briftle.

16. The *fagitta*, with a fetaceous tail, has a long and flexible body; broadeft about the middle, and filled there alfo with grey molecules; the fore-part being drawn out into a thin and tranfparent neck, and the upper end thick and black. It is found in falt-water, and feems to move by contracting and extending its neck.

17. The *gordius*, with a tail terminated by a fmall tubercle, was found in an infufion made with falt water. Its fore part throughout about one fixth of its length is tranfparent, and furnifhed with an alimentary tube of a fky colour; the lower part being

 ing bright and pointed, and the middle full of ſmall globules.

18. The *ſerpentulus*, ſomewhat pointed at both ends. This is found in the infuſions of vegetables which have been kept for ſome weeks. Its body is of a whitiſh colour, frequently convoluted, and drawn into different figures. The tail is furniſhed with a long row of very minute points.

19. The *coluber* is found in river-water; the tail is extremely ſmall, and bent ſo as to form a conſiderable angle with the body; the mouth, œſophagus, the molecules in the inteſtines, and the twiſtings of them, are eaſily diſcerned.

20. The *anguillula* is divided into four varieties: 1. The vinegar eel; 2. That in paſte; 3. That of freſh water; and, 4. That of ſalt. The two firſt are treated of under the article Animalcule; the third is exceedingly tranſparent, with a few tranſverſe lines upon the body, but without any appearance of inteſtines. Sometimes it has a long row of little globules, and is frequently furniſhed with two ſmall oval ones: the tail terminates in a point. It has been found in the ſediment formed by vegetables on the ſides of veſſels in which water had been kept for a long time. The fourth variety appears, when preſſed between two glaſs plates, to be little more than two cryſtalline ſkins with a kind of inteſtines of a clay colour. The younger ones are furniſhed with pellucid molecules.

21. The *linter*, or ventricoſe oval vibrio, with a ſhort neck, is found among the *lemnæ*, but not very frequently. It is among the larger kinds of animalcules, egg-ſhaped, pellucid, inflated, and ſomewhat depreſſed at top; having a moveable cryſtalline neck, and the belly filled with pellucid molecules.

22. The *utriculus* reſembles a bottle; the belly is full of molecular inteſtines, the neck bright and clear, the top truncated, and ſome have a pellucid point at the bottom of the belly. It has a conſtant and violent vacillatory motion, the neck moving very quickly from ſide to ſide.

23. The *faſciola* is found in water juſt freed from the froſt, and not often in any other fluid. It is pellucid, with inteſtines like points in the middle. There is likewiſe an alimentary canal gradually diminiſhing in ſize. Its motion is very quick.

24. The *colymbus* is larger than many of the other ſpecies of vibrio, and reſembles a bird in ſhape. The neck, which is a little bent, is round, ſhorter than the trunk, of an equal ſize throughout, and of a bright appearance, with the apex obtuſe. The trunk is thick, ſomewhat triangular, full of yellow molecules; the fore part broad, the hinder part acute, the motion ſlow.

25. The *ſtrictus* has a linear body, being a bright membranaceous thread; the hinder part ſomewhat thicker, round, and filled with molecules, excepting at the end, where there is a ſmall empty pellucid ſpace. It can draw in the ſlender filiform part at pleaſure.

26. The *anas*, with both ends attenuated, and the neck longer than the tail, is found in ſalt water; tho' a kind is likewiſe found in freſh water with a neck longer than the other. The trunk of this animalcule is oblong, opaque, and filled with molecules; the fore and hind parts are drawn out into a pellucid talcy membrane, which the creature can retract at pleaſure.

27. The *cygnus* is a very pellucid line, crooked at top, ſwelling in the middle, and ſharp at the end; the middle full of dark coloured molecules and pellucid inteſtines. It is very ſmall, and moves more ſlowly than any of thoſe that move and advance their necks.

28. The *anſer* is found in water where duckweed grows. The trunk is elliptic, round, and without any inequality on the ſides. It is full of molecules: the hind part ſharp and bright; the fore part produced into a bending neck, longer than the body; the apex whole and even, with blue canals paſſing between the marginal edges, occupying the whole length of the neck; and in one of them a violent deſcent of water to the beginning of the trunk is obſervable. It moves the body ſlow, but the neck more briſkly.

29. The *olor* is found in water that has been kept for a long time, and is full of vegetable green matter. The body is elliptical and ventricoſe, the hind part ſomewhat ſharp, and ſometimes filled with darkiſh molecules. The neck is three or four times longer than the body; of an equal ſize throughout, and is moved very quickly; but the motion of the body itſelf is ſlow.

30. The *falx*, with a crooked neck, and obtuſe hinder part, is pellucid and elliptical; the fore part leſſening into a little, round, bright neck, nearly as long as the trunk. The latter is ſomewhat gibbous, and filled with very ſmall molecules; and there are two ſmall bright globules, one within the hind extremity, and the other in the middle of the body. The neck of this animalcule is immoveable; whence it moves ſomething like a ſcythe.

31. The *intermedius* appears to be an intermediate ſpecies betwixt the falx and the faſciola. It ſeems to be a thin membrane conſtantly folded. The whole has a cryſtalline talcy appearance; the middle filled with grey particles of different ſizes. It has all round a diſtinct bright margin.

VI. *Cyclidium.*

A ſimple, inviſible, flat, pellucid, orbicular or oval worm.

1. The *bulla*, or orbicular bright cyclidium. This is found occaſionally in an infuſion of hay. It is very pellucid and white, but the edges ſomewhat darker than the reſt. It moves ſlowly, and in a ſemicircular direction.

2. The *millium* is very pellucid, and ſplendid like cryſtal; and of an elliptical figure, with a line through the whole length of it. The motion is ſwift, interrupted, and fluttering.

3. The *fluitans* is one of the ſmalleſt animalcula; the body ſomewhat of an oval ſhape, with two ſmall blue ſpaces at the ſides.

4. The *glaucoma* has an oval pellucid body, with both ends plain, or an oval membrane with a diſtinct well-defined edge. The inteſtines are ſo tranſparent, that they can ſcarce be diſcerned when it is empty. When full, they are of a green colour, and there are dark globules diſcoverable in the middle. When there is plenty of water this animalcule moves ſwiftly in a circular and diagonal direction; when it moves ſlowly, it ſeems to be taking in water, and the inteſtines are in a violent commotion. It generates by diviſion.

5. The *nigricans* is very ſmall, pellucid, and flat, with a black margin

Microscope

6. The *roſtratium* is oval, ſmooth, and very pellucid, with the fore part running out into an obtuſe point, with which it ſeems to feel and examine the bodies to which it comes. The inteſtines are filled with a blue liquor, the colour of which ſometimes vaniſhes, and then they ſeem to be compoſed of veſicles.

7. The *nucleus* reſembles a grape ſeed, the body being pellucid and depreſſed, the fore part obtuſely convex, and the hind part acute.

8. The *hyalinum* has a tremulous kind of motion; the body oval, flat, and bright, without any viſible inteſtines.

9. The *pediculus* is ſcarce ever ſeen but on the hydra pallida, upon which it runs as if it had feet. It is gelatinous and white; the bottom gibbous over the back; the extremities depreſſed and truncated, with one end ſometimes apparently cloven into two, which may be ſuppoſed the mouth.

10. The *dubium* is of an oval ſhape, with one ſide convex, the other concave; the margin pellucid, and the inner part containing a great number of molecules.

VII. *Paramæcium*.

An inviſible, membranaceous, flat, and pellucid worm.

1. The *aurelia* is membranaceous, pellucid, and four times longer than it is broad; the fore part obtuſe and tranſparent; the hind part filled with molecules. It has ſomewhat the appearance of a gimlet by reaſon of a fold which goes from the middle to the apex, and is of a triangular figure. It moves in a rectilinear and vacillatory manner. It is found in ditches where there is plenty of duckweed, and will live many months in the ſame water without any renewal of the latter.

2. The *chryſalis* is found in ſalt water, and differs very little from the former, only the ends are more obtuſe, and the margins are filled with black globules.

3. The *verſutum* is found in ditches, and has an oblong, green, and gelatinous body, filled with molecules; the lower part thicker than the other; and both ends obtuſe. It propagates by diviſion.

4. The *oviferum* is membranaceous, oval, grey, and pellucid, with many oval corpuſcles diſperſed through the body.

5. The *marginatum* is flat, elliptical, and every where filled with molecules, except in the lower end where there is a pellucid veſicle. It is ſurrounded by a broad double margin, and a bright ſpiral inteſtine is obſervable.

VIII. *Kolpoda*.

An inviſible, pellucid, flat, and crooked worm.

1. The *lamella* is very ſeldom met with. It reſembles a long, narrow, and pellucid membrane, with the hind part obtuſe, narrower, and curved towards the top. It has a vacillatory and very ſingular motion; going upon the ſharp edge, not on the flat ſide as is uſual with microſcopic animals.

2. The *gallinula* is found in fetid ſalt water; and has the apex ſomewhat bent, the belly oval, convex, and ſtriated.

3. The *roſtrum* is found though ſeldom, in water where the lemna grows; and has a ſlow and horizontal motion. The fore part is bent into a kind of hook; the hind part obtuſe, and quite filled with black molecules.

Microſcope

4. The *ochrea* is depreſſed, membranaceous, and flexible; one edge nearly ſtraight; the other ſomewhat bent, filled with obſcure molecules, and a few little bladders diſperſed here and there.

5. The *mucronata* is a dilated bright membrane; the apex an obtuſe point, with a broad marked border running quite round it. It is filled with grey molecules within the margin, and has a truncated appearance.

6. The *triquetra* was found in ſalt water, and appears to conſiſt of two membranes; the upper ſide flattened, the lower convex, with the apex bent into a kind of ſhoulder.

7. The *ſtriata* is likewiſe found in ſalt water, and is very pellucid and white, with the upper part rather bent, and terminating in a point; the lower part obtuſely round: there is a little black pellucid veſicle at the apex; and with a very great magnifying power the body appears covered with long ſtreaks.

8. The *nucleus* is of an oval ſhape, with the vertex pointed, and of a brilliant tranſparency, by which the viſcera are rendered viſible. Theſe conſiſt of a number of round diaphanous veſicles.

9. The *meleagris* has a dilated membrane, with very fine folds, which it varies in a moment. The fore part of the body to the middle is clear and bright; the hind part variouſly folded in tranſverſe and elevated plaits and full of molecules. Beneath the apex are three or four teeth; but in ſome the edge is obtuſely notched, and ſet with ſmaller notches. In the hinder part are 12 or more equal pellucid globules.

10. The *aſſimilis* is found on the ſea-coaſt, and has an elliptic maſs in the middle, but is not folded like the former. The margin of the fore part is notched from the top to the middle; the lower part ſwells out, and contracts again into a ſmall point.

11. The *cucullus* is found in vegetable infuſions, and in fetid hay; moving in all directions, and commonly with great vivacity. It is very pellucid, and has a well defined margin, filled with little bright veſicles differing in ſize, and of no certain number. Its figure is commonly oval, with the top bent into a kind of beak, ſometimes oblong, but moſt commonly obtuſe. It has in the inſide from 8 to 24 bright little veſicles not diſcernible in ſuch as are young. Some have ſuppoſed theſe to be animalcules which this creature has ſwallowed; but Mr Muller is of opinion that they are its offspring. When this creature is near death by reaſon of the evaporation of the water, it protrudes its offspring with violence. From ſome circumſtances it would ſeem probable that this animalcule caſts its ſkin, as is the caſe with ſome inſects.

12. The *cucullulus* is found in an infuſion of the ſonchus arvenſis. It is very pellucid and cryſtalline, with ſeveral globules, and has an oblique inciſion a little below the apex.

13. The *cuculio* is elliptical, flat on the upper ſide, and convex on the under; the fore part is clear, and from the middle to the hinder part is full of ſilver-like globules. It frequently ſtretches out the fore part, and folds it in different poſitions.

14. The

14. The *ren*, or *crassa*, is found in an infusion of hay, commonly about 13 hours after the infusion is made, and has a quick and vacillatory motion. Its body is yellow, thick, and somewhat opaque; curved a little in the middle, so that it resembles a kidney; and full of molecules. When the water in which it swims is about to fail, it takes an oval form, is compressed, and at last bursts.

15. The *pirum* has an uniform and transparent body, without any sensible inequality; and is of a pale colour, with obscure little globules. It propagates by division.

16. The *cuneus* is white, gelatinous, and without any distinct viscera; having a bright striated pellucid pustule on one side of the fore part. The apex has three or four teeth; and it can bend the hinder part into a spiral form.

IX. *Gonium*.

An invisible, simple, smooth, and angular worm.

1. The *pectorale* is found in pure water, and moves alternately towards the right and left. It is quadrangular and pellucid, with 16 spherical molecules of a greenish colour, "set in a quadrangular membrane, like the jewels in the breast-plate of the high-priest, reflecting light on both sides."

2. The *pulvinatum* is found in dunghills; and appears like a little quadrangular membrane, plain on both sides: but with a large magnifier it appears like a bolster formed of three or four cylindric pillows sunk here and there.

3. The *corrugatum* is found in various kinds of infusions; and is somewhat of a square shape, very small, and in some positions appears as streaked.

4. The *rectangulum* differs but little from the former: the angle at the base is a right one; the larger vesicle is transparent, the rest green.

5. The *truncatum* is found chiefly in pure water, and then but seldom. It has a languid motion, and is much larger than the foregoing. The fore part is a straight line, with which the sides form obtuse angles, the ends of the sides being united by a curved line. The internal molecules are of a dark green, and there are two little bright vesicles in the middle.

X. *Bursaria*.

A very simple, hollow, membranaceous worm.

1. The *truncatella* is visible to the naked eye; white, oval, and truncated at the top, where there is a large aperture descending towards the base. Most of them have four or five yellow eggs at the bottom. They move from left to right, and from right to left; ascending to the surface in a straight line, and sometimes rolling about while they descend.

2. The *bullina* is pellucid and crystalline, having splendid globules of different sizes swimming about with it. The under side is convex, the upper hollow, with the fore part forming a kind of lip.

3. The *hirundinella* has two small projecting wings, which give it somewhat of the appearance of a bird; and it moves something like a swallow. It is invisible to the naked eye; but by the microscope appears a pellucid hollow membrane.

4. The *duplella* was found among duckweed, and appears like a crystalline membrane folded up, without any visible intestines except a small congeries of points under one of the folds.

5. The *globina* has a roundish shape, and is hollow; the lower end being furnished with black molecules of different sizes, the fore part with obscure points, the rest entirely empty, and the middle quite transparent. It moves very slowly from right to left.

XI. *Cercaria*.

An invisible transparent worm with a tail.

1. The *gyrinus* greatly resembles the spermatic animalcules. It has a white gelatinous body; the fore part somewhat globular; the hind part round, long, and pointed. Sometimes it appears a little compressed on each side. When swimming it keeps its tail in continual vibration like a tadpole.

2. The *gibba* is found in the infusions of hay and other vegetables; and is small, opaque, gelatinous, white, and without any visible intestines.

3. The *inquieta* is found in salt water, and is remarkable for changing the shape of its body: sometimes it appears spherical, sometimes like a long cylinder, and sometimes oval. It is white and gelatinous, the tail filiform and flexible, the upper part vibrating violently. A pellucid globule may be observed at the base, and two very small black points near the top.

4. The *lemna* varies its form so much, that it might be mistaken for the proteus of Baker, described under the article ANIMALCULE; though in fact it is totally different. The body sometimes appears of an oblong, sometimes of a triangular, and sometimes of a kidney shape. The tail is generally short, thick, and annulated; but sometimes long, flexible, cylindric, and without rings; vibrating, when stretched out, with so much velocity, that it appears double. A small pellucid globule, which Muller supposes to be its mouth, is observable at the apex; and two black points not easily discovered, he thinks, are its eyes. Sometimes it draws the tail entirely into the body. It walks slowly after taking three or four steps, and extends the tail, erecting it perpendicularly, shaking and bending it; in which state it very much resembles a leaf of the lemna.

5. The *turbo*, with a tail like a bristle, is found among duckweed. It is of a talcy appearance, partly oval and partly spherical; and seems to be composed of two globular bodies, the lowermost of which is the smallest, and it has two little black points like eyes on the upper part. The tail is sometimes straight, sometimes turned back on the body.

6. The *poduria* is found in November and December, in marshy places covered with lemna. It is pellucid; and seems to consist of a head, trunk, and tail: the head resembles that of a herring; the trunk is ventricose and full of intestines, of a spiral form and black colour. The tail most commonly appears to be divided into two bristles. The intestines are in a continual motion when the body moves, and by reason of their various shades make it appear very rough. There are likewise some hairs to be perceived. It turns round as upon an axis when it moves.

7. The *viridis* is found in the spring in ditches of standing water; and in some of its states has a considerable resemblance to the last, but has a much greater power of changing its shape. It is naturally cylindrical,

lindrical, the lower end ſharp, and divided into two parts; but ſometimes contracts the head and tail ſo as to aſſume a ſpherical figure.

8. The *ſetifera* is found in ſalt water, but ſeldom. It is ſmall, the body rather opaque, and of a round figure. The upper part is bright, and ſmaller than the reſt: the trunk is more opaque; the tail ſharp, and near it a little row of ſhort hairs. It has a ſlow rotatory motion.

9. The *hirta* was likewiſe found in ſalt water. It is opaque and cylindrical; and when in motion, the body appears to be ſurrounded with rows of ſmall hairs ſeparated from each other.

10. The *crumena* has a ventricoſe, cylindrical, thick, and wrinkled body; the lower part ſmall; the upper part terminating in a ſmall ſtrait neck like that of a pitcher; the tail linear, and terminating in two diverging points.

11. The *catellus* has a moveable head fixed to the body by a point. The abdomen is twice as long as the head, full of inteſtines, and has a tail ſtill narrower, and terminating in two briſtles which it can unite and ſeparate at pleaſure. It moves briſkly, but without going far from its firſt place.

12. The *catelina* was found in a ditch where there was plenty of duckweed. It is larger than the preceding, and has a thicker and more cylindrical body; the lower part truncated, with two ſhort diverging points projecting from the middle.

13. The *lupus* is found in water among duckweed, and is larger than moſt of the genus. The head is larger than the body; the apex turned down into a little hook; the tail is like the body, but narrower, terminating in two very bright ſpines, which it extends in different directions. Sometimes it contracts into one half its common ſize, and again extends itſelf as before.

14. The *vermicularis* is long, cylindrical, fleſhy, and capable of changing its ſhape. It is divided into eight or nine rings or folding plaits; the apex either obtuſe, or notched into two points; the hinder part rather acute, and terminating in two pellucid thorns, between which a ſwelling is ſometimes perceived. It often projects a kind of cloven proboſcis from the inciſion at the apex. It is found in water where there is duckweed.

15. The *forcipata* is found in marſhy places, is cylindrical and wrinkled, with a forked proboſcis which it can thruſt out or pull in.

16. The *pleuronectes* is found in water which has been kept for ſeveral months. It is membranaceous, roundiſh, and white, with two blackiſh points in the fore part, the hinder part being furniſhed with a ſlender ſharp tail. It has orbicular inteſtines of different ſizes in the middle; the larger of them bright. The motion is vacillatory; and in ſwimming it keeps one edge of the lateral membrane upwards, the other folded down.

17. The *tripos* is flat, pellucid, triangular, having each angle of the baſe or fore part bent down into two linear arms, the apex of the triangle prolonged into tail. It is found in ſalt water.

18. The *cyclidium* is frequently found in pure water, and has an oval, ſmooth, membranaceous, pellucid body with a black margin. The tail is concealed under the edge, and comes out from it at every motion, but in ſuch a manner as to project but little from the edge. There is alſo a kind of border to the hinder part.

19. The *tenax* appears like an oval pellucid membrane, ſomething larger than the *monas lens*. The fore edge is thick and truncated; the hinder part acute, and terminating in a ſhort tail. It whirls about in various directions with great velocity.

20. The *diſcus* is a ſmall orbicular animalcule, with a bent tail.

21. The *orbis* is round, and has a tail conſiſting of two long briſtles.

22. The *luna* is likewiſe round, and has the forepart hollowed into the form of a creſcent.

XII. *Leucophra.*

An inviſible, pellucid, and ciliated worm.

1. The *conflictor*, with moveable inteſtines, is perfectly ſpherical and ſemitranſparent, of a yellow colour, the edges dark. It rolls from right to left, but ſeldom removes from the ſpot where it is firſt found. It is filled with a number of the moſt minute molecules, which move as if they were in a violent conflict; and in proportion to the number of theſe little combatants which are accumulated either on one ſide or other, the whole maſs rolls either to the right or left. It then remains for a little time at reſt, and the conflict ceaſes; but it ſoon becomes more violent, and the ſphere moves the contrary way in a ſpiral line. When the water begins to fail, they aſſume an oblong, oval, or cylindric figure; the hinder part of ſome being compreſſed into a triangular ſhape, and the tranſparent part eſcaping as it were from the inteſtines, which continue to move with the ſame violence till the water fails, when the molecules ſhoot into a ſhapeleſs maſs, which alſo ſoon vaniſhes, and the whole aſſumes the appearance of cryſtals of ſal ammoniac.

2. The *mamilla* is of a dark colour, and filled with globular molecules; ſhort hairs are curved inwards; and it occaſionally projects and draws in a little white protuberance. It is pretty common in marſhy water.

3. The *vireſcens* is a large, pear-ſhaped, greeniſh-coloured animalcule, filled with opaque molecules, and covered with ſhort hairs; generally moving in a ſtraight line. It is found in ſalt water.

4. The *viridis* is much ſmaller than the former, and cannot lengthen or ſhorten itſelf as it does. Sometimes it appears contracted in the middle, as if it were to be divided in two.

5. The *burſata* is found in ſalt water, and is ſimilar in many reſpects to the former. It is of a long oval ſhape, bulging in the middle, and filled with green molecules, every where ciliated except at the apex, which is truncated and ſhaped ſomewhat like a purſe; the hairs are ſometimes collected into little faſcicles.

6. The *poſthuma* is globular, and covered as it were with a pellucid net; is found in fetid ſalt water.

7. The *aurea* is yellow, oval; has both ends equally obtuſe; little hairs diſcovered with difficulty; and has in general a vehement rotatory motion.

8. The *pertuſa* is found in ſalt water; and is gelatinous

tinous and ſmall, without any molecules. The fore-part is truncated, the hind-part brought nearly to a point, with a kind of oval hole on one ſide.

9. The *fracta* is long, with ſinuated angles, white, gelatinous, and granulated, changing its form conſiderably.

10. The *dilatata* appears like a gelatinous membrane, with a few grey molecules in the fore-part, and a great number in the hinder part. It is ſometimes dilated into a triangular form with ſinuated ſides; at other times the ſhape is more irregular and oblong.

11. The *ſcintillans* was found in December among the leſſer lemnæ. It is of a green colour, oval, round, and opaque. It is ſuppoſed to be ciliated from its bright twinkling appearance, which probably ariſes from the motion it gives the water.

12. The *veſiculifera* is oval, very pellucid, with a defined dark edge and inſide, containing ſome very bright bladders or veſicles. The middle frequently appears blue, and the veſicles appear as if ſet in a ground of that colour.

13. The *globulifera* was found in a ditch where the lemna minor grew. The body is round, very pellucid, without molecules, but with three little pellucid globules, and every where ſet with ſhort hairs.

14. The *puſtulata* is found in marſhy waters; and is white, gelatinous, and ſomewhat granulated; the lower part truncated as if an oblique ſection were made in an egg near the bottom. It is covered with little erect ſhining hairs, and at the lower extremity a few bright puſtules may be diſcovered.

15. The *turbinata* is found in ſtinking ſalt water; and is round, pellucid, ſomewhat of the ſhape of an acorn, with a pellucid globule at the lower end.

16. The *acuta* is found in ſalt water, and is gelatinous, thick, capable of aſſuming different ſhapes; having the apex bright, and the reſt of the body filled with little ſpherules. Sometimes it draws itſelf up into an orbicular ſhape, at others one edge is ſinuated.

17. The *notata* is oval, round, and has a black point at the edge.

18. The *candida* is found in ſalt water; and is membranaceous, flat, very white, with no viſible inteſtines except two oval bodies not eaſily perceived. The whole edge is ciliated.

19. The *nodulata* is oblong and oval, with a double row of little nodules.

20. The *ſignata* is common in ſalt water in the months of November and December. It is oblong and ſubdepreſſed, with a black margin filled with little molecules, but more particularly diſtinguiſhed by a curved line in the middle ſomewhat in the ſhape of the letter S; one end of which is ſometimes bent into the form of a ſmall ſpiral.

21. The *trigona* is found in marſhes, but not commonly. It is a yellow triangular maſs filled with unequal pellucid veſicles, one of which is much larger than the reſt, and the edge ſurrounded with ſhort fluctuating hairs.

22. The *fluida* is ſomewhat of a kidney ſhape, but ventricoſe.

23. The *fluxa* is reniform and ſinuated.

24. The *armilla* is round and annular.

25. The *cornuta* is of the ſhape of an inverted cone, opaque, and of a green colour. This requires to be obſerved for ſome time before we can aſcertain its characters. The body is compoſed of molecular veſicles; the fore part is wide and truncated, with a little prominent horn or hook on both ſides; the hind part being conical, every where ciliated, and the hairs exceedingly minute; thoſe in the fore part are three times longer than the former, and move in a circular direction. The hinder part is pellucid, and ſometimes terminates in two or three obtuſe pellucid projections. At one time this animalcule will appear reniform and ciliated on the fore part; but at another time the hairs are concealed. It diſſolves into molecular veſicles when the water evaporates.

26. The *heteroclita* appears to the naked eye like a white point; in the microſcope as a cylindrical body, the fore part obtuſely round, the middle rather drawn in; the lower part round, but much ſmaller than the upper part. It appears wholly ciliated through a large magnifier.

XIII. *Trichoda.*
An inviſible, pellucid, hairy worm.

1. The *grandinella* is a very ſmall pellucid globule, with the inteſtines ſcarce viſible, the top of the ſurface furniſhed with ſeveral ſmall briſtles not eaſily diſcoverable, as the creature has a power of extending or drawing them back in an inſtant. It is found in pure water as well as in infuſions of vegetables.

2. The *cometa* is a pellucid globule filled with bright inteſtines, the fore part furniſhed with hairs, the hind part with a pellucid globule.

3. The *granata* reſembles the two former; and has a darkiſh nucleus in the centre, with ſhort hairs on the edge.

4. The *trochus* is ſomewhat of a pear-ſhape, and pellucid; each ſide of the fore part being diſtinguiſhed by a little bunch of hairs.

5. The *gyrinus* is one of the ſmalleſt of this genus, and is found in ſalt water. It is ſmooth and free from hairs, except at the fore part, where there are a few.

6. The *ſol* is ſmall, globular, and cryſtalline; beſet every where with diverging rays longer than the diameter of the body; the inſide full of molecules. The body contracts and dilates, but the creature remains confined to the ſame ſpot. It was found with other animalcules in water which had been kept three weeks.

7. The *ſolaris* is orbicular, bright, and filled with globular inteſtines, frequently having in it a moveable ſubſtance of the ſhape of the letter S. It has hairs ſeldom exceeding 17 in number, ſet round the circumference, each of them nearly equal in length to the diameter of the animalcule.

8. The *bomba* is of a yellow colour, and full of clay-like molecules. It moves with ſuch velocity as to elude the ſight, and appears of various ſhapes, ſometimes ſpherical, ſometimes kidney-ſhaped, &c.

9. The *orbis* is compoſed of veſicular molecules; is of a ſpherical figure, ſmooth, pellucid, and a little notched in the fore part. The notched part is filled with long hairs, but there are none on the reſt of the body.

10. The *urnula* is membranaceous, pellucid, ſomewhat in the form of a water pitcher, with the fore part hairy. It moves but ſlowly.

11. The *diota* is of a clay-colour, and filled with molecules;

Microscope molecules; the upper part cylindrical and truncated, the lower part ſpherical, the upper part of the mouth hairy at the edges.

12. The *horrida* is ſomewhat of a conical ſhape, the fore part rather broad and truncated, the lower part obtuſe, and the whole covered with radiating briſtles.

13. The *urinarium* is egg-ſhaped, with a ſhort hairy beak.

14. The *ſemiluna* is ſmooth, pellucid, and ſhaped like a creſcent.

15. The *trigona* is of a triangular ſhape, a little convex on both ſides, the fore part acute and ciliated, the hind part broader, and having the extremity as it were gnawed off.

16. The *tinea* is round, not very pellucid, narrow in the fore part, and reſembling an inverted club.

17. The *nigra* was found in ſalt water, and has an opaque body; but when at reſt one ſide appears pellucid. When in violent motion, it ſeems entirely black.

18. The *pubes* is found in water where duckweed grows, chiefly in the month of December. It has a bunch above the hind part marked with black ſpots, depreſſed towards the top, a little folded, and ſomewhat convex on the under part. The apex is furniſhed with hairs, but they are ſeldom viſible till the creature is in the agonies of death, when it extends and moves them vehemently, and attempting as it were to draw in the very laſt drop of water.

19. The *floccus* is membranaceous, the fore part rather conical, with three ſmall hairy papillæ projecting from the baſe.

20. The *ſinuata* is found in river water. It is oblong and depreſſed, with one margin hollow and hairy, and the lower end obtuſe. It is of a yellow colour, and the hollow edge ciliated.

21. The *præceps* is pellucid, the fore part formed into a kind of neck; one edge riſing into a protuberance like a hump-back, the other edge convex.

22. The *proteus* is that which Mr Baker diſtinguiſhes by the ſame name, and of which an account is given under the article Animalcule. It is found in the ſlimy matter adhering to the ſides of veſſels in which vegetables have been infuſed, or animal ſubſtances preſerved. That deſcribed by Mr Adams was diſcovered in the ſlime produced from the water where ſmall fiſhes, water-ſnails, &c. had been kept. The body reſembled that of a ſnail, the ſhape being ſomewhat elliptical, but pointed at one end, while from the other proceeded a long, ſlender, and finely proportioned neck, of a ſize ſuitable to the reſt of the animal.

23. The *verſatilis* lives in the ſea, and has ſome reſemblance to the proteus; but the neck is ſhorter, the apex leſs ſpherical, and the hinder part of the trunk acute.

24. The *gibba* is pellucid; the upper part ſwelled out, with numerous molecules, and three large globules on the inſide. The ends rather incline downwards; and when the water begins to fail, a few minute hairs may be diſcovered about the head and at the abdomen; the body then becomes ſtriated longitudinally.

25. The *foeta* ſomewhat reſembles a rolling-pin in ſhape; has both ends obtuſe, and one ſhorter than the other. It can draw in the ends, and ſwell out the ſides, ſo as to appear almoſt ſpherical.

26. The *patens* is found in ſalt water; and is of a long cylindrical ſhape, filled with molecules, the fore-part bright and clear, with a long opening near the top which tapers to a point, and is beſet with hairs. Microſcope

27. The *patula* is ventricoſe, rather inclining to an oval figure, with a ſmall tube at the fore part, the upper part of which is hairy.

28. The *foveata* is oblong and rather broad, with three little horns on the fore part.

29. The *ſtriata* is found in the month of December in river-water. It is a beautiful animalcule, of a fox colour. It is of an oblong ſhape, the lower end ſomewhat larger than the other. It has a ſet of ſtreaks running from one end to the other, and at the abdomen a double row of little eggs lying in a tranſverſe direction.

30. The *uvula* is found in the infuſion of hay and other vegetables. It is ſix times longer than broad, round, flexuous, of an equal ſize, the greater part filled with obſcure molecules; the fore part rather empty, with an alimentary canal and lucid globules near the middle. The margin of the fore part is covered with ſhort hairs.

31. The *aurantia* is of a gold colour, pellucid, and filled with veſicles.

32. The *ignita* is of a fine purple colour, with ſomething of a reddiſh caſt, pellucid, ſplendid, with a number of globules of different ſizes; the fore part ſmall, the hinder part obtuſe, with a very large opening which ſeems to run through the body.

33. The *priſma* is very ſmall, and ſo tranſparent that it cannot eaſily be delineated. It is of a ſingular ſhape; the under part being convex, the upper compreſſed into a kind of keel, and the fore part ſmall.

34. The *forceps* is found about the winter ſolſtice in water covered with lemna. It is of a yellow colour, large, ſomewhat tranſparent, and filled with molecules, with a large opaque globule in the lower part. The fore part is divided into long lobes, one of which is falciform and acute, the other dilated and obliquely truncated. It can open, ſhut, or croſs, thoſe lobes at pleaſure; and by the motion of them it appears to ſuck in the water.

35. The *forfex* is found in river water. It has the fore part formed into a kind of forceps, one of which is twice as long as the other, hooked and ciliated.

36. The *index* is found in ſalt water, and has the under part of the front of the margin hairy; the apex is formed by the fore part projecting like a finger on a direction poſt.

37. The *trichoda* is of a yellow colour, formed of two pellucid membranes ſtriated longitudinally; the lower end obliquely truncated, and the two extremities bent in oppoſite directions.

38. The *navicula* has three corners; the fore part truncated and ciliated, the hind part acute and bent a little upwards. It has a cryſtalline appearance, and a kind of longitudinal keel runs down the middle.

39. The *ſucciſa* is of a flattened oval ſhape, the edge hairy, and hollowed out in ſuch a manner as to form two unequal legs.

40. The *ſulcata* is ovated and ventricoſe, the apex acute, with a furrow at the abdomen, and both ſides of it ciliated.

41. The *anas* is found in pure water; and is ſmooth, five

five times broader than it is long, filled with darkifh molecules. It has a bright neck, under the top of which are a few unequal hairs. It moves but languidly.

42. The *barbata* is round, fomewhat linear, with both ends obtufe; the fore part narrower, forming as it were a kind of neck, under which is a row of fluctuating hairs. The trunk is full of grey molecules.

43. The *farcimen* is long, round, pellucid, and covered with very minute hairs, and has a great number of mucous veficles about the body.

44. The *crinita* is long, round, every where ciliated on the upper part, and the under part likewife hairy as far as the middle.

45. The *angulus* is long, more convex than moft of the genus, divided by a kind of articulation in the middle into two parts equal in breadth, but of different lengths; the apex has fhort waving hair.

46. The *linter* is found in an infufion of old grafs. It is egg-fhaped, oblong, with both extremities raifed fo that the bottom becomes convex, and the upper part depreffed like a boat: it is of different fhapes at different ages, and fometimes has a rotatory motion.

47. The *paxillus* is found in falt water; and is long, full of grey molecules; the fore part truncated and hairy, and rather fmaller than the other.

48. The *vermicularis* is found in river water; and is pellucid in the fore part, with the hind part full of molecules.

49. The *melitæa* is found in falt water, but very rarely. It is oblong, ciliated, with a globular apex, a dilatable neck, and a kind of periftaltic motion perceivable within it.

50. The *fimbriata* is fubovated, the apex hairy, the hinder part obliquely truncated and ferrated.

51. The *camelus* is found but rarely in vegetable infufions, and moves in a languid manner. The fore part is ventricofe; the back divided by an incifion in the middle into two tubercles; the lower part of the belly finuated.

52. The *augur* is oblong, depreffed, pellucid, and filled with molecules: the vertex is truncated, the forepart forming a fmall beak with three feet underneath; beyond which, toward the hinder part, it is furnifhed with briftles.

53. The *pupa* is roundifh, pellucid, and confifts of three parts. The head is broad, and appears to be hooded, the top being furnifhed with very fmall hairs; on the lower part of the head is a tranfparent veficle, and over the breaft from the bafe of the head hangs a production refembling the fheath of the feet in the pupa of the gnat.

54. The *lunaris* is round and cryftalline; the hinder part fmaller than the other. The edge of the back and the part near the tail are bright and clear. It bends itfelf into the form of an arch.

55. The *bilunis* is arched and flattened with an hairy apex, and two little briftles proceeding from the tail.

56. The *rattus* is oblong, with a kind of keel; the fore part hairy, and a very long briftle proceeding from the hinder part.

57. The *tigris* refembles the former, but differs in the form of the tail, which confifts of two briftles, and likewife in having a kind of incifion in the body a little below the apex.

58. The *perillum* is frequently found in marfhes. It is cylindrical, pellucid, mufcular, and capable of being folded up. It appears double; the interior part full of molecules, with an orbicular mufcular appendage, which it can open and fhut, and which forms the mouth. The external part is membranaceous, pellucid, dilated, and marked with tranfverfe ftreaks; and it can protrude or draw in the orbicular membrane at pleafure. Some have four articulations in the tail, others five; and it has two pairs of briftles, one placed at the fecond joint, the other at the laft.

59. The *clavus* has a confiderable refemblance to a common nail; the fore part is round and hairy, the hinder part terminating in a fharp tail.

60. The *cornuta* is membranaceous, elliptical, full of molecules; the fore part lunated, the other round, and terminating in a tail as long as the body.

61. The *gallina* is found in river water. It is of a grey colour, flat, with feven large molecules and globules within it; the front obtufe, fet with hairs; the hinder part terminating in a tail formed of very fine hairs.

62. The *mufculus* is found in the infufions of hay which have been kept for fome months. It is fmooth, egg-fhaped, with a double margin drawn underneath it: the fore part narrow, and furnifhed with fhort hairs which continually play about; having a fmall tail underneath. It moves flowly, and is furnifhed with molecular inteftines.

63. The *delphis* is found in river water. It is fmooth, pellucid, having the fore part dilated into a femicircle, gradually decreafing in breadth towards the tail. The front is hairy, the hairs ftanding as rays from the femicircular edge: one of the edges is fometimes contracted.

64. The *delphinus* is found in hay that has been infufed for fome months. It is pellucid, fmooth, and egg-fhaped; the hinder part terminating in a tail about half the length of the body, dilated at the upper end, truncated, and always bent upwards. It moves fometimes on its belly and fometimes on its fide.

65. The *clava*, or club trichoda, has the fore part thick, but the hinder part narrow; both extremities obtufe, pellucid, and replete with molecules; the hind part bent down towards the middle.

66. The *cuniculus* is oblong, the fore part hairy, the hinder part rather acute, and filled with molecules and black veficles.

67. The *felis* is large and curved, the fore part fmall, the hinder part gradually diminifhing into a tail, the under part befet with hairs longitudinally.

68. The *pifcis* is oblong, the fore part hairy, the hind part terminating in a very flender tail. It is fmooth, pellucid, much longer than broad, and filled with yellow molecules; the fore part obtufe, the hinder part extremely flender and tranfparent, the upper fide convex.

69. The *larus* is long, round, befet with hairs, and has the tail divided into two points.

70. The *longicauda* is cylindrical; the fore part truncated, and befet with hairs; the tail long, furnifhed with two briftles, and having two joints.

71. The *fixa* has the circumference fet with hairs, and a little folitary pedicle projecting from the body.

72. The *inquilinus* is fheathed within a cylindrical

 tranfparent bag, having a little pedicle bent back within the bag.

73. The *ingenita* is fheathed in a depreffed bag, broadeft at the bafe. The animalcule itfelf is funnel-fhaped, with one or more hairs proceeding from each fide of the mouth of the funnel. It can extend or contract itfelf within the bag, fixing its tail to the bafe, without touching the fides. It is found in falt water.

74. The *innata* is fheathed in a cylindrical bag, with a pedicle paffing through and projecting beyond it.

75. The *transfuga* is broad, the fore part hairy, the hinder part full of briftles; one fide finuated, and the other pointed.

76. The *ciliata* is ventricofe, the hinder part covered with hair.

77. The *bulla* is membranaceous, the fides bent inwards; the fore and hind parts both covered with hairs.

78. The *pellionella* is fomewhat thick in the middle, and pellucid, with a few molecules here and there; the fides obtufe, the fore part ciliated with very fine hairs, the hinder part fet with briftles.

79. The *cyllidium* has the hinder extremity filled with globules of various fizes. It vacillates upon the edge, commonly advancing on its flat fide, and continually drawing in water. It then gapes, and opens into a very acute angle, almoft to the middle of the body; but this is done fo inftantaneoufly, that it can fcarce be perceived.

80. The *curfor* is oval, the fore part hairy, and the hinder part alfo furnifhed with fome ftraight and curved hairs in two fafcicles. Its body is flat, and filled with molecules; and in the fore part is an oblong empty fpace, into which we may fometimes fee the water fucked in.

81. The *pulex* is egg-fhaped, with an incifion in the fore part; the front and bafe hairy.

82. The *lynceus* is nearly fquare, with a crooked beak and hairy mouth. It is membranaceous, and appears compreffed, ftretched out into a beak above, under which there is a little bundle of hairs; the lower edge bends in and out, and is furrounded with a few briftles. The inteftines are beautiful, and a fmall bent tube goes from the mouth to them in the middle of the body. There is likewife another tube between the fore and hind edge, filled with blue liquor. The inteftines and other tube are frequently in motion.

83. The *crofa* is orbicular, the fore part notched; one fide furnifhed with hairs, the hinder part with briftles.

84. The *roftrata* is found in water where duckweed has been kept. It is depreffed, capable of changing its fhape, yellow, with long ciliated hairs; it has four feet tapering to a point, one of them longer than the reft. Both feet and hairs are within the margin. The fhape of the body is generally triangular; the apex formed into an obtufe beak, which the creature fometimes draws in fo that it appears quite round.

85. The *lagena* is round, ventricofe, with a long neck, and the lower end fet with briftles.

86. The *charon* was found in falt water. It is oval, and refembles a boat as well in its motion as fhape: the upper part is hollowed, the under part furrowed and convex; the ftern round, with feveral hairs proceeding from it.

87. The *cimex* is about the fize of the lynceus, has an oval body, with a convex back, flat belly, and incifion in the margin of the fore part, the edges of which incifion appear to move. When this animalcule meets with any obftacles in fwimming, it makes ufe of four briftles, which appear on the under fide as feet.

88. The *cicada* differs but little from the cimex. It is oval, with an obfcure margin, the fore part covered with hairs on the under fide, and the hinder parts beardlefs.

XIV. *Kerona.*
An invifible worm with horns.

1. The *raftellum* is found in river water. It has three rows of horns on the back, which occupy almoft the whole of it.

2. The *lyncafter* is fquare, and its difc furnifhed with fhining horns.

3. The *hiftrio* appears an oblong membrane, pellucid, with four or five black points in the fore part, which are continually changing their fituation, thick fet with fmall globules in the middle, among which four larger ones are fometimes perceived, which by Mr Adams are fuppofed to be eggs. In the middle of the hind part are fome longitudinal ftrokes refembling briftles, which, however, do not feem to project beyond the body.

4. The *cypris* is found in water covered with lemna. It is fomewhat of a pear fhape, compreffed, with a broad and blunt fore part; the front furnifhed with hairs or little vibrating points inferted under the edge, fhorter in the hind part, partly extended ftraight, and partly bent down, having a retrograde motion.

5. The *hauftrum* is orbicular, with the horns in the middle, the fore part membranaceous and ciliated, with feveral briftles at the hinder part.

6. The *hauftallum* differs from the preceding only in having the hinder part without any briftles.

7. The *patella* has an univalved fhell, is orbicular, cryftalline; the fore part fomewhat notched; the flefhy body in the middle of the fhell; with horns or hairs of different lengths jutting out beyond the fhell, and acting inftead of feet and oars, fome of which are bent; and the fuperior ones conftitute a double tranfverfe row.

8. The *vannus* is oval and rather flat, with one edge bent, the oppofite one ciliated, the front furnifhed with horns, and the hind part with briftles.

9. The *pullafter* agrees in many refpects with the *trichoda pulex*: the upper part is pellucid, without any black molecules; the front truncated, the whole furface of the head covered with hair, and the fore part finuous.

10. The *mytillus* is a large animalcule; the fore and hind parts rounded, very pellucid and white, dark in the middle, with black inteftines intermixed with a few pellucid veficles; both extremities appearing as if compofed of two thin plates. It has two fmall horns, with which it agitates the water fo as to form a little whirlpool.

11. The *lepus* is egg-fhaped, compreffed, pellucid, and

Microfcope

and crowned with fhort waving hairs; the bafe terminated with briftles.

12. The *filurus* is an oval, fmooth, animalcule, fomewhat crooked and opaque, with a fafcicle of vibrating hair on the fore part: it has a fharp tail furnifhed with unequal rows of moveable hairs, the back being alfo ciliated: the hairs produce a rotatory motion. The figure varies from oval to oblong, and the filaments of the conferva are often entangled in the tail.

13. The *calvitium* is found in the infufion of vegetables. The body is broad and flat, both fides obtufe, filled with black molecules, and there is a black fpot near the hinder part, where there are likewife a few fhort briftles.

14. The *puftulata* is found in falt water. It is oval, convex; one edge of the hinder part finuated, both ends fet with hairs, and fome horns on the fore part.

XV. *Himantopus:*

A pellucid, invifible, and cirrated worm.

1. The *acarus* is lively, conical, ventricofe, full of black molecules, with a bright and tranfparent fore part. The lower part of the apex has rows of long hairs on the under part fet like rays. Four locks of long crooked hair or feet proceed from the belly, and it is continually moving thefe and other hairs in various directions.

2. The *ludio* is a lively diverting animalcule, fmooth, pellucid, full of fmall points, the fore part clubbed and a little bent, the hinder part narrow; the bafe obliquely truncated, and terminating in a tail ftretched out tranfverfely. The top of the head and middle of the back are furnifhed with long and vibrating hairs; three moveable and flexible curls hang down from the fide of the head at a diftance from each other. When the creature is at reft, its tail is curled; but when in motion, it is drawn tight and extended upwards.

3. The *fannio* is found, though feldom, in water where the lemna grows. The cilia are longer than the hairs, and are continually vibrating: it has two moveable curls hanging on the fide of the head.

4. The *volutator* is fhaped like a crefcent, and has fome cryftalline points; the convex part has a row of hairs longeft towards the tail, and underneath are four feet. It is very lively, and often turns round with a fwift circular motion.

5. The *larva* is long and cirrated in the middle; the body is depreffed and long; the hinder parts acute, and generally curved, pellucid, and filled with granular molecules.

6. The *charon* is found in fea-water, but rarely. It is oval, pellucid, and membranous, with longitudinal furrows, and feveral bent diverging rows of hair below the middle, but none on the hinder part.

7. The *corona* is a membranous lamina, very thin, pellucid, cryftalline, and femilunar: the edge of the bafe thick fet with molecular inteftines; the fore part furnifhed with a kind of mane; towards the hind part are three equal curved hairs or fpines.

XVI. *Vorticella:*

A naked worm with rotatory cilia, capable of contracting and extending itfelf.

1. The *viridis* is vifible to the naked eye, appearing like a fmall green point; but the microfcope difcovers it to be nearly cylindrical, a little thicker at the fore part than the other, and obtufe at both ends. It appears to be totally deftitute of limbs, notwithftanding which it keeps the water in continual motion; fo that it probably has fome invifible rotatory inftrument. It moves fometimes circularly, fometimes in a ftraight line.

Microfcope

2. The *fpheroida* appears alfo like a point; but thro' the microfcope as a globular mafs of a dark green colour. It occafions a vehement motion in the water, probably by means of fome fhort hairs with which it is furnifhed.

3. The *cincta* is of an irregular fhape, fometimes affuming an oval figure, and appearing as if girt round with a tranfverfe keel. It is invifible to the naked eye, ciliated on every fide; the hairs all moveable, and longer on one fide than the other.

4. The *lunifera* is found in falt water; has the fore-part obtufe, the bafe broad, and hollowed away like a crefcent, with a fhort protuberance in the middle of the concave part: the fore part is ciliated.

5. The *burfata* is found in falt water, and is ventricofe, crammed with molecules; the fore part truncated, and both fides of it pellucid: there is a prominent papilla in the middle, which when the animalcule is at reft appears notched, the edge of the aperture being ciliated; the hairs are capable of moving in various directions.

6. The *varia* is cylindrical, truncated, opaque, and blackifh coloured; the fore part ciliated.

7. The *fputarium* is found in October, with the leffer lemna, and is one of the moft fingular of the microfcopic animalcules. When viewed fidewife, it is fometimes nearly cylindrical, only tapering a little towards the hinder part, and having a broad pellucid edge. Viewed from the top, it has fometimes a broad face or difc, furnifhed with radiating hairs, the under part contracted into a globular fhape, of a dark green colour, and filled with fmall grains.

8. The *polymorpha* is vifible to the naked eye, and appears like a green point moving with great agility; but when viewed through a microfcope, it affumes fuch a variety of forms, that it is impoffible to defcribe them. The body is granulous; and a feries of pellucid points is fometimes to be obferved.

9. The *multiformis* is found in falt water, and very much refembles the former.

10. The *nigra* is found in Auguft in meadows covered with water. It may be feen with the naked eye, appearing like a black point fwimming on the furface. Through the microfcope it appears as a fmall conical body, obtufe and ventricofe at one end and acute at the other. When the extremities are extended, two fmall white hooks become vifible, by the affiftance of which it moves in the water, and it probably has a rotatory organ: it moves continually in a vacillating manner on the top of the water.

11. The *cucullus* is likewife vifible to the naked eye: it is of a dirty red colour, of a fhape fomewhat conical, and refembling a grenadier's cap.

12. The *utriculata* is green and ventricofe; the belly capable of being lengthened or fhortened; the fore part truncated, much in the fhape of a common water bottle;

bottle; the neck is ſometimes very long, ſometimes very ſhort, and filled with green molecules.

13. The *ocreata* is met with in rivers, though very ſeldom, and in ſhape ſomewhat reſembles the lower part of a boot. The apex of the upper part is truncated and ciliated, the heel pointed, and the foot round.

14. The *valga* is as broad as long, and the apex truncated and ciliated; both angles of the baſe projecting outwards, one ſomewhat like a wart, the other like a finger: It is found in marſhy waters.

15. The *papillaris* is likewiſe found in marſhes where the conferva nitida grows. It is ventricoſe; the fore part truncated, with a papillary tail, and a beautiful papillary excreſcence on the ſide.

16. The *ſacculus* is thick, of an equal diameter every where, and full of molecules. The edge of the mouth is bent back; the hinder part is obtuſe, ſometimes notched and contracted, with cilia to be ſeen on both ſides of the mouth.

17. The *cirrata* is found in ditch-water. It is ventricoſe, the aperture ſinuated, and two tufts of hair on each ſide of the belly.

18. The *naſuta* is inviſible to the naked eye, but the microſcope diſcovers it to be furniſhed with a rotatory organ encompaſſing the middle. It is pellucid, cylindrical, of an unequal ſize; the fore part truncated and ciliated, with a triangular prominence in the middle of the aperture; the hinder part is obtuſe, with a point on each ſide of the middle of the body. When the water is nearly exhaled, two rotatory organs are obſervable; one on the fore part, and the other encompaſſing the middle of the body; the hairs of the latter being in violent motion. Other faſcicles of moving hair are likewiſe to be obſerved; and the quick and various motions of this apparatus are very ſurpriſing.

19. The *ſtellina* is of an orbicular ſhape, with a molecular diſc and ciliated margin.

20. The *diſcina* is likewiſe orbicular, the edge ciliated, with a kind of handle on the under ſide.

21. The *ſcyphina* is bowl-ſhaped, cryſtalline, with an opaque ſpherule in the middle.

22. The *albina* is cylindrical in the fore part, the hinder part tapering, and almoſt ending in a point.

23. The *fritillina* is empty and cylindrical, with a truncated apex.

24. The *truncatella* is of the larger kind of animalcules, with a cryſtalline body, full of black molecules, the ſkin perfectly ſmooth and colourleſs, the hinder extremity rounded, and the anterior part truncated: at this extremity there is a large opening that ſerves for a mouth, which is thickly ciliated.

25. The *limacina* is cylindrical, truncated, and has two pair of cilia.

26. The *fraxinina* is moſtly cylindrical, the hinder part rather tapering, and full of opaque molecules; tranſparent towards the upper end. Within the edge at the top are two ſmall tubercles, from each ſide of which proceeds a pair of ſmall hairs.

27. The *cratægaria* is found in the month of April, both in the mud and on the tail of the monoculus quadricornis. They are generally heaped together in a ſpherical form, and united to one common ſtalk. They are likewiſe often to be found without a pedicle, the body rather contracted, the aperture circular, and ſurrounded with a marked margin. It has two ſmall arms; and with a powerful magnifier a violent rotatory motion may be obſerved. Sometimes an individual will ſeparate from the community, and move in a kind of ſpiral line for a little time, and then go back to the cell.

28. The *hamata* is not ciliated, nor has it any hairs upon it; the body is granulated, the fore part broad and truncated, the hinder part obtuſe, and capable of being contracted or extended.

29. The *crateriformis* is a lively animalcule, pellucid, round, longer than it is broad, approaching ſomewhat to a ſquare figure, with convex ſides: the head is ſituated at the large end, the ſkin ſmooth, and ſome traces of inteſtines may be diſcovered with difficulty. There is a conſiderable opening ſurrounded by hair at the larger end, and the filaments compoſing it are in continual motion. Two of them are ſometimes ſeen joined together, and full of ſmall ſpherules. In this ſtate they draw each other alternately different ways; the ſurface is ſmooth, and the hairs inviſible.

30. The *canaliculata* appears to the naked eye as a number of white points adhering to the ſides of the glaſs. When magnified, the fore part is narrower than the hind one; in the ſide is a kind of inciſion, and the hinder part is notched towards the middle. It excites a continual whirling motion in the water by means of a rotatory organ with which it is furniſhed.

31. The *verſatilis* is a pellucid, gelatinous animalcule, of a greeniſh colour, and furniſhed with ſmall radii about the circumference; ſo that it appears like a very ſmall water hedge-hog.

32. The *ampulla* is contained in a tranſparent bottle-ſhaped bag; the head divided into two lobes. It ſometimes lies at the bottom of the bag, and ſometimes nearly fills the whole of it.

33. The *folliculata* is gelatinous and cylindrical; and when moſt extended, the baſe appears attenuated, and the apex truncated.

34. The *larva* is of a clay colour, the aperture ciliated, with a globular projection at times appearing to proceed from it.

35. The *ſacculata* has the ſhape of an inverted cone, with an aperture in the figure of a creſcent; the lower part of the trunk notched, forming as it were two teeth; the tail biphyllous. Each of theſe is ſurrounded with a looſe bright ſkin, the head being divided from the trunk by a deep inciſion.

36. The *aurita* is cylindrical and ventricoſe, the aperture deſtitute of hairs; both ſides of it are furniſhed with rotatory cilia, and the tail is biphyllous.

37. The *tremula* has ſomething of a conical ſhape; the mouth being divided into parts which are ſet with ſmall ſpines; and a point projects from the tail.

38. The *ſerita* is muſcular, pellucid, folding variouſly; the fore part truncated: round the margin are rows of hairs; but it has alſo ſtiffer hairs or ſpines continually vibrating, with which it draws in all animate and inanimate ſubſtances which it is able to manage.

39. The *lacinulata* is ſhaped like an inverted cone, the aperture lobated, the tail ſmall and furniſhed with two briſtles. When ſwimming, the rotatory organ may be diſcovered. It moves ſwiftly in an oblique direction.

40. The

Microscope

40. The *constricta* is of two kinds; *viz.* of a pale yellow and of a white colour. They move by fixing their tail to the place where they are, and then extending their body as much as possible; fixing the fore part to the place to which they intend to move, then drawing the hinder part to it, and so on. Sometimes they turn round about upon one of the points of their tail; at other times they spring forwards with a jerk. When at rest they open their mouths very wide.

41. The *togata* has a convex body, filled with molecules, and of a dark colour; the hinder part somewhat broader than the forepart; the latter ciliated, and the tail formed of two very thin pellucid spines, which are somewhat curved, and much longer than the body.

42. The *rotatoria* is the *wheel animal* described by Mr Baker; and of which an account is given under the article Animalcule.

43. The *furcata* is commonly found in water, and has a cylindric body with a rotatory organ, consisting of a row of hairs at the apex: the tail is divided into two parts, turning a little inwards. When at rest it joins the segments of the tail, but opens them when in motion.

44. The *catulus* is commonly found in marshy waters. It is a little thick muscular animalcule, folding itself up: equally broad throughout, the body disfigured by longitudinal folds, winding in various directions. The anterior part is connected to the body by a little neck; and it occasionally shows a small rotatory organ. Its motion is rotatory, but in various directions.

45. The *canicula* is cylindrical, the aperture plain, with a short articulated tail divided into two parts.

46. The *felis* has a large body, the apex of an equal thickness, obtuse, with rotatory filaments: the tail is acute, with two pellucid spines in length about one-third part of the body, alternately separating from and approaching one another.

47. The *stentorea*. See the article Polype.

48. The *socialis*, when considerably magnified, appears like a circle surrounded with crowns or ciliated heads, tied by small thin tails to a common centre, from whence they advance towards the circumference, where they turn very briskly, occasioning a kind of whirlpool, which brings its food. When one of them has been in motion for a time, it stops and another begins; sometimes two or three may be perceived in motion at once: they are frequently to be met with separate, with the tail sticking in the mud. The body contracts and dilates very much, so as sometimes to have the appearance of a cudgel, at others to assume almost a globular form.

49. The *flosculosa* appears to the naked eye like a yellow globule adhering to the ceratophyllon like a little flower or a heap of yellow eggs. When magnified, they are seen to consist of a congeries of animalcula constituting a sphere from a mouldy centre. They contract and extend their bodies either alone or in society, and excite a vortex in the water by means of a disc. When they quit the society and act singly, they may be observed to consist of a head, abdomen, and tail; the head being frequently drawn back into the abdomen so far that it cannot be seen, only exhibiting a broad kidney-shaped disc standing out. The abdomen is oblong, oval, and transparent; the tail sharp, twice as long as the abdomen, sometimes rough and annulated, or altogether smooth.

Microscope

50. The *citrina* is found in stagnant water; the head full of molecules, round, every where of an equal size, and very transparent. Both sides of the orifice are ciliated, and each has a rotatory motion appearing sometimes without and sometimes within the edge of the mouth.

51. The *piriformis* is somewhat oval, with a very small retractile foot, which it can draw within itself.

52. The *tuberosa* has a broad upper part, the under part small, with two projections at the anterior end, furnished with a number of fibrillæ, which produce a current of water by their vibration, and thus collect food for the animal.

53. The *ringens* is pear-shaped, pellucid, the middle of the aperture convex, both sides ciliated, the pedicle four times shorter than the body. It can contract the orifice to an obtuse point.

54. The *inclinans* has a pendulous, pellucid, little head; the anterior part truncated, and occasionally contracting itself twice as short as the pedicle. It is shaped like a tobacco-pipe.

55. The *vaginata* is erect, of the shape of a truncated egg; the pedicle is contained in a sheath.

56. The *globularia* is frequent among the cyclopa quadricorni. It has a small spherical head, the aperture of the mouth ciliated, the pedicle four times larger than the body, which it contracts into a spiral form.

57. The *lunaris* has a small goblet-shaped head, the margin of the orifice protuberant, ciliated on both sides, with undulating hairs, and the pedicle eight or ten times the length of the body. The pedicle extends itself as often as the mouth is opened, but is twisted up spirally when it is shut; and this is frequently repeated in a short space.

58. The *convallaria* is the same with the *bell-animal* mentioned by Mr Baker. See the article Animalcule.

59. The *nutans* has a simple pedicle; twists itself spirally; is extremely slender, with a kind of cap on its head; the margin white and round, and seemingly encompassed with a lucid ring; the head diminishing towards the base.

60. The *nebulifera* is narrow at the base; open and truncated at the top; the margin seemingly surrounded with a ring: but, when the aperture is shut, the animalcule is of the shape of an egg, with a simple setaceous pedicle, considerably longer than the body, and commonly much bent back.

61. The *annularis* is visible to the naked eye; the head an inverted cone, convex when the mouth is shut, but truncated when it is open; with a protuberant edge; the pedicle simple, very long, thick, and, whiter at the top than any where else; the apex twisted spirally.—When contracted, it appears to be annulated.

62. The *acinosa* inhabits that whitish substance which often entirely covers plants, wood, shells, &c. When this substance is examined by a microscope, it appears to be wholly composed of living animals of the polype kind. See Polype.

 63. The

Microfcope

63. The *fafciculata* has a rotatory organ, which may fometimes be feen projecting beyond the aperture; there is a little head at the apex, and the pedicle is twifted and very flender. A congealed green mafs which is often found fwimming about in ditches is compofed of myriads of thefe animals, which are not vifible to the naked eye, and when magnified appear like a bundle of green flowers.

64. The *hians* refembles a citron; the apex is truncated, the bafe narrow, and a gaping cleft is obfervable, defcending from the apex to one third of the body.

65. The *bellis* is of a yellow colour, and much refembles the flower of a daify; is ciliated round the margin of the head, and moves in a rotatory manner.

66. The *gemella* has a long pedicle, conftantly furnifhed with two fmall heads.

68. The *pyraria*.
69. The *anaftatica*. } See the article Polype.
70. The *digitalis*

71. The *polypina*, when viewed through a fmall magnifier, they appear like fo many little trees: the upper part, or heads, are egg fhaped, the top truncated, the lower part filled with inteftines; the branches thick fet with little knobs.

72. The *racemofa* is only diftinguifhed from the vorticella focialis by always adhering to the fides of the veffel in which it is placed. By the microfcope, we difcover a long pedicle fticking to the fides of the veffels, from which proceed an innumerable quantity of cryftalline pellucid pearls; which, together with the ftalk, are varioufly agitated in the water. Sometimes they move feparately; fometimes they are drawn down to the root, and in a moment expanded again.

XVII. *Brachionus*:

A contractile worm, covered with a fhell, and furnifhed with rotatory cilia.

1. The *ftriatus* has an oblong, pellucid fhell, capable of altering its figure. The apex is truncated, with fix fmall teeth on the edge of it, twelve longitudinal ftreaks down the back, the bafe obtufe and fmooth. The teeth are occafionally protruded or retracted; and there are two fmall fpines or horns on the other fide of the fhell. The animal itfelf is of a yellow colour, cryftalline, and mufcular; now and then putting out from the apex two or three little bundles of playing hairs, the two lateral ones fhorter than that in the middle: on the under fide we may obferve a forked deglutatory mufcle, and two rigid points when the apex is drawn in. It is found in fea-water.

2. The *fquamula* has an univalve orbicular fhell, a truncated apex, four teeth, fmooth bafe, and no tail.

3. The *pala* is of a yellow colour; univalved, with an oblong excavated fhell; four long teeth at the apex; a fmooth bafe.

4. The *bipalium* is univalved, the fhell oblong and inflected, ten teeth at the apex, the bafe fmooth, and a fpurious tail.

5. The *patina* is extremely bright and fplendid, has a large body, a cryftalline and nearly circular fhell, without either incifion or teeth, only towards the apex it falls in fo as to form a fmooth notch. A double glittering organ, with ciliated edges, projects from the apex; both of them of a conical figure, and ftanding as it were upon a pellucid fubftance, which is divided into two lobes, between which and the rotatory organ there is a filver coloured crenulated membrane. Two fmall claws may likewife be difcovered near the mouth.

Microfcope

6. The *clypeatus* is univalved, the fhell oblong, apex notched, the tail naked, and bafe fmooth.

7. The *lamellaris* is univalved; the fhell extending confiderably beyond the body; the bafe divided into three fmall horns, with two hairs at the end of the tail.

8. The *patella* is found in marfhy water in the winter-time. It is univalve, the fhell oval, plain, cryftalline, with the anterior part terminating in two acute points on both fides, though the intervening fpace is commonly filled up with the head of the animal. By thefe points it faftens itfelf, and whirls about the body erect. The rotatory cilia are perceived with great difficulty.

9. The *bractea* is univalved, the fhell fomewhat orbicular, apex lunated, bafe fmooth, and the tail furnifhed with two fpines.

10. The *plicatilis* is univalved, with an oblong fhell, the apex hairy, and bafe notched.

11. The *ovalis* is bivalved; the fhell flattened, apex notched, a hollow part at the bafe, the tail formed of two tufts of hair.

12. The *tripos* is bivalved, the apex of the fhell beardlefs, three horns at the bafe, and double tail. It fixes itfelf to objects by the filaments of the tail.

13. The *dentatus* is bivalved, with an arched fhell; the apex and bafe are both toothed, and the tail formed of two fpines.

14. The *mucronatus* is bivalved, fomewhat of a fquare form; the bafe and apex pointed; the tail confifting of two fpines.

15. The *uncinatus* is one of the fmalleft bivalved animalcules; the apex and anterior part round, the hinder part ftraight, terminating in a point, furnifhed with a hook on the fore part, a fmall rotatory organ, a long tail compofed of joints, and divided at the end into two briftles. It can open its fhell both at the fore and hind part.

16. The *cirratus* is larger than the preceding; ventricofe, fomewhat tranfparent, the head conical, with a bundle of hairs on both fides; and it has likewife a rotatory organ.

17. The *paffus* has a cylindric fhell, with two long pendulous locks of hair proceeding from the front, the tail confifting of a fingle briftle.

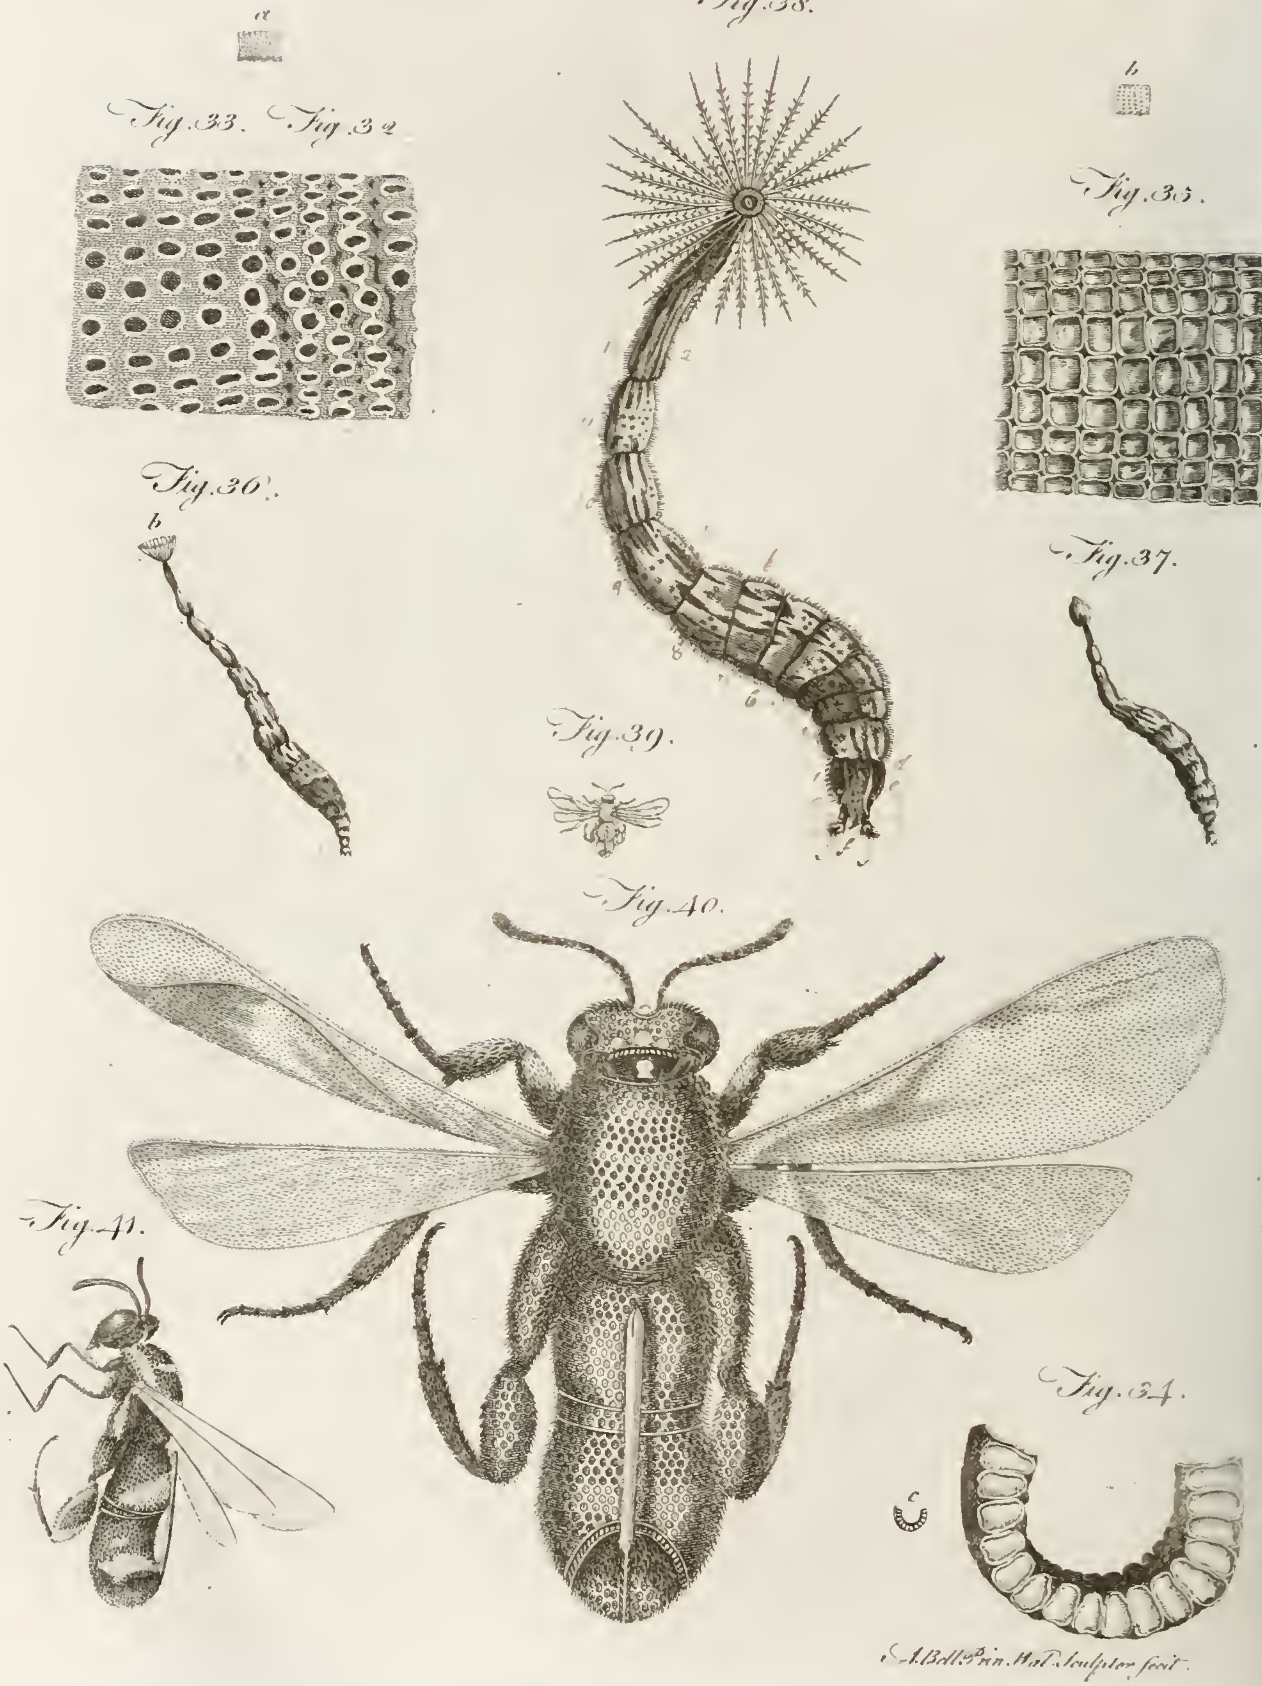
18. The *quadratus* has a quadrangular fhell, with two fmall teeth at the apex, two horns proceeding from the bafe, and no tail.

19. The impreffus has a quadrangular fhell, a fmooth undivided apex; obtufe bafe; notched margin; and flexuous tail.

20. The *urceolaris*. See Polype.

21. The *brachionus Bakeri* has a ventricofe fhell, four teeth at the apex, two horns at the bafe, and a long tail, terminating in two fhort points. The horns are frequently extended; and the circular end of each is furnifhed with a tuft of little hairs, which fometimes move in a vibratory manner, at other times have a rotatory motion. Mr Muller has alfo difcovered in this creature two fmall feelers and a tongue.

22. The *patulus* has a ventricofe fhell, with eight teeth:



A. Bell Prin. Hal. Sculptor fecit.

 teeth at the apex; the baſe lunated, or hollowed into the form of a creſcent, and furniſhed with four horns; the tail ſhort, with two ſmall points at the end.

These are the different kinds of animalcules which have yet been diſcovered. To what is ſaid of them in general under the article Animalcule, we ſhall here add the following obſervations from Mr Adams.—"How many kinds of theſe inviſibles there may be (ſays he) is yet unknown; as they are diſcerned of all ſizes, from thoſe which are barely inviſible to the naked eye, to ſuch as reſiſt the force of the microſcope as the fixed ſtars do that of the teleſcope, and with the greateſt powers hitherto invented appear only as ſo many moving points. The ſmalleſt living creatures our inſtruments can ſhow, are thoſe which inhabit the waters; for though animalcula equally minute may fly in the air, or creep upon the earth, it is ſcarce poſſible to get a view of them; but as water is tranſparent, by confining the creatures within it we can eaſily obſerve them by applying a drop of it to the glaſſes.

"Animalcules in general are obſerved to move in all directions with equal eaſe and rapidity, ſometimes obliquely, ſometimes ſtraight forward; ſometimes moving in a circular direction, or rolling upon one another, running backwards and forwards through the whole extent of the drop, as if diverting themſelves; at other times greedily attacking the little parcels of matter they meet with. Notwithſtanding their extreme minuteneſs, they know how to avoid obſtacles, or to prevent any interference with one another in their motions: ſometimes they will ſuddenly change the direction in which they move, and take an oppoſite one; and, by inclining the glaſs on which the drop of water is, as it can be made to move in any direction, ſo the animalcules appear to move as eaſily againſt the ſtream as with it. When the water begins to evaporate, they flock towards the place where the fluid is, and ſhow a great anxiety and uncommon agitation of the organs with which they draw in the water. Theſe motions grow languid as the water fails, and at laſt ceaſe altogether, without a poſſibility of renewal if they be left dry for a ſhort time. They ſuſtain a great degree of cold as well as inſects, and will periſh in much the ſame degree of heat that deſtroys inſects. Some animalcules are produced in water at the freezing point, and ſome inſects live in ſnow.—By mixing the leaſt drop of urine with the water in which they ſwim, they inſtantly fall into convulſions and die.

"The ſame rule ſeems to hold good in thoſe minute creatures, which is obſervable in the larger animals, *viz.* that the larger kinds are leſs numerous than ſuch as are ſmaller, while the ſmalleſt of all are found in ſuch multitudes, that there ſeem to be myriads for one of the others. They increaſe in ſize, like other animals, from their birth until they have attained their full growth; and when deprived of proper nouriſhment, they in like manner grow thin and periſh."

The modes of propagation among theſe animalcules are various, and the obſervation of them is extremely curious. Some multiply by a tranſverſe diviſion, as is obſerved under the article Animalcule: and it is remarkable, that though in general they avoid one another, it is not uncommon, when one is nearly divided, to ſee another puſh itſelf upon the ſmall neck which joins the two bodies in order to accelerate the ſeparation.—Others, when about to multiply, fix themſelves to the bottom of the water; then becoming firſt oblong, and afterwards round, turn rapidly as on a centre, but perpetually varying the direction of their rotatory motion. In a little time, two lines forming a croſs are perceived; after which the ſpherule divides into four, which grow, and are again divided as before. A third kind multiply by a longitudinal diviſion, which in ſome begins in the fore-part, in others in the hind-part; and from others a ſmall fragment detaches itſelf, which in a ſhort time aſſumes the ſhape of the parent animalcule. Laſtly, others propagate in the ſame manner as the more perfect animals.

In our obſervations under the article Animalcule, we ſuggeſted ſome doubts whether all thoſe minute bodies which go under the name of *animalcules* really do enjoy animal life; or whether they are not in many caſes to be accounted only inanimate and exceedingly minute points of matter actuated by the internal motion of the fluid. This has alſo been the opinion of others: but to all hypotheſes of this kind Mr Adams makes the following reply. "From what has been ſaid, it clearly appears, that their motions are not purely mechanical, but are produced by an internal ſpontaneous principle; and that they muſt therefore be placed among the claſs of living animals, for they poſſeſs the ſtrongeſt marks and the moſt decided characters of animation; and, conſequently, that there is no foundation for the ſuppoſition of a chaotic and neutral kingdom, which can only have derived its origin from a very tranſient and ſuperficial view of theſe animalcules.—It may alſo be further obſerved, that as we ſee that the motions of the limbs, &c. of the larger animals, are produced by the mechanical conſtruction of the body, and the action of the ſoul thereon, and are forced by the ocular demonſtration which ariſes from anatomical diſſection to acknowledge this mechaniſm which is adapted to produce the various motions neceſſary to the animal; and as, when we have recourſe to the microſcope, we find thoſe pieces which had appeared to the naked eye as the primary mechanical cauſes of particular motions, to conſiſt themſelves of leſſer parts, which are the cauſes of motion, extenſion, &c. in the larger; when the ſtructure therefore can be traced no farther by the eye, or by the glaſſes; we have no right to conclude that the parts which are inviſible are not equally the ſubject of mechaniſm: for this would be only to aſſert, in other words, that a thing may exiſt becauſe we ſee and feel it, and have no exiſtence when it is not the object of our ſenſes.—The ſame train of reaſoning may be applied to microſcopic inſects and animalcula: we ſee them move; but becauſe the muſcles and members which occaſion theſe motions are inviſible, ſhall we infer that they have not muſcles, with organs appropriated to the motion of the whole and its parts? To ſay that they exiſt not becauſe we cannot perceive them, would not be a rational concluſion. Our ſenſes are indeed given us that we may comprehend ſome effects; but then we have alſo a mind, with reaſon, beſtowed upon us, that, from the things which we do perceive with our senses, we may deduce the nature of those causes and effects which are imperceptible to the corporeal eye."

Leaving these speculations however, we shall now proceed to give a particular

Explanation of the figures of the various animals, with their parts, ova, &c. represented in the plates.

Plate CCCII. Fig. 32. 33. represent the eggs of the phalæna neustria, as they are taken from the tree to which they adhere, and magnified by the microscope. The strong ground-work visible in many places shows the gum by which they are fastened together; and this connection is strengthened by a very tenacious substance interposed between the eggs, and filling up the vacant spaces. Fig. 34. shows a vertical section of the eggs, exhibiting their oval shape.—Fig. 35. is an horizontal section through the middle of the egg. These eggs make a beautiful appearance through the microscope. The small figures *a*, *b*, *c*, represent the objects in their natural state, without being magnified.

Fig. 36. shows the larva of the *musca chamælcon*, an aquatic insect. When viewed by the naked eye, it appears (as here represented) to be composed of twelve annular divisions, separating it into an head, thorax, and abdomen; but it is not easy to distinguish the two last parts from each other, as the intestines lie equally both in the thorax and abdomen. The tail is furnished with a fine crown or circle of hair *b*, disposed in the form of a ring, and by this means it is supported on the surface of the water, the head and body hanging down towards the bottom, in which posture it will sometimes remain for a considerable time without any motion.—When it has a mind to sink to the bottom, it closes the hairs of the ring, as in fig. 37. Thus an hollow space is formed, including a small bubble of air; by enlarging or diminishing which, it can rise or sink in the water at pleasure. When the bubble escapes, the insect can replace it from the pulmonary tubes, and sometimes considerable quantities of air may be seen to escape from the tail of the worm into the common atmosphere; which operation may easily be observed when the worm is placed in a glass of water, and affords an entertaining spectacle. The snout of this insect is divided into three parts, of which that in the middle is immoveable; the other two, which grow from the sides of the middle one, are moveable, and vibrate like the tongues of lizards or serpents. In these lateral parts lies most of the creature's strength; for it walks upon them when out of the water, appearing to walk on its mouth, and to use it as the parrot does its beak to assist it in climbing.

The larva is shown fig. 38. as it appears through a microscope. It grows narrower towards the head, is largest about that part which we may call the thorax, converges all along the abdomen, and terminates at length in a sharp tail surrounded with hairs, as has already been mentioned. The twelve annular divisions are now extremely visible, and are marked by numbers in the plate. The skin appears somewhat hard, and resembling shagreen, being thick set with grains pretty equally distributed. It has nine holes, or spiracula, probably for the purpose of breathing, on each side; but it has none of these on the tail division *a*, nor any easily visible on the third from the head. In the latter, indeed, it has some very small holes concealed under the skin, near the place where the embryo wings of the future fly are hid. "It is remarkable (says Mr Adams) that caterpillars, in general, have two rings without these spiracula, perhaps because they change into flies with four wings, whereas this worm produces a fly with only two." The skin of the larva is adorned with oblong black furrows, spots of a light colour, and orbicular rings, from which there generally springs a hair; but only those hairs which grow on the insect's sides are represented in the figure. There are also some larger hairs here and there, as at *c c*. The difference of colour, however, in this worm arises only from the quantity of grains in the same space; for where they are in very great numbers, the furrows are darker, and paler where they are less plentiful.

The head *d* is divided into three parts, and covered with a skin which has hardly any discernible grains.—The eyes are rather protuberant, and lie near the snout; on which last are two small horns at *i i*. It is crooked, and ends in a sharp point as at *f*. The legs are placed near the snout between the sinuses in which the eyes are fixed. Each of these legs consists of three joints, the outermost of which is covered with stiff hairs like bristles *g g*. From the next joint there springs a horny bone *h h*, used by the insect as a kind of thumb: the joint is also composed of a black substance of an intermediate hardness between bone and horn; and the third joint is of the same nature. In order to distinguish these parts, those that form the upper sides of the mouth and eyes must be separated by means of a small knife; after which, by the assistance of the microscope, we may perceive that the leg is articulated by some particular ligaments, with the portion of the insect's mouth which answers to the lower jaw in the human frame. We may then also discern the muscles which serve to move the legs, and draw them up into a cavity that lies between the snout and those parts of the mouth which are near the horns *i i*. The insect walks upon these legs, not only in the water, but on the land also. It likewise makes use of them in swimming, keeping its tail on the surface contiguous to the air, and hanging downward with the rest of the body in the water. In this situation, the only perceptible motion it has is in its legs, which it moves in a most elegant manner, from whence it is reasonable to conclude, that the most of this creature's strength lies in its legs, as we have already observed.

The snout of this larva is black and hard: the back part quite solid, and somewhat of a globular form; the front *f* sharp and hollow. Three membranaceous divisions may be perceived on the back part; by means of which, and the muscles contained in the snout, the creature can contract or expand it at pleasure.

The extremity of the tail is surrounded with thirty hairs, and the sides adorned with others that are smaller; and here and there the large hairs branch out into smaller ones, which may be reckoned single hairs. All these have their roots in the outer skin, which in this place is covered with rough grains, as may be observed by cutting it off and holding it against the light upon

Microscope upon a ſlip of glaſs. Thus alſo we find, that at the extremities of the hairs there are grains like thoſe on the ſkin; and in the middle of the tail there is a ſmall opening, within which are minute holes, by which the inſect takes in and lets out the air it breathes. Theſe hairs, however, are ſeldom diſpoſed in ſuch a regular order as is repreſented in fig. 38. unleſs when the inſect floats with the body in the water, and the tail with its hairs a little lower than the ſurface, in which caſe they are diſpoſed exactly in the order delineated in the plate. The leaſt motion of the tail downward produces a concavity in the water; and it then aſſumes the figure of a wine-glaſs, wide at the top and narrow at the bottom. The tail anſwers the double purpoſe of ſwimming and breathing, and through it the inſect receives what is the principle of life and motion to all animals. By means of theſe hairs alſo it can ſtop its motion when ſwimming, and remain ſuſpended quietly without motion for any length of time. Its motions in ſwimming are very beautiful, eſpecially when it advances with its whole body floating on the ſurface of the water after filling itſelf with air by the tail.—To ſet out, it firſt bends the body to the right or left, and then contracts it in the form of the letter S, and again ſtretches it out in a ſtraight line: by thus contracting and then extending the body alternately, it moves on the ſurface of the water. It is very quiet, and is not diſturbed by handling.

Theſe creatures are commonly found in ſhallow ſtanding waters in the beginning of June; but ſome years much more plentifully than others. They crawl on the graſs and other plants which grow in ſuch waters, and are often met with in ditches floating on the ſurface of the water by means of their tail, the head and thorax at the ſame time hanging down; and in this poſture they turn over the clay and dirt with their ſnout and feet in ſearch of food, which is commonly a viſcous matter met with in ſmall ponds and ditches. It is very harmleſs, though its appearance would ſeem to indicate the contrary. It is moſt eaſily killed for diſſection by ſpirit of turpentine.

Fig. 39. ſhows in its natural ſize a beautiful inſect, deſcribed by Linnæus under the name of *Leucopſis dorſigera*, and which appears to be a kind of intermediate genus between a ſphex and a waſp. The antennæ are black and cylindrical, increaſing in thickneſs towards the extremity; the joint neareſt the head is yellow; the head and thorax are black, encompaſſed with a yellow line, and furniſhed with a croſs line of the ſame colour near the head. The ſcutellum is yellow, the abdomen black, with two yellow bands, and a deep ſpot of the ſame colour on each ſide between the bands. A deep poliſhed groove extends down the back from the thorax to the anus, into which the ſting turns and is depoſited, leaving the anus very circular; a yellow line runs on each ſide of the ſting.—The anus and whole body, when viewed with a ſmall magnifier, appear punctuated; but when theſe points are ſeen through a large magnifier, they appear hexagonal. Fig. 40. ſhows the inſect very much magnified. Fig. 41. gives a ſide view of it magnified in a ſmaller degree.

Fig. 42. ſhows an inſect lately diſcovered by Mr John Adams of Edmonton, as he happened to be at an inn. It was firſt ſeen by ſome labouring people who were there at the time, by whom it was conjectured to be a louſe with unuſually long horns, a mite, &c. Mr Adams hearing the debate, procured the inſect; and having viewed it through a microſcope, it preſented the appearance exhibited in fig. 42. The inſect ſeems to be quite diſtinct from the phalangium cancroides of Linnæus. The latter has been deſcribed by ſeveral authors, but none of their deſcriptions agree with this. The abdomen of this inſect is more extended, the claws larger, and much more obtuſe; the body of the other being nearly orbicular, the claws ſlender, and almoſt terminating in a point, more tranſparent, and of a paler colour. Mr Marſham has one in his poſſeſſion not to be diſtinguiſhed from that repreſented in fig. 42, excepting only that it wants the break or dent in the claws, which is ſo conſpicuous in this. He found that inſect firmly fixed by its claws to the thigh of a large fly, which he caught on a flower in Eſſex in the firſt week of Auguſt, and from which he could not diſengage it without great difficulty, and tearing off the leg of the fly. This was done upon a piece of writing paper; and he was ſurpriſed to ſee the little creature ſpring forward a quarter of an inch, and again ſeize the thigh with its claws, ſo that he had great difficulty in diſengaging it. The natural ſize of this creature, which Mr Adams calls the *lobſter-inſect*, is exhibited at *a*. Plate CCCIII.

Fig. 43. ſhows the inſect named by M. de Geer *Phyſapus*, on account of the bladders at its feet, (*Thrips phyſapus*, Lin.). This inſect is to be found in great plenty upon the flowers of dandelion, &c. in the ſpring and ſummer. It has four wings, two upper and two under ones (repreſented fig. 44.) but the two undermoſt are not to be perceived without great difficulty. They are very long; and fixed to the upper part of the breaſt, lying horizontally. Both of them are rather pointed towards the edges, and have a ſtrong nerve running round them, which is ſet with a hair fringe tufted at the extremity. The colour of theſe wings is whitiſh: the body of the inſect is black; the head ſmall, with two large reticular eyes. The antennæ are of an equal ſize throughout, and divided into ſix oval pieces, which are articulated together.—The extremities of the feet are furniſhed with a membranaceous and flexible bladder, which it can throw out or draw in at pleaſure. It preſſes this bladder againſt the ſubſtances on which it walks, and thus ſeems to fix itſelf to them; the bladder ſometimes appears concave towards the bottom, the concavity diminiſhing as it is leſs preſſed. The inſect is repreſented of its natural ſize at *b*.

Fig. 45. repreſents the *Cimex ſtriatus* of Linnæus, remarkable for very bright and elegantly diſpoſed colours, though few in number. The head, proboſcis, and thorax, are black: the thorax ornamented with yellow ſpots; the middle one large, and occupying almoſt one-third of the poſterior part; the other two are on each ſide, and triangular. The ſcutellum has two yellow oblong ſpots, pointed at each end. The ground of the elytra is a bright yellow, ſpotted and ſtriped with black. The nerves are yellow; and there is a brilliant triangular ſpot of orange, which unites the cruſtaceous and membranaceous

ceous parts; the latter are brown, and clouded. It is found on the elm-tree in June. It is repreſented of its natural ſize at *c*.

Fig. 46. ſhows the *Chryſomela aſparagi* of Linnæus, ſo called from the larva of the inſect feeding upon that plant. It is a common inſect, and very beautiful. It is of an oblong figure, with black antennæ, compoſed of many joints, nearly oval. The head is a deep and bright blue; the thorax red and cylindrical: the elytra are blue, with a yellow margin, and having three ſpots of theſame colour on each; one at the baſe, of an oblong form, and two united with the margin: the legs are black; but the under ſide of the belly is of the ſame blue colour with the elytra and head. This little animal, when viewed by the naked eye, ſcarcely appears to deſerve any notice; but when examined by the microſcope, is one of the moſt pleaſing opaque objects we have. It is found in June on the aſparagus after it has run to ſeed; and it is ſhown of its natural ſize at *d*. De Geer ſays that it is very ſcarce in Sweden.

Fig. 47. ſhows an inſect of a ſhape ſo remarkable, that naturaliſts have been at a loſs to determine the genus to which it belongs. In the Fauna Suecica, Linnæus makes it an *attelabus*: but in the laſt edition of the Syſtema Naturæ, it is ranged as a meloe, under the title of the *Meloe monoceros*; though of this alſo there ſeems to be ſome doubt. The true figure of it can only be diſcovered by a very good microſcope. The head is black, and appears to be hid or buried under the thorax, which projects forward like a horn: the antennæ are compoſed of many joints, and are of a dirty yellow colour, as well as the feet: the hinder part of the thorax is reddiſh, the fore-part black.—The elytra are yellow, with a black longitudinal line down the future; there is a band of the ſame colour near the apex, and alſo a black point near the baſe, the whole animal being curiouſly covered with hair. The natural ſize of it is ſhown at *e*. It was found in May. Geoffroy ſays that it lives upon umbelliferous plants.

Fig. 48—53. exhibit the anatomy of the coſſus caterpillar, which lives on the willow. The egg from which it proceeds is attached to the trunk of the tree by a kind of viſcous juice, which ſoon becomes ſo hard that the rain cannot diſſolve it. The egg itſelf is very ſmall and ſpheroidal, and, when examined by the microſcope, appears to have broad waving furrows running through the whole length of it, which are again croſſed by cloſe ſtreaks, giving it the appearance of a wicker baſket. It is not exactly known what time they are hatched; but as the ſmall caterpillars appear in September, it is probable that the eggs are hatched ſome time in Auguſt. When ſmall, they are generally met with under the bark of the tree to which the eggs were affixed; and an aqueous moiſture, oozing from the hole through which they got under the bark, is frequently, though not always, a direction for finding them. Theſe caterpillars change their colour but very little, being nearly the ſame when young as when old. Like many others, they are capable of ſpinning as ſoon as they come from the egg. They alſo change their ſkin ſeveral times; but as it is almoſt impoſſible to rear them under a glaſs, ſo it is very difficult to know exactly how often this moulting takes place.—Mr Adams conjectures that it is more frequently than the generality of caterpillars do, ſome having been obſerved to change more than nine times.

The coſſus generally faſts for ſome days previous to the moulting; during which time the fleſhy and other interior parts of the head are detached from the old ſkull, and retire as it were within the neck. The new coverings ſoon grow on, but are at firſt very ſoft.—When the new ſkin and the other parts are formed, the old ſkin is to be opened, and all the members withdrawn from it; an operation naturally difficult, but which muſt be rendered more ſo from the ſoft and weak ſtate of the creature at that time. It is always much larger after each change.

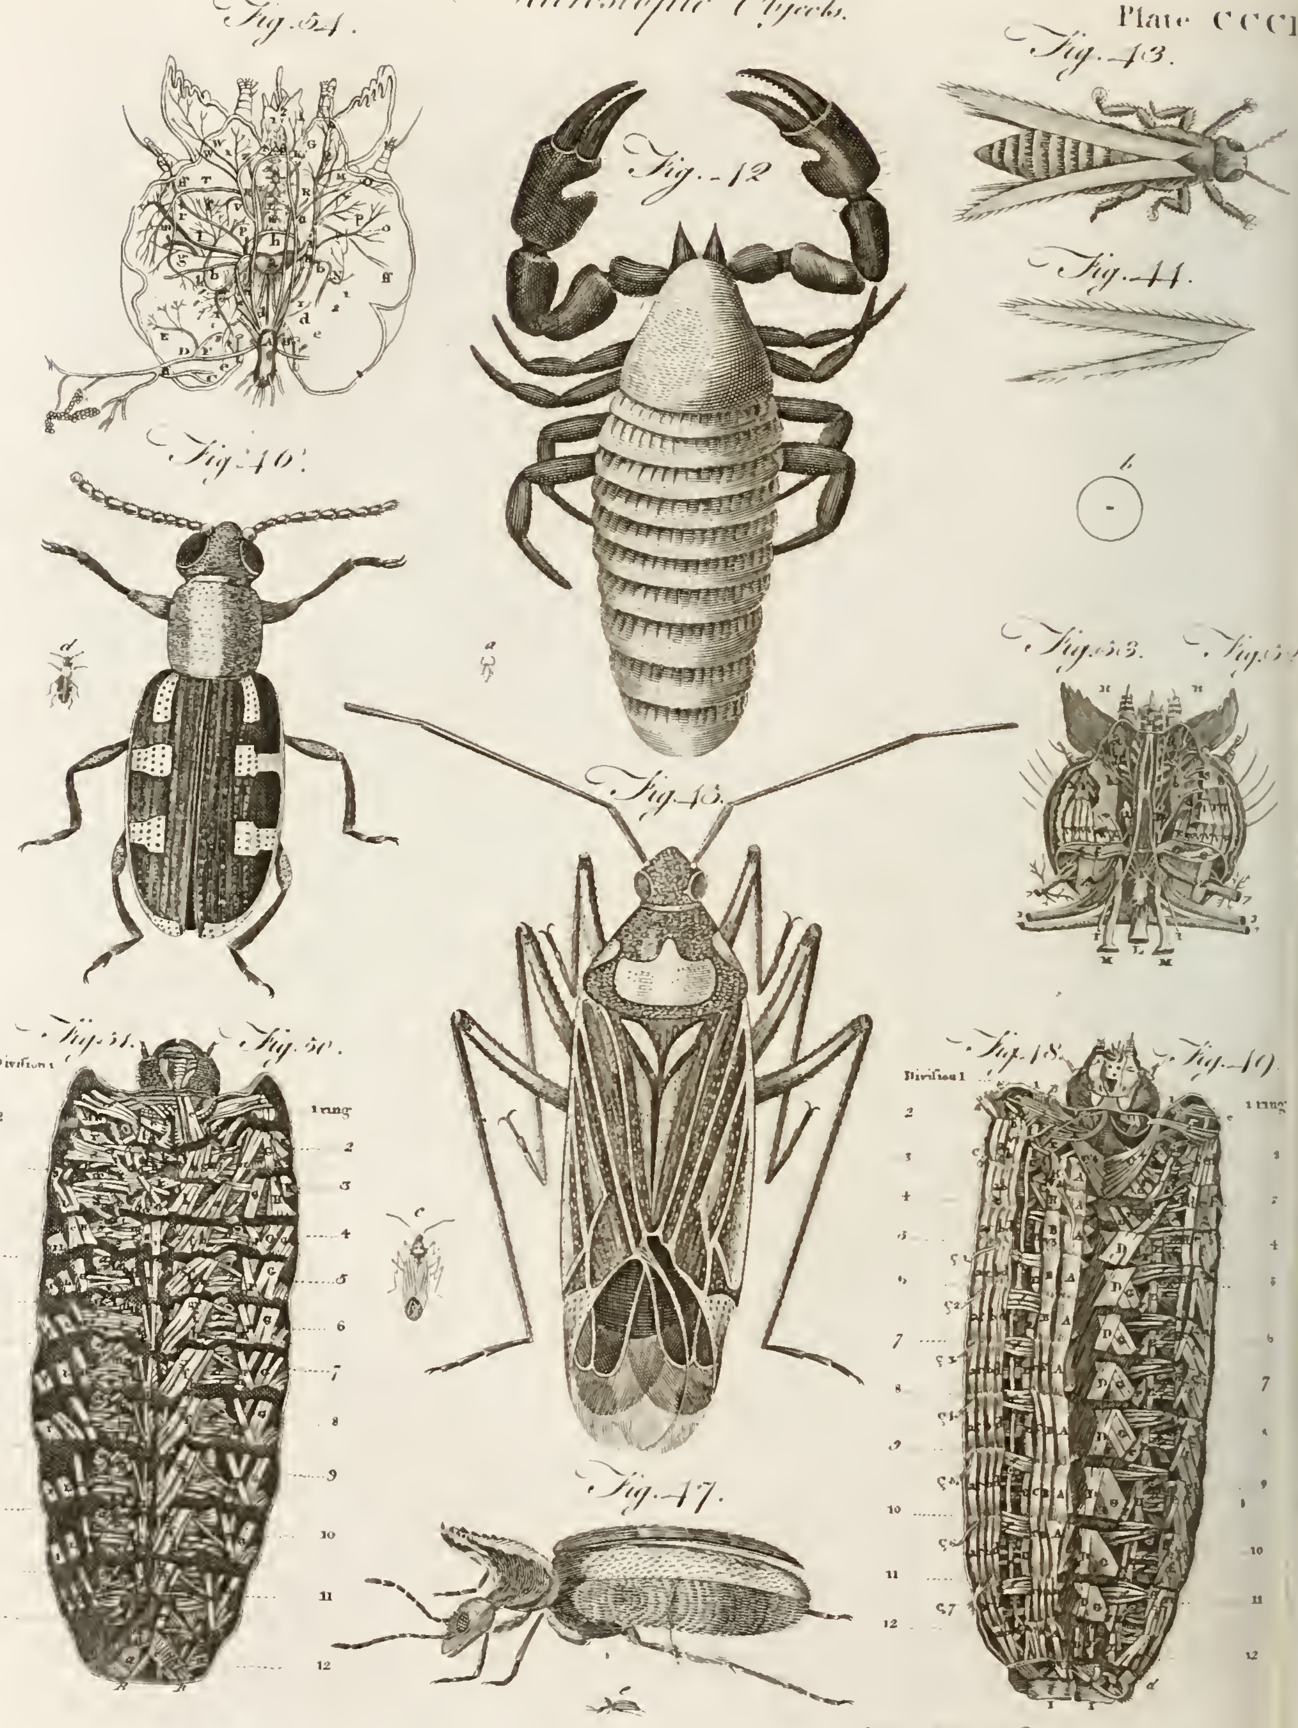
From Mr Lyonet's experiments, it appears, that the coſſus generally paſſes at leaſt two winters, if not three, before it aſſumes the pupa ſtate. At the approach of winter, it forms a little caſe, the inſide of which is lined with ſilk, and the outſide covered with wood ground like very fine ſaw-duſt. During the whole ſeaſon it neither moves nor eats.

This caterpillar, at its firſt appearance, is not above one-twelfth of an inch long; but at laſt attains the length of two, and ſometimes of three inches. In the month of May it prepares for the pupa ſtate; the firſt care being to find a hole in the tree ſufficient to allow the moth to iſſue forth; and if this cannot be found, it makes one equal in ſize to the future pupa. It then begins to form of wood a caſe or cone; uniting the bits, which are very thin, together by ſilk, into the form of an ellipſoid, the outſide being formed of ſmall bits of wood joined together in all directions; taking care, however, that the pointed end of the caſe may always be oppoſite to the mouth of the hole: having finiſhed the outſide of the caſe, it lines the inſide with a ſilken tapeſtry of a cloſe texture in all its parts, except the pointed end, where the texture is looſer, in order to facilitate its eſcape at the proper time. The caterpillar then places itſelf in ſuch a poſture, that the head may always lie towards the opening of the hole in the tree or pointed end of its caſe. Thus it remains at reſt for ſome time: the colour of the ſkin firſt becomes pale, and afterwards brown; the interior parts of the head are detached from the ſkull; the legs withdraw themſelves from the exterior caſe; the body ſhortens; the poſterior part grows ſmall, while the anterior part ſwells ſo much, that the ſkin at laſt burſts; and, by a variety of motions, is puſhed down to the tail; and thus the pupa is exhibited, in which the parts of the future moth may be eaſily traced.—The covering of the pupa, though at firſt ſoft, humid, and white, ſoon dries and hardens, and becomes of a dark purple colour: the poſterior part is moveable; but not the fore-part, which contains the rudiments of the head, legs, and wings. The fore-part of the pupa is furniſhed with two horns, one above and the other under the eyes. It has alſo ſeveral rows of points on its back. It remains for ſome weeks in the caſe; after which the moth begins to agitate itſelf, and the points are then of eſſential ſervice, by acting as a fulcrum, upon which it may reſt in its endeavours to proceed forward, and not ſlip back by its efforts for that purpoſe.

The moth generally continues its endeavours to open the caſe for a quarter of an hour; after which, by redoubled efforts, it enlarges the hole, and preſſes forward

Microscopic Objects.

Plate CCCIII



A. Bell Prin. Wal. Sculptor fecit.

ward until it arrives at the edge, where it makes a full ftop, left by advancing further it fhould fall to the ground. After having in this manner repofed itfelf for fome time, it begins to difengage itfelf entirely; and having refted for fome hours with its head upwards, it becomes fit for action. Mr Marfham fays, that it generally pufhes one third of the cafe out of the hole before it halts.

The body of the caterpillar is divided into twelve rings, marked 1, 2, 3, &c. as reprefented in fig. 48. 49. 50. 51. each of which is diftinguifhed from that which precedes, and that which follows, by a kind of neck or hollow; and, by forming boundaries to the rings, we make twelve other divifions, likewife expreffed in the figures; but to the firft of thefe the word *ring* is affixed, and to the fecond, *divifion*. To facilitate the defcription of this animal, M. Lyonet fuppofed a line to pafs down through the middle of the back, which he called the fuperior line, becaufe it marked the moft elevated part of the back of the caterpillar; and another, paffing from the head down the belly to the tail, he called the inferior line.

All caterpillars have a fmall organ, refembling an elliptic fpot, on the right and left of each ring, excepting the fecond, third, and laft; and by thefe we are furnifhed with a further fubdivifion of this caterpillar, viz. by lines paffing through the fpiracula, the one on the right fide, the other on the left of the caterpillar. Thefe four lines, which divide the caterpillar longitudinally into four equal parts, mark each the place under the fkin which is occupied by a confiderable vifcus. Under the fuperior line lies the heart, or rather thread of hearts; over the inferior line, the fpinal marrow; and the two tracheal arteries follow the courfe of the lateral lines. At equal diftances from the fuperior and two lateral lines, we may fuppofe four intermediate lines. The two between the fuperior and lateral lines are called the intermediate fuperior; the two others oppofite to them, and between the lateral and inferior lines, are called the intermediate inferior.

Fig. 48. 49. fhow the mufcles of the caterpillar, arranged with the moft wonderful fymmetry and order, efpecially when taken off by equal ftrata on both fides, which exhibits an aftonifhing and exact form and correfpondence in them. The figures fhow the mufcles of two different caterpillars opened at the belly, and fuppofed to be joined together at the fuperior lines. The mufcles of the back are marked by capitals; the gaftric mufcles by Roman letters; the lateral ones by Greek characters. Thofe marked θ are called, by M. Lyonet, dividing mufcles, on account of their fituation.

The caterpillar was prepared for diffection by being emptied, and the mufcles, nerves, &c. freed from the fat in the manner formerly directed: after which the following obfervations were made.

The mufcle A in the firft ring is double; the anterior one being thick at top, and being apparently divided into different mufcles on the upper fide, but without any appearance of this kind on the under fide. One infertion is at the fkin of the neck towards the head; the other is a little above; and that of the fecond mufcle A is a little below the firft fpiraculum, near which they are fixed to the fkin.

The mufcle marked α is long and flender, fixed by its anterior extremity under the gaftric mufcles *a* and *b* of the firft ring, to the circumflex fcale of the bafe of the lower lip. It communicates with the mufcle *c* of the fecond ring, after having paffed under fome of the arteries, and introduced itfelf below the mufcle ε.

The mufcle β is fo tender, that it is fcarce poffible to open the belly of the caterpillar without breaking it. It is fometimes double, and fometimes triple.—Anteriorly it is fixed to the pofterior edge of the fide of the parietal fcale, the lower fixture being at the middle of the ring near the inferior line.

There are three mufcles marked ξ; the firft affixed at one extremity near the lower edge of the upper part of the parietal fcale; the other end divides itfelf into three or four tails, fixed to the fkin of the caterpillar under the mufcle δ. The anterior part of the fecond is fixed near the firft; the anterior part of the third a little under the firft and fecond, at the fkin of the neck under the mufcle A. Thefe two laft paffing over the cavity of the firft pair of limbs, are fixed by feveral tails to the edge oppofite to this cavity. In this fubject there are two mufcles marked δ, but fometimes there is only one anteriorly; they are fixed to the lower edge of the parietal fcale, the other ends being inferted in the firft fold of the fkin of the neck on the belly-fide. Fig. 50. beft reprefents the mufcles β and δ; as in that figure they do not appear injured by any unnatural connection.

In the fecond and four following rings we difcern two large dorfal mufcles A and B. In the 7th, 9th, and 10th rings are three, A, B, and C; in the 11th are four, A, B, C, and D; and in the anterior part of the 12th ring are five, A, B, C, D, and E. All thefe ranges of mufcles, however, as well as the gaftric mufcles *a*, *b*, *c*, *d*, appear at firft fight only as a fingle mufcle, running nearly the whole length of the caterpillar; but when this is detached from the animal, it is found to confift of fo many diftinct mufcles, each confifting only of the length of one of the rings, their extremities being fixed to the divifion of each ring, excepting the middle mufcle *a*, which, at the 6th, 7th, 8th, and 9th rings, has its infertions rather beyond the divifion. Each row of mufcles appears as one, becaufe they are clofely connected at top by fome of the fibres which pafs from one ring to the other.

The mufcles A, which are 12 in number, gradually diminifh in breadth to the lower part of the laft ring: at the 8th and three following divifions they communicate with the mufcles B, and at the 11th with D. In the lower part of the laft ring, A is much broader than it was in the preceding ring; one extremity of it is contracted, and communicates with B; the lower infertion being at the membrane I, which is the exterior fkin of the fecal bag. The mufcles A and B, on the lower part of the laft ring, cannot be feen until a large mufcle is removed, which on one fide is fixed to the fubdivifion of the ring and on the other to the fecal bag.

The right mufcles B, which are alfo 12 in number, begin at the fecond ring, and grow larger from thence to the feventh. They are ufually narrower from thence to the 12th; the deficiency in width being

Microfcope ing fupplied by the fix mufcles C, which accompany it from the 7th to the fubdivifion of the 12th ring. The mufcles B and C communicate laterally with the 8th, 11th, and 12th divifions. C is wanting at the fubdivifion of the 12th; its place being here fupplied by B, which becomes broader at this part.

The firft of the three floating mufcles V originates at the firft ring, from whence it introduces itfelf under N, where it is fixed, and then fubdivides, and hides itfelf under other parts. The fecond begins at the fecond divifion, being fixed to the anterior extremity B of the fecond ring; from thence directing itfelf towards the ftomach; and, after communicating with the cafe of the *corpus craffum*, it divides, and fpreads into eight mufcles which run along the belly. The third begins at the third divifion, originating partly at the fkin, and partly at the junction of the mufcles B of the fecond and third ring. It directs itfelf obliquely towards the belly, meeting it near the third fpiraculum; and branching from thence, it forms the oblique mufcles of fome of the vifcera.

The thin, long, mufcle , which is at the fubdivifion of the laft ring, and covers the anterior infertion of the mufcle (*a*) where the ring terminates, is fingle. It begins at one extremity of the mufcle (*c*); at the fore-part of the ring runs along the fubdivifion round the belly of the caterpillar, and finifhes, on the other fide, at the extremity of a fimilar mufcle C.

Fig. 49. fhows the dorfal mufcles of the coffus. To view which in an advantageous manner, we muft ufe the following mode of preparation.

1. All the dorfal mufcles, 35 in number, muft be taken out, as well as the feven lateral ones already defcribed.

2. All the ftraight mufcles of the belly muft be taken away, as well as the mufcular roots (*c*), and the ends of the gaftric mufcles (*c*), which are at the third and fourth divifions.

3. At the fecond divifion the mufcle θ muft be removed; only the extremities being left to fhow where it was inferted.

The parts being thus prepared, we begin at the third ring; where there are found four dorfal mufcles C, D, E, and F. The firft one C, is inferted at the third divifion, under the mufcles . and α, where it communicates by means of fome fibres with the mufcle *f* of the fecond ring; proceeding from thence obliquely towards the intermediate fuperior line, and is fixed at the fourth divifion. As foon as C is retrenched, the mufcle D is feen; which grows wider from the anterior extremity: it lies in a contrary direction to the mufcle C, and is inferted into the third and fourth divifions. The mufcle E lies in the fame direction as the mufcle C, but not fo obliquely: the lower infertion is at the fourth divifion; the other at the third, immediately under C. The mufcle F is nearly parallel to D which joins it; the firft infertion is vifible, but the other is hid under the mufcles E and G at the fourth divifion.

In the eight following rings, there are only two dorfal mufcles; and of thefe D is the only one that is completely feen. It is very large, and diminifhes gradually in breadth from one ring to the other, till it comes to the laft, fending off branches in fome places.—E is one of the ftrait mufcles of the back; and is inferted under the dividing mufcles β, at the divifions of its own ring.

On the anterior part of the 12th ring there are three dorfal mufcles, D, E, and F. D is fimilar to that of the preceding ring, marked alfo D, only that it is no more than half the length; terminating at the fubdivifion of its own ring. E is of the fame length, and differs from the mufcle E of the preceding ring only in its direction. F is parallel to E, and fhorter than it; its anterior end does not reach the twelfth divifion.

On the pofterior part there is only one dorfal mufcle, faftened by fome fhort ones to the fubdivifion of the laft ring, traverfing the mufcles α; and being fixed there as if defigned to ftrengthen them, and to vary their direction.—γ is a fingle mufcle, of which the anterior infertion is vifible, the other end being fixed to the bottom of the foot of the laft leg; its ufe is to move the foot. The anterior part of the mufcle ρ branches into three or four heads, which crofs the fuperior line obliquely, and are fixed to the fkin a little above it. The other end is faftened to the membrane T.

Fig. 50 and 51. fhow the mufcles of the caterpillar when it is opened at the back. The preparation for this view is to difengage the fat and other extraneous matter, as before directed.

The firft ring has only two gaftric mufcles (*c*) and (*d*): the former is broad, and has three or four little tails: the firft fixture is at the bafe of the lower lip, from whence it defcends obliquely, and is fixed between the inferior and lateral line. The fmall mufcle (*d*) is faftened on one fide to the firft fpiraculum; on the other, a little lower, to the intermediate inferior and lateral line; and feems to be an antagonift to the mufcle P, which opens the fpiracula. The pofterior fixture of *g* is under the mufcle C, near the fkin of the neck: *g* is fixed a little on the other fide of C, at the middle of the ring.

In the fecond ring there are three gaftric mufcles, *g*, *h*, and *i*: *g* and *h* are fixed at the folds which terminate the ring; but only the anterior part of *i* is fixed there. The mufcle *h* is triple, and in one of the divifions feparated into two parts; that marked *i* comes nearer the inferior line, and is fixed a little beyond the middle of the ring, where the correfponding mufcle of the oppofite fide is forked to receive it.

In the third ring, the mufcle *h*, which was triple in the foregoing ring, is only double here, that part which is neareft the inferior line being broadeft: it has three tails, of which only two are vifible in the figure. It is exactly fimilar to that of the preceding ring; and is croffed in the fame manner by the mufcle from the oppofite fide of the ring.

Throughout the eight following rings, the mufcle *f* which runs through them all is very broad and ftrong. The anterior part of it is fixed at the intermediate inferior line, on the fold of the firft divifion of the ring: the other part is fixed beyond the lower divifion; with this difference, that at the 10th and 11th rings it is fixed at the laft fold of its ring; whereas, in the others it paffes over that ring, and is inferted into the fkin of the following one. In all thefe,

thefe, the firft extremity of the mufcle *g* is faftened to the fold which feparates the ring from the preceding one, and is parallel to *f*, and placed at the fide of it. The fix firft mufcles marked *g*, are forked; that of the fourth ring being more fo than the reft, nor does it unite till near its anterior infertion. The longeft tail lays hold of the following, and is inferted near the inferior line; the other inferts itfelf near the fame line, at about the middle of its own ring. The two laft do not branch out; but terminate at the divifions, without reaching the following ring. The mufcle *h*, placed at the fide of *f*, has nearly the fame direction, and finifhes at the folds of the ring.

The anterior part of the 12th ring has only one gaftric mufcle, marked *e*: it is placed on the intermediate inferior line; and is inferted at the folds of the upper divifion, and at the fubdivifion of this ring. The lower part has a larger mufcle marked *c*, with feveral divifions; one placed under *b*, with one extremity fixed near the lateral line, at the fubdivifion of its ring; the other to the fecal bag, a little lower than the mufcle *b*.

In fig. 51. all the gaftric mufcles defcribed in fig. 50. difappear, as well as thofe lateral and dorfal ones of which the letters are not to be found in this figure.

In the firft ring are the gaftric mufcles, *e*, *f*, *g*, which are beft feen here: the firft is narrow and long, paffing under and croffing *f*: one of its infertions is at the lower line, the other at the lateral, between the fpiraculum and neck: *f* is fhort, broad, and nearly ftraight, placed along the intermediate line; but between it and the lateral it paffes under *e*, and is fixed to the fold of the fkin which goes from the one bag to the other; the lower infertion is near the fecond divifion. There are fometimes three mufcles of thofe marked *g*, and fometimes four: the lower parts of them are fixed about the middle of the ring, and the anterior parts at the fold of the fkin near the neck. The mufcles *i* and *h* are fixed to the fame fold; the other end of *h* being fixed under the mufcle [11], near the fpiraculum. Above the upper end of *f*, a mufcular body, *g*, may be feen. It is formed by the feparation of two floating mufcles.

The fecond ring has fix gaftric mufcles, *k*, *l*, *m*, *n*, *o*, *p*. The firft is a large oblique mufcle, with three or four divifions placed at the anterior part of the ring: the head is fixed between the inferior line and its intermediate one, at the fold of the fecond divifion; from whence it croffes the inferior line and its correfponding mufcle, terminating to the right and left of the line. I is a narrow mufcle, whofe head is fixed to the fold of the fecond divifion; the tail of it lying under *n*, and faftened to the edge of the fkin that forms the cavity for the leg. The two mufcles marked *m* have the fame obliquity, and are placed the one on the other: the head is inferted in the fkin under the mufcle *k*, and communicates by a number of fibres with the tail of the mufcle *r*; the other end is fixed to the intermediate inferior line at the fold of the third divifion. The large and broad mufcle *n*, covers the lower edge of the cavity of the limb, and the extremity of the tail of *l*. It is fixed firft at the fkin, near the intermediate line, from whence it goes in a perpendicular direction towards *m*, and introduces itfelf under *o* and *m*, where it is fixed. The mufcle *o* is narrow and bent, and covers the edge of the cavity of the leg for a little way; one end terminating there, and the other finifhing at the third divifion near *m*. That marked *p* is alfo bent: it runs near the anterior edge of the cavity of the leg; one end meets the head of *o*, the other end terminates at a raifed fold near the inferior line. There is a triangular mufcle on the fide of the lateral mufcle *o*, fimilar to that marked *g* in the following ring: in this figure it is entirely concealed by the mufcle *m*.

The third ring has no mufcle fimilar to *m*; that marked *k* differs only from that of the fecond ring in being croffed by the oppofite mufcle. Thofe marked *l*, *n*, *o*, *p*, are fimilar to thofe of the preceding one. The mufcle *q* is triangular; the bafe is faftened to the laft fold of the ring; on the lower fide it is fixed to the mufcle *o*, the top to the fkin at the edge of the cavity for the leg.

The eight following rings have the gaftric mufcles, *i*, *k*, *l*, and *m*. The mufcle *i* is quite ftraight, and placed at fome diftance from the inferior line: it is broad at the fourth ring, but diminifhes gradually in breadth to the 11th. In the fourth it is united; but divides into two heads, which divaricate in the following rings. In the fix next rings thefe heads are fixed nearly at the fame place with *a* and *f*; and in the other two it terminates at the fold of the ring. The anterior infertion of the firft and laft is at the fold where the ring begins: that of the fix others is fomewhat lower under the place where the mufcle *i* terminates. The lower part of the oblique mufcle *k* is inferted in the fkin near *i*; the upper part at the intermediate inferior mufcle upon the fold which feparates the following ring, but is wanting in the 11th. The mufcle *l* is large, and co-operates with M: in the opening and fhutting the fpiraculum, one of its fixtures is near the intermediate inferior line, at about the fame height as *i*. The tail terminates a little below the fpiraculum.

The twelfth ring has only the fingle gaftric mufcle *d*, which is a bundle of fix, feven, or eight mufcles: the firft fixture of thefe is at the fubdivifion of the ring near the inferior line: one or two crofs this, and at the fame time the fimilar mufcles of the oppofite fide. Their fixture is at the bottom of the foot; and their office is to affift the mufcle *a* in bringing back the foot, and to loofen the claw from what it lays hold of. One of the infertions of this mufcle *a* is obferved in this figure near *d*, the other near the fubdivifion of the ring.

Fig. 52. and 53. fhow the organization of the head of the coffus, though in a very imperfect manner, as M. Lyonet found it neceffary to employ *twenty* figures to explain it fully. The head is reprefented as it appears when feparated from the fat, and difengaged from the neck. HH are the two palpi. The truncated mufcles D belong to the lower lip, and affift in moving it. K fhows the two ganglions of the neck united. II are the two veffels which affift in fpinning the filk. L, the œfophagus. M, the two diffolving veffels. The Hebrew characters דכבא fhow the continuation of the four cephalic arteries. In fig. 52. the ten abductor mufcles of the jaw

 are

are represented by SS, TT, VV, and Z. Four occipital muscles are seen in fig. 53. under *e e* and *f f*. At *a k* is represented a nerve of the first pair belonging to the ganglion of the neck; *b* is a branch of this nerve.

Fig. 54. exhibits the nerves as seen from the under part; but excepting in two or three nerves, which may be easily distinguished, only one of each pair is drawn, in order to avoid confusion. The nerves of the first ganglion of the neck are marked by capital letters, those of the ganglion (a) of the head by Roman letters; the nerves of the small ganglion by Greek characters. Those of the frontal ganglion, except one, by numbers.

The muscles of the cossus have neither the colour nor form of those of larger animals. In their natural state they are soft, and of the consistence of a jelly. Their colour is a greyish blue, which, with the silver-coloured appearance of the pulmonary vessels, form a glorious spectacle. After the caterpillar has been soaked for some time in spirit of wine, they lose their elasticity and transparency, becoming firm, opaque, and white, and the air-vessels totally disappear. The number of muscles in a caterpillar is very great. The greatest part of the head is composed of them, and there is a vast number about the œsophagus, intestines, &c. the skin is, as it were, lined by different beds of them, placed the one under the other, and ranged with great symmetry. M. Lyonet has been able to distinguish 228 in the head, 1647 in the body, and 2066 in the intestinal tube, making in all 4041.

At first sight the muscles might be taken for tendons, as being of the same colour, and having nearly the same lustre. They are generally flat, and of an equal size throughout; the middle seldom differing either in colour or size from either of the extremities. If they are separated, however, by means of very fine needles, in a drop of some fluid, we find them composed not only of fibres, membranes, and air-vessels, but likewise of nerves; and, from the drops of oil that may be seen floating on the fluid, they appear also to be furnished with many unctuous particles. Their ends are fixed to the skin, but the rest of the muscle is generally free and floating. Several of them branch out considerably; and the branches sometimes extend so far, that it is not easy to discover whether they are distinct and separate muscles or parts of another. They are moderately strong; and those which have been soaked in spirit of wine, when examined by the microscope, are found to be covered with a membrane which may be separated from them; and they appear then to consist of several parallel bands lying longitudinally along the muscle, which, when divided by means of fine needles, appear to be composed of still smaller bundles of fibres lying in the same direction; which, when examined by a powerful magnifier, and in a favourable light, appear twisted like a small cord. The muscular fibres of the spider, which are much larger than those of the caterpillar, consist of two different substances, one soft and the other hard; the latter being twisted round the former spirally, and thus giving it the twisted appearance just mentioned.

There is nothing in the caterpillar similar to the brain in man. We find indeed in the head of this insect a part from which all the nerves seem to proceed; but this part is entirely unprotected, and so small, that it does not occupy one fifth part of the head: the surface is smooth, and has neither lobes nor any anfractuosity like the human brain. But if we call this a brain in the caterpillar, we must say that it has *thirteen:* for there are twelve other such parts following each other in a straight line, all of them of the same substance with that in the head, and nearly of the same size; and from them, as well as from that in the head, the nerves are distributed thro' the body.

The spinal marrow in the cossus goes along the belly; is very small, forking out at intervals, nearly of the same thickness throughout, except at the ganglions, and is not inclosed in any case. It is by no means so tender as in man; but has a great degree of tenacity, and does not break without a considerable degree of tension. The substance of the ganglions differs from that of the spinal marrow, as no vessels can be discovered in the latter; but the former are full of very delicate ones. There are 94 principal nerves, which divide into innumerable ramifications.

The cossus has two large tracheal arteries, creeping under the skin close to the spiracula; one at the right and the other at the left side of the insect, each of them communicating with the air by means of nine spiracula. They are nearly as long as the whole caterpillar; beginning at the first spiraculum, and extending somewhat farther than the last; some branches also extending quite to the extremity of the body. Round each spiraculum the trachea pushes forth a great number of branches, which are again divided into smaller ones, and these further subdivide and spread through the whole body of the caterpillar. The tracheal artery, with all its numerous ramifications, are open elastic vessels, which may be pressed close together, or drawn out considerably, but return immediately to their usual size when the tension ceases. They are naturally of a silver colour, and make a beautiful appearance. This vessel, with its principal branches, is composed of three coats, which may be separated from one another. The outmost is a thick membrane furnished with a great variety of fibres, which describe a vast number of circles round it, communicating with each other by numerous shoots. The second is very thin and transparent, without any particular vessel being distinguishable in it. The third is composed of scaly threads, generally of a spiral form; and so near each other as scarcely to leave any interval. They are curiously united with the membrane which occupies the intervals; and form a tube which is always open, notwithstanding the flexure of the vessel. There are also many other peculiarities in its structure. The principal tracheal vessels divide into 1326 different branches.

The heart of the cossus is very different from that of larger animals, being almost as long as the animal itself. It lies immediately under the skin at the top of the back, entering the head, and terminating near the mouth. Towards the last rings of the body it is large and capacious, diminishing very much as it approaches the head, from the fourth to the twelfth division. On both sides, at each division, it has an appendage, which partly

Microscopic Objects.

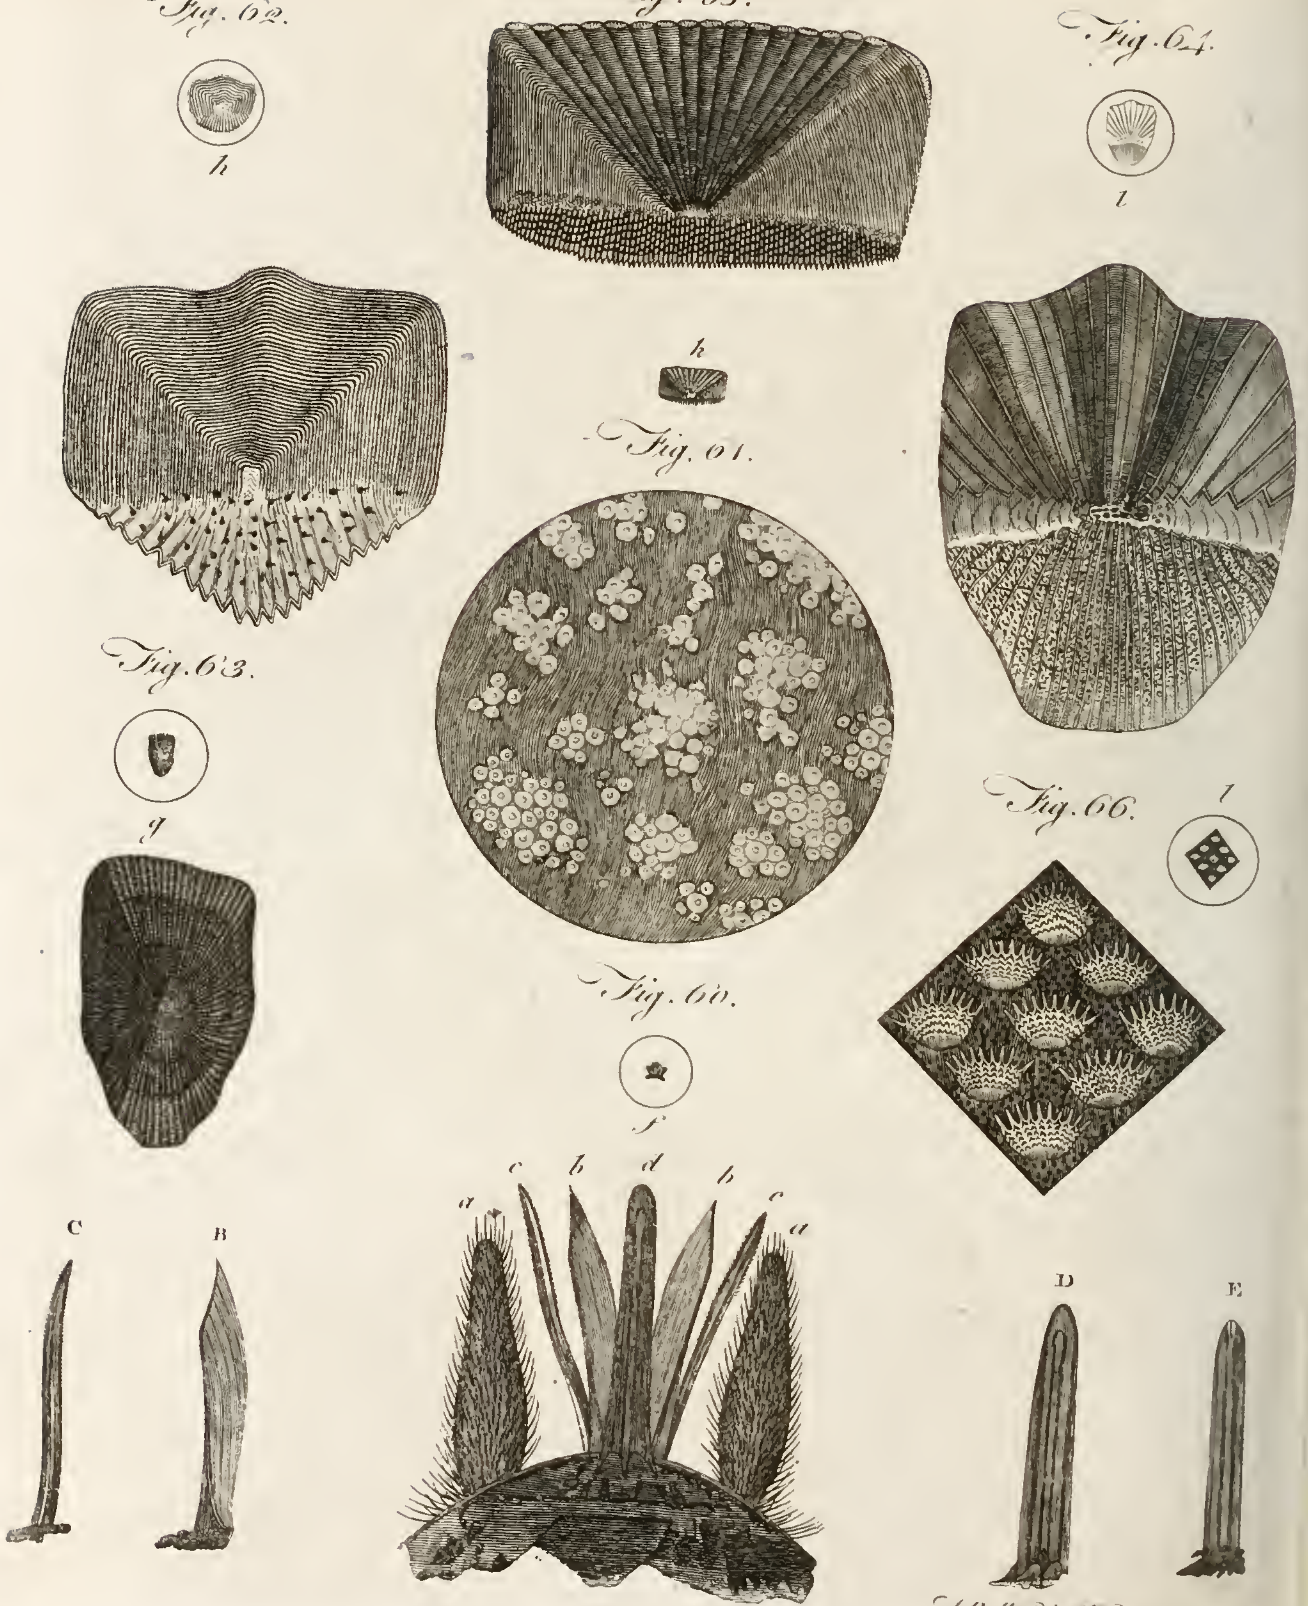
Microscopic Objects.

Plate CCCV



A. Bell Prin. Wal. Sculptor fecit.

Microfcope partly covers the mufcles of the back, but which, growing narrower as it approaches the lateral line, it forms a number of irregular lozenge-fhaped bodies.—This tube, however, feems to perform none of the functions of the heart in larger animals, as we find no veffel opening into it which anfwers either to the aorta or vena cava. It is called the heart, becaufe it is generally filled with a kind of lymph, which naturalifts have fuppofed to be the blood of the caterpillar; and becaufe in all caterpillars which have a tranfparent fkin, we may perceive alternate regular contractions and dilatations along the fuperior line, beginning at the eleventh ring, and proceeding from ring to ring, from the fourth; whence this veffel is thought to be a ftring or row of hearts. There are two white oblong bodies which join the heart near the eighth divifion; and thefe have been called *reniform* bodies, from their having fomewhat of the fhape of a kidney.

The moft confiderable part of the whole caterpillar with regard to bulk is the corpus craffum. It is the firft and only fubftance that is feen on opening it. It forms a kind of fheath which envelopes and covers all the entrails, and, introducing itfelf into the head, enters all the mufcles of the body, filling the greateft part of the empty fpaces in the caterpillar. It very much refembles the configuration of the human brain, and is of a milk-white colour.

The oefophagus defcends from the bottom of the mouth to about the fourth divifion. The fore-part, which is in the head, is flefhy, narrow, and fixed by different mufcles to the cruftaceous parts of it; the lower part, which paffes into the body, is wider, and forms a kind of membranaceous bag, covered with very fmall mufcles; near the ftomach it is narrower, and, as it were, confined by a ftrong nerve fixed to it at diftant intervals. The ventricle begins a little above the fourth divifion, where the oefophagus ends, and finifhes at the tenth. It is about feven times as long as broad; and the anterior part, which is broadeft, is generally folded. Thefe folds diminifh with the bulk as it approaches the inteftines; the furface is covered with a great number of aerial veffels, and opens into a tube, which M. Lyonet calls the large inteftine.—There are three of thefe large tubes, each of which differs fo much from the reft, as to require a particular name to diftinguifh it from them.

The two veffels from which the coffus fpins its filk are often above three inches long, and are diftinguifhed into three parts; the anterior, intermediate, and pofterior. It has likewife two other veffels, which are fuppofed to prepare and contain the liquor for diffolving the wood on which it feeds.

Plate CCCIV. Fig. 55. fhews the wing of an earwig magnified; *a* reprefents it of the natural fize. The wings of this infect are fo artificially folded up under fhort cafes, that few people imagine they have any. Indeed, they very rarely make ufe of their wings. The cafes under which they are concealed are not more than a fixth part of the fize of one wing, though a fmall part of the wing may be difcovered, on a careful infpection, projecting from under them. The upper part of the wing is cruftaceous and opaque, but the under part is beautifully tranfparent. In putting up their wings, they firft fold back the parts AB, and then fhut up the ribs like a fan; the ftrong mufcles ufed for this purpofe being feen at the upper part of the figure. Some of the ribs are extended from the centre to the outer edge; others only from the edge about half way: but they are all united by a kind of band, at a fmall but equal diftance from the edge; the whole evidently contrived to ftrengthen the wing, and facilitate its various motions. The infect itfelf differs very little in appearance in its three different ftates. De Geer afferts, that the female hatches eggs like a hen, and broods over her young ones as a hen does.

Fig. 56. reprefents a wing of the *Hemerobius perla* magnified. It is an infect which feldom lives more than two or three days.—The wings are nearly of a length, and exactly fimilar to one another. They are compofed of fine delicate nerves, regularly and elegantly difpofed as in the figure, beautifully adorned with hairs, and lightly tinged with green. The body is of a fine green colour; and its eyes appear like two burnifhed beads of gold, whence it has obtained the name of *golden eye*. This infect lays its eggs on the leaves of the plum or the rofe tree; the eggs are of a white colour, and each of them fixed to a little pedicle or foot-ftalk, by which means they ftand off a little from the leaf, appearing like the fructification of fome of the moffes. The larva proceeding from thefe eggs refembles that of the coccinella or lady-cow, but is much more handfome. Like that, it feeds upon aphides or pucerons, fucking their blood, and forming itfelf a cafe with their dried bodies; in which it changes into the pupa ftate, from whence they afterwards emerge in the form of a fly.

Fig. E, F, I, reprefent the duft of a moth's wing magnified. This is of different figures in different moths. The natural fize of thefe fmall plumes is reprefented at H.

Fig. 57. fhows a part of the cornea of the libellula magnified. In fome pofitions of the light, the fides of the hexagons appear of a fine gold colour, and divided by three parallel lines. The natural fize of the part magnified is fhown at *b*.

Fig. 58. fhows the part *c* of a lobfter's cornea magnified.

Fig. 59. fhows one of the arms or horns of the lepas antifera, or barnacle, magnified; its natural fize being reprefented at *d*. Each horn confifts of feveral joints, and each joint is furnifhed on the concave fide of the arm with long hairs. When viewed in the microfcope, the arms appear rather opaque; but they may be rendered tranfparent, and become a moft beautiful object, by extracting out of the interior cavity a bundle of longitudinal fibres, which runs the whole length of the arm. Mr Needham thinks that the motion and ufe of thefe arms may illuftrate the nature of the rotatory motion in the wheel-animal. In the midft of the arms is an hollow trunk, confifting of a jointed hairy tube, which inclofes a long round tongue that can be pufhed occafionally out of the tube or fheath, and retracted occafionally. The mouth of the animal confifts of fix laminæ, which go off with a bend, indented like a faw on the convex edge, and by their circular difpofition are fo ranged, that the teeth, in the alternate elevation and depreffion of each plate, act againft whatever comes between them. The plates are placed together in fuch a manner, that to the naked eye they form an aperture not much unlike the mouth of a contracted purfe.

Plate CCCV. Fig. 60. fhows the apparatus of the *Tabanus* or Gadfly,

fly, by which it pierces the skin of horses and oxen, in order to suck their blood. The whole is contained in a fleshy case, not expressed in the figure. The feelers *aa* are of a spongy texture and grey colour, covered with short hairs. They are united to the head by a small joint of the same substance. They defend the other parts of the apparatus, being laid upon it side by side whenever the animal stings, and thus preserve it from external injury. The wound is made by the two lancets *bb* and B, which are of a delicate structure, but very sharp, formed like the dissecting knife of an anatomist, growing gradually thicker to the back.—The two instruments *cc* and C, appear as if intended to enlarge the wound, by irritating the parts round it; for which they are jagged or toothed. They may also serve, from their hard and horny texture, to defend the tube *e* E, which is of a softer nature, and tubular, to admit the blood, and convey it to the stomach. This part is totally inclosed in a line *d* D, which entirely covers it. These parts are drawn separately at B, C, D, E. De Geer observes, that only the females suck the blood of animals; and Reaumur informs us, that having made one, that had sucked its fill, disgorge itself, the blood it threw up appeared to him to be more than the whole body of the insect could have contained. The natural size of this apparatus is shown at *f*.

Fig. 61. shows a bit of the skin of a lump-fish *(Cyclopterus)* magnified. When a good specimen of this can be procured, it forms a most beautiful object. The tubercles exhibited in the figure probably secrete an unctuous juice.

Fig. 62. shows the scale of a sea-perch found on the English coast; the natural size is exhibited at *h*.

Fig. 63. is the scale of an haddock magnified; its natural size as within the circle.

Fig. 64. the scale of a parrot fish from the West Indies magnified; *l* the natural size of it.

Fig. 65. the scale of a kind of perch in the West Indies magnified; *k* the natural size of the scale.

Fig. 66. part of the skin of a sole fish, as viewed through an opaque microscope; the magnified part, in its real size, shown at *l*.

The scales of fishes afford a great variety of beautiful objects for the microscope. Some are long; others round, square, &c. varying considerably not only in different fishes, but even in different parts of the same fish. Leeuwenhoeck supposed them to consist of an infinite number of small scales or strata, of which those next to the body of the fish are the largest. When viewed by the microscope, we find some of them ornamented with a prodigious number of concentric flutings, too near each other, and too fine to be easily enumerated. These flutings are frequently traversed by others diverging from the centre of the scale, and generally proceeding from thence in a straight line to the circumference.

For a more full information concerning these and other microscopical objects, the reader may consult Mr Adams's *Essays on the Microscope*, who has made the most valuable collection that has yet appeared on the subject. See also the articles ANIMALCULE, CRYSTALLIZATION, POLYPE, PLANTS, and WOOD, in the present Work.

MIDAS (fab. hist.), a famous king of Phrygia, who having received Bacchus with great magnificence, that god, out of gratitude, offered to grant him whatever he should ask. Midas desired that every thing he touched should be changed into gold. Bacchus consented; and Midas, with extreme pleasure, everywhere found the effects of his touch. But he had soon reason to repent of his folly: for wanting to eat and drink, the aliments no sooner entered his mouth than they were changed into gold. This obliged him to have recourse to Bacchus again, to beseech him to restore him to his former state; on which the god ordered him to bathe in the river Pactolus, which from thence forward had golden sands. Some time after, being chosen judge between Pan and Apollo, he gave another instance of his folly and bad taste, in preferring Pan's music to Apollo's; on which the latter being enraged, gave him a pair of asses ears. This Midas attempted to conceal from the knowledge of his subjects: but one of his servants saw the length of his ears, and being unable to keep the secret, yet afraid to reveal it from apprehension of the king's resentment, he opened a hole in the earth, and after he had whispered there that Midas had the ears of an ass, he covered the place as before, as if he had buried his words in the ground. On that place, as the poets mention, grew a number of reeds, which when agitated by the wind uttered the same sound that had been buried beneath, and published to the world that Midas had the ears of an ass. Some explain the fable of the ears of Midas, by the supposition that he kept a number of informers and spies, who were continually employed in gathering every seditious word that might drop from the mouths of his subjects. Midas, according to Strabo, died of drinking bull's hot blood. This he did, as Plutarch mentions, to free himself from the numerous ill dreams which continually tormented him. Midas, according to some, was son of Cybele. He built a town which he called *Ancyra*.

MIDAS, *Ear-shell*, the smooth ovato-oblong buccinum, with an oblong and very narrow mouth. It consists of six volutions, but the lower one alone makes up almost the whole shell.

MID-HEAVEN, the point of the ecliptic that culminates, or in which it cuts the meridian.

MIDDLEBURG, one of the Friendly Islands in the South Sea. This island was first discovered by Tasman, a Dutch navigator, in January 1742-3; and is called by the natives *Ea-Oo-whe:* it is about 16 miles from north to south, and in the widest part about 8 miles from east to west. The skirts are chiefly laid out in plantations, the south-west and north-west sides especially. The interior parts are but little cultivated, though very capable of it: but this neglect adds greatly to the beauty of the island; for here are agreeably dispersed groves of cocoa-nuts and other trees, lawns covered with thick grass, here and there plantations and paths leading to every part of the island, in such beautiful disorder, as greatly to enliven the prospect. The hills are low; the air is delightful; but unfortunately water i denied to this charming spot. Yams, with other roots, bananas, and bread-fruit, are the principle articles of food; but the latter appeared to be scarce. Here is the pepper-tree, or *ava-ava*, with which they make an intoxicating liquor, in the same disgusting manner as is practised in the Society Islands. Here are several odoriferous trees and shrubs, par-

particularly a ſpecies of the lemon-tribe; and the botanical gentlemen met with various new ſpecies of plants. Here alſo are a few hogs and fowls.

There are no towns or villages; moſt of the houſes are built in plantations, which are laid out in different parts, with no other order than what convenience requires. They are neatly conſtructed, but are leſs roomy and convenient than thoſe in the Society Iſles. The floors are a little raiſed, and covered with thick ſtrong mats. The ſame ſort of matting ſerves to incloſe them on the windward ſide, the others being open. They have little areas before moſt of them, which are planted round with trees or ornamental ſhrubs, whoſe fragrance perfumes the air. Their houſehold furniture conſiſts of a few wooden platters, cocoa-nut ſhells, and pillows made of wood, and ſhaped like four-footed ſtools or forms: their common clothing, with the addition of a mat, ſerves them for bedding.

The natives are of a clear mahogany or cheſnut brown, with black hair, in ſhort frizzled curls, which ſeems to be burnt at the tips; their beards are cut or ſhaven. The general ſtature of the men is equal to our middle ſize, from five feet three to five feet ten inches; the proportions of the body are very fine, and the *contours* of the limbs extremely elegant, though ſomething more muſcular than at Otaheite, which may be owing to a greater and more conſtant exertion of ſtrength in their agriculture and domeſtic economy. Their features are extremely mild and pleaſing; and differ from the old Otaheitian faces in being more oblong than round, the noſe ſharper, and the lips rather thinner. The women are, in general, a few inches ſhorter than the men, but not ſo ſmall as the lower claſs of women at the Society Iſlands. The practice of puncturing the ſkin, and blacking it, which is called *tattowing*, is in full force among the men here, for their belly and loins are very ſtrongly marked in configurations more compounded than thoſe at Otaheite. The tendereſt parts of the body were not free from theſe punctures; the application of which, beſides being very painful, muſt be extremely dangerous on glandulous extremities.

The men in general go almoſt naked, having only a ſmall piece of cloth round the loins, but ſome wrapt it in great abundance round them from their waiſt: this cloth is manufactured much like that at Otaheite, but overſpread with a ſtrong glue, which makes it ſtiff, and fit to reſiſt the wet The women are likewiſe covered from the waiſt downwards: they often have looſe necklaces, conſiſting of ſeveral ſtrings of ſmall ſhells, ſeeds, teeth of fiſhes; and in the middle of all, the round *operculum*, or cover of a ſhell as large as a crown-piece. The men frequently wear a ſtring round their necks, from which a mother-of-pearl ſhell hangs down on the breaſt; both the ears of the women were perforated with two holes, and a cylinder cut out of tortoiſe-ſhell or bone was ſtruck through both the holes. The moſt remarkable circumſtance obſerved of this people was, that moſt of them wanted the little finger on one, and ſometimes on both hands: the difference of ſex or age did not exempt them from this amputation; for even among the few children that were ſeen running about naked, the greater part had already ſuffered ſuch loſs. This circumſtance was obſerved by Taſman. Another ſingularity which was obſerved to be very general among theſe people, was a round ſpot on each cheek-bone, which appeared to have been burnt or bliſtered. On ſome it ſeemed to have been recently made, on others it was covered with ſcurf, and many had only a ſlight mark of its former exiſtence: how, or for what purpoſe it was made, could not be learnt. The women here, in general, were reſerved; and turned, with diſguſt, from the immodeſt behaviour of ungovernable ſeamen: there were not, however, wanting ſome who appeared to be of eaſy virtue, and invited their lovers with laſcivious geſtures. The language ſpoken here is ſoft, and not unpleaſing; and whatever they ſaid was ſpoken in a kind of ſinging tone. Omai and Mahine, who were both paſſengers on board the ſhip, at firſt declared that the language was totally new and unintelligible to them; however, the affinity of ſeveral words being pointed out, they ſoon caught the particular modification of this dialect, and converſed much better with the natives than any on board the ſhips could have done, after a long intercourſe. They have the neateſt ornaments imaginable, conſiſting of a number of little flat ſticks, about five inches long, of a yellow wood like box, firmly and elegantly connected together at the bottom by a tiſſue of the fibres of cocoa-nut, ſome of which were of their natural colour, and others dyed black; the ſame fibres were likewiſe uſed in the making of baſkets, the taſte of which was highly elegant, and varied into different forms and patterns. Their clubs are of a great variety of ſhapes, and many of them ſo ponderous as ſcarce to be managed with one hand. The moſt common form was quadrangular, ſo as to make a rhomboid at the broad end, and gradually tapering into a round handle at the other. Far the greater part were carved all over in many chequered patterns, which ſeemed to have required a long ſpace of time, and incredible patience, to work up; as a ſharp ſtone, or a piece of coral, are the only tools made uſe of: the whole ſurface of the plain clubs was as highly poliſhed as if an European workman had made them with the beſt inſtruments. Beſides clubs, they have ſpears of the ſame wood, which were ſometimes plain ſharp-pointed ſticks, and ſometimes barbed with a ſting-ray's tail. They have likewiſe bows and arrows of a peculiar conſtruction: the bow, which is ſix feet long, is about the thickneſs of a little finger, and when ſlack forms a ſlight curve; its convex part is channelled with a ſingle deep groove, in which the bow-ſtring is lodged. The arrow is made of reed, near ſix feet long, and pointed with hard wood: when the bow is to be bent, inſtead of drawing it ſo as to increaſe the natural curvature, they draw it the contrary way, make it perfectly ſtraight, and then form the curve on the other ſide. Moſt of their canoes have outriggers, made of poles, and their workmanſhip is very admirable: two of theſe canoes are joined together with a ſurpriſing exactneſs, and the whole ſurface receives a very curious poliſh. Their paddles have ſhort broad blades, ſomething like thoſe at Otaheitee, but more neatly wrought and of better wood

They keep their dead above ground, after the manner of the Society Iſlands; as a corpſe was ſeen depoſited on a low hut.

Here were ſeen ſeveral men and women afflicted with leprous diſeaſes, in ſome of whom the diſorder had riſen to a high degree of virulence: one man in par-

particular had his back and shoulders covered with a large cancerous ulcer, which was perfectly livid within, and of a bright yellow all round the edges. A woman w s likewise unfortunate enough to have her face destroyed by it in the most shocking manner; there was only a hole left in the place of her nose; her cheek was swelled up, and continually oozing out a purulent matter; and her eyes seemed ready to fall out of her head, being bloody and sore: though these were some of the most miserable objects that could possibly be seen, yet they seemed to be quite unconcerned about their misfortunes, and traded as briskly as any of the rest.

MIDDLELAM, a town in the north-riding of Yorkshire, situated on the river Ure, 255 miles from London. It had once a castle, where was born Edward prince of Wales, only son of Richard III.; and is noted for a woollen manufactory and frequent horse-races. Its market is on Monday; and fairs Nov. 6. and 7. The town stands on a rising ground; and the castle, which was on the south side, was formerly moated round by the help of a spring conveyed in pipes from the higher grounds. The church of Middlam is extra-parochial.

MIDDLESEX, a county of England, which derives its name from its situation amidst the three kingdoms of the East, West, and South Saxons. It is bounded on the north by Hertfordshire; on the south by the river Thames, which divides it from Surry; on the west by the river Colne, which separates it from Buckinghamshire; and on the east by the river Lea, which divides it from Essex. It extends about 23 miles in length, but hardly 14 in breadth, and is not more than 115 in circumference; but as it comprehends the two vast cities of London and Westminster, which are situated in the south-east part of the county, it is by far the wealthiest and most populous county in England. It is divided into 602 liberties, containing 200 parishes, besides a vast number of chapels of ease, and 5 maket-towns, exclusive of the cities of London and Westminster. The air is very pleasant and healthy, to which a fine gravelly soil does not a little contribute. The soil produces plenty of corn, and the county abounds with fertile meadows and gardeners grounds. In a word, the greater part of the county is so prodigiously assisted by the rich compost from London, that the whole of the cultivated part may be considered as a garden. The natural productions are cattle, corn, and fruit; but its manufactures are too many to be enumerated here, there being hardly a single manufacture practised in Great Britain but what is also established in this county.—Though London is the chief city, Brentford is the county-town where the members of parliament are elected.

MIDDLETON (Dr Conyers), a very celebrated English divine, the son of a clergyman in Yorkshire, was born at Richmond in 1683. He distinguished himself, while fellow of Trinity-college, Cambridge, by his controversy with Dr Bentley his master, relating to some mercenary conduct of the latter in that station. He afterwards had a controversy with the whole body of physicians, on the dignity of the medical profession; concerning which he published *De medicorum apud veteres Romanos degentium conditione dissertatio; qua, contra viros celeberrimos Jacobum Sponium et Richardum Meadium, servilem atque ignobilem eam fuisse, ostenditur:* and in the course of this dispute much resentment and many pamphlets appeared. Hitherto he had stood well with his clerical brethren; but he drew the resentment of the church on him in 1729, by writing "A letter from Rome, showing an exact conformity between popery and paganism," &c.; as this letter, though politely written, yet attacked Popish miracles with a gaiety that appeared dangerous to the cause of miracles in general. Nor were his Objections to Dr Waterland's manner of vindicating Scripture against Tindal's "Christianity as old as the Creation," looked on in a more favourable point of view. In 1741, came out his great work, "The history of the life of M. Tullius Cicero," 2 vols 4to; which is indeed a fine performance, and will probably be read as long as taste and polite literature subsist among us: the author has nevertheless fallen into the common error of biographers, who often give panegyrics instead of history. In 1748, he published, "A free inquiry into the miraculous powers which are supposed to have subsisted in the Christian church from the earliest ages, through several successive centuries." He was now attacked from all quarters; but before he took any notice of his antagonists, he supplied them with another subject in "An examination of the lord bishop of London's discourses concerning the use and extent of prophecy," &c. Thus Dr Middleton continued to display talents and learning, which were highly esteemed by men of a free turn of mind, but by no means in a method calculated to invite promotion in the clerical line. He was in 1723 chosen principal librarian of the public library at Cambridge; and if he rose not to dignities in the church, he was in easy circumstances, which permitted him to assert a dignity of mind often forgotten in the career of preferment. He died in 1750, at Hildersham in Cambridgeshire, an estate of his own purchasing; and in 1752, all his works, except the life of Cicero, were collected in 4 vols, 4to.

MIDDLEWICH, a town of Cheshire, 167 miles from London. It stands near the conflux of the Croke and Dan, where are two salt-water springs, from which are made great quantities of salt, the brine being said to be so strong as to produce a full fourth part sa t. It is an ancient borough, governed by burgesses; and its parish extends into many adjacent townships. It has a spacious church. Its market is on Tuesdays; and fairs on St James's-day, July 25. and Holy-Thursday. By the late inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Stafford, Warwick, Leicester, Oxford, Worcester, &c. The river Wheelock, after a course of about 12 miles from Mowcop-hill, runs into the Dan a little above this town.

MIDHURST, a town of Sussex, 52 miles from London, has been represented in parliament ever since the 4th of Edward II. It is a neat small town, on a hill surrounded with others, having the river Arun at the bottom; and is a borough by prescription, governed by a bailiff, chosen annually by a jury at a court-leet of the lord of the manor. The market is on Thursday; fairs on March 21. and the Thursday after.

MIDIAN, or Madian (anc. geog.), a town on the ſouth ſide of Arabia Petræa; ſo called from one of the ſons of Abraham by Keturah.—Another *Midian*, near the Arnon and Æoplis, in ruins in Jerome's time. With the daughters of theſe Midianites the Iſraelites committed fornication, and were guilty of idolatry. A branch of the Midianites dwelt on the Arabian gulph, and were called *Kenites;* ſome of whom turned proſelytes, and dwelt with the Iſraelites in the land of Canaan.

MID-LOTHIAN. See Lothian.

MIDSHIP-frame, a name given to that timber, or combination of pieces formed into one timber, which determines the extreme breadth of the ſhip, as well as the figure and dimenſion of all the inferior timbers.

In the article *Ship-Building*, the reader will find a full explanation of what is meant by a frame of timbers. He will alſo perceive the outlines of all the principal frames, with their gradual dimenſions, from the midſhip-frame delineated in the plane of projection annexed to that article. As the parts of which the ſeveral frames are compoſed have the ſame relation to each other throughout the veſſel, and as all the correſponding pieces, without and within thoſe frames, are alſo nearly alike, and fixed in the ſame manner, it will be here ſufficient for our purpoſe to repreſent the principal or midſhip-frame, together with its correſponding parts, which are as follow:—A, the keel, with *a* the ſalſe keel beneath it. B, the chocks fixed upon the kelſon, to retain the oppoſite pieces of the *riders* firmly together. C, one of the beams of the orlop. D, one of the lower deck beams; with *d* the beams of the upper deck. E, the hanging-knees, by which the beams are attached to the timbers. F, the ſtandards, which are fixed above the decks to which they belong. G, the clamps, which ſuſtain the extremities of the beams. H, the gun-ports of the lower-deck; with *h* the ports of the upper-deck. I, K, L, different pieces of *thick-ſtuff*, placed oppoſite to the ſeveral ſcarfs or joinings, in the frame of timbers. M, the planks of the deck. N, the water-ways. O, the planks of the ceiling, between the ſeveral ranges of thick-ſtuff. P, the ſpirketing. Q, the main-wale, to fortify the ſhip's ſide oppoſite to the lower deck. R, the channel-wale, oppoſite to the upper deck. S, the waiſt-rail. T, the ſtring, with the moulding under the gun-wale. U, the floor-timbers, which are laid acroſs the keel and bolted to it. V, the ſeveral futtocks; and W the top-timbers, which are all united into one frame. X, the kelſon.

Plate CCCXIII.

MIDSHIPMAN, a ſort of naval cadet, appointed by the captain of a ſhip of war, to ſecond the orders of the ſuperior officers, and aſſiſt in the neceſſary buſineſs of the veſſel, either aboard or aſhore.

The number of midſhipmen, like that of ſeveral other officers, is always in proportion to the ſize of the ſhip to which they belong. Thus a firſt-rate man of war has 24, and the inferior rates a ſuitable number in proportion. No perſon can be appointed lieutenant without having previouſly ſerved two years in the royal navy in this capacity, or in that of *mate*, beſides having been at leaſt four years in actual ſervice at ſea, either in merchant-ſhips or in the royal navy.

Midſhipman is accordingly the ſtation in which a young volunteer is trained in the ſeveral exerciſes neceſſary to attain a ſufficient knowledge of the machinery, movements, and military operations of a ſhip, to qualify him for a ſea-officer.

On his firſt entrance in a ſhip of war, every midſhipman has ſeveral diſadvantageous circumſtances to encounter. Theſe are partly occaſioned by the nature of the ſea-ſervice; and partly by the miſtaken prejudices of people in general reſpecting naval diſcipline, and the genius of ſailors and their officers. No character, in their opinion, is more excellent than that of the common ſailor, whom they generally ſuppoſe to be treated with great ſeverity by his officers, drawing a compariſon between them not very advantageous to the latter. The midſhipman uſually comes aboard tinctured with theſe prejudices, eſpecially if his education has been amongſt the higher rank of people; and if the officers happen to anſwer his opinion, he conceives an early diſguſt to the ſervice, from a very partial and incompetent view of its operations. Blinded by theſe prepoſſeſſions, he is thrown off his guard, and very ſoon ſurpriſed to find, amongſt thoſe honeſt ſailors, a crew of abandoned miſcreants, ripe for any miſchief or villany. Perhaps, after a little obſervation, many of them will appear to him equally deſtitute of gratitude, ſhame, or juſtice, and only deterred from the commiſſion of any crimes by the terror of ſevere puniſhment. He will diſcover, that the pernicious example of a few of the vileſt in a ſhip of war are too often apt to poiſon the principles of the greateſt number, eſpecially if the reins of diſcipline are too much relaxed, ſo as to foſter that idleneſs and diſſipation, which engender ſloth, diſeaſes, and an utter profligacy of manners. If the midſhipman on many occaſions is obliged to mix with theſe, particularly in the exerciſes of extending or reducing the ſails in the tops, he ought reſolutely to guard againſt this contagion, with which the morals of his inferiors may be infected. He ſhould, however, avail himſelf of their knowledge, and acquire their expertneſs in managing and fixing the ſails and rigging, and never ſuffer himſelf to be excelled by an inferior. He will probably find a virtue in almoſt every private ſailor, which is entirely unknown to many of his officers: that virtue is emulation, which is not indeed mentioned amongſt their qualities by the gentlemen of *terra firma*, by whom their characters are often copiouſly deſcribed with very little judgment. There is hardly a common tar who is not envious of ſuperior ſkill in his fellows, and jealous on all occaſions to be outdone in what he conſiders as a branch of his duty: nor is he more afraid of the dreadful conſequences of whiſtling in a ſtorm, than of being ſtigmatiſed with the opprobrious epithet of *lubber*. Fortified againſt this ſcandal, by a thorough knowledge of his buſineſs, the ſailor will ſometimes ſneer in private at the execution of orders which to him appear aukward, improper, or unlike a ſeaman. Nay, he will perhaps be malicious enough to ſuppreſs his own judgment, and, by a punctual obedience to command, execute whatever is to be performed in a manner which he knows to be improper, in order to expoſe the perſon commanding to diſgrace and ridicule. Little ſkilled in the method of the ſchools, he conſiders the officer

Midshipman. officer who cons his leſſon by rote as very ill qualified for his ſtation, becauſe particular ſituations might render it neceſſary for the ſaid officer to aſſiſt at putting his own orders in practice. An ignorance in this practical knowledge will therefore neceſſarily be thought an unpardonable deficiency by thoſe who are to follow his directions. Hence the midſhipman who aſſociates with theſe ſailors in the tops, till he has acquired a competent ſkill in the ſervice of extending or reducing the ſails, &c. will be often entertained with a number of ſcurrilous jeſts, at the expence of his ſuperiors. Hence alſo he will learn, that a timely application to thoſe exerciſes can only prevent him from appearing in the ſame deſpicable point of view, which muſt certainly be a cruel mortification to a man of the ſmalleſt ſenſibility.

If the midſhipman is not employed in theſe ſervices, which are undoubtedly neceſſary to give him a clearer idea of the different parts of his occupation, a variety of other objects preſent themſelves to his attention. Without preſuming to dictate the ſtudies which are moſt eſſential to his improvement, we could wiſh to recommend ſuch as are moſt ſuitable to the bent of his inclination. Aſtronomy, geometry, and mechanics, which are in the firſt rank of ſcience, are the materials which form the ſkilful pilot and the ſuperior mariner. The theory of navigation is entirely derived from the two former, and all the machinery and movements of a ſhip are founded upon the latter. The action of the wind upon the ſails, and the reſiſtance of the water at the ſtem, naturally dictate an inquiry into the property of ſolids and fluids; and the ſtate of the ſhip, floating on the water, ſeems to direct his application to the ſtudy of hydroſtatics, and the effects of gravity. A proficiency in theſe branches of ſcience will equally enlarge his views, with regard to the operations of naval war, as directed by the efforts of powder and the knowledge of projectiles. The moſt effectual method to excite his application to thoſe ſtudies, is, perhaps, by looking round the navy, to obſerve the characters of individuals. By this inquiry he will probably diſcover, that the officer who is eminently ſkilled in the ſciences, will command univerſal reſpect and approbation; and that whoever is ſatisfied with the deſpicable ambition of ſhining the hero of an aſſembly, will be the object of univerſal contempt. The attention of the former will be engaged in thoſe ſtudies which are highly uſeful to himſelf in particular, and to the ſervice in general. The employment of the latter is to acquire thoſe ſuperficial accompliſhments that unbend the mind from every uſeful ſcience, emaſculate the judgment, and render the hero infinitely more dexterous at falling into his ſtation in the dance than in the line of battle.

Unleſs the midſhipman has an unconquerable averſion to the acquiſition of thoſe qualifications which are ſo eſſential to his improvement, he will very rarely want opportunities of making a progreſs therein. Every ſtep he advances in thoſe meritorious employments will facilitate his acceſſion to the next in order. If the dunces, who are his officers or meſs-mates, are rattling the dice, roaring bad verſes, hiſſing on the flute, or ſcraping diſcord from the fiddle, his attention to more noble ſtudies will ſweeten the hours of relaxation. He ſhould recollect, that no example from fools ought to influence his conduct, or ſeduce him from that laudable ambition which his honour and advantage are equally concerned to purſue.

MIDWIFE, one whoſe profeſſion is to deliver women in labour. See MIDWIFERY.

MIDWIFERY,

THE art of aſſiſting women in the birth of children. It is ſuppoſed to comprehend alſo the management of women both before and after delivery, as well as the treatment of the child in its moſt early ſtate.

History of Midwifery. The art of midwifery is certainly almoſt coeval with mankind. The firſt *midwife* of whom mention is made under that name, aſſiſted at the ſecond labour of Rachel, the wife of Jacob. Another midwife is ſpoken of in Geneſis, at the lying-in of Thamar, who was delivered of twins. But the moſt honourable mention of midwives is that in Exodus, when Pharaoh king of Egypt, who had a mind to deſtroy the Hebrews, commanded the midwives to kill all the male children of the Hebrew women; which command they diſobeyed, and thereby obtained a recompence from God.

From all the paſſages in Scripture where midwives are mentioned, it is plain, that women were the only practitioners of this art among the Hebrews. Among the Greeks alſo women aſſiſted at labours. Phanarete, the mother of Socrates, was a midwife. Plato ſpeaks at large of midwives, explains their functions, regulates their duties, and remarks that they had at Athens the right of propoſing or making marriages. Hippocrates makes mention of midwives, as well as Ariſtotle, Galen, and Aëtius. This laſt even frequently quotes a woman called *Aſpaſia*, who was probably a midwife. They were called among the Greeks Μαιαι or Ιατρομαιαι; that is to ſay, *mamma*, or *grand-mamma*.

We are ſtill better acquainted with the cuſtoms of the Romans, and know that they employed women only. This may be deduced from the comedies of Plautus and Terence alone. We there ſee that they are women only who are called to aſſiſt perſons in labour. Beſides, Pliny, in his Natural Hiſtory, frequently ſpeaks of midwives and their duties; and names two, *Sotira* and *Salpe*, who had apparently the greateſt reputation. Women were alſo employed after the fall of the empire; and it is certain, that, till lately, all civilized nations have employed women only as midwives. This appears even from their names in many different languages, which are all feminine. There were, however, eſpecially in great cities, ſurgeons who applied themſelves to the art of midwifery, and made it their peculiar ſtudy. They were ſent for in in difficult cafes, where the midwives found their incapacity; and then the furgeon endeavoured to deliver the woman by having recourfe to inftruments ufeful in thofe cafes, as by crotchets, crows-bills, &c.; but as thefe cafes happened but feldom, women remained in poffeffion of this bufinefs. It is certain, according to Aftruc, that Maria Therefia wife of Louis XIV. employed women only in her labours; and the example of the queen determined the conduct of the princeffes and court-ladies, and likewife of the other ladies of the city. The fame author tells us, that he has been affured, that the epoch of the employment of men-midwives goes no farther back than the firft lying-in of Madam de la Valiere in 1663. As fhe defired it might be kept a profound fecret, fhe fent for Julian Clement a furgeon of reputation. He was conducted with the greateft fecrecy into an houfe where the lady was, with her face covered with a hood; and where it is faid the king was concealed in the curtains of the bed. The fame furgeon was employed in the fubfequent labours of the fame lady; and as he was very fuccefsful with her, men-midwives afterwards came into repute, and the princeffes made ufe of furgeons on fimilar occafions; and as foon as this became fafhionable, the name of *acoucheur* was invented to fignify this clafs of furgeons. Foreign countries foon adopted the cuftom, and likewife the name of *acoucheurs*, though they had no fuch term in their own language; but in Britain they have more generally been called *men-midwives*.

In oppofition to this account, which is taken from Aftruc, that author tells us, that he is aware of an objection from Hyginus, who afferts, that the ancients had no midwives; which made the women, through modefty, rather choofe to run the rifk of death than to make ufe of men on this occafion. For the Athenians, he adds, had forbid women and flaves to ftudy phyfic, that is to fay, the art of midwifery. A young woman, named *Agnodice*, defirous of learning this art, cut off her hair, dreffed herfelf in the habit of a man, and became a fcholar to one Hierophilus. She afterwards followed this bufinefs. The women at firft refufed affiftance from her, thinking fhe was a man; but accepted thereof when fhe had convinced them that fhe was a woman.

To this account our author replies, that the authority of Hyginus is by no means to be depended upon. His book is full of folecifms and barbarifms; and therefore cannot be attributed to any writer who lived before the fall of the empire; but muft have been the work of an author who lived when the Latin tongue was corrupted; that is, about the feventh or eighth century. The contradictions met with in this book alfo give room to fufpect that it is not the work of one hand, but of feveral. The authority of fuch a work, therefore, is by no means fufficient to deftroy the teftimonies of thofe writers who affirm, that among the Greeks the care of lying-in women was committed entirely to others of their own fex.

The art of midwifery feems not to have been fo foon improved as that of phyfic. Hippocrates, though an excellent phyfician, feems to have been a very bad midwife. He was acquainted with no other kind of natural labour than that in which the head prefents; and condemns footling labour as fatal both to mother and child: he would have the children in fuch cafes turned, fo that the head may prefent. If, fays he, the arm, or leg, or both, of a living child prefent, they muft, as foon as difcovered, be returned into the womb, and the child brought into the paffage with its head downwards. For this purpofe he advifes to roll the woman on the bed, to fhake her, and make her jump: he propofes the fame expedients to procure the child's delivery; and if they do not fucceed, he advifes to extract it with crotchets, and, whatever happens, to difmember it.

From the time of Hippocrates to that of Celfus, who lived in the reign of the emperor Tiberius, we have no accounts of any improvements in midwifery; but this author gives two very ufeful directions. 1. In dilating the womb: "We muft (fays he) introduce the fore-finger, well moiftened with hog's lard, into the mouth of the womb when it begins to open, and in like manner afterwards a fecond, and fo on until all the fingers are introduced, which are then to be ufed by feparating them, as a kind of dilater, to diftend the orifice, and facilitate the introduction of the hand which is to act in the womb. 2. Children may be delivered by the feet eafily and fafely, without crotchets, by taking hold of their legs. For this purpofe we muft take care to turn children, which are otherwife placed in the womb, with their head or feet downwards." It is true, Celfus fpeaks of a dead child only; but it was eafy to conclude from thence, that the fame practice might be ufed with fuccefs to deliver a living child. Neverthelefs, this was not done; and, notwithftanding the authority of Celfus, the former prejudice continued for a long time. Though Pliny, who lived under the emperors Vefpafian and Titus, was not a phyfician himfelf, yet by condemning footling labour he attefts the opinion of the phyficians of his time. He afferts, as a known fact, that footling labour was a preternatural kind of labour: he adds, that children which came into the world in this manner were called *Agrippa*, that is to fay, born with a great deal of difficulty.

But however common this opinion was, it was never univerfally received; and feveral phyficians of character rofe up, who, without fuffering themfelves to be dazzled with the common prejudice, or feduced by the authority of Hippocrates or Galen, recommended and approved of footling delivery. The queftion then was a long time undecided; and even in 1657, Riverius, a phyfician of reputation, condemned footling labour. Mauriceau alfo remarks, in the firft edition of his book on the diforders of pregnant women, printed in 1664, that many authors were ftill of opinion, that when the child prefented with its feet, it fhould be turned to make it come with its head foremoft; but after having obferved that it is difficult, if not impoffible, to execute this, he concludes, "it is much better to extract the child by its feet when they prefent, than to run the hazard of doing worfe by turning it." All practitioners, however, are now of the fame opinion; and the knowledge of midwifery has been fo much increafed within this century, that it feems to have nearly attained its ultimate perfection, and its operations reduced almoft to a geometrical certainty: And this, fays Aftruc, is not furprifing; for, after all, the art of midwifery is reduced to the following mechanical

chanical problem, "An extensible cavity of a certain capacity being given, to pass a flexible body of a given length and thickness through an opening dilatable to a certain degree." This might be resolved geometrically, if the different degrees of elasticity of the womb, and strength and weakness of the child, the greater or lesser disposition of the blood to inflammation, and the geater or lesser degree of irritability of the nerves, did not occasion that uncertainty which physical facts constantly produce in all physico-mathematical questions.

The study of midwifery in Britain as a science is not of very ancient date. The first book published on the subject appeared in the year 1540, and was intitled *The Byrthe of Mankind*, otherwise named, *The Woman's Booke*, by Thomas Raynold, physition. It underwent a second edition by Thomas Ray, a printer whose name is not much known. It was adorned with prints, and went through several editions, and appears to have been held in high estimation. In 1653, the celebrated William Harvey published his treatise on generation; and afterwards engaging in the practice of midwifery, published his *Exercitatio de partu*. Some notice is also taken by Sydenham of the diseases incident to child-bed women, and of those of young children. About this time several other tracts on subjects relating to midwifery appeared, by Wharton, Charleton, Mayow, &c.; but till about the year 1634, Dr Denman considers the treatise of Raynold already mentioned as being the standard. The appearance of the works of Ambrose Paré, which were now first published, depressed the reputation of Raynold's book; and Dr Chamberlen, a celebrated physician, likewise applied himself about the same time to midwifery. He introduced an instrument into the art called a *forceps*, but which Dr Denman supposes to have been a *vectis*.—He had three sons who likewise practised midwifery, and, as well as himself, obtained considerable character; and one of the young men went over to Paris with a view to sell the secret, or advance his fortune by a practice which he had found so successful in England. In this, however, he was disappointed; the first case in which he was engaged proved unsuccessful, and he suffered much reproach in consequence. Returning to England, therefore, in 1672, he published a translation of Mauriceau's midwifery, which continued in great estimation for many years.

Dr Willoughby, who wrote a treatise on midwifery, quoted in manuscript by Dr Denman, complains of the practice of midwives about this time. He says, that the books upon the subject all copied one another, recommending methods which could not but be prejudicial to the woman; and that particularly they did not attend to the efforts of nature, but endeavoured to force the birth before the proper time. He was the grandson of Sir Francis Willoughby, so much celebrated in the time of queen Elizabeth; and Dr Denman is of opinion, that the fame and fortune acquired by Dr Chamberlen, induced so many gentlemen as now practised midwifery to undertake the study of it, and to make use of instruments as he did. Among these was Dr Bamber; but others attempted to raise their reputation by a quite contrary practice. In 1723, Dr Maubray published a book on midwifery, intitled, *The Female Physician, or the Whole Art of New Improved Midwifery*, in which he violently declaims against the use of instruments; and next year he published an appendix, under the title of *Midwifery brought to perfection*, in which he sets forth in a pompous manner the improvements he had made. This, however, was no more than a syllabus of his lectures, he having been the first public teacher of midwifery in Britain.

Dionis's midwifery made its appearance in 1719, and Deventer's in 1729. The latter, in Dr Denman's opinion, was more esteemed than it deserved, as he generally condemns the use of instruments; notwithstanding which, he thinks it a considerable acquisition to the science in this country.

In 1727 appeared Dr Simson's work, intitled, *The System of the Womb*; "a work (says Dr Denman) of sufficient ingenuity, but not of much use in practice, even if his theory had been true." Chapman's *Treatise on the Improvement of Midwifery* appeared in 1733. He was the second public teacher of midwifery in London, and was the first who described the *forceps*; the description appearing in the third volume of the Edinburgh Medical Essays. His work contains many useful observations. Next year Dr Hody published a collection of cases in midwifery, written by Mr William Giffard. They are 275 in number, occurred in his own practice, and appear to be written with great fidelity. He also gave a plate of the forceps; and, in Dr Denman's opinion, was among the first who asserted that the placenta might be attached over the *os uteri*. In 1736, Thomas Dawke published a book, intitled, *The Midwife rightly Instructed*; and, the following year, *The Midwife's Companion*, by Henry Bracken: but these, as well as some others which made their appearance about the same time, are of no importance.

About the same time also, Sir Richard Manningham quitted the profession of pharmacy, and applied to the study and practice of midwifery. He had received the honour of knighthood in 1730; and in 1739 he established a small hospital or ward for lying-in women, which was the first thing of the kind in the British dominions. Here also he gave lectures; and at the same time qualified his students for practice. He became very eminent in his profession, which he exercised with great humanity, and was accounted a man of great learning. He published a work, intitled *Compendium Artis Obstetricæ*; and another, called *Aphorismata Medica*, relating also chiefly to the art of midwifery. In 1741, Sir Fielding Oulde of Dublin published *A Treatise of Midwifery*; the most important parts of which are some observations on the continuance of the thickness of the uterus during pregnancy, with his description of the manner in which the head of the child passes through the pelvis at the time of the birth; the truth of which observations have since been universally acknowledged.

From this time the English, according to Dr Denman ‡, might be said "to have been in full possession of the subject; all the books written in the neighbouring countries being translated, public lectures given, and an hospital established for the further improvement of the art: and as all the books printed since that time may readily be procured, every gentleman has an opportunity of forming his own opinion of their respective merits. But the college of physicians (adds he), having

‡ *Introduction to the Practice of Midwifery*, preface.

having been pleased, in the year 1783, to form a rank in which those who dedicate themselves to the study of midwifery should be placed, I trust that future accounts will be more correct; and that this measure adopted by the college will promote the public benefit, by confining the industry and abilities of one class of men to this branch of the profession."

In Scotland, though there has for a long time been professors of midwifery, yet the surgeons likewise practise that art as well as their own. Several approved treatises on the subject have appeared in this country; particularly a system by the late Dr Smellie, which has been long held in the highest estimation in both kingdoms; and, within these few years, several excellent performances by Dr Alexander Hamilton of the university of Edinburgh: And, indeed, we may venture to affirm, that both theory and practice of midwifery are as well understood in this kingdom as in any part of the world.

PART I. THEORY OF MIDWIFERY.

Description of the Pelvis in general.

THE subject of this Part comprehends, in a particular manner, the anatomical structure of the pelvis, and other parts concerned in the formation of the child, the theories of conception, generation, &c. of the nutrition, growth of the fœtus, and of the powers by which it is expelled. Of all these some account has been given under other articles; but as the particular description of the pelvis belongs peculiarly to this subject, we shall here give an account of its various conformations, as they in a great measure affect women at the time of child-bearing, and very particularly contribute to the ease or difficulty of the labour.

CHAP. I. *Description of the Pelvis in general.*

Dr DENMAN observes, that the term *pelvis* has been applied indiscriminately to the inferior cavity of the abdomen, and to the bones which form that cavity; but he thinks it most proper to confine it to the bones, and to distinguish the hollow by the name of the cavity of the pelvis. In the state of infancy, the pelvis is composed of five or six bones, most of which in the fœtus are soft and flexible; some of them being, in a manner, quite cartilaginous; while the edges of others are found covered with a substance of the same kind. This construction is thought by some to facilitate delivery, as the pelvis of the fœtus can thus change its figure like the cranium; but M. Baudelocque thinks this an erroneous opinion, "consonant neither to reason nor experience."

In the adult the pelvis consists only of four bones, viz. the *sacrum*, the *os coccygis*, and the two *ossa innominata*. These being already described under the article ANATOMY, we shall here content ourselves with observing, that an anchylosis is not unfrequently formed between the os sacrum and the ossa innominata; and sometimes an imperfect joint in consequence of their separation; whence the part is very much weakened, and the person ever afterwards walks with difficulty.

The os coccygis in infancy is cartilaginous; but in the adult it is composed of three, or more frequently of four bones, connected by intermediate cartilages, the uppermost of which is somewhat broader than the lower part of the os sacrum. In some subjects these bones coalesce, and form a single one: in others an anchylosis is formed between the sacrum and os coccygis; in consequence of which the latter is shortened and turned inwards, so as to obstruct the head of the child in its passage through the pelvis. But the impediment thereby occasioned at the time of labour may be overcome by the force with which the head of the child is propelled, and the os coccygis again separated from the sacrum with a noise loud enough to be distinctly heard. In general, however, some regressive motion is preserved between the bones of which the os coccygis is composed; and that which is produced between the *sacrum* and *os coccygis*, when the latter is pressed by the head of a child passing through the pelvis, occasions a considerable temporary enlargement of the inferior aperture of the pelvis. Any lateral motion is prevented by the insertion of the *coccygæi* muscles, part of the *levatores ani*, and some portions of the sacro-sciatic ligaments into the sides of the *os coccygis*.

The *os innominatum*, in a woman of the ordinary size, is about six inches broad from the anterior to the posterior superior spine. The height is nearly six inches and an half from the anterior spine to the bottom of the tuberosity of the ischium, and seven and an half if taken from the middle of the crista of the ilium; and hence we may in some measure be enabled to determine the depth of the cavity of the pelvis laterally from the superior to the inferior strait.

"The ossa pubis (says M. Baudelocque†) are joined together by means of a substance which has always been described by the name of cartilage, though it differs as much from that as from a ligament. According to some anatomists, each *os pubis* is covered by its own cartilage. Their junction not a true synchondrosis; but a close articulation, which admits only of insensible motions. By carefully examining this symphysis, we observe that each os pubis is really covered by a cartilage at its anterior extremity; that this cartilage is thicker before than behind, and in its superior and inferior parts than in the middle of its length; that these bones, thus covered, are bound together by means of a substance which seems ligamentous, and whose fibres, which are mostly transverse, go from one to the other; that these fibres are so disposed, that the deepest are the shortest, and the most superficial the longest; that they leave between one another a kind of meshes filled with reddish corpuscles, very like those which are seen about the moveable articulations, and which are commonly thought to be synovial glands. We observe farther, that this fibrous and ligamentous substance does not occupy the whole thickness of the symphysis, and does not bind the bones together through the whole extent of the surfaces presented by their anterior extremities; but that there exists a true articulation of the species known by the name of *arthrodia*. If we open this symphysis towards the inside of the pelvis, after a cellular tissue very thin and loose, which we meet with first, we discover a capsular membrane, whose most apparent fibres are transversal; afterwards

† *System of Midwifery*, translated by Mr Heath.

Description of the Pelvis in general.

terwards two cartilaginous facettes, smooth, polished, and moist, from six to eight lines long and two broad, of a figure a little semilunar, lightly convex on one bone and concave on the other. These facettes comprehend nearly the middle third of the length of the symphysis and the posterior third of its thickness.—This symphysis then presents in one third of its extent, or thereabouts, a true articulation; and in the rest a *syneurosis* and *synchondrosis* at the same time.

"This compound and articular substance, being detached from the bones, forms a kind of wedge, whose base constitutes the anterior part of the symphysis, and its edge the posterior; so that these bones seem to touch towards the inside of the pelvis, and appear separated to the distance of several lines without: The base of this kind of wedge is generally from four to six lines broad towards the middle of the length of the symphysis, and from eight to ten in the inferior and superior parts, while the edge at most does not exceed one line. Its thickness, taken according to that of the bones, is greater above than below; where this substance, become thinner, forms what is called the triangular ligament.

"This first means of union was not sufficient to give these bones the firmness necessary for the free exercise of the functions to which the pelvis is destined. It is covered and fortified in all parts, but especially before, by bundles of ligamentous and aponeurotic fibres. Independently of the thick and very strong ligamentous structure which forms the fore-part of the symphysis, we observe bundles of tendinous fibres which decussate each other a thousand ways, some of which arise from the interior *graciles* and the external *obturators*, and others from the external portions of the inguinal rings. The triangular expansion which terminates the symphysis inferiorly, and which forms the top of the arch of the pubes, seems to have other uses than that of binding the bones together.

"The manner in which the *os sacrum* is connected with the *ossa innominata*, differs considerably from that in which the *ossa pubis* are joined. Here each articular facette is covered by a true cartilaginous layer, and there are inequalities on each side, which mutually receive one another, while nothing of that kind is observed in the junction of the pubes; neither are there in any part of these articular facettes any of the transverse fibres which go from one bone to the other in the *ossa pubis*: these articulations, therefore, derive all their strength from the great numbers of ligaments which surround them. Most of these are very short, and do not extend beyond the edges of the articular facettes: but there are others longer to be seen above, below, and behind these symphyses.

"The *os sacrum* is not only articulated with the ilia, but with the spine and coccyx. It is joined in three places to the spine: 1. By an oblong and cartilaginous impression in the middle of the basis, which unites it to a similar impression in the body of the last *lumbar vertebra*, by means of an elastic substance. 2. By two little articular masses fixed in the posterior edge of that first impression, and which answer to similar substances in the vertebra above-mentioned.

"The elastic substance which unites the middle of the base of the sacrum to the spine, is entirely similar in its nature to that seen between the bodies of all the vertebræ. Being very thick before and thin behind, the angle resulting from the disposition of the articular facettes of these two parts is rendered more obtuse. This *sacro-vertebral* junction is surrounded by an infinity of ligaments, some without and others concealed within the spinal canal. All motion is not prohibited by this kind of junction; but, as it only depends on the compression of the intermediate substance, it can be but very small. The motion between the body of the last lumbar vertebra and the base of the sacrum, is never extensive enough to make any alteration in the degree of acuteness of the angle which results from their junction; but the convexity of the lumbar column may be augmented or diminished by means of a compound motion, formed of those which take place between each of the lower lumbar vertebræ and between the lower ones of the back. This augmentation or diminution of the convexity, in proportion as the trunk is bent backward or forward, or by raising or lowering the breech when the woman lies on her back, deserves particular attention in the practice of midwifery; for thus we may make a favourable change in the direction of the axis of the pelvis, relatively to that of the trunk, to that of the uterus, and in the direction of the expulsive forces of the latter, which may be rendered more or less efficacious according to circumstances, by making the woman preserve a proper attitude

"The junction of the coccyx with the sacrum permits the former to move, and yield to the different degrees of pressure it undergoes in different circumstances. The mobility is very great in youth; but diminishes insensibly as the patient grows older, and at last is totally lost. If entirely lost, or considerably diminished, before a woman is past child-bearing, it produces sometimes, though very rarely, an obstacle to delivery. The connections of the pelvis with the inferior extremities are not of much importance in midwifery. The natural course of labour cannot be disturbed by any fault in their configuration when the pelvis itself is well formed; but in general they are consequences of a deformity of it. They are *enarthroses*, which allow of motion in every direction."

The pelvis is divided into two parts, called the *upper* and *lower*, by a ridge sometimes elliptical, and sometimes of other shapes. The breadth of the upper part from the anterior superior spine of one ilium to another, is usually eight or nine inches, and its depth from three to four. At the back part of it is the projection of the lumbar vertebræ, and at the sides the *iliac fossæ*. The lower part forms a kind of canal, whose entrance and outlet are somewhat narrower than the middle; whence it has been distinguished into the *superior* strait, the *inferior* strait, and an excavation.—The *superior* strait is a kind of circle forming the entrance of the canal; its form, however, is various, as is also its obliquity from behind forwards. M. Levret has fixed this last at an angle of from 35 to 40 degrees.

The smallest diameter of this strait is generally about four inches, extending from the middle of the projection of the sacrum to the superior and internal part of the symphysis of the pubes. The other diameter

Description of the Pelvis in general.

diameter is usually about an inch longer, extending from one side of the strait to the other. The oblique diameters are a medium betwixt the two former, extending diagonally from each acetabulum to the sacro-iliac junction of the opposite side. The pelvis is cut at right angles by the two former, and into acute ones by the latter; but the diameters, considered in relation to delivery, are somewhat different from those just mentioned, some changes in them being occasioned by the soft parts within the pelvis.

The inferior strait is in general smaller, and of a more irregular figure than the other, being not formed like it entirely of bones. The edge, rendered unequal by three deep and large notches, is completed behind and at the sides by the sacro-ischiatic ligaments, forming a kind of circular notch before, called the *arch of the pubes*. The diameters of it are commonly about four inches in length; and though the transverse, which extends from one *ischium* to the other, be often a little longer than that which extends from the fore to the back part, it must be reckoned the smallest with regard to delivery; because the latter augments in proportion as the point of the coccyx recedes from the pubes. We must also remember, that the great diameter of the inferior strait is parallel to the smallest of the superior, and that it crosses the longest of that strait at an angle more or less acute; and by carefully attending to this, we may, in many cases, with the finger alone, when properly directed, remove obstacles which could not have been overcome even by means of instruments, without exposing the child to great inconveniences. It is likewise favourable to delivery that the middle part of the pelvis is a little larger from before backwards than the straits; which disposition proceeds from the curved figure of the *os sacrum*.—On one side this curve diminishes the numerous and long-continued frictions which the child's head would necessarily undergo if the pelvis were equally broad in all its parts; and on the other side it is equally useful in preventing the effects of a long and forcible pressure on the sacral nerves, which a flat form of the sacrum would have rendered unavoidable during the whole time of the passage of the head. The cavity of the pelvis is commonly from four to five inches deep behind, three and an half at the sides, and one and an half at most before.

The arch of the pubes, which at the top is only from one inch and a quarter to one and two-thirds in breadth, augments gradually as it descends; so that at the bottom its sides are three inches and an half, or even four inches, separated from one another; that is, if we take the line which is looked upon as the transverse diameter of the inferior strait for its base; the height being about two inches.

The axis of the superior strait of the pelvis cannot well be determined; but that of the inferior one, with regard to delivery, must be considered as passing through the centre of the opening of the vagina dilated by the child's head. Its direction is then so much inclined from behind forward, that its superior extremity traverses the lower part of the first falſe vertebra of the sacrum, and crosses that of the other strait at a very obtuse angle.

3

Hitherto we have treated only of that form of the pelvis which is most favourable for delivery: but the proportions and forms of it are various; and as it differs from those above described, the delivery is attended with more or less difficulty.

The defects of the pelvis, with regard to facility of delivery, consists in its being either too large or too small. At first sight it might be imagined, that a large pelvis would make the delivery more easy, as the head of the child will thus be exposed to fewer frictions, be more easily expelled, and the labour be less painful. But women who have a very large pelvis, are subject to those inconveniences which arise from an obliquity of the uterus, or even to a descent of it altogether; especially in the time of labour, when that viscus, being already charged with the weight of the child, is entirely subjected to the expulsive power of the abdominal muscles. In women who have had several children, the uterus is but weakly retained by its ligaments; and in subsequent pregnancies it descends still lower, until at last it rests on the margin of the pelvis. This, however, does not take place before the conclusion of the first four or five months: before that time its weight lies principally on the extremity of the rectum; and by this, as well as by its bulk, the discharge of the urine and fæces is impeded, and accidents sometimes ensue from the compression of the veins which pass through the pelvis. These symptoms sometimes vanish about the middle of pregnancy, but re-appear towards the latter end; because the head of the child is early engaged in the pelvis, and acts on the same parts that the whole uterus did before. Besides all these accidents, there are others which may take place at the time of delivery; so that, upon the whole, it cannot be reckoned any real advantage for a woman to have a large pelvis.

The accidents, however, which arise from too great a size of the pelvis, are much more easily remedied, and in themselves less dangerous, than such as arise from its narrowness. This defect may be considered as either relative or absolute. The former arises from an excess of size in the head of the child; the latter from a bad conformation of the pelvis itself. The absolute narrowness of the pelvis rarely affects all parts of it at once: it is generally found only in one of the straits; in which case, the other is usually of the natural size, nay, sometimes even larger than natural. The fault is more frequently in the superior than the inferior strait; and it is remarkable, that it most commonly affects the strait in its small diameter; very rarely in its transversal; sometimes affecting only one side. In the inferior strait it is generally caused by the approximation of the tuberosities of the ischia.

"It is easy (says M. Baudelocque) to determine why the superior strait is more frequently deformed than the inferior; and why it is almost always between the pubes and sacrum that it is defective respecting delivery. If we consider the direction of the forces which act on the pelvis of rickety children, in whom the bones are at the same time softer and more loosely connected than in the natural state, we shall see, that the greater part of those forces tend to carry the base of the sacrum forward and the *ossa pubis*

Description of the Pelvis in general.

pubis backwards. Whether the child be ftanding or fitting, if we attend to the direction of the fpinal column, we fhall fee that the weight of the body muft infenfibly pufh the bafe of the facrum towards the pubes; and that it acts in the fame manner on the inner parts of the acetabula, which ferve as a fulcrum to the inferior extremities when the child is ftanding or walking. The *offa pubis*, particularly in thefe latter cafes, muft be pufhed towards the facrum; in fuch a manner, however, that their pofterior extremities often approach a little nearer to the projection of the bafe of that bone than their anterior extremities, or the fymphyfis. If the fuperior ftrait does not conftantly prefent the fame figure in deformed *pelvifes*; if it is fometimes larger on one fide than the other; if one of the acetabula is nearer to the facrum, while the other approaches lefs; if the fymphyfis of the pubes is removed, in many cafes from a line which would divide the body into two equal parts—it is becaufe the rickets have not equally affected all the bones of the pelvis, nor equally hurt all their junctions; and becaufe the attitude which the child takes in walking or fitting may change a little the direction of the compreffing powers juft mentioned. The weight of the body may alfo equally hurt the form of the inferior ftrait, but varioufly, according to the moft ufual attitude of the child and the direction taken by the fpinal column. For example: If it fits much, the facrum will be more curved, and the ftrait more contracted from before backwards: in this attitude, if it inclines habitually to one fide, one of the ifchiatic tuberofities will be thrown inwards, the *os ilium* will be more elevated, &c. The action of the mufcles which are attached to the pelvis, the preffure of cloaths, and that which the arms of the nurfe exert on this part, contribute alfo fomething to the deformities in queftion, but much lefs than the weight of the trunk: whence we fee, of what importance it is to keep rickety children in bed, and leave them at liberty; inftead of obliging them to walk, to fit up, or have them conftantly in the arms, as is done almoft every where."

The dimenfions of the pelvis itfelf vary no lefs than the contour of the ftraits. If the diameter of fome, taken from the pubes to the middle of the projection of the *os facrum*, be only a few lines; in others the defect is feveral inches, fo that fcarcely a fingle inch is left between thefe bones. Thefe extremes, however, are not frequently met with; and the latter of them is never fo great in the inferior as in the fuperior ftrait. On comparing the dimenfions of a well-formed pelvis with thofe of a child's head, we fhall find that the former might admit of being fome inches lefs in circumference, and yet be large enough for an eafy delivery. The circumference of a common head is ufually no more than ten inches and a quarter, or ten and an half. The firft degree of narrownefs in any pelvis therefore muft be, when each diameter is fomething lefs than three inches and an half. M. Baudelocque fays, that he has feen pelvifes in which the diftance of the pubes from the facrum fuperiorly was no more than fix or eight lines; and he had in his poffeffion two others, in one of which the diftance from the back of the right acetabulum to the projection of the facrum was only three or four lines, and the other had but 14 lines between that projection and the fymphyfis of the pubes.

The narrownefs of the pelvis is to be accounted one of the principal caufes of difficult delivery.—When an opening of only three inches and a quarter is left, the labour muft be more difficult than when it is three inches and an half, as the number of frictions which the child's head muft undergo are then more numerous and frequent. When there is an opening only of three inches, the labour muft be ftill more difficult; but ftill there are inftances of natural deliveries without any affiftance, notwithftanding the difproportion betwixt the fize of the child's head and pelvis. This may even happen when the diameter of the pelvis is ftill fmaller, fuch as two inches and three quarters, or two and an half. M. Solayres obferved in a cafe of this kind, that the head was lengthened in fuch a manner, that its longeft diameter was eight inches all but two lines, that which goes from one parietal protuberance to the other being reduced to two inches five or fix lines; and M. Baudelocque has obferved fimilar changes in the form of the head, and the refpective lengths of its diameters at the inftant of birth, where the child was equally deformed, the long diameter being feven inches, and the tranfverfe one two inches fix or feven lines. The children were in good health; and the day after their birth their heads wanted very little of the ufual proportions.

But when the fmall diameter of the pelvis is lefs than two inches and an half, the head of the child cannot pafs; and then fome of the dangerous chirurgical methods muft be undertaken, which frequently prove fatal both to the mother and child. Even when the pelvis is two inches and an half in diameter, the natural delivery is not always without danger to both; as, on one hand, the foft parts which cover the pelvis are fubjected to fuch violent preffure that they become inflamed, exquifitely painful, and at laft are even threatened with gangrene; on the other, the bones of the child's cranium riding over one another, or fometimes fractured and depreffed, wound the brain, and produce internal extravafations which generally prove fatal. The bad confequences refulting from a deformed pelvis, fhow themfelves fooner or latter, according as the fuperior or inferior ftrait is vitiated. When both are fo, the obftacles to the birth begin to manifeft themfelves as foon as the labour begins; and fometimes thofe at the fuperior ftrait are fo great, that the expulfive powers are exhaufted, and the head ftops there; or if it be pufhed farther into the pelvis, and ftopping there, it will remain incapable of being delivered without the affiftance of art. The head cannot pafs this ftrait without being in a confiderable degree elongated; and when it enters the pelvis, the cavity being there fufficient for it, it naturally returns to its former dimenfions, at leaft in part, and more or lefs fo as it ftays a longer or fhorter time. The fame conformation of the head, however, which enabled it to pafs the firft ftrait, is ftill more neceffary to enable it to pafs the fecond: and hence the fymptoms which had come on with the firft pains, fometimes difappear in a great meafure during the time that the head ftays in the excavation; but increafe to a

Description of the Pelvis in general.

a greater degree than ever when the strong labour comes on.

When the superior strait alone is contracted, the head advances at first with great difficulty; but as soon as the parietal protuberances have cleared the strait, the other parts of the pelvis being relatively or absolutely larger, the head passes them with so much ease, that the delivery is frequently terminated by a few pains. The contrary is observable when the fault is in the inferior strait, if the first be of the usual size. The head then descends easily into the lower part of the pelvis; but cannot proceed any farther, until it overcome the obstacles which obstruct its course, and render it difficult and laborious. In this case, the symptoms attending obstruction appear later than in the former. In these cases, however, it is necessary that the practitioner should accustom himself by practice to form a just estimate of the powers of nature, otherwise he may easily deceive himself; in the former, supposing that a delivery is impossible; and in the latter, that a delivery will be easy which cannot be effected without the assistance of art. An instance of this is given by our author, in a case to which (he says) more than forty persons were witnesses.

The operator pronounced that the woman would be speedily delivered, on account of the facility with which the child's head had engaged with the first pains; and attributing the obstacles which soon after obstructed its course to another cause, rashly destroyed the child by using the crotchet, when its life might have been preserved by other means, having waited two days in blind security, expecting a natural delivery. M. Baudelocque obtained possession of the pelvis of this woman after she died; and tells us, that the circumference of the superior strait of the pelvis, when divested of all its coverings, measured 14 inches, but the inferior only *nine*. The distance from the point of the os sacrum to the symphysis of the pubes, as well as the interval between the ischiatic tuberosities, was but three inches. The cavity of this pelvis diminished insensibly in breadth from one strait to the other, and was as regular as possible in its contour.

The excavation, or middle part of the pelvis, is much more seldom defective in its form than the straits; and when this is the case, it must arise from some exostosis, or from the sacrum describing a right line in its anterior part, instead of being curved as usual. The straight and flat form of the sacrum generally produces fewer obstacles to delivery than the too great curvature of it. The former fault generally affects only the cavity of the pelvis, and cannot hinder the passage of the child, if the canal be otherwise well disposed: but the latter, or too great a curve of the sacrum, commonly proves injurious to both straits, contracting them from before backwards, and at the same time diminishing the depth of the pelvis at the back part, as well as the respective height of the arch of the pubes. In these cases the head, though it passes the first strait with difficulty, cannot pass the second; being stopped in its course by the inferior part of the sacrum before the occiput is long enough to engage under the arch.

Labours may also be rendered difficult by too great a length of the symphysis of the pubes; a want of elevation, or breadth of the arch of these bones; the length and wrong direction of the ischiatic spines, as well as a consolidation of the coccyx with the point of the sacrum. These faults, however, are very rare, if we except the consolidation of the coccyx: they are scarce ever met with alone, and are generally the consequences of a bad conformation of the rest of the pelvis. Even this consolidation, however, though more common than the other faults, yet cannot obstruct delivery so frequently as has been imagined; and when it does so, it is only in women who have a narrow pelvis. Our author denies the position laid down by some, that the head of the child, in all cases, pushes back the point of the coccyx half an inch, or even a whole inch. Those who assert this (he says) know not the relation betwixt the dimensions of the head and the inferior strait in most women. Whence he cannot recommend a precept founded upon this principle, by which it is directed to push back the coccyx, when the head, though low down, cannot disengage itself easily.

We must now consider a subject on which the writers upon midwifery have been greatly divided, viz. the separation of the bones of the pelvis in the time of labour. Some have imagined that this separation took place in all labours; others that it happened only in difficult cases; some, that it indicates a morbific state; and some that it was quite impossible.—M. Baudelocque allows the possibility of such a separation, but denies that it happens so frequently as is imagined. "Experience (says he) demonstrates, that this separation, far from being common, is very rarely met with, and is not more usual after a laborious than after an easy labour, nor in a distorted pelvis than in one well formed. I have sought for it twenty times in all these cases, by opening the bodies, and have scarcely met with one which could remove all doubt of its existence." In those cases where it takes place, he is of opinion, that the filtration of serum into the ligamentous tissue of the symphysis, must be regarded as the usual predisposing cause. The remote cause, of consequence, must be whatever produces this filtration. This, he thinks, cannot be done merely by the pressure of the gravid uterus on the trunks of the vessels which are distributed to these symphyses. An alteration in the fluids themselves he supposes likewise to be necessary.

But though the predisposing cause of this separation must be the relaxation of the symphyses by the infiltration of serum, we are not to look upon the swelling of the cartilages by means of this infiltration to be the immediate cause: For however the ligaments may be relaxed, the cartilages which incrust the extremities of the ossa pubis, as well as the articular facettes of the ossa ilia and the sacrum, are no thicker; so that they cannot, as some have supposed, act like wetted wedges by which large blocks of stone may be cleaved. "The wedge by which the bones of the pelvis are separated (says our author), does not act between the extremities of these bones, but in the circle formed by their assemblage in the pelvis itself: it is the uterus charged with the produce of concep-

tion

Description of the Pelvis in general.

tion in the latter periods of pregnancy, and the child's head forced down by the action of the uterus, and of the abdominal muscles in time of labour."

This separation, however, is not always the effect of a relaxation and stretching of the ligamentous tissue of the symphysis. In some cases, where the obstacles which obstruct the passage of the child are very great, and the efforts for its expulsion very strong and lasting, the symphyses tear, and permit the bones to separate much farther than they could have done by a simple relaxation. "I must add (says our author) that it is not the symphysis of the pubes, properly speaking, which tears; for no effort can break the ligamentous substance which unites these bones to each other; the symphysis detaches itself from one of them, and leaves the bone naked." The separation in question has likewise frequently taken place in instrumental deliveries, to which the natural efforts seemed to contribute nothing; and it has also been found in consequence of a stroke or fall.

"Being deceived in the principle of this separation (says M. Baudelocque), they necessarily erred in the consequence deduced from it. It has been so firmly believed to take place in all labours, that it was thought to be absolutely necessary; and that without it many women could not be delivered without extreme difficulty. Having thus mistaken the necessity and pretended advantages of this separation, the natural resistance of the symphyses, and above all the dryness and rigidity necessarily induced in them by age, were consequently reckoned among the causes of difficult and laborious births. Obstacles have been attributed to the state of these symphyses, which merely depended on the resistance of the neck of the uterus, and of the external parts; and it has been recommended to moisten and relax them by the use of baths, cataplasms, lineaments, fomentations, &c. But what can be expected from such methods, when delivery is obstructed by a narrow pelvis? Will any one venture to assert, that he has once by such means obtained the effect he expected, and that he has thus assisted labours which could not otherwise have been terminated but by the Cæsarean operation, as has so often been published? I should have dispensed with demonstrating the fallacy which has prevailed on this point, if it had not led some practitioners into a very serious consequence. In order to appretiate all these means, and fix the degree of confidence to be placed in them, supposing that they could operate to the relaxation of the symphysis of the pelvis, it is necessary to determine what degree of amplitude can be given to that cavity by the separation of the bones which constitute it. The ossa pubis cannot separate without augmenting the circumference of the pelvis; but how much will its diameter be increased? If the circumference were perfectly circular, every possible diameter would partake a third of that augmentation: but as the entrance of the pelvis is in general the more elliptic as it deviates more from its natural state, it follows, that its different diameters cannot increase in the same proportion; and we may say that there is none but the transverse one which can become larger. In a moderate separation the *antero-posterior* diameter is scarce at all augmented; and it has been repeatedly demonstrated, that the ossa pubis must separate at least an inch to procure two lines in that direction; while the transverse diameter shall be increased six lines, and often more.

"The pelvis being larger in most women than is necessary for their delivery, the separation of the bones could be of no advantage to them, nor render their delivery more easy. Far from regarding it, with some ancient authors, as a benefaction of nature, we ought to consider it as an additional source of inconveniences in those women who are subject to it: for, on one side, we see that a pelvis too large exposes the woman to a number of accidents; and on the other, that there are some which inevitably accompany the separation, and the mobility of the bones which form that cavity. Far from favouring delivery in all these cases, it could not but render it more tedious and painful to the woman, as experience has convinced me. If we ought to expect any real advantage from it, considering it only with respect to the passage of the child, it could only be in those women who have the pelvis deformed, and where the defect which rendered delivery impossible did not exceed two lines at the most; since a separation of an inch cannot procure an augmentation of more than two lines in the small diameter of the superior strait, which is almost always that which occasions the greatest obstacles to the exit of the child. If from a separation of an inch, which has never taken place between the ossa pubis without a rupture of their symphysis, we are not to expect an augmentation of more than two lines in the direction of the little diameter of the superior strait, what can we obtain from a separation always much less, and so little apparent in most women that we may doubt its existence? The examination of a great number of women who have died in child-bed, has proved to me that it is excessively rare for the separation in question to amount to two lines; and I never found it exceed that but once. But supposing (what is impossible) that art could procure a separation of an inch between the ossa pubis without dividing their symphysis, what practitioner would dare to affirm, without fear of being deceived, that the volume of the child's head did not exceed the little diameter of the superior strait by more than two lines? If it is difficult to estimate justly the degree of opening in the pelvis, it is much more difficult still to judge of the child's head; and it is only by taking the mean between the largest and the smallest that we usually establish the relation of its dimensions to those of the pelvis; but a *thereabouts*, in the case supposed, cannot supply the place of that precision which would be necessary."

From his reasoning upon this subject, M. Baudelocque concludes directly against the operation of cutting the symphysis of the pubes, as being not only useless, but attended with very dangerous consequences. "When this separation (says he) has been suddenly made, severe pains in the parts divided, an impossibity of walking, and sometimes even of moving the inferior extremities, inflammation, fever, abscesses, caries, and lastly death itself, have generally been the effects of it: but when a relaxation only takes place, the consequences are less severe; a painful and tottering walk being the only symptom attending it. If the relaxed symphysis at last grow firm again, if the bones of the pelvis recover their former stability, if the

Description of the Pelvis in general.

the lamenefs goes off entirely in fome women, how often, on the contrary, have we not obferved an inability to walk, or even to move the legs, without violent pain, continue for years afterwards?"

Thefe violent fymptoms frequently attend even flight feparations of the bones in queftion. M. Baudelocque gives an inftance of a woman who had kept her bed ten months, being all that time afflicted with the moft excruciating pains in the junction of the offa pubis, and of one of the ilia, with the facrum, whenever fhe attempted to move the inferior extremities, though no feparation of the fymphyfis could be difcovered, nor any thing befides a flight mobility in that of the pubes. The accident had been perceived during the time of labour, and the midwife had been accufed of luxating the bones.

Dr Denman has alfo treated this fubject at confiderable length. He informs us, that for many centuries it was believed that thefe bones were always feparated during the time of labour; or that there was a difpofition to feparate, and an actual feparation, if the neceffity of any particular cafe required that enlargement of the cavity of the pelvis which was confequent to it. The degree of feparation was alfo fuppofed to be proportioned to fuch neceffity; and when this did not happen naturally, inftruments were made ufe of for diftending the parts: and, on the fame principle, the fection of the fymphyfis of the pubes has been recommended. "This opinion (fays he) ought probably to be affigned as one reafon for the fuperficial notice taken by the early writers on midwifery of thofe difficulties which are fometimes found to occur in parturition from the narrownefs or deformity of the pelvis. To this may alfo be referred much of the popular treatment of women in child-bed, and many popular expreffions in ufe at prefent. But this opinion has been controverted by many writers, who affert, that there was neither a feparation nor a difpofition to feparate; but that, when either of them did happen, they were not to be efteemed as common effects attendant on the parturient ftate, but as difeafes of the connecting parts. The difputants on each fide have appealed to prefumptive arguments, and to facts proved by the examination of the bodies of thofe who died in child-bed, in juftification of their feveral opinions. But, notwithftanding all that has been faid, I know not that we are authorifed by the experience of the prefent time to fay, that a feparation, or a difpofition to feparate, prevails univerfally at the latter part of pregnancy, or at the time of labour: yet that thefe effects are often, if not generally, produced, may be gathered from the pain and weaknefs at the parts where the bones of the pelvis are joined to each other before and after delivery. In fome cafes alfo pregnant women are fenfible of a motion at the junction of the bones, efpecially at the fymphyfis of the offa pubis; and the noife which accompanies it may fometimes be heard by the byftanders.

"A ftrong prefumptive argument in favour of the feparation of the bones has been drawn from quadrupeds. In thefe the ligaments which pafs from the obtufe proceffes of the ifchia to the facrum, on which the firmnefs of the junction of the bones very much depends, and which at all other times refift any impreffion attempted to be made upon them, are for feveral days previous to parturition gradually deprived of their ftrength, and the animal walks in fuch a manner as would incline us to believe could only be produced by a feparation of the bones of the pelvis. Now it is not reafonable to conclude, that a circumftance which generally takes place in one clafs of viviparous animals fhould never occur in another, efpecially in a matter in which there is not effential difference."

Notwithftanding thefe arguments, however, Dr Denman does not look upon the matter to be yet abfolutely decided. No perfon, he fays, who has been converfant in the diffection of women who have died in child bed, can have wanted opportunities of feeing every intermediate ftate of thefe parts, from a feparation in which the furfaces of the bones were loofened and at a confiderable diftance from each other, to that in which there was not the leaft difpofition to difunite.

When this feparation takes place beyond a certain degree, it is to be looked upon as morbid: and, he fays, that it may be produced by the two following caufes. "*1ft*, A fpontaneous difpofition of the connecting parts. *2dly*, The violence with which the head of the child is protruded through the pelvis." Of each of thefe cafes he gives an example.—The firft was of a young lady of a healthy conftitution, who had been married in the 21ft year of her age, and in 1774 was delivered of her third child, which was unufually large, and the labour was fevere and tedious. For feveral days before delivery fhe had been fo much afflicted with pain and weaknefs in her loins, that fhe could not walk without affiftance. She recovered without any unfavourable circumftance, excepting that for feveral weeks fhe was incapable of ftanding upright, or putting one foot before the other; the attempt to do either being attended with pain and a fenfation of loofenefs and jarring, both at the parts where the offa innominata are joined to the facrum, and at the fymphyfis of the offa pubis. By the ufe of ftrengthening medicines fhe recovered, and in a few months was perfectly well."

It being fufpected that the complaints above mentioned had proceeded from too frequent parturition, fhe was advifed to fuckle her child for a longer time than ufual; and accordingly continued a nurfe for 15 months. Soon after this fhe became with child a fourth time. The complaints which had accompanied her former pregnancy now came on fooner, and with greater violence than before, infomuch that for three weeks before delivery fhe could neither walk nor ftand; and there was reafon to fuppofe that the bones of the pelvis were feparating. She was delivered on the 7th of July 1777, the labour being accompanied with faintings, great irritability, and a total inability to move her inferior extremities. A few days after her delivery fhe had a fever, which terminated in an abfcefs in one of her breafts, by which fhe was confined to her bed for near feven weeks. In nine weeks fhe could walk with crutches, and received confiderable benefit by being fent into the country; and likewife, as fhe imagined, by drinking half a pint of infufion of malt twice a day. In about five months fhe was able to walk without affiftance; though fometimes fenfible of

Description of the Pelvis in general.

of the motion of the bones, which seem never to have been perfectly united.

About Christmas the same year, this lady became again pregnant; and in the month of July 1778 she began to feel an inability to move; which, however, was attributed to the heat of the weather: but on a sudden the pain and weakness of her back returned to such a degree, that she could walk no more till the 11th of October, when she was delivered of a fine child, but after a most severe and tedious labour, occasioned in a great measure by her being totally unable to move. The symptoms after her delivery became very extraordinary and alarming. On the fourth day a fever came on; and though this was soon removed, the pain at the junction of the bones still continued. She had no command of her inferior extremities; and the pain, when she was moved, became so excruciating, that she felt as if tearing asunder. Her stomach was at all times much disturbed; but when the pain became violent, a nausea, vomiting, or hiccough came on. Strange sympathies were produced in various parts; as a teasing cough, sneezing, sense of weight in her eye-lids, which could not be kept open though there was no inclination to sleep. There was a noise in the bowels, and other nervous affections, all of which ceased when the pain was allayed by opiates.

Having remained for several months in this deplorable situation, it was at last thought proper to raise her from her bed, and cause her to make an effort to stand or walk, lest her complaints should be made worse by such a long course of inactivity. She had now, however, totally lost the power of supporting herself; the motion of the bones was plainly perceived; and the consequences of every trial were so painful, that there was a necessity for desisting. In 1779 she was removed, upon a couch, in a boat to Margate, for the benefit of the air and sea-bathing, from which she was always sensible of receiving advantage. In this place she continued to reside; and in *eight years* after her delivery became able to walk without crutches.

The second case was of a young woman of a healthy but delicate constitution, who was in labour of her first child. The pains were so strong, that the head of the child was forced through the external parts, and the perinæum supposed to be lacerated, in spite of all the opposition which could be made. At the instant when the head of the child was expelled, the operator perceived something to jar under his hand, and was even sensible of a noise, which he attributed to the laceration of the perinæum. In a little time the placenta was extracted without hurry or violence; and a few drops of *tinctura opii* were given to allay the uneasiness which took place, and was supposed to be occasioned by *after pains*. On the following days, however, she complained of an uneasiness in the region of the abdomen; but no particular notice was taken of it, as the milk was regularly secreted, and there was no symptom of fever; but on the fourth day, when taken out of bed, she was found to be unable either to stand or sit on her chair by reason of the pain and weakness in the part of which she originally complained. This was afterwards conjectured to arise from a separation of the bones of the pubes; to which conjecture the long continuance of the complaint seemed to give countenance. The conjecture was founded on the positions and attitudes in which the patient sought to find relief. The symptoms were as follow:—When she endeavoured to stand upright, which she could do better upon one foot than both, and with her feet close than at a distance, together with the pain at the symphysis, she had a sense of extreme weakness, accompanied with a faintness. When she first sat down on her chair, resting her elbows upon the arms, the complaints became tolerable. When she had remained a little time in this position, they again became importunate, and she supported herself with her hands upon her knees, and presently bent forwards, so as to lean her elbows upon her knees: this position becoming irksome, she was obliged to return to her bed, where she became immediately easy. When she first attempted to walk, she was compelled to bend forwards in such a manner as to rest her hands upon her knees, making a straight line from her shoulders to her feet. At the end of 14 weeks, whilst she was in a coach, into which she had often been lifted for the benefit of air and exercise, she had a discharge which she supposed to be menstruous; but which, though it ceased before her return, gave immediate relief. From this time she became better every day, and in six weeks was able to walk. She had afterwards three children, with which her labours were easy, and she never had any return of the above mentioned complaints.

From all this it is evident, that Dr Denman differs considerably in his opinion from M. Baudelocque concerning the separation of these bones. According to him, it appears that this separation, though extremely painful, does not seem to be attended with *fatal* consequences; and with regard to the *quantity* of the separation, it must undoubtedly be sometimes much greater than what M. Baudelocque supposes; for Dr Denman brings an instance from the 484th number of the Philosophical Transactions, in which the bones were separated to the distance of *four inches*. This happened in consequence of the starting of a horse when a gentleman was riding. He observes, however, that, in women, the violence which the connecting parts of the bones undergo when the head of the child is protruded through the pelvis with extreme difficulty, sometimes occasions an affection of more consequence than even the separation of the bones themselves. This is the formation of matter upon the loosened surfaces of the bones, preceded by great pain, and other symptoms of inflammation.

In the beginning of this complaint, it is difficult to ascertain whether the connecting parts of the bones, or some of those contiguous, be the seat of the disease; but when suppuration has taken place in consequence of the injury sustained at the junction of the ossa innominata with the sacrum, the abscess has sometimes been cured by the common treatment, having formed in the neighbourhood of the injured part. At other times, when matter has been formed about the symphysis of the os pubis, hectic symptoms have ensued, and the cause of them only discovered after the patient died. In some cases the matter has burst through the capsular ligament of the symphysis at the inferior edge, or perhaps made its way into the bladder; and in

Description of the Pelvis in general

in others it has insinuated itself under the *periosteum*, continuing its course along the pubes, until it arrives at the acetabulum. Thus all the symptoms were aggravated; and the matter making its way towards the surface, a large abscess has been formed on the inner or fore-part of the thigh, or near the hip; so that the patients have at last sunk under the fever and profuse discharge from the ulcer. On dissecting those who have died in this manner, the track of the matter has been followed from the aperture of the abscess to the symphysis, the cartilages of which were found to be eroded, the bones carious, and the adjacent parts very much injured or destroyed. Our author imagines it possible, by means of some particular symptom, to discover whether or not there be any disposition in the parts above mentioned to suppurate, or to know when suppuration has taken place. In all cases of unusual pain attended with equivocal symptoms, the parts ought to be examined with great care and attention: for where there is any disposition to suppurate, it might perhaps be removed by proper means; and when the matter is formed, if there be a swelling in the symphysis, and, more especially, if a fluctuation could be perceived, the propriety of making an incision to evacuate the matter, and prevent farther bad consequences, might be determined.

With regard to the possibility of re-uniting the bones of the pelvis after they have once been separated, our author has the following observations.

"When the connection of the bones of the pelvis has either been impaired or destroyed, it is probable that a confirmation or re-union may take place by a restoration of the original mode, by a callus, or by anchylosis. But it is likewise possible that the bones may remain in a state of separation, and an articulation be formed by the ends of each bone, at the symphysis of the ossa pubis, and at the junction of the ossa innominata with the os sacrum." Of this last the Doctor has seen one instance in a dead body, and has had reason to suspect the existence of it in some living persons. In the lower degrees of imperfection the former method of union probably takes place; as the complaints made by women of pain and weakness, after delivery, generally go off before their month of confinement is elapsed; but when they continue for a longer time, the best method is to enjoin the patient rest and an horizontal posture. In an increased degree of the complaint, where the health of the patient is affected, a longer time will be required for the recovery; but should the injury be too great to admit of the restoration of the original mode of union, a much longer time will be requisite for the formation of a callus, if this ever takes place except as a previous step to an anchylosis. This last has been observed frequently to take place at the junction of the ossa innominata with the sacrum, but never at the symphysis of the pubes. In this case little can be expected excepting from such remedies as tend to restore the constitution to its pristine vigour; and in the first case above related, the only thing from which the patient seemed to obtain relief was the cold-bath. She was likewise much assisted by the use of a swath, or broad belt, made of soft leather, quilted, and buckled with such firmness over the lower part of the body as to lessen, if not prevent, the motion of the bones; and this was kept in its situation by a bandage passed between the legs, from the hind to the fore part of the belt. But when a joint is formed between the separated surfaces of the bones, all hope of recovering the patient to her former health may be given up. The only thing which can then be done for her relief must be by the use of a belt, or some similar contrivance, to substitute, as much as possible, artificial firmness, instead of natural. Dr Denman saw one case in which he suspected this to have happened, and in which the life of the patient was truly miserable: He is of opinion, however, that it very rarely occurs; having been informed of another person, who, after eight years confinement to her bed, in consequence of the separation of the bones in the time of labour, was at last restored to the perfect use of her inferior extremities. Instances also, though rare, have occurred, in which women, after labours, have suffered much pain in the region of the sacrum, and totally lost the power of moving their inferior extremities.—This has been supposed a paralytic affection, and they are said to be bed-ridden; but as these patients have generally been restored, though after a very long confinement, our author thinks it reasonable to suppose that their infirmity had been occasioned by a separation of the bones, which at different periods after the accident, according to the degree of their separation, had recovered their former connection and strength.

Pregnancy.

Chap. II. *Of Pregnancy.*

At the time of conception, and for some time after, the parts which form the small fœtus are so blended together, that one cannot be distinguished from another. The whole mass is then called an *ovum*. This ovum consists of four membranes; the placenta, or after-birth; the funis umbilicalis or navel-string, leading to the child; and the surrounding watery fluid in which it floats. Before the child acquires a distinct and regular form, it is called *embryo*, and afterwards retains the name of *fœtus* till its birth. For the increase and nutrition of the fœtus, see Anatomy, n° 109. 110.

During the progress of impregnation the uterus suffers considerable changes; but, though it enlarges as the ovum increases, yet, in regard to its contents, it is never full; for, in early gestation, these are confined to the fundus only: and though the capacity of the uterus increases, yet it is not mechanically stretched, for the thickness of its sides do not diminish; there is a proportional increase of the quantity of fluids, and therefore pretty much the same thickness remains as before impregnation.

The gravid uterus is of different sizes in different women; and must vary according to the bulk of the fœtus and involucra. The situation will also vary according to the increase of its contents and the position of the body. For the first two or three months, the cavity of the fundus is triangular, as before impregnation; but as the uterus stretches, it gradually acquires a more rounded form. In general, the uterus never rises directly upwards, but inclines a little obliquely, most commonly to the right side; its position is never, however, so oblique as to prove the sole

cause

Pregnancy. caufe either of preventing or retarding delivery: its increafe of bulk does not feem to arife merely from diftention, but to depend on the fame caufe as the extention of the fkin in a growing child. This is proved from fome late inftances of extra-uterine fœtufes, where the uterus, though there were no contents, was nearly of the fame fize, from the additional quantity of nourifhment tranfmitted, as if the ovum had been contained within its cavity.

The internal furface, which is generally pretty fmooth, except where the placenta adheres, is lined with a tender efflorefcence of the uterus, which, after delivery, appears as if torn, and is thrown off with the cleanfings. This is the *membrana decidua* of Dr Hunter.

Though the uterus, from the moment of conception, is gradually diftended, by which confiderable changes are occafioned, it is very difficult to judge of pregnancy from appearances in the early months. For the firft three months the os tincæ feels fmooth and even, and its orifice as fmall as in the virgin ftate. When any difference can be perceived, about the fourth or fifth month from the defcent of the fundus through the pelvis, the tubercle or projecting part of the os tincæ will feem larger, longer, and more expanded; but, after this period, it fhortens, particularly at its fore-parts and fides, and its orifice or labia begin to feparate, fo as to have its conical appearance deftroyed. The cervix, which in the early months is nearly fhut, now begins to ftretch and to be diftended to the os tincæ; but during the whole term of utero-geftation, the mouth of the uterus is ftrongly cemented with a ropy mucus, which lines it and the cervix, and begins to be difcharged on the approach of labour. In the laft week, when the cervix uteri is completely diftended, the uterine orifice begins to form an elliptical tube, inftead of a fiffure, or to affume the appearance of a ring on a large globe; and often at this time, efpecially in pendulous bellies, difappears entirely, fo as to be out of the reach of the finger in touching. Hence the os uteri is not in the direction of the axis of the womb, as has generally been fuppofed.

About the fourth, or between the fourth and fifth month, the fundus uteri begins to rife above the pubes or brim of the pelvis, and its cervix to be diftended nearly one third. In the fifth month the belly fwells like a ball, with the fkin tenfe, the fundus about half way between the pubes and navel, and the neck one half diftended. After the fixth month the greateft part of the cervix uteri dilates, fo as to make almoft one cavity with the fundus. In the feventh month the fundus advances as far as the umbilicus. In the eighth it reaches mid-way between the navel and fcrobiculus cordis; and in the ninth to the fcrobiculus itfelf, the neck then being entirely diftended, which, with the os tincæ, become the weakeft part of the uterus. Thus at full time the uterus occupies all the umbilical and hypogaftric regions; its fhape is almoft pyriform, that is, more rounded above than below, and having a ftricture on that part which is furrounded by the brim of the pelvis.

The appendages of the uterus fuffer very little change during pregnancy, except the ligamenta lata, which diminifh in breadth as the uterus enlarges, and at full time are almoft entirely obliterated.

The moft remarkable change happens in the ovarium. A cicatrice of a roundifh figure and yellowifh colour appears in this body, called by anatomifts the *corpus luteum*. It is always to be found in one of the ovaria; and in cafes of twins a corpus luteum often appears in both ovaria. It was formerly confidered as the calyx ovi; but modern phyfiologifts think it a gland, from whence the feminal fluid is ejected. In early geftation it is moft confpicuous, when a cavity is obfervable, which afterwards collapfes; no veffels appear at the centre of this cavity which has the appearance of cicatrix, but all around that centre the fubftance is vafcular.

During the progrefs of diftenfion, the fubftance of the uterus becomes much loofer, of a fofter texture, and more vafcular than before conception; its veins particularly, in their diameters, being enlarged in fuch a manner as to get the name of *finufes;* they obferve a more direct courfe than the arteries, which run in a ferpentine manner, anaftomofing with one another and through its whole fubftance, efpecially where the placenta adheres, where this vafcular appearance is moft confpicuous.

The arteries pafs from the uterus through the decidua, and open into the fubftance of the placenta in a flanting direction. The veins alfo open into the placenta, and by injecting thefe veins from the uterus with wax, the whole fpungy or cellular part of the placenta will be filled.

The mufcular ftructure of the gravid uterus is extremely difficult to be fhown: in the wombs of women who die in labour, or foon after delivery, fibres running in various directions are obfervable more or lefs circular, that feem to arife from three diftinct origins; viz. from the place where the placenta adheres, and from the aperture or orifice of each of the tubes; but it is almoft impoffible to demonftrate regular plans of fibres, continued any length without interruption.

Chap. III. *Spurious Gravidity.*

Spurious Gravidity. The various difeafes incident to the uterine fyftem, and other morbid affections of the abdominal vifcera, will frequently excite the fymptoms and affume the appearance of utero-geftation. Complaints arifing from a fimple obftruction are fometimes miftaken for thofe of breeding; when a tumor about the region of the uterus is alfo formed, and gradually becomes more and more bulky, the fymptoms it occafions are fo ftrongly marked, and the refemblance to pregnancy fo very ftriking, that the ignorant patient is often deceived, and even the experienced phyfician impofed on.

Scirrhous, polypous, or farcomatous tumors in or about the uterus or pelvis; dropfy or ventofity of the uterus or tubes; fteatoma or dropfy of the ovaria, and ventral conception, are the common caufes of fuch fallacious appearances.. In many of thefe cafes the menfes difappear; naufea, retchings, and other fymptoms of breeding, enfue; flatus in the bowels will be miftaken for the motion of the child; and in the advanced

Superfœtation.

vcnced ſtages of the diſeaſe, from the preſſure of the ſwelling on the adjacent parts. Tumefaction and hardneſs of the mammæ ſupervene, and ſometimes a viſcid or ſerous fluid diſtils from the nipple; circumſtances that ſtrongly confirm the woman in her opinion, till time or the dreadful conſequences that often enſue at laſt convince her of her fatal miſtake.

Falſe Conception.—Mola. Other kinds of ſpurious gravidity, leſs hazardous in their nature than any of the preceding, may under this head alſo be claſſed; diſeaſes commonly known by the names of *falſe conception* and *mola*: The former of theſe is nothing more than the diſſolution of the fœtus in the early months; the placenta is afterwards retained in the uterus, and from the addition of coagula, or in conſequence of diſeaſe, is excluded in an indurated or enlarged ſtate; when it remained for months or longer, and came off in the form of a fleſhy or ſcirrhous-like maſs, without having any cavity in the centre, it was formerly diſtinguiſhed by the name of *mola*.

Mere coagula of blood, retained in the uterus after delivery, or after immoderate floodings at any period of life, and ſqueezed, by the preſſure of the uterus, into a fibrous or compact form, conſtitute another ſpecies of mola, that more frequently occurs than any of the former. Theſe, though they may aſſume the appearances of gravidity, are generally, however, expelled ſpontaneouſly, and are ſeldom followed with dangerous conſequences.

Chap. IV. *Superfœtation.*

Soon after impregnation takes place, the cervix uteri becomes entirely ſhut up by means of a thick viſcid gluten: the internal cavity is alſo lined by the external membrane of the ovum, which attaches itſelf to the whole internal ſurface of the fundus uteri: the Fallopian tubes alſo become flaccid; and are, as gravidity advances, ſuppoſed to be removed at ſuch a diſtance, that they cannot reach the ovaria to receive or convey another ovum into the uterus. For theſe, and other reaſons, the doctrine of *ſuperfœtation* is now pretty generally exploded.—A doctrine that ſeems to have ariſen from the caſe of a double or triple conception, where, ſome time after their formation in utero, one fœtus has been expelled, and another has remained; or after the extinction of life at an early period, one or more may be ſtill retained, and thrown off in a ſmall and putrid ſtate, after the birth of a full-grown child.

The uterus of brutes is divided into different cells; and their ova do not attach themſelves to the uterus ſo early as in the human ſubject, but are ſuppoſed to receive their nouriſhment for ſome time by abſorption. Hence the os uteri does not cloſe immediately after conception; for a bitch will admit a variety of dogs while ſhe is in ſeaſon, and will bring forth puppies of theſe different ſpecies: thus it is common for a grehound to have, in the ſame litter, one of the grehound kind, a pointer, and a third, or more, different from both: Another circumſtance that has given riſe to *ſuperfœtation* in the human ſubject, which can *only* happen when there is a double ſet of parts, inſtances of which are very rare.

Chap. V. *Extra uterine Fœtuſes, or ventral Conception.*

Monſters.

The impregnated ovum, or rudiments of the fœtus, is not always received from the ovarium by the tuba Fallopiana, to be thence conveyed into the cavity of the uterus; for there are inſtances where the fœtus ſometimes remains in the ovarium, and ſometimes even in the tube; or where it drops out of the ovarium, miſſes the tubes, and falls into the cavity of the abdomen, takes root in the neighbouring parts, and is thereby nouriſhed: But as theſe fœtuſes cannot there receive ſo much nouriſhment as in the ſucculent uterus, they are leſs, and generally come to their full growth before the common term.

Of theſe ſome burſt in the abdomen; and others form abſceſſes, and are thereby diſcharged; others dry, and appear bony, and remain during life, or are diſcharged as above, or by ſtool, &c.

Chap. VI. *Monſters.*

When two or more ova contained in the uterus attach themſelves ſo near one another as to adhere in whole or in part, ſo as to form only one body with membranes and water in common, this body will form a confuſed irregular maſs called *monſtrous*; and thus a monſter may be either defective in its organic parts, or be ſupplied with a ſupernumerary ſet of parts derived from another ovum. This ſeems a rational conjecture; but while every thing relative to generation is a myſtery, how can we account for the extraordinary phænomena? Some authors enumerate a third ſpecies of monſter, the product of a mixed breed, exemplified, for inſtance, in the mule, produced by the mixed generation of an aſs and a mare. In this animal there are organical parts different from what preexiſted in the parents; there is a defect of ſome parts, a luxuriant growth of others; and the defect in the parts of generation, which renders the animal unfit for propagation, conſtitutes a very curious and particular ſpecies.

Chap. VII. *Diſeaſes of Pregnancy.*

After conception, a remarkable change is ſoon produced in the genital ſyſtem. This is the ſource from whence ariſe different ſymptoms that are however liable to conſiderable variation, not only in the conſtitution of different women, but in the ſame woman in different pregnancies, and at different periods of the ſame pregnancy.

Outlines of Midwifery, by Dr Hamilton.

Pregnancy,—though a natural alteration of the animal-œconomy, which every female ſeems originally formed to undergo, and hence not to be conſidered as a ſtate of diſeaſe, occaſions, however, ſooner or later, in many women, various complaints, which evidently depend on it as a cauſe.

Diſeaſes incident to the pregnant ſtate may be conſidered, either, 1. As ariſing from ſympathy in the early months; or, 2. As depending on the ſtretching and preſſure of the uterus towards the more advanced ſtages.

I. Though

Diseases of Pregnancy.

I. Though the former of these complaints are generally to be accounted for from other causes than that of plethora; yet, in many constitutions, a certain plethoric disposition in the early months of pregnancy seems to prevail in the vascular system: And therefore, though many inconveniences may ensue from a too frequent, a too copious, or an indiscriminate use of venesection; yet, if prudently and judiciously employed, abortion by this means will not be endangered, as some late authors have alleged; but, on the contrary, on many occasions, a seasonable bleeding will be attended with the most beneficial and salutary effects.

In young women, suddenly affected with severe sickness and loathing, febrile commotion, headach, vertigo, and other symptoms of breeding, more especially in full sanguineous habits, besides a spare light diet and suitable exercise, recourse must be had to proper evacuations, the chief of which is venesection: this may be safely performed at any time of gravidation, and occasionally repeated according to the urgency of the symptoms; small bleedings, at proper intervals, are preferable to copious evacuations, which in early pregnancy ought always to be carefully guarded against.

When the stomach is loaded with putrid bile or acrid saburra, the offensive matter should be discharged by gentle vomits of ipecacuan, or of infusions of chamomile flowers. The violent efforts to retch and vomit, and the commotions thence excited, which often occasion the expulsion of the fœtus, will by this means frequently be removed, in most cases greatly diminished. During the term of breeding, the state of the belly must be also attended to. When laxative medicines become necessary, those of the mildest and gentlest kind should be administered.

In women liable to nervous complaints, where the stomach is weak, and the sickness violent and continued, the patient should be put on a course of light, aromatic, and strengthening bitters; such as infusions of bark, columbo, &c. and her diet, air, exercise, company, and amusement, should be regulated: In order to settle the stomach, and lessen the sensibility of the system, opiates will often happily succeed, when every other remedy fails.

Heart-burn and *diarrhœa*,—common symptoms of breeding, or of pregnancy, must be treated pretty much as at other times. Both complaints chiefly depend on the state of the stomach.

Tumefaction, *tension*, and *pains* in the *mammæ*.—If tight lacing here be only avoided, and the breasts have room to enlarge and swell, no inconvenience ever follows: These effects arise from a natural cause, and seldom require medical treatment. If very troublesome and uneasy, bathing with oil, or anointing with pomatum, and covering with soft flannel or fur, will in most cases prove the cure.

The *menstrual evacuation*—is in some women regular for the first, second, or third period after conception. This seldom happens but in women of sanguinary plethoric habits, such as have been accustomed to large copious evacuations at other times, when the discharge is to be considered as beneficial.

Deliquia, *nervous*, or *hysteric fits*—When these are occasioned by falls, frights, and passions of the mind, they frequently end in the loss of the child: But when they happen about the term of quickening, they seem to arise from the escape of the uterus from its confinement within the capacity of the pelvis; in which case they are commonly slight, of short duration, and never threaten any dangerous consequence.

II. The second class of complaints, viz. those that are incident to the advanced stages of utero-gestation, and that depend on the change of situation of the gravid uterus, its enlargement and pressure on the neighbouring parts are more painful in their symptoms, and more dangerous in their consequences, than those enumerated in the preceding class. The premature exclusion of the fœtus is generally the worst inconvenience resulting from the *one*; the death of the mother, along with the loss of the child, is too frequently an attendant of the *other*.

Difficulty or *suppression* of *urine*—is sometimes occasioned by the pressure of the uterus on the neck of the bladder, before the fundus uteri escapes from its confinement within the brim of the pelvis. This complaint, if early attended to, will seldom prove troublesome or hazardous; but cannot be entirely removed till the uterus rises above the brim of the pelvis, and by its enlargement becomes supported by resting on the expanded bones of the ossa ilia. But if neglected in the beginning,

A retroversion of the uterus—is generally the consequence; a case that demands particular attention.—Here the fundus uteri, instead of being loose, falls back in a reclined state within the hollow of the os sacrum: thus a tumor is formed in the vulva, whereof the os tincæ makes the superior part; the body of the uterus, by this means, becomes strongly wedged between the rectum and bladder; and, from the enlargement of the uterus itself, and accumulating load of fæces and urine, the reduction will prove in many instances utterly impracticable. A total suppression of urine, or a rupture of the coats of the bladder, fever, inflammation, or gangrene of the uterus, often ensue; and these are succeeded by delirium, convulsions, death.

The indications of cure, in this dangerous disease, are sufficiently obvious: For, in the first place, every obstacle that prevents the reduction should be removed: thus the contents of the rectum and bladder must, if possible, be evacuated; emollient fomentations and cataplasms must be applied, if indicated by inflammation or tumefaction of the parts. Secondly, The reduction of the prolapsed uterus must be attempted, by placing the patient upon her knees, with her head low and properly supported. While this is attempted within the vagina, a finger or two should also be passed within the rectum, by which the operation in some cases may be facilitated: but, at other times, no power whatever will be sufficient for this purpose. Lastly, If the reduction be accomplished, the fever, inflammatory symptoms, and other consequences of the disease, must be subdued; and a recurrence prevented by an open belly, rest, and recumbent posture, and promoting a free discharge of urine: means that ought to be persisted in till the uterus rises within the abdomen, when the patient will be secured from future danger.

Difeafes of Pregnancy.

Coftivenefs in pregnancy—is inconvenient. It may proceed from the fame caufe with the preceding complaint; it may depend on the ftomach; the febrile heat, that in many women prevails, will alfo prove an occafional caufe. It may be obviated or prevented by a proper regulation of the regimen, and by fuch gentle laxative medicines as are beft fuited to the ftate of the woman; the chief of which are ripe fruit, magnefia, lenitive electuary, cream of tartar, fulphureous and aloetic medicines, oleum ricini, emollient glyfters.

The piles—frequently arife in confequence of coftivenefs, or from preffure of the gravid uterus on the hæmorrhoidal veins. Thefe are alfo to be removed or palliated by the fame means employed on other occafions; regard being had to this diftinction, which may be applied univerfally to the gravid ftate, that all violent remedies are to be avoided: a light diet fhould be enjoined; the belly fhould be kept moderately open; and topical liniments or cataplafms fhould be applied, fuch as Balf. fulphur. Balf. traumaticum, Liniment. ex ol. palmæ, Ung. fambucin. cum laud. liquid. Poultices of bread and milk with opium, &c. according to the various circumftances of the cafe.

Oedematous fwellings of the legs and *labia*,—are occafioned by the languid ftate of the circulation, by the interruption of the refluent blood from the preffure of the diftended uterus on the vena cava, &c. Thefe, though very troublefome and inconvenient, are feldom however of dangerous confequence, except where the habit is otherwife difeafed; and feldom require puncture, as the fwelling generally fubfides very quickly after delivery. They can only, therefore, at this time, admit of palliation; for which purpofe, along with a proper diet and moderate exercife, a frequent recumbent pofture, open belly, and dry frictions applied to the legs evening and morning, will prove the moft effectual means.

Varicous fwellings in the legs and thighs—from the interruption of the venal blood in thefe parts, occafioned by the preffure of the gravid uterus, are to be treated in the fame manner with the preceding complaint

Pains in the back, loins, cholic-pains, cramp,—occafioned by the ftretching of the uterus and appendages, and from the preffure of the uterus on the neighbouring parts, fymptoms that are moft troublefome in a firft pregnancy, are to be palliated by venefection, an open belly, and light fpare diet. If the patient be of a full habit, and pre-difpofed to inflammatory complaints, where the preffure is very great in the advanced months, or in twins, &c. if proper remedies are neglected, inflammation of the uterus and adjacent vifcera, or dreadful epileptic fits, may quickly enfue; the event whereof is generally fatal. Crampifh fpafms in the belly and legs require the fame palliative treatment; to which may be added friction, and the application of æther, ol. volatil. balf. anodyn. or the like, to the parts affected.

Cough, dyfpnœa, vomitings, difficulty or incontinency of urine, occafioned by the preffure of the bulky uterus on the ftomach, liver, diaphragm, &c.—Complaints that can only be alleviated by frequent fmall bleedings, a light fpare diet, and open belly. The patient fhould be placed in an eafy pofture, fomething between fitting and lying; and when the uterus rifes high, a moderate degree of preffure from the fuperior part downwards, may in fome cafes prove ufeful. But this muft be ufed with great caution: for dreadful are the effects of violent preffure, or tight lacing, during pregnancy. It frequently kills both mother and child, and ought to be guarded from the earlieft months.

Difeafes of Pregnancy.

Epileptic fits,—are a very dreadful and alarming appearance. They generally depend on the fame caufe with the above complaints: they may alfo arife from irritation, excited by the motion and ftirring of the fœtus; and from various other caufes. Such as have had convulfions when young, are moft liable to have them during pregnancy: they happen moft frequently in firft pregnancies, or where the fœtus is very large, or in twins, triplets, &c. In fuch cafes, the diftention of the uterine fibres is fo great, that actual laceration is fometimes the confequence.

At whatever period of pregnancy they feize, the utmoft danger may be dreaded. This, however, will be in proportion to the feverity, duration, and recurrence of the paroxyfm, to the term of gravidation, to the conftitution of the patient, and her condition during the remiffion. The danger is greater towards the latter end of pregnancy than in the earlier months or in time of labour.

Such as arife from inanition, from exceffive and profufe hemorrhagies, from violent blows, falls, &c. or from a ruptured uterus, are for the moft part fatal.

Hyfteric or nervous fpafms muft be carefully diftinguifhed from true epileptic fits. The former are milder than the latter; they are not attended with foamings; they do not affect the pofture; the pulfe is fmaller, feebler, and more frequent; the woman is pretty hearty after they are over; they are followed with no bad confequences, and yield to the common treatment. Women of ftrong, robuft, vigorous conftitutions, are more generally the fubjects of the *one*; the delicate, the nervous, and the irritable, of the *other*.

Epileptic fits generally come on very rapidly; if any previous fymptoms occur, the fit is commonly announced by an intenfe pain in the ferobiculum cordis, or violent head-ach.

In the pregnant ftate, thefe fits are for the moft part fymptomatic, and will therefore only admit of a palliative cure. They may be diftinguifhed into three claffes; thofe of the early months, thofe of the latter, and thofe that come on with labour-pains.

With regard to the cure, the term of pregnancy, as well as the conftitution of the patient, and particular caufe of the difeafe, muft carefully be confidered.

1. Convulfions at an early period of pregnancy chiefly happen to young women of a plethoric fanguine habit; and can therefore only be removed or palliated by a free and bold ufe of the lancet, by an open belly, cool regimen, and fpare diet. After plentiful evacuations, if the ftomach be loaded with acrid faburra or putrid bile, a gentle puke may be of ufe: but fuch remedies, on thofe occafions, muft be employed with great caution. Inftead of a plethoric, if the patient is of a nervous habit, a very neceffary and important diftinction, the intentions of cure will effentially vary. For here opiates in lage dofes and frequently repeated, emollient glyfters, ftupes applied to the legs, the femicupium, and every other means to foothe the nerves and remove fpafmodic ftricture, will prove the moft effectual remedies. If infenfible

Difeafes. or comatous, opium, mufk, and other antifpafmodics, fhould be exhibited by way of glyfter, and the patient ought to be roufed by epifpaftic and ftimulating cataplafms applied to the legs and hams. Convulfions fucceeding profufe evacuations are generally mortal. The vis vitæ, in fuch circumftances, muft be fupported, by replenifhing the veffels with the utmoft fpeed: this is to be done by pouring in nourifhing fluids as faft as poffible by the mouth and by glyfter; warm applications fhould alfo be made to the ftomach and feet, and nervous cordials given internally along with opium.

The treatment of epileptic fits, depending on other caufes than thofe now mentioned, muft be regulated by a proper attention to the particular fymptoms with which they are attended.

2. In the advanced months, fuch complaints are more to be dreaded than in early geftation, as they generally proceed from the irritation occafioned by the diftention of the uterine fibres, or by the preffure of the uterus on the contiguous vifcera: hence the natural functions of thefe parts will be interrupted, the circulation of their fluids will be impeded, and the blood, being thus prevented from defcending to the inferior parts, will be derived in greater proportion to the brain, and overcharge that organ.

The cure muft, in this cafe, chiefly reft on copious and repeated bleedings, an open belly, and fpare diet.

3. Laftly, when fits come on with labour-pains, a fpeedy delivery, if it can be done with fafety, either by turning the child, or by extracting with the forceps when the head is within reach, will prove the moft effectual cure.

When the bladder is diftended, the contents muft be evacuated: if a ftone fticks in the urethra, it muft be pufhed back or extracted. If the fits are the effects of a ruptured uterus, immediate death is generally the confequence.

With regard to the treatment of fuch complaints, no other change is generally requifite, than what arifes from the fymptoms peculiar to this fituation. In general, till after delivery, they will only admit of palliation.

Chap. VIII. *Floodings.*

These, though confined to no particular term, may happen at every period of gravidation. The one is a frequent confequence of the other; the event of both is often hazardous, as the earlier mifcarriages are generally preceded by an effufion of blood from the uterus, which, in the advanced ftages of pregnancy, befides the lofs of the child, always endangers the life of the mother.

The *menorrhagia gravidarum*—may be defined, an effufion of blood from the uterus, confined to no regular or ftated periods, in quantity and duration various, and liable to recur on the flighteft occafions.

The immediate caufe is, a feparation of fome portion of the placenta or chorion from the internal furface of the uterus. Whatever occafions this feparation may be confidered as the remote caufe, which, though various, may be reduced to

I. Thofe that affect the general fyftem: as, Abortion.

1. External accidents changing the ftate of the circulation.
2. Changes in the circulation from internal caufes.
3. Debility.
4. Plethora.

II. Thofe that affect the uterus and placenta: as,

1. Direct affections.
2. Stimuli communicated from an affection of other parts.

With regard to the cure.—Though a flooding in fome conftitutions may happen, even in early geftation, and may remit and recur from time to time, and the woman go on to the end of her reckoning; and tho' it feldom or never happens that this complaint proves mortal to the mother in the firft five weeks of pregnancy; yet every appearance of this kind, even the flighteft, is to be dreaded; as in the early months it will often throw off the fœtus, and, in the latter, always threatens the utmoft danger both to mother and child. Floodings of gravid women we cannot propofe radically to cure; they will only admit of palliation. With this view, the indications are,

I. To leffen the force and velocity of the blood in general.

II. To promote the conftriction of the patulous mouths of the bleeding veffels, or the formation of congula in their orifices.

1. To anfwer the firft indication, reft and a recumbent pofture, cool air, tranquillity of mind, a light diet, venefection, and opiates, are the chief means.

2. To reftrain the violence of the hemorrhagy, internal aftringent medicines are recommended; but this is to be accomplifhed chiefly by means of cold ftyptic applications to the parts and their neighbourhood. But as thefe floodings often arife from fo various and oppofite caufes, it is difficult to lay down particular indications, or to point out a method of cure fuited to every cafe that may occur. The intention of cure can only be regulated by a careful and judicious confideration of the caufe, and of thofe particular circumftances with which the cafe may be attended. In early pregnancy, it may be reftrained by keeping the patient quiet and cool, by giving internally cooling things and opiates; but, in the advanced ftages, the deluge is fometimes fo profufe as to kill very fuddenly. Under fuch circumftances, when the woman is near her time, emptying the uterus by delivery, if practicable, is the only fafe expedient both for preferving the life of the mother and of the child.

If the hemorrhagy can be reftrained, a recurrence muft be guarded againft, by avoiding or counteracting the occafional or remote caufes.

Chap. IX. *Abortion, or Mifcarriage,*

May be defined, the premature expulfion of the embryo or fœtus. Some, however, make the following diftinction: When a woman mifcarries in early geftation, this they confider as an abortion; but if in the latter months, that they term a *premature birth.* The fymptoms that threaten abortion are:

Flooding.

Pain

Abortion.

Pain in the back and belly.

Bearing down pains with regular intermiffions.

The evacuation of the waters.

The death of the child, which difcovers itfelf by the following fymptoms; though in general thefe are fo doubtful and fallacious, that none of them afford an infallible fign:

1. The fubfiding of the abdominal tumor.
2. Ceffation of motion in the fœtus.
3. The fenfation of a heavy weight falling from fide to fide, as the woman turns herfelf in bed.
4. Sicknefs, faintings, rigors, cold fweats.
5. The breafts turning flaccid.
6. Coldnefs of the abdomen, and putrid difcharge from the vagina.

Abortions are feldom dangerous in the firft five months; but a frequent habit of mifcarriage debilitates the fyftem, fhatters the conftitution, and lays the foundation of chronic difeafes of the moft obftinate and dangerous nature.

In the advanced months, the prognofis will be more or lefs favourable according to the patient's former ftate of health, the occafional caufe, and fymptoms with which it is attended. The proximate caufe of abortion is the fame with that of true labour, viz. a contracting effort of the uterus and abdominal mufcles, affifted by the other expulfive powers. The remote caufes cannot be explained with precifion; as many circumftances, with regard to the nature of impregnation, and connection of the fœtus with the placenta and uterus, are fubjects ftill involved in darknefs. They may in general, however, be reduced,

I. To whatever interrupts the regular circulation between the uterus and placenta.

II. To every caufe that excites the fpafmodic contraction of the uterus, or other affifting powers.

III. To whatever occafions the extinction of life in the fœtus.

Amongft the firft are:

1. Difeafes of the uterus.
2. Impervioufnefs or fpafmodic conftriction of the extremities of the uterine blood-veffels.
3. Partial or total feparation of the placenta or chorion from the uterus.
4. Determination to other parts.

To the fecond general head belong all caufes that produce a ftrong contraction of the elaftic fibres of the uterus, or of the parts that can prefs upon it, or that occafion a rupture of the membranes: fuch as,

1. Violent agitation of mind or body.
2. A difeafe of the membranes.
3. Too large a quantity of liquor amnii.
4. The crofs pofition of the fœtus.
5. Its motion and kicking.

The laft head includes the numerous caufes of the death of the child, which, befides thofe referred to in the preceding claffes, may be occafioned by,

1. Difeafes peculiar to itfelf.
2. Difeafes communicated by the parents.
3. External accidents happening to the mother: or,
4. Accidents incident to the fœtus in utero.
5. Difeafes of placenta or funis.
6. Knots and circumvolutions of the chord.
7. Too weak an adhefion of placenta or chorion to the uterus: and,
8. Every force that tends to weaken or deftroy this attachment.

With regard to the treament. This muft be varied according to the particular circumftances of the cafe: nor is it poffible to point out particular indications, or propofe any regular plan to be purfued for this purpofe. Abortion is often preceded by no apparent fymptom, till the rupture of the membranes, and evacuation of the waters, announce the approaching expulfion of the fœtus. Either to remove threatening fymptoms, or to prevent mifcarriage when there is reafon to apprehend it, often baffles our utmoft fkill; becaufe it generally happens, that there is a ceffation of growth in the ovum; or, in other words, an extinction of life in the fœtus, fome time previous to any appearance of abortion. For inftance, in early geftation, a woman commonly mifcarries about the 11th or 12th week; but the age of the fœtus at this time is generally no more than eight weeks. At other times, when by accident the fœtus perifhes, perhaps about the fifth or fixth month, it will ftill be retained in utero, and the expulfion will not happen till near the completion of full time.

As women who have once abforbed are fo liable to a recurrence from a like caufe, at the fame particular period, fuch an accident, in future pregnancies, fhould therefore be guarded againft with the utmoft caution. On the firft appearance of threatening fymptoms, the patient fhould be confined to a horizontal pofture; her diet fhould be light and cooling; her mind fhould be kept as tranquil as poffible; a little blood from the arm may be taken occafionally; and opiates adminiftered according to circumftances: but excepting fo far as depends on thefe, and fuch like precautions, for the moft part, in the way of medicine, very little can be done.

Manual affiftance is feldom or never neceffary during the firft five months of pregnancy: the exclufion of fœtus and placenta fhould very generally be trufted to nature.

The medical treatment of abortion muft therefore be confidered with a view only to the prophylacticcure: and this again will chiefly confift in a proper

Regimen.

Chap. X. *Regimen during Pregnancy.*

Women, when pregnant, fhould live a regular temperate life; moderation in eating and drinking fhould now be very carefully obferved, and every thing that has any tendency to difagree with the ftomach fhould be avoided; otherwife the manner of life fhould be much as ufual. If complaints do occur, thefe fhould be treated as at other times; only guarding againft fuch things as, by violent operation, may endanger mifcarriage. If the woman has formerly been fubject to this accident, the caufe fhould be carefully confidered, and fuitable remedies applied; if plethoric, for inftance, fhe fhould be blooded, live fparingly, and kept quiet, till fhe gets beyond the dangerous period. If fhe be weak, delicate, and nervous, bark, light aromatic bitters, mineral waters, and the cold bath (if able to bear it), will prove the beft prophylactic remedies. The cold bath has, in many cafes, cured the moft obftinate fluor albus, and fometimes even fterility itfelf; and, in relaxed habits difpofed to mifcarriage, when every other

means

Regimen. means has failed, the cold bath has done considerable service: the practice may safely be continued for some months after conception, when it has been early begun, or when the patient has been accustomed to it. Such a shock will, however, act very differently on different systems: hence it is an expedient by no means to be indiscriminately used in the pregnant state.

Abortions that happen in early gestation, and that come on suddenly without any presaging sign, if ever they are to be prevented, it can only be done by avoiding all occasional causes, by counteracting morbific dispositions, and by confinement to a horizontal posture, for some time before, and till the critical period be over.

When a venereal taint in the parents is suspected to be the cause either of abortion or the death of the fœtus, the like accident can only be prevented by putting both parties on a mercurial course.

Pregnant women require a free pure air; their amusement should often be varied; their company should be agreeable and cheerful; their exercise should be moderate, and suited to their inclination, constitution, and the season; they should avoid crowds, confinement, travelling over rough roads in a carriage, or being exposed to sea-voyages. Riding a-horseback should also be practised with great caution, that disagreeable objects may be shunned, and shocks of every kind prevented. For this reason, when riding is judged proper, the woman should be a courageous rider; she should never ride without somebody being in company; the horse should be tame and well trained; the road should be smooth as well as private; and the exercise should be gentle and easy, and never carried the length of fatigue. Women should, with the utmost care, guard against confining the breasts or belly; early recourse should be had to jumps, and they should keep themselves as loose and easy as possible through the whole term of utero-gestation. An open belly is necessary and important in the pregnant state; it keeps the stomach in good condition, prevents cholics and other complaints that may terminate in miscarriage. When the abdomen is pendulous towards the latter months, a gentle support by proper bandage will prove useful; and the woman, when fatigued, should occasionally, through the day, indulge in rest on a bed or couch.

PART II. OF LABOURS.

LABOURS are divided into three classes: *natural*, *laborious*, and *preternatural*.

In whatever manner the head of the child presents, where the delivery at full time is performed by nature, the labour is with great propriety called *natural;* when the birth is protracted beyond the usual time, or cannot be accomplished without extraordinary assistance, it is deemed *laborious;* and *preternatural*, when any other part but the head presents.

CHAP I. *Natural Labour.*

BY whatever power the uterus is enlarged, when any further increase is prevented, a stimulus to contraction must ensue; by this means an uneasy sensation is excited, which must, in the woman, produce an effort to procure relief: and thus arise the true labour-pains, which at first are slight and of short duration, a considerable remission intervening: the periods of recurrence soon become more frequent; the pains acquire an increased force, producing more and more change on the os uteri; which, yielding to the impelling cause, gradually opens and expands; till at length it becomes completely dilated, the membranes protruded and ruptured, and the child, by the expulsive force of the uterus, assisted by that of the diaphragm and abdominal muscles, is thus pushed along and delivered.

The symptoms of approaching labour are, The subsiding of the abdominal tumor: hence a discharge of mucus from the vagina, sometimes tinged with blood; incontinency, or suppression of urine; tenesmus; pains of the belly, loins, and about the region of the pubes; restlesness, hot and cold fits, &c.

Spurious pains are to be carefully distinguished from those of genuine labour. The former arise from the stretching of the uterus and its pressure on the neighbouring parts, or from costiveness; and are to be distinguished from the latter by the following symptoms: They are most troublesome towards the evening, increase in the night, and abate through the day; they are more trifling and irregular than true uterine pains; the uterine orifice is not affected; and there is no increased flow of mucus from the parts.

True pains begin about the region of the kidneys, strike forward towards the pubes, and down the thighs: they return at regular periods: there is a copious discharge of mucus from the vagina; the os uteri gradually opens, and can be felt to dilate in time of a pain; while the membraneous bag, in a tense state, forcibly pushes against the finger.

The event of labours is so precarious, that no certain judgment can be formed from almost any symptoms, till the labour itself be considerably advanced. A prognosis in general is chiefly to be formed from the age, state of health, and temperament of the patient; from the force, duration, and recurrence of the pains; and from their effect on the uterine orifice; from the time of the rupture of the membranes; from the general make and form of the woman, but, in particular, of that of the pelvis; from the bulk and position of the child, &c.

With regard to the method of delivery, and position of the woman, this has been different at different ages, and in different countries: the chief thing, however, is to guard against cold and fatigue, observing that the woman be placed in the most favourable posture for supporting the back, for the action of the abdominal muscles, &c. and most convenient for the necessary assistants: till the labour is considerably advanced, she may be indulged in whatever posture is most agreeable; after which the bed or couch is the most proper.

With regard to assistance in natural parturition, the accoucheur

Natural Labour.

accoucheur for the moſt part has little to do, till the membranes are ruptured, and the head in perinæo. In time of labour, the woman ſhould be kept very cool, and every means of being overheated ſhould be avoided. She ſhould be put to bed in proper time, placed on her ſide or back, with her head and ſhoulders a little raiſed, a cloth tied to the bed-poſt, or held by an aſſiſtant, to ſupport her hands in time of pain, and her feet reſting againſt a foot-board; her knees ſhould be drawn up towards the belly, and a folded pillow put between them. All efforts to preſs or ſtrain, except what nature excites, are improper, hurtful, and ſhould be avoided: the membranes, if poſſible, ought not to be ruptured till they almoſt protrude at the os externum; the perinæum muſt be lubricated when formed into a tumor, and carefully ſupported while overſtretched; for this purpoſe, a cloth ſmoothly folded ſhould be applied over the part, to enable the accoucheur to have a firmer hold. This is an important part of his office; and muſt be attended to with the ſtricteſt care. From the time this protruſion begins to form till the head of the child be completely delivered, the perinæum muſt be carefully preſerved by the palm of the hand firmly applied againſt it, which ſhould be carried backwards in a direction towards the anus, and kept ſo during every pain. Thus the miſerable conſequences will be prevented to which the neglect of this preſſure expoſes: for by this ſupport the overſtretching of the perinæum will be greatly leſſened, the parts will dilate gently and gradually, the vertex will eaſily ſlip from under the pubes, and the fore-head will riſe from under the perinæum in a ſafe, ſlow, and gentle manner. The perinæum muſt now be releaſed, by cautiouſly ſliding it over the face and chin of the child; and this ought to be made further ſure of, by paſſing a finger under it round and round. After the head has thus mechanically advanced through the pelvis and vagina, a pain or two muſt be waited for, when in like manner the body will follow; nothing more being neceſſary than to ſupport the child while it is gradually puſhed forwards by the expulſive force of the natural pains.

When the child has cried, and the change in the circulation freely taken place, the funis umbilicalis muſt be tied and divided, the infant muſt be wrapped in a warm receiver, and given to the nurſe to be waſhed and dreſſed.

The parts of the woman muſt now be gently wiped, a warm ſoft cloth muſt be applied, and a proper time waited for the ſeparation of the placenta.

This is alſo the work of nature, and ſeldom requires more force to bring it along than if it lay entirely looſe within the cavity of the uterus. Thus, in pulling, no greater force ſhould be employed than is juſt ſufficient to put the funis on the ſtretch: for if it is already ſeparated, no violence is neceſſary to extract it; and if the adheſion is very firm, all violent efforts are improper, and often followed with moſt dangerous conſequences. Its advancing is known by the contraction of the uterus, and ſhifting of the abdominal tumor, and by the lengthening of the cord By the ſpontaneous contraction of the uterus, this ſeparation is effected; the expulſion will be ſlower or more expeditious, according to the ſtate and condition of the woman, according to the number of children ſhe has born, and according to the duration or violence of the labour; it is eaſier and ſooner ſeparated in a firſt birth, when the woman is in good health, and when the labour has been properly managed. In moſt caſes, this ſeparation is accompliſhed within half an hour after the delivery of the child. It adheres moſt firmly after premature births, when the woman has been ſickly during pregnancy, where the labour has been tedious and difficult, or when haſty attempts have been made to extract it. A finger, or finger and thumb, guided by the funis, and introduced within the vagina, to bring down the edge, will remove any difficulty occaſioned by the centre or bulky part paſſing the uterine or vaginal orifice.

When it becomes neceſſary to employ force in extracting the placenta, which is never requiſite but in caſes of flooding, when the woman has been in bad health during pregnancy, when ſhe has ſuffered much in time of labour, or when the ſtring has been torn from it (though the firſt of theſe caſes is perhaps the only one wherein the practice is abſolutely proper), the method of doing it is as follows: In ordinary caſes, the woman ſhould be laid on her back or ſide; but when the belly is pendulous, or when the placenta is attached to the fundus uteri, ſhe muſt be placed on her knees, which is the moſt convenient poſture.

The accoucheur, though with a certain degree of courage, yet with the utmoſt poſſible tenderneſs, muſt then paſs his hand well lubricated through the vagina into the uterus, and feel for the convex body of the after-birth; if the chord be entire, this will direct him; if not, he muſt feel for the looſe membranes at the edge of the cake, and muſt not be deceived by coagula of blood that lie in the way; if the uterus be conſtricted in the middle like a ſand-glaſs, a circumſtance that ſometimes, though rarely, occurs, this muſt be overcome by a gradual dilatation with one finger after another, till the whole hand in a conical manner can ſafely be paſſed. He muſt not content himſelf with feeling a part; he ſhould be able to move his fingers round the whole body of the cake; the adheſion muſt be ſeparated very gradually, in a direction from the ſides round and round. The placenta is diſtinguiſhed from the uterus, as well by its ſoftneſs as by its convex puckered feel. This convexity increaſes in the ſame proportion as the uterus contracts: hence the middle part or centre of the placenta is firſt detached; and if the edges are carefully ſeparated, by gently paſſing the fingers behind, the whole body becomes looſe and diſengaged, which muſt now be brought along with great caution, that no part be left behind, and that no injury be done to the woman in making the extraction.

Though bad conſequences ſometimes follow from the retention of the placenta, yet it is much to be queſtioned, if theſe are not leſs to be dreaded than the dangerous floodings, convulſions, deliquia, inflammation of the uterus, fever, &c. that may be induced from the prepoſterous practice of paſſing the hand to make the extraction: and would it not in general be better to confine the practice of introducing the hand, to caſes of uterine hemorrhagies only? Where the adheſion is ſo firm as to require force, or where its place of attachment is out of the reach of the finger, by which, for the moſt part, the edge may be brought

Difficult Labour.

down, is it not by far the safest and the most rational practice universally to trust to nature? Should the mouth or body of the uterus become constricted before the separation is effected, no matter; little is to be dreaded: it will afterwards kindly dilate; and the separation and expulsion will spontaneously be accomplished with as much safety as in other animals, where no force is ever used. Let every candid practitioner acknowledge, that for one instance where the retention of the placenta has been attended with dangerous consequences, a precipitate or forcible extraction has proved fatal to hundreds.

After the delivery of child and placenta, the woman must rest a few minutes; her strength and spirits may be recruited by some light nourishing cordial: the wet cloths, &c. must then be removed; the bed must be properly shifted and adjusted; and a gentle compression must be made on the abdomen.

During lying-in, the woman should avoid company and noise; her dress and bed-linens should be often changed; she should avoid every means of being overheated; and with regard to her diet, it should, for the first week at least, be very light and of easy digestion.

CHAP. II. *Laborious or difficult Labour.*

Hamilton's Outlines.

WHEN the birth is protracted beyond the ordinary time, or when the child's head, though naturally presenting, cannot be brought forwards without assistance, the labour is accounted difficult or laborious.

Though the causes of laborious births are various and complicated, they may in general be considered as depending,

I. On the mother.
II. On the child.
III. On the secundines.

I. The birth may be protracted, or the labour-pains interrupted, by,
  (1.) Debility in the mother, arising,
    a From disease, *viz.*
      1. Flooding.
      2. Epileptic fits.
      3. Crampish spasms.
      4. Lowness and faintishness.
      5. Inflammatory diathesis.
      6. Colic.
      7. Nauseating sickness and vomiting.
      8. Hectic or consumptive habit.
    b From passions of the mind.
    c From mismanagement in time of labour.
  (2.) Local complaints in the parts, or their neighbourhood, *viz.*
    a In the bones, occasioning narrowness and distortion.
    b In the soft parts, *viz.*
      1. Dryness and constriction of the vagina.
      2. Thickness and rigidity of the os tincæ.
      3. Scirrhous or polypous tumors about these parts
      4. Accumulated fæces in the intestines.
      5. Stone in the urethra.
      6. Prolapsus of the uterus, vagina, and rectum.
      7. Obliquity of the uterus.

Difficult Labour.

II. Difficulties also arise on the part of the child, *viz.*
  1. From the bulk and ossification of the head.
  2. The situation in which the head presents.
  3. Large broad shoulders, or their transverse descent through the pelvis.
III. The secundines, *viz.*
  1. The rigidity of the membranes, and the contrary.
  2. Too great a quantity of water.
  3. The funis umbilicalis too long or too short.
  4. The prolapsus of the funis before the child's head: and,
  5. The attachment of the placenta towards the cervix or os uteri.

The treatment of laborious births requires a very nice and careful attention to the condition of the patient and other circumstances, from whence only we can judge when assistance becomes requisite, and how it may be applied to the best advantage. That pain and misery is the unavoidable and inseparable attendant of child bearing, though dealt out in different proportions to different subjects, the testimony of all nations, and all ages, as well as daily experience, bear witness: nor is the easiest labour altogether exempted from pain, even under the most favourable circumstances. The delivery, however, promises to be safe and easy, when the woman is of proper age, in good health, the child presenting right, and the pelvis well proportioned; but the force of the natural pains may be interrupted, and of consequence labour be retarded, from,

I. Debility in the mother, arising from
  a Disease. This may appear under various forms; as,

1st, A flooding. Which is very alarming, even along with labour-pains: though less so in this case than when at a distance from full time; because as the labour-pains increase, the hemorrhagy very generally abates: or if not, breaking the membranes when the aperture of the os uteri is sufficient to admit the hand, seldom fails to produce that effect. The woman in this case must be kept cool. Opiates must be administered; she must be comforted with the best assurances of a happy delivery; and the natural pains must be waited for.

But if the hemorrhagy proceeds from a separation of the placenta, attached towards the cervix or orificium uteri; in this unhappy case, the whole body of the cake may be completely separated before the aperture of the uterus be sufficient for allowing the head to pass; and the deluge may be so sudden and impetuous, that the woman will sink immediately under it. Breaking the membranes, and making the delivery, either by turning the child, or extracting with the forceps or crotchet, according to circumstances, with as much expedition as is consistent with the mother's safety, is the only expedient by which the threatening catastrophe may be prevented.

2dly, Epileptic fits may in like manner retard labour, and endanger the life of the mother. If the child is not thrown off by a few fits, which is often the case, the delivery should be effected as soon as possible.

Difficult Labour.

3dly, Crampifh fpafms in the thighs, legs, rarely in the belly, are very troublefome. They depend on the preffure of the head on the nerves as it paffes through the pelvis, and can only be removed by delivery; which, as thefe pains are feldom if ever attended with danger, is not to be forced on this account. Breaking the membranes will fometimes remove them.

4thly, Lownefs and faintifhnefs often occur, and frequently prove the caufe of protracted labour.

No general rules with regard to the management of flow labour can be recommended. The mode of treatment, where fo many circumftances may occur, muft be fuited to the condition of the patient, as every particular cafe will in fome meafure require a different management. Much depends on the prudence and judgment of the attentive practitioner. For inftance, when the woman is nervous, low-fpirited, or weakly, from whatever caufe, in general her ftrength muft be fupported: fhe muft not be put on labour too early; fhe muft avoid heat, fatigue, and every means of exhaufting her ftrength or fpirits. When fhe is reftlefs, or the pains trifling and unprofitable, opiates are particularly indicated; they remove fpurious or grinding pains, recruit the fpirits, procure reft, and amufe time. Little elfe for the moft part is to be done. If the uterus once begins to dilate, though the dilatation goes on flowly, it is by much the beft and fafeft practice to do nothing but regulate the management as above. The pains at laft will become ftrong and forcing; and the delivery, even where the patient has been very weakly, will often have a fafe and happy termination. In thefe tedious labours, if the ftrength of the woman be properly fupported, every thing almoft is to be expected from nature. Forcible means fhould be the laft refource.

5thly, Inflammatory diathefis, in young fubjects of ftrong rigid fibres and plethoric habits, muft be obviated by venfection, an open belly, and cooling regimen.

6thly, Colic.—Many women have fevere attacks of this difeafe immediately before the labour-pains come on; the reafon of which is fufficiently obvious: the belly, which formerly rofe fo high that the fundus of the womb preffed againft the pit of the ftomach, afterwards fubfiding, by the child's finking to the lower part of the womb, and the oval of the head being applied to the oval of the bafin, the contents of the inteftines will be forced lower and lower, and the ftrait gut will be diftended. Hence colic-pains, irritation, and uneafinefs, a frequent defire to go to ftool, or frequent loofe ftools, generally enfue. The beft palliative remedy is to inject emollient glyfters repeatedly till the bowels be entirely emptied. Although fome degree of purging fhould attend the tenefmus, it will be neceffary to wafh the ftrait gut, by the ufe of one or more glyfters. The irritating caufe being in this way removed, an opiate, if no inflammatory heat or fever prevents, may be afterwards given with advantage.

7thly, Naufeating ficknefs, with vomiting.—When thefe fymptoms occur, warm water or chamomile-tea muft be drunk freely. Sicknefs and vomiting happen in fome degree in the eafieft labours. Sometimes they proceed from a difordered ftate of the ftomach; but in general are to be accounted for from the well-known fympathy of the womb with the ftomach; and accompany the ftretching of the os uteri only.

8thly, Hectic or confumptive habit.—It is a melancholy thing to attend a labouring woman in this ftate. The pains are weak and trifling; fhe cannot force much down; and fhe is feeble, and liable to faint when the pain goes off. But however apparently exhaufted, the progrefs of labour goes on, in moft cafes, much better than could be well expected. The orifice of the womb gives little refiftance to the force of the pains, weak and trifling as they are; the parts are foft and lax, and foon ftretch in fuch a manner, that, if there be no fault in the pelvis, the child readily obtains a paffage.

Here little is to be done but fupplying the patient from time to time with light nourifhment; with cordials that do not heat: and keeping up a free circulation of cool air all around her: for this purpofe the curtains fhould be quite drawn afide, doors and windows widely opened; and fhe fhould be placed in a pofition with her head and breaft well raifed, that an eafy refpiration may be promoted. Hectic women under proper management rarely fink immediately after delivery; they generally furvive a week or longer, tho' they feldom outlive the month.

b. Paffions of the mind. Any piece of news in which the patient, her family, or relations, are interefted, fhould be carefully concealed, as well as every thing that tends in general to affect the paffions; as labour may not only be interrupted from this caufe, but the moft dangerous fymptoms, as floodings, convulfions, deliquia, and fatal fyncope, may be induced.

c. From mifmanagement in time of labour often arifes debility; fo that the patient's ftrength is exhaufted, the pains at length entirely ceafe, and the head of the child remains locked in the pelvis, merely from want of force or pain to pufh it forwards. In all cafes where the labour has the appearance of being tedious, the woman's patience muft, as much as poffible, be fupported. During the grinding pains, fhe muft be kept cool and quiet: opiates may be exhibited to pafs the time, till the forcing throes enfue, when fhe will acquire refolution, the parts will dilate kindly, and the labour end happily; whereas, if fhe confiders herfelf in labour from the earlieft appearance of grinding pains, fhe is frightened at the length of time, and her patience runs out. Slow lingering labours happen chiefly to elderly women having a rigidity in the parts, to nervous fubjects, and to fuch as have been weakly during pregnancy. It is of great confequence, and the advice cannot be too much inculcated, to avoid exhaufting the woman's ftrength too much at firft.

2. *Local complaints in the parts, or their neighbourhood.*

a. Narrownefs or diftortion of the bones of the pelvis. Where there is any material defect in this cavity, a fuperficial knowledge of the form and ftructure of the parts will enable us to judge. If, from the figure of the woman's body, there is reafon to fufpect a faulty pelvis; if the fpine is twifted, the legs crooked, the breaft-bone raifed, or the cheft narrow; whether the pelvis be affected or not, fhe will require a particular management; for the conftitution of fuch women is weak

Difficult Labour.

weak and feeble, and they cannot be much confined to bed on account of their breathing. We can never be abfolutely certain of a diftortion of the pelvis (except when the diftortion is confined to the inferior aperture) till the uterine orifice is confiderably dilated. After this time, if the pains are ftrong and forcible, and the head of the child makes no advance, a narrow pelvis or large head is to be fufpected. The pelvis may be faulty at the brim, bottom, or in the cavity or capacity. The firft of thefe, which moft frequently occurs, is the moft difficult to be difcovered. The fecond can be readily perceived by the touch: for we can feel the defects in the fhape of the os facrum and coccyx, in the pofition of the ifchia, and in the bending of the pubes; and where the diftortion is fo general, that the whole cavity of the pelvis is affected, the fhape of the woman's body, the flow progrefs of the labour, and the ftate of the parts to the touch, will afford fufficient information.

In the firft cafe, we can only know the diftortion by the fymptoms; for we fhould not attempt to introduce the hand till the mouth of the womb be dilated: it is afterwards unneceffary; for we know that the pelvis is too fmall, or the head too large, by its not advancing in proportion to the pains, and by feeling a fharp ridge like a fow's back on the top of the child's head, which is occafioned by the bones rifing over each other in confequence of the preffure.

How long nature, in fuch circumftances, can fupport the conflict, it is difficult to fay. It is fufficient to obferve, that when things are properly prepared for the advance of the child, when the firft ftage of the labour is accomplifhed, but its progrefs is then fufpended, it is of little confequence to the midwife whether the obftacle is to be referred to the child or to the mother; and a man-midwife ought to be immediately called in.

If the patient's ftrength declines; if the head, from being locked in the bones of the pelvis, begins to fwell, and the parts of the woman to be affected with tumefaction and inflammation; nature, in this cafe, feems infufficient, and it will be dangerous longer to delay the proper means of making the delivery; as mother, or child, or both, may fall a victim to our neglect. We muft not, however, allow ourfelves to be impofed on, either by the impatience of the diftreffed mother, or by the clamours of the officious impertinents about her. In affording that affiftance we are able to give, we are only to be directed by the fymptoms of the cafe: we muft remember, that the gentleft affiftance our hands or inftruments in laborious births can afford, is always attended with hazard and rifk; that if inftruments be applied too early, nature will be thus interrupted in her work, and the moft fatal confequences may enfue; and that if affiftance be delayed too long, the mother may die undelivered: we ought, however, to be informed, that the former practice of having too early recourfe to forcible means, where, in time, nature unaffifted might do her bufinefs, has proved by far more fatal than the latter. We ought therefore carefully to confider the general hiftory of the patient, and particular circumftances of the cafe, that we may hit the proper time of making the delivery; which, in thefe laborious labours, is exceedingly difficult to determine; yet is a matter of the utmoft importance, as there is always one, often two or more lives at ftake, and the accoucheur is accountable for the confequences of his mifconduct or neglect.

b. The fault may be in the foft parts: as,

1. Drynefs and conftriction of the vagina. Here all ftretching and fcooping is to be avoided. The natural moifture is to be fupplied by lubricating with pomatum or butter, or by throwing up injections of warm oil; the parts are likewife to be relaxed by the application of warm ftupes, or by warm fteams directed to them.

2. Thicknefs and rigidity of the os tincæ. This happens chiefly in women well advanced in life, where the parts open more flowly, and the labour generally proves more tedious. Here alfo little is to be done but waiting on with patience, comforting the woman as well as poffible, and giving an opiate from time to time. The parts may be relaxed with butter or pomatum, by throwing into the vagina injections of warm oil, or by the application of warm ftupes to the os externum. Every forcible attempt to open or ftretch the uterus, as fome authors prefume to advife, is apt to induce inflammation and its confequences, and to interrupt the natural pains: it is therefore univerfally the fafeft practice to truft in every cafe to thefe; though tedious, or even violent, the labour for the moft part will end more happily, and the woman recover better, than if force had been employed.

3. Polypous tumors, &c.—There is feldom occafion, in cafe of cicatrices in the vagina, to dilate with the fcalpel, to remove polypous tumors by excifion, or to cut upon and extract a ftone from the urethra in time of labour. But if circumftances are urgent, fuch expedients are fafe and practicable, and warranted by many precedents.

4. Accumulated fæces in the inteftines ought always to be removed by repeated emollient glyfters on the firft appearance of approaching labour.

5. A ftone in the urethra, if it cannot be pufhed back, muft be cut upon and extracted, as already advifed.

6. Prolapfus of the uterus may happen even at full time, in a pelvis too wide in all its dimenfions; for which, however, nothing can be done but to fupport the uterus in time of a pain, that the ftretching of the parts may be gradual. Prolapfi of the vagina and rectum muft be reduced at the remiffion of the pain, and a return by gentle preffure muft be prevented.

7. Obliquity of the uterus, though a favourite theory of fome authors, never happens in fuch a dergee as to influence delivery, except in the cafe of a pendulous abdomen, or where it depends on the make or diftortion of the pelvis. The firft of thefe, though it may, by throwing the child's head over the pubes, occafion perhaps fome little delay, will feldom prove any material obftacle to the progrefs of the labour.

II. The protraction of labour may depend on the child, and may arife from,

1ft, the bulk or offification of the head.

There may be either a natural difproportion between the head and body, or the fwelling may be occafioned by a putrid emphyfema in confequence of the child's death, or the enlargement may proceed from a hydrocephalus.

Difficult Labour.

cephalus. The firſt of theſe caſes can only be diſcovered by the ſlow progreſs of the labour, when the pains are ſtrong and frequent, the ſoft parts ſufficiently dilated, the woman in good health, and no other apparent cauſe to account for the remora. The ſecond is diſcovered from the hiſtory of the caſe, from the common ſymptoms of a dead child, *viz.* the puffy emphyſematous feel of the preſenting part of the head, and from the ſeparation of the cuticle when touched. Laſtly, the hydrocephalus is diſcovered by the head falling down in the pelvis in a large bulky form, by the bones of the head being ſeparated at conſiderable diſtances, and by a fluctuation evident to the touch. On the whole, however, it may here be obſerved, that the moſt probable or ſuſpicious ſymptoms of the child's death are often deceitful.

From whatever cauſe the head is enlarged, if the difficulty ariſes from this cauſe, and the force of the pains prove inſufficient to puſh the head forwards, recourſe muſt be had to inſtruments; and if the bulk of the head is too large to paſs the diameter of the pelvis, the cranium muſt be opened to diminiſh its ſize, and the brain evacuated previous to the extraction.

2dly, The poſition of the head, which may be ſqueezed into the pelvis in ſuch a manner as not to admit of that compreſſion neceſſary for its paſſing. Such a cauſe of difficulty, however, more ſeldom occurs than many authors have imagined. The raſh and prepoſterous application of inſtruments has, in ſuch caſes, proved the bane of thouſands. Here though the labour will prove more painful and more tedious, yet nature in general, unaſſiſted, will accompliſh her own work with more ſafety to mother and child, than by the intruſion of officious hands. Turning here is always difficult, often dangerous. The ſame obſervation will hold of inſtruments, which ſhould never be employed but when alarming ſymptoms occur: the aſſertion perhaps is not more bold than true, that, in general, the moſt diſadvantageous poſition in which the head can offer is not ſufficient, without ſome other cauſe concurring, either to prevent delivery, or to endanger the life of mother or child ſo much as would be done by the movement of the gentleſt hands. Yet, in ſome caſes, where the woman is weak and exhauſted, and the pains trifling; if the head of the child be large, the bones firm, and the ſutures cloſely connected; or if there be any degree of narrowneſs in the pelvis, a difficult labour is to be expected; and the life of both mother and child will depend on a well-timed and ſkilful application of the ſurgeon's hands.

The unfavourable poſition of the head may be referred to two kinds, which include a conſiderable variety. 1. When the fontanella, or open of the head, preſents inſtead of the vertex. 2. Face caſes.

If no other obſtacle appears but the preſenting of the fontanella, the labour will by proper management generally end well; and much injury may be done by the intruſion of officious hands.

Face-caſes are the moſt difficult and laborious of all kinds of births; and our ſucceſs in theſe will chiefly depend upon a prudent management, by carefully ſupporting the ſtrength of the woman. The varieties of face-caſes are known by the direction of the chin; for the face may preſent, 1. With the chin to the pubes; 2. To the ſacrum; 3. To either ſide. The rule in all theſe caſes is to allow the labour to go on till the face be protruded as far down as poſſible. It is often as difficult and hazardous to puſh back the child, and to bring down the crown or vertex, as to turn the child and deliver it by the feet. Sometimes a ſkilful artiſt may ſucceed in his attempt to alter the poſition, when he has the management of the delivery from the beginning; or, in thoſe caſes where the face is conſiderably advanced in the pelvis, may be able to give aſſiſtance by paſſing a finger or two in the child's mouth, and pulling down the jaw; which leſſens the bulk of the head; or, by preſſing on the chin, to bring it under the arch of the pubes; when the crown getting into the hollow of the os ſacrum, the head will afterwards paſs eaſily.

3dly, The breadth of the ſhoulders, or their tranſverſe deſcent through the pelvis, rarely proves the cauſe of protracted labour. The head is always pretty far advanced before any obſtruction can ariſe from this cauſe; and if the head has already paſſed, in a pain or two the ſhoulders will follow. The ſame reaſoning will alſo apply with regard to the aperture of the uterus itſelf, if the head paſſes freely, in like manner will the ſhoulders; the os uteri rarely, if ever, is capable of contracting upon the neck of the child, and thus preventing the advance of the ſhoulders; and ſhould this prove the caſe, what can we do but wait with patience? After the delivery of the head, if the woman falls into deliquia, or if, after ſeveral pains, the ſhoulders do not follow, and the child's life be in danger from delay, we ſhould naturally be induced to help it forward in the gentleſt manner we are able, by paſſing a finger on each ſide as far at the axilla, and thus gradually pulling along.

III. Laſtly, From the ſecundines, difficulty and danger ſometimes ariſe.

1ſt, The rigidity of the membranes, and the contrary. From the firſt of theſe cauſes, the birth is ſometimes rendered tedious; but as the ſame effect is much oftener produced by the oppoſite cauſe, and the conſequences of the latter are more troubleſome and dangerous than the former, we ſhould always be exceedingly cautious of having recourſe to the common expedient of breaking the membranes, which ought never to be done till we be certain the difficulty depends upon this cauſe; and, even then, the head of the child ſhould be well advanced, and the membranes protruded almoſt as far as the os externum. Many inconveniences ariſe from a premature evacuation of the waters; for thus the parts become dry and rigid, a conſtriction of the os uteri for a time enſues, the pains often either remit or become leſs ſtrong and forcing, though not leſs painful and fatiguing; the dilatation goes on ſo ſlow, and the labour becomes ſo ſevere, that the woman's ſtrength and ſpirits, by the unprofitable labour, are quite overcome and exhauſted; ſo that the head remains confined in the paſſage, merely from want of force of pain to puſh it forwards. The woman in the beginning of labour ſhould therefore be treated with the utmoſt delicacy and gentleneſs. The work of nature is too often ſpoiled by officious hands. She ſhould be ſeldom touched while the membranes are whole, leſt they ſhould be ruptured; and, even when touching is neceſſary, this ſhould only be done when the

Difficult Labour.

the pains begin to remit, and the tenfe membranous bag to relax.

2dly, Too great a quantity of water may prevent the uterus from contracting, and thus weaken the force of the pains. Though this may, however, occafion a delay, it will never be attended with more dangerous confequences; and the fame advice already given will hold equally good in this cafe. that the membranes fhould never be broken till the foft parts be completely dilated; and we are affured that the difficulty or delay proceeds only from this caufe.

3dly, The funis umbilicalis too long. The funis may be faulty from its too great length, or the contrary: thus the extraordinary length, by forming circumvolutions round the child's neck or body, fometimes proves the caufe of protracting the labour. But as this can only happen when the chord is of an uncommon length, there is generally enough left to admit of the exit of the child with fafety; and it is time enough, in general, after the child is born, to flip the noofe over the fhoulders or head: there is feldom occafion to divide the chord in the birth; a practice that may be attended with trouble and hazard.

The practice of introducing a finger in ano, to prefs back the coccyx, or to prevent the head, when it advances, from being retracted by circumvolutions of the chord, is now entirely laid afide; an expedient that can anfwer no end, but that of fretting and bruifing the parts of the mother, and injuring thofe of the child.

Funis too fhort. The funis is fometimes thick and knotty, or preternaturally thickened by difeafe. In this cafe, part of the placenta may be feparated as the child advances through the pelvis, and thus a flooding will enfue; or the funis may be actually ruptured, and occafion the death of the child, if the birth does not quickly follow. Such cafes, however, rarely happen.

An inconvenience, at leaft fully as bad as the former, may arife from the too great length of the funis, though it may depend on other circumftances: *viz*.

4thly, The prolapfus of the funis before the head. In this cafe, the funis, if poffible, fhould be pufhed up above the prefenting part; for, if the labour pains are flow, and the chord becomes cold, or the pulfation in it begins to grow languid, the circulation will thus be interrupted, and the life of the child deftroyed. If the head is far advanced in the pelvis, and the child's life in danger, the delivery may be performed with the forceps. But to pufh up the head, and turn the child with a view to preferve its life, as many author's recommend, is a practice by no means adviseable: we fhould feldom, in this pofition, be enabled to fave the child; and turning under fuch circumftances can never be done but at the immediate hazard of lofing the mother

5thly, Placenta attached towards the cervix or os uteri. This cafe is truly melancholy; for, if the delivery is not fpeedily accomplifhed, the effufion from the uterine veffels will be fo copious and profufe, that the unfortunate woman muft in a very fhort time perifh. On this occafion the delivery muft be conducted in the beft manner the judgment and fkill of the operator can direct, and with as much expedition as the fafety of the mother will admit.

Thus, in moft laborious cafes, provided the woman's ftrength be fupported, the management properly regulated, the natural moifture of the parts when deficient fupplied, manual affiftance very feldom becomes requifite: but as cafes do occur, wherein nature, with all advantages, will fail, and the common methods of relief prove unfuccefsful, recourfe muft be had to more powerful means, while the woman is able to fupport the conflict. In all fuch cafes, the condition of the patient, the ftructure and ftate of the parts, and pofition of the prefenting part of the child, muft very carefully be confidered.

Method of Delivery by Inftruments.

When the powers of nature are infufficient to expel the child, extraordinary affiftance muft be had recourfe to. In laborious births, this is chiefly of two kinds.

I. The head is either extracted as it prefents: or,

II. Its diameter is diminifhed previous to the extraction.

The head may be detained from advancing through the pelvis by all the caufes formerly enumerated.—Thefe are chiefly included in four general ones.

1. Weaknefs in the mother.
2. Narrownefs of the pelvis.
3. The bulk of the head of the child; or,
4. Its difadvantageous pofition.

Whatever is the caufe, when the natural pains begin to remit, and the parts of the woman begin to fwell; when her ftrength declines, her pulfe grows feeble, and there is no profpect of advantage to be gained by delay; meafures muft be taken for affifting the delivery, otherwife both mother and child may perifh from neglect.

As inftruments are never to be employed but in the moft urgent and neceffitous cafes, and exprefsly with a view to preferve the life of mother or child, or both; thofe of a fafe and harmlefs kind fhould always be made trial of, in preference to thofe of a deftructive nature.

Ufe of the Forceps.

The forceps is an inftrument intended to lay hold of the head of the child in laborious births, and to extract it as it prefents. This inftrument, as now improved, in the hands of a prudent and cautious operator, may be employed without doing the leaft injury either to mother or child.

In every obftetrical cafe, wherein manual affiftance becomes neceffary, the contents of rectum and bladder fhould, if poffible, be previoufly emptied.

The membranes alfo fhould be broken, the foft parts completely dilated, and the head of the child as far as poffible advanced, previous to the ufe of any inftrument.

The form and ftructure of the parts of the woman, the fituation and progrefs of the prefenting part of the child, muft at this time be carefully confidered. The concavity of the facrum, for inftance, will determine the progrefs of the labour. The touch of the vertex, fontanella, lambdoidal, or fagittal future, the fore or back

Difficult Labour.

back part of the ear, or some part of the face, will ascertain the true presentation of the child.

The lower the head is advanced in the pelvis, our success with the forceps is the more to be depended on. For when it has proceeded as far as the inferior aperture, by means of this instrument it may be readily relieved: but when the head of the child is confined at the brim, both the application of instruments, and the extraction by this means, are exceedingly difficult and dangerous.

The head may be so firmly wedged in the pelvis, that the forceps can neither be introduced nor fixed without bruising or tearing the parts of the woman: whatever, therefore, insurmountable difficulties occur, either in applying or extracting with the forceps, the life of the mother must not be endangered by fruitless efforts: the head of the child must immediately be opened, and the delivery accomplished without further delay.

In laborious births, the proper forcep-cases may be reduced to two, which include, however, a considerable variety. These are,

I. The smooth part of the cranium.

II. The face, presenting.

The head may present,

1st, Naturally, when low advanced in the pelvis, with the vertex to the pubes, and the forehead or face in the hollow of the sacrum. Or,

2dly, When higher in the pelvis, the vertex may present with the face laterally, the ears to the pubes and sacrum. Or,

3dly, The fontanel may present with the face to the pubes and vertex to the sacrum; or with the vertex to the pubes and face to the sacrum.

1. When the head presents naturally. The woman in this case must be placed on her back a-cross the bed, properly supported; the accoucheur, seated before or in a kneeling posture, after gradually lubricating the perinæum and vagina, must proceed gently to stretch the parts, by passing the hand in a conical manner through the os externum vaginæ, pushing it forwards by the side of the child's head, till it advances as far as an ear, if possible: along this hand he is to guide a blade of the forceps, which with the other hand he introduces in the direction of the line of the pelvis, holding the handle backwards towards the perinæum, and keeping the clam closely applied to the child's head. This must be insinuated very gradually by a kind of wriggling motion, pushing it on till the blade is applied along the side of the head over the ear; he must then gently withdraw the first hand from the pelvis, with which he must secure the handle of the blade of the forceps already introduced, till the other blade be passed along the other hand, in the same slow cautious manner: the handles must then be brought opposite to each other, carefully locked, and, lest they slip in extracting, properly secured by tying a fillet or garter round them; but this must be loosed during the remission of pulling, to prevent the brain from being injured by the pressure The extraction must be made by very slow and gentle degrees, and with one hand only, while the other is employed to guard the perinæum: the motion in pulling should be from blade to blade; the accoucheur must rest from time to time, and, if the pains are not gone, should always in his efforts only co-operate with those of nature. The child and mother will suffer less by going on in this gradual manner than by precipitating the birth, which can never be done but at the risk of destroying both. If, in making the extraction, the forceps slip, they must be cautiously withdrawn blade by blade, and again introduced in the same manner.—When the tumor of the perinæum forms, and the vertex begins to protrude at the os externum, the accoucheur must rise from his seat, raise the handle gently upwards, and, by a half-round turn, bring the hind-head from under the symphysis or arch of the pubes; remembering carefully to guard the perinæum from laceration and its consequences, to which it is now so greatly exposed.

In attempting the introduction of either blade, if it meets with any interruption, it must be as often withdrawn, and pushed up again in a proper direction, till every difficulty be surmounted; and if, from the smallness or contriction of the parts, the introduction of the second blade shall seem impracticable, the former one must be withdrawn, and the latter must be first introduced.

2. The vertex may present with the face laterally in the pelvis. It is always difficult to apply the forceps till the bulky part of the head has passed the brim; and here it is not only difficult to the operator, but extremely hazardous to the patient, to introduce this instrument till the ear of the child has got under the pubes. When the ears thus present to pubes and sacrum, the woman should be placed on her side or knees; the most difficult blade of the forceps should be first applied, which is the one under the pubes; when both are passed, and properly secured, the patient should again be turned to her back, before the operator attempts to extract, and the head in this case (as the quarter-turn can seldom be made with safety) should be delivered in the manner wherein it presents; because, when confined any time in the passage, its figure is altered by the overlapping of the bones, in such a manner that it passes along, in general, with far less difficulty than to attempt to push up and make the mechanical turns; a work often altogether impracticable, by which contusion or laceration of the parts of the woman, and the most fatal consequences, may be occasioned. The handles of the forceps must here particularly be well pressed backwards towards the perinæum, that the clams may humour the curvature and intrusion of the sacrum, and accommodate themselves to the form of the child's head.

This is a case wherein the forceps often fail; if so, they will sometimes succeed by varying the mode of application, and fixing them over the forehead and occiput; if this method fails also, the size of the head must be diminished, and the extraction made with the blunt hook or crotchet.

3. The fontanella may present with the face to the pubes. This is the most common of the fontanel cases; though sometimes the face is lateral in the pelvis, sometimes diagonal, and sometimes it is turned to the sacrum. The true position is ascertained by the direction of the fontanel, and that of the ear. Here, as in other laborious births, nature should be intrusted as long as we dare. The head does not always de-

Difficult Labour.

fcend mechanically through the capacity of the pelvis, as fome practitioners have fuppofed; nor will the deviation from its ordinary mode of defcent always of itfelf influence the delivery, at leaft very rarely in fuch a manner as to require extraordinary affiftance. In whatever manner the head prefents, when it is fituated high in the pelvis, the delivery cannot be effected without difficulty or hazard; in fuch circumftances, the application of the forceps will frequently baffle the utmoft efforts of the accoucheur, and the confequences of fuch attempts may prove fatal to mother and child.

When extreme weaknefs in the mother, floodings, convulfions, or other urgent fymptoms, render it neceffary to force the delivery, whether the face be to pubes or facrum, the forceps may be applied along the ears, in the fame manner as directed in a natural labour; and the head, for the reafons already given, fhould be brought along in the manner it prefents: the extraction fhould be made with great deliberation, that the parts of the woman may have time to ftretch; the perinæum muft be carefully fupported; the forceps muft be gently releafed, when the head is delivered; and the reft of the delivery conducted as in a natural labour.

In this cafe, when fituated high in the pelvis, the fontanel prefenting, and the face either to pubes or facrum, the long axis of the head interfects the fhort diameter of the pelvis, and very often, though the forceps be applied, and a firm hold of the head be obtained, it is not poffible to bring it along with all the force we dare exert. If this method therefore fails, the common forceps fhould be cautioufly withdrawn, and the long ones applied, if poffible, over the forehead and occiput, when the fize of the head, by the compreffion it fuffers in paffing along, being perhaps fomewhat diminifhed, the extraction will be fuccefsfully performed. This method alfo failing, previous to the operation of embryotomy, Dr Leak's forceps, with the third blade, may be had recourfe to. But of this little can be faid with confidence, till the inftrument has been more generally employed. From the difficulty of fucceeding in the application of the common forceps, it may, *à priori*, be concluded, that the introduction of a third blade, even in the hands of an expert practitioner, however ingenious the invention, is an expedient not eafily to be put in practice. Neither is Roonhuyfe's lever, or a blade of the forceps paffed up between the pubes and fore-head or hindhead of the child, in order to procure the delivery of the head, to be recommended in fuch cafes: however fome have boafted of its fuccefs, it is an inftrument that may do much mifchief; and few practitioners can ufe it with fafety.

II. *Face prefenting.*—Of laborious births, face-cafes, as we have already obferved, are the moft difficult and the moft dangerous. From its length, roughnefs, and inequality, the face muft occafion greater pain; and from the folidity of the bones, it muft yield to the propelling force with much more difficulty, than the fmooth moveable body of the cranium. Face-cafes are the moft troublefome that occur in the practice of midwifery, and in which the moft expert practitioners may be foiled in their attempts; and thefe attempts, if too early exerted, will be followed in many inftances with fatal confequences. Whatever way the face prefents, it fhould be allowed to advance as low as poffible in the pelvis; by which means the accefs will be more eafy, and the pofition, for the application of inftruments, more favourable. In this aukward fituation, much mifchief may be done by rafhnefs; whereas, if time be allowed, and the patient be properly fupported, the delivery will generally end well.

The face may prefent with,

1. The chin to the pubes.
2. to the facrum.
3. laterally.

From the difficulty of applying inftruments in thefe cafes, fome authors recommend, as an univerfal practice, to turn the child, and deliver by the feet. But this in general is a dangerous practice, and feldom or never advifeable, except when the membranes remain entire, till the os uteri is completely dilated, and the head continues loofe about the brim of the pelvis; and even then the propriety of the practice is doubtful; becaufe if the head is fmall, or the pelvis be well proportioned, the face will defcend without much difficulty; and if otherwife, befides the rifk in attempting to turn, the child may be loft from the preffure of the chord, or the difficulty of extracting the head after the delivery of the body.

When affiftance becomes neceffary, the beft practice in face-cafes is the following: Having placed the patient in a convenient pofture, let the accoucheur in the gentleft manner pafs his hand within the pelvis; and, during the remiffion of pain only, endeavour to raife the head of the child, fo that he may pufh up the fhoulders entirely above the brim of the pelvis, and thus change the pofition of the face: by this means, if fuccefsful, he will be able to reduce the firft of thefe cafes, fo as to make the fontanel prefent with the face to the pubes; he will reduce the fecond fo as to bring down the vertex, with the face to the facrum; and the third he will reduce to a vertex cafe, with the face lateral. The delivery may be afterwards trufted to nature; which failing, there is eafier accefs for the application of inftruments to make the extraction, as already directed. The fuccefs, however, of the accoucheur, in altering the pofition of the head, by pufhing it up, will entirely depend on the time he is called; for, fhould the head be firmly wedged in the pelvis, no force he dares employ will be fufficient to alter the pofture.

If therefore every attempt to reduce the face, and make the vertex or fontanel prefent, fhall prove unfuccefsful, and fymptoms are urgent, the forceps muft be applied over the ears of the child, and the extraction performed in the beft manner the operator is able. And, failing thefe, immediate recourfe muft be had to the crotchet.

1. In the firft cafe, previous to the introduction of the forceps, the chin, if poffible, fhould be advanced below the pubes.

2. In the fecond, the chin fhould be advanced to the inferior part of the facrum. And,

3. In the third, the chin fhould be as low as the hinder part of the tuber ifchii: and although in general the head is to be extracted as it prefents, if the operator meets with confiderable refiftance, it muft be gently pufhed up and turned with the chin, either laterally,

terally, below the pubes, or into the hollow of the facrum, according to the particular circumftances of the cafe, and in a direction beft accommodated to the form and diameter of the pelvis.

Ufe of the Sciffars, Crotchet, and Blunt Hook.

When the head of the child, from its fize, unfavourable pofition, or from a fault in the pelvis, cannot be protruded by the force of natural pains, nor extracted by the forceps, recourfe muft be had to more violent means, and the life of the child muft be deftroyed in order to preferve that of the mother. This operation was by the ancients called *embryotomy*.

When the head, from its extraordinary bulk, is detained at the brim of the pelvis; on evacuating the contents, the bones of the cranium immediately collapfe, and the head is afterwards propelled by the force of the labour pains; failing which only, the extraction muft be made with the blunt-hook or crotchet.

The unfavourable pofition of the head is of itfelf a caufe infufficient to juftify the ufe of deftructive inftruments, which ought never to be employed but in extreme cafes, after every milder method has failed. From the difficult accefs to the cranium in order to make a perforation and evacuate the brain, a face-cafe makes a very troublefome and dangerous crotchet one. Very luckily, in narrow pelvifes, the face rarely prefents, and very feldom advances far in that direction; at other times, the pofition may be fo altered, that the crown, the back of the ear, or fome other part of the cranium, can be reached; otherwife the crotchet muft be fixed in the mouth, orbit of the eye, &c. and the head brought along in that direction, till the fciffars can be employed to open the fkull.

But the grand caufe of difficult labour is, the narrownefs or diftortion of the pelvis. For when, at the brim, inftead of four inches and a quarter from pubes to facrum, it meafures no more than one and a half, one and three-fourths, two, or two inches and one-fourth, the ufe of inftruments becomes abfolutely requifite, and very frequently in thofe of two inches and one-half, and three inches; or when the diameters through the capacity, or at the inferior aperture, are retrenched in the fame proportion, difficulties will in like manner arife, and the delivery, except the labour be premature, or the child of a fmall fize, cannot be accomplifhed without the affiftance of deftructive inftruments.

We judge of the form of the woman; by the progrefs of the labour; by the touch. When the fault is at the inferior aperture, the touch is pretty decifive; *e. g.* if a hump is felt in the os facrum inftead of a concavity; if the coccyx is angulated; if the fymphyfis pubis projects inwards in form of an acute angle; if the tuberofities of the ifchia approach too near each other: or the one tuber be higher than the other; fuch appearances are infallible marks of a diftorted pelvis. But when the narrownefs is confined to the brim, this is only to be difcovered by the introduction of the hand within the pelvis: the projection of the lumbar vertebræ over the facrum, is a fpecies of narrow pelvis that moft frequently occurs in practice. In this cafe, the child's head, by the preffure it fuftains between the pubes and facrum, is moulded into a conical or fugar-loaf form, the parietal bones are fqueezed together, over-lapping one another, and will be felt to the touch when the labour is advanced, like an acute ridge, fomething in the form of a fow's back.

Inftead of the complicated inftrumental apparatus invented by the ancients, fuch as fcrews, hooks, &c. for fixing in, laying hold of, and extracting the head, as it prefented, an operation in many cafes difficult and dangerous, when the head was bulky or the pelvis narrow, as the woman frequently loft her life in the attempt; the practice of diminifhing the fize of the head, by opening the cranium and evacuating the brain, previous to the extraction, is a modern improvement, and an important one: the inftruments for this purpofe confift fimply of a pair of long fciffars, a fharp curved crotchet, and a blunt hook: thefe are preferable to every other, whether of ancient or modern conftruction.

When the accoucheur is under the difagreeable neceffity of deftroying the child to preferve the mother, fhe muft be laid in the fame pofition as already advifed for the application of the forceps; and the fame rules, recommended for the one operation, will in general apply to the other.

Thus, in the narroweft pelvis that occurs, previous to opening the cranium, the foft parts fhould be completely dilated, and the head of the child fhould be fixed fteadily in the pelvis and advanced as far as poffible; for while the head is high and loofe above the brim, the application of inftruments is very difficult as well as hazardous.

The long fciffars muft be cautioufly introduced into the vagina, directed by the hand of the accoucheur; the points muft be carefully guarded, till they prefs againft the cranium of the child, which they muft be made to perforate with a boring kind of motion, till they are pufhed on as far as the refts; they muft then be opened fully, carefully re-fhut, half turned, and again widely opened, fo as to make a crucial hole in the fkull. They muft afterwards be pufhed beyond the refts, opened diagonally again and again, in fuch a manner as to tear and break to pieces the bones of the cranium; they muft then be fhut with great care; and withdrawn along the hand, in the fame cautious manner as they were introduced, left they fhould bruife or tear the uterus, vagina, or any other part of the woman. After a free opening in the cranium has thus been made, the brain muft be fcooped out with the fingers or blunt-hook, and the loofe fharp pieces of bone muft be carefully feparated and removed, that no part of the woman be tore while the head is extracting. The teguments of the fcalp fhould now be brought over the ragged bones of the cranium, and the woman fhould be allowed to reft an hour or two, according to her ftrength and other circumftances: the bones of the cranium will now collapfe; and if the woman has as much ftrength remaining, or the pelvis be not much diftorted, the head being thus diminifhed, will be protruded by the force of natural pains: otherwife it muft be extracted, either by means of two fingers introduced within the cavity of the cranium, by the blunt-hook introduced in the fame manner, guarding the point on the oppofite fide while making the extraction; or, failing thefe, by the crotchet, which, though dan-

Difficult Labour.

dangerous in the hands of an ignorant rash operator, may be employed by the prudent practitioner with as much safety as the bluntest instrument.

The method of introduction is the same with a blade of the forceps. The chief thing to be attended to is, to guard the point till it be applied against the head, and firmly fixed in its hold, which should always be somewhere on the outside of the cranium: provided a firm hold is obtained, no matter where, behind the ears, about the os petrosum, orbits of the eyes, maxilla inferior, &c. according to the presentation of the head. The woman being properly secured, and the handle of the instrument covered with a cloth, the operator must then pull, at first gently, afterwards more forcibly, resting from time to time, and endeavouring to make the extraction in the best manner the circumstances of the case will admit of. If the pelvis be much distorted, so that, by means of the utmost strength the accoucheur can exert, little purchase is made, he may apply to the opposite side a blade of the forceps, which are now so constructed as to lock with the crotchet; let him then bring the handles together, secure properly, and thus endeavour to make the extraction. Should this expedient also fail, the blade of the forceps must be withdrawn, the other blade of the crotchet must be applied, the handles brought together and secured, and the extraction made, moving from blade to blade.

Should the head present in such a manner, that, in attempting to extract it, the crotchet divides the vertebræ of the neck, and the head is thus severed from the body, an accident that can only happen in the hands of an ignorant blundering practitioner; the head must be pushed up above the brim of the pelvis, the crotchet or blunt hook must be fixed under the axilla, the arms must be brought down, and the body extracted, by fixing the crotchet below the scapula on the sternum, or among the ribs; the head must afterwards be extracted in the manner already advised: or should the head in extracting be pulled from the body, as may happen when the child has been long dead, or when it is putrid, the delivery of the body must be effected by means of the crotchet as now directed; a method preferable to that of turning, as some advise.

If the head, instead of yielding to the force of pulling, be at last cut and broken in pieces, the operator must endeavour to bring down an arm of the child, to fix the crotchet about the jaw or neck, pull at both holds, and thus attempt to make the extraction; this also failing, he must bring down the other arm, fix the crotchet in the thorax, and, in a word, must tear the child in pieces, that the delivery may be accomplished by any means.

In face-cases, where it is impracticable to alter the position, and when the pelvis is much distorted, the double crotchet is sometimes requisite; the handles must be well secured, kept well backwards towards the perinæum, and the motion always from blade to blade. It very seldom, however, happens, that there is occasion for the double crotchet: by this means the head is flattened in pulling; whereas if one blade only can be employed, the head is lengthened, and, in pulling, can better accommodate itself to the shape of the pelvis as it passes along.

Preternatural Labour.

Chap. III. *Preternatural Labour.*

In whatever manner the child presents when the body is delivered before the head, the birth is accounted preternatural.

Preternatural labours may be referred to one of the four following classes.

I. When one or both feet, knees, or the breech, present.

II. When the child lies across in a rounded or oval form, with the arm, shoulder, side, back, or belly, presenting.

III. When one or both of the upper extremities present, the child lying in the form of a sheath, the feet towards the fundus uteri, the waters evacuated, and the uterus strongly contracted round the body of the child.

IV. Lastly, Premature or flooding cases, or others in which it may be necessary to force the delivery, either previous to the rupture of the membranes, or quickly after it.

The causes of cross labours most commonly assigned by authors are, The obliquity of the uterus; circumvolutions of the funis umbilicalis round the child's body; the shortness of the funis, or attachment of the placenta towards the fundus uteri; shocks affecting the mother when pregnant, &c. The position of the fœtus may also be influenced by its own motion and stirrings, by the particular form and bulk of its body, by the manner of stretching of the uterus, by the quantity of liquor amnii, and by many other circumstances.

The symptoms that indicate an unfavourable position of the child, before it can be discovered by the touch, are very uncertain and fallacious: a cross birth may, however, be suspected,

1st, If the pains be more slack and trifling than ordinary.

2dly, If the membranes be protruded in a long form like a gut, or the finger of a glove.

3dly, If no part of the child can be discovered when the uterine orifice is considerably opened.

4thly, If the presenting part through the membranes be smaller, feels lighter, and gives less resistance than the bulky ponderous head.

5thly, Lastly, after the rupture of the membranes, if the meconium of the child be passed along with the waters, it is a sign that the breech presents, or that the child is dead.

Preternatural labours are difficult or hazardous, according to,

1. The form of the pelvis, and general health and constitution of the woman.

2. The bulk of the child, and its manner of presenting.

3. The time the waters have been evacuated, and the uterus contracted round the body of the child.

4. When complicated with plurality of children; the prolapsis of the funis umbilicalis; the limbs of the child entangled with the chord; profuse and violent flood-

Preternatural Labour.

floodings from the attachment of the placenta towards the cervix uteri, &c

Turning is often laborious, and always dangerous in proportion to the force used in searching for and bringing down the feet; though, in general, the difficulty and hazard are not so great, as in many cases strictly called *laborious*, when the head presents; the treatment of preternatural labours being better known, and for the most part easier put in practice.

Each class of the general division of cross labours includes a variety of different cases. By considering a few of every class, a general idea of the whole will be formed.

CLASS I.

CASE I. The simplest and easiest case is the Agrippan posture, when the child presents with the feet.

The foot is to be distinguished from the hand, first, by the weight and resistance it gives to the touch; secondly, by the shortness of the toes; thirdly, by the projecting heel.

When the feet present in the passage, the labour should be allowed to go on as if natural. If the child be of an ordinary size, the woman in health, the parts well proportioned, in the way of assistance nothing further seems necessary but the application of a warm cloth round the body of the child, which must be properly supported till it advances as far as the pains are able to force it. If the size be ordinary, or rather small, it will sometimes make the mechanical turns, and be entirely pushed along by the force of the natural pains; but it generally stops at the shoulders, after the breech protrudes without the os externum, where the resistance is so great, that the accoucheur's assistance becomes requisite.

In this case, the patient must be placed on her back, properly supported; the hand of the accoucheur must be cautiously introduced; the parts of the woman must be gently stretched; the feet of the child must be laid hold of, and brought as low in the vagina as possible; a soft warm cloth must be wrapped round them, and the extraction must be performed in a slow cautious manner, making large motions in a circular or lateral direction, resting from time to time, if the pains are gone; and if not, always waiting for the natural efforts. When advanced as far as the breech, the body, if not already in a proper direction, must be pushed up, and gently turned with the face towards the mother's back; and to make sure that the face turns with the body, or to prevent the chin, vortex, or shoulders, from catching on the pubes, or angle of the sacrum, an extraordinary quarter-turn more must be made: this must be reversed previous to the extraction; and the difficulty arising from the obstruction of the shoulders must be removed in the following manner: While the breast and legs of the child are supported over the palm and fore-arm of the one hand of the accoucheur, which he draws towards one side, he must introduce two fingers of the other hand at the opposite side into the vagina, over the back part of the shoulder, as far as the elbow, and endeavour in the most gentle manner to bring down the arm, always remembering in his movements to humour the natural motions of the joint: he must then shift hands, when the other arm is to be relieved in the same manner: both arms being brought down, the woman must now rest a little, when a pain or two generally follows, and the head is also forced along. But should the woman be much exhausted, and if the head does not quickly advance, the child may be lost from delay. The extraction of the head in preternatural labours is often the most difficult and the most dangerous part of the delivery; the cause of resistance, when it does not advance, is chiefly owing to its confinement between the angle of the sacrum and pubes, when the bulky part of the head is detained at the brim; whether the resistance be here or towards the inferior aperture of the pelvis, if the head does not advance in a pain or two, the extraction must be made in this manner: While the right hand of the accoucheur supports the body of the child below, with two fingers pressing on either shoulder, the left hand and fingers must in the same manner be placed over the back of the neck, and pulling gently in the direction from pubes to sacrum, he must thus endeavour to bring it along: but, should the pelvis be narrow, or the child's head of a large size, or the face be laterally or anteriorly placed in the pelvis, or, what rarely happens, the os uteri contracted round the neck of the child; in either of these cases, the accoucheur will sometimes meet with the utmost difficulty. When the above method therefore fails, he must introduce two fingers of the right-hand into the child's mouth, while those of the left-hand are expanded over the shoulders, as already directed; and in this way he must endeavour to relieve it, pulling from pubes to sacrum, alternately raising and depressing the head till it advances low down, so that the face descends from the hollow of the sacrum, when the accoucheur must rise from his seat, and bring the hind-head from the pubes with a half-round turn, imitating that of a natural labour.

If the position be unfavourable, the face, if possible, should be turned to the sacrum, by pushing up the head, or by pushing back the chin: If the contraction of the uterus is the cause of resistance, which rarely occurs, it must be gently stretched with the fingers. Or if the difficulty arises from circumvolution of the chord round the legs, thighs, body, or neck of the child, these must be disengaged in the easiest manner possible; it is rarely necessary to divide the funis on this account.

Should every method fail in bringing down the head, the delivery must be effected by means of the forceps cautiously passed over the ears, with the handles under the child's body, in a direction downwards towards the perinæum. If the pelvis be very narrow, or the head of a large size, it must be opened by pushing the sciffars through the occipital bone, so that the contents of the cranium may be evacuated, and the extraction made by means of the forceps, blunt-hook, or crotchet. But if the head, by the efforts to extract it, be actually severed from the body, and left behind in the uterus, an accident which sometimes occurs, it must be delivered by inclosing it in the forceps, while secured from rolling by pressing externally on the abdomen. If the forceps cannot be applied, the cranium must be opened, the texture of the brain destroyed, and the extraction performed by the fingers of the accoucheur, by the blunt-hook, or by the crotchet. If the under-jaw remains, the

hed

Preternatural Labour.

head may be effectually fecured till locked in the forceps, or till its bulk be diminifhed, by introducing a finger into the mouth, thrufting it through the jaw under the chin, drawing it down, and paffing a ligature through the perforation.

In cafes where the child has been long dead, fhould the belly or thorax be diftended with air or water, and prove the caufe of obftruction, the contents muft be evacuated by opening with the fciffars, or tearing with the crotchet; and in general, where difficulties occur, the delivery muft be accomplifhed in that manner the circumftances of the cafe will beft admit of.

Cafe 2. When inftead of two, one foot only falls into the vagina, the other is fometimes detained by catching on the pubes, and, if eafily come at, fhould be brought down, always remembering to humour the natural motion of the joint; but, fhould the leg be folded up along the child's body, the attempt is fometimes both difficult and dangerous, and ought not to be perfifted in, as the breech will either be forced down by the affiftance of natural pains, or by gently pulling by one leg only.

Cafe 3. When one or both knees prefent, the delivery muft be conducted in the fame manner with that of the feet.

Cafe 4. When the feet offer along with the breech, this laft muft be pufhed up, while the former are fecured and brought down, till it be reduced to a footling cafe, and otherwife managed as above.

Cafe 5. The breech may prefent with the fore-parts to the mother,

1ft, Anteriorly;

2dly, Laterally; or,

3dly, Pofteriorly.

Sometimes the breech may be difcovered, previous to the rupture of the membranes; but afterwards with more certainty, by the meconium of the child paffed with the waters, and by the touch.

In whatever manner the breech prefents, the delivery fhould be fubmitted to nature, till the child be advanced as far as the thorax, when the feet are to be brought down and laid hold of, the child, if neceffary, pufhed up, the mechanical turns effected; and the delivery otherwife conducted as in a footling cafe. There is much lefs hazard in general, agreeable to an old obfervation of Mauriceau, in allowing the child to advance double, than in precipitating the extraction by pufhing up to bring down the feet before the parts have been fufficiently dilated; a practice difficult and troublefome to the operator; painful, and fometimes dangerous, to the mother; and by which the child is expofed to the rifk of ftrangulation, from the retention of the head after the delivery of the body. If the child be fmall, though doubled, it will eafily pafs in that direction; if large, though the labour be painful, the natural throes are lefs violent and lefs dangerous than the prepofterous help of the accoucheur: If the child thus advances naturally, it will be lefs expofed to fuffer; if it does not advance, the parts of the mother will be prepared for the accoucheur to pafs his hand into the pelvis, to raife up the breech, to bring down one or both feet, and deliver as above.

Weaknefs in the mother, floodings and convulfions, a very large child, or narrow pelvis, the prolapfus of the funis, or its compreffion between the thighs of the child, or between the child and pelvis, by which its life is endangered, if the chord cannot be reduced above the prefenting part, are the only exceptions to the general rule of treating the breech as a natural labour.

The practice of helping forward the breech, by paffing the blunt-hook under the ham, is now entirely laid afide: this can never be done with fafety, till the breech be fo low advanced, that the hand of the accoucheur can be ufed, which may be employed with more advantage as well as fafety.

CLASS II.

In the former clafs of preternatural labours, it is advifeable to truft to nature in many cafes, as the birth will often be accomplifhed without manual affiftance: but when the child lies a-crofs, no force of pain can make it advance in that pofition; and, without proper affiftance, both the mother and child would perifh.

If the accoucheur has the management of the labour from the beginning, the child may be turned, in the worft pofition, without difficulty; but when the waters have been for fome time evacuated, and the uterus ftrongly contracted, turning is laborious to the operator, painful and dangerous to the mother. In fuch cafes, the ancients endeavoured to make the head prefent; but, from its bulk, they often failed, and the attempt was often attended with fatal confequences. The method of delivering by the feet is the moft important modern improvement in the practice of midwifery; an improvement to which many thoufands owe their lives.

When the child lies in a tranfverfe pofition, the accoucheur muft infinuate his hand through the vagina into the uterus in the gentleft manner, fearch for the feet, bring them down with the utmoft caution, and finifh the delivery as in footling-cafes. To effect this, the following rules fhould be obferved.

1. The patient muft be placed in a convenient pofture, that the operator may be able to employ either hand, as the various circumftances of the cafe may require.

2. Though the beft pofture, in general, is laying the woman on her back, it will be fometimes neceffary to turn her to her fide; and, in thefe cafes, where the abdomen is pendulous, where it is difficult to reach the feet, or where they lie towards the fundus uteri, the woman fhould be placed on her knees and elbows.

3. An exact knowledge of the true pofition of the child, and of the ftructure and ftate of the parts, fhould be acquired, before attempting to make the delivery.

4. The orifice of the uterus fhould be enlarged, fo as freely to admit the hand; and the ftronger pains fhould be abated, before any attempt be made to deliver.

5. Should the waters be drained off, the parts dry and rigid, and the uterus contracted round the child, warm oil muft be injected into the uterus, otherwife its rupture may be endangered.

6. In paffing the hand into the uterus, this muft be done

Preternatural Labour.

done in the gentlest manner; the parts must be well lubricated with butter or pomatum; the line of the pelvis must be attended to; the efforts of the operator must be slow and gradual; and thus the utmost rigdity in the soft parts will, in time, be overcome.

7. The hand must be introduced only during the remission of pain; when pain comes, the accoucheur must always rest; otherwise he may push his hand, or the fœtus, through the body of the uterus.

8. In pushing up, to come at the feet, this must never be done with the points of the fingers, nor with the hand clenched, but with the palm of the hand, or the broad expanded fingers, and always during the remission of pain, and the latter should also be observed in bringing down the legs; but, in making the extraction of the body, the efforts of the operator should always co-operate with those of nature.

9. The hand should, if possible, be introduced along the anterior parts of the child; and both feet, if easily come at, should be laid hold of.

10. In turning, the accoucheur should never consider the child as dead, nor allow himself to be deceived by symptoms doubtful and fallacious; the child is sometimes born alive when he would least of all expect it; therefore, in pushing up, bring down the legs, or extracting the body, it should be handled with the greatest delicacy.

11. When the hand is within the pelvis, it should not always be moved in the line of the umbilicus, but rather towards one side of the spine, by which more room is gained, and the prominent angle of the sacrum avoided.

12. The hand should be passed as far as the middle of the child's body, before attempting to search for the feet; or before attempting to break the membranes, should these remain entire, till the aperture of the uterus will admit of the hand.

13. If the hand cannot pass the presenting part of the child to come at the feet, instead of violently pushing back, the part should be as it were lifted up in the pelvis, and moved towards a side; by which means difficulties may be surmounted, and great danger often prevented.

By attending carefully to the above rules, laceration of the uterus, floodings, convulsions, inflammations, and their consequences, may be prevented; accidents that frequently happen in the hands of ignorant rash operators.

Case 1.—*The arm presenting.* The right is to be distinguished from the left by laying hold of the child's hand, in the same manner as in shaking hands; and thus the general position of the child may be judged of.

When the accoucheur is called in early, the reduction is generally practicable; but if the arm protrudes through the vagina, and the shoulder be locked in the pelvis, it is needless, by fruitless efforts, for the accoucheur to fatigue himself, and distress his patient, to attain a point by which he will gain no very material advantage; as the hand can be passed into the uterus by the side of the child's arm, which will, of course, return into the uterus when the feet are brought down into the vagina.

In order to make the delivery, the hand of the accoucheur, well lubricated, must be conducted into the uterus by the side of the child's arm, along the thorax, at the opposite side of the pelvis where the head lies; if any difficulty occurs in coming at the feet, this hand must be withdrawn, and the other introduced in its stead; and if still the hand cannot easily pass beyond the child's head or shoulder, the presenting part must be raised up, or gently pushed to a side, that one or both feet may be laid hold of, which must be brought as low as possible, pushing up the head and shoulders, and pulling down the feet alternately, till they advance into the vagina, or so low that a noose or fillet can be applied; and thus by pulling with the one hand by means of the noose, and pushing with the other, the feet can be brought down and the delivery finished, however difficult.

The method of forming the noose is by passing the two ends of a tape or garter through the middle when doubled; or, should the garter be thick, by making an eye on one extremity, and passing the other end through it: this, mounted on the points of the fingers and thumb of the accoucheur's hand, must be conveyed into the uterus, passed over one or both feet and ankles, and secured by pulling at the other extremity.

Case 2.—*The side.* This is discovered by feeling the ribs.

Case 3.—*The back.* This is discovered by feeling the spine.

Case 4.—*The belly.* This is known by the funis.

These cases occur rarely, as the uterus must with difficulty admit of such positions. When any of these parts do present, the child seldom passes any part of the brim of the pelvis, and is, in general, more easily turned than in several postures in which it may offer. The belly, from the difficulty with which the legs can be bended backwards, except the child be flaccid, putrid, or before the time, will very seldom directly present; if so, it will be early and readily discovered by the prolapsus of the funis, and there will be no great difficulty to come at the feet, and deliver. The rule in all these cases is, to pass the hand into the womb in the gentlest manner possible, and to search for the feet and bring them down.

CLASS III.

When the child lies longitudinally in the uterus, with the arm or shoulder presenting, and the head more or less over the pubes, or laterally in the pelvis, the feet towards the fundus uteri, the waters evacuated, and uterus contracted round the child's body; these are the most difficult and laborious of all the cases of preternatural labours. Here the protruding arm ought, if possible, to be reduced, and the head brought into the pelvis; for unless the child be very small, it is impossible for the head and arm to pass along together.

In order to effect the reduction of the arm, different instruments have been invented; but the hand of the accoucheur is preferable to every thing of this kind, whether of ancient or modern invention. This, conducted by the arm that protrudes, must be insinuated through the vagina into the uterus, as far as the shoulder of the child, which if the accoucheur can raise up, he will generally succeed in reducing the arm

Preternatural Labour.

arm. Should this method fail, he must attempt to push up the fore-arm at the elbow; but, in bending it, must be very cautious, to avoid overstraining or dislocating the joint. In whatever manner the reduction is accomplished, if any method proves successful, the arm must be retained till the head, by the force of natural pain, enters the pelvis, and prevents its return; otherwise the arm will descend as often as it is reduced.

But if the attempts for reduction prove impracticable, the woman must be placed on her knees and elbows, and the accoucheur, with great deliberation, must endeavour gently to slide up his hand between the uterus and child as far in the uterus as possible, to lift up the head and shoulders, and search for and bring down one or both feet, in the best manner the various circumstances of the case will admit of. As soon as they can be laid hold of, they must be gradually brought down into the vagina, so low that the noose can be applied over them, which must be fixed and pulled with the one hand, while the head and upper parts of the body are raised and gently pushed up with the other.

Should the arm have been long protruded without the os externum, much swelled, and cold; the waters drained off; the uterus strongly contracted; and the position of the child such as to render it impracticable, either to reduce the protruded limb or to search for and bring down the feet; the head, if easily come at, must be opened and extracted with the blunt hook or crotchet; or a crotchet must be fixed amongst the ribs, and the breech or feet thus pulled down.

Should the pelvis be very narrow, and unsurmountable difficulties occur, the arm must be twisted off at the elbow, though this expedient is rarely necessary; and the delivery must in general be accomplished as the prudence and judgment of the operator can best direct; always remembering, when one life must fall a sacrifice, that the tree must be preserved at the expence of the fruit.

In this, as in other cases, the swelling and coldness of the arm, and even want of pulsation in the artery, are not infallible signs of the child's death; and should this even be so, it makes little difference in the mode of delivery, unless that it will lead us to pay all our attention to the mother: For a living child gives no more assistance in the birth than a dead one, whatever authors have said to the contrary.

When both arms present, the delivery must be conducted in the same manner as when one only presents. The former case is less difficult than the latter, as the head seldom advances far when both arms fall into the passage, so that they can either be reduced, or there is easy access to come at the feet to bring them down and deliver.

CLASS IV.

When the membranes remain entire, till the soft parts are so much dilated that the hand will readily find admittance; or when the hand can be passed within the cavity of the uterus, immediately after the rupture of the membranes, so that part of the water may be retained; the delivery may be accomplished, in the most troublesome preternatural cases, with the greatest safety and expedition. But when the waters have been long evacuated, and the uterus closely contracted round the body of the child, the case will prove laborious to the operator, painful and dangerous to the mother and child.

Preternatural Labour.

When there is reason to suspect that the child lies across, which can often be ascertained, either by feeling the presenting part through the membranes, or by some of the signs of preternatural labours already mentioned; the woman should be managed in such a manner, that the membranes may be preserved entire as long as possible: for this purpose she should keep quiet in bed, and her posture should be such as is least favourable for straining, or exerting force during the pain: she should be touched as seldom as possible, till the os internum be sufficiently dilated. The accoucheur should then introduce his hand in a conical form, well lubricated, into the vagina, and through the aperture of the internal orifice, insinuating it between the uterus and the membranes, till it advances almost as high as the fundus uteri, when he must break the membranes, by pinching some part of them between a finger and thumb, or by forcibly pushing a finger thro' them; he must then search for, and endeavour to lay hold of, one or both feet, and deliver.

Should the membranes be ruptured in the attempt, he must be ready to run up his hand as quickly as can be done with safety, when, part of the waters by his arm being retained, the operation of turning will be facilitated. Should the placenta adhere on that side of the uterus where the hand is passed, it must again be withdrawn, and the other hand be introduced in the opposite side.

Floodings. It has been already observed, that a flooding seldom proves fatal to the mother before the seventh month of pregnancy; after which period, from its duration or excess, the life of both the mother and child may suffer. Should therefore a flooding attack a woman in the two last months of pregnancy, from whatever cause it may arise, and whether attended with labour-pains or not, if the hæmorrhagy be so considerable that she is ready to sink under it, and that cold applications and other means of checking the evacuation shall fail, the woman must be placed in a proper posture, her frinds prudently apprised of her danger, and the delivery must be immediately performed, by stretching the vagina and os uteri, till the hand of the operator can easily gain admittance to break the membranes, catch hold of the feet, and extract the child.

If it can possibly be prevented, the membranes in flooding cases should never be broken till the aperture of the uterine orifice will freely admit the hand to pass, that, after the evacuation of the waters, the accoucheur may have it in his power either to make the delivery or not according as the effusion continues or abates.

Soon after attempting to stretch the parts, should the labour-pains come on, the waters begin to be collected, and the uterine hemorrhagy diminish, the accoucheur must then withdraw his hand, and manage the delivery according to circumstances. And if, for instance, the child presents naturally, the delivery must be trusted to nature; otherwise, if the flooding continues, or the child presents across, the accoucheur must persist in his work, going on slowly, and with the utmost

Preternatural Labour.

moſt delicacy, till he be able to reach the feet, to bring them down, and deliver; always remembering, during this proceſs, that the ſtrength of the woman, by proper nouriſhment, be ſupported.

But ſhould the placenta adhere to the cervix, or upon the os uteri, the greateſt danger is to be dreaded; for thus the flooding will commence from the moment the os uteri begins to ſtretch, and will increaſe ſo rapidly, that the woman, if not ſpeedily delivered, muſt inevitably ſink under it. The whole body of the placenta, in ſuch caſes, is ſometimes ſeparated when the labour has made but little progreſs; ſo that the woman will often periſh whether delivery be attempted or not. As this, however, is the only expedient by which her life, and that of the child, can be ſaved; in every caſe where the placenta preſents, which the accoucheur will readily diſcover by the touch of the ſoft pappy ſubſtance of that body, he muſt immediately place the woman in a proper poſture, inſinuate his hand gently by the ſide of the protruding placenta, break the membranes, ſearch for the feet of the child, and bring them down, ſo that the delivery may be finiſhed with all poſſible expedition; for, in this unhappy caſe, a few minutes delay may prove fatal.

The after-birth ought never to be extracted before the child, if it can poſſibly be avoided.

After delivery, time ſhould be given for the uterus to contract, that nature may thus throw off the placenta, which never ought to be hurried away, unleſs the continuance or a recurrence of the hemorrhagy render it neceſſary.

Prolapſus of the funis. Difficulties ariſing from the funis falling down into the vagina, and preſenting along with ſome part of the child, may, in this claſs of the diviſion of preternatural labours, be included.

A preſſure on the chord, in ſuch a degree as to interrupt the circulation, muſt infallibly deſtroy the life of the child: hence a coldneſs and want of pulſation in the chord is the trueſt criterion of the death of the child; and hence, in every caſe where the chord is prolapſed before any bulky part of the child, if the delivery be not accompliſhed with expedition, the child will periſh. This is only to be prevented by replacing the chord, and retaining it above the preſenting part, till this laſt, by the force of labour-pains, be ſo far advanced as to prevent the return of the former; or the child muſt be turned and brought by the feet, provided this can be done with ſafety to the mother. But it is often difficult to ſucceed in the attempt of the one or other; and, if the woman has ſtrong pains, ſuch attempts are not to be hazarded, as the conſequences may prove fatal.

When the accoucheur is thus ſituated between two puzzling difficulties, the preference muſt always be given to the mother. If the child be ſmall, and the pelvis well formed, which may be known by the hiſtory of former deliveries, and if the labour goes on quickly, the child will generally be born alive; but if, on the contrary, the child be above the ordinary ſize, and the pelvis rather narrow, turning will prove a dangerous operation to the mother, and there is little proſpect of ſaving the infant by this means.

Beſides our former diviſion of labours, *plurality of children, monſters, extra-uterine fœtuſes*, and the *Cæſarean operation*, are parts of the ſubject that yet remain to be conſidered.

Plurality of Children.

CHAP. IV. *Plurality of Children.*

The caſe of twins often occurs: of triplets ſeldom: of quadruplets rarely: nor is there perhaps a ſingle inſtance, where five or more diſtinct fœtuſes have been found contained in the human uterus, though many ſuch fabulous hiſtories have been recorded by credulous authors.

The ſigns of two or more children, ſuch as the ſudden or extraordinary increaſe of the uterine tumor, motion felt in different parts of the abdomen, &c. are very doubtful and fallacious: this can only be aſcertained after the delivery of one child; and even then a recurrence or continuance of labour-pains is not a certain and infallible criterion; neither is the abſence of pains a ſure indication of the contrary; as many caſes have occurred, where ſeveral days have intervened between the birth of a firſt and ſecond child. The chief ſymptoms to be depended on are, 1ſt, The child being of a ſmall ſize, and the quantity of liquor amnii ſo inconſiderable as not to account for the bulk of the woman in time of pregnancy. 2dly, The bleeding of the funis umbilicalis next the mother. 3dly, The remora of the placenta. 4thly, The uterine tumor not ſenſibly diminiſhed, which, very ſoon after delivery, in ordinary births, will be found gradually ſhifting lower and lower, and will feel at laſt as if a hard circumſcribed tumor like a ball between the umbilicus and pubes. Hence the utility of the general practice of applying the hand externally on the abdomen, in every caſe after delivery; by which an accurate knowledge will be formed of the nature and manner of the uterine contraction. When, from any of theſe circumſtances, there is reaſon to ſuſpect another child, the moſt certain and infallible manner of diſcovering it is, the paſſing of a finger, or the introduction of the hand into the uterus, where another ſet of membranes will be perceived, and probably ſome part of the child preſenting through them.

The poſition of twins or triplets is commonly that which is moſt commodious, and which will occupy the leaſt room in utero: their ſituation is often diagonal; tho' they may preſent in every poſſible poſture. Thus, therefore, the general rules recommended for the delivery of one child, are equally applicable in the caſe of twins, triplets, &c.

It has been the general practice with many, after the birth of one child, to paſs the hand immediately into the uterus, to break the membranes, catch hold of the feet of the child, and thus deliver. But this is certainly bad practice, whatever authors have ſaid to the contrary. If the woman is healthy, and the child preſents favourably, that is, with the head, breech, or feet, natural pains ought to be waited for, when the child will be expelled by the force of theſe only; failing which, manual aſſiſtance, as in other caſes, muſt be had recourſe to.

It very rarely happens, when the firſt birth is preternatural, that the ſecond membranes are ruptured in making the extraction. Should this prove the caſe, the

Plurality of Children.

limbs of the children may be confounded, fo that a leg and an arm, or three legs, or arms of different children, may prefent; which, however, will make little difference in the mode of delivery; the accoucheur will endeavour to lay hold of the foot or feet moft readily within his reach, and will be cautious, in bringing them down, to make fure they belong to the fame body.

If the child prefents crofs; if floodings, convulfions, or other dangerous fymptoms, fhall take place; if the woman has fuffered much in the firft labour; and if, after feveral hours, a recurrence of labour-pains does not enfue; the hand muft then be introduced into the uterus, the membranes muft be broken, and the child muft be extracted by the feet; or, if the head remains locked in the pelvis, and, from want of ftrength in the woman, cannot be expelled, the treatment is the fame as in other laborious births.

In twin-cafes it may be recommended as a general rule, to avoid precipitating the delivery of the fecond child till the woman fhall have refted a proper time, and till, by the contraction of the fundus uteri, the fecond fet of membranes occupy the place of the firft, and be protruded as far as the os externum; when, and not before, the delivery may fafely be affifted, fhould circumftances occur to render fuch affiftance neceffary: whereas, by breaking the membranes and evacuating the waters when the child lies high in the uterus, a flooding may be brought on, or a fpafmodic conftriction of the uterus round the body of the child may be occafioned, which may render the delivery both difficult and dangerous.

The placentæ of twins, triplets, &c. generally adhere, though fometimes they are diftinct, and may be thrown off at different times after the birth of the different children; fo that the practitioner fhould be on his guard, and never fhould leave his patient till he makes fure there be no more children. When a fecond child is difcovered, no attempts ought to be made to extract the placenta till after the birth of the remaining child or children; as the woman would be fubject to flooding, which might prove of fatal confequence before the uterus could be emptied of its contents.

In cafe of plurality of children, a fecond ligature fhould be applied on the funis, on that end next the mother, immediately after the birth of every child; and a gentle compreffion fhould be made on the abdomen of the woman after the firft delivery, which muft be gradually tightened after every fucceeding one, to prevent the confequences of a fudden removal of uterine preffure, which is to be dreaded where the diftenfion has been confiderable.

The placenta, in fuch cafes, muft be managed in much the fame manner as ufual. In twins, &c. it generally feparates with great facility, provided time has been given for the uterus to contract. Both chords fhould be gently pulled; and when it advances towards the uterine orifice, where, being large and bulky, it commonly meets with confiderable refiftance, it requires the introduction of a finger or two into the vagina for bringing down the edge, after which the body readily follows.

Chap. V. *Monfters.*

These are of various fizes and forms, and, unlefs very fmall, the pofture favourable, and the woman well made, will prove the caufe of a difficult and troublefome delivery. Sometimes a child is monftrous from a preternatural conformation of parts, fuch as a monftrous head, thorax, abdomen, &c. At other times, there is a double fet of parts, as two heads, two bodies with one head, four arms, legs, &c. But fuch appearances very feldom occur in practice; and, when they do, the delivery muft be regulated entirely according to the circumftances of the cafe. A large head, thorax, or belly, muft be opened. If two bodies united together are too bulky to pafs entire, they muft be feparated; the fame of fupernumerary limbs. If the pofture be unfavourable, it muft be reduced when practicable; otherwife the extraction muft be made with the crotchet, in the beft manner the circumftances of the cafe will admit of; always, in cafes of danger or difficulty, giving the preference to the fafety of the mother, without regarding that of the child.

Chap. VI. *Cæfarean Operation.*

Cæfarean Operation.

When the delivery could not be accomplifhed by other means, or when a woman died fuddenly with a living child in her belly, an operation to preferve the life of mother and child in the former cafe, and to fave the child in the latter, has been recommended, and fuccefsfully performed, by different authors, and in different ages.

This operation is of ancient date; it is the *fectio Cæfarea* or *partus Cæfareus* of the Latins, and the *hyfterotomia* of the Greeks. Whether it was ever fuccefsfully performed on the living fubject amongft the ancients feems uncertain; but that it has been fuccefsfully practifed by the moderns on various occafions, and in feveral different countries of Europe, there are fo many authentic hiftories on record, that the fact will fcarce admit of doubt: but as this, like many other falutary inftitutions, has been much abufed, and in many cafes improperly and injudicioufly employed, (for fome of thofe women who furvived the operation, were afterwards fafely delivered of living children), the circumftances which render this operation neceffary demand a very particular inquiry, viz.

1. A narrownefs, or bad conformation of the bones of the pelvis.

2. Imperforated vagina, or contractions in the vagina, cicatrices, tumors, or callofities in the os uteri, &c.

3. The efcape of the child through the uterus when torn.

4. Ventral conceptions.

5. Herniæ of the uterus.

6. The pofition or bulk of the child.

It will be neceffary carefully to examine thefe different caufes, in order to fhow that they are by no means, in every cafe, fufficiently powerful motives for having recourfe to it.

I. Bad conformation of the bones of the pelvis. When the hand of the operator cannot be introduced within the pelvis; or, in other words, when its largeft diameter does not exceed one inch, or one inch and a half, this conformation is perhaps the only one which renders the Cæfarean operation abfolutely neceffary: happily, however, fuch a ftructure very feldom occurs in practice; and when it does, the accoucheur will readily

readily difcover it, by attending to the following circumftances, and to the common marks of a narrow pelvis. Wherever the capacity of the pelvis is fo ftrait as not to admit any part of the child's head to enter, nor two fingers of the accoucheur's hand to conduct proper inftruments to tear, break down, and extract the child piece-meal; in this cafe, recourfe muft be had to the Cæfarean fection; an expedient, though dreadful and hazardous, that will give the woman and child the only chance of life; and which, if timely and prudently conducted, notwithftanding of the many inftances wherein it has failed, may be performed with fome probability of fuccefs.

It is true, the fuccefs of the operation in the city of Edinburgh, where it has been done five times, has proved difcouraging, as none of the women had the good fortune to furvive it many days. This, however, is not the fault of the operation, but is to be imputed to the low, weak ftate of the patients at the time, who had previoufly been feveral days in labour, and their ftrength greatly exhaufted, before the operator was called. Delivery by every other means was utterly impracticable; the operation, though the event was doubtful, alone gave a chance of life; and three of the children by this means were extracted alive.

Mr Hamilton furgeon and profeffor of midwifery in Edinburgh, having been an eye-witnefs of the operation the laft time it was performed here, gives the following account of the cafe which fell under his obfervation.

Elifabeth Clerk, aged 30, had been married for feveral years, became pregnant, and mifcarried in the third month; the expulfion of the abortion occafioned fo fevere a ftrefs, as actually to lacerate the perinæum. Some time after her recovery, fhe was irregular, afterwards had one fhow of the menfes, again conceived, and the child, as fhe imagined, arrived at full time. She was attacked on Monday the 3d of January 1774, about midnight, with labour-pains, which went on flowly, gradually increafing till Saturday the 15th, when fhe was brought from the country to the Royal Infirmary here. Upon examination, the pelvis feemed confiderably diftorted; but the body was otherwife well fhaped, though of fmall fize; the os externum vaginæ was entirely fhut up, nor could any veftige of vagina be obferved, nor any appearance of labia pudendorum: inftead of this, there was a fmall aperture at the fuperior part of the vulva, immediately under the mons veneris, probably about the middle anterior part of the fymphyfis pubis. This aperture (which had a fmall procefs on the fuperior part, fomewhat refembling the clitoris) was no larger than juft to allow the introduction of a finger; the meatus urinarius lay concealed within it; a confultation of furgeons was called, and the Cæfarean fection was determined on. Having had no ftool, nor voided any urine for two days, an injection was attempted to be thrown up; but it did not pafs, nor was it poffible to pufh the female catheter into the bladder. Mr William Chalmer was the operator in this cafe. At fix in the evening, he made an incifion on the left fide of the abdomen in the ordinary way, through the integuments, till the peritonæum was expofed; two fmall arteries fprung, which were foon ftopped by a flight compreffion: the wound was then continued through the peritonæum into the cavity of the abdomen, when the bladder appeared flightly inflamed, much diftended, reaching with its fundus near as far as the fcrobiculus cordis: another unfuccefsful attempt was made to pafs the female catheter; at length a male catheter was procured, which was, after fome difficulty, introduced into the bladder, and the urine evacuated to the quantity of above four pounds, high-fmelled and fetid. This occafioned a neceffary interruption for a few minutes, between making the opening into the abdomen and uterus; the bladder collapfing, the uterus, which before lay concealed, now came in view, through which an incifion was made, and a ftout male child was extracted alive; and immediately afterwards the fecundines. The uterus contracted rapidly. After cleanfing the wound, the lips were brought together by the quill-future, and dreffed fuperficially. The patient fupported the operation with furprifing courage and refolution; nor was there more than five or fix ounces of blood loft on the occafion.

Being laid in bed, fhe complained of ficknefs, and had a flight fit of vomiting; but, by means of an anodyne, thefe fymptoms foon abated: fhe was affected with univerfal coldnefs over her body, which alfo abated on the application of warm irons to the feet: fhe then became eafy, and flept for four or five hours. Next morning, the 16th, about two o'clock, fhe complained of confiderable pain in the oppofite fide, for which fhe was blooded; and an injection was given, but without effect; for the pain increafed, ftretching from the right fide to the fcrobiculus cordis; nor did fomentations feem to relieve her; her pulfe became frequent, fhe was hot, and complained of drought. At 7 A. M. the injection was repeated, but with no better fuccefs; and eight ounces more of blood were taken from the arm; a third injection ftill failed to evacuate any fæces: the drought increafed; and the pulfe rofe to 128 ftrokes in a minute. At 11 A. M. the pulfe became fuller; and the refpiration much oppreffed. No ftool nor urine paffed fince the operation. At 12 fhe was blooded again, when the fizinefs appeared lefs than formerly. She now took a folution of *fal Glauber. manna and cr. tart.* at fhort intervals; fhe vomited a little after the laft dofe, had a foft ftool, and voided a fmall quantity of urine. At 3 P. M. her pulfe was 136, and fhe had another ftool, when thin fæces were evacuated; fhe was then ordered two fpoonfuls of a cordial anodyne mixture every fecond hour: the vomiting now abated; the pulfe became fmaller and more frequent; fhe paffed urine freely; but the pain and oppreffed breathing increafed. At feven P.M. her pulfe rofe to 142, and became weak and fluttering; fhe called for bread, and fwallowed a little with fome difficulty; her drought was intenfe; the dyfpnœa ftill increafed. She was now much oppreffed, and began to tofs; the pulfe funk and became imperceptible; fhe complained of faintifhnefs, but on belching wind her breathing was relieved, and the pulfe returned, growing fuller and ftronger: the pain of the fide ftill increafing, 12 ounces of blood, very fizy, were taken away; and two glyfters of warm water with oil were injected without effect: at 8 P. M. the pulfe became lefs frequent and fmaller; fhe complained much of the pain towards the fcrobiculus cordis: her breathing was much oppreffed; her belly was tenfe, and fwelled as big

Cæfarean Operation

big as before the operation; her pulfe was now fmall and feeble; fhe looked ghaftly; and expired a little after eight, 26 hours after the operation.

It is to be regretted that the relations would not permit the body to be opened.

Since the firft certain accounts of the operation fuccefsfully practifed by a fow-gelder on his own wife, in the beginning of the 16th century, there are on record above 70 well-attefted hiftories, wherein it has been fuccefsfully performed: for, of all the cafes related by authors, it has not proved fatal to the patient above once in ten or nine inftances; which evidently fhows the propriety of the practice, and probability of fuccefs, both in regard to the mother's own recovery, and for certainly preferving the life of the child. But it fhould never be attempted, excepting in thofe cafes only where it is abfolutely impoffible to deliver the woman by any other means whatever; for there are pelvifes to be met with, where, without having recourfe to this operation, both mother and child muft inevitably perifh: fuch have occurred to many practitioners, who, from want of refolution or from ill-founded prejudice, have allowed their patients to perifh from neglect, contrary to a well-known maxim in phyfic, That, in a defperate cafe, it is better to employ a doubtful and even defperate remedy, than to abandon the patient to certain and utter ruin. Such, for inftance, is a cafe related by Saviard, of a girl aged 27, whofe ftature was only three feet, who came to lie-in at Paris, in the *Hotel Dieu;* every method but the operation was in vain attempted; both mother and child died. Mauriceau alfo relates the hiftory of a woman who was left to die, where the aperture of the pelvis was fo fmall as not to admit the hand of the accoucheur. And, not to multiply inftances, Mr De la Roche gives a cafe where the woman had been feven days in labour; the child was faved by the operation; but the woman died the fifth day after, probably from its being too long delayed: the diftance, in this fubject from the lower vertebra lumborum and os pubis, was no more than two fingers breadth. The operation, when the neceffity is evident, ought therefore to be early performed, that the patient, who from her make and conftitution is generally delicate and puny, may have every chance of recovery in her favour, without being exhaufted by the fruitlefs efforts of a tedious and painful labour, as too often has been the cafe. On thefe occafions, the prudent accoucheur fhould call in the advice of his elder brethren of the profeffion, and, by his cautious and prudent conduct, avoid every caufe of cenfure or reproach.

Exoftofes from the bones of the pelvis is a fpecies of deformity very rarely met with in practice, and which feldom or never takes place to fuch a degree as to render this operation neceffary.

II. Conftriction, callofity, tumors, &c. about the vagina or os tincæ. The vagina and os tincæ are often affected with conftrictions from cicatrices, with callofities and tumors; but it is feldom, if ever, neceffary to perform the Cæfarean fection on this account. Tumors in the vagina may generally be removed with fafety, even after the commencement of labour, and delivery happily fucceed; or it may be fometimes practicable for the accoucheur to pafs his hand by the fide of the tumor, to turn the child, and deliver. With regard to conftrictions in the vagina, and callofities in the os uteri, there are many inftances where, at the commencement of labour, it was impoffible to introduce a finger into the vagina; yet the parts have dilated as labour increafed, and the delivery terminated happily. At other times, the dilatation has begun during pregnancy, and been completed before delivery. There is a hiftory, for inftance, in the *Mem. de l'Acad. des Scienc.* 1712, of a woman whofe vagina was no larger than to admit a common writing quill; fhe had been married at 16, and conceived 11 years after: towards the fifth month of her pregnancy, the vagina began to dilate, and continued to do fo till full time, when fhe was fafely delivered. Guilemeau dilated, and La Mott extirpated, callofities in the vagina and os tincæ, when the children were fuccefsfully expelled by the force of natural labour.

Cæfarean Operation.

Harvey relates a cafe where the whole vagina was grown together with cicatrices; nature, after a tedious labour, made the dilatation, and a large child was born.

La Mott mentions his having delivered three women, who had not the fmalleft veftige of an orifice through the vagina to the uterus. Dr Simpfon cut through a callofity of an os uteri which was half an inch thick, &c.

Upon the whole, tumors in the vagina, or about the orificium uteri, may be fafely extirpated without danger of hemorrhagy or other fatal fymptoms, and the delivery will happily fucceed: and if the vagina be impervious, the os externum fhut up, or the labia grown together, the parts fhould be opened with the fcalpel, rather than rifk an operation, at beft in the iffue doubtful and precarious: an operation never allowable in fuch cafes, and therefore univerfally improper in difeafes or malconformation of the foft parts of generation. If the os externum be entirely clofed, if the cavity of the vagina be entirely filled up, or the paffage confiderably obftructed by tumors, callofity, or conftriction from cicatrice, and there is no reafon to fufpect a fault in the pelvis, of which a judgment may be formed by the common marks of deformity, under fize, or a rickety habit; it is by much the beft practice to open a paffage through the vagina, and deliver the woman in the ordinary way. If there be no defect in the pelvis, the head of the child, or any other bulky part that prefents, will advance in this direction, till it meets with a refiftance in the foft parts: thus the teguments will at length be protruded before the child's head, in form of a tumor, when a fimple incifion downwards to the perinæum, in the direction of the anus, will remove the caufe of difficulty, by relieving the head; the child will afterwards fafely pafs, and the wound will heal without any bad confequence.

The ftate of the pelvis, and progrefs of the labour in thefe cafes, may often be learned by the touch of the finger in ano.

III. Lacerated uterus is another caufe for which this operation has been recommended. The uterus may be ruptured from violence in making the delivery; or fuch an accident may happen naturally, either from the crofs prefentation of the child in time of pregnancy, or in time of labour, when the pelvis is narrow: thefe cafes are generally fatal; and it is very feldom, if

Cæſarean Operation.

if ever, that the life of the mother can be ſaved by the Cæſarian ſection, after the fœtus eſcapes through the torn uterus into the cavity of the abdomen: becauſe it often happens, that inflammation and ſphacelus has affected the parts of the uterus that ſuſtained the preſſure previous to the rupture; or, if otherwiſe, convulſions or other fatal ſymptoms ſoon enſue, from the quantity of blood, waters, &c. poured into the cavity of the abdomen.

When the child cannot be extracted by the natural paſſages, tremors, ſingultus, cold ſweats, ſyncope, and the death of the mother, for the moſt part, ſo quickly follow, that it will at leaſt ſeem doubtful, to a prudent humane practitioner, how far it would be adviſeable, after ſo dreadful an accident, the woman apparently in the agonies of death, raſhly to perform another dangerous operation, even with a view to preſerve the child, till he had waited till the mother recruits or expires.

If part of the child be contained within the uterus, and the feet can be reached, the practice is to deliver by the orifice of the womb: but when the whole fœtus has eſcaped entirely without the uterus, the Cæſarean operation is recommended as the only means of preſerving both mother and child.

If the operation on this occaſion be ever allowable, it may be aſked,

1. At what time muſt it be performed?

2. Would it not have the appearance of inhumanity to have recourſe to this expedient immediately after the uterus burſts, when the woman is ſeemingly ready to expire, although it be the only time when there is a chance of ſaving the child?

3. In moſt caſes where this accident happens, ſhould the Cæſarean ſection be made, is it not highly improbable that the mother will ſurvive ſo terrible a laceration?

4. For if it be done with a view to ſave the mother, in what manner is the extravaſated blood, &c. to be evacuated from the cavity of the abdomen?

What ſeems to make caſes of this kind unfavourable, when the accident happens in time of labour, is,

1mo, That here the parts before rupture in moſt caſes are in a gangrenous ſtate.

2do, As the rupture is commonly towards the cervix, there is generally a much greater hemorrhagy, by reaſon of the ſlow contraction of the uterus at this place.

3tio, The uncertainty, whether, or how long, the patient will ſurvive it, ſeems alſo a conſiderable obſtacle to the operation under ſuch diſagreeable circumſtances, *Ne occidiſſe videatur, quem ſors interemit.*

IV. Ventral conceptions is a fourth indication for this operation. Theſe are either in the ovaria, tubes, or cavity of the abdomen, and ſeldom arrive at great ſize; or are retained, very often a long time, without occaſioning much complaint. The iſſue of theſe conceptions has alſo been no leſs various than extraordinary; for after being retained for a great many years in an indolent ſtate, at length abſceſſes or ulcerations have formed, and they have been diſcharged through all the different parts of the abdomen.

Moſt women feel pain and violent motion at the time of ordinary delivery in theſe caſes of ventral conception; if therefore the operation be ever neceſſary, now is the proper time to perform it. But in general, as the ſeparation of extra-uterine fœtuſes from their involucra may occaſion immediate death in many caſes, from the vaſt hemorrhagy that might enſue from the non contractile power of the parts to which they adhere; unleſs they point outwardly, or excite the moſt violent ſymptoms, they ought univerſally to be left to nature.

V. Herniæ of the uterus are ſeldom or never ſufficient to induce us to perform the Cæſarian ſection, as the uterus is very rarely influenced in ſuch a manner, that the orifice cannot be reached, and the delivery ſucceſsfully made. Many inſtances are to be found among ſurgical authors, where deliveries, under ſuch circumſtances, have been happily performed, without having recourſe to ſo hazardous an expedient. Thus Mauriceau mentions a caſe, where the uterus, in a ventral hernia, was puſhed along with the inteſtines above the belly, and contained in a tumor of a prodigious ſize; the woman, however, was delivered at the end of her time in the ordinary way. La Mott relates the hiſtory of a woman in a preternatural labour, whoſe uterus and child hung down pendulous to the middle of her thigh, but whom, notwithſtanding, he ſafely delivered: and Ruyſch gives a caſe where the midwife reduced the hernia before delivery; although it was prolapſed as far as the knee, the delivery was ſafely performed, and the woman had a good recovery.

Laſtly, The poſition or bulk of the child.

Since the practice of turning the child and delivering by the feet, and the late improvement of obſtetrical inſtruments, this operation is never to be performed on account of poſition, monſtroſity, or any other obſtacle on the part of the child.

Upon the whole, when the pelvis is faulty to ſuch a degree, that no inſtrument can be conducted to tear and extract the child, this perhaps is the only caſe wherein this operation ſhould be performed on the living ſubject. Inciſions through the teguments of the abdomen to extract extra uterine fœtuſes, or bones of fœtuſes, do not properly fall under the name of *Cæſarean ſection*, as that name implies inciſion of the uterus alſo.

When a woman advanced in pregnancy dies ſuddenly, either by accident or by natural diſeaſe, the Cæſarean ſection is recommended as an expedient to preſerve the life of the child. This is a very proper meaſure, provided the death of the mother be aſcertained; but ſometimes it is a very nice and difficult point to diſtinguiſh between a deliquium and death; and therefore the accoucheur on ſuch an occaſion muſt act with the utmoſt circumſpection. If the operation be delayed but a very ſhort while after the mother expires, it will probably be in vain to make the attempt; for, whatever fabulous ſtories may be related to the contrary, there are few authentic caſes of the fœtus of any animal ſurviving the mother, perhaps an hour; and therefore every thing ſhould be in readineſs to extract the child with all poſſible expedition, after the event of the mother's death. But, in ſuch caſes, the agonies of death often perform the part of labour, and the child is ſometimes thrown off *in articulo mortis*; or the os uteri is ſo much dilated, that there is eaſy acceſs to paſs the hand, turn the child, and deliver. Thus one ſhould be very cautious in having recourſe to this opera-

Cæfarean Operation.

operation, even in the above circumftances; which fhould never be done,

1. Till the death of the mother be afcertained beyond doubt;

2. Till the ftate of the os uteri be examined;

3. Till the confent of the relations be obtained; And,

Laftly, It need not be undertaken, except where the mother dies fuddenly, between the 7th and 9th month.

It is unneceffary where the difeafe has been lingering; in fuch cafes the child commonly dies before the mother.

When it is doubtful whether the child be alive or not, it may be determined by applying the hand on the abdomen of the mother about the time of, and for a little while after, her death, when the life of the child will be difcovered by its motions and ftruggling.

Thus having pointed out the different caufes that determine this operation, it may be obferved, that it is a frightful and hazardous one; and although performed fuccefsfully in a number of cafes, yet, in many others, it has failed, and the woman has died either immediately or foon after. It fhould never, therefore, be undertaken but on extraordinary and defperate occafions; and then it is not only advifeable, but incumbent, on every practitioner to whom fuch cafes occur.

To conclude, it may not be improper to give a few directions with regard to the method of performing the operation on the living fubject.

Having emptied the bladder, and evacuated the contents of the inteftines with repeated emollient glyfters; the patient being encouraged, with proper cordials, and every other requifite in readinefs, fhe muft be placed on a table or bed, with her left fide gently raifed with pillows or bolfters, and properly fecured by affiftants. An incifion muft be made with a common convex fcalpel, beginning rather below the navel at the middle fpace between it and the fpine of the os ilium, carrying it obliquely forwards towards this bone, fo that the wound in length may exceed fix inches. This external wound is to be carried through the common teguments of the abdomen till the peritonæum is expofed, when the operator fhould reft a little, till the hemorrhagy be entirely abated. He muft then, with great caution, make a fmall opening through this membrane, introduce his finger, and upon this a fcalpel (which is preferable to fciffars), and with great expedition make a complete dilatation; he muft now wipe away the blood with a fponge, prefs the omentum or inteftines gently to a fide, if in the way, and endeavour to difcover to what part of the uterus the placenta adheres, that it may be avoided in making the incifion. This may eafily be known by a thicknefs and folidity in the part, which diftinguifh it from the reft of the uterus; it is ftill more eafily difcovered when the membranes are entire. The blood-veffels are lefs in number, and fmalleft in the middle and anterior part of the uterus, which therefore, if the placenta does not interfere, is the proper place for making the incifion, which muft be performed with the utmoft attention, left the child fhould be wounded: if the membranes are entire, more freedom may be ufed, and *vice verfa*. The direction and length of the wound of the uterus muft be the fame with the external one. The child muft now be quickly extracted, and the placenta carefully feparated: thefe muft be given to an affiftant, who will divide the chord, and take care of the child, as the operator's attention muft be wholly beftowed on the mother. The coagulated blood, &c. being removed by a fponge wrung out of warm water (left the uterus or inteftines be protruded, which are very troublefome to reduce), the lips of the external wound muft be quickly brought together, and retained by an affiftant till fecured by a few ftitches; generally three will be fufficient: as many needles fhould be ready threaded with pretty large broad ligatures; the middle ftitch ought to be made firft; the needle fhould be introduced at a proper diftance, *i.e.* about an inch and one-fourth from the fide of the wound, carrying it firft from without inwards, and then from within outwards, fecuring with a double flip a knot, to be ready to untie, left violent tenfion or inflammation fhould enfue; under the knot a foft comprefs of lint, fharpee, or rolled plafter, fhould be applied, and the whole dreffings muft be fecured by a proper comprefs and bandage. The patient muft be afterwards treated in the fame manner as after lithotomy, or any other capital operation.

Quæritur, To what caufe is the unfuccefsful event of this operation to be imputed? When the operation proves fatal, to what immediate caufe are we to afcribe the death of the patient? Is it nervous, or uterine irritation, from cutting, that kills? Is it internal hemorrhagy, or the extravafation of fluids into the cavity of the abdomen? Or are not the fatal confequences rather to be imputed to the accefs of the air on the irritable vifcera? This can only therefore be prevented by expofing thefe parts for as fhort a fpace of time as poffible. Dr Monro, the prefent anatomical profeffor at Edinburgh, in making experiments on young fmall animals, fuch as bitches, cats, frogs, &c. by opening the cavity of the abdomen, and tying the biliary ducts, remarks, that though a large opening into the abdomen be made by incifion, if the wound be quickly clofed and ftitched, the animal will recover, and no bad confequences follow; but if expofed a few minutes to the air, dreadful pain foon comes on, which the creature expreffes by the fevereft agonies; convulfions at laft enfue, and death within four or fix hours after the operation. On opening the abdomen after death, the whole vifcera are found to be in an inflamed ftate, and univerfally adhering to one another. He has often repeated the experiment, and the fame appearances as often take place.

May not the analogy here juftly apply to the human fubject? And, in performing the Cæfarean operation, fhould we not be very careful that the vifcera be expofed as little as poffible, and that the wound be covered with the utmoft poffible expedition?

Chap. VII. *Of the Section of the Symphyfis.*

M. Baudelocque, as has already been obferved, condemns this operation; and, from what he has advanced, apparently with reafon. As no theory, however, can be looked upon as thoroughly eftablifhed until it be

Section of the Symphysis.

be confirmed by experience, this gentleman has collected together a number of the principal *facts* relating to this subject. He supposes, that unless it has been successful in saving both the life of the woman and child, the cutting of the symphysis of the pubes cannot by any means be said to have answered its purpose. It is not sufficient that the child has shown some signs of life at its birth, and that the mother has survived for some time. In this respect the Cæsarean operation has the advantage of it, as it always saves the life of the child, and it is very rare for the woman to sink under it immediately. He is of opinion, that there is scarcely one of the cases of this operation, the relation of which may not be justly contested, or solid objections raised against it; either because the operators have been deceived with regard to the dimensions of the pelvis and of the child's head, or because they have greatly exaggerated the advantage gained by the separation of the bones.—The first and most remarkable instance of success in this operation is of a woman named *Souchot;* but though it is not denied that the woman was delivered, and recovered after the operation, yet it has been said by those who take the contrary side, that there was no necessity for performing it. It is certain that this woman had been delivered four times before; in all of which cases the child was killed. M. Baudelocque does not enter into the merits of this question: he considers only what advantage could possibly be gained by it.

"Whatever degree of separation (says he) took place between the ossa pubis after the section of the symphysis, it must have augmented the size of the passage; that is an incontestable fact: but how much did it enlarge in the direction in which it was originally too narrow? The solution of this problem would be easy, if we knew the dimensions of Souchot's pelvis as well as we know those of her child's head. According to the estimation made of it by the physicians who performed the operation, the diameter of the pelvis was only two inches and a half in the direction from the pubes to the sacrum superiorly, and that of the child's head was just three inches and a half. The excess of the latter was consequently one inch, as well as the amplitude to be procured to the former. A separation of two inches and a half between the ossa pubis, the greatest which it was then thought could be obtained, not being able to give more than six lines to the diameter of the pelvis in the aforesaid direction, they thought to make the remaining surplus of the head pass into the separation between the bones; and, moreover, they had the precaution to make the partial protuberances pass successively through the strait, in order to get another line by that means; so that by this system, the section of the pubes produced a result of 13 lines at least, considering it relatively to delivery. Notwithstanding this ingenious calculation, and this great product, the passage was still found narrow enough to give some obstruction to the child's head, and to endanger its life.

"It seems evident that this plan was not formed till after the execution; and that they have only sought to explain what they must have done according to the opinion which they entertained that the diameter of the child's head was an inch larger than that of the pelvis, and not according to what they did and observed: because no one had yet determined the product of a separation of two inches and a half between the ossa pubis, with respect to the different diameters of the pelvis, and particularly respecting that which goes from before backward; because they did not measure the separation as they affirm they did, neither in the case of *Souchot* nor in any other; because the accoucheurs of that woman were then agitated, *much agitated*, as they have publicly confessed; lastly, because this great product, and those sage calculations which we admire in their history of it, were not then necessary. Though they have allowed but two inches and a half to the small diameter of the superior strait, other accoucheurs equally skilful have assigned it six lines more; and they were not deceived if they considered it a little diagonally, as the smallest diameter of the child's head always presents; that is to say, from one of the sides of the projection formed by the base of the sacrum to the symphysis of the pubes."

Our author now goes on to show at great length, that the pelvis of the woman in question was less out of proportion than had been represented; that only two lines of enlargement were necessary, and no more than two were obtained. In like manner, he says, that all the other women upon whom M. Sigault operated were equally well formed excepting one named *Vespres.* This woman died after passing five days in great agony. The ossa pubis were separated about an inch and an half; and in consequence of this separation, the sacro-iliac symphyses were plainly injured, as well as the neighbouring parts. On inspecting the body, these were found open, with the periosteum separated from them: there was also a collection of purulent matter of a dark grey colour, extending very far into the cellular tissue of the left iliac fossa, &c.

In this case, both the mother and her child perished; and M. Baudelocque looks upon it to be sufficient to show the inefficacy of the operation: and he tells us, that out of five women whom Sigault delivered in this way, one died, and four of the children; but M. le Roy, a more successful operator, out of an equal number saved all the children. In a case related by this gentleman, the ossa pubis are said to have separated two inches; and by parting the thighs, an opening of near three inches was obtained: but in this case again, M. Baudelocque controverts the measurements of Le Roy. Another woman named *Du Belloy*, on whom the operation was performed, began to walk on the tenth day after; and this seems to be almost the only case against which M. Baudelocque has not some objection. He mentions, however, an experiment performed on the body of a woman who had died on the 11th day after the Cæsarean operation had been performed in the linea alba. The body was œdematous, which rendered the case more favourable; and a dead child was placed in the belly, after taking out the uterus. The pelvis was only 20 lines in the small diameter, and four inches and a quarter in the transverse. The diameter of the child's head was but three inches five or six lines from one parietal protuberance to the other; the trunk was thin, and every part of the body had been pressed and kneaded, to restore as much as possible the suppleness which death had taken away. An attempt was then made

Section of the Symphysis.

to bring the child through the pelvis by pulling its feet; but it was found impossible thus to disengage it farther than the breast. The symphysis of the pubes was then laid bare by an incision of two inches and an half; preserving, below, the anterior commissure of the *labia pudendi;* and above, an extent of 18 or 20 lines under the inferior angle of the Cæsarean operation. The ossa pubis separated at first no more than nine lines; which opening was augmented as gradually as possible to 21 lines by separating the thighs, and afterwards it was farther increased to two inches and an half by pulling the hips. It was next attempted to bring away the head, which had spontaneously placed itself in the most advantageous situation: but, though several gentlemen of the profession employed their strength successively at the trunk, and on the lower jaw with two fingers in the mouth, it did not advance a single line; nor would it pass the strait until M. Baudelocque seconded those efforts by pressing on the head with one hand placed in the belly, and by compressing it strongly in the direction of its thickness. At the instant when it cleared the strait, the inferior angle of the incision in the teguments tore to the vulva; and the wound was so lengthened towards that of the Cæsarean operation, that those three openings were very near making but one. The sacro-iliac symphyses, which were already a little open, and the ligaments and periosteum ruptured by the time that the ossa pubis were separated 21 lines, now gave way entirely, and with so much noise as to be distinctly heard by every one of the assistants. The ossa pubis, after the passage of the head, remained at the distance of three inches from each other; the angle of the right os pubis was two inches and six lines from the centre of the projection of the sacrum, and the angle of the left os pubis only two inches and three lines; so that the diameter of the pelvis was augmented seven lines in one way and ten in the other.

From this experiment, M. Baudelocque concludes, that very little advantage can be expected from the operation where the pelvis presents only 18 or 19 lines, or even 21 superiorly, such as was the pelvis of Belloy. We must observe, however, that we cannot argue with propriety from a dead to a living subject: though if the measurements are wrong, as our author *afterwards* says, although at first he "had nothing particular to object" to her case, the whole argument in favour of the operation must fall to the ground.

Objections of a similar kind are made to every other case which M. Baudelocque relates: And as it is impossible for those who were not acquainted with the parties to judge of the propriety or impropriety of the operation, we shall content ourselves with describing from M. Baudelocque the appearances met with in the body of a woman who had died in the operation. "The left *labium* was very much swelled and livid; the sacro-iliac symphyses were of a brownish colour to the extent of an inch at least, on account of the blood extravasated under the periosteum which was detached from them; they were overflown with a purulent and ichorous discharge, more abundant on the left side than the right; and which sprung from the bottom of them, through several openings, which were so many rents, whenever the ossa ilia were moved and pressed towards the sacrum; the left symphysis was open five lines, and the right only three: a gangrenous abscess was seen on the right side behind and above the acetabulum, which extended to the anterior and inferior part of the uterus, where there was an eschar of the same nature; an ulcer also gangrenous, and in form of a chink, was observed in the posterior part of that viscus, from the upper part of its neck to the insertion of the ligament of the ovarium, and it penetrated into its cavity. The diameter of the pelvis was two inches and a half from the pubes to the base of the sacrum; five inches from one side to the other; and four and an half from one acetabulum to the sacro-iliac junction of the opposite side. The section had been made on the left os pubis, which was cut clean, and without the smallest notch."

From these, and a number of other examples which our limits will not allow us to insert, our author deduces the following conclusions.

"Though the section of the pubes has been thought more simple, more easy, and certain, than the Cæsarean operation, at a time when experience had not yet demonstrated the difficulties it might present, and the dangers that might follow it, ought we to think the same of it at present? How many times already has it been necessary to have recourse to the saw to separate the ossa pubis? and how often has it not been found impossible to procure any distance between them after the separation? How often has this operation produced a free passage for the child, whose preservation ought necessarily to enter into the plan of the operator, as well as that of the mother, and constitute a part of its success?

"This new operation will appear more simple and less painful than the Cæsarean, if we only consider the extent of the incision, and the nature and importance of the parts concerned in it: that is an indisputable fact. It is only the teguments and the fat which is divided, at most only two inches and an half, and the symphysis of the pubes; there are usually only small vessels cut, incapable of furnishing much blood, and the instrument does not touch the uterus; the child comes into the world by the way that nature intended, and which the section of the pubes renders more or less accessible; there is no considerable hæmorrhagy to be feared, nor those extravasations of milky and purulent matter which almost always mortally injure the interior viscera which they fall upon; there are no absolute difficulties in the execution of this operation but what arise from the intimate consolidation of the bones; and it no way exposes women to subsequent hernias which have been so frequently seen after the Cæsarean operation: this is the idea which its partisans have had of it, and which the greater part of them still entertain.

"But the section of the pubes seldom procures the child an easy exit; for hitherto the greater part have died in the passage, or have been victims, a few minutes after their exit, to the efforts necessary to effect it. When the separation of the ossa pubis has been made, it has not always been possible to remove them from each other, on account of the consolidation of the ilia with the sacrum; and this case, which does not seem to be exceedingly rare, and which cannot be known till after the operation, renders it fruitless, and cannot dispense us from the Cæsarean operation.

Section of the Symphysis.

"If we reflect ever so little on the danger to which the child is exposed in a preternatural labour, where we are obliged to bring it by the feet, and on the small number that then escape death, when the mother's pelvis has not, pretty nearly, all its natural dimensions, we discover another source of accidents which accompanies the section of the pubes; and which we doubtless should diminish, if we could commit the expulsion of the child to the contractions of the uterus, or take hold of the head with the forceps, as some practitioners have already done: but, except in that very small number of cases, the child has always been extracted by the feet whether the head presented or not

"Though this operation very seldom secures the child's life, even when the pelvis is not excessively deformed, it is not then always exempt from the severest consequences to the mother. The death of both is certain when that deformity is extreme. The consequences of a spontaneous separation of the ossa pubis, and of the ossa ilia and sacrum, in some natural or laborious labours, long since announced those which might be expected from this new operation; the example of Vespres, those of the fifth woman on whom M. le Roy performed it, the fourth by M. Cambon, that at Arras, at Dusseldorp, at Spire, at Lyons, at Gênes, that by M. Riollay, by M. Matthiis, &c. have proved that it was not without cause that those accidents were dreaded. A devastation in the external parts and the neck of the uterus; an inflammation and gangrene of that viscus; collections of purulent, sanious, and putrid matter, in the cellular tissue of the pelvis; a hernia of the bladder between the ossa pubis; echimoses along the psoæ muscles; injury to the canal of the urethra; incontinence of urine, and gangrenes more or less profound, &c. form the group of accidents of which this new operation is susceptible. Granting that those of the Cæsarean operation are as formidable for the mother, at least it presents a certain resource, exempt from every danger, for the child. Which of the two operations, therefore, ought to be preferred?

"Even if we could, without inconveniences to the woman, obtain a separation of two inches and an half between the ossa pubis after the section of their symphysis, the Cæsarean operation would still be the sole resource in cases of extreme deformity of the pelvis; the section of the pubes cannot enter into comparison with it, except when the small diameter of the superior strait shall have, at least, an extent of two inches and an half. Though I suspended my judgment, at the time I published my first edition, concerning the preference to be given to one of these two methods, in the latter case, till I could procure more positive information of the innocence or danger of so considerable a separation; though I required that men who had no interest in vaunting this new method to the detriment of the former; in one word, that its adversaries should have seen a separation of two inches and an half, without a rupture of the sacro-iliac symphyses, and without inconveniences to make me adopt this new operation; at present, better informed on all these points, I am not afraid to reject it, and to affirm that no one has ever separated the ossa pubis two inches and a half without destroying the life of the woman. It has had no success but when it has been performed on pelvises at least two inches three quarters in the small diameter, and when the separation has been limited to much less than the point to which they fancied it was carried; in those cases, in fact, where it was absolutely useless; the pelvis being larger still, for I have found it to be more than three inches in some of the women. The section of the pubes cannot at present maintain any comparison with the Cæsarean operation; at most, it might be substituted for the forceps, in some particular cases only: for it cannot, without great inconveniences, give the pelvis an increase of more than two lines from the pubes to the sacrum superiorly; and that instrument may, without danger, reduce the diameter of the child's head as much. But what practitioner would prefer a new operation, which seems to be surrounded by rocks on every side, to one that has been crowned with a thousand successes? If we allow the former any advantages, they would never be more evident than in that species of locked head mentioned by Roederer, where we cannot (says he) introduce any instrument between the head and the pelvis, at whatever part we attempt it; in that case, it would merit a preference over opening the cranium, the use of the crotchets, and the Cæsarean section proposed by the same author: it would be preferable also, in cases where the inferior strait is contracted transversely, provided that a small separation were sufficient to give that diameter the necessary extent."

Part III. Of DISORDERS subsequent to DELIVERY.

Chap. I. *Of the general Management of Women after Delivery.*

The woman being delivered of the child and placenta, let a soft linen-cloth, warmed, be applied to the external parts; and if she complains much of a smarting sorness, some pomatum may be spread upon it. The linen that was laid below her, to spunge up the discharges, must be removed, and replaced with others that are clean, dry, and warm. Let her lie on her back, with her legs extended close to each other; or upon her side, if she thinks she can lie easier in that position, until she recovers from the fatigue: if she is spent and exhausted, let her take a little warm wine or caudle, or, according to the common custom, some nutmeg and sugar grated together in a spoon: the principal design of administering this powder, which among the good women is seldom neglected, is to supply the want of some cordial draught, when the patient is too weak to be raised, or supposed to be in danger of retchings from her stomach's being overloaded. When she hath in some measure recovered her strength and spirits, let the cloths be removed from the parts, and others applied in their room; and, if there is a large discharge from the uterus, let the wet linen below her be also shifted, that she may not run the risk of catching cold.

Management after Delivery.

When the patient is either weak or faintish, she ought not to be taken out of bed, or even raised up to have her head and body shifted, until she is a little recruited; otherwise she will be in danger of repeated faintings, attended with convulsions, which sometimes end in death. To prevent these bad consequences, her skirt and petticoats ought to be loosened and pulled down over the legs, and replaced by another well warmed, with a broad head-band to be slipt in below, and brought up over her thighs and hips: a warm double cloth must be laid on the belly, which is to be surrounded by the head-band of the skirt pinned moderately tight over the cloth, in order to compress the viscera and the relaxed parietes of the abdomen, more or less as the woman can easily bear it; by which means the uterus is kept firm in the lower part of the abdomen, and prevented from rolling from side to side when the patient is turned: but the principal end of this compression is to hinder too great a quantity of blood from rushing into the relaxed vessels of the abdominal contents, especially when the uterus is emptied all of a sudden by a quick delivery. The pressure being thus suddenly removed, the head is all at once robbed of its proportion of blood, and the immediate revulsion precipitates the patient into dangerous lypothymia.

For this reason the belly ought to be firmly compressed by the hands of an assistant, until the bandage is applied; or, in lieu of it, a long towel, sheet, or roller, to make a suitable compression: but for this purpose different methods are used in different countries, or according to the different circumstances of the patients. The head-cloaths and shift ought also to be changed, because with sweating in time of labour they are rendered wet and disagreeable. Several other applications are necessery, when the external or internal parts are rent or inflamed; misfortunes that sometimes happen in laborious and preternatural cases. We shall conclude this chapter with giving some necessary directions with regard to air, diet, &c.

Although we cannot remove the patient immediately after delivery into another climate, we can qualify the air so as to keep it in a moderate and salutary temper, by rendering it warm or cold, moist or dry, according to the circumstances of the occasion. With regard to diet, women, in time of labour, and even till the ninth day after delivery, ought to eat little solid food, and none at all during the first five or seven: let them drink plentifully of warm diluting fluids, such as barley-water, gruel, chicken-water, and teas: caudles are also commonly used, composed of water-gruel boiled up with mace and cinnamon, to which, when strained, is added a third or fourth part of white wine, or less if the patient drinks plentifully, sweetened with sugar to their taste: this composition is termed *white caudle;* whereas, if ale is used instead of wine, it goes under the name of *brown caudle.* In some countries, eggs are added to both kinds; but, in that case, the woman is not permitted to eat meat or broths till after the fifth or seventh day: in this country, however, as eggs are no part of the ingredients, the patient is indulged with weak broth sooner, and sometimes allowed to eat a little boiled chicken. But all these different preparations are to be prescribed weaker or stronger, with regard to the spices, wine, or ale, according to the different constitutions and situations of different patients: for example, if she is low and weak, in consequence of an extraordinary discharge of any kind, either before or after delivery, or if the weather is cold, the caudles and broths may be made the stronger; but if she is of a full habit of body, and has the least tendency to a fever, or if the season is excessively hot, these drinks ought to be of a very weak consistence, or the patient restricted to gruel, tea, barley and chicken-water, and these varied according to the emergency of the case.

Her food must be light and easy of digestion, such as panada, biscuit, and sago; about the fifth or seventh day she may eat a little boiled chicken, or the lightest kind of young meat; but these last may be given sooner or later according to the circumstances of the case and the appetite of the patient. In the regimen as to the eating and drinking, we should rather err on the abstemious side than indulge the woman with meat and strong fermented liquors, even if these last should be most agreeable to her palate; for we find by experience that they are apt to increase or bring on fevers, and that the most nourishing and salutary diet is that which we have above prescribed. Every thing that is difficult of digestion, or quickens the circulating fluids, must of necessity promote a fever, by which the necessary discharges are obstructed, and the patient's life endangered.

As to the article of sleeping and watching, the patient must be kept as free from noise as possible, by covering the floors and stairs with carpets and cloths, oiling the hinges of the doors, silencing the bells, tying up the knockers, and in noisy streets strowing the pavement with straw; if, notwithstanding these precautions, she is disturbed, her ears must be stuffed with cotton, and opiates administered to procure sleep; because watching makes her restless, prevents perspiration, and promotes a fever.

Motion and rest are another part of the nonnaturals to which we ought to pay particular regard. By tossing about, getting out of bed, or sitting up too long, the perspiration is discouraged and interrupted; and in this last attitude the uterus, not yet fully contracted, hangs down, stretching the ligaments, occasioning pain, cold shiverings, and a fever: for the prevention of these bad symptoms, the patient must be kept quiet in bed till after the fourth or fifth day, and then be gently lifted up in the bed-cloaths, in a lying posture, until the bed can be adjusted, into which she must be immediately reconveyed, there to continue, for the most part, till the ninth day; after which period women are not so subject to fevers as immediately after delivery. Some there are who, from the nature of their constitutions, or other accidents, recover more slowly; and such are to be treated with the same caution after as before the ninth day, as the case seems to indicate: others get up, walk about, and recover, in a much shorter time: but these may some time or other pay dearly for their foolhardiness, by encouraging dangerous fevers; so that we ought rather to err on the safe side than run any risk whatsoever.

What next comes under consideration is the circumstance of retention and excretion. We have formerly observed, that, in time of labour, before the head of the child is locked into the pelvis, if the woman has not had an easy passage in her belly that same day, the rectum and colon ought to be emptied by a glyster

Flooding.

glyſter, which will aſſiſt the labour, prevent the diſagreeable excretion of the fæces before the child's head, and enable the patient to remain two or three days after, without the neceſſity of going to ſtool. However, ſhould this precaution be neglected, and the patient very coſtive after delivery, we muſt beware of throwing up ſtimulating glyſters, or adminiſtering ſtrong cathartics, leſt they ſhould bring on too many looſe ſtools, which, if they cannot be ſtopt, ſometimes produce fatal conſequences, by obſtructing the perſpiration and lochia, and exhauſting the woman, ſo as that ſhe will die all of a ſudden; a cataſtrophe which hath frequently happened from this practice. Wherefore, if it be neceſſary to empty the inteſtines, we ought to preſcribe nothing but emollient glyſters, or ſome very gentle opener, ſuch as manna, or *elect. lenitivum.* But no excretion is of more conſequence to the patient's recovery than a free perſpiration; which is ſo abſolutely neceſſary, that unleſs ſhe has a moiſture continually on the ſurface of her body for ſome days after the birth, ſhe ſeldom recovers to advantage: her health, therefore, in a great meaſure, depends upon her enjoying undiſturbed repoſe, and a conſtant breathing ſweat, which prevents a fever, by carrying off the tenſion, and aſſiſts the equal diſcharge of the lochia: and when theſe are obſtructed, and a fever enſues with pain and reſtleſſneſs, nothing relieves the patient ſo effectually as reſt and profuſe ſweating, procured by opiates and ſudorifics at the beginning of the complaints; yet theſe laſt muſt be more cautiouſly preſcribed in exceſſive hot than in cool weather.

The laſt of the nonnaturals to be conſidered are the paſſions of the mind, which alſo require particular attention. The patient's imagination muſt not be diſturbed by the news of any extraordinary accident which may have happened to her family or friends: for ſuch information hath been known to carry off the labour-pains entirely, after they were begun, and the woman has ſunk under her dejection of ſpirits; and, even after delivery, theſe unſeaſonable communications have produced ſuch anxiety as obſtructed all the neceſſary excretions, and brought on a violent fever and convulſions, that ended in death.

Chap. II. *Of violent Floodings.*

All women, when the placenta ſeparates, and after it is delivered, loſe more or leſs red blood, from the quantity of half a pound to that of one pound, or even two; but ſhould it exceed this proportion, and continue to flow without diminution, the patient is in great danger of her life: this hazardous hemorrhagy is known by the violence of the diſcharge, wetting freſh cloths as faſt as they can be applied; from the pulſe becoming low and weak, and the countenance turning pale; then the extremities grow cold, ſhe ſinks into faintings, and, if the diſcharge is not ſpeedily ſtopped or diminiſhed, is ſeized with convulſions, which often terminate in death.

This dangerous efflux is occaſioned by every thing that hinders the emptied uterus from contracting, ſuch as great weakneſs and laſſitude, in conſequence of repeated floodings before delivery; the ſudden evacuation of the uterus; ſometimes, though ſeldom, it proceeds from part of the placenta's being left in the womb; it may happen when there is another child, or more, ſtill undelivered; when the womb is kept diſtruded with a large quantity of coagulated blood: or when it is inverted by pulling too forcibly at the placenta.

After-pains.

In this caſe, as there is no time to be loſt, and internal medicines cannot act ſo ſuddenly as to anſwer the purpoſe, we muſt have immediately recourſe to external application. If the diſorder be owing to weakneſs, by which the uterus is diſabled from contracting itſelf, ſo that the mouths of the veſſels are left open; or, though contracted a little, yet not enough to reſtrain the hemorrhagy of the thin blood; or if, in ſeparating the placenta, the accoucheur has ſcratched or tore the inner ſurface or membrane of the womb; in theſe caſes, ſuch things muſt be uſed as will aſſiſt the contractile power of the uterus, and hinder the blood from flowing ſo faſt into it and the neighbouring veſſels; for this purpoſe, cloths dipped in any cold aſtringent fluid, ſuch as oxycrate, or red tart wine, may be applied to the back and belly. Some preſcribe veneſection in the arm, to the amount of five or ſix ounces, with a view of making revulſion; if the pulſe is ſtrong, this may be proper; otherwiſe, it will do more harm than good. Others order ligatures, for compreſſing the returning veins at the hams, arms, and neck, to retain as much blood as poſſible in the extremities and head. Beſides theſe applications, the vagina may be filled with tow or linen-rags, dipped in the abovementioned liquids, in which a little alum or ſachar-ſaturni hath been diſſolved; nay, ſome practitioners inject proof-ſpirits warmed, or, ſoaking them up in a rag or ſpunge, introduce and ſqueeze them into the uterus, in order to conſtringe the veſſels.

If the flooding proceeds from another child, the retention of the placenta, or coagulated blood, theſe ought immediately to be extracted; and if there is an inverſion of the uterus, it muſt be ſpeedily reduced. Should the hemorrhagy, by theſe methods, abate a little, but ſtill continue to flow, though not in ſuch a quantity as to bring on ſudden death, ſome red wine and jelly ought to be preſcribed for the patient, who ſhould take it frequently, and a little at a time; but above all things chicken or mutton broths, adminiſtered in the ſame manner, for fear of overloading the weakened ſtomach, and occaſioning retchings; theſe repeated in ſmall quantities, will gradually fill the exhauſted veſſels, and keep up the circulation. If the pulſe continues ſtrong, it will be proper to order repeated draughts of barley-water, acidulated with elixir vitriol: but if the circulation be weak and languid, extract of the bark, diſſolved in *aq. cinnamomi tenuis*, and given in ſmall draughts, or exhibited in any other form, will be ſerviceable; at the ſame time, lulling the patient to reſt with opiates. Theſe, indeed, when the firſt violence of the flood is abated, if properly and cautiouſly uſed, are generally more effectual than any other medicine.

Chap. III. *Of the After-pains.*

After-pains commonly happen when the fibrous part of the blood is retained in the uterus or vagina, and formed into large clots, which are detained by the ſudden contraction of the os internum and exter-

num,

Lochia.

num, after the placenta is delivered: or, if these should be extracted, others will sometimes be formed, though not so large as the first, because the cavity of the womb is continually diminishing after the birth. The uterus, in contracting, presses down these coagula to the os internum; which being again gradually stretched, produces a degree of labour-pains, owing to the irritation of its nerves: in consequence of this uneasiness, the woman squeezes the womb as in real labour; the force being increased, the clots are pushed along, and when they are delivered she grows easy.—The larger the quantity is of the coagulated blood, the severer are the pains, and the longer they continue.

Women in the first child seldom have after-pains; because, after delivery, the womb is supposed to contract and push off the clots with greater force in the first than in the following labours: after-pains may also proceed from obstructions in the vessels, and irritations at the os internum. In order to prevent or remove these pains, as soon as the placenta is separated and delivered, the hand being introduced into the uterus, may clear it of all the coagula. When the womb is felt through the parietes of the abdomen larger than usual, it may be taken for granted that there is either another child, or a large quantity of this clotted blood; and, which soever it may be, there is a necessity for its being extracted. If the placenta comes away of itself, and the after-pains are violent, they may be alleviated and carried off by an opiate: for, by sleeping and sweating plentifully, the irritation is removed, the evacuations are increased, the os uteri is insensibly relaxed, and the coagula slide easily along. When the discharge of the lochia is small, the after-pains, if moderate, ought not to be restrained; because the squeezing which they occasion promotes the other evacuation, which is necessary for the recovery of the patient. After-pains may also proceed from an obstruction in some of the vessels, occasioning a small inflammation of the os internum and ligaments; and the squeezing thereby occasioned may not only help to propel the obstructing fluid, but also (if not too violent) contribute to the natural discharges.

Chap. IV. *Of the Lochia.*

We have already observed, that the delivery of the child and placenta is followed by an efflux of more or less blood, discharged from the uterus, which, by the immediate evacuation of the large vessels, is allowed to contract itself the more freely, without the danger of an inflammation, which would probably happen in the contraction, if the great vessels were not emptied at the same time: but as the fluids in the smaller vessels cannot be so soon evacuated, or returned into the vena cava, it is necessary that, after the great discharge is abated, a slow and gradual evacuation should continue, until the womb shall be contracted to near the same size to which it had before pregnancy; and to this it attains about the 18th or 20th day after delivery, though the period is different in different women.

When the large vessels are emptied immediately after delivery, the discharge frequently ceases for several hours, until the fluids in the smaller vessels are propelled into the larger, and then begins to flow again, of a paler colour.

Milk-fever.

The red colour of the lochia commonly continues till the fifth day, though it is always turning more and more serous from the beginning: but, about the fifth day, it flows of a clear, or sometimes (though seldom) of a greenish tint; for, the mouths of the vessels growing gradually narrower by the contraction of the uterus, at last allow the serous part only to pass: as for the greenish hue, it is supposed to proceed from a dissolution of the cellular or cribriform membrane or mucus, that surrounded the surface of the placenta and chorion; part of which, being left in the uterus, becomes livid, decays, and, dissolving, mixes with and tinctures the discharge as it passes along.

Though the lochia, as we have already observed, commonly continue till the 18th or 20th day, they are every day diminishing in quantity, and soonest cease in those women who suckle their children, or have had an extraordinary discharge at first; but the colour, quantity, and duration, differ in different women: in some patients, the red colour disappears on the first or second day; and in others, though rarely, it continues more or less to the end of the month: the evacuation in some is very small, in others excessive: in one woman it ceases very soon, in another flows during the whole month: yet all of these patients shall do well.

Some allege, that this discharge from the uterus is the same with that from a wound of a large surface; but it is more reasonable to suppose, that the change of colour and diminution of quantity proceed from the slow contraction of the vessels; because, previous to pus, there must have been lacerations and imposthumes, and, in women who have suddenly died after delivery, no wound or excoriation hath appeared upon the inner surface of the womb, which is sometimes found altogether smooth, and at other times rough and unequal, on that part to which the placenta adhered. The space that is occupied before the delivery, from being six inches in diameter, or 18 inches in circumference, will, soon after the birth, be contracted to one third or fourth of these dimensions.

Chap. V. *Of the Milk-fever.*

About the fourth day, the breasts generally begin to grow turgid and painful. We have formerly observed, that, during the time of uterine gestation, the breasts in most women gradually increase till the delivery, growing softer as they are enlarged by the vessels being more and more filled with fluids; and by this gradual distension they are prepared for secreting the milk from the blood after delivery. During the two or three first days after parturition, especially when the woman has undergone a large discharge, the breasts have been sometimes observed to subside and grow flaccid; and about the 3d or 4th day, when the lochia begin to decrease, the breasts swell again to their former size, and stretch more and more, until the milk, being secreted, is either sucked by the child, or frequently of itself runs out at the nipples.

Milk-fever. Moft of the complaints incident to women after delivery, proceed either from the obftruction of the lochia in the uterus, or of the milk in the breafts, occafioned by any thing that will produce a fever; fuch as catching cold, long and fevere labour, eating food that is hard of digeftion, and drinking fluids that quicken the circulation of the blood in the large veffels; by which means the fmaller, with all the fecretory and excretory ducts, are obftructed.

The difcharge of the lochia being fo different in women of different conftitutions, and befides in fome meafure depending upon the method of management, and the way of life peculiar to the patient, we are not to judge of her fituation from the colour, quantity, and duration of them, but from the other fymptoms that attend the difcharge; and if the woman feems hearty, and in a fair way of recovery, nothing ought to be done with a view to augment or diminifh the evacuation. If the difcharge be greater than fhe can bear, it will be attended with all the fymptoms of inanition; but as the lochia feldom flow fo violently as to deftroy the patient of a fudden, fhe may be fupported by a proper nourifhing diet, affifted with cordial and reftorative medicines. Let her, for example, ufe broths, jellies, and affes milk; if the pulfe is languid and funk, fhe may take repeated dofes of the *confect. cardiac.* with mixtures compofed of the cordial waters and volatile fpirits: fubaftringents and opiates frequently adminiftered, with the *cort. Peruvian.* in different forms, and auftere wines, are of great fervice. On the other hand, when the difcharge is too fmall, or hath ceafed altogether, the fymptoms are more dangerous, and require the contrary method of cure: for now the bufinefs is to remove a too great plenitude of the veffels in and about the uterus, occafioning tenfion, pain, and labour, in the circulating fluids; from whence proceed great heat in the part, reftlefsnefs, fever, a full, hard, quick pulfe, pains in the head and back, naufea, and difficulty in breathing. Thefe complaints, if not at firft prevented, or removed by reft and plentiful fweating, muft be treated with venefection and the antiphlogiftic method.

When the obftruction is recent, let the patient lie quiet, and encourage a plentiful diaphorefis, by drinking frequently of warm, weak, diluting fluids, fuch as water-gruel, barley-water, tea, or weak chicken-broth.

Should thefe methods be ufed without fuccefs, and the patient, far from being relieved by reft, plentiful fweating, or a fufficient difcharge of the obftructed lochia, labour under an hot dry fkin, anxiety, and a quick, hard, and full pulfe, the warm diaphoretics muft be laid afide; becaufe, if they fail of having the defired effect, they muft neceffarily increafe the fever and obftruction, and recourfe be had to bleeding at the arm or ankle to more or lefs quantity, according to the degree of fever and obftruction; and this evacuation muft be repeated as there is occafion. When the obftruction is not total, it is fuppofed more proper to bleed at the ankle than at the arm; and at this laft, when the difcharge is altogether ftopped, her ordinary drink ought to be impregnated with nitre.

If fhe is coftive, emollient and gently opening glyfters may be occafionally injected; and her breafts muft be fomented and fucked, either by the mouth or pipe-glaffes. If by thefe means the fever is abated, and the neceffary difcharges return, the patient commonly recovers; but if the complaints continue, the antiphlogiftic method muft ftill be purfued. If, notwithftanding thefe efforts, the fever is not diminifhed or removed by a plentiful difcharge of the lochia from the uterus, the milk from the breafts, or by a critical evacuation by fweat, urine, or ftool, and the woman is every now and then attacked with cold fhiverings; an abfcefs or abfceffes will probably be formed in the uterus or neighbouring parts, or in the breafts; and fometimes the matter will be tranflated to other fituations, and the feat of it foretold from the part's being affected with violent pains: thefe abfceffes are more or lefs dangerous according to the place in which they happen, the largenefs of the fuppuration, and the good or bad conftitution of the patient.

If, when the pains in the epigaftric region is violent, and the fever increafed to a very high degree, the patient fhould all of a fudden enjoy a ceffation from pain, without any previous difcharge or critical eruption, the phyfician may pronounce that a mortification is begun; efpecially if, at the fame time, the pulfe becomes low, quick, wavering, and intermitting: if the woman's countenance, from being florid, turns dufky and pale, while fhe herfelf, and all the attendants, conceive her much mended; in that cafe, fhe will grow delirious, and die in a very fhort time.

What we have faid on this fubject regards that fever which proceeds from the obftructed lochia, and in which the breafts may likewife be affected: but the milk-fever is that in which the breafts are originally concerned, and which may happen tho' the lochia continue to flow in fufficient quantity; neverthelefs, they mutually promote each other, and both are to be treated in the manner already explained; namely, by opiates, diluents, and diaphoretics, in the beginning; and, the prefcriptions failing, the obftructions muft be refolved by the antiphlogiftic method defcribed above. The milk-fever alone, when the uterus is not concerned, is not fo dangerous, and is much more eafily relieved. Women of an healthy conftitution, who fuckle their own children, have good nipples, and whofe milk comes freely, are feldom or never fubject to this diforder, which is more incident to thofe who do not give fuck, and neglect to prevent the fecretion in time; or, when the milk is fecreted, take no meafures for emptying their breafts. This fever likewife happens to women who try too foon to fuckle, and continue their efforts too long at one time; by which means the nipples, and confequently the breafts, are often inflamed, fwelled, and obftructed.

In order to prevent a too great turgency in the veffels of the breafts, and the fecretion of milk, in thofe women who do not choofe to fuckle, it will be proper to make external application of thofe things which, by their preffure and repercuffive force, will hinder the blood from flowing in too great a quantity to this part, which is now more yielding than at any other time: for this purpofe, let the breafts be covered with *emp. de minia*, *diapalma*, or *emp. fimp.* fpread upon linen, or cloths dipped in camphorated fpirits, be frequently applied to thefe parts and the arm-pits; while the patient's diet and drink is of the lighteft kind, and given

Evacuations.

given in small quantities. Notwithstanding these precautions, a turgency commonly begins about the third day; but by rest, moderate sweating, and the use of these applications, the tension and pain will subside about the fifth or sixth day, especially if the milk runs out at the nipples: but if the woman catches cold, or is of a full habit of body, and not very abstemious, the tension and pain increasing, will bring on a cold shivering succeeded by a fever; which may obstruct the other excretions, as well as those of the breast.

In this case, the sudorifics above recommended must be prescribed; and if a plentiful sweat ensue, the patient will be relieved; at the same time the milk must be extracted from her breasts, by sucking with the mouth or glasses: should these methods fail, and the fever increase, she ought to be blooded in the arm; and instead of the external applications hitherto used, emollient liniments and cataplasms must be substituted, in order to soften and relax. If, in spite of these endeavours, the fever proceeds for some days, the patient is frequently relieved by critical sweats, a large discharge from the uterus, miliary eruptions, or loose stools mixed with milk, which is curdled in the intestines; but should none of these evacuations happen, and the inflammation continue with increasing violence, there is danger of an imposthume, which is to be brought to maturity, and managed like other inflammatory tumors; and no astringents ought to be applied, lest they should produce scirrhous swellings in the glands.

As the crisis of this fever, as well as of that last described, often consists in miliary eruptions over the whole surface of the body, but particularly on the neck and breast, by which the fever is carried off, nothing ought to be given which will either greatly increase or diminish the circulating force, but such only as will keep out the eruptions. But if, notwithstanding these eruptions, the fever, instead of abating, is augmented, it will be necessary to diminish its force, and prevent its increase, by those evacuations we have mentioned above. On the contrary, should the pulse sink, the eruptions begin to retreat inwardly, and the morbific matter be in danger of falling upon the viscera, we must endeavour to keep them out by opiates and sudorific medicines; and here blisters may be applied with success.

Chap. VI. *Of the Evacuations necessary at the end of the Month after Delivery.*

Those who have had a sufficient discharge of the lochia, plenty of milk, and suckle their own children, commonly recover with ease, and, as the superfluous fluids of the body are drained off at the nipples, seldom require evacuations at the end of the month; but if there are any complaints from fulness, such as pains and stitches, after the 20th day, some blood ought to be taken from the arm, and the belly gently opened by frequent glysters, or repeated doses of laxative medicines.

If the patient has tolerably recovered, the milk having been at first sucked or discharged from the nipples, and afterwards discussed, no evacuations are necessary before the third or fourth week; and sometimes not till after the first flowing of the menses, which commonly happens about the fifth week; if they do not appear within that time, gentle evacuations must be prescribed, to carry off the plethora, and bring down the catamenia.

Explanation of the Plates.

EXPLANATION of the PLATES.

Plate CCCXVI. fig. 1. represents a well formed pelvis.

AAAA, The *ossa ilia*, properly so called. *a a*, The iliac fossæ. *b b b b*, The angle which divides transversely and obliquely, from behind forward, the internal face of the os ilium into two parts, making part of the brim of the pelvis. *c c c c*, The cristæ of the ossa ilia. *e e*, Their anterior superior spines. *f f*, The angle formed by the internal lip of the crista of the os ilium, to which is attached a ligament inserted at the other end in the transverse apophysis of the last lumbar vertebra. *g g*, The inferior angle of the os ilium, which makes part of the acetabulum.

BB, The os ischium. *h h*, Its tuberosities. *i i*, Its branches. *k k*, Its posterior part, making part of the acetabulum.

CC, The body of the os pubis. *l l*, Its angle. *m m*, Its posterior extremity, making part of the acetabulum. *n n*, Its descending branch, uniting with that of the ischium.

DDD, The os sacrum. 1, 2, 3, 4, The anterior holes. *o o o*, Its base. *p p*, The sides. *q*, The point. E, The coccyx. F, The last lumbar vertebra. *r r*, The transverse apophysis of that vertebra. *s s*, The ligament proceeding from the transverse apophysis of the last vertebra to the angle of the internal lip of the crista of the os ilium, marked *f f*. *t t*, Another ligament which descends from the same apophysis to the superior edge of the sacro-iliac symphysis.

GG, The femur or thigh-bone. VV, Its head received in the acetabulum. *u*, *u*, The foramina ovalia.

H, The symphysis of the ossa pubis. II, The sacro-iliac symphyses. K, The sacro-vertebral symphysis.

Fig. 2. represents the superior strait of a well formed pelvis.

a a, The iliac fossæ. *b*, The sacro-vertebral angle, or projection of the sacrum. *c*, The last lumbar vertebra. *d d*, The lateral parts of the base of the sacrum. *e e*, The sacro-iliac symphyses. *f f*, The parts over the acetabula. *g*, The symphysis of the pubes.

The lines denote the different diameters of the superior strait. AB, The little diameter. CD, The transverse or great diameter. EF, GH, The oblique diameter, extending from the left acetabulum to the right sacro-iliac junction.

Fig. 3. shows the inferior strait of a well formed pelvis.

a a, The external faces of the ossa ilia. *b b*, Their anterior superior spines. *c c*, Their anterior inferior spines. *d d*, The acetabula. *e e*, The foramina ovalia, with the obturator ligaments. *f f*, The ischiatic tuberosities. *g g*, The ossa pubis. *h h*, The branches of the os pubis and ischium united. *i i*, The sacrum. *k*, The coccyx. *l l*, The sacro-ischiatic ligaments. *m*, The symphysis of the pubes. *n*, Its arch.

Explanation of the Plates.

The diameters of the inferior ftrait are marked by the lines. AA, The *antero-pofterior*, or great diameter. BB, The tranfverfe or little diameter. CC, DD, The oblique diameters.

Fig. 4. fhows a deformed pelvis.

aa, The offa ilia. *bb*, The offa pubis. *cc*, The offa ifchia. *ddd*, The laft lumbar vertebræ. *e*, The projection of the facrum. *ff*, The facro-iliac fymphyfes. *g*, The fymphyfis of the pubes. *hh*, The foramina ovalia. *ii*, The branches of the offa pubis and ifchia, which form the anterior [illegible] of the pelvis. *kk*, The acetabula.

AA, The *antero-pofterior* diameter; the natural length being 14 or 15 lines. BB, The tranfverfe diameter; the natural length four inches and ten lines. CC, The diftance from the projection of the facrum to that point of the margin which anfwers to the left acetabulum, being 13 lines. DD, The diftance from the fame point of the facrum to that of the margin which anfwers to the right acetabulum, 20 lines.

Fig. 5. fhows a vertical fection of the pelvis.

A, A, A, A, The four laft lumbar vertebræ. B, B, B, The os facrum. CC, The coccyx. *dd*, The furface refulting from the fection of the fymphyfis of the pubes. E, The left iliac foffa. F, The left fide of the fuperior ftrait. G, The facro-ifchiatic ligament. H, The tuberofity of the ifchium.

ii, The entrance of the vagina. K, one of the labia pudendi. L, The anus. M, The mons veneris. N, The left natis.

Plate CCCVII.

Fig. 10. gives a front-view of the uterus *in fitu*, fufpended in the vagina; the anterior parts of the offa ifchium, with the offa pubis, pudenda, perinæum, and anus, being removed, in order to fhow the internal parts.

A, the laft vertebra of the loins. BB, the offa ilium. CC, the acetabula. DD, the inferior and pofterior parts of the offa ifchium. E, the part covering the extremity of the coccyx. F, the inferior part of the rectum. GG, the vagina cut open longitudinally, and ftretched on each fide of the collum uteri, to fhow in what manner the uterus is fufpended in the fame.

HH, part of the vefica urinaria ftretched on each fide of the vagina, and inferior part of the fundus uteri.

I, the collum uteri. K, the fundus uteri. LL, the tubi Fallopiani and fimbriæ. MM, the ovaria. NN, the ligamenta lata and rotunda. OO, the fuperior part of the rectum.

Fig. 11. gives a front view of the uterus in the beginning of the firft month of pregnancy; the anterior part being removed that the embryo might appear through the amnios, the chorion being diffected off.

A, the fundus uteri. B, the collum uteri, with a view of the rugous canal that leads to the cavity of the fundus. C, the os uteri.

Fig. 12. In the fame view and fection of the parts as in fig. 10. fhows the uterus as it appears in the fecond or third month of pregnancy.

F, the anus. G, the vagina, with its plicæ.

HH, the pofterior and inferior part of the urinary bladder extended on each fide; the anterior and fuperior part being removed.

II, the mouth and neck of the womb, as raifed up when examining the fame by the touch, with one of the fingers in the vagina.

KK, the uterus as ftretched in the fecond or third month, containing the embryo, with the placenta adhering to the fundus.

Fig. 13. In the fame view and fection of the parts with the former figures, reprefents the uterus in the eighth or ninth month of pregnancy.

A, the uterus as ftretched to near its full extent, with the waters, and containing the fœtus entangled in the funis, the head prefenting at the upper part of the pelvis.

BB, the fuperior part of the offa ilium. CC, the acetabula. DD, the remaining pofterior parts of the offa ifchium. E, the coccyx. F, the inferior part of the rectum. GGG, the vagina ftretched on each fide. H, the os uteri, the neck being ftretched to its full extent or entirely obliterated. II, part of the vefica urinaria. KK, the placenta, at the fuperior and pofterior part of the uterus. LL, the membranes. M, the funis umbilicalis.

Fig. 14. gives a front view of twins *in utero* in the beginning of labour.

A, the uterus as ftretched, with the membranes and waters. BB, the fuperior parts of the offa ilium. CC, the acetabula. DD, the offa ifchium. E, the coccyx. F, the lower part of the rectum. GG, the vagina.

H, the os internum ftretched open about a fingerbreadth, with the membranes and waters, in time of labour pains.

II, the inferior part of the uterus, ftretched with the waters which are below the head of the child that prefents.

KK, the two placentas adhering to the pofterior part of the uterus, the two fœtufes lying before them, one with its head in a proper pofition at the inferior part of the uterus, and the other fituated preternaturally with the head to the fundus; the bodies of each are here entangled in their proper funis, which frequently happens in the natural as well as preternatural pofitions.

LLL, the membranes belonging to each placenta.

Fig. 15. fhows, in a lateral view and longitudinal divifion of the parts, the gravid uterus when labour is fomewhat advanced.

A, the loweft vertebra of the back; the diftance from which to the laft mentioned vertebra is here fhown by dotted lines. CC, the ufual thicknefs and figure of the uterus when extended by the waters at the latter end of pregnancy. D, the fame contracted and grown thicker after the waters are evacuated. EE, the figure of the uterus when pendulous. FF, the figure of the uterus when ftretched higher than ufual, which generally occafions vomitings and difficulty of breathing. G, the os pubis of the left fide. HH, the os internum. I, the vagina. K, the left nympha. L, the labium pudendi of the fame fide. M, the remaining portion of the bladder. N, the anus. OP, the left hip and thigh.

Fig. 16. fhows the forehead of the fœtus turned backwards to the os facrum, and the occiput below the pubes, by which means the narrow part of the head is to the narrow part of the pelvis, that is, between the inferior parts of the offa ifchium.

Explanation of the Plates.

A, the uterus contracted closely to the fœtus after the waters are evacuated. BCD, the vertebræ of the loins, os sacrum, and coccyx. E, the anus. F, the left hip. G, the perinæum. H, the os externum beginning to dilate. I, the os pubis of the left side. K, the remaining portion of the bladder. L, the posterior part of the os uteri.

Plate CCCVIIII. Fig. 17. is principally intended to show in what manner the perinæum and external parts are stretched by the head of the fœtus, in a first pregnancy, towards the end of the labour.

A, the abdomen. B, the labia pudendi. C, the clitoris and its preputium. D, the hairy scalp of the fœtus, swelled at the vertex, in a laborious case, and protruded to the os externum. E, F, the perinæum and anus pushed out by the head of the fœtus in form of a large tumor. GG, the parts that cover the tuberosities of the ossa ischium. H, the part that covers the os coccygis.

Fig. 18. shows in what manner the head of the fœtus is helped along with the forceps, as artificial hands, when it is necessary for the safety of either mother or child.

AABC, the vertebræ of the loins, os sacrum, and coccyx. D, the os pubis of the left side. E, the remaining part of the bladder. FF, the intestinum rectum. GGG, the uterus. H, the mons veneris. I, the clitoris, with the left nymph. X, the corpus cavernosum clitoridis. V, the meatus urinarius. K, the left labium pudendi. L, the anus. N, the perinæum. QP, the left hip and thigh. R, the skin and muscular parts of the loins.

Fig. 19. shows the head of the fœtus, by strong labour-pains, squeezed into a longish form, with a tumor on the vertex, from a long compression of the head in the pelvis.

K, the tumor on the vertex. L, the forceps. M, the vesica urinaria much distended with a large quantity of urine from the long pressure of the head against the urethra. N, the under part of the uterus. OO, the os uteri.

Fig. 20. shows, in the lateral view, the face of the child presenting and forced down into the lower part of the pelvis, the chin being below the pubes, and the vertex in the concavity of the os sacrum: the water being likewise all discharged, the uterus appear closely joined to the body of the child.

Fig. 21. shows, in a lateral view, the head of the child in the same position as in the former figure.

AB, the vertebræ of the loins, os sacrum, and coccyx. C, the os pubis of the left side. D, the inferior part of the rectum. E, the perinæum. F, the left labium pudendi. GGG, the uterus.

Fig. 22. gives a lateral internal view of a distorted pelvis, divided longitudinally, with the head of a fœtus of the seventh month passing the same.

ABC, the os sacrum and coccyx. D, the os pubis of the left side. E, the tuberosity of the os ischium of the same side.

Fig. 23. gives a side view of a distorted pelvis, divided longitudinally, with the head of a full grown fœtus squeezed into the brim, the parietal bones decussating each other, and compressed into a conical form.

ABC, the os sacrum and coccyx. D, the os pubis of the left side. E, the tuberosity of the os ischium. F, the processus acutus. G, the foramen magnum.

Explanation of the Plates.

Plate CCCIX. Fig. 24. shows, in a front view of the pelvis, the breech of the fœtus presenting, and dilating the os internum, the membranes being too soon broke.

Fig. 25. is the reverse of the former, the fore-parts of the child being to the fore part of the uterus.

Fig. 26. represents, in a front view of the pelvis, the fœtus compressed, by the contraction of the uterus, into a round form, the fore-parts of the former being towards the inferior part of the latter, and one foot and hand fallen down into the vagina. In this figure, the anterior part of the pelvis is removed, by a longitudinal section through the middle of the foramen magnum.

AA, the superior parts of the ossa ilium. BB, the uterus. C, the mouth of the womb stretched and appearing in OOOO, the vagina. D, the inferior and posterior part of the os externum. EEEE, the remaining part of the ossa pubis and ischium. FFFF, the membrana adiposa.

Fig. 26. represents, in the same view with fig. 27. the fœtus in the contrary position; the breech and fore-parts being towards the fundus uteri, the left arm in the vagina, and the fore-arm without the os externum, the shoulder being likewise forced into the os uteri.

Plate CCCVI. fig. 8. shows a deformed pelvis of which the small diameter of the superior strait is only 2 inches seven lines. The figure is triple: F. I. shows it in its natural state; F. II. the ossa pubis separated 18 lines; and F. III. with a separation of two inches and an half, in order to show the quantiy of amplification which the section of the symphysis in such a pelvis can produce.

F. I. *a a*, the two last lumbar vertebræ; *bbbb*, the transverse apophyses of these vertebræ; *cc*, ligaments proceeding from the transverse apophyses of the last of these vertebræ to the middle and posterior part of the internal lip of the crista of the os ilium; *dd*, other ligaments descending from the same apophyses to the superior part of the sacro-iliac symphyses; *e*, the projection of the sacrum; *ff*, the lateral parts of the base of the sacrum; *gg*, part of the ossa ilia: the rest of those bones being concealed by F. II. and III.

hh, The bodies of the ossa pubis; *ii*, their angles.

kk, The ossa ischia; *ll*, the branches of these bones, and of the pubes.

m, The arch of the ossa pubis at the fore part of the pelvis.

nn, The foramina ovalia concealed by the ossa pubis of F. II. and III.

A, The symphysis of the ossa pubis seen perspectively. B B, the sacro-iliac symphyses.

F. II. *oo*, Part of the ossa ilia.

PP, The bodies of the ossa pubis; *qq*, their angles; *rr*, their articular facettes seen perspectively; *ff*, very small portions of the branches of the ossa pubis.

ss, The ossa ischia appearing behind the foramina ovalia of nº III; *tt*, articular facettes of the ossa ilia, corresponding to similar ones observed at the sides of the sacrum.

F. III. *uu*, The ossa ilia; *vv*, their cristæ; *xx*, the angle formed by the internal lip of the crista in the middle and posterior part of its length; *yy*, the anterior and superior

Explanation of the Plates.

superior spines of the ossa ilia; *z z*, the anterior spines of these bones; & &, articular facettes of the ossa ilia, making part of the sacro-iliac symphyses.

1 1, The ossa pubis; 2 2, their angles; 3 3, their articular facettes seen perspectively.

4 4, The ossa ischia; 5 5, the united branches of the ossa ischia and pubis; 6 6, the acetabula.

The lines indicate the natural size of the pelvis in the different directions in which they are traced; and their dotted extremities, the amplification which the superior strait acquires in those same directions at a separation of eighteen lines, and of thirty lines between the ossa pubis. Line I. Antero-posterior diameter of the superior strait, or the distance from the pubes to the projection of the sacrum; two inches seven lines. Line II. Transverse diameter of the superior strait, in its most extensive part; four inches seven lines. Line III. Oblique diameter of the superior strait, which extends from that point of the strait which corresponds with the anterior edge of the left acetabulum, to the right sacro-iliac junction; three inches eleven lines. Line IV. The other oblique diameter, which extends from that point of the strait which answers to the anterior edge of the right acetabulum, to the left sacro-iliac symphysis; four inches.

By giving the smallest attention to the relation of these dimensions to those which the head of a fœtus of the usual size presents in their direction in time of labour, we shall see that they are very favourable; except the first, which is, strictly speaking, eleven lines too short, being only thirty-one lines in extent: whereas the transverse diameter of the head is commonly forty-two. It is only in this latter direction, and to the extent of eleven lines, that it would be necessary to augment the capacity of such a pelvis, to favour delivery. As the greater part of those who have performed this new operation, have only obtained a separation of eighteen lines or thereabouts between the ossa pubis, it is fixed at that degree in the second figure.

By such a separation in a pelvis perfectly similar to that here represented, the angle of each os pubis recedes from the centre of the projection of the sacrum three lines or very near beyond their natural distance from it. (See the lines V. and VI). The antero-posterior diameter receives but the same increase, if we consider it as lengthened to the middle of the dotted line IX. IX. which marks the depth at which it may be presumed the lateral convexity of the head engages. Both the oblique diameters augment five lines before, and about two lines and an half backward; and the transverse diameter seven lines or very nearly.

It is evident, that a separation of eighteen lines on such a pelvis cannot remove the disproportion which exists between the small diameter of the superior strait and the small diameter of the child's head; since the former augments only three lines, considered in the most favourable point of view. The amplification which the other diameters receive from a similar separation, is absolutely useless; those diameters being naturally large enough.

Supposing that the ossa pubis recede in an equal degree, in separating two inches and an half, the angle of each of them will remove from the centre of the projection of the sacrum, only six lines farther than the distance they were from it before; which also gives an increase of but six lines between these two points. (See the lines VII. and VIII). The small diameter of the entrance of the pelvis does not gain much more, considering it to the middle of the dotted line XX. which marks the bounds beyond which the convexity of the head could not engage between the ossa pubis, even if the pelvis were divested of all its soft parts: which does not happen in the section of the pubes, for the neck of the bladder, the canal of the urethra, their cellular tissue, the anterior semicircle of the orifice of the uterus, and the anterior part of the vagina present at the opening and before the child's head. At this degree of separation, the transverse diameter augments about thirteen lines, and each oblique diameter nearly fourteen lines: a superfluous increase, since those diameters, in the pelvis represented, have all the length requisite for delivery.

The posterior extremities of the oblique diameters, which are dotted and marked with the figures XI and XII, show the separation which is to be feared in the sacro-iliac symphyses, by separating the ossa pubis two inches and an half. It was at that degree that Mr Baudelocque observed they were open in most of his experiments; since he could easily put the end of his finger, and even of his thumb, into them.

Admitting that the convexity of one of the sides of the child's head may let itself in between the ossa pubis separated to two inches and an half, as far as the dotted line X X, traced on that very convexity, it is evident that that separation cannot procure the relation of dimensions necessary for an easy delivery, when the pelvis has originally but two inches six or seven lines in the small diameter: whence it follows that the section of the pubes, supposing that we could obtain a separation of two inches and an half in the living woman without exposing her to disagreeable accidents, would not answer in the case of a pelvis similar to that represented in this plate.

Fig. 9. shows a pelvis with only 14 or 15 lines in the small diameter of its entrance, and four inches ten lines in the largest. The figure is triple like the former. F. I. represents it in its natural situation; F. II. with the ossa pubis separated two inches and a half; and F. III. with a separation of three inches. M. le Roy says, that he constantly obtained these two degrees of separation without any inconvenience.

F. I. *aaa*, The three last lumbar vertebræ. *b*, The projection formed by the last of those vertebræ, with the base of the sacrum. *cc*, The sides of the base of the sacrum. *ddd*, The transverse apophyses of the right side of the above-mentioned vertebræ. *ee*, A ligament extending from the first of those apophyses to the angle made by the internal lip of the crista of the os ilium towards its middle and posterior part. *ff*, Another ligament which depends from that apophysis to the superior part of the sacro-iliac symphysis. *gggg*, Part of the os ilium. *hh*, The bodies of the ossa pubis: *ii*, their angles. *kk*, The ossa ischia. *ll*, The branches of the ossa ischia and pubis. *m*, The arch of the ossa pubis. *nn*, The foramina ovalia. A, the symphysis of the ossa pubis. BB, The sacro iliac symphyses.

F. II.

Explanation of the Plates.

F. II. *o o o o*, Part of the offa ilia. *f f*, The articular facettes of the offa ilia, making part of the facro-iliac fymphyfes. *p p*, The bodies ofthe offa pubis. *q q*, The angles of the offa pubis feparated two inches and an half. *r r*, The cartilaginous facettes of the offa pubis feen perfpectively. *s s*, The branches of the offa ifchia and pubes.

F. III. *t t*, The offa ilia: *u u*, their criftæ: *v v*, their anterior fuperior fpines: *x x*, their anterior inferior fpines.

y y, The anterior inferior fpines of the offa ilia of F. II. *z z*, Their anterior articular facettes, making part of the facro iliac fymphyfis.

& &, The bodies of the offa pubis: 1 1, their angles. 2 2, The articular facette of each os pubis feen perfpectively. 3 3, The united branches of the offa pubis, and ifchia feen perfpectively.

4 4, The offa ifchia. 5 5, The foramina ovalia, behind which is feen part of the offa ifchia of F. II. 6 6, The acetabula.

The lines indicate the length of the different diameters of the fuperior ftrait, in the direction in which they are traced; and their dotted extremities, the amplification to be expected from a feparation of two inches and an half, and of three inches.

Line I, The antero-pofterior, or fmall diameter of the fuperior ftrait; one inch two or three lines. Line II, The tranfverfe diameter of the fame ftrait: this line, which is four inches ten lines in extent, paffes under the projection of the facrum. Line III, The diftance from the middle and left lateral part of the projection of the facrum, to that point of the margin of the pelvis which anfwers to the anterior edge of the acetabulum on the fame fide; one inch. Line IV, The diftance from the middle and right lateral part of the projection of the facrum, to that point of the margin which anfwers to the anterior edge of the acetabulum on the fame fide; one inch eight lines.

The relation of thefe dimenfions to thofe of a child's head of the ufual fize, is fuch, that the fmall diameter of the latter, fuppofed always to be three inches and an half, furpaffes the fmall diameter of the entrance of fuch a pelvis by 27 or 28 lines. This pelvis would be large enough in the direction of the line II, II.

By feparating the offa pubis two inches and an half, we augment the breadth of the entrance of the pelvis about three quarters of an inch in the direction of the line II, II: as much, or nearly in the direction of the line III, and only fix lines in that of the line IV. The angle of each os pubis marked by the letter *q*, recedes from the centre of the projection of the facrum, nine or ten lines beyond what it was diftant from it before the feparation of the bones: the entrance of the pelvis increafes as much in the direction of the line V, and only half an inch in the courfe of the line VI. The fmall diameter, or the line I, continued to the middle of the dotted line IX, IX, which fhows the depth to which the child's head may be let in between the offa pubis feparated two inches and an half, if the pelvis were divefted of all its foft parts: this diameter will then be augmented only feven lines; whence we fee that it would ftill be an inch and an half, at leaft, fhorter than the fmall diameter of the head of a child of the ufual fize.

The fection of the pubes would therefore be fruitlefs on fuch a pelvis, if it could only procure a feparation of two inches and an half; which feems a very exorbitant one. With more reafon would it be unfuccefsful, if we could feparate the offa pubis only 18 lines, as has moft frequently happened; fince it could not procure the proportion neceffary for delivery, even if we could turn that feparation entirely to the advantage of the fmall diameter of the fuperior ftrait.

Let us fee if a feparation of three inches could procure that proportion.

By feparating the offa pubis three inches, we augment the breadth of the pelvis 12 or 13 lines in the direction of the line II, II; 10 lines at moft in the courfe of the line III; only feven in the line IV; about an inch in the line V; and only feven lines in the direction of the line VI: the angle of each os pubis recedes an inch farther from the projection of the facrum, than the diftance it was at before the feparation of the bones; which augments the opening of the pelvis to the amount of an inch or thereabouts in the direction of the line VII, and only half an inch in the line VIII. The antero-pofterior diameter of the entrance of this pelvis, confidered as far as the middle of the dotted line X, X, which fhows the greateft depth to which the child's head could be let in between the offa pubis feparated three inches, if the pelvis were divefted of the foft parts, increafes but 10 lines or thereabouts; which cannot remove the difproportion that exifted before the fection of the pubes, between that diameter and the thicknefs of the child's head which muft pafs in that direction. From whence we ought to conclude that this feparation alfo would have no fuccefs, if the pelvis were as much deformed as that defigned.

The dotted lines XI and XII, fhow the feparation to be feared in the facro-iliac fymphyfes, by feparating the offa pubis three inches.

The two other dotted lines, marked by the characters IX, IX, and X, X, fhow how far the child's head may be let in between the offa pubis feparated to the two degrees ftated: they were traced on the convexity of a real head applied behind the offa pubis in a pelvis ftripped of its foft parts.

Plate CCCX. fig. 29. fhows a well formed pelvis, the anterior part of which is taken away, to fhow one of the tranfverfe pofitions of the face of the child, and explain more fully the mechanifm of that kind of labour.

a, a, Part of the iliac foffæ. *b, b*, Part of the criftæ of the offa ilia. *c, c*, Their anterior fuperior fpines.

d, d, The ifchiatic tuberofities. *e, e*, The acetabula. *f, f*, The thicknefs of the offa ifchia fawn through vertically before their tuberofities.

g, g, The bodies of the offa pubis fawn through before the acetabula.

h, h, h, A circle reprefenting a vertical fection of the uterus, the anterior part of which is taken away, in order to fhow the child. *i*, The child's chin. *k*, The pofterior extremity of the head. *l, l, l*, The lever applied along the crown of the head, the extremity of it extending beyond the pofterior fontanella.

Explanation of the Plates.

m, The left lateral, and inferior part of the pelvis. *n*, A portion of the right lateral part of the uterine cavity. *o*, The left hand. *p*, *q*, The fore and middle fingers, placed at the fides of the nofe, and prefling againft the upper jaw. R, The right hand grafping the extremity of the lever.

Plate CCCX.

Fig. 30. fhows the fame vertical fection of a pelvis as the laft; with the child's body entirely difengaged from it. The head grafped by the forceps is retained at the fuperior ftrait, with the occiput over the pubes, and the lower part of the fore-head againft the projection of the facrum.

a, *a*, The laft lumbar vertebræ. *d*, *d*, The canal of thefe vertebræ, and of the facrum. *g*, *g*, *g*, *g*, Spiny tubercles of the vertebræ above mentioned. *b*, *b*, *b*. *b*, The falfe vertebræ of the facrum. *c*, *c*, *c*, The coccyx. *e*, *e*, The flatted portion of the anterior face of the facrum.

f, The left facro-ifchiatic ligament. *h*, The cartilaginous and ligamentous facette of the left os pubis, making part of the fymphyfis.

i, The mons veneris. *k*, *k*, *k*, *k*, A circle reprefenting the fection of the uterus, the right fide of which is taken away to fhow the head and the inftrument. *l*, *l*, A portion of the placenta attached to the fuperior and anterior part of the uterus.

m, *m*, *m*, The female branch of the forceps applied on the left fide of the head, which anfwers to the right fide of the pelvis. *n*, *n*, The male branch of the forceps, applied at the left fide of the pelvis, and the right fide of the head. *o*, Part of the left fmall facro-ifchiatic ligament. P, Part of the left os ilium, the reft being concealed by the head.

q, The point to which we ought to bring the lower extremity of the forceps, in bringing the head down into the cavity of the pelvis.

R, The point of elevation at which the extremity of the forceps muft be held, when the head occupies the bottom of the pelvis, after having replaced the face underneath.

Fig. 31. fhows alfo the vertical fection of a pelvis; but it is fuppofed to have only three inches fix lines in the fmall diameter of its entrance. The bafe of the cranium is engaged in it in a tranfverfe direction, the occiput being turned towards the left fide, and the face to the right fide; fo that the greateft thicknefs of the head is ftill above the ftrait.

a, *a*, The two laft lumbar vertebræ. *b*, *b*, *b*, *b*, *b*, The five falfe vertebræ of the facrum. *c*, *c*, *c*, The three pieces of the coccyx. *d*, *d*, The canal of the aforefaid vertebræ. *e*, *e*, *e*, *e*, Their fpinous apophyfes. *f*, *f*, Part of the anterior face of the facrum.

g, The left facro-ifchiatic ligament. *h*, The cartilaginous and ligamentous facette of the left os pubis, making part of the fymphyfis. *i*, The mons veneris.

k, *k*, *k*, *k*, A circle indicating the fection of the uterus in the fame direction as that of the pelvis. *l*, *l*, A portion of the placenta attached to the fundus of the uterus.

m, *m*, *m*, The female branch of the forceps, applied on the left fide of the child's head, and under the fymphyfis of the pubes. *n*, *n*, *n*, The female branch of the forceps applied on the right fide of the head, and before the facrum. *o*, A dotted line, in the direction of which the inftrument muft be pulled to bring down the head hea! into the pelvis. *p*, The point of elevation at which the forceps muft be held when the head is brought down to the bottom of the pelvis, after having turned the face into the curve of the os facrum.

Explanation of the Plates.

Plate CCCVI. fig. 6. fhows M. Baudelocque's calipers for meafuring the antero-pofterior diameter of the fuperior ftrait.

a, *a*, The branches of the calipers. B, The hinge which unites the two branches. *c*, *c*, Lenticular buttons which terminate the branches. *d*, A graduated fcale nine inches long, intended to demonftrate the thicknefs of the body comprifed between the two branches. This fcale is contained in a deep groove cut lengthwife in the branch of the calipers, from the letter *e* to the hinge B; and paffes through a mortoife made in the other branch under the letter *f*. *e*, The place where the fcale is united by a kind of hinge. *f*, A little fcrew with a flat head, defigned to fix the fcale, while we calculate the thicknefs of the body comprifed between the two branches.

Fig. 7. fhows the pelvimeter of M. Coutonli developed in the pelvis.

A, A, The firft branch; whofe fquare, B, is applied to the projection of the facrum. C, *c*, A kind of hooks intended to keep the firft branch in its place, while we introduce and develope the fecond. This has a dove-tailed groove, in which the body of the fecond branch is lodged and moved. *d*, *d*, the fecond branch of the inftrument, whofe fquare *e* is placed againft the fymphyfis of the pubes. F, a fcale four inches long, graduated in the branch *d*, *d*; and intended to fhow the degree of opening from the pubes to the facrum.

Plate CCCVIII. fig. 21. reprefents, in a lateral view of the pelvis, the method of extracting, by means of a curved crotchet, the head of the fœtus, when left in the uterus, after the body is delivered and feparated from it; either by its being too large, or the pelvis too narrow.

ABC, the os facrum and coccyx.

D, the os pubis of the left fide.

EE, the uterus.

F, the locking part of the crotchet.

g, *h*, *i*, The point of the crotchet on the infide of the cranium.

Plate CCCIX.

Fig. 32. reprefents the forceps and blunt hook.

A, the ftraight forceps, in the exact proportion as to the width between the blades, and length from the points to the locking part; the firft being two and the fecond fix inches, which, with three inches and a half (the length of the handles), make in all 11 inches and a half.

B reprefents the pofterior part of a fingle blade, in order to fhow the width and length of the open part of the fame, and the form and dimenfions of the whole.

C, the blunt hook, which is ufed for three purpofes: 1. To affift the extraction of the head, after the cranium is opened with the fciffars, by introducing the fmall end along the ear on the outfide of the head to above the under-jaw, where the point is to be fixed; the other extremity of the hook being held with one hand, whilft two fingers of the other are to be introduced into the forefaid opening, by which hold the head is to be gradually extracted. 2. The fmall end

is

Explanation of the Plates.

is ufeful in abortion, in any of the firft four or five months, to hook down the fecundines, when lying loofe in the uterus, when they cannot be extracted by the fingers or labour-pains, and when the patient is much weakened by floodings. 3. The large hook at the other end is ufeful to affift the extraction of the body, when the breech prefents; but fhould be ufed with great caution, to avoid the diflocation or fracture of the thigh.

Fig. 33. A reprefents the whale-bone fillet, which may be fometimes ufeful in laborious cafes, when the operator is not provided with the forceps, in fudden and unexpected exigencies.

BB, two views of a peffary for the prolapfus uteri. After the uterus is reduced, the large end of the peffary is to be introduced into the vagina, and the os uteri retained in the concave part, where there are three holes to prevent the ftagnation of any moifture. The fmall end without the os externum has two tapes drawn through the two holes, which are tied to four other tapes, that hang down from a belt that furrounds the woman's body, and by this means keep up the peffary. This peffary may be taken out by the patient when fhe goes to bed, and introduced again in the morning; but as this fometimes rubs the os externum, fo as to make its ufe uneafy, the round kind, marked C, are of more general ufe. They are made of wood, ivory, or cork, (the laft covered with cloth and dipped in wax): the peffary is to be lubricated with pomatum, the edge forced through the paffage into the vagina, and a finger introduced in the hole in the middle lays it acrofs within the os externum. They ought to be larger or fmaller, according to the widenefs or narrownefs of the paffage, to prevent their being forced out by any extraordinary ftraining.

DD gives two views of a female catheter, to fhow its degree of curvature and different parts.

Fig. 34. *a*, reprefents a pair of curved crotchets locked together in the fame manner as the forceps. The dotted lines along the infide of one of the blades reprefent a fheath contrived to guard the point till it is introduced high enough: the ligature at the handles marked with two dotted lines is then to be untied, the fheath withdrawn, and the point being uncovered is fixed as in fig. 21. (Pl. cccviii.)

b, Gives a view of the back-part of one of the crotchets, which is 12 inches long.

c, A front view of the point, to fhow its proportional length and breadth.

d, The fciffars for perforating the cranium in very narrow and diftorted pelvifes. They ought to be made very ftrong, and at leaft nine inches in length, with ftops or refts in the middle of the blades, by which a large dilatation is more eafily made.

Plate CCCX. fig. 35. gives an anterior view of the improved lever by Roonhuyfen, an inftrument now come into confiderable reputation. Fig. 36. fhows the fame in profile. Fig. 37. the lever recommended by M. Baudelocque. Fig. 38. one of the blades of a lever recommended by M. Herbinaux, fixed in the handle. Fig. 39. an anterior view of the fame blade with the ftrap. Fig. 40. the fpout of the fyringe, when the inftrument is ufed for injecting oil, or any other liquid into the uterus. The following is a general defcription of Roonhuyfen's lever, with the method of ufing it, as given by M. Preville, and added to his edition of Smellie's Midwifery. "The lever is an oblong piece of iron, 11 inches long, one broad, and about an eighth of an inch in thicknefs, it is ftraight in its middle for four inches, and becomes gradually curved at each extremity: the curves are of different lengths and depths; the edges are rounded; and the extremities for the fpace of an inch, and alfo the middle of the inftrument, are directed to be covered with plafter, and then the whole of it to be fheathed with thin dogfkin; taking care to avoid inequalities or folds, which might injure the woman or child. In ufing it, the accoucheur muft introduce the fore-finger of his left hand into the vagina near the anus, to ferve as a guide for the inftrument, which muft now be gently infinuated between his finger and the head of the child, taking care that no part of the uterus be included between the lever and the head. The inftrument muft then be moved to the right and to the left, to find where there is the greateft fpace, and in fome degree to loofen and difengage the head; and then gradually carried round, until it comes under the pubes, lifting the end of it from time to time, to obtain a freer paffage. The handle of it muft now be raifed, and the inftrument gently fhifted about, until the occiput is exactly lodged in its curve. The more completely and exactly the curve touches and embraces the head, the more fpeedily and eafily the delivery will be effected. The inftrument being thus firmly and equally applied to the head, the accoucheur muft flowly and uniformly raife the handle with his right hand, while with his left he preffes the middle of it downward; by this means the coccyx is forced backward, and the lower part of the pelvis is enlarged. By continuing to raife the handle of the lever and to prefs down its middle or centre, the head of the child is made to defcend into the dilated cavity of the vagina: and this is commonly effected in a few minutes; when the left hand muft be applied firmly againft the anus and perinæum, forcing thofe parts upwards and forwards towards the orifice of the vagina, to prevent laceration; for which purpofe alfo the whole operation muft be performed flowly and cautioufly, imitating as much as poffible a natural labour."

"We found (add the authors of the paper,) a cord fixed round one of the ends of the inftrument, about the middle of the curve. This cord, we imagine, ferved no other purpofe than to point out the end of the inftrument commonly made ufe of, or to meafure the length of the part introduced."

END OF THE ELEVENTH VOLUME.
